RESTAURANT

STANDARD URBAN STORM WATER MITIGATION PLAN

DEFINITION

A restaurant is a facility that sells prepared foods and drinks for consumption, including stationary lunch counters and refreshment stands selling prepared foods and drinks for immediate consumption. (SIC code 5812)

BACKGROUND

The municipal storm water National Pollutant Discharge Elimination System (NPDES) permit (Permit) issued to Los Angeles County and 85 cities (Permittees) by the Los Angeles Regional Water Quality Control Board (Regional Board) on July 15, 1996, required the development and implementation of a program addressing stormwater pollution issues in development planning for private projects.

The requirement to implement a program addressing development planning is based on the primary objectives of the 1987 amendments to the Clean Water Act that established a framework for regulating stormwater discharges from municipal, industrial, and construction activities under the NPDES. The primary objectives are to:

- Effectively prohibit non-storm water discharges, and
- Reduce the discharge of pollutants from stormwater conveyance systems to the Maximum Extent Practicable.

This Standard Urban Stormwater Mitigation Plan (SUSMP) was developed as part of the program addressing Development Planning for the private sector. The Permittees will use this SUSMP to develop their own citywide SUSMP. Discretionary projects (as defined by CEQA), that fall into one of the seven categories (10-99 Home Subdivision, 100+ Home Subdivision, Single-Family Hillside Residence, 100,000 Square Foot Commercial Development, Automotive Repair Shop, Retail Gasoline Outlet, and Restaurant) will need to implement the appropriate SUSMP requirements into their project plans. This SUSMP outlines the necessary Best Management Practices (BMPs) which must be incorporated into design plans for Restaurant projects. Should any conflict be discovered with the new guidelines and any pre-existing regulation, the pre-existing regulation will prevail.

For development projects where the cost of new improvements exceeds a pre-determined threshold, the new and the existing improvements shall comply with this SUSMP. When the cost of new improvements is less than the pre-determined threshold, only the new improvements need to comply with this SUSMP. The pre-determined threshold shall be consistent with the local jurisdiction's policy for application of other building codes to new improvements.

REQUIREMENTS

1. PEAK STORM WATER RUNOFF DISCHARGE RATES

Peak storm water runoff discharge rates shall not exceed pre-development levels for developments where an increased peak storm water discharge rate may result in an increased potential for downstream erosion.

2. PROTECT SLOPES AND CHANNELS

If applicable, the project plans must include BMPs consistent with local code and ordinance to decrease the potential of slopes and/or channels from eroding and impacting stormwater runoff:

- Convey runoff safely from the tops of slopes and stabilize disturbed slopes.
- Stabilize permanent channel crossings.
- Vegetate slopes with native or drought tolerant vegetation.
- Install energy dissipaters, such as riprap, at the outlets of new storm drains, culverts, conduits, or channels that enter unlined channels in accordance with applicable specifications to minimize erosion.

3. PROPERLY DESIGN EQUIPMENT/ACCESSORY WASH AREAS

Equipment/accessory washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the stormwater conveyance system. To alleviate this problem, include in the project plans an area for the washing/steam cleaning of equipment and accessories. This area must meet the following:

- This area must be self-contained, equipped with a grease trap, and properly connected to a sanitary sewer.
- If this wash area is to be located outdoors, it must be covered, paved, have secondary containment, and be connected to the sanitary sewer.

4. PROVIDE STORM DRAIN SYSTEM STENCILING AND SIGNAGE

Storm drain stencils are highly visible source controls that are typically placed directly adjacent to storm drain inlets. The stencil contains a brief statement that prohibits the dumping of improper materials into the stormwater conveyance system. Graphical icons, either illustrating anti-dumping symbols or images of receiving water fauna, are effective supplements to the anti-dumping message.

- All storm drain inlets and catch basins must be stenciled with prohibitive language (such as: "NO DUMPING – DRAINS TO OCEAN") and/or graphical icons to discourage illegal dumping.

- Signs and prohibitive language and/or graphical icons discouraging illegal dumping must be posted along channels and creeks.

- Legibility of stencils and signs must be maintained.

5. PROPERLY DESIGN OUTDOOR MATERIAL STORAGE AREAS

Improper storage of materials outdoors can allow toxic compounds, oil and grease, heavy metals, nutrients, and suspended solids to enter the stormwater conveyance system. Where proposed project plans or activities may result in outdoor areas for storage or use of materials that may contribute pollutants to the stormwater conveyance system, the following structural BMPs are required:

- Areas where materials are to be stored must be: (1) placed in an enclosure such as, but not limited to, a cabinet, shed, or similar structure that prevents contact with runoff or spillage to the storm water conveyance system; or (2) protected by secondary containment structures such as berms, dikes, or curbs.

- The storage area must be paved and sufficiently impervious to contain leaks and spills.

- Where feasible, the storage area should have a roof or awning to minimize collection of storm water within the secondary containment area.

6. PROPERLY DESIGN TRASH STORAGE AREAS

Loose trash and debris can be easily transported by the forces of water or wind into nearby storm drain inlets, channels, and/or creeks. All trash container areas must meet the following requirements:

- Trash container areas must have drainage from adjoining roofs and pavement diverted around the area(s).

- Trash container areas must be screened or walled to prevent off-site transport of trash.

7. PROVIDE PROOF OF ONGOING BMP MAINTENANCE

Improper maintenance is one of the most common reasons for water quality controls to not function as designed or to fail entirely. It is important to consider who will be responsible for maintenance of a permanent BMP, and what equipment is required to perform the maintenance properly. As part of project review, if a project applicant has included (or will be required to include) structural BMPs in project plans, Permittee staff will require that the applicant provide verification of maintenance provisions.

For all properties, this verification will consist of having the developer sign a statement declaring responsibility for all structural BMP maintenance until the time the property is transferred. This transfer of property must have conditions requiring the recipient to assume responsibility for maintenance of any structural BMPs to be included in the sales or lease agreement for that property, and will be the owner's responsibility.

If structural BMPs are located within a public area proposed for transfer, they will be the responsibility of the developer until they are accepted for transfer by the County or other appropriate public agency. The structural BMP proposed for transfer will need prior approval from the County or other appropriate public agency and will be considered on a case by case basis.

RETAIL GASOLINE OUTLET

STANDARD URBAN STORM WATER MITIGATION PLAN

DEFINITION

A retail gasoline outlet is primarily engaged in selling gasoline and lubricating oils. These establishments frequently sell other merchandise, such as tires, batteries, and automobile parts. Frequently, these establishments also perform minor automotive repair work. Gasoline stations combined with other activities, such as grocery stores, convenience stores, or car wash facilities, are classified according to the primary activity.

BACKGROUND

The municipal storm water National Pollutant Discharge Elimination System (NPDES) permit (Permit) issued to Los Angeles County and 85 cities (Permittees) by the Los Angeles Regional Water Quality Control Board (Regional Board) on July 15, 1996, required the development and implementation of a program addressing stormwater pollution issues in development planning for private projects.

The requirement to implement a program addressing development planning is based on the primary objectives of the 1987 amendments to the Clean Water Act that established a framework for regulating stormwater discharges from municipal, industrial, and construction activities under the NPDES. The primary objectives are to:

- Effectively prohibit non-storm water discharges, and

- Reduce the discharge of pollutants from stormwater conveyance systems to the Maximum Extent Practicable.

This Standard Urban Stormwater Mitigation Plan (SUSMP) was developed as part of the program addressing Development Planning for the private sector. The Permittees will use this SUSMP to develop their own citywide SUSMP. Discretionary projects (as defined by CEQA), that fall into one of the seven categories (10-99 Home Subdivision, 100+ Home Subdivision, Single-Family Hillside Residence, 100,000 Square Foot Commercial Development, Automotive Repair Shop, Retail Gasoline Outlet, and Restaurant) will need to implement the appropriate SUSMP requirements into their project plans. This SUSMP outlines the necessary Best Management Practices (BMPs) which must be incorporated into design plans for Retail Gasoline Outlet projects. Should any conflict be discovered with the new guidelines and any pre-existing regulation, the pre-existing regulation will prevail.

For development projects where the cost of new improvements exceeds a pre-determined threshold, the new and the existing improvements shall comply with this SUSMP. When the cost of new improvements is less than the pre-determined threshold, only the new improvements

need to comply with this SUSMP. The pre-determined threshold shall be consistent with the local jurisdiction's policy for application of other building codes to new improvements.

REQUIREMENTS

1. PEAK STORM WATER RUNOFF DISCHARGE RATES

Peak storm water runoff discharge rates shall not exceed pre-development levels for developments where an increased peak storm water discharge rate may result in an increased potential for downstream erosion.

2. PROPERLY DESIGN FUELING AREA

Fueling areas have the potential to contribute oil and grease, solvents, car battery acid, coolant and gasoline to the stormwater conveyance system. The project plans must include the following BMPs:

- Where feasible, fuel dispensing areas should be covered with an overhanging roof structure or canopy. The canopy's minimum dimensions must be equal to or greater than the area within the grade break. The canopy must not drain onto the fuel dispensing area, and the canopy downspouts must be routed to prevent drainage across the fueling area.

- Fuel dispensing areas must be paved with portland cement concrete (or equivalent smooth impervious surface), and the use of asphalt concrete shall be prohibited.

- The fuel dispensing area must have a 2% to 4% slope to prevent ponding, and must be separated from the rest of the site by a grade break that prevents run-on of stormwater to the extent practicable.

- At a minimum, the concrete fuel dispensing area must extend 6.5 feet (2.0 meters) from the corner of each fuel dispenser, or the length at which the hose and nozzle assembly may be operated plus 1 foot (0.3 meter), whichever is less.

3. PROVIDE STORM DRAIN SYSTEM STENCILING AND SIGNAGE

Storm drain stencils are highly visible source controls that are typically placed directly adjacent to storm drain inlets. The stencil contains a brief statement that prohibits the dumping of improper materials into the stormwater conveyance system. Graphical icons, either illustrating anti-dumping symbols or images of receiving water fauna, are effective supplements to the anti-dumping message.

- All storm drain inlets and catch basins must be stenciled with prohibitive language (such as: "NO DUMPING – DRAINS TO OCEAN") and/or graphical icons to discourage illegal dumping.

- Signs and prohibitive language and/or graphical icons discouraging illegal dumping must be posted along channels and creeks.

- Legibility of stencils and signs must be maintained.

4. PROPERLY DESIGN OUTDOOR MATERIAL STORAGE AREAS

Improper storage of materials outdoors can allow toxic compounds, oil and grease, heavy metals, nutrients, and suspended solids to enter the stormwater conveyance system. Where proposed project plans or activities may result in outdoor areas for storage or use of materials that may contribute pollutants to the stormwater conveyance system, the following structural BMPs are required:

- Areas where materials are to be stored must be: (1) placed in an enclosure such as, but not limited to, a cabinet, shed, or similar structure that prevents contact with runoff or spillage to the storm water conveyance system; or (2) protected by secondary containment structures such as berms, dikes, or curbs.

- The storage area must be paved and sufficiently impervious to contain leaks and spills.

- Where feasible, the storage area should have a roof or awning to minimize collection of storm water within the secondary containment area.

5. PROPERLY DESIGN TRASH STORAGE AREA

Loose trash and debris can be easily transported by the forces of water or wind into nearby storm drain inlets, channels, and/or creeks. All trash container areas must meet the following requirements:

- Trash container areas must have drainage from adjoining roofs and pavement diverted around the area(s).

- Trash container areas must be screened or walled to prevent off-site transport of trash.

6. PROPERLY DESIGN REPAIR/MAINTENANCE BAYS

Oil and grease, solvents, car battery acid, coolant and gasoline from the repair/maintenance bays can negatively impact stormwater if allowed to come into contact with stormwater runoff. Therefore, design plans for repair bays must include the following:

- Repair/maintenance bays must be indoors or designed in such a way that doesn't allow stormwater run-on or contact with stormwater runoff.

- Design a repair/maintenance bay drainage system to capture all washwater, leaks and spills. Connect drains to a sump for collection and disposal. Direct connection of the repair/maintenance bays to the storm drain system is prohibited. If required by local jurisdiction, obtain an Industrial Waste Discharge Permit.

7. PROPERLY DESIGN VEHICLE/EQUIPMENT WASH AREAS

Vehicle/equipment washing/steam cleaning has the potential to contribute metals, oil and grease, solvents, phosphates, and suspended solids to the stormwater conveyance system. To alleviate this problem, consider including in the project plans an area for washing/steam cleaning of vehicles and equipment. If such an area is included in the site design, it must meet the following:

- This area must be self-contained, covered, equipped with a clarifier, or other pretreatment facility, and properly connected to a sanitary sewer.

8. PROVIDE PROOF OF ONGOING BMP MAINTENANCE

Improper maintenance is one of the most common reasons for water quality controls to not function as designed or to fail entirely. It is important to consider who will be responsible for maintenance of a permanent BMP, and what equipment is required to perform the maintenance properly. As part of project review, if a project applicant has included (or will be required to include) structural BMPs in project plans, Permittee staff will require that the applicant provide verification of maintenance provisions.

For all properties, this verification will consist of having the developer sign a statement declaring responsibility for all structural BMP maintenance until the time the property is transferred. This transfer of property must have conditions requiring the recipient to assume responsibility for maintenance of any structural BMPs to be included in the sales or lease agreement for that property, and will be the owner's responsibility.

If structural BMPs are located within a public area proposed for transfer, they will be the responsibility of the developer until they are accepted for transfer by the County or other appropriate public agency. The structural BMP proposed for transfer will need prior approval from the County or other appropriate public agency and will be considered on a case by case basis.

SINGLE FAMILY HILLSIDE RESIDENCE

STANDARD URBAN STORM WATER MITIGATION PLAN

DEFINITION

"Hillside" is as defined by the local jurisdiction. For example, one jurisdiction defines "hillside" as a property located in an area with known erosive soil conditions, where the development contemplates grading on any natural slope that is 25% or greater, and where grading contemplates cut or fill slopes 30 feet high or greater.

BACKGROUND

The municipal storm water National Pollutant Discharge Elimination System (NPDES) permit (Permit) issued to Los Angeles County and 85 cities (Permittees) by the Los Angeles Regional Water Quality Control Board (Regional Board) on July 15, 1996, required the development and implementation of a program addressing stormwater pollution issues in development planning for private projects.

The requirement to implement a program addressing development planning is based on the primary objectives of the 1987 amendments to the Clean Water Act that established a framework for regulating stormwater discharges from municipal, industrial, and construction activities under the NPDES. The primary objectives are to:

- Effectively prohibit non-storm water discharges, and

- Reduce the discharge of pollutants from stormwater conveyance systems to the Maximum Extent Practicable.

This Standard Urban Stormwater Mitigation Plan (SUSMP) was developed as part of the program addressing Development Planning for the private sector. The Permittees will use this SUSMP to develop their own citywide SUSMP. Discretionary projects (as defined by CEQA), that fall into one of the seven categories (10-99 Home Subdivision, 100+ Home Subdivision, Single-Family Hillside Residence, 100,000 Square Foot Commercial Development, Automotive Repair Shop, Retail Gasoline Outlet, and Restaurant) will need to implement the appropriate SUSMP requirements into their project plans. This SUSMP outlines the necessary Best Management Practices (BMPs) which must be incorporated into design plans for Single-Family Hillside Residence projects. Should any conflict be discovered with the new guidelines and any pre-existing regulation, the pre-existing regulation will prevail.

For development projects where the cost of new improvements exceeds a pre-determined threshold, the new and the existing improvements shall comply with this SUSMP. When the cost of new improvements is less than the pre-determined threshold, only the new improvements need to comply with this SUSMP. The pre-determined threshold shall be consistent with the local jurisdiction's policy for application of other building codes to new improvements.

REQUIREMENTS

1. PEAK STORM WATER RUNOFF DISCHARGE RATES

Peak storm water runoff discharge rates shall not exceed pre-development levels for developments where an increased peak storm water discharge rate may result in an increased potential for downstream erosion.

2. CONSERVE NATURAL AREAS

If applicable, the following items are required and must be implemented in the site layout during the subdivision design and approval process, consistent with applicable General Plan and Local Area Plan policies:

- Every effort shall be made to concentrate or cluster development on portions of a site while leaving the remaining land in a natural undisturbed condition.
- Limit clearing and grading of native vegetation at a site to the minimum amount needed to build lots, allow access, and provide fire protection.
- Maximize trees and other vegetation at each site by planting additional vegetation, clustering tree areas, and promoting the use of native and/or drought tolerant plants. Wherever practical, promote natural vegetation by using parking lot islands and other landscaped areas.
- Preserve riparian areas and wetlands.

3. PROTECT SLOPES AND CHANNELS

If applicable, the project plans must include BMPs consistent with local code and ordinance to decrease the potential of slopes and/or channels from eroding and impacting stormwater runoff:

- Convey runoff safely from the tops of slopes and stabilize disturbed slopes.
- Stabilize permanent channel crossings.
- Vegetate slopes with native or drought tolerant vegetation.

- Install energy dissipaters, such as riprap, at the outlets of new storm drains, culverts, conduits, or channels that enter unlined channels in accordance with applicable specifications to minimize erosion.

4. PROVIDE STORM DRAIN SYSTEM STENCILING AND SIGNAGE

Storm drain stencils are highly visible source controls that are typically placed directly adjacent to storm drain inlets. The stencil contains a brief statement that prohibits the dumping of improper materials into the stormwater conveyance system. Graphical icons, either illustrating anti-dumping symbols or images of receiving water fauna, are effective supplements to the anti-dumping message.

- All storm drain inlets and catch basins must be stenciled with prohibitive language (such as: "NO DUMPING – DRAINS TO OCEAN") and/or graphical icons to discourage illegal dumping.

- Signs and prohibitive language and/or graphical icons discouraging illegal dumping must be posted along channels and creeks.

- Legibility of stencils and signs must be maintained.

5. PROVIDE PROOF OF ONGOING BMP MAINTENANCE

Improper maintenance is one of the most common reasons for water quality controls to not function as designed or to fail entirely. It is important to consider who will be responsible for maintenance of a permanent BMP, and what equipment is required to perform the maintenance properly. As part of project review, if a project applicant has included (or will be required to include) structural BMPs in project plans, Permittee staff will require that the applicant provide verification of maintenance provisions.

For all properties, this verification will consist of having the developer sign a statement declaring responsibility for all structural BMP maintenance until the time the property is transferred. This transfer of property must have conditions requiring the recipient to assume responsibility for maintenance of any structural BMPs to be included in the sales or lease agreement for that property, and will be the owner's responsibility. For residential properties where the structural BMPs are located within a common area which will be maintained by a homeowner's association, language regarding the responsibility for maintenance must be included in the projects conditions, covenants and restrictions (CC&R's). Printed educational materials will be required to accompany the first deed transfer to highlight the existence of the requirement and to

provide information on what stormwater management facilities are present, signs that maintenance is needed, how the necessary maintenance can be performed, and assistance that the Permittee can provide. It will also encourage the transfer of this information with subsequent sale of the property.

If structural BMPs are located within a public area proposed for transfer, they will be the responsibility of the developer until they are accepted for transfer by the County or other appropriate public agency. The structural BMP proposed for transfer will need prior approval from the County or other appropriate public agency and will be considered on a case by case basis.

MEMORANDUM

August 19, 1999

TO: Ed Schroder, Director of Public Works

FROM: John Hunter

SUBJECT: NPDES Requirements for New Development Projects
Numerical Limits and Anticipated Costs to Developers

The NPDES Development Planning Program will have a significant impact on building developments throughout Los Angeles County. This program requires that Cities review and approve Standard Urban Storm Water Mitigation Plans (SUSMPs) for many types of new developments prior to issuing any approvals to build. In the SUSMPs, developers will describe measures that will be incorporated into the project design to mitigate stormwater pollution in the long term. The exact format and requirements of the SUSMPs are the only major unresolved items of the overall Development Planning Program.

On September 16, 1999, the California Regional Water Quality Control Board will meet to consider approval of "Numerical Limits" for the SUSMPs. Everyone interested in commenting should attend. The Executive Advisory Committee is opposed to the inclusion of the numerical standards due to the lack of baseline receiving water and runoff monitoring data, the unproven cost-effectiveness of the proposed BMPs and the lack of flexibility inherent in a numerical standard (i.e. what is adequate for one development area may not be sufficient for another).

The cities in Los Angeles County have been working together with the County for over two years in developing the current versions of the model programs and SUSMPs. The SUSMPs contained within the Development Planning model program specifically excluded numerical limits, as opposed to the SUSMPs developed by the County for unincorporated areas, which include numerical limits. The establishment of limits at this point may well void a large amount of work that has already been completed and found acceptable to most of the cities involved.

As of July 30, 1999 Los Angeles County began requiring developers in unincorporated areas to include provisions to treat the first flush of rainfall from each storm. The County's standard calls for treatment of the first 0.75 inches of rainfall from each storm. Cities are not automatically obligated to follow the County's standards, however it appears that the Regional Board is leaning towards using it as a model and may incorporate it into the SUSMP requirements for other cities.

92% HIGH DENSITY SINGLE
68% MULTI-FAMILY

The numerical standard would apply to all new priority projects (discretionary 10+home subdivisions, auto repair facilities, restaurants, and 100,000 sq. ft. commercial/industrial developments, etc.). The cost of implementing the standard will vary from site to site depending upon many factors. A typical scenario would be:

- A ¾ inch rain falling on a one acre site with a 100% impervious surface will generate approximately 20,000 gallons of runoff.

80 - 95° ⇒ MOST BASIC

- **Option 1 - Create Retention/Infiltration Area:** At such a site, construction of a sloped (45°) trench 6 feet wide, 3 feet deep and 300 feet long should be sufficient to capture the requisite ¾ inch of rainfall and allow for infiltration. The cost would be roughly

Design and construction cost of the trench including erosion control. On the sides (jute mesh and vegetation) and overflow	$6,500
Land value of the trench (estimated at $10 per square foot).	$18,000*
First years maintenance	$500
Estimated Total	$25,000

*- If setback area is used, land cost will be essentially zero

The maintenance cost included above does not account for the potential for contamination of the underlying soil with metals, hydrocarbons, or solvents that may be discharged with storm water runoff. This possibility depends heavily on the actual use of the property, i.e. residential areas would be less likely to be contaminated than industrial areas. The cost for removal of such contamination, if it occurred, would depend on the amount and concentration of contaminants and the volume of soil affected.

- **Option 2 – Basket Filters Installed in Yard Drains:** Assuming that 4 yard drains will be sufficient for drainage from the site, basket filters can be installed in each drain to remove sediment and any oils or pollutants entrained with the sediment. Absorbent pads can be added to remove dissolved pollutants although the effectiveness of the absorbent for removing pollutants from rainfall is yet to be adequately demonstrated.

Purchase and installation cost of 4 Basket Filters	$2,500*
Absorbent material (if needed)	$1,000
Yearly maintenance	$1,000
Estimated Total	$4,500

* - If not already included in project, drain boxes would add approximately $2,000 to the project cost.

The maintenance costs are based on yearly cleaning and upkeep of the drains and filters. Depending on the use of the property and the presence of

contaminants in storm water runoff, the absorbent material may require replacement on a regular basis, a cost that is not figured into the yearly maintenance figure.

Please note that these estimated costs are based upon vacant land undergoing development. The cost for retrofitting existing facilities undergoing modification could be significantly higher.

In summation:

- New development for restaurants, service stations, major industrial facilities, 10+ home subdivisions, etc. are now required to prepare SUSMPs for the City's review and approval as part of the permit approval process.
- It appears that developers will be required to design and install treatment systems with the capability to capture and treat the first flush (0.6 to 0.75 inches) of rainfall.
- Treatment methods can range from retention and infiltration basins to storm water clarifiers and vegetative swales.
- The SUSMP guidelines are not finalized yet, but may be as early as the regional Board's hearing on September 16, 1999.

SUBJECT: Standard Urban Stormwater Mitigation Plans

At the last EAC meeting several cities expressed an interest in obtaining the services of a consultant to prepare an analysis of the Regional Board's proposal to amend the SUSMP we submitted. It was also expressed that we should find someone to make a professional, Power Point-type presentation at the Board meeting when this item is heard.

With the intent of the above in mind, we have scheduled a meeting with Mr. Bob Collacott of URS Greiner Woodward Clyde. The time and location of the meeting is as follows:

Monday, October 25, 1999 - 2:00 p.m.
City of Downey City Hall
Desi Alvarez's office, 2nd floor
11111 Brookshire Avenue, Downey

The purpose of the meeting is to come to a consensus on the content of an analysis and presentation as well as the associated cost. If you cannot make it in person, feel free to send an alternate. However, be prepared to commit to a course of action.

If you have any questions, or wish to discuss the matter, please call me at 562-989-7355, or Desi Alvarez at 562-904-7101

SECTION THREE LOS ANGELES COUNTY REQUIREMENTS

3.1 CATEGORIZATION OF DEVELOPMENT PROJECTS

Beginning June 1999, the DPW divisions that have responsibility for review of development project plans will categorize proposed projects as "Planning Stormwater Priority Projects" or "Planning Stormwater Exempt Projects" with respect to the potential for a significant effect on stormwater quality. Planning Stormwater Priority Projects shall be required to incorporate appropriate post-construction BMPs into project plans prior to the issuance of any building or grading permit.

In order to categorize a project as a Planning Stormwater Priority Project or a Planning Stormwater Exempt Project, project type, characteristics, and activities will be assessed for potential contribution to stormwater pollution. The DPW Building and Safety/Land Development Division shall conduct a screen check for projects utilizing a standardized checklist ("Priority/Exempt Checklist") that lists project type and project characteristics and activities that are believed to be significant potential contributors to stormwater pollution. The Priority/Exempt checklist that shall be used for categorizing projects as a Planning Stormwater Priority Project or a Planning Stormwater Exempt Project is shown in Figure 3-1 and included in Appendix A.

In utilizing the Priority/Exempt Checklist, a commercial or industrial development of 100,000 or more square feet shall be based on total impermeable area as opposed to lot size or building footprint. This interpretation shall be used because of the intent to manage storm water runoff from paved areas associated with buildings. A restaurant is a facility that would use the Standard Industrial Classification (SIC) code of 5812 and an automotive repair shop is a facility that would use one of the following SIC codes: 5013, 5014, 5541, 7532-7534, or 7536-7539. Hillside development shall be defined as development having any of the following characteristics:

- location in an area known to have erosive soil conditions as identified in the *Los Angeles County Department of Public Works Hydrology/Sedimentation Manual*;
- grading on any natural slope where the natural slope is 25% or greater; or
- plans include cut or fill slopes that are 30 feet high or greater.

Since the County's Department of Regional Planning also has a fundamental role in approval of development projects, a process has been developed to incorporate the screen check for

categorizing projects as a Planning Stormwater Priority Project or a Planning Stormwater Exempt Project early in the planning stages of "discretionary"[1] projects. A flowchart depicting this process is provided as Figure 3-2.

[1] Section 15357 of the California Environmental Quality Act Guidelines defines "discretionary project" as a project which requires the exercise of judgment or deliberation when the public agency or body decides to approve or disapprove a particular activity, as distinguished from situations where the public agency or body merely has to determine whether there has been conformity with applicable statutes, ordinances, or regulations.

FIGURE 3-1. CHECKLIST FOR CATEGORIZING PROJECTS AS PLANNING STORMWATER PRIORITY OR PLANNING STORMWATER EXEMPT

Project Name: _____

Project Location: _____

The project is a Planning Stormwater Priority Project if any of the project types listed in Part A or any of the project characteristics or activities listed in Part B are applicable.

Part A. Type of Proposed Project:	Check If Applicable
A 100+ home subdivision	
A 10-99 home subdivision	
A 100,000+ square-foot commercial or industrial development	
An automotive repair shop (SIC codes 5013, 5014, 5541, 7532-7534, and 7536-7539)	
A retail gasoline outlet	
A restaurant (SIC code 5812)	
A hillside-located single-family dwelling	

Part B. Project Characteristics or Activities:	Check If Applicable
Automotive or equipment repair and/or maintenance	
Car wash	
Automotive or equipment washing or cleaning area(s)	
Gas station or fuel dispensing	
Parking lot with 25 or more parking spaces	
Outdoor material or waste handling or storage	
Chemical handling and/or storage of petroleum products, paints, solvents, concrete, or hazardous waste	
Outdoor equipment or product fabrication including welding; cutting; sawing; metal fabrication; assembly; application of paints, coatings, or finishes; pre-cast concrete fabrication; etc.	
Outdoor areas for equipment or machinery repair and/or maintenance	
Dry cleaning factory	
Food service	
Food processing plant	
Hospitals, laboratories, or other medical facilities	
Nursery (plant materials)	
Animal slaughtering	
Animal containment, pet care facilities, stables, kennels, etc.	
Public recreation uses such as tennis courts, swimming pools, golf courses	
10 or more dwelling units	
Hillside location	
Landscaped areas > 5 acres, including cemeteries, golf courses, etc.	
Location adjoining to, bisected by, or discharging to a designated environmentally sensitive area[2], riparian corridor, or wetland	

R0070947

[2] "Environmentally sensitive areas" may be, but not limited to, wetlands, habitats of endangered, threatened, or rare species, wildlife dispersal or migration corridors, areas of locally-designated species such as heritage trees, or locally-designated natural communities such as oak forest or coastal habitat.

To: Dennis Dickerson

RESOLUTION NO._____

A RESOLUTION OF THE CITY OF RANCHO PALOS VERDES URGING THE CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD, LOS ANGELES REGION, NOT TO REQUIRE CITIES TO IMPOSE NUMERIC LIMITS ON THE TREATMENT OR RETENTION OF STORM WATER RUNOFF FROM NEW DEVELOPMENTS PURSUANT TO THE LOS ANGELES COUNTY MUNICIPAL NPDES PERMIT

Whereas, the California Regional Water Quality Control Board, Los Angeles Region (hereinafter "regional board") is considering the incorporation of numeric limits into the Standard Urban Storm Water Runoff Mitigation Plan component of the model development planning program – a requirement associated with the Los Angeles County Municipal NPDES permit (hereinafter, "municipal NPDES permit");

Whereas, such numeric limits are intended to retain or treat storm water runoff volume (either .60" or .75" of rain) from 7 categories of new development projects, including gas stations, restaurants, auto repair facilities, 10-99 home sub-divisions, 100-plus home sub-divisions, single-family hillside homes, and 100,000 square foot commercial developments;

Whereas, meeting the proposed numeric limits would necessitate the imposition of structural controls on new developments, including but not limited to extended detention basins, wet ponds, infiltration basins/ponds (which reduce the amount developable space), storm drain-connected oil/grit separators, catch basin inserts, grassy swales, and other devices, many of which have not been proven to be cost-effective;

Whereas, such structural controls would require post-construction operation and maintenance, for which cities would be responsible;

Whereas, such controls, if not properly designed or maintained, could become sources of pollution rather than pollution mitigants;

Whereas, storm water treatment and retention numeric limits are not mandated in the municipal NPDES permit and are not required of other municipal NPDES permits in the State of California;

Whereas, neither the regional board nor any other interested party has provided compelling justification for the use of numeric limits for treating or retaining storm water runoff from new developments;

Whereas, neither the regional board nor any other interested party has demonstrated that storm water retention/treatment numeric limits would result in the improvement or protection of a beneficial use of a receiving water;

Whereas, imposing such unproven and questionable numeric limits on cities constitutes an unfunded state mandate, one that has not been evaluated in cost-effective terms, as required by state law;

NOW, THEREFORE, the City of Rancho Palos Verdes does hereby resolve as follows:

Section 1. Advise regional board members of its opposition to storm water treatment/retention numeric limits; and

Section 2. Recommend that the regional board approve the Standard Urban Storm Water Mitigation Plan, which does not include numeric limits, as proposed by the Executive Advisory Committee on August 11, 1999.

The City of Long Beach

Los Angeles, CA 90013

Re: *Start at the Source* Workshop

Dear Dennis,

I am writing to follow-up on a phone conversation we had several weeks ago about our facilitating a workshop on post-construction stormwater controls in Los Angeles. I have taken some time to send you the information I promised because I was waiting to complete our Final Report on the workshops that we have recently completed in the San Francisco Bay Area for the Bay Area Stormwater Agencies Association (BASMAA).

The workshop that we propose to facilitate in Los Angeles would follow a similar format of interactive exercies and presenations. These were held at several locations in the San Francisco Bay Area to support *Start at the Source: Design Guidance Manual for Stormwater Quality Protection.* To provide more information about these workshops, I am enclosing a copy of the Manual and our "Final Report- 1999 Outreach Program." This Final Report details the workshop agenda, the exercises, and the participant response. Though the Manual was written for the S.F. Bay Area, its principles and concepts are applicable to southern California. However, we can tailor the exercises and presentation to focus on specific local issues of interest.

Our fee for the workshop is Six thousand dollars ($6,000), plus travel expenses. This fee includes the following services and materials:

- In consultation with you, modify workshop as necessary to adjust to local issues.
- Provide a workshop flyer (if requested). One copy camera ready art.
- Provide materials required for workshop interactive exercises (excluding AV equipment).
- Provide at least one staff member to every twelve participants (1:12 ratio, with 100 participants, maximum).
- Facilitate workshop.

Urban Design and Landscape Architecture

654 Gilman Street • Palo Alto, CA 94301
Voice **650.462.8880** • Fax 650.325.1018
www.tomrichman.com

R0070950

We anticipate travel expenses would be needed for three of our employees who would come from northern California. As the workshop starts early in the morning, these expenses would include airfare and one night's lodging. As we have done in the past, we would draw additional facilitators from graduate students at local landscape architecture and planning programs.

The following items are not included in our services and would be provided by you or some other host organization.

- Develop attendee or mailing list
- Duplicate or mail flyers
- Manage registration and sign-in
- Provide meeting room
- Provide morning refreshments and lunch
- Provide one copy of *Start at the Source* for each participant.

The retail price of *Start at the Source* is $43 including shipping, available from Forbes Custom Publishing (toll free 877 773.7247). I understand that BASMAA is considering providing copies of the Manual to other stormwater programs at a significant discount. Please contact BASMAA's Executive Director, Geoff Brosseau (510 622.2300) for more information about obtaining the Manuals at a discount. Geoff can also give you his impression of the workshop and its effectiveness.

As you will see in the Final Report, the workshops and Manual have been enthusiastically received, and we are eager to bring them to Southern California. We already have experience with some of your issues, as we have held sessions in Santa Monica and participated in a design charette at Los Angeles in 1997 sponsored by T.R.E.E.S. and various municipal organizations.

Please call me if you have questions about any aspect of the workshop. Thanks again for your interest. We look forward to bringing the workshop to your region.

Sincerely,

Tom Richman, ASLA, AICP
Registered California Landscape Architect 2741

The Regional Water Quality Control Board has invited Camp Dresser & McKee to present a discussion of the hydrology of water quality. Camp Dresser & McKee is widely recognized for its expertise in environmental engineering, and has extensive experience in California and the U.S. working with public agencies to develop implementable storm water quality control programs.

Dr. Brahsear has more than 12 years of experience in environmental and water resources engineering, including storm water quantity and quality management, watershed management, water and wastewater treatment, modeling of water quantity and quality, and management of wet weather impacts to collection systems. Dr. Brashear is experienced with a range of surface water quantity and quality models, including MIKE BASIN, TAMUWRAP, SWMM4, WMM, WASP, MOUSE, HYDROWORKS, and STORM.

Dr. Brashear holds a Bachelor's Degree in Civil Engineering, a Master's Degree in Environmental Engineering, and a Doctorate in Environmental Engineering from Texas Tech University. He is currently CDM's water resources practice leader in the southwest.

100+ HOME SUBDIVISION

STANDARD URBAN STORM WATER MITIGATION PLAN

DEFINITION

A 100+ home subdivision is defined as any subdivision lot being developed for more than 100 single-family or multi-family homes.

BACKGROUND

The municipal storm water National Pollutant Discharge Elimination System (NPDES) permit (Permit) issued to Los Angeles County and 85 cities (Permittees) by the Los Angeles Regional Water Quality Control Board (Regional Board) on July 15, 1996, required the development and implementation of a program addressing stormwater pollution issues in development planning for private projects.

The requirement to implement a program addressing development planning is based on the primary objectives of the 1987 amendments to the Clean Water Act that established a framework for regulating stormwater discharges from municipal, industrial, and construction activities under the NPDES. The primary objectives are to:

- Effectively prohibit non-storm water discharges, and

- Reduce the discharge of pollutants from stormwater conveyance systems to the Maximum Extent Practicable.

This Standard Urban Stormwater Mitigation Plan (SUSMP) was developed as part of the program addressing Development Planning for the private sector. Discretionary projects (as defined by CEQA), that fall into one of the seven categories (10-99 Home Subdivision, 100+ Home Subdivision, Single-Family Hillside Residence, 100,000 Square Foot Commercial Development, Automotive Repair Shop, Retail Gasoline Outlet, and Restaurant) will be need to implement the appropriate SUSMP requirements into their project plans. This SUSMP outlines the necessary Best Management Practices (BMPs) which must be incorporated into design plans for 100+ Home Subdivision projects. Should any conflict be discovered with the new guidelines and any pre-existing regulation, the pre-existing regulation will prevail.

For development projects where the cost of new improvements exceeds 50% of the market value of the existing improvements, existing and new improvements shall comply with this SUSMP. When the cost of new improvements are less than 50% of the market value of the existing improvements, only the new improvements need to comply with this SUSMP.

REQUIREMENTS

1. CONSERVE NATURAL AREAS

If applicable, the following items are required and must be implemented in the site layout during the subdivision design and approval process, consistent with applicable General Plan and Local Area Plan policies:

- Concentrate or cluster development on portions of a site while leaving the remaining land in a natural undisturbed condition.
- Limit clearing and grading of native vegetation at a site to the minimum amount needed to build lots, allow access, and provide fire protection.
- Maximize trees and other vegetation at each site by planting additional vegetation, clustering tree areas, and promoting the use of native and/or drought tolerant plants. Wherever practical, promote natural vegetation by using parking lot islands and other landscaped areas.
- Preserve riparian areas and wetlands.

2. MITIGATE STORMWATER RUNOFF

Stormwater runoff from a site has the potential to contribute oil and grease, suspended solids, metals, gasoline, pesticides, and pathogens to the stormwater conveyance system. The development must be designed so as to mitigate (infiltrate and/or treat) the site runoff generated from each and every storm event of up to and including 0.6-inches of rainfall from impervious directly connected areas that may contribute pollutants of concern to the stormwater conveyance system. Pollutants of concern, as defined by the Permit, consist of any pollutants that exhibit one or more of the following characteristics: current loadings or historic deposits of the pollutant are impacting the beneficial uses of a receiving water, elevated levels of the pollutant are found in sediments of a receiving water and/or have the potential to bioaccumulate in organisms therein, or the detectable inputs of the pollutant are at a level high enough to be considered potentially toxic to humans and/or flora and fauna. In designing your project to meet this requirement, you are not limited to the BMPs below.

In meeting this specific requirement, "treatment" of runoff will require the incorporation of that BMP or combination of BMPs best suited to maximize the reduction of pollutant loadings in that runoff. Those BMPs best suited to that purpose are, at a minimum, those listed in the California Storm Water Best Management Practices Handbooks as "likely to have significant impact" beneficial to water quality for targeted pollutants that are of concern at the site in question.

However, it is possible that a combination of BMPs not so rated may, in a particular circumstance, be best suited to maximize the reduction of the pollutants.

Reducing Post-Development Runoff

Limiting impervious areas will help reduce the amount of site runoff generated. The following are examples which can be used for this purpose (See Table 1: Suggested Resources for additional sources of information):

- Provide reduced width sidewalks and incorporate landscaped buffer areas between sidewalks and streets. However, sidewalk widths must still comply with regulations for the Americans with Disabilities Act and other life safety requirements.

- Design residential streets for the minimum required pavement widths needed to comply with all zoning and applicable ordinances to support travel lanes; on-street parking; emergency, maintenance, and service vehicle access; sidewalks; and vegetated open channels.

- Complying with all zoning and applicable ordinances, minimize the number of residential street cul-de-sacs and incorporate landscaped areas to reduce their impervious cover. The radius of cul-de-sacs should be the minimum required to accommodate emergency and maintenance vehicles. Alternative turnarounds should be considered.

- Use permeable materials for private sidewalks, driveways, parking lots, or interior roadway surfaces (examples: hybrid lots, parking groves, permeable overflow parking, etc.).

- Use open space development that incorporates smaller lot sizes.

- Reduce building density.

- Complying with all zoning and applicable ordinances, reduce overall lot imperviousness by promoting alternative driveway surfaces and shared driveways that connect two or more homes together.

- Complying with all zoning and applicable ordinances, reduce the overall imperviousness associated with parking lots by providing compact car spaces, minimizing stall dimensions, incorporating efficient parking lanes, and using pervious materials in spillover parking areas.

- Direct rooftop runoff to pervious areas such as yards, open channels, or vegetated areas and avoid routing rooftop runoff to the roadway and the stormwater conveyance system.

Mitigating Stormwater Runoff

The following are examples of Treatment Control BMPs that can be used for mitigating the site runoff generated from each and every storm event of up to and including 0.6-inches of rainfall from impervious directly connected areas that may contribute pollutants of concern to the stormwater conveyance system (See Table 1: Suggested Resources for additional sources of information):

- Vegetated swales and strips (Applicability and design criteria to be added)
- Extended/dry detention basins (Applicability and design criteria to be added)
- Infiltration basins (Applicability and design criteria to be added)
- Infiltration trenches (Applicability and design criteria to be added)
- Wet ponds (Applicability and design criteria to be added)
- Constructed wetlands (Applicability and design criteria to be added)
- Oil/Water separators (Applicability and design criteria to be added)
- Catch basin inserts (Applicability and design criteria to be added)
- Storm drain inserts (Applicability and design criteria to be added)
- Media filtration (Applicability and design criteria to be added)
- Bioretention facility (Applicability and design criteria to be added)
- Dry-wells (Applicability and design criteria to be added)
- Cisterns (Applicability and design criteria to be added)
- Foundation planting (Applicability and design criteria to be added)

3. PROTECT SLOPES AND CHANNELS

If applicable, the project plans must include BMPs to decrease the potential of slopes and/or channels from eroding and impacting stormwater runoff:

- Safely convey runoff from the tops of slopes and stabilize disturbed slopes.
- Stabilize permanent channel crossings.
- Vegetate slopes with native or drought tolerant vegetation.
- Energy dissipaters, such as riprap, must be installed at the outlets of new storm drains, culverts, conduits, or channels that enter unlined channels in accordance with applicable specifications to minimize erosion.

4. PROVIDE STORM DRAIN SYSTEM STENCILING AND SIGNAGE

Storm drain stencils are highly visible source controls that are typically placed directly adjacent to storm drain inlets. The stencil contains a brief statement that prohibits the dumping of improper materials into the stormwater conveyance system. Graphical icons, either illustrating anti-dumping symbols or images of receiving water fauna, are effective supplements to the anti-dumping message.

- All storm drain inlets and catch basins must be stenciled with prohibitive language (such as: "NO DUMPING – DRAINS TO OCEAN") and/or graphical icons to discourage illegal dumping.
- Signs and prohibitive language and/or graphical icons discouraging illegal dumping must be posted along channels and creeks.
- Legibility of stencils and signs must be maintained.

5. PROPERLY DESIGN COMMON[1] OUTDOOR MATERIAL STORAGE AREAS

Improper storage of materials outdoors can allow toxic compounds, oil and grease, heavy metals, nutrients, and suspended solids to enter the stormwater conveyance system. Where proposed project plans or activities may result in outdoor common areas for storage or use of materials the following structural BMPs are required:

- Areas where materials are to be used or stored must be protected by secondary containment structures such as berms, dikes, or curbs.
- The storage area must be paved and sufficiently impervious to contain leaks and spills.
- Where feasible, the storage area should have a roof or awning to minimize collection of stormwater within the secondary containment area.

6. PROPERLY DESIGN COMMON TRASH STORAGE AREAS

Loose trash and debris can be easily transported by the forces of water or wind into nearby storm drain inlets, channels, and/or creeks. All common trash container areas must meet the following requirements:

- Trash container areas must have drainage from adjoining roofs and pavement diverted around the area(s).
- Trash container areas must be screened or walled to prevent off-site transport of trash.

1 Common areas are areas which are designed and intended for active or passive use, or are for the purpose of providing access or services to the owners (or their designees). Examples of common areas are: parking areas, driveways, service areas, recreational amenities such as swimming pools, spas, picnic areas and tables, benches, tot lots, play areas, ball courts, barbecue areas, sitting areas, lawn and grass areas, landscape areas, planter areas, slopes, trails, walkways, and trash areas.

7. PROVIDE PROOF OF ONGOING BMP MAINTENANCE

Improper maintenance is one of the most common reasons for water quality controls to not function as designed or to fail entirely. It is important to consider who will be responsible for maintenance of a permanent BMP, and what equipment is required to perform the maintenance properly. As part of project review, if a project applicant has included (or will be required to include) structural BMPs in project plans, Permittee staff will require that the applicant provide verification of maintenance provisions.

For all properties, this verification will consist of having the developer sign a statement declaring they are responsible for all structural BMP maintenance until the time the property is transferred. This transfer of property must have conditions requiring the recipient to assume responsibility for maintenance of any structural BMPs to be included in the sales or lease agreement for that property, and will be the owner's responsibility. For residential properties where the structural BMPs are located within a common area which will be maintained by a homeowner's association, language regarding the responsibility for maintenance must be included in the projects conditions, covenants and restrictions (CC&R's). Printed educational materials will be required to accompany the first deed transfer to highlight the existence of the requirement and to provide information on what stormwater management facilities are present, signs that maintenance is needed, how the necessary maintenance can be performed, and assistance that the Permittee can provide. It will also encourage the transfer of this information with subsequent sale of the property. If structural BMPs are located within a public area proposed for transfer, they will be the responsibility of the developer until they are accepted for transfer by the County or other appropriate public agency. The structural BMP proposed for transfer will need prior approval from the County or other appropriate public agency and will be considered on a case by case basis.

TABLE 1: SUGGESTED RESOURCES

SUGGESTED RESOURCES	HOW TO GET A COPY
Start at the Source (1997) by Bay Area Stormwater Management Agencies Association Detailed discussion of permeable pavements and alternative driveway designs presented.	Bay Area Stormwater Management Agencies Association 2101 Webster Street Suite 500 Oakland, CA 510-286-1255
Design of Stormwater Filtering Systems (1996) by Richard A. Claytor and Thomas R. Schuler Presents detailed engineering guidance on ten different stormwater filtering systems.	Center for Watershed Protection 8391 Main Street Ellicott City, MD 21043 410-461-8323
Better Site Design: A Handbook for Changing Development Rules in Your Community (1998) Presents guidance for different model development alternatives.	Center for Watershed Protection 8391 Main Street Ellicott City, MD 21043 410-461-8323
Design Manual for Use of Bioretention in Stormwater Management (1993) Presents guidance for designing bioretention facilities.	Prince George's County Watershed Protection Branch 9400 Peppercorn Place, Suite 600 Landover, MD 20785
Operation, Maintenance and Management of Stormwater Management (1997) Provides a thorough look at stormwater practices including, planning and design considerations, programmatic and regulatory aspects, maintenance considerations, and costs.	Watershed Management Institute, Inc. 410 White Oak Drive Crawfordville, FL 32327 850-926-5310
California Storm Water Best Management Practices Handbooks (1993) for Construction Activity, Municipal, and Industrial/Commercial Presents a description of a large variety of structural and good housekeeping BMPs. CHAPTER 40C-42

ENVIRONMENTAL RESOURCE PERMITS: REGULATION OF STORMWATER MANAGEMENT SYSTEMS

40C-42.011	Scope.
40C-42.021	Definitions.
40C-42.022	Permits Required.
40C-42.0225	Exemptions From Permitting for Stormwater Management Systems.
40C-42.023	Requirements for Issuance.
40C-42.024	Standard General and Individual Permits.
40C-42.025	Design and Performance Criteria for Stormwater Management Systems.
40C-42.026	Specific Design and Performance Criteria.
40C-42.0265	Design and Performance Criteria for Wetlands Stormwater Management Systems.
40C-42.027	Legal Operation and Maintenance Entity Requirements.
40C-42.028	Operation Phase Permits.
40C-42.029	Monitoring and Operational Maintenance Requirements.
40C-42.031	Exemptions for Stormwater Management Systems.(Repealed)
40C-42.032	Limiting Conditions.
40C-42.033	Implementation.
40C-42.035	Stormwater General Permits. (Repealed)
40C-42.041	Individual Permit Requirements for New Stormwater Discharge Facilities. (Repealed)
40C-42.061	Relationship to Other Permitting Requirements.
40C-42.071	Permit Processing Fee.
40C-42.081	General Provisions.
40C-42.091	Publications Incorporated by Reference.
40C-42.900	Forms and Instructions.

40C-42.011 Scope.

(1) This chapter governs stormwater management systems which are designed and constructed or implemented to control discharges necessitated by rainfall events. These systems may incorporate methods to collect, convey, store, absorb, inhibit, treat, use or reuse water to prevent or reduce flooding, overdrainage, environmental degradation and pollution, or otherwise affect the quality and quantity of discharges. Standard general and individual environmental resource stormwater permits are required under this chapter for construction, operation, maintenance, alteration, removal, or abandonment of systems that are not permitted under provisions of chapters 40C-4, 40C-40, or 40C-400, F.A.C. Permits issued under this chapter must be consistent with the objectives of the District and not cause harm to the water resource.

R0070984

(2) A permit under this chapter will be required only for certain stormwater management systems as defined herein. This provision shall not affect the District's authority to require appropriate corrective action whenever any system causes or contributes to violations of state water quality standards.

(3) Stormwater discharges to groundwaters shall be regulated under the provisions of section 62-28.700, F.A.C., and other applicable rules of the Department of Environmental Protection .

Specific Authority 373.044, 373.113, 373.171, 373.418 FS. Law Implemented 373.416, 403.812, 403.814 FS. History--New 4-1-86. Amended 9-25-91, 10-3-95.

40C-42.021 Definitions.

(1) "Appropriate Registered Professional" or "Registered Professional" means, for purposes of this rule, a professional registered in Florida with the necessary expertise in the fields of hydrology, drainage, flood control, erosion and sediment control, and stormwater pollution control to design and certify stormwater management systems. Examples of registered professionals may include professional engineers licensed under chapter 471, F.S., professional landscape architects licensed under chapter 481, F.S., and professional geologists licensed under chapter 492, F.S., who have the referenced skills.

(2) "As-Built Drawings" means plans certified by an appropriate registered professional or registered surveyor which accurately represents the constructed condition of a system.

(3) "Completion of Construction" means the time at which the stormwater management system is first placed into operation, when the project passes final building inspection or when the project receives a certificate of occupancy, whichever occurs first.

(4) "Construction" means any activity including land clearing, earth moving, or the erection of structures which will result in the creation of a stormwater management system.

(5) "Control Device" or "Bleed-down Device" means that element of a discharge structure which allows the gradual release of water under controlled conditions.

(6) "Control Elevation" means the lowest elevation at which water can be released through the control device.

(7) "Detention with Filtration" or "Filtration" means the selective removal of pollutants from stormwater by the collection and temporary storage of stormwater and the subsequent gradual release of the stormwater into surface waters in the state through at least 2 feet of suitable fine textured granular media such as porous soil, uniformly graded sand, or other natural or artificial fine aggregate, which may be used in conjunction with filter fabric and/or perforated pipe.

(8) "Detention" or "To Detain" means the collection and temporary storage of stormwater with subsequent gradual release of the stormwater.

(9) "Direct Discharge" means, for purposes of this chapter, a point or nonpoint discharge which enters Class I, Class II, or Outstanding Florida Waters, or Class III waters which are approved, conditionally approved, restricted, or conditionally restricted for shellfish harvesting without an adequate opportunity for mixing and dilution to prevent significant degradation. Examples of direct discharge include the following:

(a) discharge without entering any other water body or conveyance prior to release to the Class I, Class II, Outstanding Florida Waters, or Class III waters which are approved, conditionally approved, restricted, or conditionally restricted for shellfish harvesting;

(b) discharge into an intermittent watercourse which is a tributary of a Class I, Class II, Outstanding Florida Water, or Class III waters which are approved, conditionally approved, restricted, or conditionally restricted for shellfish harvesting; and

(c) discharge into a perennial watercourse which is a tributary of a Class I, Class II, Outstanding Florida Water, or Class III waters which are approved, conditionally approved, restricted, or conditionally restricted for shellfish harvesting when there is not an adequate opportunity for mixing and dilution to prevent significant degradation.

(10) "Dry detention" means a system designed to collect and temporarily store stormwater in a normally dry basin with subsequent gradual release of the stormwater.

(11) "Effective Grain Size" means the diameter of filter sand or other aggregate that corresponds to the 10 percentile finer by dry weight on the grain size distribution curve.

(12) "Intermittent Watercourse" means a stream or waterway that flows only at certain times of the year, flows in direct response to rainfall, and is normally an influent stream except when the ground water table rises above the normal wet season level.

(13) "Littoral zone" means, in reference to stormwater management systems, that portion of a wet detention pond which is designed to contain rooted aquatic plants.

(14) "Off-line" means the storage of a specified portion of the stormwater in such a manner so that subsequent runoff in excess of the specified volume of stormwater does not flow into the area storing the initial stormwater.

(15) "Operational Maintenance" means any activity or repair required to keep a stormwater management system functioning as permitted and designed.

(16) "Operate" or "Operation" means to cause or to allow a stormwater management system to function.

(17) "Perennial Watercourse" means a stream or waterway which is not an intermittent watercourse.

(18) "Permanent Pool" means that portion of a wet detention pond, which normally holds water (e.g., between the normal water level and the pond bottom) excluding any water volume claimed as wet detention treatment volume pursuant to paragraph 40C-42.026(4)(a), F.A.C.

(19) "Pollution" means the presence in waters of the state of any substances, contaminants, or manmade or man-induced impairment of waters or alteration of the chemical, physical, biological, or radiological integrity of water in quantities or at levels which are or may be potentially harmful or injurious to human health or welfare, animal or plant life, or property or which unreasonably interfere with the enjoyment of life or property, including outdoor recreation unless authorized by applicable law.

(20) "Registered Surveyor" means a registered professional land surveyor licensed in the state of Florida under chapter 472, F.S.

(21) "Reconstruction" means rebuilding or construction in an area upon which construction has previously occurred.

(22) "Retention" means a system designed to prevent the discharge of a given volume of stormwater runoff into surface waters in the state by complete on-site storage. Examples may

include excavated or natural depression storage areas, pervious pavement with subgrade, or above ground storage areas.

(23) "Seasonal high ground water table elevation" means the highest level of the saturated zone in the soil in a year with normal rainfall.

(24) "Semi-impervious" means land surfaces which partially restrict the penetration of water; included as examples are porous concrete and asphalt pavements, limerock, and certain compacted soils.

(25) "Sensitive Karst Areas" means those areas of the District delineated in chapters 40C-4 and 40C-41, F.A.C., in which the Floridan aquifer is near the land surface.

(26) "Stormwater" means the flow of water which results from, and which occurs immediately following, a rainfall event.

(27) "Stormwater Discharge Facility" means a stormwater management system which discharges stormwater into surface waters of the State.

(28) "Stormwater Management System" means a system which is designed and constructed or implemented to control discharges which are necessitated by rainfall events, incorporating methods to collect, convey, store, absorb, inhibit, treat, use or reuse water to prevent or reduce flooding, overdrainage, environmental degradation, and water pollution or otherwise affect the quality and quantity of the discharges.

(29) "Swale" means a manmade trench which:

(a) Has a top width to depth ratio of the cross-section equal to or greater than 6:1, or side slopes equal to or greater than 3 feet horizontal to 1 foot vertical; and,

(b) Contains contiguous areas of standing or flowing water only following a rainfall event; and,

(c) Is planted with or has stabilized vegetation suitable for soil stabilization, stormwater treatment, and nutrient uptake; and,

(d) Is designed to take into account the soil erodibility, soil percolation, slope, slope length, and drainage area so as to prevent erosion and reduce pollutant concentration of any discharge.

(30) "Underdrain" means a drainage system installed beneath a stormwater holding area to improve the infiltration and percolation characteristics of the natural soil when permeability is restricted due to periodic high water table conditions or the presence of layers of fine textured soil below the bottom of the holding area. These systems usually consist of a system of interconnected below-ground conduits such as perforated pipe, which simultaneously limit the water table elevation and intercept, collect, and convey stormwater which has percolated through the soil.

(31) "Underground Exfiltration Trench" or "Exfiltration Trench" means a below-ground system consisting of a conduit such as perforated pipe surrounded by natural or artificial aggregate which is utilized to percolate stormwater into the ground.

(32) "Uniformity Coefficient" means the number representing the degree of homogeneity in the distribution of particle sizes of filter sand or other granular material. The coefficient is calculated by determining the D^{60}/D^{10} ratio where D^{10} and D^{60} refer to the particle diameter corresponding to the 10 and 60 percentile of the material which is finer by dry weight.

(33) "Waters" are as defined in subsection 373.019(8), F.S.

(34) "Wet Detention" means the collection and temporary storage of stormwater in a permanently wet impoundment in such a manner as to provide for treatment through physical, chemical, and biological processes with subsequent gradual release of the stormwater.

(35) "Wetlands Stormwater Management System" means a stormwater management system which incorporates those wetland described in subsection 40C-42.0265(2), F.A.C., into the stormwater management system to provide stormwater treatment.

Specific Authority 373.044, 373.113, 373.171, 373.418 FS. Law Implemented 373.413, 373.416 FS. History--New 4-1-86. Amended 9-25-91, 3-21-93, 4-11-94, 10-3-95

40C-42.022 Permits Required.

(1) A permit is required under this chapter for construction (including operation and maintenance) of a stormwater management system which serves a project that exceeds any of the following thresholds:

(a) Construction of 4,000 square feet or more of impervious or semi-impervious surface area subject to vehicular traffic. This area includes roads, parking lots, driveways, and loading zones;

(b) Construction of 5000 square feet or more of building area or other impervious area not subject to vehicular traffic; or

(c) Construction of 5 acres or more of recreational area. Recreation areas include but are not limited to golf courses, tennis courts, putting greens, driving ranges, or ball fields.

(2) A permit is required under this chapter for alteration, removal, reconstruction, or abandonment of existing stormwater management systems which serve a project which may be expected to result in any of the following:

(a) Increase pollutant loadings (including sediment) in stormwater runoff from the project,

(b) Increase in peak discharge rate,

(c) Decrease in onsite or instream detention storage,

(d) Replacement of roadside swales with curb and gutter,

(e) Construction of 4,000 square feet or more of impervious or semi-impervious surface area subject to vehicular traffic. This area includes roads, parking lots, driveways, and loading zones;

(f) Construction of 5,000 square feet or more of building area or other impervious area not subject to vehicular traffic; or

(g) Construction of 5 acres or more of recreational area. Recreation areas include but not limited to golf courses, tennis courts, putting greens, driving ranges, or ball fields.

(3) These thresholds include all cumulative activity which occurs on or after September 25, 1991.

(4) For purposes of this section, the calculation of the amount of impervious surface shall not include water bodies.

(5) Applications received by the District for which a permit has not been issued prior to the rule revisions effective April 11, 1994, and which do not require a permit pursuant to sections (1) or (2), above, may be withdrawn by the applicant.

(6) Permits issued by the District for systems which no longer require a permit pursuant to sections (1) or (2), above, may either be abandoned or relinquished by the permittee subject to the following:

(a) Local governments may have concurrent jurisdiction with the District over a stormwater system. The permittee is not relieved by this rule of the responsibility to comply with any other applicable rules or ordinances which may govern such system.

(b) The permittee provides reasonable assurance that there will not be a violation of state water quality standards as set forth in chapter 62-302 and 62-550, F.A.C.;

(c) The permittee provides reasonable assurance that adjacent or nearby properties not owned or controlled by the applicant will not be adversely affected by drainage or flooding; and

(d) The permittee must apply to the District for and receive written authorization from the District prior to abandonment of the system.

Specific Authority 373.044, 373.113, 373.171, FS. Law Implemented 373.413, 373.416 FS. History--New 9-15-91. Amended 4-11-94, 11-22-94.

40C-42.0225 Exemptions From Permitting for Stormwater Management Systems. The following types of stormwater management systems are exempt from the notice and permit requirements of this chapter:

(1) Systems designed to accommodate only one single family dwelling unit, duplex, triplex, or quadruplex, provided the single unit, duplex, triplex or quadruplex is not part of a larger common plan of development or sale.

(2) Systems which are designed to serve single family residential projects, including duplexes, triplexes and quadruplexes, of less than 10 acres total land area and which have less than 2 acres impervious surface and if the systems:

(a) Comply with all regulations or ordinances applicable to stormwater management adopted by a city or county;

(b) Are not part of a larger common plan of development or sale; and

(c) Discharge into a stormwater management system exempted or permitted by the District under this chapter which has sufficient capacity and treatment capability as specified in this chapter and is owned, maintained, or operated by a city, county, special district with drainage responsibility, or water management district; however, this exemption does not authorize discharge to a system without the system owner's prior written consent.

(3) Systems that qualify for a noticed general permit pursuant to chapter 40C-400, F.A.C. and which comply with the requirements of such noticed general permit.

Specific Authority 373.044, 373.113, 373.171, 373.413 FS. Law Implemented 373.413, 373.416, 403.812 FS. History--New 9-25-91. Amended 3-21-93, 10-3-95.

40C-42.023 Requirements for Issuance.

(1) To receive a general or individual permit under this chapter the applicant must provide reasonable assurance based on plans, test results and other information, that the stormwater management system:

(a) will not result in discharges from the system to surface and ground water of the state that cause or contribute to violations of state water quality standards as set forth in chapters 62-3,

62-4, 62-302 and 62-550, F.A.C., including any antidegradation provisions of sections 62-4.242(1)(a) and (b), 62-4.242(2) and (3), and 62-302.300, F.A.C., and any special standards for Outstanding Florida Waters and Outstanding National Resource Waters set forth in sections 62-4.242(2) and (3), F.A.C.;

(b) will not adversely affect drainage and flood protection on adjacent or nearby properties not owned or controlled by the applicant;

(c) will be capable of being effectively operated and maintained pursuant to the requirements of this chapter; and

(d) meets any applicable basin criteria contained in chapter 40C-41, F.A.C.

(2)(a) A showing by the applicant that the stormwater management system complies with the applicable criteria in sections 40C-42.024, 40C-42.025, 40C-42.026, and 40C-42.0265, F.A.C., shall create a presumption that the applicant has provided reasonable assurance that the proposed activity meets the requirements in paragraphs (a), above.

(b) A showing by the applicant that the stormwater management system complies with the criteria of subsections 40C-42.025(8) and (9), F.A.C., shall create a presumption that the applicant has provided reasonable assurance that the proposed activity meets the requirements in paragraph (b), above.

(c) A showing by the applicant that the stormwater management system complies with the applicable criteria of sections 40C-42.027, 40C-42.028, and 40C-42.029, F.A.C., shall create a presumption that the applicant has provided reasonable assurance that the proposed activity meets the requirements in paragraph (c), above.

Specific Authority 373.044, 373.113, 373.171, 373.418 FS. Law Implemented 373.413, 373.416 FS. History--New 9-25-91. Amended 3-21-93, 10-3-95.

40C-42.024 Standard General and Individual Permits.

(1) Any person proposing to construct, alter, operate, maintain, remove, or abandon a stormwater management system, which requires a permit pursuant to sections 40C-42.022, F.A.C., except those exempted pursuant to section 40C-42.0225, F.A.C., or noted in section 40C-42.061, F.A.C, shall apply to the District for a standard general or individual environmental resource stormwater permit, prior to the commencement of construction, alteration, removal, operation, maintenance, or abandonment of the stormwater management system. No construction, alteration, removal, operation, maintenance, or abandonment of a stormwater management system shall be undertaken without a valid standard general or individual environmental resource stormwater permit as required pursuant to this section.

(2) The following types of stormwater management systems qualify for a standard general environmental resource stormwater permit and shall be processed according to the administrative procedures set forth in chapter 40C-40, F.A.C.:

(a) Systems which discharge into a stormwater management system which is permitted pursuant to paragraph 40C-42.024(2)(b), (c), or (d), F.A.C., or subsection 40C-42.024(3), F.A.C., or which was previously approved pursuant to a noticed exemption under section 17-25.030 where the appropriate treatment criteria specified in this chapter and applied to the permitted or exempt system are not exceeded by the discharge; however, this does not authorize discharge to the permitted or exempt system without the system owner's prior written consent.

(b) Systems which meet the applicable design and performance standards of section 40C-42.025, F.A.C., and which comply with any one or more of the following:

1. Retention systems which meet the criteria of subsection 40C-42.026(1), F.A.C.;

2. Underdrain systems which meet the criteria of subsection 40C-42.026(2), F.A.C.;

3. Underground exfiltration trench systems which meet the criteria of subsection 40C-42.026(3), F.A.C.;

4. Wet detention systems which meet the criteria of subsection 40C-42.026(4), F.A.C.; or

5. Swale systems which meet the criteria in subsections 40C- 42.021(30) and 40C-42.026(5), F.A.C.

6. Dry detention systems within project areas less than 5 acres in size, and which serve draiage area less than 5 acres in size, and which meet the criteria of subsection 40C-42.026(6), F.A.C.

(c) Modification or reconstruction by a city, county, state agency, federal agency, or special district with drainage responsibility, of an existing stormwater management system which is not intended to increase the original design capacity, and which will not increase pollution loading, or change points of discharge in a manner that would adversely affect the designated uses of waters in the state.

(d) Paving of existing public dirt roads by a public entity if all of the following conditions are met:

1. The road will not serve new development.

2. Additional traffic lanes are not added to the road;

3. The traffic load is not expected to significantly increase;

4. The drainage system serving the road is not significantly altered;

5. Erosion and sediment controls are utilized to prevent turbidity during construction;

6. The project does not involve dredging or filling in wetlands or other surface waters, other than in ditches that were excavated through uplands ;

7. Permanent vegetative cover is established on both sides of the pavement within the road right of way; and

8. Swale blocks, or other means, are utilized to retain runoff and promote infiltration in areas with soil having good infiltration (i.e., SCS hydrologic soil groups "A" and "B").

(3) The following types of stormwater management systems will be processed as an individual permit according to the administrative procedures set forth in chapter 40C-4, F.A.C.:

(a) Wetlands stormwater management systems which are designed pursuant to the criteria in sections 40C-42.025 and 40C-42.0265, F.A.C.;

(b) Systems which propose to satisfy the standards of subsection 40C-42.023(1), F.A.C., by employing an alternative treatment methodology or device other than those described in subsection (2) or paragraph (3)(a), above. An affirmative showing by the applicant that the system design will provide treatment equivalent to retention systems described in paragraph (2)(b)1., above, will create a presumption in favor of satisfying the standards in paragraphs 40C-42.023(1)(a), F.A.C. In addition, systems which have a direct discharge to Class I, Class II, Outstanding Florida Waters, or Class III waters which are approved, conditionally approved, restricted, or conditionally restricted for shellfish harvesting shall provide an additional level of

treatment (i.e., additional treatment volume and off-line treatment) pursuant to section 40C-42.026, F.A.C., or an alternative demonstrated by the applicant to be equivalent.

(c) Systems which do not meet the applicable criteria of sections 40C-42.025, 40C-42.026, or 40C-42.0265, F.A.C. An affirmative showing by the applicant based on plans, test results, calculations, or other information that an alternative design is appropriate for the specific site conditions will create a presumption in favor of satisfying the applicable standards in subsection 40C-42.023(1), F.A.C.

(4) In otherwise determining whether reasonable assurance has been provided for paragraphs (3)(b) and (c), above, the District shall, where appropriate, consider:

(a) Whether best management practices are proposed, such as those described in "Stormwater Management Manual (October, 1981)," "The Florida Development Manual: A Guide to Sound Land and Water Management (June, 1988)," or best management practices described in manuals adopted by the Environmental Regulation Commission pursuant to section 62-25.050, F.A.C., or other appropriate best management practices (the manuals listed above by name are adopted and made a part of this rule by reference. Copies of these documents may be inspected at all District offices);

(b) The public interest served by the system;

(c) The probable efficacy and costs of alternative controls; and

(d) Whether reasonable provisions have been made for the operation and maintenance of the proposed system.

(5) The standard general or individual environmental resource stormwater permit which is granted will include a specified period for which the permit will be valid. Such period, unless the permit is modified or revoked, is generally:

(a) five years for permits to construct, alter, or remove a system; and

(b) permanent for permits to operate, maintain, or abandon a system.

(6) Procedures governing transfers, permit revocation, permit modifications, and extensions are found in chapters 40C-1 and 40C-4, F.A.C., and apply to permits obtained pursuant to this chapter. Procedures governing converting construction to operation permits and transferring the system to the operation and maintenance entity are found in section 40C-42.027, F.A.C., below. *Specific Authority 373.044, 373.113, 373.118, 373.171, 373.418 FS. Law Implemented 373.413, 373.416, 403.813 FS. History--New 9-25-91. Amended 3-21-93, 4-11-94, 10-3-95.*

40C-42.025 Design and Performance Criteria for Stormwater Management Systems. The following criteria shall apply to stormwater management systems unless otherwise noted:

(1) Erosion and sediment control best management practices shall be used as necessary during construction to retain sediment on-site. These management practices shall be designed and certified by an appropriate registered professional experienced in the fields of soil conservation or sediment control according to specific site conditions and shall be shown or noted on the plans of the stormwater management system. The registered professional shall furnish the contractor with information pertaining to the construction, operation and maintenance of the erosion and sediment control practice. Sediment accumulations in the system from construction activities shall be removed to prevent loss of storage volume.

(2) Stormwater management systems which either receive stormwater from areas with greater than 50 percent impervious surface or are a potential source of oil and grease contamination in concentrations that exceed applicable water quality standards shall include a baffle, skimmer, grease trap or other mechanism suitable for preventing oil and grease from leaving the stormwater management system in concentrations that would cause or contribute to violations of applicable water quality standards in the receiving waters. For purposes of this subsection, the calculation of the amount of impervious surface shall not include water bodies.

(3) Unless applicable local regulations are more restrictive, for purposes of public safety the following requirements apply:

(a) Normally dry basins designed to impound more than two feet of water or permanently wet basins shall be fenced or otherwise restricted from public access, or shall contain side slopes that are no steeper than 4:1 (horizontal:vertical) out to depth of two feet below the control elevation; and,

(b) Control devices that are designed to contain more than a two foot depth of water within the structure under the design storm and have openings greater than one foot minimum dimension shall be restricted from public access.

(4) All stormwater basin side slopes shall be stabilized by either vegetation or other materials to minimize erosion and sedimentation of the basins.

(5) Stormwater management systems must be designed to accommodate maintenance equipment access and to facilitate regular operational maintenance (such as underdrain replacement, unclogging filters, sediment removal, mowing and vegetation control). Operational maintenance and operation easements shall be provided when necessary to facilitate equipment access.

(6) The applicant must obtain sufficient legal authorization as appropriate prior to permit issuance for stormwater management systems which propose to utilize offsite areas to satisfy the requirements in subsection 40C-42.023(1), F.A.C.

(7) Stormwater management systems (except retention and exfiltration trench systems) shall provide gravity or pumped discharge that effectively operates under one of the following tailwater conditions:

(a) Maximum stage in the receiving water resulting from the mean annual 24-hour storm. This storm depth is described in "Rainfall Analysis for Northeast Florida;" St. Johns River Water Management District Technical Publication No. SJ 88-3 (May, 1988). Lower stages may be utilized if the applicant demonstrates that flow from the project will reach the receiving water prior to the time of maximum stage in the receiving water;

(b) Mean annual high tide for tidal areas;

(c) Mean annual seasonal high water elevation. This elevation may be determined by water lines on vegetation or structures, historical data, adventitious roots or other hydrological or biological indicators, design of man-made systems, or estimated by a registered professional using standard hydrological methods based on the site and receiving water characteristics; or

(d) As an alternative, the applicant may propose any applicable criterion established by a local government, state agency, or stormwater utility with jurisdiction over the project.

(8) Stormwater management systems which require a permit pursuant to subsection 40C-42.022(1), F.A.C., and which serve new construction area with greater than 50 percent

R0070993

impervious surface (excluding water bodies) must demonstrate that the post-development peak rate of discharge does not exceed the pre-development peak rate of discharge for one of the following:

(a) The mean annual 24-hour storm event. This storm depth is described in "Rainfall Analysis for Northeast Florida;" St. Johns River Water Management District Technical Publication No. SJ 88-3 (May, 1988). The criteria contained in sections 10.3.5 - 10.3.8 of the Management and Storage of Surface Waters Applicant's Handbook, (A.H.), are herein incorporated by reference;

(b) The mean annual 24-hour storm event utilizing the modified rational hydrograph method. This storm depth is described in the publication referenced in paragraph (a), above. This methodology should only be used for systems meeting the following criteria:

1. The drainage area is less than 40 acres;

2. The pre-development time of concentration for the system is less than 60 minutes; and,

3. The post-development time of concentration for the system is less than 30 minutes; or

(c) As an alternative to paragraphs (a) or (b), above, the applicant may propose a storm event, duration, and criteria specified by a local government, state agency, or stormwater utility with jurisdiction over the project.

(9) Stormwater management systems which alter existing conveyance systems must not adversely affect existing surface water conveyance capabilities. It is presumed that a system meets this criteria if one of the following are met:

(a) The existing hydraulic conveyance is maintained;

(b) The applicant demonstrates that changes in flood elevations or velocities will not adversely impact upstream or downstream off-site property;

(c) The applicant demonstrates that the criteria in 10.5.2(b), Applicant's Handbook, are met; or

(d) As an alternative, the applicant may propose to comply with applicable criteria established by a local government, state agency, or stormwater utility with jurisdiction over the project.

(10) The construction plans and supporting calculations must be signed, sealed, and dated by an appropriate registered professional as required by the relevant statutory provisions when the design of the stormwater management system requires the services of an appropriate registered professional.

(11) Stormwater management systems located within Sensitive Karst Areas must meet the requirements of subsection 40C-41.063(6), F.A.C.

Specific Authority 373.044, 373.113, 373.171, 373.418 FS. Law Implemented 373.117, 373.413, 373.416, 403.0877 FS. History--New 4-1-86. Amended 9-25-91, 3-21-93.

40C-42.026 Specific Design and Performance Criteria.

(1) Retention systems shall:

(a) Provide for one of the following:

1. Off-line retention of the first one half inch of runoff or 1.25 inches of runoff from the impervious area, whichever is greater;

2. On-line retention of an additional one half inch of runoff from the drainage area over that volume specified in subparagraph 1., above;

3. On-line retention that provides for percolation of the runoff from the three year, one-hour storm; or

4. On-line retention of the runoff from one inch of rainfall or 1.25 inches of runoff from the impervious area, whichever is greater, for systems which serve an area with less than 40 percent impervious surface and that contain only U.S. Department of Agriculture Soil Conservation Service (SCS) hydrologic group "A" soils.

(b) Provide retention in accordance with one of the following for those systems which have direct discharge to Class I, Class II, Outstanding Florida Waters, or Class III waters which are approved, conditionally approved, restricted, or conditionally restricted for shellfish harvesting:

1. At least an additional fifty percent of the applicable treatment volume specified in subparagraph 1., above. Off-line retention must be provided for at least the first one half inch of runoff or 1.25 inches of runoff from the impervious area, whichever is greater, of the total amount of runoff required to be treated;

2. On-line retention of an additional fifty percent of the treatment volume specified in subparagraph 2., above;

3. On-line retention that provides percolation of the runoff from the three-year, one-hour storm; or

4. On-line retention that provides at least an additional 50 percent of the runoff volume specified in subparagraph 40C-42.026(1)(a)4., above, for systems which serve an area with less that 40 percent impervious surface and that contain only U.S. Department of Agriculture Soil Conservation Service (SCS) hydrologic group "A" soils.

(c) Provide the capacity for the appropriate treatment volume of stormwater specified in paragraphs (a) or (b) above, within 72 hours following the storm event assuming average antecedent moisture conditions. The storage volume must be provided by a decrease of stored water caused only by percolation through soil, evaporation or evapotranspiration.

(d) Be stabilized with pervious material or permanent vegetative cover. Permanent vegetative cover must be utilized, except for pervious pavement systems, when U.S. Department of Agriculture Soil Conservation Service (SCS) hydrologic group "A" soils underlie the retention basin.

(2) Underdrain stormwater management systems shall:

(a) Provide for either of the following:

1. Off-line storage of the first one half inch of runoff or 1.25 inches of runoff from the impervious area, whichever is greater; or

2. On-line storage of an additional one half inch of runoff from the drainage area over that volume specified in subparagraph 1., above.

(b) Provide either of the following for those underdrain systems which have direct discharge to Class I, Class II, Outstanding Florida Waters, or Class III waters which are approved, restricted, or conditionally restricted for shellfish harvesting:

1. At least an additional fifty percent of the applicable treatment volume specified in subparagraph 1., above. Off-line storage must be provided for at least the first one half inch of

runoff or 1.25 inches of runoff from the impervious area, whichever is greater, of the total amount of runoff required to be treated; or

2. On-line storage of the runoff from a three-year, one-hour storm or an additional fifty percent of the treatment volume specified in subparagraph 2., above, whichever is greater.

(c) Provide the capacity for the appropriate treatment volume of stormwater specified in paragraphs (a) or (b), above, within 72 hours following a storm event. The storage volume must be provided by a decrease of stored water caused only by percolation through soil with subsequent transport through the underdrain pipes, evaporation or evapotranspiration.

(d) Provide at least two feet of indigenous soil between the bottom of the stormwater holding area and the underdrain pipe(s).

(e) Be designed with a safety factor of at least two unless the applicant affirmatively demonstrates based on plans, test results, calculations or other information that a lower safety factor is appropriate for the specific site conditions. Examples of how to apply this factor include but are not limited to reducing the design percolation rate by half or designing for the required drawdown within 36 hours instead of 72 hours.

(f) Contain areas of standing water only following a rainfall event.

(g) Be stabilized with permanent vegetative cover.

(h) Include, at a minimum, a capped and sealed inspection and cleanout ports which extend to the surface of the ground at the following locations of each drainage pipe:

1. The terminus; and

2. Every 400 feet or every bend of 45 or more degrees, whichever is less.

(i) Utilize filter fabric or other means used to prevent the soil from moving and being washed out through the underdrain pipe.

(3) Underground exfiltration trench systems shall:

(a) Provide for either of the following:

1. Off-line storage of the first one half inch of runoff or 1.25 inches of runoff from the impervious area, whichever is greater; or

2. On-line storage of an additional one half inch of runoff from the drainage area over that volume specified in subparagraph 1., above.

(b) Provide either of the following for those exfiltration trench systems which have direct discharge to Class I, Class II, Outstanding Florida Waters, or Class III waters which are approved, conditionally approved, restricted, conditionally restricted for shellfish harvesting:

1. At least an additional fifty percent of the applicable treatment volume specified in subparagraph 1., above. Off-line storage must be provided for at least the first one half inch of runoff or 1.25 inches of runoff from the impervious area, whichever is greater, of the total amount of runoff required to be treated; or

2. On-line storage of the runoff from the three-year, one-hour storm or an additional fifty percent of the treatment volume specified in subparagraph 2., above, whichever is greater.

(c) Provide the capacity for the appropriate treatment volume of stormwater specified in paragraphs (a) or (b), above, within 72 hours following a storm event assuming average antecedent moisture conditions. The storage volume must be provided by a decrease of stored water caused only by percolation into the soil.

R0070996

(d) Be designed with a safety factor of at least two unless the applicant affirmatively demonstrates based on plans, test results, calculations or other information that a lower safety factor is appropriate for the specific site conditions. Examples of how to apply this factor include but are not limited to reducing the design percolation rate by half or designing for the required drawdown within 36 hours instead of 72 hours.

(e) Be designed with a twelve (12) inch minimum pipe diameter.

(f) Be designed with a three (3) foot minimum trench width.

(g) Be designed so that aggregate in the trench is enclosed in filter fabric.

(h) Provide cleanout and inspection structures which extend to the surface of the ground at the inlet and terminus of each pipe. Inlet structures should include sediment sumps.

(i) Be designed so that the invert elevation of the trench must be at least two feet above the seasonal high ground water table elevation unless the applicant demonstrates based on plans, test results, calculations or other information that a alternative design is appropriate for the specific site conditions.

(j) Be designed so that the system must have the capacity to retain the required treatment volume without considering discharges to ground or surface waters.

(4) Wet detention stormwater management systems shall:

(a) Provide a treatment volume of the greater of the following:

1. First one inch of runoff; or

2. 2.5 inches of runoff from the impervious area.

(b) Be designed so that the outfall structures shall bleed down one-half the volume of stormwater specified in paragraph (a), above, within 48 to 60 hours following a storm event, but no more than one-half of this volume will be discharged within the first 48 hours.

(c) Contain a permanent pool of water sized to provide an average residence time of at least 14 days during the wet season (June - October).

(d)1. Provide a littoral zone to be designed as follows:

a. The littoral zone shall be gently sloped (6:1 or flatter). At least 30 percent of the wet detention system surface area shall consist of a littoral zone. The percentage of littoral zone is based on the ratio of vegetated littoral zone to surface area of the pond at the control elevation.

b. The treatment volume should not cause the pond level to rise more than 18 inches above the control elevation unless the applicant affirmatively demonstrates that the littoral zone vegetation can survive at greater depths.

c. Eighty percent coverage of the littoral zone by suitable aquatic plants is required within the first twenty-four months of completion of the system or as specified by permit conditions.

d. To meet the 80% coverage requirement, planting of the littoral zone is recommended. As an alternative, portions of the littoral zone may be established by placement of wetland top soils (at least a four inch depth) containing a seed source of desirable native plants. When utilizing this alternative, the littoral zone must be stabilized by mulching or other means and at least the portion of the littoral zone within 25 feet of the inlet and outlet structures must be planted.

2. In lieu of the requirements of subparagraph 1., above, the applicant may provide either of the following:

R0070997

a. At least fifty percent additional permanent pool volume over that specified in paragraph (c), above; or

b. Treatment of the stormwater pursuant to subparagraphs 40C- 42.024(2)(b)2., 3., 4., or 6., F.A.C., prior to the stormwater entering the wet detention pond.

(e) Be designed so that the mean depth of the permanent pool is between 2 and 8 feet and the maximum depth does not exceed 12 feet below the invert of the bleed down device, unless the applicant affirmatively demonstrates that alternative depths will not inhibit the physical, chemical, and biological treatment processes or cause the resuspension of pollutants into the water column due to anaerobic conditions in the water column.

(f) Be designed so the flow path through the pond has an average length to width ratio of at least 2:1. The alignment and location of inlets and outlets should be designed to maximize flow paths in the pond. If short flow paths are unavoidable, the effective flow path should be increased by adding diversion barriers such as islands, peninsulas, or baffles to the pond. Inlet structures shall be designed to dissipate the energy of water entering the pond.

(g) Be designed so that bleed down devices incorporating dimensions smaller than three inches minimum width or less than 20 degrees for "v" notches shall include a device to eliminate clogging. Examples include baffles, grates, and pipe elbows.

(h) Be designed so that bleed down structure invert elevations are at or above the estimated post-development normal ground water table elevation. If the structure is proposed to be set below this elevation, ground water inflow must be considered in the drawdown calculations, calculation of average residence time, estimated normal water level in the pond, and pollution removal efficiency of the system.

(i) Provide for permanent maintenance easements or other acceptable legal instruments to allow for access to and maintenance of the system, including the pond, littoral zone, inlets, and outlets. The easement or other acceptable instrument must cover the entire littoral zone.

(j) Be designed so that the average pond side slope measured between the control elevation and two feet below the control elevation is no steeper than 3:1 (horizontal:vertical).

(k) Wet detention systems which have direct discharge to Class I, Class II Outstanding Florida Waters, or Class III waters which are approved, conditionally approved, restricted, or conditionally restricted for shellfish harvesting shall provide either of the following in addition to the requirements in paragraphs (b), (d), and (e) - (j), above:

1. An additional fifty percent of the applicable treatment volume specified in paragraph (a), above, and an additional fifty percent of the applicable permanent pool volumes specified in paragraphs (c) or subparagraph (d)2., above; or

2. Treatment pursuant to subsections (1), (2), (3) above, or (5) below, prior to discharging into a wet detention pond designed pursuant to paragraphs (a) - (j), above.

(5) Swale systems shall:

(a) Percolate 80% of the runoff from the three year, one-hour storm.

(b) Percolate the runoff from the three-year, one-hour storm for those swale systems which have direct discharge to Class I, Class II, Outstanding Florida Waters, or Class III waters which are approved, conditionally approved, restricted, or conditionally restricted for shellfish harvesting.

R0070998

(c) -- Provide the capacity for the given volume of stormwater pursuant to paragraphs (a) or (b), above, and contain no contiguous areas of standing or flowing water within 72 hours following the storm event referenced in paragraphs (a) and (b), above, assuming average antecedent moisture conditions. The storage volume must be provided by a decrease of stored water caused only by percolation through soil, evaporation or evapotranspiration.

(d) Meet the criteria in subsection 40C-42.021(29), F.A.C.

(6) Dry detention systems shall:

(a) Provide off-line detention of the first one inch of runoff or 2.5 inches of runoff from the impervious area, whichever is greater.

(b) Provide at least an additional fifty percent of the applicable treatment volume specified in subparagraph 1., above, for those systems which have direct discharge to Class I, Class II, Outstanding Florida Waters, or Class III waters which are approved, conditionally approved, restricted, or conditionally restricted for shellfish harvesting.

(c) Be designed so that the outfall structures shall discharge one-half the appropriate treatment volume of stormwater specified in paragraphs (a) or (b), above, between 24 to 30 hours following a storm event.

(d) Be designed so that discharge structures shall include a device to prevent the discharge of accumulated sediment, minimize exit velocities, and prevent clogging. Examples include perforated riser enclosed in a gravel jacket and perforated pipes enclosed in sand or gravel.

(e) Contain areas of standing water for no longer than 3 days following a rainfall event.

(f) Be stabilized with permanent vegetative cover.

(g) Be designed so the average flow path through the basin has a length to width ratio of at least 2:1. The alignment and location of inlets and outlets should be designed to maximize flow paths in the basin. If short flow paths are unavoidable, the effective flow path should be increased by adding diversion barriers such as baffles to the basin.

(h) Be designed so inlet structures dissipate the energy of water entering the basin.

(i) Be designed to include a maintenance schedule for removal of sediment and debris on at least a bi-monthly basis from the basin and mowing and removal of grass clippings.

(j) Be designed so the basin floor is level or uniformly sloped toward the outfall structure.

(k) Be designed so that the basin floor and control elevation is at least one foot above the seasonal high ground water table elevation. Sumps may be placed up to one foot below the control elevation.

Specific Authority 373.044, 373.113, 373.118, 373.177, 373.418 FS. Law Implemented 373.413, 373.416, 403.813 FS. History--New 9-25-91. Amended 3-21-93, 6-15-93, 4-11-94, 7-20-95.

40C-42.0265 Design and Performance Criteria for Wetlands Stormwater Management Systems.

(1) The wetlands stormwater management system design and performance criteria and other provisions relating to such systems are an initial but necessary step by the District in a field in which there exists limited knowledge. In an effort to further refine the District's wetlands stormwater management system policies, monitoring data and other pertinent information relating to the performance criteria will be collected and analyzed and periodic reports of the results of this

R0070999

monitoring shall be made available to the public. The District must attempt to ensure that the wetlands stormwater management system is compatible with the ecological characteristics of the wetlands utilized for stormwater treatment and to ensure that water quality standards will not be violated by discharges from wetlands stormwater management system. To achieve these goals, specific performance criteria are set forth in this section for systems which incorporate wetlands for stormwater treatment.

(2) The only wetlands to be used for stormwater treatment are those:

(a) Which are isolated wetlands; and

(b) Which would be isolated wetlands, but for a hydrologic connection to other wetlands or surface waters via another watercourse that was excavated through uplands.

(3) Applications for wetland stormwater management systems shall be processed by the District as an individual permit application according to the administrative procedures set forth in chapter 40C-4, F.A.C.

(4) In the review of wetlands stormwater management system permit applications, the District shall consider the following:

(a) Compliance of the wetlands stormwater management system permit with the performance criteria specified in subsection 40C-42.0265(5).

(b) If the applicant is unable to show compliance with the performance criteria in subsection 40C-42.0265(5), the applicant shall qualify for a wetlands stormwater management system permit using alternative design and performance criteria if the applicant affirmatively demonstrates that the use of the wetlands is compatible with the ecological characteristics of the wetland and the applicant complies with the standards in section 40C-42.023, F.A.C.

(c) If the applicant proposes to dredge or fill in the wetlands used for stormwater treatment, the District in its review of the permit application shall evaluate the adverse effects of the dredging or filling on the treatment capability of the wetland.

(5) A showing by the applicant that the wetlands stormwater management system design complies with the performance criteria listed below shall create a presumption in favor of the issuance of the permit:

(a) The system complies with the requirements of section 40C-42.025 and subsection 40C-42.0265(2), F.A.C.

(b) The system is part of a comprehensive stormwater management system that utilizes wetlands in combination with other best management practices to provide treatment of the runoff from the greater of the following:

1. First one inch of runoff; or

2. 2.5 inches times the impervious area.

(c) Those systems which direct discharge to Class I, Class II, or Outstanding Florida Waters shall provide an additional fifty percent of the applicable treatment volume specified in paragraph (b), above.

(d) The wetlands stormwater management system must provide treatment for the runoff as specified in paragraph 40C-42.0265(5)(b) or (c), F.A.C., within the wetlands. The design features of the system shall maximize residence time of the stormwater within the wetland. The outfall structure shall be designed to bleed down one-half the volume specified in paragraph 40C-42.0265(5)(b) or (c) within the first 60 to 72 hours.

(e) Stormwater shall be discharged into the wetlands utilized so as to minimize the channelized flow of stormwater by employing methods including, but not limited to, sprinklers, overland flow or spreader swales.

(f) The use of wetlands for stormwater must meet the criteria in section 12.0, Environmental Considerations, of the Applicant's Handbook: Management and Storage of Surface Waters, adopted by reference in section 40C-4.091, F.A.C.

(6) In order to establish a reliable, scientifically valid data base upon which to evaluate the performance criteria and the performance of the wetlands stormwater management system, a monitoring program may be required. Monitoring programs shall provide the District with comparable data for different types of wetlands and drainage designs. Data to be collected shall include (unless irrelevant to the permitted system): sedimentation rate, sediment trace metal concentrations, sediment nitrogen and phosphorus concentrations, changes in the frequency, abundance and distribution of vegetation, and inflow and outflow water quality for nutrients, metals, turbidity, oils and greases, bacteria and other parameters related to the specific site conditions. Inflow and outflow water quality parameters will be monitored on such storm event occurrences as established by the District based on a site specific basis. The District shall eliminate the requirement to continue the monitoring program upon its determination that no further data is necessary to evaluate the performance criteria or ensure compliance with the performance criteria and applicable water quality standards.

Specific Authority 373.044, 373.113, 373.177, 373.418 FS. Law Implemented 373.413, 373.416 FS. History--New 9-25-91, 3-21-93, 10-3-95.

40C-42.027 Legal Operation and Maintenance Entity Requirements.

(1) The District considers the following entities to be acceptable for meeting the requirements necessary to ensure that a stormwater management system will be operated and maintained in compliance with the requirements of this Chapter and other District regulations in chapters 40C-4 or 40C-40, F.A.C.:

(a) Local governmental units including counties or municipalities, or Municipal Service Taxing Units established pursuant to section 125.01, F.S.;

(b) Active water control districts created pursuant to chapter 298, F.S., or drainage districts created by special act, or Community Development Districts created pursuant to chapter 190, F.S., or Special Assessment Districts created pursuant to chapter 170, F.S.;

(c) State or federal agencies; or

(d) Duly constituted stormwater, communication, water, sewer, electrical or other public utilities.

(2) The property owner or developer is normally not acceptable as a responsible entity when the property is intended to be subdivided. The property owner or developer shall be acceptable in any of the following circumstances:

(a) Written proof is furnished either by letter or resolution, that a governmental entity or such other acceptable entity as set forth in paragraphs (a)-(d) above, will accept the operation and maintenance of the stormwater management system at a time certain in the future;

(b) Proof of bonding or assurance of a similar nature is furnished in an amount sufficient to cover the cost of the operation and maintenance of the stormwater management system;

(c) The property is wholly owned by the permittee and ownership is intended to be retained. This would apply to a farm, corporate office or single industrial facility, for example; or

(d) The ownership of the property is retained by the permittee and is either leased or rented to third parties such as in shopping centers or mobile home parks.

(3) Profit or non-profit corporations including homeowners associations, property owners associations, condominium owners associations or master associations shall be acceptable only under certain conditions that ensure that the corporation has the financial, legal and administrative capability to provide for the long term operation and maintenance of the stormwater management system.

(4) Entity Requirements.

(a) If a multimember association such as a Homeowner, Property Owner, Condominium or Master Association is proposed, the owner or developer must submit Articles of Incorporation for the Association, and Declaration of Covenants and Restrictions, or such other organizational and operational documents which affirmatively assign authority and responsibility for the operation or maintenance of the stormwater management system.

(b) The Association shall have sufficient powers reflected in its organizational or operational documents to:

1. Operate and maintain the stormwater management system as permitted or exempted by the District;

2. Establish rules and regulations;

3. Assess members a fee for the cost of operation and maintenance of the system, and enforce collection of such assessments;

4. Contract for services (if the Association contemplates employing a maintenance company) to provide the services for operation and maintenance;

5. Exist in perpetuity. The Articles of Incorporation must provide that if the association is dissolved the stormwater management system shall be transferred to and maintained by an entity acceptable to the District as defined in this section. Transfer of maintenance responsibility shall be effectuated prior to dissolution of the association;

6. Enforce the restrictions relating to the operation and maintenance of the stormwater management system;

7. Provide that the portions of the Declarations which relate to the operation and maintenance may be enforced by the District in a proceeding at law or in equity; and

8. Require that amendments to the documents which alter the stormwater management system beyond maintenance in its original condition must receive District approval prior to taking effect.

(5) Phased Projects.

(a) If an Operation and Maintenance entity is proposed for a project which will be constructed in phases, and subsequent phases will utilize the same stormwater management systems as the initial phase or phases, the entity shall have the ability to accept responsibility for the operation and maintenance of stormwater management system for future phases of the project.

(b) If the development scheme contemplates independent operation and maintenance entities for different phases, and the stormwater management system is integrated throughout the project, the entities either separately or collectively shall have the authority and responsibility to operate and maintain the stormwater management system for the entire project. That authority shall include cross easements for stormwater management and the ability to enter and maintain the various systems, should any sub-entity fail to maintain a portion of the stormwater management system within the project.

(6) The applicant shall be an acceptable entity from the time construction begins until the stormwater management system is dedicated to and accepted by a legal entity established pursuant to this section. The applicant shall provide proof of the existence of an entity pursuant to this section or of the future acceptance of the system by an entity described in this section prior to initiating construction.

Specific Authority 373.044, 373.113, 373.171 FS. Law Implemented 403.812, 403.814 FS. History--New 4-1-86. Amended 9-25-91, 3-21-93.

40C-42.028 Operation Phase Permits.

(1) The operation phase of a stormwater management system permit which was designed by an appropriate registered professional does not become effective until all of the following criteria in this subsection and subsection (3) have occurred:

(a) Within 30 days after completion of construction of the stormwater management system, permittee shall submit a signed and sealed certification by an appropriate registered professional indicating that the system has been constructed and that the system is ready for inspection by the District.

(b) The certification prepared by a registered professional (not necessarily the project design registered professional but one who has been retained by the permittee to provide professional services during the construction phase of project completion) shall be made on form number 40C-1.181(13), As Built Certification by a Registered Professional.

(c) The registered professional shall certify that:

1. The system has been constructed substantially in accordance with approved plans and specifications, or;

2. Any deviations from the approved plans and specifications will not prevent the system from functioning in compliance with the requirements of this chapter. The registered professional shall note and explain substantial deviations from the approved plans and specifications and provide two copies of as-built drawings to the District.

(d) The certification shall be based upon on-site observation of construction (scheduled and conducted by the professional or by a project representative under his or her direct supervision) or review of as-built drawings for the purpose of determining if the work was completed in compliance with approved plans and specifications.

(e) As-built drawings shall be the permitted drawings revised to reflect any changes made during construction. Both the original and revised specifications must be clearly shown. The plans must be clearly labeled as "as-built" or "record" drawings. All surveyed dimensions and elevations required shall be certified by a registered surveyor. The following information, at a minimum, shall be verified on the as-built drawings:

R0071003

1. Dimensions and elevations of all discharge structures including all weirs, slots, gates pumps, pipes, and oil and grease skimmers;

2. Locations, dimensions, and elevations of all filter, exfiltration, or underdrain systems including cleanouts, pipes, connections to control structures, and points of discharge to the receiving waters;

3. Dimensions, elevations, contours, or cross-sections of all treatment storage areas sufficient to determine stage-storage relationships of the storage area and the permanent pool depth and volume below the control elevation for normally wet systems, when appropriate;

4. Dimensions, elevations, contours, final grades, or cross-sections of the system to determine flow directions and conveyance of runoff to the treatment system;

5. Dimensions, elevations, contours, final grades, or cross-sections of all conveyance systems utilized to convey off-site runoff around the system;

6. Existing water elevation(s) and the date determined; and

7. Elevation and location of benchmark(s) for the survey.

(2) The operation phase of a stormwater management system permit which was not designed by an appropriate registered professional does not become effective until all of the criteria in this subsection, and subsection (3) below, have occurred. Within 30 days after completion of construction of the stormwater management system, permittee shall submit a certification, on form number 40C-1.181(14), As Built Certification, that the system has been constructed in accordance with the design approved by the District and shall notify the District that the system is ready for inspection.

(3) The permittee shall submit documentation to the District showing that adequate provisions have been made for the operation and maintenance of the system and for meeting any special permit conditions. Entities which qualify to operate and maintain systems for purposes of this rule are listed at section 40C-42.027, supra. Documentation must include an affirmative indication that the entity intends to or agrees to take over maintenance responsibility for the system, unless the transfer is associated with the conversion of the construction permit to its operation phase and the maintenenac entity exists as approved under the permit.

(4) The permit will be converted from a construction permit to an operation permit once the project is determined to be in compliance with the permitted plans and an appropriate entity exists for maintenance of the system. The District will transfer the permit to the maintenance entity upon request, pursuant to section 40C-4.351, F.A.C., once all conditions for converting the construction permit to an operation permit have been met.

Specific Authority 373.044, 373.113, 373.171, 373.418 FS. Law Implemented 373.413, 373.416 FS. History--New 9-25-91, 3-21-93. Amended 7-20-95.

40C-42.029 Monitoring and Operational Maintenance Requirements.

(1) The operation and maintenance entity is required to provide for periodic inspections of the stormwater management system to insure that the system is functioning as designed and permitted. The entity shall submit inspection reports to the District, certifying that the stormwater management system is operating as designed. In addition, the entity will state in the report what operational maintenance has been performed on the system. The reports shall only be required for those systems which are subject to operation phase permits pursuant to subsection 40C-42.028(1),

F.A.C., after the effective date of this rule adoption, unless indicated otherwise in a permit. The reports shall be submitted to the District as follows unless otherwise required by a permit condition:

(a) Inspection reports for retention, underdrain, wet detention, swales, and wetland stormwater management systems shall be submitted two years after the completion of construction and every two years thereafter on form number 40C-1.181(15), Registered Professional's Inspection Report, for systems designed by a registered professional. For systems not designed by a registered professional, the inspection reports shall be submitted on form number 40C-1.181(16), Statement of Inspection Report. However, reports for those systems in sensitive karst areas must be submitted pursuant to paragraph (c) below.

(b) Inspection reports for dry detention, exfiltration, and pumped systems shall be submitted one year after the completion of construction and every two years thereafter on form number 40C-1.181(15), Registered Professional's Inspection Report. A registered professional must sign and seal the report certifying the dry detention, filtration, exfiltration, or pumped system is operating as designed. However, reports for those systems in sensitive karst areas must be submitted pursuant to paragraph (c) below.

(c) Systems in sensitive karst areas must be inspected monthly for the occurrence of sinkholes and solution pipes. The inspection reports for these systems must be submitted to the District annually on form number 40C-1.181(15), Registered Professional's Inspection Report, for systems designed by a registered professional. For systems not designed by a registered professional, the inspection reports shall be submitted on form number 40C-1.181(16), Statement of Inspection Report.

(2) Permittees which operate stormwater management systems that are designed and constructed to accept stormwater from multiple parcels within the drainage area served by the system shall notify the District annually of the stormwater discharge volumes of all new parcels which have been allowed to discharge into the system in the previous year and shall certify that the maximum allowable treatment volume of stormwater has not been exceeded.

(3) The following operational maintenance activities shall be performed on all permitted systems on a regular basis or as needed:

(a) Removal of trash and debris,

(b) Inspection of inlets and outlets,

(c) Removal of sediments when the storage volume or conveyance capacity of the stormwater management system is below design levels, and

(d) Stabilization and restoration of eroded areas.

(4) Specific operational maintenance activities are required, depending on the type of permitted system, in addition to the practices listed in subsection (3), above.

(a) Retention, swale and underdrain systems shall include provisions for:

1. Mowing and removal of grass clippings, and

2. Aeration, tilling, or replacement of topsoil as needed to restore the percolation capability of the system. If tilling or replacement of the topsoil is utilized, vegetation must be established on the disturbed surfaces.

(b) Exfiltration systems shall include provisions for removal of sediment and debris from sediment sumps.

(c) Wet detention systems shall include provisions for operational maintenance of the littoral zone. Replanting shall be required if the percentage of vegetative cover falls below the permitted level. It is recommended that native vegetation be maintained in the littoral zone as part of the system's operation and maintenance plan. Undesirable species such as cattail and exotic plants should be controlled if they become a nuisance.

(d) Dry detention systems shall include provisions for mowing and removal of grass clippings

(e) Systems in sensitive karst areas shall include provisions for the repair of any sinkhole or solution pipe that develops in the system.

(5) If the system is not functioning as designed and permitted, operational maintenance must be performed immediately to restore the system. If operational maintenance measures are insufficient to enable the system to meet the design and performance standards of this chapter, the permittee must either replace the system or construct an alternative design. A permit modification must be obtained from the District prior to constructing such alternative design pursuant to section 40C-4.331, F.A.C.

Specific Authority 373.044, 373.113, 373.171, 373.418 FS. Law Implemented 373.413, 373.416 FS. History--New 9-25-91. Amended 3-21-93, 4-11-94.

40C-42.031 Exemptions for Stormwater Management Systems.

Specific Authority 373.044, 373.113, 373.171 FS. Law Implemented 403.812, 403.814 FS. History--New 4-1-86. Amended 8-11-91. Repealed 9-25-91.

40C-42.032 Limiting Conditions.

(1) The Governing Board shall impose upon any permit granted pursuant to this Chapter such reasonable conditions as are necessary to assure that construction and operation of the permitted system will not be inconsistent with the District's permitting standards set forth in section 40C-42.023, F.A.C., and will not be harmful to the water resources of the District.

(2)(a) In addition to project-specific special conditions, the following standard limiting conditions shall be attached to all permits issued pursuant to this Chapter unless waived by the Board upon a determination that the conditions are inapplicable for the work authorized by a given permit:

1. This permit for construction will expire five years from the date of issuance unless otherwise specified by a special condition of the permit.

2. Permittee must obtain a permit from the District prior to beginning construction of subsequent phases or any other work associated with this project not specifically authorized by this permit.

3. Before any offsite discharge from the stormwater management system occurs, the retention and detention storage must be excavated to rough grade prior to building construction or placement of impervious surface within the area served by those systems. Adequate measures must be taken to prevent siltation of these treatment systems and control structures during construction or siltation must be removed prior to final grading and stabilization.

4. The permittee must maintain a copy of this permit complete with all conditions, attachments, exhibits, and permit modifications, in good condition at the construction site. The

complete permit must be available for review upon request by District representatives. The permittee shall require the contractor to review the complete permit prior to commencement of the activity authorized by this permit.

5. All activities shall be implemented as set forth in the plans, specifications and performance criteria as approved by this permit. Any deviation from the permitted activity and the conditions for undertaking that activity shall be considered a violation of this permit.

6. District authorized staff, upon proper identification, must be granted permission to enter, inspect and observe the system to insure conformity with the plans and specifications approved by the permit.

7. Prior to and during construction, the permittee shall implement and maintain all erosion and sediment control measures (best management practices) required to retain sediment on-site and to prevent violations of state water quality standards. All practices must be in accordance with the guidelines and specifications in chapter 6 of the Florida Land Development Manual: A Guide to Sound Land and Water Management (Florida Department of Environmental Regulation 1988), which are hereby incroporated by reference, unless a project specific erosion and sediment control plan is approved as part of the permit, in which case the practices must be in accordance with the plan. If site specific conditions require additional measures during any phase of construction or operation to prevent erosion or control sediment, beyond those specified in the erosion and sediment control plan, the permittee shall implement additional best management practices as necessary, in accordance with the specifications in chapter 6 of the Florida Land Development Manual: A Guide to Sound Land and Water Management (Florida Department of Environmental Regulation 1988). The permittee shall correct any erosion or shoaling that causes adverse impacts to the water resources.

8. If the permitted system was designed by a registered professional, within 30 days after completion of the stormwater system, the permittee must submit to the District the following: District Form No. 40C-1.181(13) (As Built Certification By a Registered Professional), signed and sealed by an appropriate professional registered in the State of Florida, and two (2) sets of "As Built" drawings when a) required by a special condition of this permit, b) the professional uses "As Built" drawings to support the As Built Certification, or c) when the completed system substantially differs from permitted plans. This submittal will serve to notify the District staff that the system is ready for inspection and approval.

9. If the permitted system was not designed by a registered professional, within 30 days after completion of the stormwater system, the permittee must submit to the District the following: District Form No. 40C-1.181(14) (As Built Certification), signed by the permittee and two (2) sets of "As Built" drawings when required by a special condition of this permit, or when the completed system substantially differs from permitted plans. This submittal will serve to notify the District staff that the system is ready for inspection and approval.

10. Stabilization measures shall be initiated for erosion and sediment control on disturbed areas as soon as practicable in portions of the site where construction activities have temporarily or permanently ceased, but in no case more than seven (7) days after the construction activity in that portion of the site has temporarily or permanently ceased.

11. Should any other regulatory agency require changes to the permitted system, the permittee shall provide written notification to the District of the changes prior to implementation so that a determination can be made whether a permit modification is required.

12. Within thirty (30) days after sale or conveyance of the permitted stormwater management system or the real property on which the system is located, the owner in whose name the permit was granted shall notify the District of such change of ownership. Transfer of this permit shall be in accordance with the provisions of section 40C-1.612, Florida Administrative Code. All terms and conditions of this permit shall be binding upon the transferee. The permittee transferring the permit shall remain liable for any corrective actions that may be required as a result of any permit violations prior to such sale, conveyance or other transfer.

13. The stormwater management system must be completed in accordance with the permitted plans and permit conditions prior to the initiation of the permitted use of site infrastructure. The system must be completed in accordance with the permitted plans and permit conditions prior to transfer of responsibility for operation and maintenance of the stormwater management system to a local government or other responsible entity.

14. The operation phase of the permit shall not become effective until the requirements of condition No. 8 or 9 have been met, the District determines that the system complies with the permitted plans, and the entity approved by the District in accordance with section 40C-42.027, F.A.C., accepts responsibility for operation and maintenance of the system. The permit cannot be transferred to such an approved responsible operation and maintenance entity until the requirements of section 40C-42.028, F.A.C., are met, and the operation phase of the permit becomes effective. Following inspection and approval of the permitted system by the District in accordance with section 40C-42.028, F.A.C., the permittee shall request transfer of the permit to the responsible approved operation and maintenance entity, if different from the permittee. Until the permit is transferred pursuant to subsection 40C-42.028(4), F.A.C., the permittee shall be liable for compliance with the terms of the permit.

15. Prior to lot or unit sales, or upon completion of construction of the system, whichever occurs first, the District must receive the final operation and maintenance document(s) approved by the District and recorded, if the latter is appropriate. For those systems which are proposed to be maintained by county or municipal entities, final operation and maintenance documents must be received by the District when maintenance and operation of the system is accepted by the local government entity. Failure to submit the appropriate final document will result in the permittee remaining personally liable for carrying out maintenance and operation of the permitted system.

16. This permit does not eliminate the necessity to obtain any required federal, state, local and special district authorizations prior to the start of any activity approved by this permit. This permit does not convey to the permittee or create in the permittee any property right, or any interest in real property, nor does it authorize any entrance upon or activities on property which is not owned or controlled by the permittee, or convey any rights or privileges other than those specified in the permit and Chapter 40C-42, F.A.C.

17. The permittee shall hold and save the District harmless from any and all damages, claims, or liabilities which may arise by reason of the activities authorized by the permit or any use of the permitted system.

18. The permittee shall immediately notify the District in writing of any previously submitted information that is later discovered to be inaccurate.

19. Activities approved by this permit shall be conducted in a manner which do not cause violations of state water quality standards.

(b) This section shall not be construed as a limitation on the authority of the Board to impose such other limiting conditions as may be necessary in order to assure that the permitted system is consistent with the requirements for issuance listed in section 40C-42.023, F.A.C.
Specific Authority 373.044, 373.113, 373.171 FS. Law Implemented 373.409, 373.413, 373.416, 373.419, 373.423, 373.426 FS. History--New 3-21-93, 10-3-95.

40C-42.033 Implementation.

(1) This chapter shall become effective on September 25, 1991.

(2)(a) Each construction permit issued under chapter 40C-42, F.A.C., prior to the effective date of this rule shall remain valid according to its terms.

(b) Each construction permit application which is filed with the District prior to the effective date of this rule will be processed and evaluated under the rules implemented on April 1, 1986.

(c) Each construction permit application which is not filed with the District prior to September 25, 1991, will be processed and evaluated according to the rule provisions implemented on September 25, 1991.

(3) If the validity of any provisions of chapter 40C-42, F.A.C., or the application thereof to any person or circumstance is challenged pursuant to Chapter 120 or 373, F.S., or pursuant to any other basis in law, it is the intent of the Governing Board of the St. Johns River Water Management District that neither a challenge to the validity of a provision or application thereof nor the invalidation of a provision or application thereof shall affect the validity or application of other provisions of the rule which can be given effect without the challenged or invalidated provision or application and to this end the provisions of chapter 40C-42, F.A.C., are declared severable.
Specific Authority 373.044, 373.113, 373.171, 373.429 FS. Law Implemented 373.416 FS. History--New 9-25-91.

40C-42.035 Stormwater General Permits.
Specific Authority 373.044, 373.113, 373.171 FS. Law Implemented 403.812, 403.814 FS. History--New 4-1-86. Repealed 9-25-91.

40C-42.041 Individual Permit Requirements for New Stormwater Discharge Facilities.
Specific Authority 373.044, 373.113, 373.171 FS. Law Implemented 403.812, 403.814 FS. History--New 4-1-86. Repealed 9-25-91.

40C-42.061 Relationship to Other Permitting Requirements.

(1) Whenever the construction, alteration, removal, operation, maintenance, or abandonment of a stormwater management system requires that an environmental resource permit be secured pursuant to Chapters 40C-4 or 40C-40 , F.A.C., the requirements in this chapter shall be reviewed as part of those permit applications. A separate permit application under this chapter shall not be required. However, the applicant must provide the required technical information as part of those applications to demonstrate compliance with this chapter. If the applicant requests a separate environmental resource stormwater permit, the applicant must notify the District of any other District permits, exemptions, or certifications which have or will be requested for the project.

(2) When a permit is required pursuant to this chapter and an individual environmental resource permit is required pursuant to chapter 40C-4 for the same system, the time frames of chapter 40C-4 shall apply to issuance of a permit under section 40C-42.024(2), F.A.C.

(3) This rule does not apply to any stormwater discharge facility listed in (a) and (b) below, unless such facility is modified pursuant to section 40C-42.024, F.A.C.:

(a) Which was in existence on February 1, 1982; or

(b) Which was permitted, modified, or found to be exempt, under Chapter 62-25, F.A.C., by the Department of Environmental Regulation (DER) after February 1, 1982, but prior to April 1, 1986, provided the facility was constructed in accordance with the DER permit or exemption, and is functioning in accordance with the requirements of chapter 62-25, F.A.C.

(4) The operation phase permit requirements set forth in subsection 40C-42.028(1), F.A.C., shall not apply to systems permitted and found to be in compliance with all rule requirements prior to the effective date of this rule.

(5) Applications for conceptual agency review of stormwater management systems, as required by section 380.06, F.S., will be reviewed in accordance with the procedure used by the District to review conceptual approval permit applications pursuant to subsection 40C-4.041(2), F.A.C.

(6) Systems for agricultural lands will be regulated under chapter 40C-44, F.A.C.

Specific Authority 373.044, 373.113, 373.171 FS. Law Implemented 373.413, 373.416, 380.06(9) FS. History--New 4-1-86. Amended 9-25-91, 3-21-93, 4-11-94, 7-20-95, 8-3-95.

40C-42.071 Permit Processing Fee. There shall be a non-refundable permit processing fee as specified by section 40C-1.603, F.A.C., payable to the District at the time that an application for a permit is submitted.

Specific Authority 373.044, 373.113, 373.171 FS. Law Implemented 373.109, 373.113 FS. History--New 4-1-86. Amended 9-25-91.

40C-42.081 General Provisions. Nothing under this chapter shall preclude:

(1) Stormwater effects from being considered in the evaluation of other types of permits where such consideration is relevant to a determination of compliance with applicable District requirements.

R0071010

(2) The legal joinder in a permitting proceeding under this chapter of any person who owns or controls an unpermitted stormwater management system or systems which comprise a significant portion of the stormwater management system.

(3) The District from taking appropriate legal action including but not limited to the requiring of a permit to prevent the impairment of a use for which a water of the state has been designated under chapter 62-3, F.A.C.

(4) The District from entering interagency or interlocal agreements to accomplish the provisions of this chapter.

Specific Authority 373.044, 373.113, 373.171 FS. Law Implemented 403.812, 403.814 FS. History--New 4-1-86. Amended 9-25-91.

40C-42.091 Publications Incorporated by Reference.

(1) The Governing Board adopts by reference Part I "Policy and Procedures", Part II, "Criteria for Evaluation", and Part III "Operation and Maintenance", of the document entitled "Applicant's Handbook: Regulation of Stormwater Management Systems, Chapter 40C-42, F.A.C.", effective 10-3-95.

(2) This document provides information regarding the stormwater management system permitting program

Chapter 6

Stormwater and Erosion and Sediment Control Best Management Practices for Developing Areas

This chapter contains a comprehensive summary of BMPs used for stormwater management and erosion and sediment control. Part 1 discusses various non-structural source controls that can be used to reduce the generation and accumulation of potential stormwater contaminants. Part 2 discusses structural stormwater BMPs that can be used to reduce the pollutant load discharged from stormwater systems. Part 3 discusses erosion and sediment control BMPs that can be used to reduce erosion and retain sediment on-site, especially during construction.

The BMP guidelines represent a summary of the best available information at the time of publication. However, the state-of-the-art is still quite young and these guidelines will probably change as new research is completed and as we gain more experience with using the various BMPs. Design engineers and others in the development community are encouraged to send the department information about actual experiences with the BMPs so that the guidelines can be periodically updated.

The erosion and sediment control BMP descriptions have been largely taken verbatim from the Virginia Erosion and Sediment Control Manual although the information was "Florida-ized" by the Soil Conservation Service and others. These BMP descriptions are written in the form of mandatory standard and specifications because of Virginia's Erosion and Sediment Control Act. It is not the intention of the department to require strict compliance with these standards although they do represent excellent guidelines based on years of actual implementation.

Engineers are encouraged to use the information presented in this chapter in conjunction with their own expertise to assure that the BMPs will be properly designed and constructed for their particular site and situation.

CHAPTER 6

STORMWATER AND EROSION AND SEDIMENT CONTROL BEST MANAGEMENT PRACTICES FOR DEVELOPING AREAS

TABLE OF CONTENTS

Section	Page
INTRODUCTION	6-1
OVERVIEW OF PRACTICES	6-2
Nonstructural Source Controls	6-2
Structural Runoff Controls	6-3
Erosion and Sediment Control Practices	6-5
GUIDELINES FOR USING NONSTRUCTURAL SOURCE CONTROLS	6-9
2.01 - Fertilizer Application Control	6-10
2.02 - Pesticide Use Control	6-14
2.03 - Solid Waste Collection and Disposal	6-28
2.04 - Source Control on Construction Sites	6-36
2.05 - Street Cleaning	6-40
STRUCTURAL STORMWATER CONTROLS	6-47
3.01 - Concrete Grid and Modular Pavement	6-48
3.02 - Detention Basins	6-53
3.03 - Exfiltration Trenches	6-93
3.04 - Grassed Waterways and Swales	6-121
3.05 - Parking Lot Storage	6-164
3.06 - Porous Asphalt Pavement	6-168
3.07 - Retention Basins	6-196
3.08 - Rooftop Runoff Disposal	6-224
3.09 - Storage/Treatment Facilities	6-230
3.10 - Underdrains and Stormwater Filter Systems	6-235
EROSION AND SEDIMENT CONTROL PRACTICES	6-301
1.01 - Temporary Gravel Construction Entrance	6-302
1.02 - Construction Road Stabilization	6-305
1.05 - Straw Bale Barrier	6-308
1.06 - Silt Fence	6-315
1.07 - Brush Barrier	6-322
1.08 - Storm Drain Inlet Protection	6-325
1.15 - Temporary Diversion Dike	6-335
1.16 - Temporary Fill Diversion	6-339
1.17 - Temporary Right-of-Way Diversion	6-342
1.18 - Diversion	6-346
1.25 - Temporary Sediment Trap	6-351
1.26 - Temporary Sediment Basin	6-360
Appendix 1.26a - Design Procedure for Temporary Sediment Basin	6-370
1.30 - Temporary Slope Drain	6-389

CHAPTER 6

STORMWATER AND EROSION AND SEDIMENT CONTROL BEST MANAGEMENT PRACTICES FOR DEVELOPING AREAS

INTRODUCTION

Chapters 1 through 4 of this manual discuss the threat which stormwater runoff, as well as construction and development in urbanizing areas, may pose to the quality of Florida waters. Chapter 6 consists of descriptions and guidelines for various management practices used for urban stormwater pollution abatement and erosion and sediment control. The treatment measures discussed herein have been divided among three categories and are presented in three separate sections of the chapter as follows:

1. Nonstructural Controls for Reducing Urban Stormwater Pollutants: Practices that are intended to improve runoff quality by reducing the generation and accumulation of potential stormwater runoff contaminants at or near their sources.

2. Structural Stormwater Controls: Practices that are aimed at controlling the volume and discharge rate of runoff from urban areas, as well as, reducing the magnitude of pollutants in the discharge water through physical containment or flow restrictions designed to allow settling, physical removal through filtration, percolation, chemical precipitation or flocculation, and/or biological uptake.

3. Erosion and Sediment Controls: Practices that can be used to prevent and/or correct problems related to the transport of eroded material or soil by runoff waters particularly from construction and other land disturbing activities.

It should be emphasized that practices for controlling erosion and sedimentation from development-related land-disturbing activities are an integral part of the collection of urban BMP's presented in this manual. The erosion and sediment control BMPs have been compiled extensively from information contained in the Virginia Erosion and Sediment Control Handbook and the Virginia Urban Best Management Practices Handbook, published by the Virginia Soil and Water Conservation Commission, and the Virginia State Water Control Board. Their efforts early on in the field of stormwater management and erosion control have helped to make the task of developing a similar set of guidelines for Florida much easier. Their cooperation is greatly appreciated and acknowledged by the State of Florida as is that of the State Office of the Soil Conservation Service, members of the Florida Engineering Society and water management district staff who helped to modify the BMPs to Florida conditions.

R0071029

OVERVIEW OF PRACTICES

Following is a summary of stormwater management practices recommended for use in Florida. These practices are numbered to facilitate cross-referencing and designation of their use on stormwater plans.

NONSTRUCTURAL SOURCE CONTROLS

2.01 - Fertilizer Application Control: This practice involves managing the use of fertilizer so as to keep it on the land and out of our waterways. Implementation will result in maximum effectiveness of the nutrients on vegetation and reduced nutrient loads in our waterways. The practice covers concepts such as public education, the need for soil testing, and the proper timing of fertilizer applications.

2.02 - Pesticide Use Control: This practice involves eliminating excessive pesticide use by proper application procedures and the use of alternatives to chemical pest control. The goal is to reduce the load of pesticide-related contaminants in urban stormwater runoff. The practice covers legal requirements for pesticide application, methods of application, equipment cleaning, disposal of unused chemicals and empty containers, pesticide storage, alternative pest control methodologies, and public education. Both commercial-scale application and private home use are discussed.

2.03 - Solid Waste Collection and Disposal: This practice involves the routine management and handling of urban refuse, litter and fallen leaves in ways that will prevent their becoming water pollutants. Recommendations range from municipal trash and leaf collection and disposal operations to public education concerning collecting procedures and schedules to concepts such as recycling wastes. Responsibility for implementation lies equally with the municipality and the citizenry.

2.04 - Source Control on Construction Sites: This practice encourages the use of good management and "housekeeping" techniques on construction sites to reduce the availability of construction-related pollutants that contaminate runoff water and, where runoff contamination cannot be avoided, to retain the pollutants and polluted water on the site. Concepts covered include erosion and sediment control, equipment maintenance and repair, storm sewer inlet protection, trash collection and disposal, the use of designated washing areas for cleaning equipment, proper material storage, dust control at demolition sites, use of proper sanitary equipment and pesticide use control.

2.05 - Street Cleaning: This practice involves sweeping, vacuuming, flushing, or otherwise cleaning streets, parking lots and other paved

vehicular traffic areas. The objective is to remove dry-weather accumulations of pollutants, especially fine particulate matter, before washoff can occur, thus reducing the potential for pollution impacts on receiving waters. In the past, street cleaning operations were conducted primarily for aesthetic purposes; however, they are now known to be an effective method for improving the quality of runoff.

STRUCTURAL RUNOFF CONTROLS

3.01 - Concrete Grid and Modular Pavement: This practice involves the use of a special pervious paving material in low traffic areas. The pave-pavement consists of concrete grids or other structural units alternated with pervious fillers such as sod, gravel or sand. The resultant pavement provides an adequate bearing surface and yet allows a significant amount of infiltration thereby reducing runoff volume, discharge rate, pollutant load and improving the water quality.

3.02 - Detention Basins: This practice involves the construction or modification of surface water impoundments in a manner which will protect downstream areas from potential water quality degradation, flooding, and stream channel degradation due to upstream urban development. The objective is to detain stormwater and release it at a controlled rate. Downstream water quality is improved through sediment removal, plant uptake of nutrients, chemical transformations, and other processes.

3.03 - Exfiltration Trenches: This practice involves the excavation of pits or trenches which are backfilled with sand and/or graded aggregates. Stormwater runoff from impervious surfaces can be directed to these facilities for detention and infiltration. Permeable soils are a prerequisite. The potential for groundwater pollution must also be carefully evaluated.

3.04 - Grassed Waterways and Swales: This practice involves using grassed surfaces to reduce runoff velocities, enhance infiltration and remove runoff contaminants, thus improving runoff quality and reducing the potential for downstream channel degradation and sediment pollution.

3.05 - Parking Lot Storage: This practice involves the use of impervious parking areas or landscape islands as temporary impoundments during rainstorms. Parking lot stormwater systems can be designed to temporarily detain stormwater in specially designated areas, and release it at a controlled rate. The objective is to protect down-stream areas from increased flooding, stream channel degradation and pollutant loads caused by urban development. It is important that these facilities be designed to minimize potential safety hazards and inconvenience to motorists and pedestrians.

3.06 - Porous Asphalt and Concrete Pavement: This practice involves the use of a special asphaltic or concrete paving material which allows stormwater to infiltrate at a high rate. Infiltration water is stored below the pavement in a high-void aggregate base. This practice provides for stormwater detention and, in some cases, increases infiltration into the ground. Use of the practice can contribute to reduced sewer overflows, decreased flooding and stream channel degradation, and improved water quality. This type of pavement offers many other benefits not related to water quality, including enhanced visibility, increased safety and reduced drainage system costs.

3.07 - Retention Basins: This practice pertains to the construction of infiltration reservoirs or basins (usually dry) to provide complete on-site storage of a specific volume of stormwater runoff. For pollution control purposes, these facilities are usually designed and constructed to divert and percolate runoff volume associated with the first flush of stormwater pollutants leaving the site. The practice incorporates both pollution control and groundwater recharge concepts into the design. Such facilities are practical wherever soil permeability is sufficient to allow rapid percolation between storms. They are especially applicable in parts of Florida where rapid urbanization in coastal areas and salt water encroachment present a hazard to potable water supplies. Potential groundwater contamination may be a problem associated with these systems and must always be considered in their design.

3.08 - Rooftop Runoff Disposal: This practice encourages the disposal of rooftop runoff by systems and techniques that avoid or replace direct connections of roof drainage systems to stormsewer systems. The objective is to help reduce storm sewer flows. Proposed alternatives to sewer connection include surface drainage through swales, subsurface infiltration, and runoff collection and storage.

3.09 - Storage/Treatment: This practice involves the use of some water treatment unit operations applied at such a scale that they are less involved and less costly than treatment plant technology. These procedures are most applicable when used in conjunction with other best management practices to remove contaminants from collected stormwater. Unit operations considered applicable are the physical processes of settling, filtration, and screening; and the chemical processes of flocculation and disinfection.

3.10 - Underdrains and Stormwater Filter Systems: This practice usually consists of a conduit, such as a pipe and/or a travel filled trench which intercepts, collects, and conveys drainage water following infiltration and percolation through the soil, suitable aggregate, and/or filter fabric. Underdrain or filtration systems may be used in combination with a variety of stormwater management measures where

R0071032

space, soil permeability or high water table conditions limit the magnitude of pollutant removal that can be achieved through natural percolation, sedimentation, or other means. Pollutant removal primarily occurs as the prescribed volume of stormwater passes through the sand, gravel, and filter cloth which usually surrounds the conduit.

EROSION AND SEDIMENT CONTROL PRACTICES

Following are summary overviews of the erosion and sediment control practices recommended for use in Florida. The practices are numbered according to the following categories of use:

Structural Practices

- Road Stabilization (1.01 - 1.04)
- Sediment Barriers (1.05 - 1.14)
- Dikes and Diversions (1.15 - 1.24)
- Sediment Traps and Basins (1.25 - 1.29)
- Flumes (1.30 - 1.34)
- Waterway and Outlet Protection (1.35 - 1.44)
- Miscellaneous Structural Contours (1.50 - 1.59)

Vegetative Practices

- Site Preparation for Vegetation Establishment (1.60 - 1.64)
- Grass Establishment (1.65 - 1.74)
- Mulches (1.75 - 1.79)
- Other Vegetation (1.80 - 1.84)
- Miscellaneous Vegetative Control (1.85 - 1.99)

In each category, some numbers were left unassigned to facilitate future practice additions or modifications. Summaries of the individual practices follow:

1.01 - **Temporary Gravel Construction Entrance**: A gravel pad, located at points of vehicular ingress and egress on a construction site, to reduce the mud transported onto public roads and other paved areas.

1.02 - **Construction Road Stabilization**: Temporary stabilization with stone of access roads, subdivision streets, parking areas and other traffic areas immediately after grading to reduce erosion caused by vehicles during wet weather, and to prevent having to regrade permanent roadbeds between initial grading and final stabilization.

1.05 - **Straw Bale Barrier**: A temporary sediment barrier composed of straw bales placed across or at the toe of a slope to intercept and detain sediment and decrease flow velocities from drainage areas of

limited size; applicable where sheet and rill erosion from low to moderate channel flows may be a problem. Maximum effective life is 3 months.

1.06 - Silt Fence: A temporary sediment barrier constructed of posts, filter fabric and, in some cases, a wire support fence, placed across or at the toe of a slope or in a minor drainageway to intercept and detain sediment and decrease flow velocities from drainage areas of limited size; applicable where sheet and rill erosion or small concentrated flows may be a problem. Maximum effective life is 6 months.

1.07 - Brush Barrier: A temporary sediment barrier composed of limbs, weeds, vines, root mat, soil, rock and other cleared materials pushed together to form a berm; located across or at the toe of a slope to intercept and detain sediment and decrease flow velocities.

1.08 - Storm Drain Inlet Protection: The installation of various kinds of sediment trapping measures around drop inlet or curb inlet structures prior to permanent stabilization of the disturbed area; limited to drainage areas not exceeding one acre, and not intended to control large, concentrated stormwater flows.

1.15 - Temporary Diversion Dike: A ridge of compacted soil located at the top or base of a sloping disturbed area to divert off-site runoff away from unprotected slopes and to a stabilized outlet, or to divert sediment-laden runoff to a sediment trapping structure. Maximum effective life is 18 months.

1.16 - Temporary Fill Diversion: A channel with a supporting ridge on the lower side cut along the top of an active earth fill to divert runoff away from the unprotected fill slope to a stabilized outlet or sediment trapping structure; applicable where the area at the top of the fill drains toward the exposed slope and continuous fill operations make the use of a Temporary Diversion Dike unfeasible; maximum effective life is one week.

1.17 - Temporary Right-Of-Way Diversion: A ridge of compacted soil or loose gravel constructed across a disturbed right-of-way or similar sloping area to shorten the flow length within the disturbed strip and divert the runoff to a stabilized outlet. Earthen diversions are applicable where there will be little or no construction traffic within the right-of-way, and gravel structures are applicable where vehicular traffic must be accommodated.

1.18 - Diversion: A permanent channel with a ridge on the lower side constructed across a slope to reduce slope length and intercept and

R0071034

divert stormwater runoff to a stabilized outlet to prevent erosion on the slope.

1.25 - Temporary Sediment Trap: A small ponding area, formed by constructing an earthen embankment with a gravel outlet across a drainage swale, to detain sediment-laden runoff from small disturbed areas for enough time to allow most of the sediment to settle out. Maximum effective life is 18 months.

1.26 - Temporary Sediment Basin: A basin with a controlled stormwater release structure, formed by constructing an embankment of compacted soil across a drainageway, to detain sediment-laden runoff from disturbed areas greater than 5 acres for enough time to allow most of the sediment to settle out. Can be constructed only where there is sufficient space and appropriate topography. Maximum effective life is 18 months unless designed as a permanent pond by a qualified professional engineer.

1.30 - Temporary Slope Drain: A flexible or rigid tube or conduit, used before permanent drainage structures are installed, intended to conduct concentrated runoff safely from the top to the bottom of a disturbed slope without causing erosion on or below the slope.

1.31 - Paved Flume: A permanent concrete-lined channel constructed to conduct concentrated runoff from the top to the bottom of a slope without causing erosion on or below the slope.

1.35 - Stormwater Conveyance Channel: A permanent channel designed to carry concentrated flows without erosion. Applicable to man-made conveyances, including roadside ditches, and to natural channels that need modification to accommodate increased flows generated by land development. Not applicable for stormwater treatment.

1.36 - Outlet Protection: The installation of paved and/or riprap channel sections and/or stilling basins below storm drain outlets to reduce erosion from scouring at outlets and to reduce flow velocities before stormwater enters receiving channels below these outlets.

1.37 - Riprap: A permanent, erosion-resistant ground cover of large, loose, angular stone usually underlain by erosion matt or filter fabric installed wherever soil conditions, water turbulence and velocity, expected vegetative cover, etc., are such that soil may erode under design flow conditions.

1.38 - Check Dams: Small, temporary dams constructed across a drainage ditch to reduce the velocity of concentrated flows, reducing erosion of the swale or ditch. Limited to use in small open channels which drain 10 acres or less; should not be used in live stream.

1.39 - Waterway Drop Structure: A permanent structure or series of structures designed to step water flow down a slope without causing channel erosion; applicable in natural or man-made channels with long, relatively steep reaches.

1.40 - Level Spreader: An outlet for dikes and diversions consisting of an excavated depression constructed at zero grade across a slope to convert concentrated, sediment-free runoff to sheet flow and release it onto areas of undisturbed soil stabilized by existing vegetation.

1.50 - Subsurface Drain: A perforated conduit installed beneath the ground to intercept and convey groundwater. Prevents sloping soils from becoming excessively wet and subject to sloughing, and improves the quality of the vegetative growth medium in excessively wet areas by lowering the water table. Can also be used to drain detention structures.

1.60 - Surface Roughening: Grading practices such as stair-stepping or grooving slopes or leaving slopes in a roughened condition by not fine-grading them. Reduces runoff velocity, provides sediment trapping and increases infiltration, all of which facilitate establishment of vegetation on exposed slopes. Applicable to all slopes steeper than 3:1 or that have received final grading but will not be stabilized immediately. Also recommended for other exposed slopes.

1.61 - Topsoiling: Preserving and using topsoil to provide a suitable growth medium for vegetation used to stabilize distrubed areas. Applicable where preservation or importation of topsoil is most cost-effective method of providing a suitable growth medium; not recommended for slopes steeper than 2:1.

1.65 - Temporary Seeding: Establishment of temporary vegetative cover on disturbed areas by seeding with appropriate rapidly-growing plants on sites that will not be brought to final grade for periods of 30 days to one year.

1.66 - Permanent Seeding: Establishment of perennial vegetative cover by planting seed on rough-graded areas that will not be brought to final grade for a year or more or where permanent, long-lived vegetative cover is needed on fine-graded areas.

1.67 - Sodding: Stabilizing fine-graded areas by establishing permanent grass stands with sod. Provides immediate protection against erosion, and is especially effective in grassed swales and waterways or in areas where an immediate aesthetic effect is desirable.

GUIDELINES FOR USING
NONSTRUCTURAL SOURCE CONTROLS

SW BMP 2.01

FERTILIZER APPLICATION CONTROL

Definition

Managing the use of fertilizer so as to keep it on the land.

Purpose

To prevent fertilizer nutrients from reaching watercourses. The same management procedures will assure maximum effectiveness of the nutrients on land, reduce the load on waste treatment plants, and save money.

Conditions Where Practice Applies

Fertilizers are used everywhere in urban areas. Sites include parks, cemeteries, plant nurseries, roadsides and medians, golf courses and other "green" areas; grounds of institutions, business and industrial establishments; and individual home lawns and gardens.

Planning Considerations

Excessive nitrogen and phosphorus in water bodies deplete their oxygen, stimulate algal growth and, in aggravated cases, cause eutrophication and stagnant conditions that require drastic measures to correct.

Collectively the amount of fertilizer runoff from urban areas, because of their size and the geographic concentration of activities, can be a signficant factor in water quality. At a minimum any increment from fertilizers increases the burden routinely imposed on receiving waters by the normal urban waste load. In extreme cases the nutrient load discharged to watercourses, from whatever sources, has required municipalities to install expensive advanced wastewater treatment to reclaim the water.

In any circumstance, any diminution of fertilizer runoff will be a positive contribution to water quality. This contribution should hold particular charm since the basic remedy consists simply of eliminating excessive use and holding what is used in its intended place to do its intended job. This saves money!

The kinds of fertilizer and methods of application used by managers of large areas will differ from those used by private individuals on home lawns and

R0071038

gardens. The focus of concerns may also differ. But the same common-sense principles apply for both categories.

Landscaping supervisors, developers, golf course superintendents and others dealing with large areas and routinely concerned with the cost element will not likely use excess fertilizer or fertilize at unfavorable times. They may need to give more heed to other aspects, including prior site preparation and later maintenance.

Homeowners, however, may apply fertilizer in the wrong weather or season. And some -- apparently under the familiar logic that if one aspirin is good, two or three are bound to be better -- are known to use far more fertilizer (and pesticides) on lawns and gardens than they need. Since built-up residential areas border streets or other drainageways that can transport pollutants quickly to waterways, misuse or over-application of fertilizer in residential areas and washoff of the excess can cumulatively register a significant adverse impact on water quality.

Education

To reduce waste treatment costs as well as nonpoint source water pollution, municipalities may find it worthwhile to remind property owners and occupants of the potential for water quality degradation inherent in misapplication or excessive use of fertilizers (and of pesticides). Reminders periodically enclosed with water and sewer bills might prove most effective for reducing the problem if they bring home the point of savings to the taxpayer in his own as well as the public budget. The notices should go to institutions, businesses and industries as well as homeowners.

The County Agricultural Extension Service also has educational pamphlets that can help property owners understand fertilizer requirements of lawns, shrubs and gardens. These will help teach fertilizer users how to determine how much they need and when and where to apply the fertilizer.

Erosion Control

Whenever fertilizer is used to aid in vegetative establishment on bare soil areas, erosion control is of primary importance in preventing fertilizer washoff. Soil, enriched with fertilizer nutrients, can be easily eroded and carried away in runoff if adequate soil stabilization techniques are not used.

Straw mulch, chemical soil stabilizers, and degradable ground covering fabrics are examples of techniques which can be used to protect the soil from erosion during vegetative establishment. Applicable erosion control techniques should be applied wherever the potential for soil erosion exists during vegetative establishment. In Maryland, it has been shown that the application of temporary vegetative cover (rye-grass) on construction sites

where bare ground will be left open for more than a week can reduce soil loss by up to 90%. Similar recommendations are applicable in Florida, especially in the panhandle where slopes may exceed 3% and the soil texture is fine.

"Commercial"-Scale Fertilizer Use

Procedures for large-scale application of fertilizer resemble those for agricultural operations. Large-area users -- institutional, business, industrial and governmental -- should obtain guidance on fertilizer management from specialists such as those of the Florida Cooperative Extension Service and USDA, Soil Conservation Service or private firms.

Residential Area Use

Homeowners may also obtain advice on lawns and gardens from field extension agents of the Cooperative Extension Service. Soil testing is available at the nominal charge of $3.00 to determine lime and fertilizer needs.

Among other reasons for a soil test, extension specialists recommend it in the interest of conservation of soil nutrients -- to avoid the application of unnecessary nutrients. They point out that a soil may well need nitrogen (N) but need little phosphorus (P) or potassium (K) -- yet in the absence of a test the homeowner may needlessly apply a fertilizer high in all three nutrients when lower doses of P and K would do.

When used in gardens granular fertilizer should be worked into the soil, which preferably should be moist at the time of application. The granular form will be less apt to wash away than sprays or slurries, especially when these are carelessly applied. However, liquid applications, as currently practiced by a growing number of home lawn maintenance companies, are considered to be just as resistant to runoff as the granular form.

Organic fertilizers -- compost, manures, etc. -- are less soluble than formulated chemical fertilizers. However, specialists note that in many if not most instances the organics are applied at heavier rates in order to feed the soil over longer periods of time. In such cases, they report, the amount that may find its way to watercourses through erosion may be as great as or greater than the amount lost from formulated fertilizers.

Others advocate wider use of compost. An extra benefit of its use will be to create a market for the compost, which can be generated in quantity from municipal refuse and/or sewage sludge. It is necessary, however, to ensure that the heavy metals content of the composted domestic sludge or refuse is within safe limits if the material is used on soil to grow foodstuff or feed. The criteria for the application of these materials on agricultural lands is listed in Florida Administrative Code 17-7, Section 17-7.54 (2, 3, 4, & 5) F.A.C.

Timing the Applications

In fertilizing lawns with chemicals the prevalent habit of many homeowners is to "wait until the storm clouds gather" and then spread the material just ahead of the rain. The effect can be precisely the reverse of what is desired, and the worst result for water quality. However, applying fertilizer under dry weather conditions is dangerous as salt injury to the vegetation could result. The extension recommendation is to make the application when there is already adequate soil moisture and little likelihood of immediate heavy rain -- then sprinkle the lawn. Thus the material will have been incorporated into the soil before the next rain can take it away.

General Guides

Landscaping - Proper landscaping of new developments will minimize the needs for fertilizer. The process of cutting, filling and grading soils if improperly carried out can produce low fertility, acidity, compaction, and excessive dryness or wetness. Topsoil removed during excavation or site development must always be put back in place afterwards, and revegetation started promptly. Topsoil should never be carried off from the site. Erosion and sediment control should be assured. For establishment of new lawns, turf mats or grass sod are recommended in preference to seeding.

Testing - A soil test is recommended, especially for new lawns, to assure the use of optimum lime and fertilizer application rates. Extension specialists advocate a repeat test at least every three years.

Season for Application - The kind of turf being maintained should determine the time for fertilizing. Cool season turf (ryegrass) should be fertilized in the fall and early winter. Warm season grasses (Bermudas, Bahia, Centipede and St. Augustine) should be fertilized in the spring and summer.

A supplemental application of low nitrogen is also usually recommended in the fall. Once again, the rate of application should be determined according to a soil test whenever possible.

SW BMP 2.02

PESTICIDE USE CONTROL

Definition

Eliminating excessive pesticide use by proper application procedures and/or the use of alternatives to chemical pest control.

Purpose

To reduce the pesticide load in stormwater runoff from urban areas.

Conditions Where Practice Applies

Wherever pesticides are used in urban areas. Sites include grounds of institutions, business and industrial establisments of all kinds; rights-of-way of roads, power lines, pipelines and railroads; construction projects; parks, recreation areas, plant nurseries, fairgrounds, zoos, cemeteries, water bodies, wooded and other "green" areas; dumps and landfills; home lawns and gardens.

The term "pesticides" is construed broadly to cover chemicals used against pests of all kinds -- insecticides to kill insects; herbicides to kill weeds, brush or other unwanted vegetation; fungicides to control fungi that cause molds, rots, plant and animal diseases; nematicides to kill nematodes, the minute eel worms in soil that attack plant roots; rodenticides to kill rats and other rodents.

Planning Considerations

General

Pesticides are poisons. In water as on land they can cause acute toxicity or might cause insidious effects in the food chain. Persistent pesticides pass unchanged through conventional waste treatment plants. Gross amounts of some of these can kill the bacteria that are essential to break down other wastes in the treatment process.

Because of the great variety of uses to which pesticides are put and the near universality of their use in one form or another, the collective amount reaching watercourses in runoff from urban areas is significant. Pesticides vary widely in toxicity and persistence. However, since all are intended to kill something, caution in their use is always essential.

R0071042

Excessive applications and misuse are the most immediate problems. On the premise that more of anything is better, the widespread tendency is to use an excess. Since built-up residential areas border streets or other drainageways that can transport pollutants quickly to watercourses, the cumulative over-application of pesticides on home lawns and gardens from which washoff (or aerial drift) can carry away the chemicals is an important part of the picture. Total use on large open spaces is the other main urban component.

Common acceptance of a few simple guidelines can significantly reduce the pesticide load to watercourses. Expert advice is available from County Agriculture Extension Agents and other state agencies.

Prevention is the best control for any problem. The first question in considering the possible use of any pesticide must be whether it is necessary at all. On this score it should be kept in mind that pest control is never absolute since it is biologically impossible to eradicate all pests. The goal is to reduce their effects to acceptable levels. In this context there may be alternatives to pesticides which, in the long term, may be much less costly than the chemical.

Where alternatives are not found, the broad objective is to prevent overtreatment. Eliminating excessive pesticide use will save money for all users, private and public.

Experts provide these general guidelines for pesticide use:

- Other factors being equal, one should use the least toxic chemical that will accomplish the purpose.
- Pesticides that degrade rapidly are less apt than others to become water pollutants.
- Pesticides with low solubility in water are less apt than others to cause water pollution through drainage and runoff. Loss of such chemicals can be greatly reduced by preventing erosion.
- Some pesticide formulations have a broad spectrum of activity. These should be used whenever possible instead of serial applications of highly specific materials.

Legal Requirements

Pesticides are regulated by several federal and state agencies, operating under a variety of statutes. The most significant federal statute is the Federal Insecticide, Fungicide and Rodenticide Act (FIFRA), which has been amended several times since its enactment in 1947. The United States

R0071043

Department of Agriculture (USDA) administered FIFRA until 1970, when the United States Environmental Protection Agency (EPA) was created.

FIFRA emphasizes pesticide registration and labeling requirements as the means to ensure that pesticides, used according to label instruction, will be safe. EPA must approve all pesticide labels and use compliance with label requirements is mandated: "The label is the law."

In Florida, the Department of Agriculture and Consumer Services (DACS) maintains the state pesticide registration program, licenses dealers of state pesticide registration program, licenses dealers of restricted-use pesticides, and inspects foodstuffs for quality and safety. DACS may also certify applicators.

The Department of Health and Rehabilitative Services (DHRS) shares applicator certification authority with DACS. DHRS administers the Florida Pest Control Act (Chapter 482, F.S.) and DHRS supervises pest control activities in many non-agricultural areas, including residences and businesses.

Because of possible "unreasonable adverse effects in the environment" and potential injury to persons applying them, restricted-use pesticides may only be applied by or under the "direct supervision" of certified applicators.

State standards require licensing for commercial and public applicators working in any of the following categories of pest control. The categories are:

- Industrial, institutional, structural and health-related
- Right-of-Way
- Ornamental and turf
- Aquatic
- Public health
- Regulatory (for public agencies controlling regulated pests)
- Demonstration and research
- Seed treatment
- Forest
- Agricultural, for treatment of farm plants and animals by applicators other than farmers
- Aerial application

In addition, farmers, nurserymen and others who would use restricted pesticides on their own property or in their business also must obtain certification to be "private applicators."

It is intended that all categories of licensed applicators must be informed on product labeling, safety, nature of the pests and pesticides, equipment application techniques, laws and regulations, and the potential environment consequences of the use and misuse of pesticides as may be influenced by such factors as:

a) Weather and other climatic conditions;

b) Types of terrain, soil or other substrate;

c) Presence of fish, wildlife and other non-target organisms; and

d) Drainage patterns.

However, both federal and state law define "direct supervision" such that the certified applicator only "control" the pesticide use. His or her physical presence is not required. Given a large number of applicators and few inspectors, significant amounts of restricted-use pesticides are used by persons who may not have been instructed about the environmental and health risks involved.

DHRS certifies applicators in a variety of categories including fumigation, general household pest control, lawn and ornamental pest control and termite control. An examination is required for each specialty. Certificates must then be reviewed annually. Although reports of spills and of container disposal methodology are not required, DHRS rules require immediate notification of cases of accidental human poisoning, and routine reports of names, amounts, uses, dates and places of application of restricted-use pesticides.

DACS certification of pesticide applicators is somewhat less rigorous than DHRS's. In order to take the DHRS exam, formal educational or training requirements must be satisfied, whereas DACS only requires that applicants pass the DACS exam. Prior to an early 1983 rule change, DACS "private applicators" were exempt from examination and recordkeeping requirements. DACS now requires all applicators to be certified but recertification is only required quadrennially. Because of a new class of examinees (private applicators) and reduction in application fees, it is understandable that DACS increased the time requirements for recertification. However, as a result new information about the environmental hazards of certain pesticides may not reach pesticide applicators in a timely fashion under these revised certification procedures.

In contrast to the detailed certification and training requirements to which commercial applicators are subject, few legal restraints are placed upon the individual citizen in the application of pesticides. While it is unlawful for any person to use or to dispose of containers of unused portions of pesticides in a manner inconsistent with label directions, the impracticality of policing and enforcing stringent requirements throughout a state population is self-evident. Complaints can be acted on. However, education and voluntary restraint by the citizen offer the only currently realistic answer to the problem.

All-Purpose Guides

Certain considerations pertinent across-the-board to large- and small-scale users of pesticides are discussed here. Factors of concern particularly to one or the other category are covered in separate sections for each.

1) Safety - Proximity to people, human habitations, animals and water, and the topography in relation to all of them, require more than normal consideration in urban areas. These factors must be weighed from the safety standpoint, before any plans are made final for selection of chemicals, actual treatment, and fund outlays. Conscious effort will be needed in some areas to anticipate unexpected appearance and unpredictable patterns of children and pets even though none may normally be in the vicinity.

   Home users in residential areas, where children and pets are regularly close at hand, need to keep them in mind not only throughout actual application of the chemicals but in choosing the sites for storing containers and application equipment to assure that these are out of reach at all times.

   Disposal of unused pesticides and "empty" containers requires as much care as application of the chemicals. In getting rid of containers, users will want to give thought not only to safeguarding children and others at the premises but to protecting the safety of refuse collectors who will pick up the discards, and the safety of final handlers at the municipal landfill.

   Urban area governments that permit any open burning are diminishing in number. Even where such burning is allowed, pesticide containers should preferably not be burned. They should never be burned in built-up areas. Herbicide containers must never be burned. Certain other pesticides also carry a "No Burning" label.

2) Sources of Advice - Technical advice on pesticide use is available throughout the state from local agents of the Cooperative Extension Service operating through the University of Florida, Institute of Food and Agricultural Sciences Extension Division. Advice on the disposal of pesticides and containers is available from the same sources, or the Bureau of Groundwater Management, Florida Department of Environmental Regulation, and from the Florida Department of Agriculture and Consumer Services (FDACS).

3) Selecting the Materials and Methods of Application - The physical form in which a pesticide chemical is formulated may have an impact on its potential for water pollution. Timing and weather conditions will be crucial in the application of some materials. Topography is an obvious basic. Broad guides by category of

material follows.

Dusts - Are highly susceptible to wind drift, not only when being applied but also after they reach their target. If dusting offers the only acceptable control practice, the operation should be carried out during the early morning or late evening hours when there is little or no air movement. The distance between the application equipment and the target is also a factor to consider.

Sprays - May be in the form of solutions, emulsions or suspensions. Droplet size is an important factor in determining susceptibility to wind drift. Large droplets fall faster and are less likely to contaminate non-target areas. Here again, apply during periods of low air movement. Ground sprays followed by soil incorporation are not likely to be a source of water pollution unless excessive erosion occurs.

Granular formulations - Are applied to either the surface of the ground or below the soil surface. Surface applications may or may not be followed by soil incorporation. Pollution from granular formulations is unlikely unless heavy runoff or erosion occurs soon after treatment. Loss of granular formulations can be controlled for the most part with adequate soil conserving practices.

Fumigants - Must be kept in place for specific lengths of time in order to be effective. Containment methods include soil compaction, water seal, and sealing of the area with a plastic cover. Most fumigants act rapidly and degrade quickly. Consequently, water pollution is usually not a problem.

Antimicrobial paints and other surface coatings - Are designed to resist weathering and are therefore not considered as likely sources of pollution. Empty containers, however, should be disposed of in accordance with the rules for all pesticide containers.

Preplant treatments - Seed, roots, tubers, etc., are frequently treated with pesticides prior to planting. Treatment is usually by dust, slurry or liquids. Little pollution hazard exists from use of treated plant parts. Care must be taken, however, in disposing of unused treated plant parts and residual treatment materials. The same standards applicable to disposal of other pesticides should be observed.

4) Dosage - The universal rule is: Never exceed the manufacturer's dosage recommendations. At times, amounts less than the label recommends may be used. Consult the experts.

5) Leftovers - The most effective way to minimize the disposal problem is to prevent accumulation of a surplus. A careful evaluation of needs should be made in advance and purchases limited to a one-year or season supply. Methods of disposal of chemicals and containers are described in subsequent sections. Even a small residue can be a source of water pollution.

"Commercial" Scale Pesticide Use

With the constant introduction of new and sometimes more effective pesticides and occasional banning of some products when unanticipated detrimental effects or hazards emerge, the first rule of commercial applicators must be to stay abreast of developments. Owners or operators of facilities requiring the services of applicators will want to assure that their own employees having direct responsibility in this field keep informed. Exterminators and other professional applicators operating their own services obviously must be certified. Persons such as golf course superintendents, nursery and tree maintenance personnel, some industrial and institutional employees and certain municipal employees will also need state certification. Additionally, any individual actually applying pesticides in large amounts should be certified, not just the individual's employer or supervisor.

Protection of Water Sources During Preparation and Cleanup

Large-scale users in their planning and operations will have as a particular concern the prevention of water source contamination both during the mixing and preparation of chemicals for application and in the cleaning of equipment and disposal of unused pesticides and "empty" containers after treatment.

Surface water, subsurface water and pipeline distribution systems must be kept in mind throughout the preparatory and cleanup stages as well as during actual treatment. The pointers that follow are those offered farm users.

Lake or stream - If water is removed from these sources for mixing or cleanup it should be withdrawn with a pumping system separate from that of the pesticide application equipment if at all possible. Equipment should not be driven into the stream or lake for filling and cleaning. Equipment flushing should take place in an area where runoff of pesticides can be avoided. If the equipment must be filled at the stream or lake, only a suction line should be placed in the water. The equipment should be driven to another location for dumping.

Groundwater - Toxic chemicals should not be placed on the soil where there is a danger of contaminating subsurface water through percolation or through rock fissures. Groundwater contamination could occur through a pressurized system using a well as a supply. Anti-backflow devices should be used on hose connections if the hose will

come in contact with the chemical during mixing and filling operations.

Pits used for dumping flush water should be impervious enough to avoid contamination by percolation and be designed to professional standards.

Pressurized Distribution Systems - The largest danger here is the siphoning effect that can be created by other users drawing water concurrently with filling or flushing operations. All hose connections should be equipped with anti-backflow devices.

Additional precautions include the following:

- Avoid storage of pesticides in pumphouses or other buildings adjacent or in close proximity to streams, ponds, lakes, canals, or wells from which application equipment is filled.
- Pesticides should not be mixed and application equipment should not be filled, emptied, or repaired where spilled pesticides could drain or be washed into streams, ponds, canals or other bodies of water.
- Aprons and sumps should be constructed at the loading site to catch any overflow and drainage.
- Check valves should be installed on all intake hoses to prevent back-siphoning from sprayer tanks, particularly if the same pump is used for both filling and spraying.
- A filler hose should be suspended so as to provide an air space between the house and the surface of the spray mix in a full tank to prevent back-siphoning.
- Stay with the sprayer while filling. Do not let it run over while unattended.

Disposal of Unused Pesticides

The following possibilities should be considered before undertaking final disposal:

1) Use small quantities for the purpose intended in accordance with product label directions until supplies are exhausted.

2) Return any undamaged, unopened containers to the dealer or manufacturer.

After these options are exhausted, other possible disposal methods include:

1) Incineration (where facilities are available) at appropriate temperatures and times to cause complete destruction of the pesticide.

2) Disposal by burial in a specifically designated landfill.

3) Soil injection, but only with specific professional guidance.

4) Chemical methods suitable to degrade or detoxify pesticides to forms which are not hazardous to the environment.

Excess pesticides should never be disposed of:

- In a manner inconsistent with the product label or labeling directions.
- So as to cause or allow opening dumping of a pesticide.
- So as to cause or allow opening burning of a pesticide.
- So as to cause or allow water dumping or ocean dumping except in accordance with established regulations.

Disposal of Containers

Containers should be allowed to drain in vertical position for some 30 seconds after normal emptying. The container should then be rinsed three times with water or other diluting material being used, allowing 30 seconds for draining after each rinse. A good rule of thumb is to refill the container 1/4 to 1/5 full for each rinse: (i.e., use one quart of water or diluting material for each gallon container; one gallon for 5-gallon containers; and five gallons for 30- or 55-gallon drums). Each rinse should be drained into the spray tank.

Pesticide containers should not be re-used even after the triple rinse procedure has been completed.

Containers in good condition may sometimes be returned to the pesticide manufacturer or formulator or drum reconditioner for re-use with the same chemical class of pesticide previously contained. Other rinsed metal containers should be punctured to facilitate drainage, and crushed before transporting to a facility for recycle as scrap metal or for disposal. Containers may be buried in designated landfills.

Users of pesticides should obtain information from the Department's Bureau of Groundwater Protection and Waste Management on special recommendations and

R0071050

precautions that may be necessary for the disposal of some chemical containers.

Any specific disposal directions or procedures on pesticide product labels must be carefully followed.

Disposal of containers should be supervised by someone qualified and licensed for the application and handling of pesticides. The disposal of the containers is as much a part of proper handling as is the application of the chemical to the target area.

Storage of Unused Pesticides

Different chemicals require different types of facilities for proper storage. The following are basic principles which should be followed when selecting a storage facility or location:

1) The site should provide adequate protection against excessive heat, cold and moisture.

2) Storage facilities should not be subject to flooding.

3) The site selected should lend itself to preventing contaminated runoff if leakage should occur.

4) Pesticides should not be stored longer than the maximum time recommended by the manufacturer, as leakage may develop.

5) Facilities should provide for security to prevent non-qualified individuals from dispensing the chemicals.

6) Manufacturer's storage recommendations should be followed in order to maintain the integrity of the chemical.

The storage facility should be maintained in an "as-built" condition.

Residential Use

Easily the most important all-purpose single rule for home area users of pesticides to observe, if they look no further, is the experts' advice. Follow the manufacturer's instructions on the label. Never exceed its recommendations and remember that sometimes lesser amounts will be enough. The label message additionally includes the target point for application on plant or soil; the recommended application times (early morning or late evening, when temperatures are down and the air is still); safety advice, and referrals to Extension Service guidance. Heeding the advice of experts to "follow the label" translates to protection of water quality through

R0071051

eliminating the excessive or misplaced pesticide that is most apt to become available for runoff.

Conscious consideration by all residents during their use of pesticides can materially expand the beneficial impact of proper use. Hopefully, this awareness will extend to consideration of the forms of pesticide least likely to reach waterways, as summarized earlier, as the preferred forms to buy and use where a choice is possible.

Application

To get the pesticide onto its intended target and nowhere else, these general guides are offered:

1) Physical form: Granular formulations are generally preferable to liquids because application losses are lower.

2) Placement: Apply pesticides in a narrow rather than wide band; do not broadcast them over an entire lawn area. Spot spray infected areas rather than apply excess amounts of pesticides as an insurance against pests. Never apply over impervious surfaces. This precaution especially applies to water sprays.

3) Time of application: Pesticides should be used when they will have the greatest effect. Pesticides should be sprayed only when wind speeds are less than 7 mph. Spray in the early morning or ate dusk when wind speeds are usually at their lowest. Air temperatur should range between 40° - 80°F.

Before and After

Householders will want to use the same care in preparing for use and in cleaning their smaller pesticide application equipment as is recommended for large area equipment. Added precautions for the home user include taking care not to rinse equipment in driveways, roads, drainageways and other impervious areas. Pesticides should also never be disposed of in stormwater, sanitary or combined sewer systems.

No amount of leftover chemicals, small or large, should be thrown away into the environment. Small leftovers should be used up if possible rather than stored -- but used always according to the directions for regular use. "Empty" containers should always be cleaned before they are thrown away. See the recommendations for rinsing and cleaning larger containers under "Disposal of Container" -- but note that home users must also follow different procedures.

R0071052

Disposal of containers by urban householders should be the home refuse receptacles for municipal collection -- but the containers must always first be rendered unusable and then thoroughly wrapped to prevent harm to anyone and to minimize later harm to the environment.

Until better methods are developed, pesticide specialists urge observance of the following procedures by home users for disposing of "empty" small containers including one-gallon or smaller vessels for liquids and five-pound or smaller bags for solid pesticides:

- Glass containers: Triple rinse thoroughly, break the glass, and wrap in several layers of newspaper.
- Metal containers: Triple rinse thoroughly, puncture, and wrap in several layers of newspaper.
- Bags and inner liners: Wrap in several layers of newspaper after triple rinsing.
- Put the package in the trash or garbage receptacle used for other refuse to be picked up by the collection service.
- **"NEVER FLUSH"** pesticides down the toilet, nor pour leftover material into the sewer system **OR** into watercourses.

Education

As with fertilizer use, municipalities may wish to remind citizens of the potential for water pollution inherent in overuse of pesticides, and how to avoid it. Brief advices might be enclosed periodically with sewer and water bills. Reminders might note the possible savings to the taxpayer in both his own and the local government budget from reducing nonpoint source pollution. Such notices, soliciting responsible citizens' help, might also serve the interests of reducing waste treatment plant problems or costs and eliminating problems with pesticides at landfills. The notices should go to institutions, businesses and industries as well as householders.

Garden clubs and similar groups might elect to institute their own educational program.

Alternatives to Pesticides

Chemicals are by no means the sole weapon to control pests. Natural controls have always operated and continue to operate, otherwise insects would have taken over the world.

However, alternatives available to urban facilities and residents are distinctly more limited than those successfully used in agriculture or forestry. The reason is chiefly a matter of scale. Large areas and a span of time typically are needed for major "biological" or other non-chemical measures to exert their impact. Additionally, expert supervision is sometimes needed.

However, all urban dwellers and facilities operators have at hand a pair of elementary and universally proved preventives for pests, and some alternative controls that in some situations can either obviate the need for chemical pesticides entirely or reduce the amount needed.

Prevention

The preventives are cleanliness and avoidance of continuing dampness. Rubbish and refuse heaps, indoors or out, invite insects and rodents. Good sanitation prevents the creation of such breeding nests and grounds for pests. Keeping the lid tight on refuse receptacles is the simplest of all steps, yet often overlooked. Areas constantly damp invite fungi and insects, endangering molds, other plant diseases and rot. Drying out reduces the future problem, even though other remedies may be needed initially. Draining stagnant pools of water from any open containers, old tires or other rubbish left lying outdoors to collect rainfall will remove breeding grounds for mosquitoes and some other insects, may reduce the need to spray for them somewhat.

Control Alternatives

Such sophisticated approaches as sterilization of male insects, and the use of synthesized female insect sex hormones to lure males to traps -- both now successful in special cases -- are beyond ordinary application. Individual measures with some pertinence for urban use include:

1) Crop rotation - An age-old farm practice useful in reducing damage from certain nematodes, soil-borne insects and plant diseases. It has little or no effect on controlling weeds or the insects themselves. For the gardener who has enough space, moving the location of the garden may be a partial answer especially for nematode control.

2) Biological controls - One of the most venerable is the use of "milky spore disease" to control Japanese Beetle grubs. The bacterium B.thuringiensis controls the cabbage looper and other such caterpillars. The material is available to the residential gardner as a dust or liquid from many garden supply stores. Other biological controls can be investigated with the help of local agents of the Cooperative Extension Service.

3) Mechanical controls - Bug lights, insect strips, screens and mesh nets have their uses against flying insects.

4) Eradication of alternate hosts - A straightforward method of dealing with certain plant diseases and fungi that require more than one host species in order to complete their life cycles. The method simply breaks the life cyle by removing one of the host species. It is used in this state on cedar apple rust, a fungus that first infects red cedar trees -- a common Florida species -- and then must move to apple and crab trees to complete its life. The fungus can be controlled, especially in orchard areas, by removing or reminding the homeowner not to plant red cedars in the area. The method has little or no value for control of insects or weeds. Extension Service personnel can help determine in some other cases whether a situation exists that can be improved by eradication of a host.

I.P.M.

Encompassing all approaches is a technique called Integrated Pest Management. I.P.M. involves the reduction of pest problems by the application of combination of control methods based on a thorough understanding of the life system of the pest. It attempts to combine the best features of biological, chemical, cultural and mechanical control. Several applications are in use, such as the combination of crop rotation with use of resistant crop varieties. Programs are still in the developmental stage, and much research remains to be done. More emphasis is now being placed on putting I.P.M. principles into practice. Extension personnel will have the latest information.

Individual citizens as well as facilities operators will want to keep an eye on I.P.M., which has as its objective the achievenment of acceptable pest control with a minimum of chemical pesticides.

SW BMP 2.03

SOLID WASTE COLLECTION AND DISPOSAL

Definition

Elements of a municipally regulated program of refuse collection, litter control and leaf disposal.

Purpose

To manage the handling of urban refuse, litter and fallen tree leaves routinely in ways that will prevent their becoming water pollutants. Effective systems will also provide traditional benefits in health protection, nuisance abatement, fire safety and aesthetics.

Conditions Where Practice Applies

Wherever refuse, litter and leaves accumulate. Principal urban sources of refuse are residential areas; industrial and commercial areas; streets, sidewalks, and alleys; vacant lots and unmaintained green spaces. Principal sources of leaf accumulations are residential areas; parks and other managed green spaces; and some commercial areas such as malls and shopping centers.

Planning Considerations

Urban refuse, litter and tree leaves, if washed away in runoff, can quickly become water pollutants. The practical means to prevent their doing so is a coordinated municipal program combining effective systems of refuse collection, litter control and leaf disposal. The closer the control is extended to the sources of accumulation, the more effective the program will be. The most effective program will be the one that establishes good control at the originating premises.

The traditionally recognized benefits of nuisance abatement, reduction of fire hazards, improved aesthetics and in particular, health protection form improved insect and rodent control, will continue to be the primary benefits of such a program. They furnish the justification for it.

Improved water quality is an additional benefit. Nonpoint source pollution can be generated from refuse, litter and leaves when these are uncontainerized or where poor practices are followed in loading and unloading collection vehicles.

Resource recovery will also be a constant consideration in the total program in the future. Wherever economics of scale and available facilities make possible the institution of any measures to recover even portions of wastes for recycling and reuse, these steps will have to be instituted to claim the fuel potential and to reduce the drain on other dwindling natural resources, as well as to extend the life of landfills. To the extent that resource recovery reduces the total volume of wastes, it will automatically provide further protection of water quality by reducing the quantity of contaminants that may reach watercourses directly in runoff or leach into them from landfills.

A resource recovery approach may be based on separation of salvageable wastes at their sources for collection by the municipality and disposal to processors for recycling. Or, if the population is sufficiently large, a full-scale recovery and processing facility may be developed by a local jurisdiction or two or more jurisdictions jointly. Source separation will be necessary where no central recovery facility or operation exists. Urban officials say source separation is satisfactory for recycling effort, but that to operate a large resource recovery program it is better (having a central plant) to separate at the recovery plant itself. They note that in large areas it is expensive and labor intensive to collect separated wastes at the source.

The key to either program is adequate containerizing of the wastes. A conscious and continuing effort to inform the public is an absolute prerequisite.

The overall, long-term objective must be prevention--to cut down the total volume of waste generated in the first place.

The Problem, and Some Classifying

The components of urban waste include a multitude of materials from a variety of sources. The quantities and characteristics vary with the time of year, geographic location, and habits of a population. "Solid" waste is construed to take in all putrescible and non-putrescible wastes except body wastes. Included are garbage, rubbish, paper, ashes, autos, old tires, street sweepings, dead animals, cast-off appliances and furniture, hospital wastes, dead vegetation, tree stumps, construction debris, institutional and industrial solid wastes.

For convenience of classification along the practical lines of the systems used for handling and control, such material may be categorized as either refuse or litter, depending upon the condition and/or location in which it occurs. In general, it may be considered refuse when concentrated at individual premises and packaged or contained; it is litter when diffuse, scattered, or of such size or quantity as not to be amenable to handling in

routine collection service. Thus in a broad sense, litter once packaged or contained becomes refuse.

Fallen tree leaves and other vegetation may become water pollutants directly when they are raked into swales and street gutters. These actions may also increase pollution indirectly by blocking storm sewer inlets, thus aggravating flooding. Public education to teach citizens about these adverse effects is a vital part of any refuse control program.

Expert Assistance Overall

Ultimate disposal of solid waste is governed by regulations of the Florida Department of Environmental Regulation (Chapter 17-7 F.A.C.). Its Division of Waste Management (2600 Blairstone Rd., Tallahassee, FL 32399-2400) should be consulted for advice on special problems.

The System Pattern

Necessity and convention have set the pattern for handling urban waste material routinely discarded directly from private property. Consideration for water quality on a continuing basis may well improve the efficiency of the system.

On-Premises Storage

Maintenance of adequate sanitary facilities for temporarily storing refuse on private premises prior to collection is considered a responsibility of the individual householder or business. Not only is proper on-premises storage essential from a sanitation standpoint, but the efficiency of the entire collection and disposal system depends to a considerable degree on the extent of individual cooperation accorded this initial storage phase. Ordinances governing the sanitation program and containing specifications for home storage are essential, but the most desirable approach for improving home storage conditions lies in public education. Enforcement should have a minor role relative to the dependence to be placed on the willingness of individuals to cooperate when they are made aware of the hazards and nuisances associated with insanitary practices.

Education

Local requirements for refuse collection must be brought to the attention of every householder to ensure compliance. Instructions should be distributed as necessary stating the specifications for containers, separation of wastes by type, where to place containers for collection, established collection schedules, and schedule changes when made. The notices should explain the reasons for the requirements--including water quality protection. Violations will still occur. For such cases, some localities refuse to pickup waste materials which are improperly placed, packaged, or separated for disposal. Several have found it helpful to attach a tag to the container outlining the

nature of the violation. Most householders usually will comply, although follow-up will still be necessary in a few instances.

Storage Containers

Receptacles for the temporary storage of refuse should be designed specifically for the waste to be stored. They should be covered and the bottoms leakproof. Since the loaded container must be hoisted to the collection vehicle, often by one man, the size should be given consideration and limits should be specified in the regulatory ordinance itself.

In some localities where refuse collection is performed by private contractors, governments leave the entire program to the contractor. Often, the result is that no standards are set. The range of size and types of containers should be specified by ordinance regardless of who performs the collection service.

Some cities furnish plastic bags for rubbish, and replace full bags with empty ones. Those containers used to store garbage should be washed at frequent intervals.

Refuse Collection

Refuse collection itself has little impact on nonpoint pollution. The connection between the two lies in the loading of the refuse collection vehicle and the travel of the vehicle along its route and to the disposal site. The objective is essentially to reduce the amount of refuse that becomes litter (uncontainerized waste). Refuse collection crews should be instructed to use caution when emptying trash cans or otherwise loading their vehicles in order to limit amounts of the material blown either from the cans or out of the vehicle hopper during the loading activities. This is especially important on windy days. The local authority can minimize the blowing of litter from the collection vehicle hopper by requiring that the vehicle's compaction mechanism be used at each collection stop. This cleans the hopper and moves the waste material into the enclosed body of the truck before the vehicle is driven to the next collection stop. However, this compaction policy notably reduces collection efficiency and thus increases costs.

The refuse collection vehicle itself should be fully enclosed and watertight. This will prevent solids from blowing out of the truck and liquids from leaking from it. Periodic inspections and preventive maintenance of the collection vehicles should assure that these attributes of the vehicle are not impaired.

Operations at the waste disposal site also are important in reducing nonpoint pollution. The area of particular concern is the blowing of the waste

R0071059

materials from the vehicles as they are unloaded or blowing of wastes, particularly paper, from the disposal site itself. The effects of both occurrences can be controlled through the use of enclosed unloading areas in the case of incinerators or transfer stations and the use of appropriate fencing around sanitary landfills, including portable litter control fences that surround the active disposal area.

Litter Control

Litter is defined as "uncontainerized solid waste." Litter is the visible trash found along roadsides, vacant lots, sidewalks and parks. Non-routine discards from individual households, such as old appliances, and large-quantity wastes from all sources including households must also be considered for their potential as litter and for the special handling that must be provided for them in order to have a complete disposal program for all contingencies.

Most litter is biodegradable and in water will create an oxygen demand as it decomposes. It also will act as a transporting agent for bacteria, pesticides, heavy metals and other pollutants. In sufficient quantity and depending on its nature, litter is a pollutant and should be removed before it becomes available for transport by stormwater runoff.

There are seven major sources of litter. These sources should be the target of any litter control program.

1) **Household Waste**: Containerization is a must for routine wastes in residential areas. Trash collectors should report all violations or messy conditions to their superiors.

2) **Commercial and Industrial Wastes**: Containerization is again a requirement. Since the volume and/or nature of waste from these areas can be formidable, frequent inspection is recommended. The source should be held responsible for day-to-day cleanliness of the immediate area around storage areas. Collection agencies should be held responsible for cleaning up material they may spill during pickups.

3) **Hauling Vehicles**: Haulers of any loose material should be required to cover the load in transit. Trucks and other hauling equipment should have sealed bottoms to prevent leaks or seepage.

4) **Loading Docks**: Loading docks can generate large volumes of litter. Docks should be swept and, at places where food is handled (for example, restaurants), they should be washed daily, but not into nearby stormsewers. Strict enforcement is required to eliminate this major source of litter.

5) Construction Site: Construction activities yield large amounts of solid waste. Special practices are recommended for nonpoint source pollution control on such sites. In addition, daily policing is recommended to ensure that "good housekeeping" on these sites becomes routine.

6 & 7) Motorists and Pedestrians: Contrary to popular belief, these two sources of litter account for less than 25% of it all. However, because they are on the move, enforcement is difficult. Strict enforcement can help create a psychological climate promoting observance of the law. Vacant lots and other vegetated areas should be made secure as feasible against illegal dumping.

Elements of Litter Control

There are four major components of a good litter control program.

1) Technology (and Costs): In addition to collection equipment, localities must provide a secure and safe means for either landfilling the collected litter or transferring it to users who will recycle it. Oversized discards are especially costly to remove. Some municipalities have suggested a special tax or disposal fee at the time of purchase to cover the ultimate disposal costs of such items.

2) Periodic Cleanup Campaigns to ensure continuing results.

3) Education: If the public remains apathetic or does not comply with the program, it is doomed to failure. Information programs should be conducted both in the school system and for the adult population. In localities that charge for trash pickup, information flyers can be inserted with the bill.

4) Law Enforcement: Compliance with the ordinance(s) is basic to the success of any litter control program. Police and, if necessary, health and sanitation workers should be delegated authority to enforce local ordinances. Checkups conducted for possible violations can be useful. Checkups conducted promptly in the wake of special cleanup campaigns may be particularly effective for establishing a climate of acceptance.

Leaf Disposal

Vegetative litter transported in stormwater runoff can add significant organic and nutrient pollution to receiving streams. Leaves may also be washed to the grates covering entrances to storm sewers effectively blocking the stormwater from entering the system. They thus aggravate urban flooding and increase the volume of uncontrolled runoff carrying pollutants to streams.

R0071061

The smoke from leaf burning in built-up areas is a hazard to persons with respiratory ills, and can be a nuisance to others. When leaves are burned, the ash is reported to contain a significant amount of phosphorus. If burning is done in street gutters or ditches, the phosphorus carried by stormwater can increase the nutrient load to streams. Many urban localities now ban leaf burning. This prohibition makes a proper collection and disposal system for vegetative litter more essential than in the past.

Leaves may be shredded for mulch, plowed into a garden, or composted to provide important ingredients of good soil for lawns and gardens. However, shredded leaves left on the lawn may form an impermeable thatch that can damage grass.

Planning the System

In addition to considerations of the volume of material to be handled, the equipment and manpower needed, the necesary disposal areas, and methods of financing, planning must take into account the seasonal nature of the problem and the special demands this will place on the system.

Ordinances should require that leaves be bagged and stored away from drainageways until they are collected. The ordinance should specify the preferred method of storage for pickup. Bagging is usually the most practical method. Other means may be specified if a locality has equipment for collecting loose leaves. However, where leaves are held loose in bulk for pickup, extra care is required to keep them out of drainageways pending collection.

Leaf collection programs can be expensive. Some localities have private contractors provide the service for a fee from property owners.

The scope and cost of a collection program can be reduced by householders' mulching or composting of leaves at their homesites. A further alternative for the municipality after collecting leaves, is to provide shredded leaves or leaf compost to residents for their use.

Citizens should be made aware of all the factors and alternatives involved in the development of an effective leaf disposal system, with emphasis on the benefits to both home soil water quality and the municipal budget to be realized by resort to the conservation approach.

Resource Recovery

While total systems to salvage all potentially reusable major components of urban wastes may for the moment be only marginally feasible, systems for reclaiming one or more components are widely used. The approach to resource recovery with the most immediate potential for reducing nonpoint pollution could be source separation. Source separation is the removal of recyclable

R0071062

materials from the waste stream prior to mixing with other discards. Materials most often source separated include newspaper, glass and cans from residential sources; white ledger paper and computer paper in office buildings; and corrugated material from commercial activities, particularly supermarkets.

The storage/collection activity is the phase with the highest potential for causing nonpoint pollution. At office buildings and commercial establishments, most storage of recyclable materials is provided within the building or inside closed containers. However, in the case of residential source separation, materials are stored inside the home and then placed outdoors, usually at the curb, for collection.

These materials have the potential of being wind-blown or disturbed by animals before they are collected. Source separation programs including newspapers usually require that they be bundled or placed in grocery bags for collection. Both approaches will usually prevent the papers from being blown. Glass and cans are often set out in separate cans similar to trash cans or they are stored in grocery bags.

The latter approach is quite susceptible to scattering caused by animals knocking the bags over in attempting to get at any remaining food. Programs that include the source separation of cans and glass should require that these materials be placed at the collection point in tightly covered containers in the same manner as mixed wastes.

Materials that are source separated by householders are usually collected using the normal refuse collection vehicles or other types of truck. When the refuse collection vehicles are used, the separation materials are usually placed in bins or racks that are mounted under the normal collection body. This collection is accomplished simultaneously with the mixed waste collection system.

Where this rack approach is used, the racks should be securely fastened to the vehicle and provided with a door or other cover so that the papers do not spill out and become wind-blown from the truck. Where separate vehicles are used for materials collection, they may have either closed or open bodies. It is strongly recommended that vehicles collecting paper have closed bodies or closed compartments for the newspaper. Glass and can collection is less susceptible to being wind-blown; however, a closed compartment for these materials is also recommended.

R0071063

SW BMP 2.04

POLLUTION SOURCE CONTROLS ON CONSTRUCTION SITES

Definition

Minimizing nonpoint source pollution from construction sites through good management and "housekeeping" techniques.

Purpose

To reduce the availability of construction-related pollutants which can contaminate runoff water and, where runoff contamination cannot be avoided, to retain pollutants and polluted water on the site insofar as possible.

Conditions Where Practice Applies

This practice applies to all construction projects. The level of planning and management necessary to control nonpoint source pollution adequately is dependent upon the size and complexity of the construction site.

Planning Considerations

Construction activities, by their nature, create many sources of potential pollutants which can contaminate runoff and thereby affect the quality of downstream receiving waters. Accelerated erosion and sedimentation caused by land-disturbing activities is one of the major pollution problems caused by construction. Control measures and practices to limit sediment pollution are specified in the final section of this chapter.

There are, however, many other potential pollutants associated with construction activities such as gasoline, oils, grease, paints, cements, and solvents, to name only a few. Even non-toxic materials such as paper and cardboard can be classified as potential pollutants when they are washed into streams and lakes in large quantities.

The best way to prevent nonpoint source pollution on construction sites is to use "good housekeeping" practices, which usually entails simply maintaining the site in a neat and orderly condition. Specific practices should be employed to retain runoff and to deal with toxic substances and materials. An overall plan for the control of nonpoint source pollution is advisable so that specific control measures can be spelled out and implemented in an effective manner.

R0071064

Following are some specific elements which should be considered in nonpoint source pollution control planning on a construction site:

1) Erosion and Sediment Controls

Practices which minimize erosion and retain sediment on site are effective in controlling many other nonpoint source pollutants associated with construction activities as well. Development and impelementation of a good erosion and sediment control plan is a key factor in controlling nonpoint source pollutants other than sediment on a construction site.

2) Equipment Maintenance and Repair

Maintenance and repair of construction machinery and equipment should be confined to areas specifically designated for that purpose. Such designated areas should be located and designed so that oils, gasoline, grease, solvents and other potential pollutants cannot be washed directly into receiving streams or stormwater conveyance systems. These areas should be provided with adequate waste disposal receptacles for liquid as well as solid waste. Maintenance areas should be inspected and cleaned daily.

On a construction site where designated equipment maintenance areas are not feasible, exceptional care should be taken during each individual repair or maintenance operation to prevent potential pollutants from becoming available to be washed into streams or conveyance systems. Temporary waste disposal receptacles should be provided.

3) Storm Sewer Inlet Protection

Inlets to storm sewers should be protected by suitable filtering devices during construction to keep settleable pollutants from entering conveyance systems.

4) Waste Collection and Disposal

A plan should be formulated for the collection and disposal of waste materials on a construction site. Such a plan should designate locations for trash and waste receptacles and establish a special collection schedule. Methods for ultimate disposal of waste should be specified and carried out in accordance with applicable local and state health and safety regulations. Special provisions should be made for the collection and disposal of liquid wastes and toxic or hazardous materials.

Receptacles and other waste collection areas should be kept neat and orderly to the extent possible. Waste should not be allowed to overflow

its container or accumulate for excessively long periods of time. Trash collection points should be located where they will least likely be affected by concentrated stormwater runoff.

5) Washing Areas

Vehicles such as cement or dump trucks and other construction equipment should not be washed at locations where the runoff will flow directly into a watercourse or stormwater conveyance system. Special areas should be designated for washing vehicles. These areas should be located where the wash water will spread out and evaporate or infiltrate directly into the ground, or where the runoff can be collected in a temporary holding or seepage basin. Wash areas should have gravel or rock bases to minimize mud generation.

6) Storage of Construction Materials, Chemicals, Etc.

Sites where chemicals, cements, solvents, paints or other potential water pollutants are to be stored, should be isolated in areas where they will not cause runoff pollution.

Toxic chemicals and materials, such as pesticides, paints and acids, should be stored in accordance with manufacturers' guidelines. Groundwater resources should be protected from leaching by placing a plastic mat, packed clay, tar paper, or other impervious materials on any areas where toxic liquids are to be opened and stored.

7) Demolition Areas

Demolition projects usually generate large amounts of dust with significant concentrations of heavy metals and other toxic pollutants. Dust control techniques should be used to limit the transport of the airborne pollutants. However, water or slurry used to control dust should be retained on the site and not be allowed to run directly into watercourses or stormwater conveyance systems.

8) Sanitary Facilities

All construction sites should be provided with adequate sanitary facilities for workers in accordance with applicable health regulations.

9) Pest Control

Pesticides used during construction should be stored and used in accordance with manufacturers' guidelines. Overuse should be avoided and great care should be taken to prevent accidental spillage. Pesticide containers should never be washed in or near flowing streams

or stormwater conveyance systems. Further guidelines for pesticide use control are contained in other standards available in this section.

10) **Dust Control**

The use of calcium chloride, oils or other chemical dust control agents on construction roads should be avoided. Periodic watering of these areas is a preferred alternative.

SW BMP 2.05

STREET CLEANING

Definition

Urban street cleaning programs incorporating NPS pollutant control elements.

Purpose

To conduct urban street cleaning operations routinely in ways that will prevent street contaminants from becoming water pollutants. Accustomed benefits to aesthetics would continue, and could be enhanced.

Conditions Where Practice Applies

Most applicable for paved streets having curbs and gutters, but applicable to all paved vehicular traffic areas including parking lots, alleyways, driveways, etc.

This practice is particularly applicable to lower the pollutant load from existing built out areas where space for conventional structural treatment systems is simply not available or is extremely costly. The expected pollutant removal efficiency is highly variable. Most equipment will not remove the fine particulates where significant roadway pollutants abound. Consequently, whenever possible, even the most rigorous of programs (i.e., complete sweeping on a daily basis) should be used in conjunction with other measures to achieve a level of removal approaching the 80 to 90% range. Credit toward the normal treatment volume specified for a particular management practice will usually be given by the Department on a case by case basis.

Planning Considerations

The primary objective of municipal street cleaning practices has been to enhance the aesthetic appearance of streets by periodically removing accumulated litter, debris, dust, and dirt. Such practices, however, also have an impact upon the amount and type of roadway pollutants which may be washed into receiving waters during runoff events. Consequently, street cleaning is widely considered as a candidate management practice for reducing stormwater pollution loadings at its source.

As a basic principle: Any jurisdiction that has a street cleaning program will provide more protection to water quality than a jurisdiction that has

R0071068

no such program. It is necessary, however, that the program be compatible with the type of stormwater conveyance system in the locality.

For nonpoint source pollution control purposes, the conventional methods of street cleaning must be evaluated in terms of their pollutant removal effectiveness. Street cleaning operations directed primarily at litter control and aesthetic enhancement may have little effect upon important water pollutants such as BOD, pesticides, nutrients and heavy metals. Consideration of the water pollution factors may justifiably alter the choice of methods for cleaning the streets. At a minimum, such factors should always be considered in the conduct of street cleaning operations. At best, whenever choices exist at the outset in the setting up of new street cleaning programs, these factors should be a major consideration in planning the operation to be used.

The Pollutants

Streets are primary collectors of most types of urban pollutants. Besides the familiar bits of garbage, paper and plastic wrappings, the contaminants include food, animal wastes, grit and cinders, oil and grease, heavy metals, and other by-products of motor vehicle traffic, particles from industrial operations, air pollutants settled out or brought down in precipitation, fertilizer and pesticides from lawns and gardens. The variety and quantity of pollutants that accumulate on streets are directly related to the type and density of surrounding land uses, as well as, the use of the street itself.

Particle Size Implications

Research has shown that the majority of nutrient, oxygen-demanding and toxic substances reaching the streets are attached to fine particles. The main pollutant load therefore is contained in the dust and dirt fraction. For example, about 56% of the phosphates and 32% of the nitrates are associated with particle sizes of less than 43 microns. Fifty-one percent of all heavy metals and 73% of all pesticides are associated with particles less than 246 microns in size. The obvious conclusion to be drawn from these data is that street cleaning practices that can remove fine particles (less than 246 microns) will be the most effective for nonpoint source pollution control.

Cleaning Frequency

A regular periodic cleaning schedule is recommended. Logically, more frequent cleaning will result in greater pollutant removal. Each municipality must evaluate its own needs, conditions and costs to determine the best cleaning schedule.

Pollutant Location

The majority of particulate contaminants which are deposited on streets are

blown to the side by moving vehicles. It is estimated that 90% of street contaminants accumulate within 12 inches of the curbline of guttered streets. To a lesser extent, this concept has also been shown to apply to parking areas. Daily cleaning operations should concentrate on cleaning curb and gutter lines for maximum pollutant removal efficiency. However, in order to achieve high removal efficiencies the entire surface area of parking facilities must also be swept periodically; but this operation can be conducted on a less regular basis (weekly to bi-weekly).

Street Cleaning Alternatives

There are basically two alternative methods of street cleaning which are commonly used today. They are street sweeping and street flushing.

Street sweeping involves the use of machines which physically pick up contaminants from the street surface and deposit them in a self-contained bin or hopper. Street flushing on the other hand consists simply of moving contaminants by flowing water from the street to a stormwater conveyance system.

There are many variations of each type of system with differing applicabilities dependent upon local conditions and circumstances. Both of these street cleaning techniques are discussed in detail in the following sections.

Street Sweeping

The most common methods of street sweeping are mechanical (broom type) sweepers and vacuum sweepers.

Mechanical sweepers are the most commonly used and, understandably, the majority of the currently available performance literature deals with this type of sweeper. Mechanical sweepers basically consist of a gutter broom and a main broom which rotate at high speeds forcing the debris from the gutter broom and street surface into a conveyor belt and subsequently into a hopper. Water is usually sprayed on the surface for dust control.

The effectiveness of mechanical sweepers is recognized to be a function of a number of factors, including: (1) particle size distribution of accumulated surface contaminants; (2) sweeping frequency; (3) number of passes; (4) equipment speed; and (5) pavement conditions.

Most conventional mechanical sweepers are currently considered to be in the range of 50% effective for overall particle removal. However, their efficiency in the smaller particle range drops off dramatically. Table 6-1 illustrates the efficiency of typical mechanical sweepers with respect to particle size. Newer sweeper models may have greater removal efficiencies.

R0071070

The second type features vacuum action over the entire path, assisted by a gutter broom. Still, some of the particulates that are embedded in the road surface do not receive sufficient agitation to become air-suspended and, therefore, the vacuum is unable to draw them into the hopper.

A relatively new concept is the regenerative air system. Sweepers of this type force air down onto the pavement, suspending the particles, which are then picked up by the vacuum suction. These sweepers may be the most efficient in removing fines.

Some types of vacuum sweepers can serve another municipal maintenance function. If the unit is equipped with a wandering hose attachment, it can be used for sewer and catch basin cleaning. This type of sweeper would also be best suited for use on porous asphalt pavements which require deep particle removal to maintain porosity.

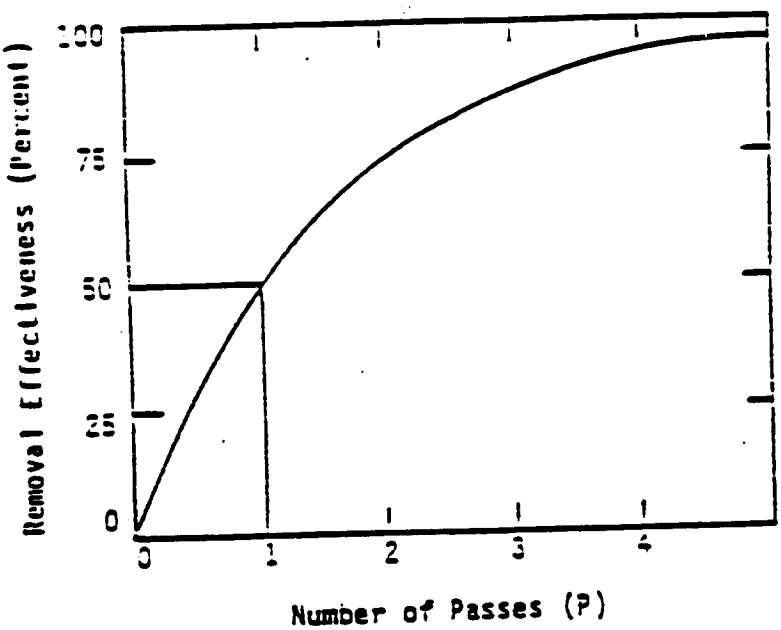
Besides equipment selection, there are other considerations which must be taken into account when developing an effective street sweeping program for nonpoint source pollution control. Some of these "fringe" considerations include:

1. Road surfaces: Smooth streets are easy to clean. Rough and broken surfaces are difficult--and may also contribute their own addition of asphalt and other materials to the burden. Roadways are typically raised in the center. Alleys may have the opposite configuration, making them difficult to clean with conventional, brush-type sweepers and requiring other devices.

2. Parking: Street sweeping will be effective only where no-parking regulations are effectively enforced. Public cooperation and awareness are essential. Even when parked cars are towed away, the cleaning operation is delayed pending towing. Some cities sweep downtown streets during rush hours when curbside parking is banned. Where curbside parking normally is permitted, adequate advance notice of sweeping and no-parking hours must be posted. To attempt to conduct street sweeping operations without strict enforcement of the ban is a waste of time, effort and money.

3. Operator Training: The most sophisticated equipment will be useless if badly run or maintained. Training for operators and maintenance personnel should stress the importance of their task as well as how to obtain maximum efficiency from the machines, including maximum removal of potential NPS pollutants.

Street Flushing



Street flushing is a practice which is employed in many cities as an alternative to or in addition to street sweeping. Street flushers typically consist of an 800- to 3500-gallon water supply tank mounted on a truck or

Table 6-1

RELATIONSHIP BETWEEN MECHANICAL SWEEPER EFFICIENCY AND PARTICLE SIZE

Particle Size (microns)	Sweeper Efficiency (% removal)
≥2,000	76

trailer which is equipped to allow water to be sprayed through three or more directional nozzles onto the street surface. As currently practiced, street flushing does not pick up contaminants, but primarily serves to transport them from the center of the street surface to the gutter. The volume of water used is generally insufficient to transport the accumulated material to the nearest drain.

The efficiency of this type of street flushing can be improved, however, by using specially designed flushing equipment with high-pressure spray nozzles. A comparison of curves shown in Figure 6-2 indicates that a flusher of this type is a superior method of moving street contaminants. Conventional street flushers, however, are not likely to be as effective as this specially designed unit.

The applicability of any type of street flushing program for NPS pollution control is primarily dependent upon what happens to the flush water when it leaves the street. The relocation of pollutants from street surfaces to sewers helps ensure that they will be washed into receiving waters during the next runoff event. The practice must be accompanied by a means of recovering the polluted flush water or transporting it to a treatment facility or holding basin for later treatment. Combined sewer systems can provide this capability. Systems with separate storm sewer cannot.

Thus it must be noted that using a street flusher can do more harm than good with the latter systems. The storm sewers will simply transport the flushed pollutants--untreated and probably in more concentrated doses than otherwise--direct to receiving streams. In general only older localities in Florida have combined sewers. Street flushing should not be done in areas where there are separate storm sewers and sanitary sewers.

The practice of street flushing is most applicable in areas with combined sewers which can accommodate the flush water during periods of dry weather flow. Such an application must also be accompanied by sewer flushing, however, to insure that the pollutants don't just accumulate in the sewer system for later transport to receiving waters.

Flushing may also be applicable to smaller paved areas such as parking lots where the flush water can be collected in holding basins or cisterns before release. Much of the pollutant load can be removed through sedimentation or percolation in the detention or retention facility.

Maintenance

The primary maintenance consideration of street cleaning programs concerns the equipment. As with many other municipal services, the effectiveness of the program is highly dependent upon the operating efficiency of the equipment used. Whether street sweepers or street flushers are involved, they should be adequately maintained to insure economical and effective operation.

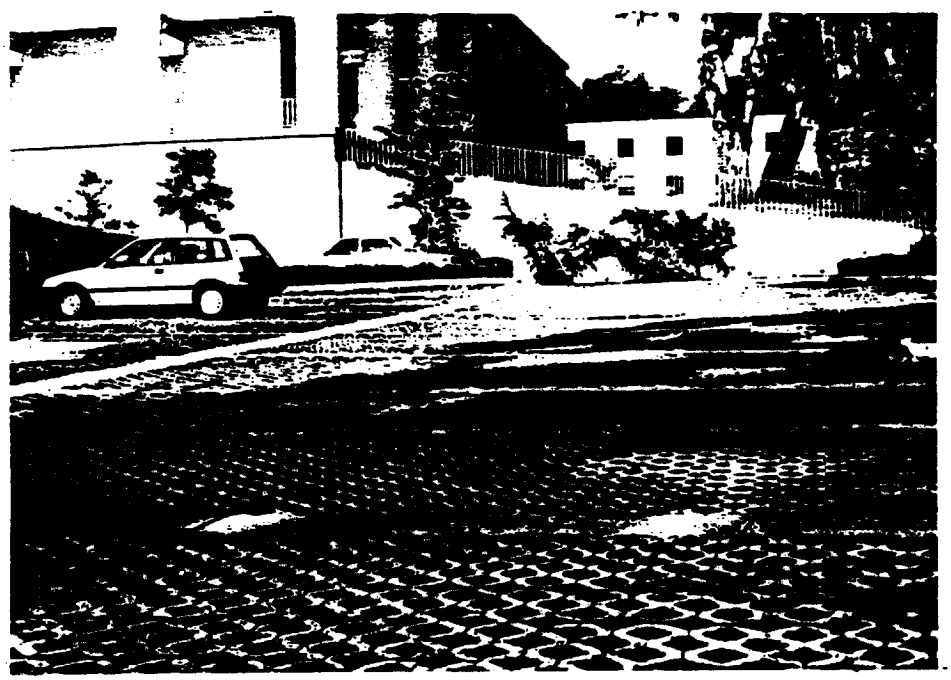
GUIDELINES FOR USING

STRUCTURAL STORMWATER CONTROLS

SW BMP 3.01

CONCRETE GRID AND MODULAR PAVEMENT

Definition



A pavement consisting of strong structural materials having regularly interspersed void areas which are filled with pervious materials, such as sod, gravel or sand.

Purpose

To reduce water pollution from low-volume traffic areas by providing a bearing surface having adequate strength to accommodate vehicles while allowing infiltration of surface water and filtration of pollutants. The approach is intended to achieve this purpose by:

1. Reducing the volume and peak rate of runoff flow, thus reducing the likelihood of sewer overflows, flooding, and downstream erosion and sediment pollution.

2. Reducing the loading and concentration of pollutants in the runoff.

R0071076

Conditions Where Practice Applies

Where pavement is desirable or required for low-volume traffic areas and the underlying soils allow for rapid drainage. This practice is most applicable for new construction, but it can be used in existing developments to expand a parking area or even to replace existing pavement if that is a cost-effective measure. This practice should NOT be used in areas where infiltrated pollutants may reach and degrade groundwater to below state standards.

Possible areas for use of these paving materials include:

1. Parking lots, especially fringe or overflow parking areas.

2. Parking aprons, taxiways, blast pads, and runway shoulders at airports (heavier loads may demand the use of reinforced grid systems).

3. Emergency stopping and parking lanes and vehicle cross-overs on divided highways.

4. On-street parking aprons in residential neighborhoods.

5. Recreational vehicle camping area parking pads.

6. Private roads, easement service roads and fire lanes.

7. Industrial storage yards and loading zones (heavier loads may demand the use of reinforced grid systems).

8. Driveways for residential and light commercial use.

9. Bike paths, walkways, patios and swimming pool aprons.

Planning Considerations

Pavement Types (See Figure 6-3)

Pervious pavement systems vary considerably in configuration. Categories include:

1. **Poured-in-Place Concrete Slabs** -- Reinforced concrete slabs covering large areas are poured in place on the ground to be covered. Special forms are used to shape the void areas, and a flat surface results. Because the slab is continually reinforced with steel, this pavement is suitable for heavy loads and has maximum resistance to movement caused by frost heave or settling.

2. **Pre-Cast Concrete Grids** -- Concrete paving units incorporating void areas are usually precast in a concrete products plant and trucked to a job site for placement on the ground. However, for large jobs these units can be formed and cast at the site. There are two types of grid pavers:

   a. **Lattice Pavers** -- generally flat and grid-like in surface configuration.

   b. **Castellated Pavers** -- distinguished by a more complex surface configuration characterized by crenels and merlons that are exposed when pervious materials are added. These units show a higher percentage of grass surface.

3. **Modular Unit Pavers** -- Smaller pavers which may be clay bricks, granite sets, or cast concrete of various shapes. These pavers are monolithic units which do not have void areas incorporated into their configuration. They are installed on the ground to be covered with pervious material placed in the gaps between the units.

Production of Units

There are a number of manufacturers of precast concrete grids and unit pavers, and various styles can be purchased from distributors. Forms are required for poured-in-place systems. These systems should be installed by contractors who have been trained in the use of the forms.

Site Characteristics

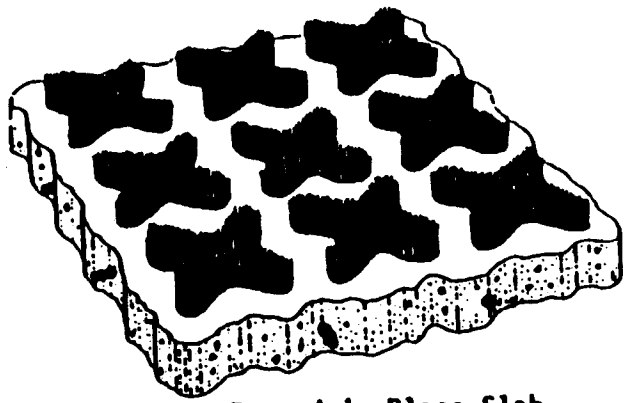
To determine the suitability of the types of paving materials and to plan and design their installation, the following information about the site should be known:

1. **Environmental data:** Soil permeability and bearing capacity; slope; depth, direction of movement, natural quality, and confined or unconfined condition of groundwater; and surface drainage conditions.

2. **Pollution information:** Types of pollutants generated by the prevailing and intended land uses and the effect of the practice on pollutants, generally and specifically. Pollution control effectiveness is not currently documented for these products, but research into these factors is in progress and results are expected to be forthcoming.

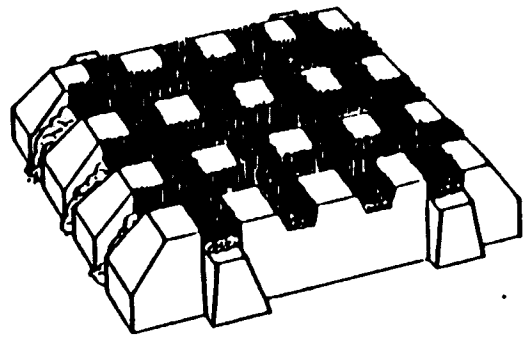
3. **The intended use of the area:** This is a key determinant of the choice of paving material. Is the installation temporary or permanent? What type of maintenance will be necessary? Is pavement coloring desired? What type of performance will be required of the paving surface? Can the practice be coupled with other BMPs for increased effectiveness?

4. Pre-development and projected post-development runoff determinations and other hydrologic data: To determine the need for overflow or back-up stormwater facilities, when required by local agencies for flood control. Few manufacturers list runoff or infiltration coefficients for their products, but research on these factors is in process.



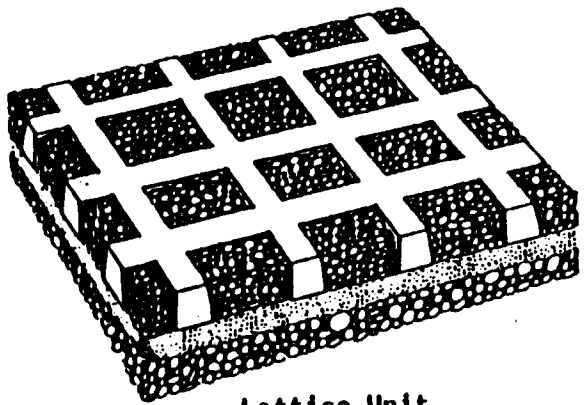
Design Criteria and Construction Specifications

All installations of pervious pavement should be designed and constructed according to the manufacturer's specifications. To be consistent with other forms of treatment, these systems must be capable of percolating at least 80% of the 3 year-1 hour design storm over a 1 hour period. Alternately, if these systems are designed such that they can provide a storage volume for the first half inch of runoff above the soil surface and including the subgrade base (if applicable) they may also be considered to provide 80-90% pollutant removal. Stored water must be percolated prior to the time limit specified for other onsite retention systems (72 hours). However, facilities using vegetative cover in combination with pavers must be capable of disposing of stored waters within time limits necessary to avoid damage to the ground cover (24 to 36 hours for most grasses). Parking areas should avoid extensive ponding for periods exceeding more than an hour or two.



In the design of these systems experience shows a definite potential for large margins of error involved in estimating the infiltration rate of the underlying soils for the purpose of evaluating the storage recovery period to compare with the Department's requirements. Consequently the use of a safety factor of two or more is normally recommended. This allowance may be accomplished by reducing the percolation rate by one-half its original value or by limiting the drawdown period to half the allowable 72-hour value. Stormwater facilities as discussed in the Porous Pavement (SW BMP 3.06) may also be incorporated into these facilities to improve storage.

Maintenance



Where turf is incorporated into these installations, normal turf maintenance -- watering, fertilizing and mowing -- will be necessary. Mowing is seldom required in areas of frequent traffic. It is documented that the hard surfaces in these installations require very little maintenance. However, fertilizers, pesticides and other chemicals may have adverse effects on concrete products. The use of such chemicals should be restricted as much as possible.

STORMWATER DETENTION BASINS

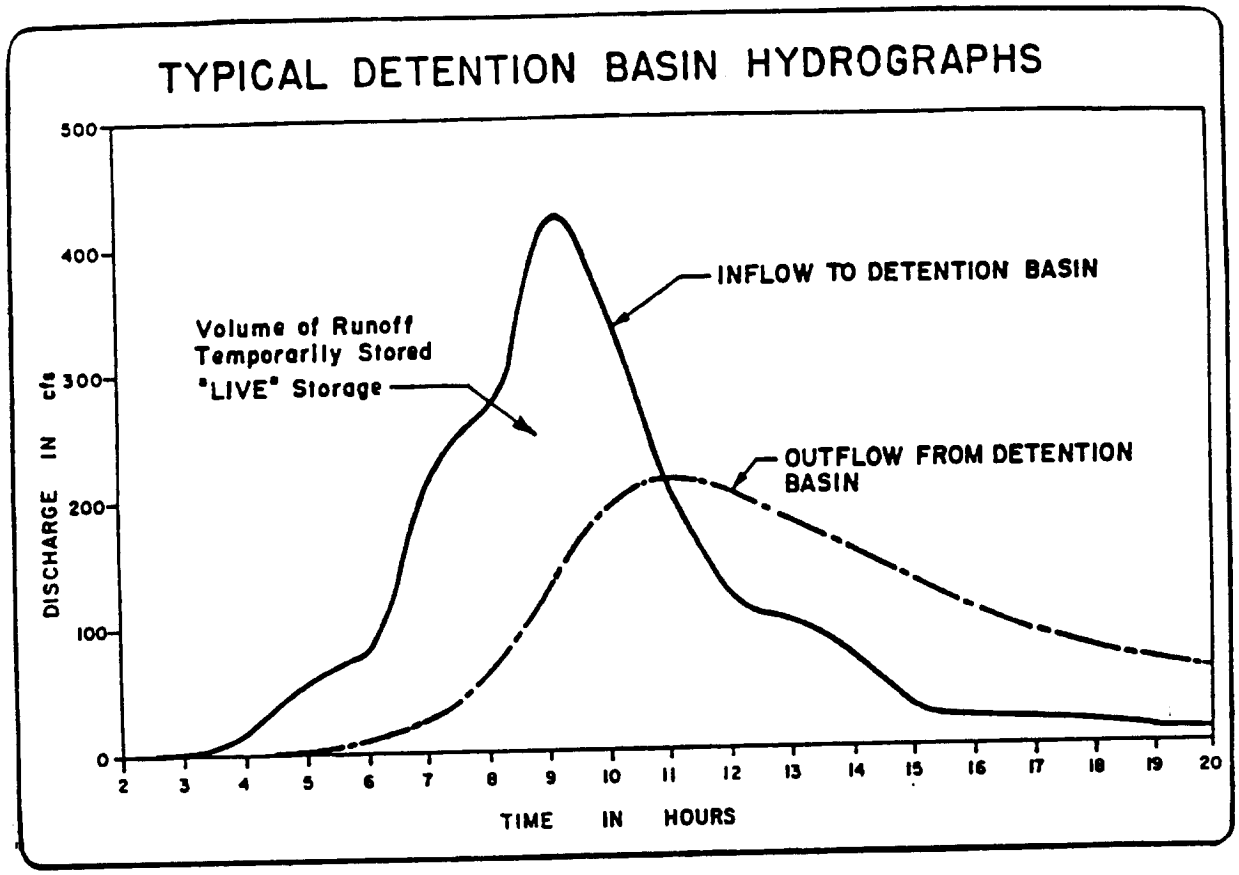
Definition

On-site detention refers to the temporary storage of excess runoff on the site prior to its' gradual release after the peak of the storm inflow has passed. Runoff is held for a short period of time and is slowly released to a natural or man-made water course, usually at a rate no greater than the predevelopment peak discharge rate.

Purpose

The objective of a detention facility is to regulate the runoff from a given rainfall event and to control discharge rates to reduce the impact on downstream stormwater systems, either natural or manmade. Generally, detention facilities will not reduce the total volume of runoff, but will redistribute the rate of runoff over a period of time by providing temporary "live" storage of a certain amount of stormwater. The volume of temporary "live" storage provided is the volume indicated by the area between the inflow and outflow hydrographs as shown in Figure 6-4.

A major benefit derived from properly designed and operated detention facilities is the reduction in downstream flooding problems. Other benefits include reduced costs of downstream stormwater conveyance facilities, reduction in pollution of receiving streams and enhancement of aesthetics within a development area by providing the core of "blue-green" areas for parks and recreation.



Example of a Typical Wet Detention Basin for Stormwater Control

(Source: Photo courtesy of Mr. Will Miller, Aurora Inc. South)

R0071081

Figure 6-4

Planning Considerations

Throughout the design process the designer should be committed to considering the potential impacts of the completed facility. Such impacts can be positive or negative and can be as broadly classified as social, economic, political and environmental. Designers can often influence the positive or negative aspects of these impacts by their careful evaluation of decisions made in the design process. Generally speaking, the completed facility should provide for safety to people as well as protection of real property, water quality and wildlife habitats.

Multiple Uses: Multi-purpose use of the facility and aesthetic enhancement of the general area should also be major considerations. Above all, the facility should function in such a manner as to be compatible with overall stormwater systems both upstream and downstream to promote a watershed approach to providing stormwater management as well as local flood control.

R0071082

Water Quality Improvement: In planning new impoundments, it should be kept in mind that the goal of improved water quality downstream may conflict with certain desired uses of the impoundment. It is only logical that if the basin is used to remove pollutants, the water quality within the basin itself will be lowered, thus reducing the applicability for uses such as water supply, recreation and aesthetics. In planning the facility the engineer or planner should have a good knowledge of the runoff constituents and an understanding of the possible effects on the quality of the stored water.

Depending upon the impoundment design, downstream water quality may be improved for the following reasons:

1) Soil, sediment and other particulate pollutants settle out and are trapped to a degree.

2) Delayed release of runoff stretches out the loading to the receiving stream of runoff-borne sediment, organic materials, chemicals and bacteria thus reducing the "first-flush" or shock loading effects of stormwater effluent.

3) To some extent increased infiltration of runoff through the soil may occur so that the water is cleansed before reaching lakes, canals, or streams and the augmented groundwater volume later helps to sustain base flow.

4) Decreased runoff rates reduce stream channel erosion and subsequent sediment pollution.

5) Some amount of chemical transformation and biological uptake occurs which helps upgrade runoff quality while the water is detained in the detention pond. This upgrading process can be further enhanced through mechanical aeration and the use of aquatic plant species which can assimilate pollutants.

6) Downstream pollution by litter and debris is reduced to the extent that such pollutants are trapped within the impoundment area or pretreatment devices.

The exact level of treatment or pollutant removal which may be obtained from each or all of these mechanisms is difficult to predict. The efficiency of these systems has been shown to vary depending on a number of factors including the holding time, amount of littoral zone available, and the location of the inlet relative to the outlet of the facility, and the incorporation of other BMPs into an overall treatment train. Detention systems should be integrated with other BMPs such as swales, modified stormsewer inlets, etc. to reduce loading to the detention pond, especially if it will serve as an aesthetically pleasing "lake".

Stormwater detention impoundments can vary greatly in size and design. Until recently, the "dry pond" was often used. These structures impound water only during a storm and are designed to completely drain at an allowable release rate usually equivalent to predevelopment conditions. The primary purpose is to limit the peak rate of discharge. The entire storage volume is discharged within a matter of a few hours following an event. Consequently, in most instances little if any improvement (0% - 30%) in the quality of the water is likely to occur.

"Wet ponds" have been shown to function better for pollutant removal. Therefore, the information provided here is primarily associated with this type of installation. Such facilities are used extensively over much of south Florida and in low lying areas especially along the coast. These impoundments have a "normal water level" with additional capacity above the control elevation for runoff storage during storms. The structures are often designed with multiple uses in mind such as recreation, aesthetics, etc. Recent studies conducted in Florida as well as information collected during the National Urban Runoff Program (US EPA, 1982) demonstrate that these facilities are capable of providing a high level of pollutant abatement (80% or greater) for many constituents particularly nutrients.

Watershed-Wide Planning: The design of urban impoundments should be coordinated with a watershed-wide plan for managing stormwater runoff. In a localized situation an individual property owner can, of course, by his or her actions alone provide effective assistance to the next owner downstream if no other areas are contributing to that owner's problems. However, uncontrolled proliferation of impoundments within a watershed can severely alter natural flow conditions, causing compounded flow peaks or increased flow duration which can contribute to downstream degradation. In addition, upstream impacts due to future land use changes should be considered when designing the structure. Land use planning and regulation may be necessary to preserve the intended function of the impoundment.

Sediment and Debris: More often than not, detention ponds are expected to serve primarily as sedimentation basins during construction when erosion rates are particularly high. In and of itself this situation does not present a problem. Unfortunately, these facilities are often installed without the benefit of the designer having evaluated the capacity of either the initial or the final (post-construction) design configuration to perform this type of function.

In settlability analysis, removal by gravity settling is viewed to occur when the average velocity of flow through the pond is less than the settling velocity of the minimum size particles that the designer wishes to capture. Chemical flocculation, although expensive, can aid in this process as heavier sediments overtake and coalesce with the smaller

lighter fractions to form still larger particulates. Consequently, the opportunity for settling fine textured collodial material which happen to absorb and carry many other pollutants is projected to be enhanced as the average velocity decreases and the residence time and depth of the pond increases.

If a facility is to be used as the principal means to avoid having excessive levels of turbidity discharged from the site during construction, the engineer should evaluate the pond geometry in conjunction with the rate of outflow and grain size distribution of the soils. The application of a set of standards and specifications pertinent for flood control or even post construction water quality management can not necessarily be depended on to prevent excessive sediment delivery down stream. Adherence to typical predevelopment rate control criteria does not provide assurance that the average velocity of water moving through the detention basin will not exceed the settling velocity of the particulates that must be removed to avoid excessive levels of turbidity. Likewise, treatment schemes based on the control of small magnitude storms (i.e., one inch or less) as mandated by the statewide stormwater rule (17-25 F.A.C.) would not be expected to function properly since the major environmental damage that is likely to occur due to erosion and sedimentation would normally be associated with less frequent but greater magnitude storms (i.e., two inches or more in size). Consequently, a sizeable portion of major events that contribute to construction related problems would bypass the system practically untreated.

If a detention facility is to be used for sediment retention, the major objective should be to maximize sediment-trapping efficiency. One method of doing this is to maximize the hydraulic flow length within the basin. Long basins are generally more efficient than short wide ones, given equal depth.

Hydraulic flow length can be increased by installing a system of baffles within the basin which causes the flow to meander, allowing more time for sediment deposition to occur. See TEMPORARY SEDIMENT BASIN, (ES BMP 1.26) Appendix 1.26A, for recommendations pertaining to basins and baffles to promote improved sedimentation.

Marsh Establishment: Establishment of fresh water marshes in ponds can aid in water quality improvement. Marsh areas create a sink for many pollutants with a high degree of water treatment or purification possible, depending upon the runoff detention time and the availability of wetland plants and aquatic life which can assimilate pollutants.

Wetland associated plants will establish themselves naturally in a shallow, wet pond. It may be beneficial, however, to accelerate marsh establishment by planting appropriate native vegetation in shallow areas. Certain wetland plant species have a greater capacity for pollutant assimilation and are less maintenance intensive than others. The Center for Wetlands at the University of Florida, can help in the selection of appropriate species

for the specific site conditions. The Nonpoint Source Management Section of the Department, the local FDER district office, or the regional Water Management District may also be of assistance. These agencies are good sources for information concerning private consultants and nurseries that can also be of assistance in restoration or revegetation of aquatic systems.

Marsh establishment for stormwater treatment is still in the experimental stages in Florida. However, preliminary indications show that such measures can be appropriate for the following applications:

1) At the perimeter of deep impoundments to filter direct sheet flow runoff from the adjacent drainage area.

2) On shallow sills or shelves separating inline tandem ponds or forebays to filter runoff before it enters the major impoundment from tributaries or stormsewer inlets.

3) At the edge or surrounding the outflow of detention facilities to promote assimilation of dissolved pollutants before water exits the primary impoundment.

Marsh establishment in facilities that also serve as temporary sediment basins may be difficult during construction due to frequently required cleanout of accumulated sediment. To continue functioning, marshes will require periodic sediment removal. Sediment should be removed from the deepest parts of the basin where vegetation is sparse. Heavily vegetated areas should be disturbed as little as possible. Overhead scooping equipment works well for dredging selected portions of marsh areas.

The presence of marshes in established urban areas is perceived by many people to be undesirable. They are often thought of as mud holes where mosquitoes and other insects breed. Actually, once a marsh becomes fully established, it can become a welcomed addition to an urban community. Created fresh water marshes provide miniature wildlife refuges to which ducks, songbirds, turtles, raccoons, fish, and other wildlife have migrated. While insect populations are increased, insect predators also increase, often reducing the problem to a tolerable level.

Fresh water marshes can greatly increase the pollution removal efficiency of urban ponds. For this reason, vegetated littoral zones are a necessary part of any wet detention system.

Tandem Ponds and Forebays: The multiple-use purpose of certain impoundments may be preserved by installing a smaller settling basin directly upstream of the major basin. The smaller pond would serve to remove a large portion of the particulate pollution and release higher quality water into the major impoundments. The term "tandem pond" refers to a settling basin and adjacent detention or retention basin both resulting from constructed embankments. A "forebay" is an excavated settling basin at the head of the primary impoundment. The efficiency of the smaller settling basins can be

increased through the use of chemical flocculants which causes small colloidal particles to settle at a faster rate. See STORMWATER STORAGE/TREATMENT SYSTEMS (SW BMP 3.09), for more information.

Heavy Metal Contamination: Studies have shown high accumulation rates of lead, zinc and copper on and near heavily traveled highways and streets. Therefore, runoff from highways and streets can be expected to carry significant concentrations of these heavy metals. If a significant portion of the drainage area into a pond consists of highways, streets, or parking areas or other known sources of heavy metal contamination, there is a potential environmental health hazard. In such cases the multiple use functions of the pond should be limited and accessibility should be restricted.

The increased construction of multi-purpose impoundments with controls for nonpoint source pollution could mean the accumulation of sediment contaminated with heavy metals or other toxic materials. This may require special disposal sites for sediment dredged out of the basins during maintenance cleaning. However, investigators of sediments removed from detention ponds to date have found that the pollutants are tightly bound with only a slight possibility of leaching. To be safe, sediments to be removed should be analyzed and elutriate tests performed to verify that the sediment can be safely disposed of by conventional methods.

Design Criteria

In urban or urbanizing areas, failure of an impoundment structure can cause significant property damage and even loss of life. Such structures should be designed only by professional engineers who are qualified and experienced in impoundment design.

Wherever they exist, local safety standards for impoundment design and construction should be followed. Where no such criteria exist, widely recognized design criteria such as those used by the USDA Soil Conservation Service or U.S. Army Corps of Engineers are recommended. The following are intended to supplement other acceptable design and safety criteria only. They apply to pollution control purposes the adherence to which should not be construed to satisfy other design objectives.

Wet Detention Systems

Presently there are numerous sets of standards which have been promulgated with the intent to maximize the treatment (pollutant removal) capacity of permanently wet detention facilities. Guidelines have been developed by several of Florida's five water management districts as well as the Department of Environmental Regulation. All are somewhat different. However, most if not all permitting authorities seem to agree that a sizeable littoral zone should be provided to encourage better assimilation. Planting, preferably with native aquatic species, is usually recommended. Some degree

R0071087

of dimensional criteria pertaining to storage volume, depth, width, length, and the orientation of the inlet and outlet are also common. Designs which maximize residence time, encourage reaeration, and discourage short circuiting are principal goals.

The current guidelines established by the Department for wet detention systems follow, along with a list of available plant species that are encouraged. Each is still subject to changes. Research into the performance of these systems and the mechanisms by which they may best function is still in its infancy. Designers are reminded that these requirements may be slightly different in areas of the state where stormwater quality permitting has been delegated to the local Water Management District.

Current Department of Environmental Regulation Criteria for Wet Detention Systems are listed as follows:

a) One inch of runoff storage above the control (bleed down) elevation of the permanent pool.

b) This volume is to be recovered at a slow rate. No more than one-half the volume may be discharged in the first sixty hours following an event.

c) The volume in the permanent pool must provide for a residence time of at least fourteen days. This volume may be determined by estimating 3.83% of annual average runoff. A more empirical approach sometimes used is calculated by taking two inches times the impervious acreage in the project plus one-half inch times the pervious acres. The value in cubic feet is determined through multiplication times the appropriate conversion factor (i.e., 3630).

d) A littoral shelf should be provided by extending and gently sloping the sides of the facility (6:1 or flatter) out to a point 2-3 ft. below the normal water level or control elevation. Facilities that are planned with sides that are steeper than 4:1 out to a depth of two feet below the level of the permanent pool must be fenced to restrict public access for purposes of safety (Ref. 17-25.025(6) F.A.C.)

e) No more than 70% open water is recommended. The remaining 30% (i.e., littoral shelf) typically is established with aquatic vegetation. A layer of muck (6" recommended) may be incorporated into the littoral area to promote establishment of wetland vegetation. Planting of native aquatic plant species is highly recommended. Lining the bottom and sides of these facilities with a layer of organic material such as muck appears to be an attractive alternative when potential groundwater contamination problems are apparent. However, the use of muck that has been transported to the facility from areas where cattails or willows are predominant can cause nusiance weed problems and should be avoided.

f) A maximum depth of 8-10 feet below the invert of bleed down device should be planned for the permanent pool.

g) Inlet structures should be designed to dissipate the energy of water entering the pond. Baffles are the most commonly used structures for such purposes. Inlets should not be located in close proximity to the outlet so as to prevent short circuiting.

h) Facilities that are potential sources for oil and grease contamination must include a skimmer or other mechanism to prevent these substances from leaving the facility.

i) Erosion and sediment control BMP's must be used to retain sediment on site during construction. BMP's must be shown on the design plans and the engineer must provide instructions for proper O & M. Sod all areas above the normal water level of ponds to prevent erosion and sedimentation of plantings.

j) If the facility is planned as a "real estate" lake to enhance property values and promote the aesthetic value of the land, pretreatment in the form of landscape retention areas or perimeter swales should be incorporated into the stormwater management facility. If possible, catch basins should be located in grassed areas. By incorporating the "treatment train" concept into the over-all collection and conveyance system, the engineer can prolong the utility of these permanently wet installations and improve their appearance. Any amount of runoff waters, regardless how small, that is filtered or percolated along its' way to the final detention area can remove oil and grease, metals, and sediment; as well as, reduce the annual nutrient load to prevent the wet detention lake from eutrophying. A credit against the required wet detention storage volume may be provided depending upon the amount of stormwater infiltrated. A notice should be posted warning residents of potential water borne disease that may be associated with body contact recreation such as swimming in these facilities.

Littoral Zone Planting Criteria: Specific conditions for projects involving wet ponds with vegetated littoral zones are very similar to requirements pertaining to wetlands replacement and restoration. In each instance, monitoring in the form of photographic documentation of percentage survival of plant species and coverage of naturally occurring or propagated vegetation is usually requested. Submittals of this information will usually be on a quarterly basis for the first year. The frequency declines to once or twice a year during the next two year period.

Most permitting agencies will ask that the applicant remove nuisance species (e.g., cattails) during the establishment period. An 85% survivorship guarantee is usually required for all planted species. Annual replanting will be required if survival falls below the 85% level.

Whenever possible, the Department (FDER) encourages the use of native vegetation for "aquascaping" around and within detention ponds. These

R0071089

species require less intensive maintenance and are not as likely to become a nuisance as some of the more notorious introduced varieties that are often used in Florida for nutrient assimilation and pollution control (e.g. water hyacinth). In the design of the planting it is important to consider the need for future access to high maintenance areas such as inflow and outflow structure and sediment sumps.

The following list of herbacious plants and trees and shrubs is intended to provide the reader with some background information pertaining to the various types of vegetation that may be acquired from nurseries for establishment in and along the shoreline of wet detention facilities. It is by no means an exhaustive list and other species may be used if more suitable. Most of the plants in the "trees and shrubs" category are primarily used for their wildlife enhancement value and for landscaping landward of in the zone of fluctuating water that is temporarily detained and stored above the normal pool elevation. The herbacious species shown have a wide range of growth habits and preferred environments. The table also provides an indication of pool and comments regarding other features of interest as well.

TABLE 6-2

NATIVE PLANT SPECIES SUITABLE
FOR LITTORAL ZONE PLANTINGS AND LANDSCAPING AROUND DETENTION PONDS

SCIENTIFIC NAME	COMMON NAME	PLANTING ZONE *	FEATURES
	TREES SHRUBS AND PALMS		
Acer rubrum	Red maple	1-2	Medium sized tree specimen known for its' attractive brilliant red fall color.
Betula nigra	River birch	1	Medium sized tree. Known for its' attractive bark. Prefers moist soils. Is often planted in clumps.
Carpinus caroliniana	American hornbean "Blue Beech"	1	Medium sized tree with attractive bark, and interesting form.

* Planting Zones:
1) + 0.5 feet or more higher than the normal level of the permanent pool.

2) + 0.5 feet above to - 1.0 feet below normal pool.

3) - 1.0 feet to - 3.0 feet below the control elevation of the permanent pool.

4) - 3.0 feet to - 5.0 feet below normal water level.

SCIENTIFIC NAME	COMMON NAME	PLANTING ZONE*	FEATURES
Carya aquatica	Water hickory	1-2	Large specimen. Leaves are relatively large. Fall color (bright yellow).
Cephalanthus occidentalis	Buttonbush	1-2	Large shrub up to 3m. (9.8 ft) tall with white flowers resumbling buttons. Buttonbush has a scrubby appearance owing to the dying of leader shoots leaving dead stumps.
Clethra alnifolia	Sweet pepper bush	2	Highlighter, shrub with attractive berries.
Crataegus spp.	Haw apple	1	Small tree with white flowers and attractive red fruit.
Fraxinus caroliniana	Popash	1-2	Large specimen with attractive foliage and deep furrowed bark.
Gordonia lasianthus	Loblolly bay	1-2	Medium to large tree. Large white flowers and attractive foliage.
Hypericum spp.	St. Johns Wort	2	Highlighter, shrub.
Ilex cassine	Dahoon holly	1	Small tree or shrub with prominent red berries and attractive evergreen foliage.
Ilex vomitoria	Yaupon	1	General landscape shrub with attractive red berries.
Illicium floridanum	Florida anise	1	Shrub with attractive aromatic foliage and purple flowers.
Liquidambar styraciflua	Sweetgum	1-2	Medium to large specimen. Attractive unusual shaped foliage and good fall color. Not tolerant of long term inundation
Liriodendron tulipifera	Yellow poplar "Tuliptree"	1	Large specimen; attractive large showy flowers and unusual shaped foliage.

R0071091

SCIENTIFIC NAME	COMMON NAME	PLANTING ZONE*	FEATURES
Magnolia virginiana	Sweet bay	1	Medium sized tree with attractive foliage and white flowers.
Myrica cerifera	Wax myrtle	1	Large shrub with attractive aromatic evergreen foliage. Bluish green berries in autumn and winter are eaten by many birds. Often used in groups for general landscaping and highlighting or accent around ponds.
Nyssa biflora	Blackgum tupelo	1-2	Glossy foliage turning bright red in autumn. Fruit matures in the fall; is consumed by many birds. Flowers are a source for honey.
Ostrya virginiana	Hop hornbean "ironwood"	1	Slow growing small tree with fruit clusters resembling "beer" hops. Trunk looks like sinewy muscle. Nutlets and buds are eaten by wildlife.
Persea palustris	Swamp redbay	1-2	Attractive aromatic glossy evergreen foliage. Bitter fruit is eaten by wildlife. Does not do well in submerged locations.
Quercus laurifolia	Laurel oak	1	Large tree with attractive nearly evergreen foliage. Acorns eaten by wildlife.
Quercus nigra	Water oak	1	Large deciduous tree with small fine textured foliage. Acorns provide food for wildlife.
Rhapidophyllum hystrix	Needle palm	1	Small to medium sized palm with attractive foliage used for providing tropical highlights. Sharp needles along the trunk lead to its' name.
Sabal palmetto	Cabbage palm	1	Large palm suited to all areas. Attractive tropical fan shaped foliage.

R0071092

SCIENTIFIC NAME	COMMON NAME	PLANTING ZONE*	FEATURES
Taxodium spp.	Cypress "Bald" or "Pond"	1-2	Large aquatic deciduous conifer of picturesque form. Preliminary observation shows good survival and rapid growth of either species when used for storm-water enhancement purposes.

FRESHWATER AQUATIC PLANT SPECIES
(Herbs, Sedges, Grasses and Ferns)

Bacopa caroliniana	Lemon bacopa "Water hyssops"	2	Crushed leaves and stems lemon scented. Flowers blue.
Canna flaccida	Golden canna "Canna lily"	2	Very good highlighter. Used at fringe of ponds and lakes. Large showy yellow flowers.
Cladium jamaicense	Saw-grass	1-2	Coarse perennial sedge up to 3m (9.8 ft) tall. Grows equally well in water or several feet above water level. Long narrow and serrated leaf blades. Provides nesting, protection and food (seeds) for water fowl and other birds.
Coreopsis nudata	Tickseed	2	Short perennial herb with attractive "daisy shaped" lavender flowers. Prefers shallow water or wet soil at edge of ponds or lakes.
Crinum americanum	Swamp lily	2	Good highlighter at pond fringes. Showy white fragrant flowers. Stems usually less than waist high.

SCIENTIFIC NAME	COMMON NAME	PLANTING ZONE*	FEATURES
Cyperus odoratus	Umbrella sedge	1-2	Good accent plant usually grown in clumps at edge of ponds. Areas of fluctuating water provide good habitat but umbrella sedge can also survive in more upland areas. Its stems are usually less than 3 ft. tall with a conspicuous umbrella shaped foliage and brown seed head.
Diodia virginiana	Buttonweed	1-2	Wet soils along the border of ponds provides a good environment. Buttonweed is a relatively low growing perennial herb. Main branches are usually less than 8 dm (2.6 ft) long. Stems branch from the base and grow along the ground. Small white flowers are borne between the junction of the leaves and stem. Does not prefer submerged conditions.
Dryopteris ludoviciana	Southern shield "Leatherwood fern"	1-2	Suited to wet soils in the zone of fluctuation above the permanent pool of detention ponds.
Echinochloa crusgalli	Barnyard grass "wild millet"	1-2	Predominately suited to the margins of ponds and lakes. A common annual with stems up to 1.2 m (3.9 ft.) tall. Seeds are heavily used by waterfowl and songbirds.
Eleocharis spp.	Spikerushes	2	Suitable for establishing marshes along the coast. Slender, dwarf and water spikerushes may be submerged. Other varieties grow along the landward edge of ponds. Green leafless stems vary in thickness from thread to pencil size and from ankle to shoulder high. May be grown in clumps or as colonies depending on species.

SCIENTIFIC NAME	COMMON NAME	PLANTING ZONE*	FEATURES
Eriocaulon decangulare	Hat pins	2	Hat pins are a low growing plant with slender spikes arising from the base. The top is tipped with a small white "button". Provides a pleasing contrast when mixed into areas dominated by wetland grasses or sedge.
Hibiscus spp.	Marsh hibiscus	1-2	Normally used for accent at the periphery of ponds. Stems are waist high or slightly higher. Large flowers, 4" to 8" in diameter, white or pink, sometimes with a red center.
Hydrocotyle umbellata	Water pennywort	2	Numerous round partly to deeply lobed leaves centrally attached to a stem up to 12 inches in length. Grows well on the surface of the water or as a ground cover rooted along the margin of ponds.
Hymenocallis spp.	Spider lilies	1-2	Provides good ground cover or may be used for accent at the edge of ponds. Showy white flowers. Best on wet soils. Average height 3 ft.
Iris Hexagona	Anglepod blue flag	2	Prefers wet soils at the fringes of lakes and ponds. The average height is about 1 ft. Used extensively as highlighters, planted in groups at the edges of wetland vegetation due to it's showy blue flowers.
Iris virginicus	Southern Blue Flag Iris	2	Prefers similar habitat to the "Anglepod" variety. However, this species is more upright in its growth habit. The flowers are larger and borne at the ends of each stem. Although very showy, either species of iris will only flower briefly for several weeks in spring.

R0071095

SCIENTIFIC NAME	COMMON NAME	PLANTING ZONE*	FEATURES
Nebumbo lutea	American lotus	3-4	This plant is an attractive large leafed rooted aquatic. The leaves are circular, up to 60 cm. (24 inches) across. The American lotus has very showy large yellow flowers. Dried seed pods are often used in flower arrangements. Similar to other "water-lilies", this species is planted along the outside of the littoral zone in groups spaced about 25 feet apart.
Nuphar luteum	Spatterdock	3-4	This "water-lily" has large oval or heart shaped leaves up to 40 cm (16 inches) long and 25 cm (10 inches) wide. Its flowers are small yellow and spherical shaped giving the appearance of a "bud" that hasn't completely opened. The rootstock provides spawning habitat for black crappie and shellcrackers in many of Floridas' artificial lakes and ponds.
Juncus effusus	Soft rush	2	Very attractive plant with pale green hollow stems up to 4 ft. tall. Commonly used in large clumps scattered along the edge of ponds or lakes. However, soft rush is also used in large concentrated groupings in ponds and covering the bottom of wet swales. The seeds are utilized by waterfowl.
Nymphaea mexicana	Yellow water lily	3-4	Similar in form and use as the other water lilies discussed previously. However, this species is distinguished by its attractive bright yellow flowers.

R0071096

SCIENTIFIC NAME	COMMON NAME	PLANTING ZONE*	FEATURES
Nymphaea odorata	Fragrant water lily	4	Along with Canna lily, Sagittaria, and Pickerelweed this species will produce flowers throughout the spring, summer and fall months. It is the most commonly utilized water-lily for "aquascaping" in urban impoundments. It has a sweet scented, white showy flower. Nymphaea is installed in clusters of three to five plants every 25 feet.
Nymphoides aquatica	Floating hearts	2-4	Very similar to other water lilies. A cluster of small white flowers reaches just out of the water. Short thick roots sometimes are found dangling from the stalk just under the leaf.
Osmunda cinnamomea	Cinnamon fern	2	Attractive lush foliage these plants are primarily suitable for use in shaded areas interm... to or approaching the periphery of cypress or other wooded wetlands.
Osmunda regalis	Regal fern	2	Similar in habit to the cinnamon variety where it is not already established this species may be used to add a "rain forest" like appearance to any deeply shaded area suitable for detaining run-off. Small depressions blended into a landscape such that the facility is over shadowed by large trees and tall buildings would represent one of the primary uses for either species in respect to stormwater enhancement purposes.

R0071097

SCIENTIFIC NAME	COMMON NAME	PLANTING ZONE*	FEATURES
Panicum hemitomon	Maidencane	1-2	This grass has narrow stems usually between .5 and 1.0m (1.6 - 3.3 ft.) tall. It may be grown in relatively dry soils or with the bases in a foot or two of water. Maidencane will form dense colonies in wet areas and in the shallows of ponds. This species supplies valuable cover and spawning habitat around its roots. Its aggressive growth habit tends to overshadow its valuable characteristics.
Peltandra virginica	Green arum "Arrow-arum"	2	This perennial herb has arrow shaped leaves up to waist-high. The blades vary in size up to a foot wide and one and a half feet long.
Polygonum spp.	Smartweed	2	Smartweed is an annual or perennial herb with creeping stems that run along the ground. Most types have small narrow lance shaped leaves. At the end of the stems are spikes of small pink and white flowers. The seeds are heavily used by birds, waterfowl and small mammals.
Pontederia cordata	Pickerelweed	3	Pickerelweed forms the core of most littoral zone enhancement efforts in Florida relative to wet stormwater detention ponds. It has attractive, dark green lance shaped leaves. Each stem produces a spike of numerous violet blue flowers that is quite showy.

R0071098

SCIENTIFIC NAME	COMMON NAME	PLANTING ZONE*	FEATURES
Sagittaria lancifolia	Arrowhead	3	Along with pickerelweed the "arrowheads" form the core of the mid-zone in most littoral shelf establishment efforts. Lancifolia has attractive narrow elliptical lance shaped leaves up to 2 ft. in length and 4 inches wide. It has small white flowers. Is not considered an important wildlife food source.
Sagittaria latifolia	Broadleaf arrowhead	3	This type of arrowhead is attractive with deeply lobed and arrow shaped leaves. They may be up to a foot long and slightly less wide. The species also has small white flowers extending above the leaves. Valued as a wildlife food source.
Scirpus californicus	Giant bulrush	2-3	Giant bulrush has blunt triangular stems up to 3m (9.8 ft.) tall. This sedge was introduced from California and is relatively common in Florida. It is similar in habit to "soft ste bulrush" but of larger stature.
Scirpus validus	Soft stem bulrush	2-3	The stems are cylindrical and may attain heights of 2.5m (8.2 ft.). Leaves are absent in bulrushes. Attractive brown spikelets are borne at the ends of the stem. The seeds are eaten by waterfowl and many marsh and songbirds. Soft stem bulrush will grow in mud or up to several feet of water.
Spartina bakeri	Sand cordgrass	1-2	This grass grows in stout rather large dense clumps up to several feet in diameter. It is quite suitable as an accent plant at the fringes of detention ponds in coastal areas. Cordgrass has long narrow wire like leaves. It's growth habit presents a thick fine textured broom like appearance. When flowering the plant has a reddish tinge at th- periphery.

R0071099

Nursery sources are recommended by the Department wherever possible. Small (2-4 inch) containers are encouraged to avoid transporting large amounts of potting soil to the pond. White roots and active basal budding indicate a healthy stock. Small pots seem to encourage active root growth when finally unconfined.

Most "aquascaping" specialists prefer to have someone on site during the construction phase to ensure that the littoral shelf is located and graded properly. Knowing exactly where the normal water level of the facility will reside after construction is absolutely essential to the success of this element of the system.

Bank erosion is often a significant problem during the initial stages of development. Stabilization with sod down to the normal pool and preventing undue sediment deposition is required for the planting to survive. There is no cheap way out. Costs typically run in the neighborhood of $2,000 - $10,000/acre. Therefore, it is important to do everything possible to ensure immediate success for both water quality and the sake of the client.

Storage Volume and Release Rate: Design of the storage volume and release rate of an impoundment depends upon the purpose for which the structure is built. Typical urban purposes which require different design strategies include flood control, stream channel erosion control, and consumptive uses (i.e., water supply, fire protection, irrigation, etc.). The purpose of pollution removal also requires a different design strategy. The following are some examples of typical design criteria for different impoundment purposes.

Flood Control: The design criteria for this purpose depends upon the level of flooding to be controlled. Usually, a locality will specify that stormwater runoff from a developing drainage area must be controlled so that the post-development peak runoff rate does not exceed the pre-development rate for a specific design storm. In some localities a ten year design storm is specified to protect downstream drainage structures. Other localities require protection from larger storms and specify that a fifty year or one hundred year storm must be detained and released at a reduced rate.

Stream Channel Erosion Control: In Florida, the criteria used to evaluate a stormwater discharge facility for this purpose is usually tied to the erosion potential of the area soils. The velocity associated with the peak rate of discharge expected from the design event (25 year/24 to 72-hour duration, typical) is compared to the maximum permissible rate (ft/sec), given the textural class of the substrate and a bare channel. Such information has been published by the Soil Conservation Service (USDA, S.C.S., 1974. pg. 4.18). Unless the local or regional permitting authority has established a lower set of limits, the maximum velocity allowed may be expected to range from 1.5 ft/sec for sands and sandy loam, to 2.0 ft/sec for sandy clay loam, and up to 2.5 ft/sec for clay.

Nonpoint Source Pollution Control: The primary design strategy for this purpose is to maximize the detention time of captured runoff. It is believed that basin drawdown times in excess of 60 to 120 hours will result in significant pollutant removal. However, the required storage volume is usually tied to the capture of the first, most pollutant laden, portion of a storm (i.e., the initial one inch of runoff).

Flow Routing: A stormwater detention basin acts as a constriction in the stream or conveyance system. A portion of the flow backs up and is temporarily stored. The procedure used to determine the volume of water which will be held behind the detention structure during a design rainfall event is known as flow or flood routing. In order to properly size a detention basin, a flow routing procedure must be used to determine the storage volume for a range of design storms given the maximum allowable release rate which is deemed to be necessary to satisfy the objective or objectives for which the structure is being designed.

Most flow routing procedures involve a trial and error process. The storage volume or outflow rate is varied depending on the desired depth, or space, and any number of other limitations. The basic premise is that the volume of runoff entering the detention basin minus the amount of water leaving over a given interval of time is equal to the required volume of storage. Consequently, flow routing can be extremely time consuming when done manually.

Rather than present a lengthy in-depth explanation or an over-simplified version of the subject of flood routing in this handbook, the reader is referred to the Soil Conservation Service, (SCS) National Engineering Handbook Section 4, Chapter 17. That reference provides a good explanation of flood routing for calculating detention storage volumes. The SCS TR-20 and DAMS 2 computer programs provide accurate methods of analysis. The Stormwater Management and Design Aid (SMADA) program developed for the Department by the University of Central Florida is also available on diskettes for use with IBM personal computers. These are just a few of the acceptable routing models recognized by regulatory authorities around the state.

Manual Method: A simpler, but less accurate method of estimating detention storage volume is the "Manual Method" outlined in SCS Technical Release No. 55, Chapter 6. It involves the use of a single graph which was developed based upon average storage and routing effects of many structures.

The primary advantage of this method is its simplicity and compatibility with SCS runoff calculation procedures described in Chapter 5 of this manual. It is particularly suited for small detention basin design, and estimating the required size of basins during the project planning phase.

A common application of the design procedure for the Manual Method is

presented here, however, its use is subject to the following limitations:

1) The drainage area must be less than 2000 acres.

2) Failure of the structure must not result in loss of life or major property damage.

3) The procedure should not be used to perform final design if an error in storage of 25% cannot be tolerated. The SCS design aid is biased to prevent undersizing of outflow devices, but it may significantly overestimate the required storage capacity. More detailed hydrograph development and routing will often pay for itself through reduced construction costs.

The following design procedure will only determine the required storage volume of the basin. The design of an appropriate discharge structure, which will maintain the allowable release rate at the design storage elevation, should also be done by a qualified engineer.

In Florida the discharge control structure for a detention pond intended to satisfy both water quantity and water quality objectives would be a two stage device. In most instances the first stage is regulated by a small orifice (usually round) that is designed to provide intended storage for treatment of the first inch of runoff from the contributing area. The water is released at a very slow rate. The required storage volume (Vs1) in cubic feet is determined by simply multiplying the drainage area (A) in acres times one inch of runoff (R) times the appropriate conversion factor (3630).

During the design process for flood routing the volume is viewed as static since its rate of release is so relatively slow. Moreover, this volume of storage is normally required in addition to that established for peak discharge control. Many local governments or water management districts responsible for flood control have determined that a sizeable portion of this storage could be taken up and therefore be rendered unavailable by smaller magnitude storms that may occur nearly daily during the period of the year when larger events approaching the design conditions for peak discharge control have the highest probability of occurring. Consequently, the most common application of these procedures is a two fold process. The storage volume for water quality control (Vs1) is first determined. Part two involves an estimate of the additional storage volume (Vs2) which must be provided to meet peak discharge limitations. The SCS manual method of flow routing described in TR-55 may be used for these purposes subject to the previously discussed limitations.

DESIGN PROCEDURE

Step 1 - Determine the storage volume (Vs1) to satisfy water quality control objectives.

Input Requirements and Procedures

The most frequent application is to estimate storage volume (Vs1) for situations where the drainage or contributory area is equal to the project area. The required inputs are the drainage area (A) in acres and the required "runoff" depth (R) to be stored as specified by the appropriate regulatory agency. This depth may range from a minimum of 0.5 inch to 1 inch or more depending on jurisdiction. The value Vs1 in cubic feet is calculated as follows:

Vs1 = A (ac) x R (in.) x 3630 (conversion factor acre inches to cubic feet)

Example:

A 75-acre medium to high density residential development is planned to discharge through a single outlet into an existing drainage canal designed for present land use conditions. No off-site drainage will be delivered by the project's conveyance system. How much storage (Vs1) will be required above the seasonal high water table elevation (10 ft NVGD) to meet the state's water quality treatment criteria? Assume that the project is required to provide for the first inch of runoff (R) stored above the level of the permanent pool. What is the invert elevation of the facility so as not to lower the existing water table? What is it's average size (square feet) assuming the depth of storage is limited to one foot?

The storage equation is:

$$Vs1 = AR\ (3630)$$

where:

A = Watershed Area (75 acres)
R = Runoff Treatment Depth Criteria (1 inch specified)

$$Vs1 = (75)\ (1)\ (3630) = 272{,}250 \text{ cu.ft.}$$

The facility's size may be determined since the maximum depth of the detained water is specified. Use the following equation:

$$a = Vs1/d$$

where:

a = average size of detention pond (square feet)

Vs1 = storage volume (272,250 cu.ft.)

d = depth of storage (1 ft. specified)

R0071103

therefore:

$$a = 272{,}250 \text{ ft}^2 \text{ or } 6.25 \text{ acres}$$

The invert elevation of the discharge control structure orifice must be set equal to or above the seasonal high water table elevation to avoid changing the existing conditions as specified. Therefore, the bottom of the bleed down orifice should be no lower than 10 feet NVGD as stated by the information given.

Step 2 - Determine the size of the device needed to limit the rate of drawdown for the first stage to satisfy state or local criteria.

Input Requirements and Procedures

In Florida, the most commonly used means of metering the first stage of detention facilities is accomplished by cutting or drilling one or more small round openings (i.e., orifices) at the appropriate elevation along the barrel of a riser pipe, through a weir, or through the face of a concrete box drop inlet spillway. The required inputs for estimating the size of the orifice required is average depth of storage or head (h) effecting the orifice during the drawdown period considered and the desired release rate. The storage volume Vs1 and the minimum drawdown time are usually required to determine the allowable rate of release.

The orifice equation is modified to solve for A (area of orifice) as follows:

$$Q = CdA(2gh)^{1/2}$$

$$A = \frac{Q}{Cd(2gh)^{1/2}}$$

where:

Q = rate of discharge (cfs)
A = orifice area (ft^2)
g = gravitational constant (32.2 ft/sec^2)
h = depth of water above the flow line (center) of orifice (ft)
Cd = orifice coefficient (usually assumed = .6)

R0071104

By setting "h" equal to the average depth between two stages and calculating the average rate of drawdown during the interval, the designer can calculate the orifice area required. The average rate of discharge is determined by dividing the volume of storage available between the intervals of elevation by the time period of concern in seconds. Using the existing state guidelines for these systems would stipulate that the device must limit outflow to no more than .5 Vs1 over the first 60 hours. This translates to a value of 2.315×10^{-6} Vs1 cfs as the controlling rate of discharge. The entire solution for the previous example is shown below.

Example:

Given the 75 acre residential project mentioned previously, what is the orifice area required to limit drawdown to one-half the storage volume over a sixty (60) hour period? Recall that the storage required to meet water quality criteria (i.e., Vs1) is equal to 272,250 cubic feet. Also recall that the depth of storage was specified to be one foot.

Rearrange the orifice equation and solve for (A)

$$A = \frac{Q}{Cd(2gh)^{1/2}}$$

Substitute the following values in the equation:

Cd = .6
A = orifice cross section area (ft^2)
g = 32.2 ft/sec^2
Q = 272,250 ft^3 (2.315×10^{-6}) = .63 cfs
h = $\frac{1.0 \text{ ft} + .5 \text{ ft}}{2}$ = .75 ft

(NOTE): This is the average depth of storage during the drawdown period where one-half the storage volume is presumed to be recovered.)

Therefore:

$$A = .63 \text{ cfs} / .6 \left[(2)(32.2 \text{ ft/sec}^2)(.75 \text{ ft})\right]^{1/2}$$

or;

A = .15 sq.ft.

To determine the diameter of a circular orifice rearrange the equation for the area of a circle and solve for D (diameter) as follows:

Eq. for area of a circle; $A = \frac{\pi D^2}{4}$

Rearrange and solve for D

$$D = (4A/\pi)^{1/2}$$

Substituting A = .15 sq.ft. from above,

$$D = [4(.15)/3.1416]^{.5} = .44 \text{ ft.}$$

Use a 5 inch diameter orifice

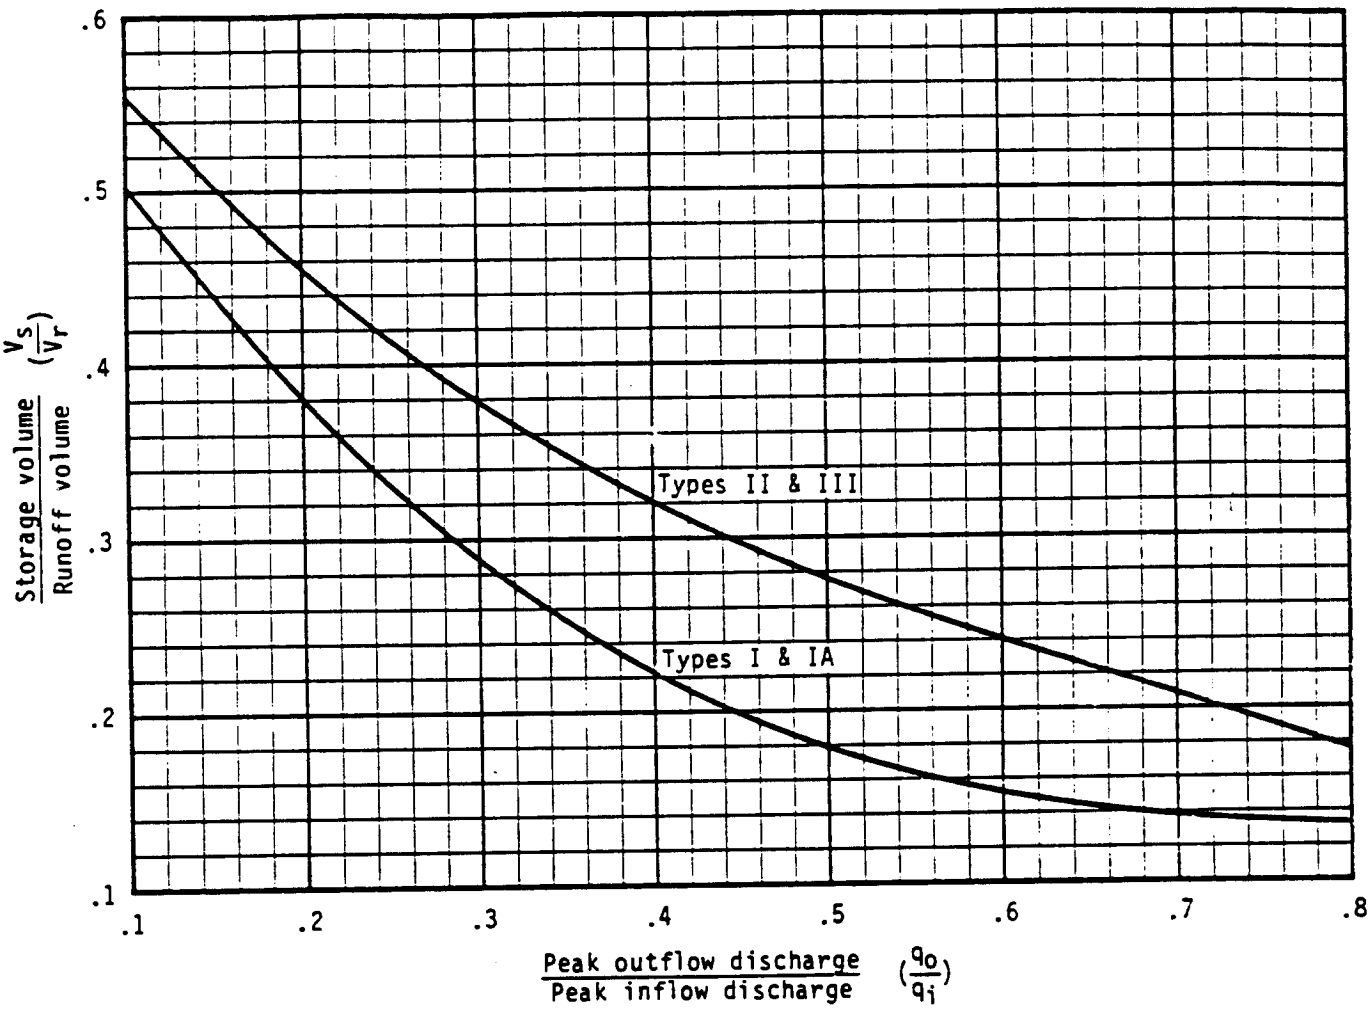
Step 3 - Use Figure 6-5 to estimate Vs, storage volume for peak discharge control.

Input requirements and procedures

Figure 6-5 may be used to estimate storage volume (Vs) required or peak outflow discharge (q_o). The most frequent application is to estimate Vs, for which the required inputs are runoff volume (V_r), q_o, and peak inflow discharge (q_i). To estimate q_o, the required inputs are Vr, Vs, and q_i.

Estimating V_s

To estimate the storage volume required, use the following procedure:



a) Determine q_o. Many factors may dictate the selection of peak outflow discharge. The most common is to limit downstream discharges to a desired level, such as predevelopment discharge. Another factor may be that the outflow device has already been selected.

b) Estimate q_i by procedures outlined in chapters 4 or 5 of TR-55, Second Edition published by SCS, June 1986. Do not use peak discharges developed by any other procedure. When using the Tabular Hydrograph method to estimate q_i for a subarea, only use peak discharge associated with $T_t = 0$.

c) Compute q_o/q_i and determine V_s/V_r from Figure 6-5.

FIGURE 6-5

APPROXIMATE DETENTION BASIN ROUTING FOR RAINFALL TYPES I, IA, II AND III

U.S.D.A. Soil Conservation Service, 210-VI-TR-55,
Second Ed., June 1986.

R0071107

d) Q (in inches) is determined when computing q_i in step b above. However it must be converted to the units in which V_s is to be expressed - most likely, acre-feet or cubic feet. To convert Q to V_r expressed in acre-feet:

$$V_r = .083\ Q(A)$$

where:

V_r = runoff volume (acre-feet),
Q = runoff (in),
A = drainage area (ac.) and
.083 = conversion factor from acre-inches to acre-feet.

e) Use the results of steps c and d to compute V_s:

$$V_s = V_r \frac{V_s}{V_r}$$

where V_s = storage volume required (acre-feet).

The stage in the detention basin corresponding to V_s for stage 1 plus stage 2 must be equal to the stage used to generate q_o.

Example

Going back to the situation mentioned earlier, recall that a 75-acre development is being planned that discharges into an existing channel designed for present conditions. Assume the watershed is in the type II storm distribution region. Suppose that the present channel capacity, 180 cfs, was established by computing discharge for the 25-year-frequency storm by the Graphical Peak Discharge method (Chapter 4 SCS, 210 VI - TR-55, Second Edition, June 1986.) Further presume that the developed-condition peak discharge (q_i) computed by the same method is 360 cfs, and runoff (Q) is 3.4 inches. Since outflow must be held to 180 cfs, a detention basin having the maximum outflow discharge (Q_o) will be built at the watershed outlet.

How much storage (V_s) will be required to meet the maximum outflow discharge (Q_o) of 180 cfs, and what will be the approximate dimensions of a rectangular weir outflow structure? Figure 6-6 shows how SCS TR-55 worksheet 6a is used to estimate required storage (V_s stage 2 = 5.9 acre-feet) and maximum stage (E_{max} = 12.0 feet).

R0071108

R0071109

The rectangular weir was chosen for its simplicity; however, several types of outlets can meet the outflow device proportion requirement. Most hydraulic references, along with considerable research data that are available, provide more guidance on variations of outlet devices than can be summarized here.

An outlet device should be proportioned to meet specific objectives. A weir is suitable here because of the low head. The weir crest elevation is 11.0 feet.

Figure 6-6 also shows how SCS TR-55 worksheet 6a may be slightly modified and used to record the storage volume (V_s) of 6.25 acre-ft and elevation ($E^{max.}$) of 11.0 ft. MSL for the first stage of the control structure. The invert or crest elevation of the second stage weir to be used for peak discharge control corresponds to the maximum storage elevation (11.0 ft. MSL) for the first stage device. Recall that these values were determined in the example for "Step-2" of this analysis.

The datum of the stage one control device is the center or flow line of the five-inch diameter circular orifice. Consequently, the invert or ultimate control elevation of the structure would be slightly (i.e., 2.5 inches) below the mean high groundwater elevation (10.0 ft. MSL). If this small deviation cannot be tolerated, the designer may still use the procedure to establish the minimum orifice required. Setting the invert elevation at datum when the structure is installed would not present a problem. While stage one would not optimize the allowable bleed down capacity, the structure would remain in compliance with state criteria since the end result would be a reduction in the actual rate of discharge and a concurrent increase in drawdown time.

The second stage is proportioned to discharge the correct amount at 12.0 ft. (Figure 6-6, step 11). However, the maximum allowable rate of discharge for the second stage equals the total discharge minus discharge through the first stage. Consequently, the designer must first compute the discharge through the first stage for elevation 12.0 ft. using the orifice equation.

$$Q = C_d A\ (2gh)^{1/2}$$

where:

Q = Discharge (cfs)
A = Orifice Cross-Sectional Area (ft^2)
g = Gravitational Constant (32.2 ft/sec^2)
h = Head over Orifice (ft.)
C_d = Orifice Discharge Coefficient
(.6 usually presumed)

R0071110

h and A are determined as follows:

$$h = E_{max} - \text{Flowline Elev. of Orifice}$$
$$= 12.0 - 10.0 = 2.0 \text{ ft.}$$

Since A was established equal to 0.15 sq.ft. during the "Step 2" analysis, the equation may be solved for Q

$$Q = .6\ (.15)\ (2 \times 32.2 \times 2)^{.5}$$
$$= 1.0 \text{ cfs}$$

As may be seen, in this instance the contribution associated the maximum allowable discharge (180 cfs) specified on the worksheet for the second stage device (Figure 6-6, step 4). In this instance the first stage can be ignored and the required weir crest length (Lw) for the second stage may be determined as though the control structure was a single stage device.

Using the total storage V_s = 12.15 acre-ft (Figure 6-6, step 10) and the elevation-storage curve, the maximum stage (E_{max}) is approximately 12.0 ft.

The rectangular weir equation is

$$q_o = 3.2\ L_w H_w^{1.5}$$

where:

q_o = peak outflow discharge (cfs),
L_w = weir crest length (ft, and
H_w = head over weir crest (ft).

H_w and q_o are computed as follows:

$$H_w = E_{max} - \text{weir crest elevation}$$
$$= 12.0 - 11.0 = 1.0 \text{ ft.}$$

Since q_o is known to be 180 cfs, solving the weir equation for L_w yields;

$$L_w = 3.2\ H_w 1.5$$

$$= \frac{180}{3.2\ (1.0)^{1.5}} = 56 \text{ ft.}$$

In summary, the outlet structure is a rectangular weir with crest length of 56 ft, H_w = 1.0 ft, and q_o = 180 cfs corresponding to a V_s = 12.15 acre-ft. of which 6.25 acre-ft. is associated with the stage one water quality criteria.

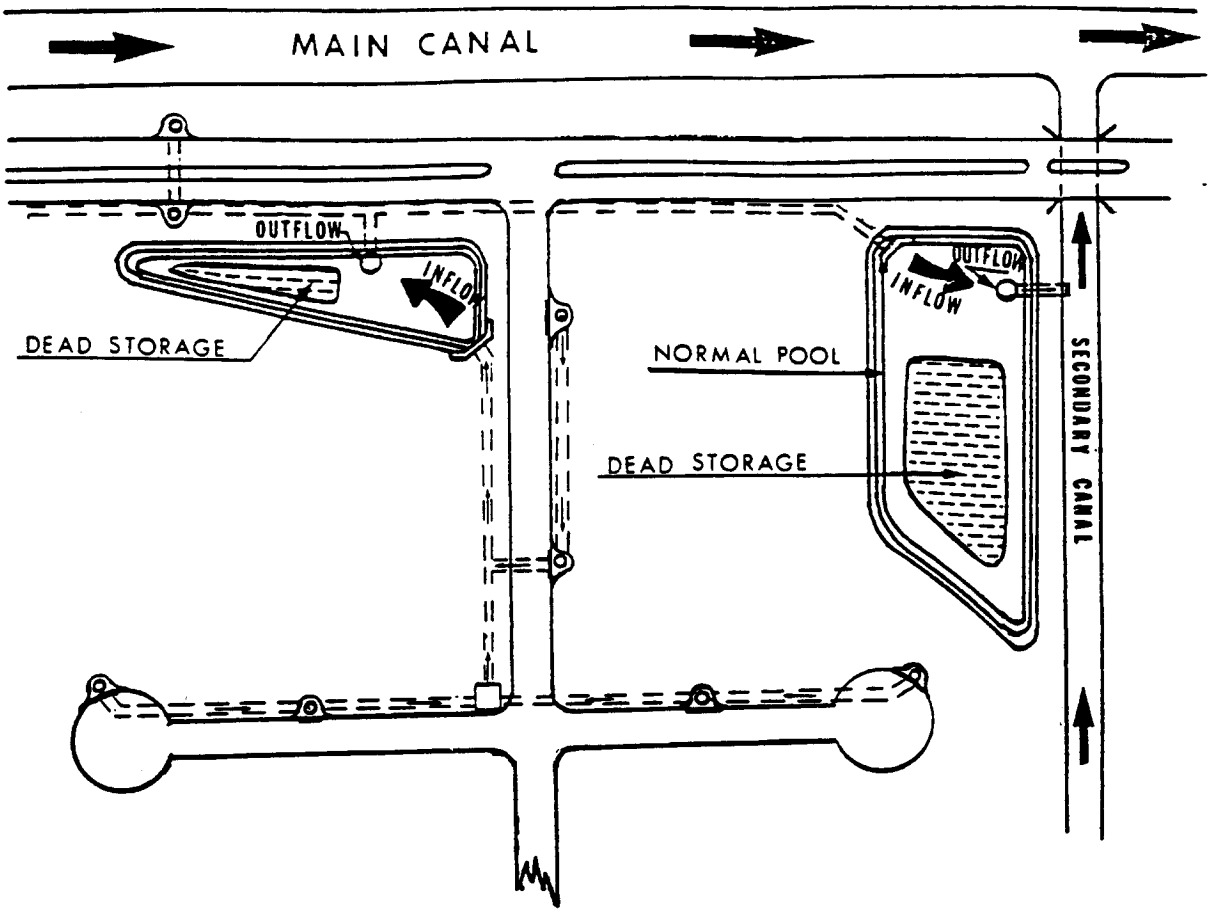
R0071111

If the width of the control structure (weir) exceeds either the physical capacity of the site or the owners pocket-book the designer may wish to increase the depth of storage (H) associated with stage one. In this example, an increase in the depth of the first stage to 1.5 ft. or elevation 11.5 MSL and a corresponding increase in H_w to slightly less than 3.0 ft. (E_{max} = 13.0 ft. MSL) would result in a sizeable reduction in crest length L_w = 30.6 ft. However, the designer should be aware that fluctuations in the design depth of stage one exceeding one foot can make the selection of plantings difficult and drastically influence the possibility of success in the establishment of a viable littoral zone. Recent reports seem to support the findings that nuisance species such as cattails and willows will out compete the preferred native aquatic species in these situations.

Pollutant Removal Parameters

There are several parameters that will determine the pollutant removal efficiency of a wet pond. These parameters include the pond geometry, wet pond depth, the area ratio, and the volume ratio. These parameters are discussed in detail in the following sections.

Pond Geometry



Most experts agree that the pond geometry has a strong influence on how effectively the permanent pool volume is used to remove pollutants. In some cases, there are areas of the pond that are ineffective in providing any pollutant control. This occurs in dead storage areas where inflow is bypassed without mixing. Figure 6-7 shows several examples of reservoir shapes which have large dead storage volumes and are to be avoided.

To avoid dead storage areas where mixing and settling of inflow pollutants do not occur, the length to width ratio should be no less than 3:1. In addition, a wedge shaped reservoir with the inlet located at the narrow end will maximize inflow mixing. If dead storage areas of flow are unavoidable based on topographic conditions, the effective length of flow can be increased by adding diversion barriers in the pond. These barriers may be created by a small island, a peninsula, or some sort of baffle.

Wet Pond Depth

Selecting the wet pond depth is dependent on the intended use of the pond. If the pond is to be a multiple purpose facility, the depth of the permanent pool will vary to provide water quality enhancement, wildlife benefits, and recreational uses.

Figure 6-7
EXAMPLES OF DEAD STORAGE AREAS IN WET PONDS

A shallow marsh habitat or wetlands environment can be created by a wet pool depth ranging from 1/2 to 2 feet. The shallow depth will allow emergent aquatic vegetation to be established which is very beneficial in removing nutrients and other attached pollutants from the water column. A shallow marsh area also provides an excellent environment for wildlife (Godfrey, 1985).

Florida Game and Freshwater Fish Commission has specified that optimum fish production will normally be achieved given a 6 to 8 feet deep pool over at least 1/3 of the surface area. A minimum surface area of 1/4 acre is also recommended for pond management purposes by some agencies such as the Soil Conservation Service.

With respect to water quality enhancement, a pond containing areas of both shallow depths (less than 2 feet) and deep depths (greater than 3 feet) may be the most beneficial. The emergent aquatic vegetation in the shallow areas will reduce nuturient loads into the pond which will prevent excessive algae growth. The deeper areas of the pond will provide pollutant removal by gravity settling during and after storm events.

Wet ponds should generally be limited to a maximum depth of 8-10 feet. Ponds that are deeper are envisioned to present a greater possibility for contributing toward potential groundwater contamination. Likewise, the

R0071113

creation of anaerobic conditions over large areas of the lake bottom is also seen as more likely under these circumstances. Consequently, the solublization of pollutants (e.g., metals and phosphorus) normally bound in the sediment and their release to the overlying water column is perceived to be probable by many regulatory agencies including the Department of Environmental Regulation.

Area and Volume Parameters of Wet Ponds

There are two important area and volume parameters that effect the pollutant removal efficiency of wet ponds. These parameters are the area ratio (A/A_S), and the volume ratio (VB/VR).

The area ratio (A/A_S) is determined by dividing the drainage area (A) by the wet pool surface area (A_S). For an example, an area ratio of 40 represents a 2 acre basin surface area serving an 80 acre drainage area.

Adherance to state guidelines that were discussed pertaining to the temporary storage and slow release of the first 1 inch of runoff will result in an area ratio of 18 or lower provided the depth of stage one is limited to no more than 18 inches. A basin surface area with a percentage of the contributing catchment area of 5 or more will maximize pollutant removal for most standard parameters including solids, traffic related metals, and nutrients (EPA, 1987). An area ratio of 18 or lower translates to a value of 5 percent or more in terms of the EPA criteria. Consequently, it may be concluded that the state criteria indirectly result in a maximization of design in this particular respect.

The volume ratio (VB/VR) is equal to the wet pool volume (VB) divided by the mean runoff volume (VR). The mean runoff volume (VR) can be estimated by multiplying the mean rainfall depth times the rational runoff coefficient (C), the drainage area of the basin, and the appropriate conversion factor.

In regard to (VB), for purposes of maximizing the assimilation of pollutants in wet ponds, particularly nutrients, the following statements were offered to the Department (CDM, 1985):

"Since the major biological mechanisms (e.g., algal uptake) for pollutant removal in a wet detention basin are essentially lake eutrophication processes, eutrophication modeling theory can be used to adequately size the permanent pool" .... A residence time of 2 weeks is considered to be the minimum duration that ensures adequate opportunity for algal growth."

The consultant goes on to state:

> "A design residence time of about 2 weeks is in the same order of magnitude as the residence times achieved by several of the wet pond BMPs monitored under the EPA NURP Study ... As may be seen, these recommended permanent pool storage volumes are equivalent to approximately 2.0 inches per impervious acre plus 0.5 inches per pervious acre."

In the consultants opinion, based on field experience, adherence to this simple to apply empirical approach will result in a detention basin wet pool volume (VB) sufficient to ensure that a hydraulic residence time approaching 2 weeks is achieved. The facility would also be expected to perform well from a water quality perspective. Consequently, it may be concluded that the basin volume to runoff volume ratio (VB/VR) determined by estimating VR and VB as discussed above is appropriate. However, it may be seen that the proper ratio will be highly variable. Its' value will depend on the average rainfall per event per region, the runoff coefficient, and the amount impervious area.

A slightly more rigorous approach to confirm that the appropriate basin volume to runoff volume is achieved, incorporates the average interval between storms into the previous assessment. In this procedure, VR is calculated as before. The value of VR is then multiplied times fourteen (14) days and divided by the average interval (days) between events to determine the volume of the basin permanent pool (VB).

For example, consider a 75-acre project, as discussed before, with an associated coefficient of runoff (C=.4), located in Tallahassee where the mean storm volume (P) is .65 inches. Rainfall statistics recorded at the airport show that the average interval between events equals 86 hours or 3.6 days. The appropriate basin volume (VB) in acre feet is determined as follows:

$$VB\ (Ac.Ft.) = [VR(A)\ (14\ days)/(Days\ interval\ between\ events)] \times CF\ (.083)$$

where:

VR = Coeffficient of runoff (C) x mean storm volume (P) inches.
Watershed area (acres)
CF = Conversion factor ac-in. to ac.ft. (.083)

The equation can be solved, assuming that the watershed area (A) is equivalent to the project area (75 acres) given the values of (C) and (P) that were specified above and an interval of 3.6 days.

VB (Ac-Ft.) = .083 (.4) (.65) (75) (14/3.6)
= 6.3 Ac.Ft.

The mean runoff volume VR would equal:

VR = CF (C) (P) (A) or
VR = .083 (.4) (.65) (75)
= 1.6 Ac.Ft.

Therefore the appropriate volume ratio in this example is VB/VR = 6.3/1.6 = 3.9.

Planning and Design Considerations

Emergency Spillway: In Florida designers often fail to provide for the occurence of catastrophic events. These oversights are not advisable. In any circumstance where damage to downstream property or public safety is jeopardized impoundment structures should be provided with emergency spillways which, as a minimum, can pass runoff from the one hundred year frequency storm without damage to the impoundment structure.

Discharge Structures: Discharge control devices may be either single-stage multi-stage devices. They should be designed such that the permissible release rate is not exceeded at the highest water level. The control structure should be adequately designed to prevent failure and resultant property damage and loss of life. Due consideration should be given to preventing the plugging of the discharge structure by debris. High intensity landuse areas with significant percentages of impervious surfaces should include provisions to prevent hydrocarbons (oil and grease) from exiting the discharge facility.

The outlet of the discharge device shall be protected from scouring. Riprap, plunge pools, energy dissipators or other acceptable means should be used for this purpose.

Sediment: Probable quantities of sediment from the drainage area should be estimated for the expected life of the pond taking into consideration future development trends. The structure should include capacity for sediment storage and provisions for periodic sediment removal if necessary.

Shoreline Protection: The shoreline of large impoundments should be adequately protected from littoral currents or wave action which can cause shoreline erosion.

Draining: Provisions should be made for completely draining wet ponds to allow periodic cleaning, inspection and maintenance. Drain facilities may be an integral part of the flow control structure or a separate structure. However, these features invite misuse. Permitting authorities have begun to require that gate valves for this purpose be locked. Keys are supplied only in the appropriate circumstances.

Multi-Purpose Ponds: Permanent ponds designed for multiple use should meet the specific requirements of the uses intended in addition to the stormwater management requirements stated herein.

R0071116

Safety: Ponds which are readily accessible to populated areas should incorporate all possible safety precautions. Steep side slopes at the perimeter should be avoided or fenced and dangerous outlet facilities should be protected by enclosure. Warning signs for deep water and potential health risks associated with body contact recreation should be used wherever appropriate.

Aesthetics: A storage facility is an integral part of the environment and therefore should serve as an aesthetic improvement to the area if possible. Use of good landscaping principles is encouraged. The planting and preservation of desirable trees and other vegetation should be an integral part of the storage facility design.

Construction Specifications

Widely acceptable construction standards and specifications such as those developed by the USDA - Soil Conservation Service or the U.S. Army Corps of Engineers for embankment ponds and reservoirs should be followed to build the impoundment. Attention to details of construction and adherence to specifications are as important as adequate investigations and safe design. A safe design can be ruined by poor construction.

Chapter 17 of the SCS Engineering Field Manual provides guidance on construction methods for the various elements of a pond or reservoir. Specifications for the work should conform to methods and procedures for installing earthwork, concrete, reinforcing steel, pipe, watergates, metalwork, woodwork and masonry, that are applicable to the site and the purpose of the structure.

Maintenance

Maintenance is of primary importance if urban impoundments are to continue to function as originally designed. A local government, a designated group such as a homeowners' association, or some individual must accept the responsibility for maintaining the structures and the impoundment area. A specific maintenance plan should be formulated outlining the schedule and scope of maintenance operations.

Debris removal in detention basins can be achieved through the use of trash racks or other screening devices.

Maintenance of sediment and debris basins is extremely important. Plans should include provisions for sediment removal when a certain storage elevation is reached. Debris should be removed from the basin following each storm.

Design with maintenance in mind. Good maintenance will be crucial to successful use of the impoundment. Hence provisions to facilitate maintenance

R0071117

operations must be built into the project when it is installed. Maintenance must be a basic consideration in design and in determination of first cost.

A permanent easement at least fifteen feet in width should be provided around the perimeter of an impoundment to allow for maintenance and to provide a buffer from encroachment. The easement should be measured from the maximum elevation of the storage pool. An easement also must be provided for access to the impoundment location.

The following are some items which should be considered in formulating a maintenance plan:

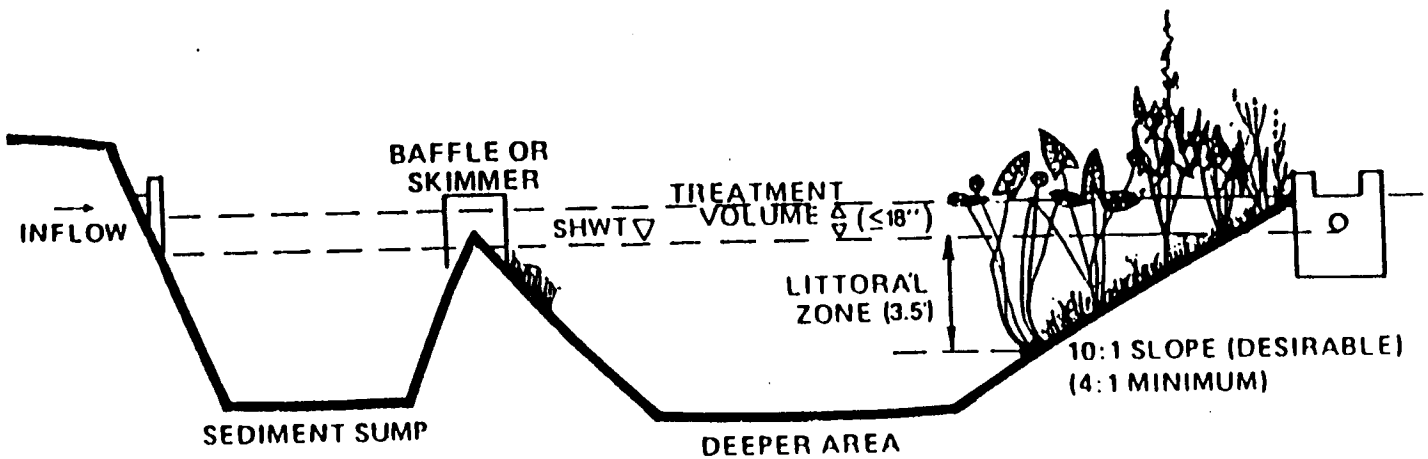
Sediment: Sediment deposition should be continually monitored in the basin. The maintenance plan should specify a specific point or elevation at which the sediment should be removed. Owners, operators, and maintenance authorities should be aware that significant concentrations of heavy metals (e.g., lead, zinc., and cadmium) as well as some organics such as pesticide, may be expected to accumulate at the bottom of these treatment facilities. Testing of sediment (EP Toxicity) especially near points of inflow should be conducted to determine the leaching potential and level of accumulation of hazardous material before disposal via landspreading or filling is prescribed.

Inlets: Pipe inlets should be inspected after each major storm, and accumulated debris and sediment should be removed each year.

Outlets: During each year of operation pipe outlets should be inspected after each storm to determine whether outflow is causing erosion. Wherever such erosion is detected, effective measures should be taken to stabilize and protect the affected area. These precautions are particularly important during the immediate post construction phase of the project.

Vegetation: Trees and shrubs should be kept off of dam and emergency spillway areas. Should these plants die from disease, lighting or other causes, their large and decaying root system can seriously reduce the stability of an embankment. Vegetation should be maintained for critical area stabilization as specified in vegetative practices contained in this handbook.

Insects: Precautions should be taken to minimize the production of fast-breeding insects in and around the ponded area. Possible control measures include controlling the growth of grass at shorelines, varying the water depth every few days, and stocking the pond with larvae-eating fish.



Safety Inspections: All permanent impoundments should be inspected periodically by a qualified professional engineer to insure that they remain structurally sound and mechanically efficient. An annual safety inspection is ecommended where the potential for downstream damage and loss of life due to impoundment failure is high. All structures should be inspected following major storms as well.

EXFILTRATION TRENCHES

(also referred to as infiltration pits and trenches)

Definition

On-site retention of stormwater accomplished below the ground. The subsurface retention facilities most commonly used in Florida are excavated trenches, backfilled with coarse graded aggregate. Stormwater runoff is collected for temporary storage and infiltration. These facilities often include perforated pipe. Water is exfiltrated from the pipe and infiltrates the trench walls and, to some extent, the trench bottom for disposal and treatment. The addition of the pipe is viewed to increase the storage available in the system and helps promote infiltration by making delivery of the runoff waters more effective and evenly distributed over the length of the facility. Most designs include a weir overflow structure or a diversion sometimes called a "smart box". The device is installed at the point of inflow to the trench system. Its' purpose is to route a specified volume of stormwater in the perforated pipe and trench for percolation into the surrounding soil. Excess water from larger storms is by-passed away from the facility (see Figure 6-10).

Purposes

1) To retain the "first flush" of stormwater runoff to promote water quality improvement.

2) To reduce the runoff volume and peak discharge rate from a site, thus contributing to a reduction in downstream flooding and channel degradation.

3) To filter contaminants out of runoff before it reaches receiving waters and promote recharge of groundwater supplies.

R0071121

Conditions Where Practice Applies

Where the subsoil is sufficiently permeable to provide a reasonable rate of infiltration, and where the water table is sufficiently lower than the design depth of the facility to prevent pollution of the groundwater. This practice is normally used where space is limited and land is expensive. Frequently used for the disposal of runoff from roof drains, parking lots, tennis courts and roadways. This practice is not recommended where runoff water contains high concentrations of suspended materials unless a presettling or filtering mechanism is provided. Likewise, grease and oil traps are also highly recommended prior to discharge to these systems. These precautions are primarily for maintenance reasons since exfiltration systems are very susceptible to clogging and sediment build up reducing their hydraulic efficiency and storage capacity to unacceptable levels.

Planning Considerations

Under conditions of natural vegetative cover, a considerable portion of the rainfall from minor storms evaporates or is held or absorbed by the vegetation. Most of the remainder infiltrates into soil so that very little runoff occurs. Conditions can change radically with typical urban developments such that considerably less rainfall is taken up by plants or infiltrated into the soil. Infiltration measures offer a way to restore the hydrologic balance on a developed site by providing a facsimile of the natural process of infiltration.

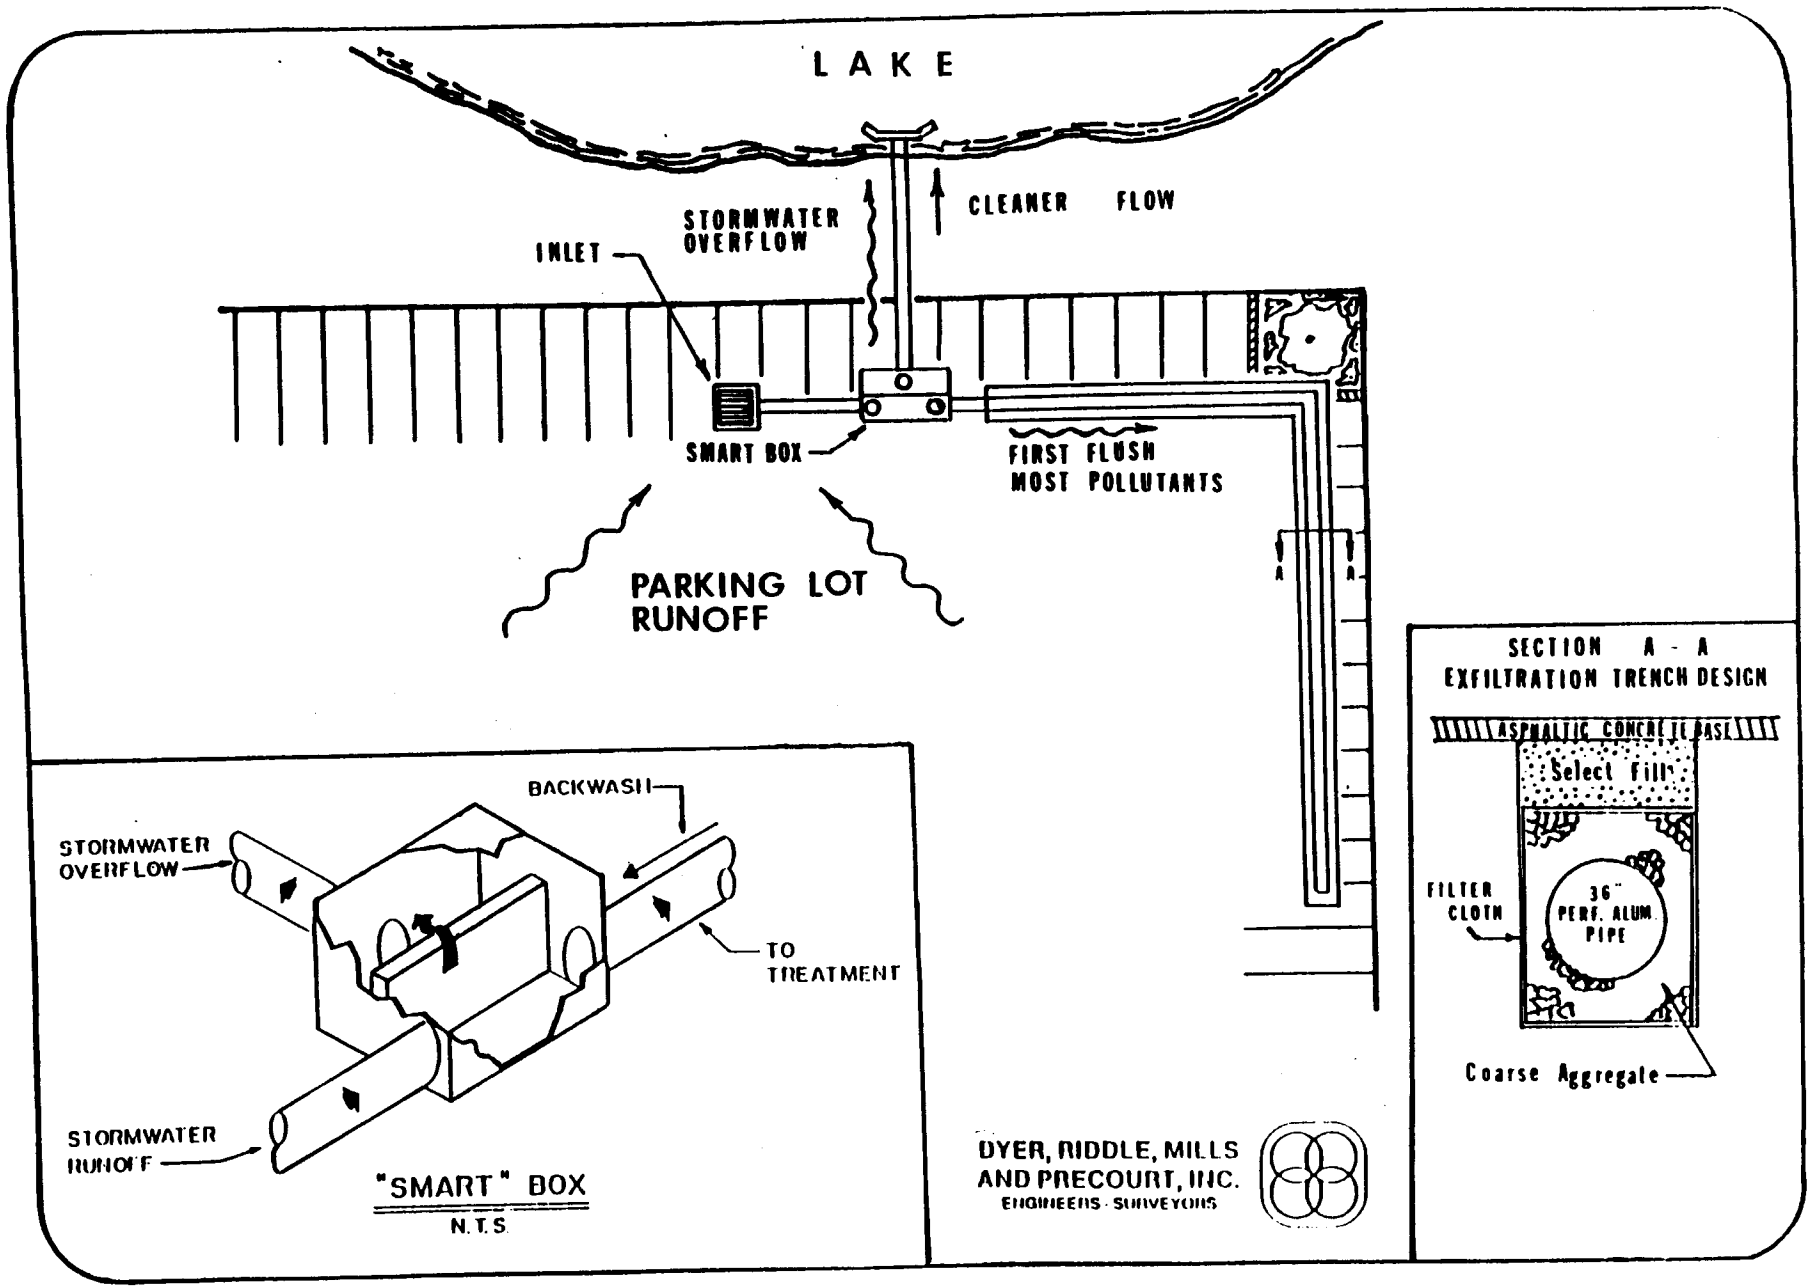
Site Characteristics: The degree to which subsurface infiltration can be used depends upon the physical characteristics of the soils, the nature of the local groundwater system, and the depth of bedrock. Typically, exfiltration/infiltration systems would not be recommended in high water table areas nor locations where the limestone aquifer is within a few feet of the land surface. This advisory is due to an obvious reduction in the capacity to percolate water and the increased potential for groundwater contamination. Nonetheless, exfiltration systems have become widely used in several areas where such conditions persist. There are a variety of reasons for their popularity, including high land cost, lack of space for other means of treatment and deteriorating surface waters in coastal areas associated with highly polluted runoff from development and increasing levels of salinity (salt water intrusion) due to over drainage.

Integrated Runoff Control: Infiltration may be incorporated as one part of an overall runoff control system using several different techniques. For larger sites, or in places where most of the site is impervious, infiltration measures may be capable of handling only a portion of the runoff and pollutant loading.

Types of Facilities: Exfiltration and infiltration trenches consist of long narrow excavations with depths normally less than 6 feet. The geometry

of these facilities can be variable; however, wide, shallow trenches usually have higher infiltration rates than deep narrow ones. As a general rule, the ratio of side area to bottom area should not exceed 4:1. Figure 6-10 shows a cross section of a typical trench draining a paved parking area.

Exfiltration trenches of various design represent the primary stormwater quality treatment practice used in Florida to address existing highly urbanized problem spots (retrofitting). Since the mid to late 1970's both Dade County and the City of Miami Department of Public Works have been installing underground storage and percolation trenches to reduce the level of direct stormwater discharges to their extensive canal system. Likewise, the City of Orlando has used exfiltration trenches as a primary means to lower the stormwater pollutant load impacting the quality of its' lakes, beginning with Lake Eola located in the heart of the downtown business district. Both efforts have been reasonably successful.



The principal types of these management practices that would normally be installed to improve the water quality of existing systems in Miami, Florida are illustrated in Figures 6-11 and 6-12. These practices are designed to provide various amounts of on-line retention, typically accommodating runoff from a three-year to ten-year design storm, depending on land use. A sizeable portion of the runoff water is usually percolated directly into the limestone.

The Dade County (208) Areawide Water Quality Management Plan (1979) notes that the French drain method was very cost effective. As shown in Figure 6-11, French drains are supported by ballast rock. Such structures are used mainly in northern Dade County, where the soils are not capable of supporting an open straight sided trench. Most French drain systems use 24" pipe at a cost of $28/linear foot (1979 prices). Larger pipes are necessary only in areas where an excessive amount of stormwater is expected. The maintenance costs published for this system range from $3/linear foot for the flushing of the pipes to $30/year/catch basin for removal of debris.

Much like a French drain, a slab covered trench is no more than a ditch cut at least one foot below the water table. The main difference in the two systems, as seen in Figure 6-12, is that the slab covered trench contains no coarse aggregate nor a distribution pipe. The system allows a free, unobstructed interaction with the groundwater. Again, as with the French drain, a catch basin(s) must accompany each trench. The cost of the system is identical to that of the French drain with maintenance costs also being similar (catch basin cleaning). Covered trenches are installed in the central and southern parts of the county where the substrata is limerock. Wide use of these facilities is possible due to the high transmissivity of the shallow aquifer in Dade County. These systems handle water quantity and hopefully improve water quality. They are thought to attenuate pollutants through chemical reactions within the aquifer.

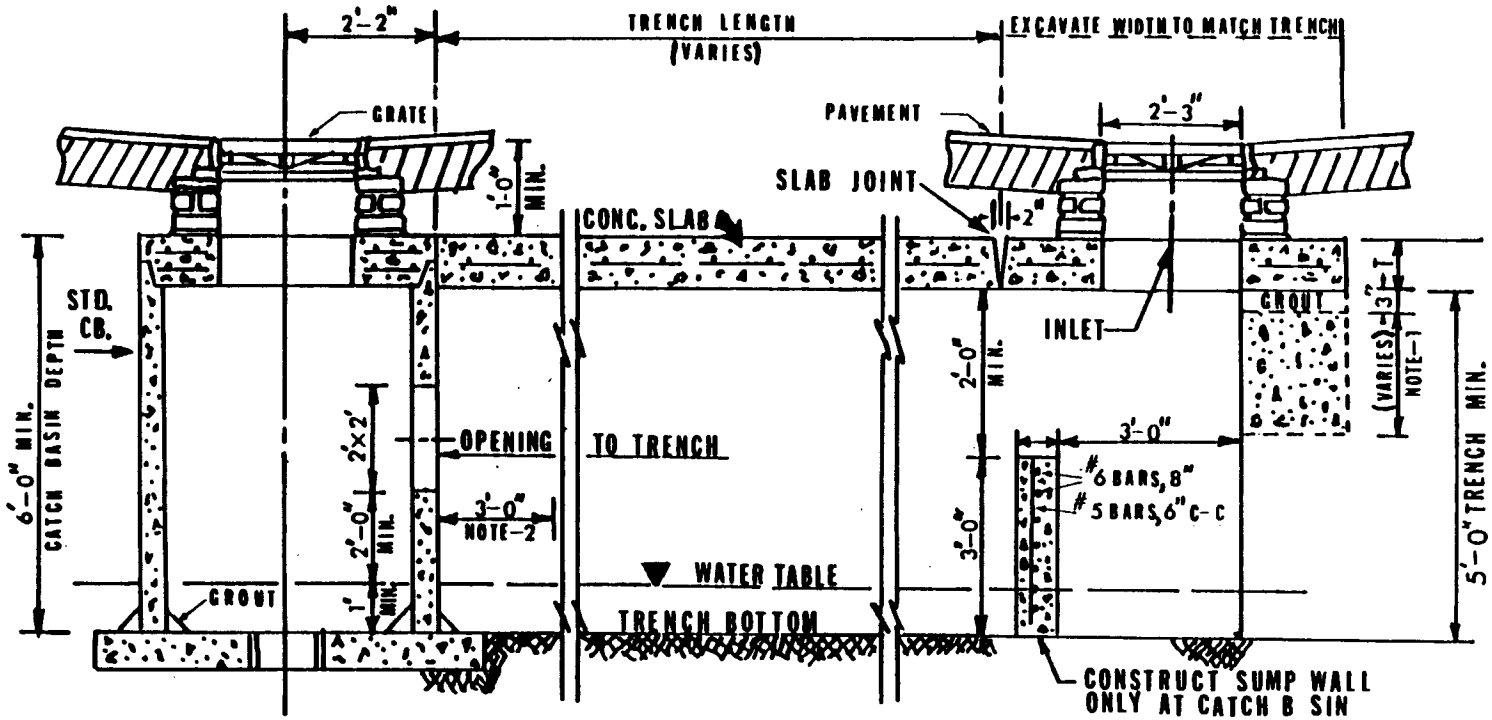
FIGURE 6-11
FRENCH DRAIN (EXFILTRATION TRENCH), DADE COUNTY, FLORIDA

NOTES:

1) If 10" conc bell & spigot pipe 5' long is not available, pipe, up to 24" in diameter may be substituted.

2) If conc bell & spigot pipe is not used or if the length of pipe used is greater than 5', 3/4" saw cuts shall be made at intervals of 2' thru the upper half of pipe, 5' lengths may be used for vitrified clay pipe.



3) The contractor has the option of installing the following pipe types:
   A. Concrete - perforated or non-perforated (bell spigot)
   B. Vitrified Clay - " " " " " "
   * C. Corrugated Metal - Bituminous coated (perforated)
   * D. Corrugated Aluminum (perforated)

4) No pipe perforations for 10' ±.

* 1/4" to 3/8" dia. hole, spaced at 2-3/4" ± (minimum 162 holes per lin.ft.)

R0071125

TYPICAL SECTION, SLAB COVERED TRENCH, DADE COUNTY, FLORIDA

LONGITUDINAL SECTION

NOTES:

1) If material at edge of ditch is unsuitable for foundation underslab, clean out and backfill with concrete. Depth of backfill varies.

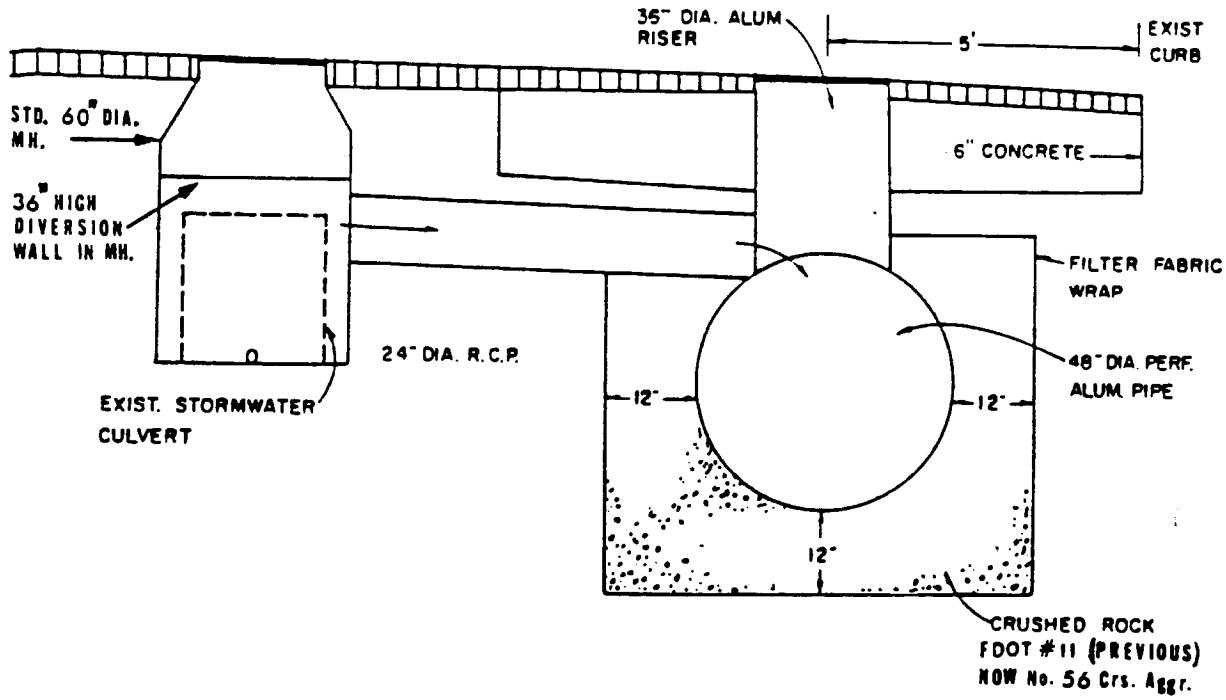
2) Transition to trench bottom when it is lower than catch basin bottom.

In cases where pollutants such as oil and grease are expected in high quantities, added protection is given to the groundwater through separation devices built into the seepage system design. However, the verdict is not in on any potential negative impacts these systems may have on the quality of groundwater supplies. In Dade County, special attention is given to those facilities lying in heavily industrialized areas and within the cone of influence of a wellfield. Nevertheless, such procedures are not strongly encouraged by the Department on a general use basis. Unless pretreatment is provided a case by case evaluation of the groundwater characteristics and the probable effects given the constituents expected in the stormwater is normally required.

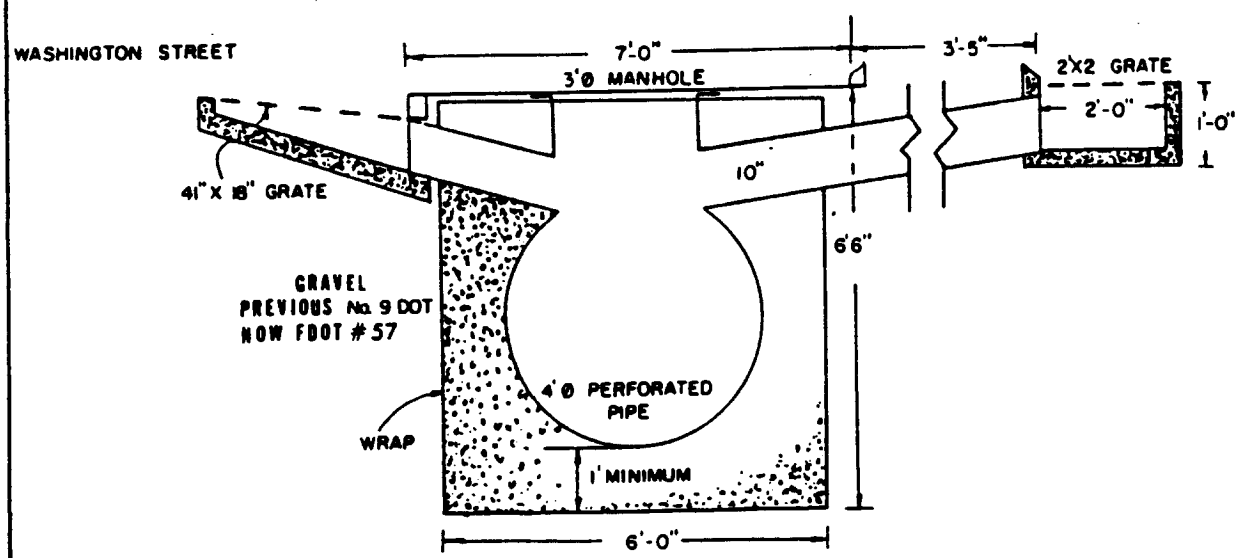
The counterpart of the Dade County exfiltration system as applied in the Orlando, Lake Eola watershed is illustrated by Figure 6-13. Notice that the system shown at the top of the page includes a baffle or spliter as discussed previously. The purpose is to divert the "first flush" or initial one-half inch of runoff into the exfiltration system.

Also notice that the second system shown receives runoff directly from the street. This circumstance is not normally recognized as a good idea from an operation and maintenance perspective. However, the city reports that several of these systems have functioned without failure and with only minimal maintenance for nearly ten years. Other jurisdictions have not been so lucky.

Stormwater discharge that may include synthetic organic compounds such as solvents should be monitored for several storms before design plans are made. This precaution is particularly important in any area where the aquifer must be protected. The absence or occurrence of any pollutants that might not be treatable via filtration through the soil, sand or limerock should be established prior to designing a treatment system. In these instances it is always possible that the physical, chemical, and hydrologic properties of the constituent may be known such that an effective scheme could be devised to increase the effectiveness of the system to handle these exotic pollutants.



Runoff Filtering: To improve the length of time between major maintenance, grease, oil, floatable organic materials and settleable particles should be removed from runoff water before it enters the infiltration facility. These materials can take up storage capacity and reduce infiltration rates. Runoff filtering devices such as grass borders or filter strips, swales, sediment traps, and grease traps can be used to remove objectionable materials. Figure 6-14 illustrates the concept of using a vegetated area for these purposes as practiced in Maryland.



Design Criteria

Local criteria for the design of infiltration and exfiltration facilities

FIGURE 6-13

Pretreatment of Runoff Prior to Exfiltration in Frederick Co. MD

R0071129

should be followed when they exist. Since this practice may also be used for flood control to some extent, local regulations may affect (increase) the minimum design requirements established by the state for water quality protection as discussed herein.

Storage Capacity: The size of an infiltration facility is dependent upon its purpose. For pollutant removal purposes, the larger the storage capacity the greater the removal efficiency. A storage volume to accommodate the first half-inch of runoff or the runoff from the first inch of rainfall is estimated to provide up to 80% annual removal efficiency.

To meet minimum state retention requirements, the trench must have the capacity to retain the above volume without direct discharge. Storage volumes may be calculated in the same way as other retention facilities. These systems are usually located in highly impervious but rather small watersheds. In these instances, the time of concentration usually will not effect the overall storage capacity. Water from the most distant reaches of the watershed will be delivered to the treatment facility within a few minutes of water from down gradient. Consequently, the storage capacities will not need to be significantly increased to maintain the desired level of pollutant removal (i.e., 80% - 90%). Therefore, the effect of watershed shape, size, and time of delivery may usually be ignored.

The storage volume required may be calculated very simply if exfiltration from the system is not used in an attempt to reduce the size of the facility.

Volume of Storage Required (ft^3) = VsR

$$VsR = 1/2 \text{ in.} \times A \text{ (acres)} \times \frac{43560 \text{ ft}^2}{\text{Ac}} \times \frac{1 \text{ ft}}{12 \text{ in.}}; \text{or,}$$

$$VsR \ (ft^3) = 1815 \ A$$

Void Space: Most infiltration facilities are designed with aggregate fillers as shown in Figures 6-10 through 6-13. To estimate the available storage volume, the designer must know the void ratio of the aggregate. Generally, stone of up to 1.5-inch diameter is acceptable. Rounded stones have higher void ratios than angular crushed stone.

In most areas of Florida, the volume associated with coarse aggregate is computed based on 40% - 50% voids. The storage volume available in an exfiltration trench without a distribution pipe (as illustrated by Figure 6-14) may be determined as follows:

Volume Storage Available: VsA (ft^3) = volume of void space.

VsA = 0.5 (i.e., void ratio) x W x H x L; or,
VsA = 0.5 WHL ft^3

where:

W = trench width (ft)
H = depth of trench or that part above the seasonal high water table (ft)
L = trench length (ft)

In order to satisfy the general permit criteria in Chapter 17-25 F.A.C.

VsA must be equal to or greater than VsR

by substitution;

0.5 WHL = 1815A

In most cases the depth of the trench (H) and the width (W) are predetermined or selected by the engineer. Trench dimensions of 4 ft. x 4 ft. or 3 ft. x 3 ft. are quite commonly chosen by many designers. However, the equation may be rearranged to solve for any of the three trench dimensions desired. To determine the length of trench (L) required (most common situation) the equation becomes:

$$L = \frac{3630\ A}{WH}$$

where:

A = contributing drainage area in (acres); and,

All other terms are the same as discussed in the previous equation.

Open Space in Pipes: Facilities with perforated pipes for distribution may include the area inside the pipe above the water table as available storage. The equation for calculating the length of trench required given this circumstance is derived as follows:

Volume of Storage Required (VsR) = 1815 A;
as before, VsR must = Volume of Storage Available (VsA)
VsA = pipe volume + [(trench volume - pipe volume) x (void ratio)]

Assume:

- L = trench length and that pipe length and trench length are approximately equal.
- Void ratio of coarse aggregate in the trench surrounding the pipe = .5
- trench volume = WHL

Given:

- Storage Volume in the pipe (pipe volume) = $\frac{\pi d^2 L}{4}$; and,

by substitution:

$$1815\ A = \frac{\pi d^2 L}{4} + (WHL - \frac{\pi d^2 L}{4})\ (.5)$$

$$= \frac{\pi d^2 L}{4} + \frac{(WHL - .25\pi d^2 L)}{2}$$

$$= \frac{\pi d^2 L}{4} + \frac{2\ WHL}{4} - \frac{.5\pi d^2 L}{4}$$

multipling both sides by 4 the equation becomes:

$$7260\ A = \pi d^2 L + 2\ WHL - .5\pi d^2 L$$
$$= \pi\ 2\ WHL + .5\pi d^2 L$$
$$= \pi\ (2WH + .5\pi d^2)\ (L)$$

solving for L

$$L = \frac{3630\ A}{WH + .25\pi d^2}$$

where all symbols are the same as in previous equations or as discussed above and d = pipe diameter in (ft.).

Example Problem

Given: A 4' x 4' exfiltration trench constructed for a 2 acre project. What is the length of trench required to retain the first half-inch of runoff? Assume a 12-inch diameter perforated pipe is used to distribute

runoff water evenly along the entire length of the system and that the percent voids or porosity of coarse aggregate = 0.5 or 50%.

Solution

Working through the various factors in the equation previously discussed:

A = area = 2 acres
W = trench width = 4 ft.
H = trench depth = 4 ft.
π = constant = 3.1416
d = pipe diameter = 12 in. or 1 ft.

substituting into the equation

$$L\ (ft) = \frac{3630\ (2)}{(4)\ (4) + \frac{\pi\ (1)}{4}} = 432.5\ ft.$$

If the 1 ft. diameter perforated pipe was not used for distribution or to increase storage, the trench length required would have equaled 453.75 ft. As may be seen, small diameter (1 ft or less) pipe makes little difference in trench length (slightly less than 5%). However, using 24-inch pipe can reduce trench length to 379.3 ft. while 36-inch pipe reduces the system to 314.7 ft. or approximately 16% and 31% respectively.

Analysis of Drawdown Time: Similar to other retention systems, exfiltration facilities designed to meet state pollution control requirements must also demonstrate the capacity to percolate the required treatment volume (1/2" runoff) within a 72 hour time frame. This factor may be checked with Darcy's Equation (Q = KiA) using the results of field percolation or infiltration testing described in Appendix 6-2. The infiltration velocity "K" (length/time increment) is equated to flow "Q" (volume/time increment) based on horizontal cross-sectional area "A" of the trench (width x length) with an assumed gradient of unity (i = 1).

The exfiltration rate calculated using this equation is subsequently divided into the retention volume required to determine drawdown time. If the time for drawdown exceeds 72 hours the length of the system is expanded and rechecked until the final design meets both retention volume and drawdown requirements. A safety factor of 2 is normally used, to double the above result.

Alternative Sizing Procedures: The method of sizing exfiltration systems discussed above is strictly related to the department's pollution control requirements for stormwater. It is based upon a showing of a specific amount of retention available in the trench above the water table regardless of the infiltration which takes place during the course of a storm.

Other procedures have been developed for sizing these facilities in which the designer determines the time related inflow and infiltration. These designs include consideration of both storage in the trench soil infiltration inherent in the system.

The two major elements of these designs consist of a mass inflow or runoff analysis for the project and an analysis of mass outflow (volume exfiltrated) with time. A specific design storm (e.g., 3-year 1-hour duration) is sometimes stipulated by the regulating authority for these evaluations; or, the designer may be asked to check a range of event sizes for the critical storm (e.g., the one which requires the maximum level of storage). Storage is usually provided within the trench for the difference between inflow and exfiltration. The most often used sizing criteria of this type (developed by the South Florida Water Management District) is based on a volume of storage equivalent to 50% of the greater of the first inch of runoff from the total project or 2.5 inches of runoff times the impervious acreage. The length of the system is determined using a safety factor of 2 equating the runoff volume generated from the design event with the storage volume available in the trench (50% voids assumed) plus the volume exfiltrated out of the trench during the course of the storm (1 hr.).

Obviously, there is a rather sizeable disparity between the treatment volume required by the South Florida Water Management District (SFWMD) versus that which is specified by the department. At a minimum the volume to be exfiltrated is double the one-half inch treatment volume associated with retention type systems permitted for other regions of Florida. Consequently, it is logical to presume that trench systems constructed in accordance with the SFWMD design equation would be larger and therefore more expensive than those planned and built on the basis of the state criteria. This anomaly is likely to lead most designers to question the wisdom of using the SFWMD procedure in any cases where it is not required.

However, as may be seen after an examination of the information in Table 6-3, the larger volume of treatment does not necessarily result in longer exfiltration systems. Trench lengths are inversely related to an increasing potential in the rate of percolation (e.g., hydraulic conductivity). Likewise, the SFWMD method outlined in the Volume IV Permit Information Manual results in a lowering of the amount of exfiltration trench required as the percentage impervious acreage is reduced if all other factors are equal. Consequently, when the potential rate of percolation is relatively high (e.g., 12 in./hr. or greater) and as the percentage impervious area approaches 70% or less, the designer may fair better using the alternative procedure.

Given a system that can be expected to actually percolate and store the volume of runoff required by SFWMD, these shorter facilities would still be expected to achieve a level of treatment equivalent to other systems that are permitted by state regulations. However, the water management district staff

Breakpoint Evaluation
of the
Effect of Hydraulic Conductivity on Trench Length

(For 4' trench, total depth 7', H=6', Hz=5', Ds=2', & Du=4')

		CRITICAL "K" (IN/HR) (1)	
PERCENT IMP (%)	(2) FDER (L)	VOLUME IV METHOD	LINE SOURCE METHOD
70	3244	6.78	9.79
80	3244	8.12	14.01
90	3244	9.45	18.98
95	3244	10.11	21.75

ASSUMES: Depth of bore hole for perc test (hw) = total depth of trench.
re/rw = 30/.375 = 80
depth below water table of bore hole (he) = Ds.

NOTE:

1) Values less than K will result in Trench Length greater than FDER Length Equation Values shown in Column 2. Values greater than K will result in Trench Length less than FDER method.

2) Based on W = 4', H = 4' above WT, A = 15 acres pipe diameter 1 ft. and void ratio = .5 for one-half inch runoff storage.

$$L = \frac{3630\ A}{WH + \frac{\pi}{4} d^2}$$

R0071135

recently complete preliminary research which demonstrates that the standard trench design procedure referred to as the "Volume IV Method" has a tendency to yield trench lengths that are too short to accomplish the degree of infiltration for which they were designed. In tests of two exfiltration trenches that were constructed at the district office in West Palm Beach, computer exfiltration rates obtained using the standard (Volume IV) method were found to be greater than observed rates measured during the one hour design period by 32% to 158% (SFWMD, 1988)

An alternate procedure **"The Line Source Method"** was also explored by the district staff during the study. This method is most sophisticated in accounting for transient conditions relative to changes in head and the depth of the saturated and unsaturated zone, as well as the reduction in the hydraulic gradient which occurs after a storm begins and the trench is filled with runoff waters and groundwater or water table mounding begins to take place. The procedure results in a lowering of the rate of percolation projected during the course of the design storm. Consequently, a concommittant increase in the length of exfiltration trench required is projected. Table 6-3 also demonstrates the magnitude of difference in trench length which resulted when the Line Source Procedure was used to size this particular trench system.

The input data is slightly more rigorous to obtain, but the method shows evidence of much improvement in accuracy. The alternate method was found to provide estimates within 13% of measured rates in the study cited earlier. The procedure currently is being considered for adoption by the district. Table 6-4 lists the results of an assessment that was performed to determine the exact value in the soil hydraulic conductivity (K) by percentages of impervious acreage which, if exceeded, would result in trench lengths less than those required by the Department. The evaluation was based on the same hypothetical trench configuration used to generate the data in Table 6-3. The results show that the break point or critical value of K is quite variable depending on which sizing equation is used by the designer.

While not shown on the table, it should be noted that the break point changes depending on the trench dimensions and water table configuration as well as the size of pipe used in the trench. However, the general relationship between the three methods is static. As shown in Table 6-4, the use of the Line Source Method serves to expand the range over which the SFWMD procedures will produce trench lengths longer than those computed using the DER method.

On the promise that the more storage provided in the trench the greater the treatment capacity, it may be concluded that the information in Table 6-3 and Table 6-4 demonstrates that either SFWMD procedure is likely to provide treatment (pollutant removal) greater than that required by the state given rates of percolation of six to ten inches/hour or less. In this particular instance, the new Line Source Method would provide equal or better treatment

TABLE 6-4

NOTES: The hydraulic conductivity (K) inches/hour was converted to ft/sec and was used directly to determine length (L) in the Line Source Equation shown in Appendix 6-3. The (K) value (ft/sec) wa also used to determine (Qp) the inflow rate to bore hole (cfs) for the Line Source Method percolation test.

The radius of influence (re = 30') was assumed static for all comparisons. The total depth of the bore hole (hw = 7') was assumed equal to total trench depth. The radius of the bore hole (rw = $.75/_2$) for all situations. The value of Qp was subsequently substituted into the Usual Open Hole Test formula also in Appendix 6-3 to determine (K_{IV}) the Volume IV discharge coefficient (cfs/ft^2 - ft Head), assuming H_z = 5 ft, Ds = 2 ft and d = .75'. The value of K IV was used in the Standard Volume IV length equation to determine (L).

R0071137

over a wider range of soil conditions with maximum (K) values from 10 in./hour to nearly 22 in./hour as the percentage of impervious acreage increases from 70% to 95% respectively. Given a location with soil conditions such that the hydraulic conductivity (K) would exceed 24 in./hour, one may find that even the Line Source Method would result in a lower level of treatment. In this particular instance, a well drained sandy soil with rapid internal drainage would have resulted in less treatment than a similarly situated system designed according to the DER recommended procedure. Nonetheless, this circumstance does not necessarily indicate that the treatment level would be unsatisfactory. The potential percentage removal associated with either of the two SFWMD design procedure has not been established.

However, it is safe to conclude that the DER method, wherein the infiltration rate is not a factor in sizing (except at rates less than 1 in./hour) inadvertently works to ensure that facilities constructed in areas with more porous soil conditions will achieve a greater level of treatment than that associated with lesser permeable soils. Therefore, to the extent that the department's first half-inch treatment criteria can be relied on to accomplish 80 - 90% removal given the more moderate rate of percolation (e.g., 6 in./hr.), the DER method can be foreseen to result in more trench length than may be cost effective under highly permeable soil conditions (e.g., 24 in./hr. or more). Consequently, the (SFWMD) Line Source Method would be a more appropriate design equation given these circumstances.

A discussion of these procedures may be found in Appendix 6-3 at the conclusion of this chapter. For more information the reader may wish to refer to the SFWMD Permit Information Manual for the Management and Storage of Surface Waters.

Information Required Planning An Exfiltration System

Soils Analysis: A soils analysis should be submitted with the design plans to ensure that the substrate is suitable for percolation. It is recommended that the trench must have a percolation rate of not less than 0.6 inches per hour. Further evaluation should be made if the soils contain a high percentage of fine particles, since such materials have a much greater tendency to clog. Existing soil surveys may provide an estimate of percolation rates but it is helpful to have field tests performed in the vicinity of a proposed trench or pit. It is important to evaluate the permeability of all strata to a depth exceeding that of the proposed trench.

When using soil survey information, a site visit should always be conducted by a professional soil engineer or the Soil Conservation Service (SCS) to confirm the soil types and point out any obvious limitations to percolation that may not be included on the survey sheet. It is important to note that the SCS publications present a range of permeability values for any given

soil type at a particular location. The designer should use the lowest value since the actual infiltration capacity of the soil has been shown to be close to the minimum rate listed in these publications.

Topographic Information: Sufficient information concerning elevation changes land use, and cover must be available to perform a mass runoff analysis when the more complicated sizing procedures referred to earlier are used. On sloping lands these facilities must be built parallel to lines of equal grade perpendicular to the plane of the hill. Otherwise, the sizing procedures discussed previously would not apply. Facilities constructed along the plane of sloping lands are likely to experience extreme problems due to super saturation and potential piping of cover and fill material at the down gradient end of these structures.

Construction Design Criteria

Trench construction criteria for three different soil and geologic conditions are discussed below:

Trenches in Rock: Exfiltration facilities cut into permeable rock are quite often used in the Miami vicinity. These trenches are the least expensive infiltration system to construct; however, the following conditions must be met:

1) The rock must be able to support a specified wheel load on a covering concrete slab or other suitable cover.

2) The rock must be amenable to excavation without blasting, or the cost becomes prohibitive.

The inlet to the system can be placed directly over the slab cover, with discharge directly into the trench (see Figure 6-12). A more acceptable method is to set the inlet and catch basin adjacent to the trench and pipe the inflow to the trench. This technique lessens the introduction of debris into the system. Manhole access must be provided to facilitate cleaning and inspection.

Trenches in Stable Soil: In this type of trench, perforated or slotted pipe is normally used as the conduit. Coarse aggregate between the pipe and trench wall prevents side wall collapse and distributes collected water to the trench walls. Whether the pipe is included or not, the trench is usually 4 to 5 feet in width and of sufficient depth to reach a permeable soil layer.

Coarse aggregate or other free-draining material is generally placed in the bottom of the trench and brought up to a specified pipe flowline grade, generally a minimum of 2 feet. Perforated or slotted pipe is then placed in the trench and the trench is backfilled with the coarse aggregate to the design storage elevation. A typical Dade County installation sometimes

R0071139

includes a 6-inch thickness of finer textured filter material or pea rock placed over the aggregate backfill as shown in Figure 6-11. The trench will normally be covered with a barrier consisting of building felt, tarpaper, or other suitable material to prevent the sand or fill used for cover from piping and possible surface subsidence.

The trench cross-sections shown in Figure 6-11 and Figure 6-12 are typical of most installations in extreme southern Florida. The configuration is applicable in other areas where the soil or substrate is stable and provides sufficient infiltration capacity. Even where infiltration rates are marginal, the system could supplement the drainage requirements of a positive outfall system by storing, and infiltrating a portion of the storm water into the soil; thereby reducing the downstream requirements of the positive system.

Trenches in Cohesionless Soil or Sand: Although trenches in cohesionless soil require a different type of construction, the design, final shape, and size are the same as for a trench in stable soil. However, side slopes of 1.5:1 or 2:1 may be required, if the walls are not shored during construction. Filter cloth must be used along the periphery of the trench to prevent migration of soil fines into the coarse aggregate backfill.

In a trench system where perforated pipe is used, a non-perforated section some 6 to 8 feet in length is used to connect the trench to the catch basin or inlet. This procedure serves to prevent piping near structures and subsidence around the inlet. A concrete slab is generally placed around the catch basin or inlet.

In the design of a trench system, any one of the above types or combination thereof, may be used. It is recommended that a positive overflow pipe or bypass also be provided to allow for large storm events.

General Recommendations:

Proper construction and routine maintenance are extremely important for successful trench applications. A substantial number of trenches have failed shortly after being built, primarily due to poor construction practices, inadequate field testing or because sediment was not filtered or trapped before entering the trench. The discussion below highlights construction and erosion control procedures that should minimize the risk of premature clogging.

1) Before the entire development site is graded, the area planned for the trench should be roped off to prevent heavy equipment from compacting the underlying soils.

2) Diversion berms should be placed around the perimeter of the trench during all phases of construction. Sediment and erosion control plans

for the site should be oriented to keep sediment and runoff completely away from the trench area. Otherwise, actual construction of the trench should not begin until after the site is completely stabilized.

3) The trench should be excavated using a backhoe or trencher equipped with tracks or over-sized tires. Normal rubber tires should be avoided since they compact the subsoil and may reduce infiltration capability. For the same reason, the use of bulldozers or front-end loaders should be avoided.

4) Sediment control is critical. It is therefore important that sediment and erosion controls be inspected following each storm to make sure they still work. If a vegetated buffer strip is planned for pre-treatment of runoff entering the facility, grass should be established immediately, preferably by sodding. When hydroseeding is used, reinforced silt fences must be placed between the buffer and trench to prevent sediment entry before the buffer becomes fully established.

Trench Construction Specifications

Trench construction techniques will vary with local site conditions. Strict adherence to OSHA's Trench Safety Code or other local regulations relative to acceptable construction practice, should be observed. Depending upon the length and width of trench, either backhoe or wheel or ladder type trencher may be used for excavation. Excavated material should be stored at least 10 feet from the trench to avoid backsliding and cave-ins.

Perforated or Slotted Pipe: When perforated pipe is used for conveyance and distribution a liberal number of holes to ensure free and rapid flow in and out of the walls of the pipe should be provided. Large-sized pipe adds to total storage in the trench. The use of a pipe in the trench system also allows for ease of maintenance as described in the next section. The pipe serves as a catchment for sediment without reducing overall efficiency.

Pipes manufactured of plastic, steel, aluminum, concrete or other materials are available for this application. Perforated metal pipes usually have 3/8-inch diameter perforations uniformly spaced around the full periphery of a pipe. Specifications stipulate not less than 30 perforations per square foot of pipe surface. Other perforations not less than 5/16 inch in diameter or slots, are permitted if they provide a total opening area of not less than 3.31 square inches per square foot of pipe surface.

Tentative specifications for slotted concrete pipe with cast slots have been developed based on field performance and cooperative testing by Florida DOT and industry. Concrete pipe with 3/8-inch wide slots is usually specified. Slots should be circumferential in direction, approximately 3/8-inch in width and not less than 4 inches in length at the inside of the pipe. Four rows of

slots are generally specified for pipe 30 inches in diameter or less. Six rows are specified for pipe 36 inches in diameter and larger.

Pipe Backfill: Coarse aggregate backfill material serves to support the sides and top of an infiltration trench following construction. It also provides good bedding for distribution and overflow pipes. Aggregates for this purpose must be sound and comply with FDOT established specifications for durability. The material must provide sufficient void space to allow for the storage of the required volume of runoff. The designer should also allow for the accumulation of the normally encountered fine sands, silts, silty clays, and other material in stormwater to pass through the perforations or slots in the pipe conduit into the backfill during the expected life of the facility.

Clean, washed stone aggregate should be placed in the excavated trench in lifts, lightly compacted to form the base. Unwashed stone has enough associated sediment to pose a clear risk of clogging at the soil/filter cloth interface. Granite, washed pea-gravel or river rock is usually acceptable. Where possible, the use of crushed limestone aggregate should be avoided unless the limestone is washed, contains little or no phosphorus and is of the "hard" variety.

Pea Rock or Gravel: This material is often placed in a 6-inch layer over the top of the aggregate for the pipe backfill as illustrated in Figure 6-11. This layer serves as a filter below the impervious barrier (builders felt). The gradation for this layer should consist of 100% material passing the 1-inch sieve with not more than 5 percent passing the No. 4 sieve.

Synthetic Filter Fabrics:

When fine native materials are encountered in the excavation, a filter cloth envelope or wrap should be placed around the coarse aggregate backfill. This practice serves to prevent migration of fine materials from the surrounding soil that could result in clogging of the trench following reverse flow conditions resulting from high groundwater. A number of plastic woven or non-woven filter fabrics can be used for this purpose. However, care should be taken to prevent tearing or puncture of the fabric. Likewise, adjacent sheets should be well overlapped and secured to prevent openings from developing.

To ensure good performance, synthetic fabrics (either woven or non-woven) must be carefully selected, based on the properties required. As with aggregate filters, fabric filters must provide two very important functions:

1) They must be able to prevent clogging of the drain by the migration of erodible soil or other material from the substrate into the trench, which could also result in erosion, piping, or other problems with the facility being protected; and

2) They must not inhibit the free flow of water.

Care should be taken in selecting the proper kind of filter fabric, as available brands differ significantly in their permeability and strength. If desired, a six inch deep filter of clean, washed sand may be substituted for filter fabric on the bottom of the trench.

Likewise, the use of filter fabric directly surrounding slotted corrugated polyethelene pipe has recently become a popular derivation to the typical exfiltration trench design. In these facilities, sedimentation and filtration of particulates larger than the silt/clay size range takes place within the perforated pipe. Consequently, the pipe is more prone to clogging and large reductions in capacity will occur more often than usual. While this may seem unacceptable, manufacturers point out that the pipe may be cleaned relatively easy using high pressure hoses, vacuum systems, etc. On the other hand, conventional designs require complete replacement when clogging occurs.

Observation Well

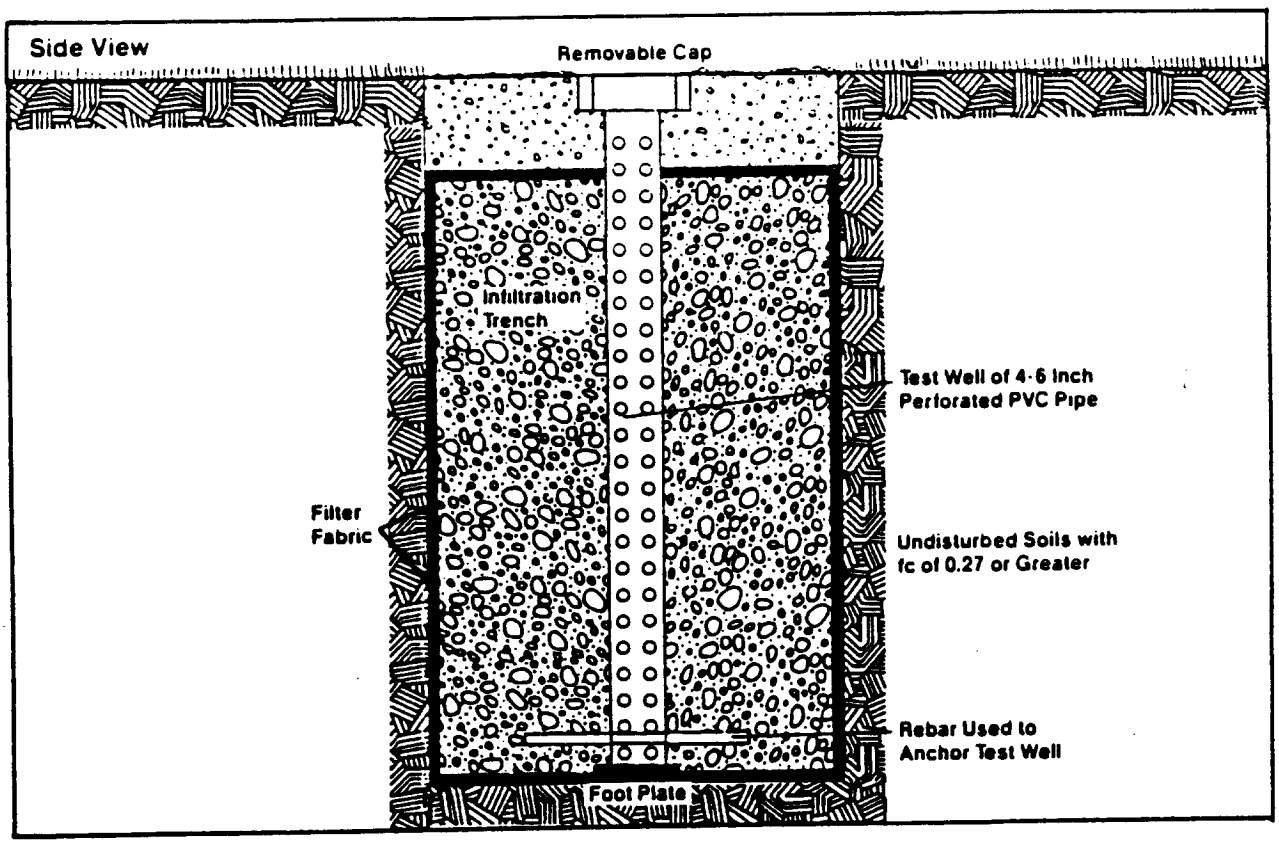
An observation well is recommended for installation in every infiltration trench. The observation well will serve two primary functions:

1) It will indicate how quickly the trench dewaters following a storm; and

2) It will provide a method of observing how quickly the trench fills up with sediments.

A simple observation well may consist of perforated PVC pipe, 4 to 6 inches in diameter. It is usually located in the center of the facility and is constructed flush with the ground elevation of the trench as shown in Figure 6-15. The top of the well should be capped to discourage vandalism and tampering.

The observation well is needed to monitor the performance of the trench. It is also useful in marking the trench location. The drain time for a trench can be measured by placing a graduated dip-stick down the well immediately after a storm and again twenty-four and forty-eight hours later.



For the first year after completion of construction, the well should be monitored on a quarterly basis and after every large storm. It is recommended that a log book be maintained indicating the rate at which the facility dewaters after large storms and the depth of the well for each observation. Once the performance characteristics of the structure have been verified, the monitoring schedule can be reduced to an annual basis, unless the performance data indicate that a more frequent schedule is required.

A monitoring well in the top foot of stone aggregate will be required when the trench has a stone surface. Sediment build-up in the top foot of stone

R0071143

FIGURE 6-15

Detailed Schematic of a Typical Observation Well

Source: Schueler (1987)

R0071144

aggregates or the surface inlet should be monitored on the same schedule as the observation well. Sediment deposited shall not be allowed to build up to the point where it will significantly reduce the rate of infiltration into the trench.

Overflow: Unless the facility is designed to accommodate the total amount of anticipated runoff from a large design storm, some provisions should be made for overflow. In order to have maximum benefit in reducing downstream flood peaks, these structures should be designed to overflow before the total storage capacity is reached. There are many ways to accomplish this. Pipes can be used, for instance, to connect a sequence of infiltration facilities so that when the first one fills, it passes water through to the next one, and so on. Generally, several smaller facilities are more effective than one large one, though the latter may be necessary when there are space limitations. The capacity and cost of overflow discharge systems can be reduced by allowing temporary storage space above the infiltration trenches.

Because of the small drainage areas controlled by the exfiltration trench, an emergency spillway usually is not necessary. In all cases, however, the overland flow path of any surface runoff exceeding the capacity of the trench should be evaluated to preclude the development of an uncontrolled, erosive watercourse.

Seepage Analysis and Control

An analysis shall be made to determine any possible adverse effects of seepage zones when there are nearby building foundations, roads, parking lots or sloping sites. Developments on sloping sites often require the use of extensive cut and fill operations. The use of infiltration trenches on fill sites with steep slopes is not recommended. Fill areas can be very susceptible to slope failure due to slippage along the interface of the in-situ soil and the fill material. This condition could be further aggravated if the fill material is allowed to become saturated using retention practices. The methods for seepage analysis and estimation of infiltration rates using Darcy's law and flow nets can be used to conduct the seepage analysis.

When exfiltration trenches are used in residential areas, special care must be taken to prevent seepage from causing unstable soil conditions near foundations. Trenches three or more feet deep shall be located at least 10 feet down gradient from foundation walls.

Maintenance

Preventive maintenance is vital to the continued effectiveness of infiltration facilities. The use of pretreatment measures to filter out

suspended materials that might clog the facilities is necessary because once void areas become clogged, maintenance entails a complete replacement of the filler material. The use of filter fabrics over the surface of an infiltration trench that is open to the surface for runoff can be most effective in keeping objectionable material from entering the facility. Of course, periodic cleaning or replacement of clogged filter fabric will be necessary.

Routine Maintenance

The routine maintenance requirements of trenches are not great. However, getting property owners to actually perform them may be very difficult. Trenches are smaller and more inconspicuous than most other BMPs, and when located underground, they may not be visible or accessible. As a result, residents or homeowner associations are not likely to exhibit much concern over trench maintenance as they might for more visible BMPs, such as detention ponds. For these reasons, a public sector commitment to regularly inspect privately owned trenches is a necessity. Property owners and associations will need to be educated about the function and maintenance requirements of the trench. A legally binding maintenance agreement should be included with the property deed that clearly describes maintenance tasks and schedules. Further, the agreement should grant access for regular inspections, and enable the public sector to perform maintenance (and bill the owners) if the trench has been neglected. Some of the normal maintenance tasks for trenches are detailed below.

Inspection

The trench should be inspected several times in the first year of operation, and at least annually thereafter. The inspections should be conducted after large storms to check for surface ponding that might indicate local or wide spread clogging. Water levels in the observation well should be recorded over several days to check trench drainage. Surface trenches can be inspected by hand by digging with a trowel down to the first layer of filter fabric located one foot below the surface.

Buffer Maintenance

The condition of the grass buffer strips used in conjunction with trenches should be inspected regularly. Growth should be vigorous and dense. Bare spots, or eroded areas, should be reseeded or re-sodded. Watering and/or fertilization should be provided during the first few months after the strip is established, and may periodically be needed in times of drought.

Mowing

Grass filter strips should be mowed regularly to prevent the uncontrolled growth of briars and weeds which make inspections difficult, as well as,

reduce aesthetic values. Filter strips in residential or commercial areas will need to be mowed more frequently (10 to 14 times per year). Filter strip performance will be impaired if the grass is cut too short. To prevent lawn clippings from clogging the trench, mowers should be equipped with baggers.

Sediment Removal

The pre-treatment inlets of underground trenches should be checked periodically and cleaned out when sediment depletes more than 10% of available capacity. This can be done manually or by a vacuum pump. Inlet and outlet pipes should be checked for clogging and vandalism.

Tree Pruning

Adjacent trees may need to be trimmed if their branches extend over a surface trench such that falling leaves would be likely clog the grate or top of the facility. In addition, pioneer trees that start to grow in the vicinity of a trench should be removed immediately thereby avoiding root puncture of the filter fabric through which sediment might enter the structure.

Non-Routine Maintenance

The primary non-routine maintenance task involves rehabilitation of the trench after it becomes clogged. There is no reliable estimate as to how long trenches will function before they clog. Emphasis throughout this chapter has been on designs and procedures which minimize the likelihood of clogging. However, it is probable that the longevity of trenches may be on order of ten years at best.

Clogging in surface trenches is most likely to occur near the top of the trench, between the upper layer of stone and the protective layer of filter fabric. Surface clogging can be relieved by carefully removing the top layer of stone, removing the clogged filter fabric, installing new filter fabric, and cleaning or replacing the top stone layer. The costs for rehabilitating a surface trench would usually not be expected to exceed 20% of the initial construction cost.

Clogging of underground trenches is a much more serious problem as it is likely to occur at the bottom of the trench, at the filter fabric/soil interface. Rehabilitation of an underground trench requires the removal of the pavement or the topsoil/vegetation layer, the protective plastic layer, the stone aggregate, and the bottom filter fabric layer. Then, the subsoil layer must be tilled to promote better infiltration, and each layer must be replaced. If pavement or concrete constitute the surface layer (instead of topsoil/grass), the rehabilitation effort becomes more difficult and costly.

R0071147

Total Maintenance Costs

No reliable data is presently available to assess maintenance costs for trenches. Routine maintenance costs will probably run higher for surface trenches than underground trenches, primarily due to the frequency. As noted before, the opposite is probably true for non-routine maintenance tasks. It is reasonable to assume that the cost of rehabilitating an underground trench will be roughly equivalent to the initial construction cost. Surface trench rehabilitation should be approximately 20% of the initial construction cost; however, there are reasons to expect that the clogging of surface trenches may occur more frequently.

If it is assumed that surface and underground trenches will need rehabilitation every five to fifteen years, respectively, then an annual maintenance set-aside of 5% - 10% (surface trenches) and 10% - 15% (underground trenches) of the initial construction cost may be needed to cover routine/non-routine maintenance expenditures. It must be emphasized that these estimates are highly uncertain. Until more local experience is obtained, the issue of trench maintenance costs remains largely speculative.

SW BMP 3.04

SWALES USED FOR EROSION AND POLLUTION CONTROL

Definition

A) Swales or grassed waterways are natural or constructed conveyances shaped or graded to required dimensions and established in suitable vegetation for the safe disposal and treatment of runoff.

B) Chapter 403 F.S. and Chapter 17-25 F.A.C. further defines the term "swale" by requiring a cross-section with a top width to depth ratio of 6:1 or greater or side slopes of three horizontal to one vertical or flatter. In addition, these rules also specify that the conveyance must only contain standing or flowing water following a storm, be planted with or have stabilized vegetation, and be designed to prevent erosion and reduce pollutant concentration.

Historical Perspective and Purpose

A) "Grassed waterways" are used primarily for erosion control as safe outlets for conservation practices such as terraces in agricultural areas.

B) It is the usual practice to use existing topographic draws and rework when needed.

C) With slight modification, swales/waterways can be used for the treatment and removal of pollutants from stormwater runoff in urban situations.

Conditions Where Practice Applies

All sites where added capacity, vegetative protection or both are required to control erosion and/or reduce the pollutant load from concentrated stormwater runoff; and, where such control can be achieved by the use of this practice alone or in combination with others. Example uses include: as outlets for diversions and terraces; as conveyances to or outlets from surface and subsurface detention and filtration systems; to dispose of stormwater collected along roadways or discharged from residential areas; to rehabilitate or stabilize natural draws carrying concentrations of runoff to provide for or improve percolation and treatment of stormwater; and as pretreatment practices to reduce stormwater pollutant loads before conveying stormwater to other management practices.

R0071149

Typical Residential Roadside Swale with
Drop Inlet Slightly Raised for Storage

Fringing Swale to Provide Pretreatment of Runoff
Entering a Stormwater Detention Pond or Lake

Planning Considerations

The grass-lined waterway or swale is one of the basic conservation practices historically used by farmers. When rainfall exceeds the rate or volume at which the soil can take in and store moisture, surplus water will pass over the land in the form of runoff. In agricultural areas this practice is primarily intended for removal of this surplus water without undue erosion or flooding. Conventional agricultural waterways can be slightly modified to slow the runoff velocity such that sedimentation, filtration of the runoff through vegetation, and percolation can take place thereby allowing swales to provide stormwater treatment in urbanizing watersheds.

Generally the use of swales is limited to slopes of less than 10% and drainage areas of less than 150 acres (60 hectares). Design and engineering problems can be expected where the velocity or the volume of discharge is too great so as to cause erosion or limit pollutant removal via sedimentation, vegetative filtration, and/or percolation. In these circumstances the gradient may be reduced and/or pollutant removal capability improved by the introduction of spillways, check dams, elevated driveway culverts, or other control structures designed to reduce the velocity between each section of the waterway, making the grass lining more feasible and increasing the time for percolation.

To be effective in removing stormwater pollutants, swales must not be subjected to low flows of long duration nor kept wet for long periods. This will kill the vegetation and saturate the soil reducing pollutant removal. A tile drain beneath the channel or other means of providing drainage and protecting the center of the waterway should be considered when planning and designing swales for sites where a high water table or seepage problems are expected.

The successful swale system is dependent on good stormwater treatment throughout its watershed. Good management practices reduce the peak rate of runoff and the volume of water to be carried, percolated, or filtered by the waterway. The swale should be protected by using a combination of the following steps depending on what best fits the needs of the site:

- Construct the waterway in advance of any other channels or facilities that will discharge into it.
- Divert all flow from the waterway during the establishment period.
- Establish the vegetative cover according to recommended techniques. See TEMPORARY SEEDING (ES BMP 1.65), PERMANENT SEEDING (ES BMP 1.66) and SODDING (ES BMP 1.67).
  - Protect the channel seeding with mulch (manure, stubble,

straw, jute netting, or wired and staked mulch).

- Sod the channel.

- Use a portable or temporary sprinkler line to irrigate the new seeding or sodding to ensure and hasten establishment.

° Reduce the required capacity by dividing the runoff between two or more outlets when needed.

° Use stable natural topographic conveyances where possible.

° Maintain vegetative cover by mowing and performing other maintenance work as needed.

The most satisfactory location for a waterway is in a well vegetated natural draw. These locations should be used where possible since they have one or more of the following advantages:

° Flattest grade in the immediate area.

° Most stable channel conditions.

° Soil and moisture conditions most favorable to vegetative growth.

° Usually are available for immediate use.

° Sufficient depth for outletting diversions, terraces or other treatment facilities at grade.

The natural waterway into which the draw flows may need to be shaped, enlarged and stablized to accommodate the increased flow delivered to it. However, the natural waterway should not be altered without checking with the Department of Environmental Regulation to see whether a dredge and fill, stormwater or other permit will be required.

A grassed strip or border may be used in lieu of a constructed or natural channel. However, the surface of such areas should be checked to ensure that a uniform surface of adequate width is available to spread the flow, and that the type and density of vegetation is adequate to withstand the expected velocities and/or provide an adequate level of percolation for pollution control.

An area of land parallel to the project boundary is frequently used to provide an outlet for secondary conveyances that cannot be extended to a natural draw. In all cases the outlet should be away from buildings or other critical areas. The designer should always avoid the use of a gullied

R0071152

natural draw that would be impractical to control. Likewise, existing road ditches for the disposal of runoff water should be checked to ensure that they have adequate capacity. They should be avoided unless the channel is stable and in conformance with these design requirements, state regulations specified for this practice and overall stormwater treatment requirements.

Waterways are frequently planned where the slope is variable and where there is a wide difference in the watershed area at various points along the channel. In such cases, the waterway is designed in reaches. A reach is usually a portion of the channel having a near-uniform slope and drainage area. A point of significant break in slope is a point of division between two reaches. The point of entrance of a diversion or other tributary where the watershed area is significantly increased also may be a point of division between two reaches. Where there is a significant difference in velocity or capacity between adjoining reaches, it may be necessary to install a transition section between them.

Design Criteria

Design for conventional purposes involves calculating the peak runoff expected from a design storm (usually a ten year, 24-hour event) and checking the velocity and channel discharge capacity to ensure that erosion and flooding will be avoided.

Design for pollution control requires that the waterway also be capable of percolating a substantial amount of runoff. Therefore:

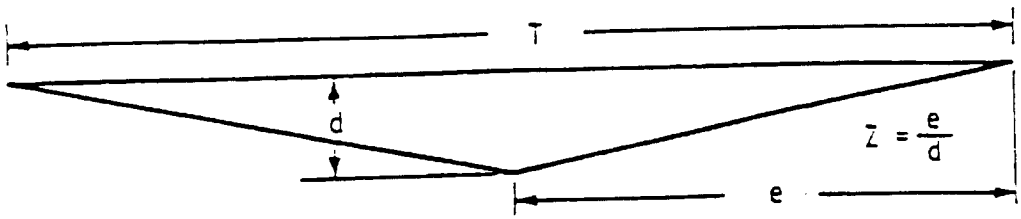
- Estimation of the percolation rate is critical to the design procedure.
- The state stormwater rule, FAC Chapter 17-25, requires that 80% of the three year, one-hour design storm be percolated.

Typical waterway shapes are illustrated in Figure 6-16.

Preliminary Design Needs or Basic Data

1) A survey must be performed to provide relevant watershed information for locating and sizing the waterway.

2) Information obtained should include drainage area or watershed boundaries of the contributory area, soil types, ground cover and slopes.



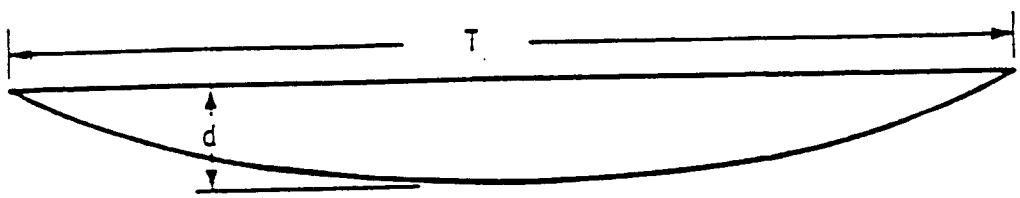
3) The original ground surface should be profiled in enough detail to permit dividing the waterway into reaches of uniform slope and shape.

FIGURE 6-16

Typical Waterway Shapes and Mathematical Expressions for Calculating Cross-sectional Area, Top Width, and Hydraulic Radius

CHANNEL GEOMETRY

V - Shape

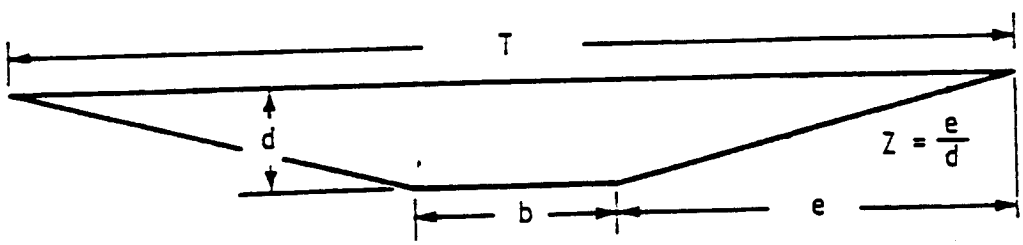


Cross-Sectional Area (A) = Zd^2

Top Width (T) = $2dZ$

Hydraulic Radius (R) = $\frac{Zd}{2\sqrt{Z^2 + 1}}$

Parabolic Shape



Cross-Sectional Area (A) = $\frac{2}{3}$ Td

Top Width (T) = $\frac{1.5\ A}{d}$

Hydraulic Radius = $\frac{T^2 d}{1.5T^2 + 4d^2}$

Trapezoidal Shape

Cross-Sectional Area (A) = $bd + Zd^2$

Top Width (T) = $b + 2dZ$

Hydraulic Radius = $\frac{bd + Zd^2}{b + 2d\sqrt{Z^2 + 1}}$

Source: USDA-SCS

R0071154

4) This survey should also provide data to enable the designer to determine the adequacy of the outlet or receiving stream into which the waterway discharges. Information should include tne slope and cross-sectional area of the receiving channel and notes of tne following:

   A) Irregularities of the channel cross-section (i.e., lack of uniformity)

   B) Obstructions

   C) Vegetation

   D) Meandering

   Adjustments should be made by the designer to account for such situations.

Example Design Procedure

The design of a swale involves sizing for erosion control and then checking to ensure adequate area is available for percolation to meet pollution control objectives.

Suppose a system of swales is needed for a 10 acre (660 ft. x 660 ft.) single family residential project with 1/4 acre lots. The site survey indicates that the soils are in hydrologic soil group B (e.g. Orangeburg). The pervious area consists of lawns in good condition, the slope is uniform at 3% (.03 ft/ft) and the project is located in Tallahassee. There are three streets which span this small development. Swales are planned to provide drainage and stormwater treatment on each side of all three streets.

Determine the size conveyance required to safely dispose of the ten year, 24-hour design storm without exceeding the channel capacity and the maximum permissible velocity for the type of vegetative lining. Assume the slope approximates that given for the project area and the ground cover desired is bermuda grass.

Step #1: **Determine the peak discharge expected from the ten year/recurrence interval design storm.**

Many methods are available to the engineer for estimating peak runoff as discussed in Chapter 5. The procedures developed by the Soil Conservation Service (SCS) for small watersheds up to 2000 acres would be suitable for the example above. The Rational or Runoff Coefficient Method is another, but only for small watersheds.

R0071155

Description

Step #

1-1: Determine the magnitude of rainfall associated with the design storm.

A) NOAA 24-hour maximum rainfall distribution charts are used in the SCS procedure (Figure 6-17).

B) FDOT Intensity Duration Frequency (IDF) Curves are used in application of the Rational Method (Figure 6-18). NOAA maps for different return periods and IDF charts for each zone of precipitation are included in Chapter 5.

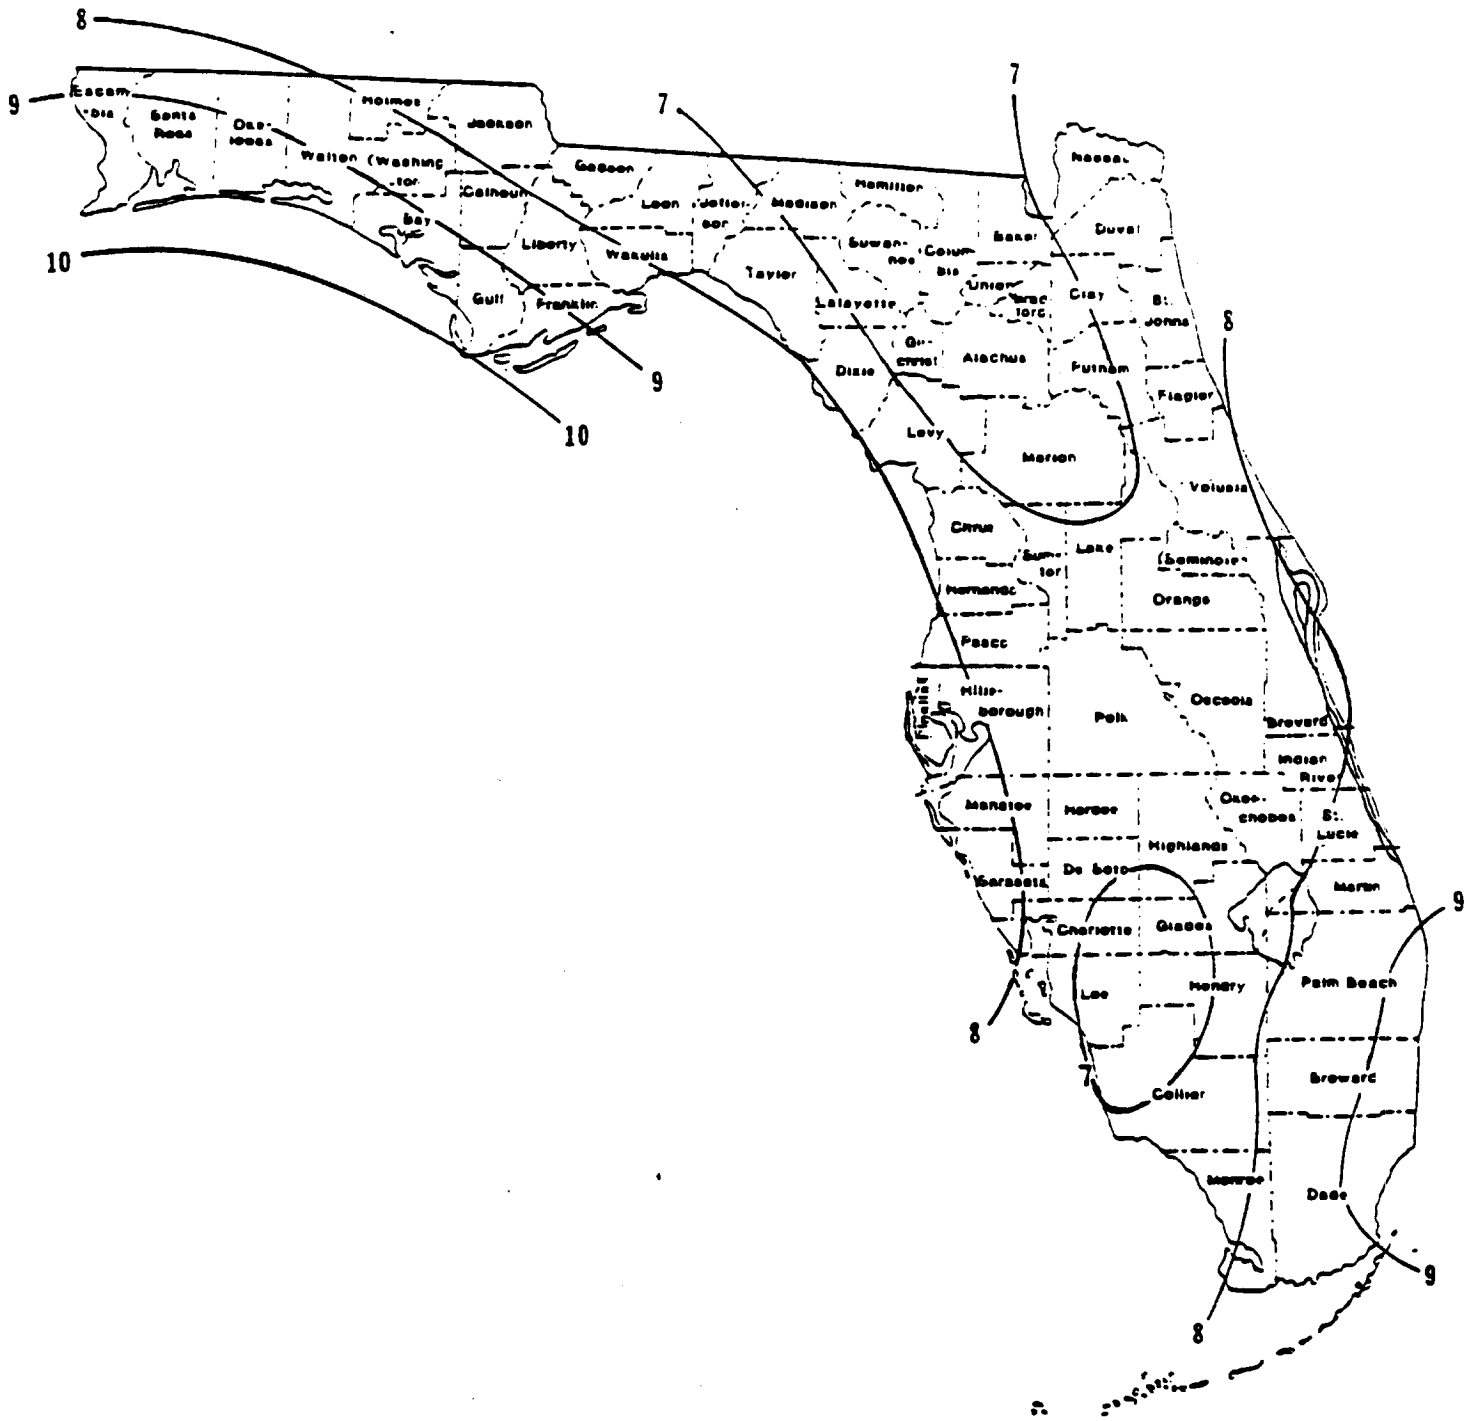
When using the Rational Method for peak discharge calculations the designer must first determine the time of concentration (Tc) in hours. The storm duration which is viewed to produce the highest peak discharge of runoff is the duration equal to "Tc" otherwise known as the rainfall intensity averaging time. Procedures for calculating Tc are also presented in Chapter 5. For this example assume the time of concentration (Tc) expected after development is approximately 18 minutes or 0.30 hours.

Example Question: Given that the project is located in Tallahassee, what is the magnitude and intensity (I) of precipitation (P) associated with the ten year design event?

Answer: P = 7.5 in. based on the NOAA map.
I = 6.0 in./hr. based on the FDOT Intensity-Duration Frequency curve for Zone 2/and Tc = 18 min. = duration

1-2: **Determine the SCS curve number (CN) or the rational coefficient (C).**

Tables of both CN and C can be found in many references and manuals. Table 6-5 lists a range of CN's for various land use types and hydrologic soil groups (HSG's). Table 5-1 found in the preceding chapter lists appropriate values for the coefficient of runoff (C) for various land cover classes.



Problem: Using Table 6-5 and 5-1 determine the Curve Number and the Runoff Coefficient for the project described previously. Assume average antecedent moisture condition II; Orangeburg = HSG-B for estimating CN.

Good (Woods are protected from grazing and litter and brush adequately cover the soil)	.....	30	55	70	77

[1]Average runoff condition, and $I_a = 0.2s$.

[2]The average percent impervious area shown was used to develop the composite CN's. Other assumptions are as follows: impervious areas are directly connected to the drainage system, impervious areas have a CN of 98, and pervious areas are considered equivalent to open space in good hydrologic condition. CN's for other combinations of conditions must be computed.

[3]CN's shown are equivalent to those of pasture. Composite CN's may be computed for other combinations of open space cover type.

(Source: USDA. Soil Conservation Service, TR-55, Second Ed., June 1986)

R0071160

Solution: CN = 75

C = 0.30-0.50 (Single Family Residental Areas)

Larger more complex areas or watersheds require the designer to determine a weighted average CN. In the example below, the curve numbers shown are for hydrologic soil group C. This information is presented to illustrate the averaging procedure. The resulting value is not intended for use in the sequence of example problems which follow. CN = 75 will be used in these instances.

LAND USE	PERCENT	CURVE NUMBER	PRODUCT
Detached houses with lot size 1/4 acre	50	83	4,150
Streets with curbs, plazas, etc.	25	98	2,450
Townhouses with lot size 1/8 acre	10	90	900
Open space, parks, etc.	15	74	1,110
	100		8,610

Weighted CN = $\frac{8,610}{100}$ = 86

1-3: **Determine the depth of runoff** by using Table 6-6 which lists the solution to the SCS runoff equation for a range of CN's and rainfall amounts. Given that rainfall equals 7.5 inches and the Curve Number equals 75, what is the total amount of runoff (RO) expected?

Answer: (RO) = 4.6 in.

1-4: **Determine the maximum discharge expected from the design storm.**

A) When using the Rational Method the peak discharge is calculated according to the following equation:

$$Qp = CiA$$

The appropriate input value for the rainfall intensity (i = 6.0 in./hr.) and the range of the runoff coefficient (C - 0.30 - 0.50) was specified in step 1-1 and 1-2 of this example. Be conservative in selecting (C). In this case presume that C = 0.50.

INTERPOLATE THE VALUES SHOWN TO OBTAIN RUNOFF DEPTHS FOR CN'S OR RAINFALL AMOUNTS NOT SHOWN.

(SOURCE USDA. SOIL CONSERVATION SERVICE, TR-55, SECOND ED., JUNE 1986)

R0071162

Substituting tne values for "C" and "i" into tne equation, this (10-acre) project would be estimated to have the following associated peak discharge:

Qp = 0.50 x 6 in./hr. x 10 ac = 30 cfs
(Note: 1 ac.in./hr. = 1 cfs)

However, this value would be divided uniformily among each of the six swale systems serving the project. The designer may proceed to step #2 at this point.

B) If using the SCS procedure the designer must first determine the unit peak discharge (UPD) expected from the design storm. The most simple and easily derived projections may be accomplished by using Figure 6-19. This graphical solution to predictive equations for peak discharge was developed by the SCS to calculate the unit peak discharge for uniform watersheds where the runoff can be represented by one curve number.

The input requirements for the Graphical Method are as follows:

1) Time of concentration "Tc" (hrs.)

2) Drainage area (sq. mi.)

3) Appropriate rainfall distribution (Type I, IA, II, or III)

4) The 24-hour rainfall (inches); and

5) Curve Number (CN)

If pond and swamp areas are spread throughout the watershed and are not considered in the Tc computation, an adjustment for pond and swamp areas is also needed.

In this example the value of Tc = 0.30 hours was determined in step 1-1B. The drainage area of ten acres (previously specified) must be converted to square miles. The appropriate rainfall distribution may be determined based on the geographic boundaries shown on Figure B-2 of TR-55 (SCS, 1986). In this instance the location (Tallahassee, Leon County) lies along the boundary for the Type III rainfall distribution. The 24-hour rainfall value (P = 7.5 inches) was specified in the example for step 1-1(b). Lastly, the curve number (CN = 75) was previously established during step 1-2.

To use Figure 6-19, the designer must first determine the initial abstraction (Ia) from Table 6-7 based on the curve number. The decimal ratio Ia/P is then computed.

TABLE 6-7

I_a Values for Runoff Curve Numbers

CURVE NUMBER	I_a (IN)	CURVE NUMBER	I_a (IN)
40	3.000	70	0.857
41	2.878	71	0.817
42	2.762	72	0.778
43	2.651	73	0.740
44	2.545	74	0.703
45	2.444	75	0.667
46	2.348	76	0.632
47	2.255	77	0.597
48	2.167	78	0.564
49	2.082	79	0.532
50	2.000	80	0.500
51	1.922	81	0.469
52	1.846	82	0.439
53	1.774	83	0.410
54	1.704	84	0.381
55	1.636	85	0.353
56	1.571	86	0.326
57	1.509	87	0.299
58	1.448	88	0.273
59	1.390	89	0.247
60	1.333	90	0.222
61	1.279	91	0.198
62	1.226	92	0.174
63	1.175	93	0.151
64	1.125	94	0.128
65	1.077	95	0.105
66	1.030	96	0.083
67	0.985	97	0.062
68	0.941	98	0.041
69	0.899		

In this example the value (I_a/P = .67/7.5 or 0.09) is outside the range of curves included with Figure 6-18. Consequently, the graph (I_a/P = .10) should be used.

The unit peak discharge per square mile per inch of runoff is obtained from Figure 6-18 by using T_c = 0.30 hrs., rainfall distribution type

R0071164

III, and I_a/P ratio = .10. Assume that ponding is not a factor in the watershed following development. Select the appropriate Tc (0.3 hrs.) and proceed vertically up the chart to where the line crosses the curve (Ia/P = .10), then read the value of discharge recorded on the left. Note that the units are in cfs/square mile of drainage area/inch of runoff (csm/in.).

Unit Peak Discharge (UPD) = 500 csm/in.(approximately).

C) To calculate total peak discharge, convert acreage of the project to square miles (mi^2).

Note: $\frac{\text{Acreage}}{640} = mi^2$, therefore, $\frac{10 \text{ Ac.}}{640 \text{ Ac/mi}^2} = 0.016 \text{ mi}^2$

Determine total discharge by using the following equation:

mi^2 x RO (in.) x UPD ($cfs/mi^2/in.$)=Total Peak Discharge (cfs)

Total Peak Discharge = 37 cfs.

This value represents the minimum design discharge capacity for a single waterway at the outlet. However, in regard to each lateral, the drainage is to be evenly divided between six swales each 660 ft. long. Consequently each reach must be capable of handling only 6.2 cfs without exceeding the erosive velocity.

Step #2

Both the capacity of the channel and the velocity of flow are functions of the channel lining, its cross-sectional area, and its slope. The task of the designer is to determine a channel section and lining which will have sufficient discharge capacity and be stable for a given slope.

Two equations are used to calculate the flow in open channels. They are:

(1) Manning's Equation, $V = \frac{1.49}{n} R^{2/3} S^{1/2}$

Where,

V = the average velocity in the channel (ft/sec)
n = Manning's roughness coefficient, based upon the lining of the channel
R = the hydraulic radius (ft)
S = the slope of the channel (feet/foot)

(2) Continuity Equation, $Q = AV$

Where,

Q = flow in the channel (ft^3/sec)
A = cross-sectional area of the channel (ft^2)
V = average velocity in the channel (ft/sec)

Manning's Equation and the Continuity Equation are used simultaneously to determine flow capacity and velocity in the channel. The methodology is suitable for determining a cross-section and lining for straight, uniform channel reaches with a constant slope.

The following is a step-by-step procedure for designing a stormwater conveyance channel using the Manning's and Continuity Equations:

Step #	Description

2-1: Select a channel cross-section shape and lining and determine the slope.

A) Select a Channel Cross-Section: The three most commonly used channel cross-sections are vee, parabolic, and trapezoidal shapes. Figure 6-11 gives mathematical formulas for determining the area, hydraulic radius and top width of these shapes. Parabolic shapes are the most common and generally are the most satisfactory. It is a more natural shape and low flows are less likely to meander. Trapezoidal sections tend to revert to parabolic sections over time. For this exercise assume that the designer has selected a parabolic shape cross-section.

B) Select a Channel Lining: For design purposes, erosion resistance is a function of flow velocity in the channel. There are a number of possible linings to choose from. Commonly used channel linings include grass, riprap and concrete.

Concrete and similar structural linings generally do not erode and their design is not restricted by maximum permissable flow velocities. However, these areas cannot be counted as a part of the functional treatment component of a swale since they lack capacity for pollutant removal. Riprap and grass-lined channels do have maximum permissible velocities beyond which they will erode. It was specified earlier that the lining selected would be bermuda grass.

C) Determine Channel Slope: The slope of the channel is generally fixed by the topography and proposed route of the channel. However, slope modification may often need to be considered to allow greater percolation to meet pollution control objectives.

The slope was noted earlier to be 3% (i.e., .03 feet/foot).

Therefore:

A parabolic waterway with a bermuda grass lining and a 3% slope represents the design conditions.

2-2: Determine the maximum permissible velocity (V) for the grass to be used (Table 6-8). Enter the table in the appropriate slope category (0-5%) and read the maximum rate recorded opposite the type of cover or lining to be used (bermuda).

Permissible Velocity (V) = 6 ft/sec

2-3: Determine an initial channel size (area (A), top width (T), and depth (d). Initial estimates of the cross-sectional area follows:

A = Q/V or 6.2 cfs/6 (ft/sec)

A = 1.03 ft^2

However, an area larger than 1.0 ft^2 should be assumed initially since the capacity and velocity will be calculated with different roughness coefficients. Try A = 2 square feet.

To complete the evaluation the designer must also specify the top width (T) and depth (d) of the conveyance. Assume an initial top width. In this case try T = 4 ft. The depth (d) can be determined from equations listed on Figure 6-16. Use the information listed for parabolic shapes.

$T = \frac{1.5\ A}{d}$ Therefore: $d = \frac{1.5\ A}{T}$

In this case d = 0.75 ft

To be in compliance with state stormwater treatment criteria outlined in 17-25 F.A.C., parabolic and "V" shaped swales must have a top width to

R0071167

oth ratio of 6:1 or larger. Therefore, if the designer desires to hold e top width (T = 4 ft), the depth (d = 8 in.) must be used to satisfy ate criteria.

Given these dimensions then:

$$A = 2/3\ Td = 1.8\ ft^2$$

2-4: Calculate the hydraulic radius (R) of the channel (e.g. cross-sectional area divided by the wetted perimeter). Equations are listed with Figure 6-16.

$$\text{Hydraulic Radius } (R) = \frac{T^2 d}{1.5\ T^2 + 4d^2}$$

$$R = \frac{(4)^2\ (0.67)}{1.5\ (4)^2 + 4\ (0.67)^2} = \frac{10.72}{25.80}$$

$$R = \underline{0.42}\ ft$$

2-5: Use Table 6-9 and Figure 6-20 to determine n. Assume a retardance Class B for calculating capacity and a retardance Class D for checking velocity.

Note that in using Figure 6-20 you must first determine the product of the permissible velocity and hydraulic radius (R).

$V \times R = 6\ fps \times 0.42\ ft = \underline{2.52}\ ft^2/sec$
$n = \underline{0.087}$ (retardance Class B for checking capacity)
$n = \underline{0.043}$ (retardance Class D for checking velocity)

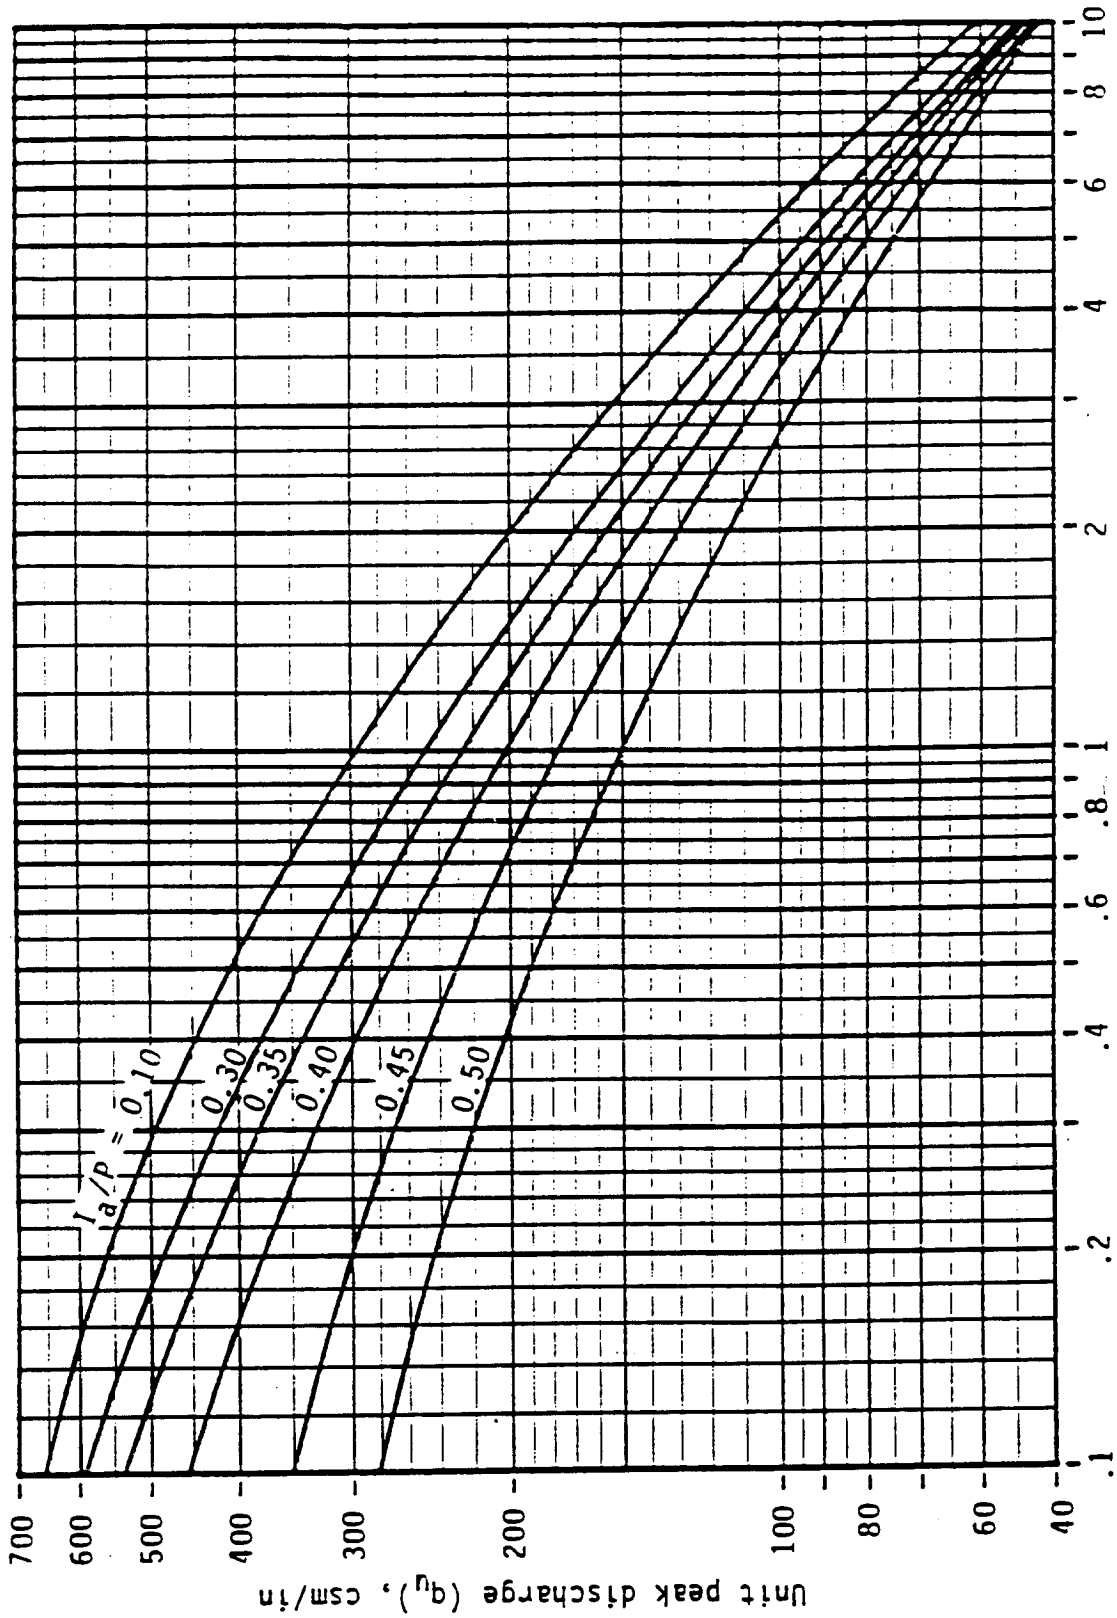
2-6: Check capacity against required discharge capacity determined in Step 1-4.

$$Q = \frac{1.49}{n} (R)^{2/3} (S)^{1/2} A$$

$$= \frac{1.49}{0.087} (0.42)^{2/3} (0.03)^{1/2} (1.8)$$

$Q = \underline{3.0}$ cfs, which is less than 6.2 cfs required.

2-7: Check velocity against permissible velocity (6 ft/sec)



$$V = \frac{1.49}{n} (R)^{2/3} (S)^{1/2}$$

$$= \frac{1.49}{0.043} (0.42)^{2/3} (0.03)^{1/2}$$

$$= 3.4\ ft/sec$$

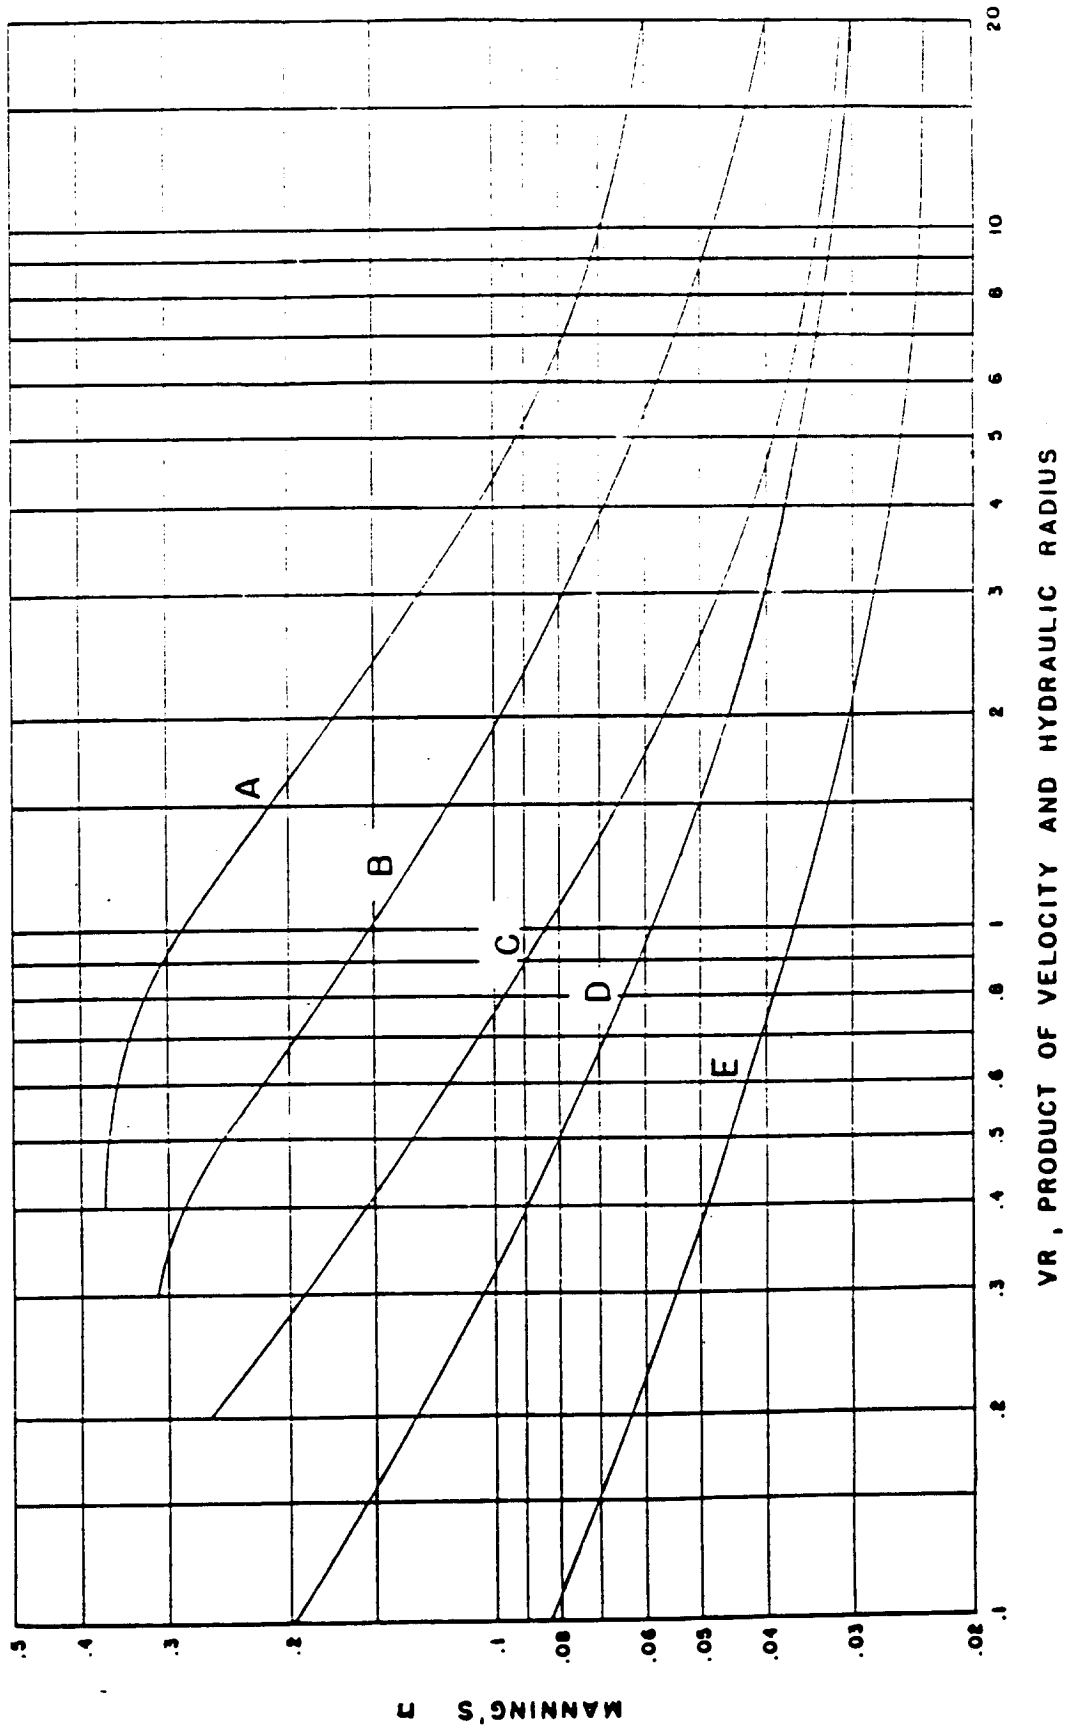
	Sericea lespedeza	2.5 ft/sec
	Annual lespedeza	2.5 ft/sec
	Small grains (temporary)	2.5 ft/sec
5-10%	Bermudagrass	5 ft/sec
	Bahia	4 ft/sec
	Bluestem (broomsedges)	4 ft/sec
	Grass-legume mixture	3 ft/sec

TABLE 6-9

CLASSIFICATION OF VEGETATION COVER AS TO DEGREE OF RETARDANCE



RETARDANCE CLASS	COVER	CONDITION
A	Bluestem (broomsedges)	Excel. stand, tall (average 36")
B	Bermudagrass or Bahia	Good stand tall (average 12")
	Native grass mixture (bluestem, vasey grass and other long and short wet prairie grasses)	Good stand, unmowed
	Lespedeza sericea	Good stand, not woody, tall (average 19")
C	Bahia	Good stand, uncut (6-8")
	Bermuda grass	Good stand, mowed (average 6")
	Centipede grass or St.Augustine	Very dense cover (average 6")
D	Bermudagrass or Bahia	Good stand, cut to 2.5" height
	Lespedeza sericea	After cutting to 2" height. Very good stand before cutting.
E	Centipede grass or St. Augustine	Good stand, cut to 1.5" height

FIGURE 6-20

Manning's "n" Related to Velocity, Hydraulic Radius, and Vegetal Retardance
(Source: USDA., SCS - FL)

R0071171

$$V = \frac{3.4}{} \text{ ft/sec}$$

In this case the permissible velocity (6 ft/sec) is not exceeded but the swale must be redesigned since it will not have the required conveyance capacity.

Try a new parabolic cross-section with a top width of 6 ft. and a depth of 1.0 ft.

Return to Step 2-4.

$$R = \frac{T^2 d}{1.5T^2 + 4d^2} = \frac{36}{(1.5)(36) + 4(1)^2} = \frac{36}{58} = .62$$

Proceed to Step 2-5

$V \times R = 6 \times .62 = 3.72$
$n = .072$ (for retardance Class B)
$n = .038$ (for retardance Class D)

Recheck capacity as in Step 2-6.

$$Q = \frac{1.49}{n} (R)^{2/3} (S)^{1/2} A$$

New $A = 2/3\ Td = 2/3\ (6)(1) = 4.0$ sq. ft.

$$Q = \frac{1.49}{.072} (.62)^{2/3} (.03)^{1/2} (4/0)$$

Q = 10.4 cfs which is greater than 6.2 cfs required capacity

Recheck permissible velocity

$$V = \frac{1.49}{.038} (.73) (.17)$$

= 4.9 ft/sec which is less than 6 fps

Final swale design for erosion control is a parabolic cross section that is 1 ft. deep and with a 6 ft. top width.

Channel dimensions may also be determined using procedures and charts for waterways outlined in Chapter 7 of the Soil Conservation Service Engineering Field Manual. A discussion of these SCS procedures and the appropriate tables and figures may be found in Appendix 6-4 at the end of this chapter.

Step #3

As required by Chapter 17-25, once the conveyance has been sized to safely transport the required flow of water, the design must be checked to determine the swale's ability to percolate water.

Several studies conducted by the University of Central Florida for the Florida Department of Transportation document the importance of percolation as the primary mechanism for pollutant removal in roadside swale areas. Other research by the United States Geological Survey in Dade and Broward counties, the Tallahassee Leon County 208 program and Brevard County 208 program support this finding. Anderson (1982) states "Favorable soil conditions which enhance substantial infiltration are controlling criteria for swale system placement. Varying soil moisture affects runoff curve numbers, soil moisture storage depletion capacity and infiltration capacity. The combination of the above site-specific parameters determines the applicability and effectiveness of swale systems for stormwater quantity and quality control". He further concludes that an appropriate input to swale design methodology is a specific quantity of precipitation which must be subject to treatment. Section 17-25.025(1)(d) F.A.C. advises an applicant of a specific set of sizing criteria for swales based on the infiltration capacity of the soil and a specific design storm event. These standards are intended to encourage the use of swales or waterway systems in areas where the soil infiltration capacity is high and runoff is low. Conversely, they should discourage the use of this practice as the sole treatment mechanism for a project where the opposite condition exists and the level of efficiency (pollutant removal) would be insufficient to meet state requirements.

Wanielista (1981) notes that swale systems must be able to percolate at least 80% of the yearly runoff waters to be consistent with the performance levels of some of the other practices which Chapter 17-25 F.A.C. requires (i.e., retention devices). He also notes that the estimation of the percolation rate and volume is critical to good design procedures. These publications conclude that percolation of 80% of the three year 1-hr. design storm should be sufficient to accomplish this objective. Therefore, this is the design criterion currently specified in the state stormwater rule.

Channel Size for Pollutant Abatement

Several mechanisms including sedimentation, plant filtration, vegetative uptake and percolation through the soil usually function in the removal of undesirable substances from runoff waters subjected to treatment via a swale or grassed waterway. It may be possible to size a system which can be expected to obtain a specified level of treatment based on all of these

processes. However, removal efficiencies associated with sedimentation, plant filtration and vegetative uptake are difficult to estimate.

Dr. Martin Wanielista of the University of Central Florida has developed a simplified design procedure which, in most instances, may be used to size these facilities. The methodology regards a waterway as a treatment system that removes pollutants primarily by percolation. Therefore, estimation of the rate at which water can be taken into and transmitted through the soil is critical to the design procedure. In this respect the designer is sure to be confronted with many judgement decisions. Sometimes referred to as percolation rates by sanitarians or as rates of permeability in soil surveys, the movement of water into and through Florida soils may range from 100 inches/hour for some coarse sands to less than .005 inches/hour for a few of the clay soils of the panhandle.

Information published by the Soil Conservation Service pertaining to permeability rates in conjunction with detailed soils maps may be used to establish an estimate of the system's capacity for percolation. However, a site survey by a professional soil engineer or SCS personnel should be requested to confirm the soil types and percolation in the project area prior to design. To ensure that the swale is properly designed, field testing of the percolation rate is preferred. Care must be taken to ensure representative testing locations and climatic conditions. The double ring infiltrometer type of field test is recommended over the more conventional standard "borehole type percolation test" for these evaluations.

Avellaneda (1985) discusses the results of tests pertaining to the infiltration capacity of swale systems in Central Florida. He notes that soil types in the vicinity of the experimental systems included Leon fine sand, 0-2 percent slopes; Blanton fine sand, 0-5 percent slope; and Iberia clay loam. The SCS permeability (in./hr.) was listed as 10-20 for the Leon series and 5-10 for the Blanton/Iberia complex. Most importantly, based on the results of twenty-two experiments at five sites, he concludes that:

1) Emphasis must be made on predicting a reasonable rate of infiltration because it has the greatest effect on the accuracy of the design.

2) The SCS values for permeability represents a wide range of values which makes it difficult for the designer to predict a value that accurately describes the infiltration behavior of the swale. Therefore, the designer should use the most conservative value for the infiltration rate.

R0071174

3) The longitudinal slope is a very important parameter to be considered, because the steeper the slope, the less predictable the infiltration rate from permeability data.

4) If the double-ring infiltrometer is used, a value of infiltration rate equal to one-half of the value obtained with the double-ring method is recommended. If the lab permeability can be obtained, also a value of one-half of the permeability should be used as the infiltration rate.

5) When few estimates are available, the lower of each estimate should be used to determine how each value would affect the geometry of the swale, and then the proper selection for the final design should be made.

The steps in the design of swales for stormwater pollutant removal may be summarized as follows:

Step #	Description
3-1:	**Determine the simplified rational method hydrograph for the three year one-hour design storm based on procedures illustrated in Chapter 5.** It should be noted that the time of concentration (Tc) of the contributory area must be estimated to determine the shape of the hydrograph. In most instances, projects using swales will be composed of a single reach or a number of reaches wherein Tc will be one hour or less.

Example

Determine the discharge associated with the three year one-hour design storm for a 10-acre project located in Tallahassee (FDOT rainfall intensity - duration frequency curve, Zone 2, Figure 6-18). Assume the developed project has a rational runoff coefficient equal to 0.5 and the time of concentration is 20 minutes.

The peak discharge for the inflow from the three year one-hour storm is:

$QpI = CiA$ Where, $C = 0.5$, $A = 10$ AC, $i = 2.5$ in/hr, $Tc = 20$ minutes

$QpI = 0.5 \times 2.5$ in/hr $\times$ 10 Ac

$QpI =$ **12.5 Ac in/hr or 12.5 cfs**

The volume of runoff associated with the inflow hydrograph must also be determined.

$$\text{Vol. Inflow } V_I \text{ (ft}^3\text{)} = QpI(D) \times 60$$
$$= (12.5)\ (60)\ (60)$$
$$V_I = 45{,}000 \text{ ft}^3$$

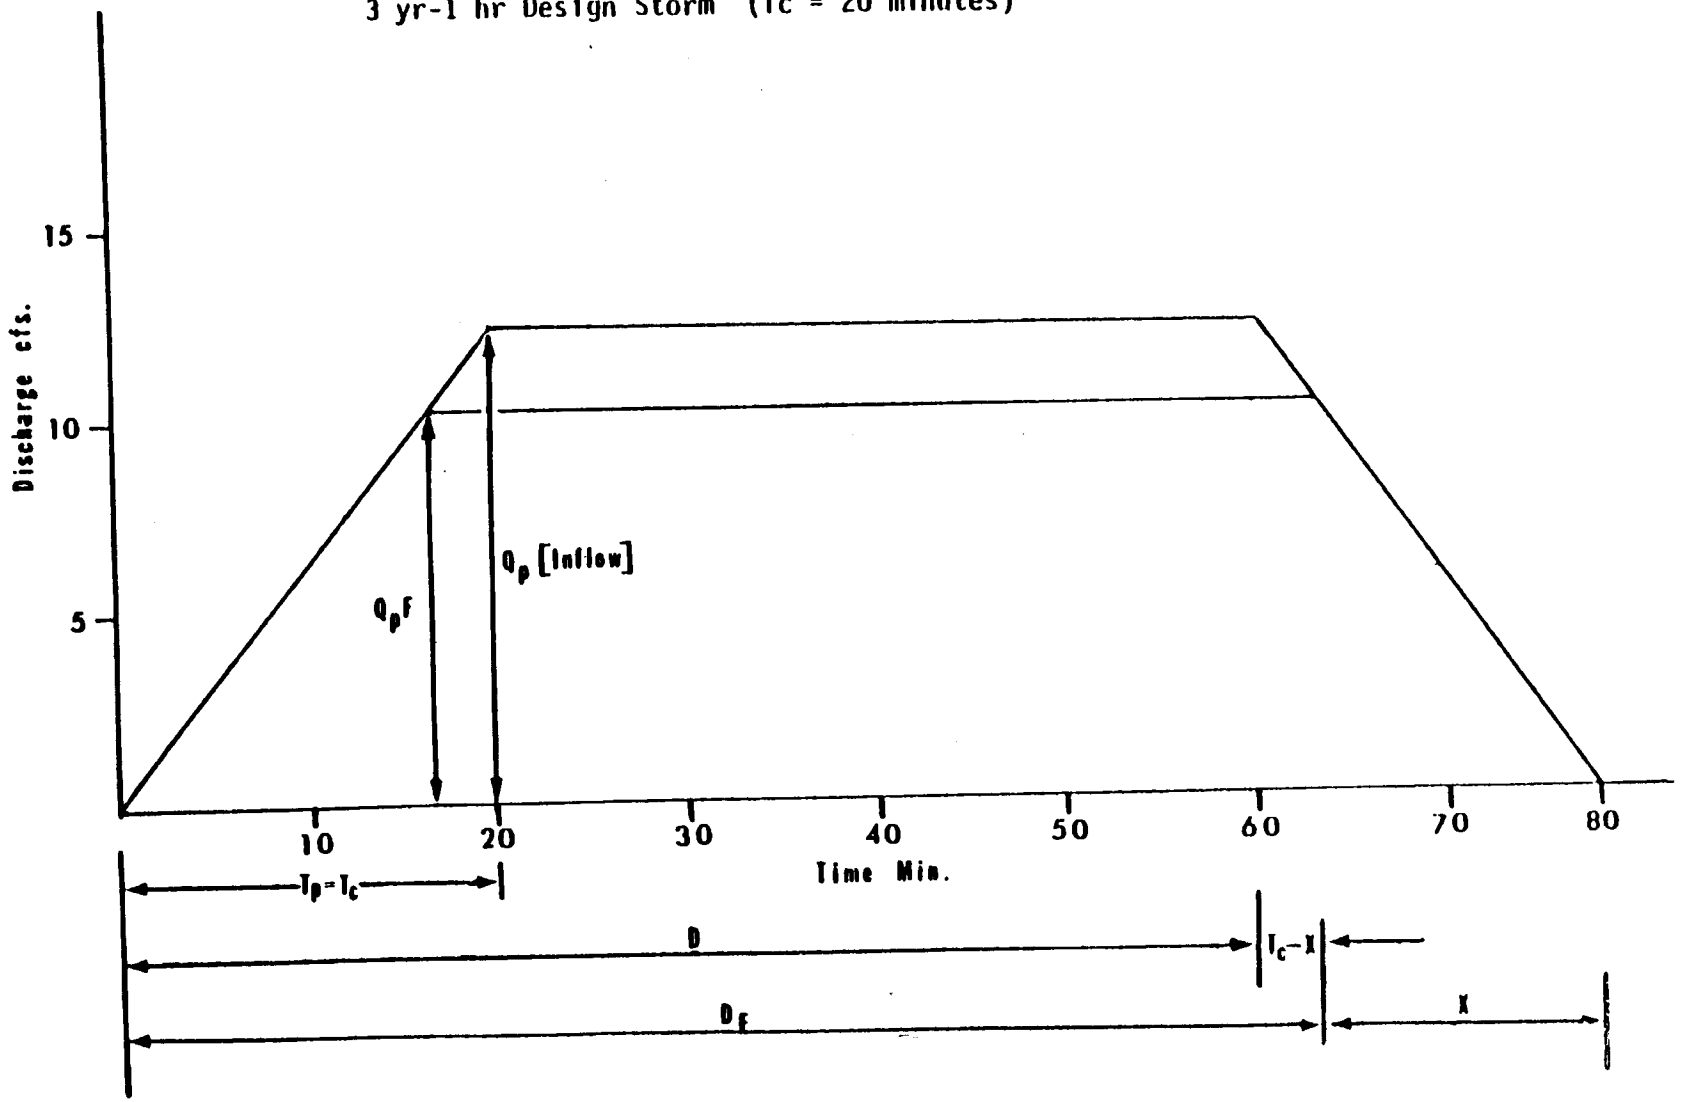
Where,

V_I = Vol. Inflow (ft^3)
QpI = Peak discharge from inflow hydrograph (ft^3/sec)
D = Duration of rainfall (minutes)
60 = Conversion factor (60 sec./min.)

The simplified inflow hydrograph for this example is illustrated, see Figure 6-21.

3-2: **Percolation from a swale will produce an associated infiltration hydrograph.** The volume of infiltration expected to occur during the duration of the runoff hydrograph must be determined in order to check the swale's ability to percolate at least 80% of the runoff volume (V_I) from the three year one- hour design storm.

The volume (V_F) associated with the infiltration hydrograph (shown superimposed on the inflow graph with Figure 6-21) may be determined by calculating the peak rate of percolation associated with the swale (QpF) and multiplying by the value of the rainfall duration plus the extra time required until the receding leg of the inflow hydrograph and the infiltration hydrograph intersect each other. For lack of a better term this expression is shown as (D_F) in the figure. Mathematically the equation for the relationship may be written:



$$V_F = (QpF \times D_F \times 60)$$

Where all terms are as discussed above and 60 is a conversion factor for minutes to seconds.

The value of D_F may be considered equal to (D+Tc-x) as shown. In this example problem the values of D and Tc are known to equal 60 minutes and 20 minutes respectively. The value of (x) may be determined from the principle of proportional triangles as follows:

FIGURE 6-21

Typical Simplified Inflow and Infiltration Hydrograph for the 3 yr-1 hr Design Storm (Tc = 20 minutes)

R0071177

$$\frac{x}{QpF} = \frac{Tc}{QpI} \quad \text{or} \quad x = \frac{Tc\ (QpF)}{QpI}$$

Therefore; substituting this value into the two relationships discussed above,

$$D_F = (D + Tc - x) = D + Tc - \frac{Tc\ (QpF)}{QpI}$$

and;

$$V_F = QpF \times D_F \times 60 = [QpF]\ [D + Tc - \frac{Tc\ (QpF)}{QpI}] \times 60$$

Where,

V_F = Volume of Infiltration (ft^3)
QpF = Peak rate of Infiltration (ft^3/sec)
QpI = Peak rate of inflow (ft^3/sec)
D = Duration rainfall (minutes)
Tc = Time of concentration (minutes)
60 = Conversion factor

In the above expression all values except QpF are known or have been previously determined. QpF may be calculated assuming the percolation rate of the soil is known and the swale area has been predetermined.

Example

Assume the project is 10 acres as noted earlier. Further presume that the watershed is relatively square, 660 ft on each side and the design calls for swales (6 ft wide) along both sides of each of three streets through the subdivision. A total of 3,960 ft (660 x 6) of swales is planned for the project.

Question: Will 3,960 ft of swale be sufficient to percolate 80% of the three year one-hour storm, assuming the SCS soil permeability is listed at 6-12 inches/hr.?

The rate of percolation (K) to be used is: 6 inches or 0.5 ft/hr

Maximum swale area (A) available for percolation equals length (L) x wetted perimeter (P). In equation form this relationship may be expressed as follows:

$$A = L \times P$$

In this instance the swale length is (L = 3960ft)as noted above. The appropriate value for P is dependent on the geometry or swale shape that the designer proposes. Vee shaped and parabolic swales are commonly used in residential areas. Trapezoidal shapes are used by the Florida Department of Transportation along roadsides.

The trapezoidal shape is the most proficient from an infiltration standpoint. More soil/water contact area (A) is available per given unit of top width and depth when using this swale configuration. However, as noted in previous sections of this discussion trapezoidal shapes tend to revert to parabolic or "V" shaped conveyances. The available surface area associated with parabolic swales is intermediate and should be used given these circumstances.

The following equations may be used to calculate the appropriate value for the wetted perimeter (P).

$$P = 2\sqrt{1+Z^2}\ d \quad \text{(Vee Shaped)}$$

$$P = b + 2d\sqrt{1+Z^2} \quad \text{(Trapezoidal)}$$

$$P = T + 8d^2/3T \quad \text{(Parabolic)}$$

All terms are the same as discussed earlier. For an illustration see Figure 6-16 regarding the individual shapes.

In this example assume the swale system is a parabolic design as discussed previously.

$$T = 6 \text{ ft and } d = 1 \text{ ft}$$

Therefore:

$P = T + 8d^2/3T = 6.44$ ft

$A = Lx\ P = 3960$ ft x 6.44 ft = **25,502 sq.ft.**

Infiltration Rate (QpF) = KiA.
Assume i = 1 (conservative assumption) then
$QpF = 0.5$ ft/hr x 1 x 25,502 ft^2
$= 12{,}751\ ft^3/hr$ x 1 hr./3600 sec.

$QpF =$ **3.54 ft^3/sec.**

Volume of Infiltration

$$V_F = [QpF][D + Tc - \frac{Tc\ (QpF)}{QpI}] \times 60$$

Where $QpF = 3.54\ ft^3/sec$
$QpI = 12.5\ ft^3/sec$ (Step 3-1, Example)
$D = 60$ minutes (1 hour storm)
$Tc = 20$ minutes (Step 3-1, Example)

$$V_F = (3.54)\ (60 + 20 - \frac{20\ (3.54)}{12.5})\ (60)$$

$V_F =$ **15,789 ft^3**

Is the value of V_F, 80% or more of V_I (from Example: Step 3-1)?

$$\frac{V_F}{V_I} \times 100 = \frac{15{,}789}{45{,}000} \times 100\% =$$ **35%**

As may be seen in this example the designer has not provided enough swale area to accomplish the treatment requirements specified by Chapter 17-25 F.A.C. With the possible exception of those areas of Florida where the percolation rate is extremely rapid it is highly unlikely that any swale can be designed to infiltrate eighty percent of the rainfall excess from a three year one-hour storm event. Since this design is short on area or percolation capacity it would be permissable to incorporate small check dams into the swale system or elevate the culverts crossing the swale at driveways so that storage is provided for the difference in volume between 80% V_I and V_F. Likewise, since swales are primarily conveyance systems which remove pollutants by percolation, a tile drain beneath the channel or other means of providing drainage could be considered.

Our example system could not provide sufficient storage even if it were completely blocked and built on a perfectly flat gradient. In these circumstances it would usually be advantageous for the engineer to consider the system as a linear retention/detention facility. In this manner it is possible to use check dams and/or other structures such as elevated outlets or spillway pipes in order to hold the first half inch of runoff. Thereby, the swale area may be capable of

R0071180

satisfying other general permitting provision contained in Chapter 17-25 F.A.C. pertaining to retention or detention with filtration.

Planning a Swale System or Waterways

Surveys Required: As noted earlier sufficient topographic, vegetative cover and soil survey information is needed to determine drainage area size, runoff magnitude and velocity, significant changes in elevation or direction of flow; the location of natural draws and depressions; and the percolation rate at the site.

Equipment Needs: If tne swale or waterway must be crossed or maintained with large equipment, consideration should be given to the need for increased width and flat cross section. Large mowing equipment may require a significant increase in width over that needed for hydraulic capacity and freeboard. This problem deserves careful study in each project area so that the proper modifications are made in swale width and side slopes to meet the needs of equipment common to the locality.

Construction

Equipment: Many kinds of farming and construction equipment are adapted to the construction of waterways and swales. However, it may be necessary to use equipment that can load and transport the excavated material to locations where it is needed. These points of need might be low spots in the surrounding area or washes in the conveyance that need filling. Small scrapers that can be pulled by farm tractors are satisfactory units for construction. However, large scrapers, bulldozers and motor patrols are excellent types of equipment for constructing these systems and may be used when needed.

Site Preparation: The waterway should be staked for construction. All trees, stumps, brush and similar material should be removed from the site and disposed of in such manner as to not interfere with proper functioning of the system. Design and construction survey notes should be kept according to standard engineering practice.

Excavation: The soil removed from the waterway should be deposited where it will not interfere with flow of water into the waterway. Normally it can be used to fill low spots or build diversions to keep runoff from the swale during vegetation establishment.

The topsoil should be saved and spread in the constructed waterway if necessary for obtaining a good vegetative cover. When this is done, the

R0071181

waterway should be over-excavated to allow for replacement of the topsoil without encroaching on the design cross section.

Establishing Vegetation: Vegetation is established usually by seeding or by planting the roots or other vegetative parts of the selected plants. In the more critical sections of some waterways it may be desirable to provide immediate protection by transplanting a complete sod cover.

Jute, plastic, or paper mesh and straw or hay mulch may be used to protect the center portion or entire width of a waterway or swale until the vegetation becomes established.

All seeding, planting and sodding should conform to sound agronomic recommendations (see ES BMP 1.65, 1.66 and 1.67).

The swale and its outlet shall be protected against erosion by vegetative means as soon after construction as practical and before diversions or other channels are connected to them. Consideration should be given to sodding the channel to provide erosion protection as soon after construction as possible. The following steps will help to ensure good vegetative cover:

1) Grade and smooth as needed and feasible to permit the use of conventional equipment for seedbed preparation, seeding and mulching.

2) Install other needed erosion control practices such as berms, diversion or interceptor ditches to protect the area during establishment of vegetation.

3) Apply fertilizer and lime in accord with applicable standards as determined by a soil test.

4) Prepare a good smooth seedbed. Incorporate fertilizers and lime into the top two or three inches of soil. Firm with cultipacker before seeding.

5) Select a suitable plant species. Apply seed uniformly with a cyclone seeder, drill cultipacker seeder or hydroseeder. If hydroseeder is used the slurry will contain the seed and fertilizer.

6) All vegetative channels or outlets should be mulched. See MULCHING (ES BMP 1.75).

7) Where feasible, temporary diversions or other erosion control practices should be used to dispose of runoff water during period of establishing vegetative cover.

8) If soil moisture is deficient when planting, apply adequate water for seed germination and plant emergence. Continue to irrigate as needed until plants are well established and have provided adequate ground cover to protect the area.

Operation and Maintenance

Timely maintenance is important to keep a swale in good working condition. Fertilizing and mowing should be done frequently enough to keep the vegetation in vigorous condition. The cut vegetation should be removed to prevent the decaying organic litter from adding pollutants to the discharge from the swale.

Vehicular traffic should be excluded from the waterway. Following heavy rainfall always inspect the area for failures and make necessary repairs, replacements, or re-seeding within the planting season. If complete re-seeding is necessary, apply half the original recommended rate of fertilizer with a full rate of seed.

Many residents in areas which use swales find these areas to be convenient sites for the disposal of leaf litter, grass clippings, and other types of refuse. The proper operation of these facilities from both a hydraulic and treatment standpoint is dependent on the integrity and knowledge of the residents the system serves. A few careless individuals can result in an outlet getting plugged with debris. These circumstances lead to abnormally high levels of organic material being delivered to downstream waters, and sometimes flooding of a neighbors property. Public education programs should be undertaken, as necessary, to ensure that swales are not used as trash disposal areas.

SWALE BLOCK DESIGN

These appurtenances may appear to be simply mounds of soil piled across a swale. However, for proper operation and stability the use of suitable procedures for sizing and spacing is imperative. A swale block system that is not designed to store the runoff from the appropriate design storm (three year one-hour) and which does not consider overflow will not only fail to provide for the intended level of treatment; but, it is also sure to lack structural integrity. Such facilities may be expected to wash out after several consecutive storms. Consequently, the over-all performance of the swale system in terms of its capacity to percolate runoff, promote improved sedimentation, and thus remove pollutants is highly dependent on the proper

R0071183

design and installation of these rather innocuous structures. Several researchers at the University of Central Florida have worked to develop design procedures which may be used to assist in swale block sizing and spacing (Rehmann-Koo, 1984; Wanielista et.al., 1985; and Wanielista et.al., 1986). Essentially, rainfall excess as well as the geometry of the swale, its' slope and the infiltration capacity of the soil will determine the size and the distance between swale blocks.

Calculating the Volume of Storage:

The volume of storage that must be provided can be determined in one of two ways. The first was illustrated in the example problem discussed previously. As noted earlier, the method consists of estimating the volume of runoff associated with the three year one-hour storm. Its' eightieth percentile value is then compared with the amount of water which can be infiltrated by the swale during the course of the design event. The excess runoff (i.e., 80% runoff volume minus the swale infiltration volume) must be stored behind swale blocks for percolation following the storm.

In similar fashion, the second procedure also involves compiling an estimate of runoff (R) for the design rainfall. However, a swale volume runoff coefficient (Cv) is used to translate the watershed runoff volume into swale discharge according to the following equation:

$$S = C_V R = 3630\ C_V cPA$$

where:

S = swale volume of discharge (cu.ft.)
C_V = swale volume runoff coefficient (dimensionless)
R = 3630 cPA
c = watershed area runoff coefficient from Table 5-1 (dimensionless)
P = rainfall depth (inches)
A = watershed area (acres), and
3630 = conversion factor (ac.in. to cu.ft.)

The value of (S) is subsequently subtracted from the value of (R) to determine the volume of swale infiltration (F).

$F = R-S$; or
$F = R - (C_V R) = R(1-C_V)$

The volume of storage (V_S) which must be provided in the swale block pool may be determined as follows:

$Vs = .8R-F$
$Vs = R(.8 - (1-C_V))$

R0071184

Therefore, swales with a volume runoff coefficient (C_v) exceeding a value .2 will require some degree of storage (Vs).

Selecting the Appropriate Swale Volume Runoff Coefficient (C_v):

Experiments clearly indicate that the higher the value of the beginning water content of the soil profile, the smaller the value of the infiltration rate. Therefore, the coefficient (C_v) increases as the moisture content increases, and the coefficient of discharge decreases as the length of swale is increased.

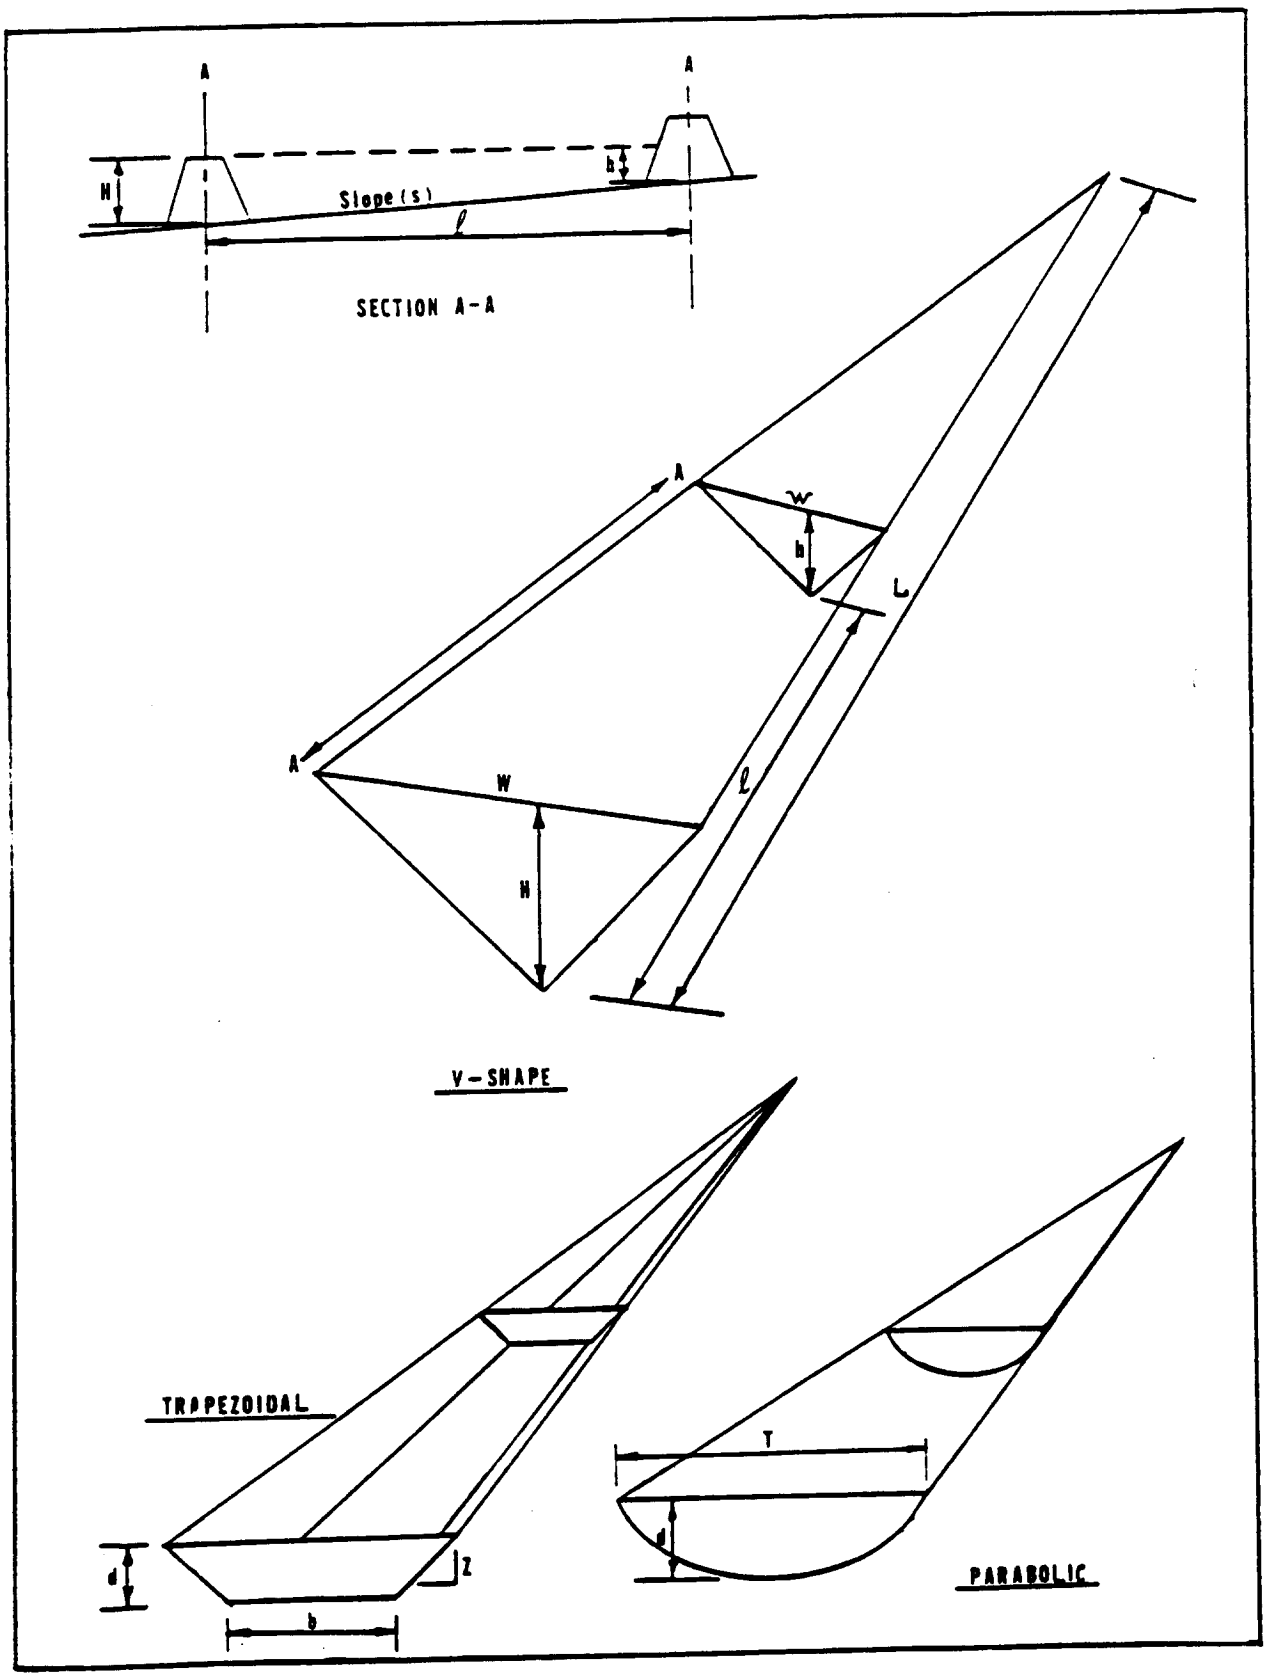
Unfortunately, very little data is available to the design engineer that is suitable for the purpose of obtaining an accurate estimate of C_v. Since there is a wide variety of watershed conditions, each location must be examined individually. The results of ten field experiments to evaluate the water flow characteristics for several (three) swale areas in central Florida (Wanielista, 1985) show values of C_v ranging from 0.0 to 0.74. The median and mean value recorded were 0.59 and 0.52 respectively. A conservatively high value of C_v = 0.70 was recommended for subsequent design problems pertaining to road-side swale systems.

Spacing Between Swale Blocks:

Since the slope of the channel is generally fixed by the topography the spacing of swale blocks is predominantly determined by the longitudinal slope(s) along the proposed route of the channel and the maximum depth of storage (d) determined at the descretion of the designer. Values of d are generally limited to two feet or less for reasons of safety in residential developments. Similar restrictions are normally followed for both public safety and road bed protection reasons when swales are associated with highway construction.

Therefore, as an example if the slope or grade of the swale is equal to .5 feet/100 feet (i.e., s = .005 ft./ft.) and the maximum depth is limited to (d = 2 ft.), the optimum spacing (i.e., greatest amount of storage per structure) would be achieved when the distance between structures (L) is equal to 400 feet. This value is determined as follows:

$$L = d/s$$



where:

L = optimum length of swale pool (ft.)
d = depth of storage (ft.)
s = longitudinal slope or grade of the swale (ft./ft.)

R0071185

FIGURE 6-22

SWALE BLOCK ISOMETRIC FOR CALCULATING STORAGE VOLUMES

R0071186

By substituting the previously derived values for slope and depth into the equation:

$$L = 2/.005 = \boxed{400 \text{ ft.}}$$

Estimating the Number of Swale Blocks Required:

Depending on its spacing, a swale block is viewed to produce a pool of water similar in shape to either a pyramid or a frustum of a pyramid (see Figure 6-22).

The available storage can be estimated for various cross sections and slopes of swales using the equation given below:

$$S = (\ell/3)\ (A + a + Aa)$$

where:

ℓ = truncated length of swale block (feet)
L = total or optimum length (feet)
S = Volume at end of swale (cubic feet)
A = Cross-sectional area at berm (square feet)
= (W) (H)/2 "V-Shape", bd + Zd^2 Trapezoidal", and 2/3 Td "Parabolic"
a = Cross-sectional area upstream of berm if obstructed upstream (square feet)
W&T = Top width of swale at berm (feet)
H&d = Maximum depth of swale at berm (feet)
b = bottom width of swale (feet)
Z = side slope ratio feet horizontal/foot vertical rise

Example Problem:

Continuing to expand on the hypothetical situtation and data generated in the preceding section, the use of this design procedure is illustrated in the following discussion. However, since it has already been established that the previous swale system has no possibility of providing the level of storage required, for illustration lets presume that the swale cross-section is expanded and that the longitudinal slope is much more flat. In this instance suppose the swale is parabolic but that the top width (T = 12 ft) and depth (d = 2 ft) are double their earlier values.

Assume the longitudinal slope of the swale system is 0.5% or .005 ft/ft as discussed earlier in this example. Further presume that runoff is split evenly between the six branches of the system, and that swale

R0071187

blocks are planned at the outflow and in the middle of each reach. A total of twelve swale block pools will be created and each must handle an equal proportion of the total runoff (i.e., 45,000/12 cu.ft.) as calculated in the previous problem. Since each reach is a constant slope with similar landuse and other hydrologic conditions the designer can design the structures for one branch and this configuration will also be applicable to the other five sections of the system. The value (R = 3750 cu.ft.) may be used to size each of the twelve elements in this project.

Experience shows that it is desirable to limit the swale block height (d) to no more than 1.5 feet from a safety and maintenance viewpoint. To begin the analysis the designer should first determine the maximum length (L) of the swale block pool given the desired depth or height of the swale block. As noted earlier:

$$L = d/s$$

Where;

d = height of the swale block

= 1.5 ft (presumed)

s = longitudinal slope

= .005 ft/ft (given)

Therefore:

$$L = \boxed{300 \text{ ft.}}$$

Since the value of (L) is less than the spacing desired (i.e., 330 ft) the swale pool is not truncated and ($L = \ell$). Using a swale volumetric runoff coefficient Cv of 0.70 as recommended in the previous section of this document the following calculations for swale design result.

Volume of storage (Vs) which must be provided in the swale block pool for each cell:

$$Vs = R\ (.8 - (1 - Cv))$$
$$Vs = 3750 \text{ cu.ft. } (.5) \text{ or}$$

$$Vs = \boxed{1875 \text{ cu.ft.}}$$

The Volume of Storage (S) Available:

$$S = (L/3)\ (A)$$

Where; $A = 2\ Td/3$ and,

$T = 6d$ (as specified by rule)
$d = 1.5$ ft.

$A = 9$ sq.ft.

$L = 300$ ft (previously calculated)

By substitution:

$S = (300/3)\ (9)$ or,

$S =$ **900 cu ft**

The result shows that the proposed configuration does not provide sufficient storage to satisfy the designer's objectives. There are other options, however. The most simple course of action is to reduce swale block spacing and increase the number of cells within each reach.

Suppose, that four swale blocks are used. Each pool would be (660 ft/4 = 165 ft) in length. The volume of storage which must be provided in each pool is one-half its former value or ($Vs = 1875/2 = 937.5$ cu.ft.). Since the spacing is now less than optimum where (L = 300 ft) each pool will be truncated forming a frustrum of a pyramid in shape. The designer must determine the upstream area (a) to determine available storage (S) in comparison to (Vs) required.

The upstream depth (d2) must first be determined. It may be calculated as follows:

$$d_2 = d_1 - (\ell \times s)$$

Where;

d_2 = upstream depth (ft)
d_1 = height of swale block
= 1.5 ft.
ℓ = truncated length
= 165 (ft)
s = longitudinal slope
= .005 ft/ft

$d_2 = 1.5 - (165 \times .005) =$ **0.675 ft.**

R0071189

The area (a) may now be determined.

a = 2 Td/3 as before,

Where:

T = 6d and
d = d_2 = .675 ft.

Therefore;

a = (2) (6 x .675) (.675)/3 or,

a = **1.82 sq.ft.**

Solve the Storage Equation to Determine (S)

$S = (\ell/3)(A + a + Aa)$

Where:

ℓ = 165 ft (from above)
A = 9 sq.ft. (calculated previously)
a = 1.82 sq.ft. (from above)

Therefore:

S = **1496 cu.ft.**

Since the value of (S = 1496 cu.ft.) is greater than the storage volume required (Vs = 937.5 cu.ft.) the designer may use this design. However, this system exceeds design capacity by a substantial amount. Consequently, the engineer may wish to continue these iterations until a more optimum configuration is derived.

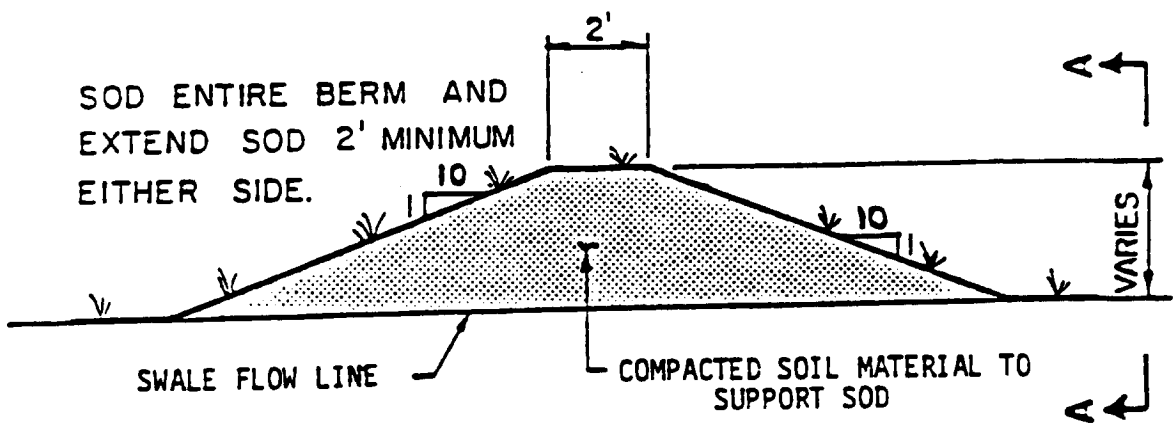
Details for Swale Block Construction

Swale blocks may be constructed using a variety of materials including wood, concrete, asphalt, metal, natural soil or a mixture of each. The most common application is the use of native in place soil fashioned in the form of a low berm. Regardless of the material or materials chosen to form the restriction the designer should take proper precautions to ensure that the facility is not subject to undercutting and erosion especially along its toe.

A typical cross section of a berm type system is shown below. (See Figure 6-23). Research conducted by the University of Central Florida indicates that three swale block systems constructed in accordance with the specifications shown still existed for more than two years after their

construction. Wash out did not occur even though three storms greater than three inches were recorded during this period.

These researchers suggest that swale block height should be limited to 1.5 feet for public safety and roadway subgrade protection. It is also recommended that the following guidelines be applied to ensure good structural integrity and easy maintenance (mowing).



1) The front and back slope of the structure should not be steeper than ten feet horizontal to 1 ft vertical unless pavement or other equally stabile material is used to protect the berm from erosion during overflow conditions.

2) Berms should be constructed of clean stable material suitable for the construction of embankments. The material should be free from tree roots, construction debris and other extraneous material. Clayey sand, Unified Soil Class (SC) which was mechanically compacted was used by the UCF researchers. Inorganic silts, (ML and MH), organic silts (OL), and organic clays (OH), as well as peat or other highly organic soil (PT) should not be considered. The designer should also be aware that cover (i.e. grass) may be hard to establish when using material of high permeability in classes (SW) and (SP) for example.

3) Sod should be used to protect these embankments from erosion. Protection should be provided extending at least two feet from the toe of the berm along both the face and back slope of the structure.

SW BMP 3.05

PARKING LOT STORAGE

Definition

Providing temporary surface storage and controlled release of stormwater runoff on paved (impervious) parking areas or within parking lot landscaped islands.

Purpose

To reduce the adverse impact of runoff from impervious parking surfaces on receiving waters.

Conditions Where Practice Applies

Where portions of large, paved parking lots can be temporarily used for stormwater storage without significantly interferring with normal vehicle and pedestrian traffic. Shopping centers and large employee parking areas are likely places for use of this measure. Wherever parking lot landscaped islands are required.

Planning Considerations

Paved parking areas can have a significant impact on downstream receiving waters. The impervious surface which often replaces natural vegetative cover causes increases in the volume and peak rate of runoff and also provides a place for traffic-generated residues and airborne pollutants to accumulate and become available for washoff.

Detention of stormwater on paved parking surfaces or within recessed landscaped islands is a technique used in many localities to deal primarily with the problem of increased runoff peaks from relatively minor storms. This practice in itself can also contribute to a decrease in nonpoint source pollution for the following reasons:

1) In areas with combined sewers, the reduction in peak runoff rate can contribute to a reduction in the frequency and magnitude of sewer overflows.

2) In areas without combined sewers, the reduction in runoff peak can contribute to decreased stream channel erosion and subsequent sediment pollution downstream.

R0071192

3) By temporarily ponding runoff there is an increased opportunity for particulate matter to settle out.

4) The first flush or shock loading effect of the polluted runoff is decreased because the stormwater is released over a longer period of time.

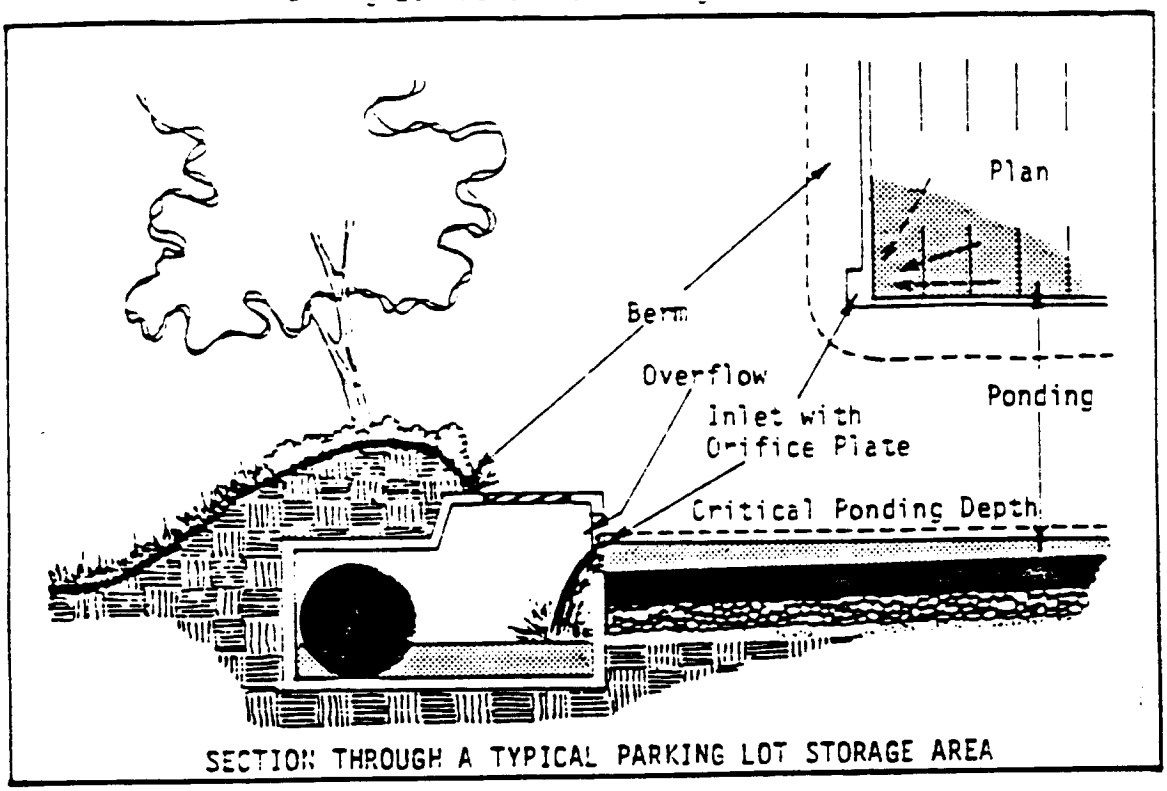
5) By placing raised storm sewer inlets in recessed landscaped areas, some infiltration and settling will occur before the stormwater is conveyed by the storm sewer.

Parking lot ponding is usually accomplished by using specifically designed or modified inlet structures which cause stormwater to temporarily pond in specially graded areas of a parking lot. An illustration of a typical parking lot storage system cross-section is shown in Figure 6-24.

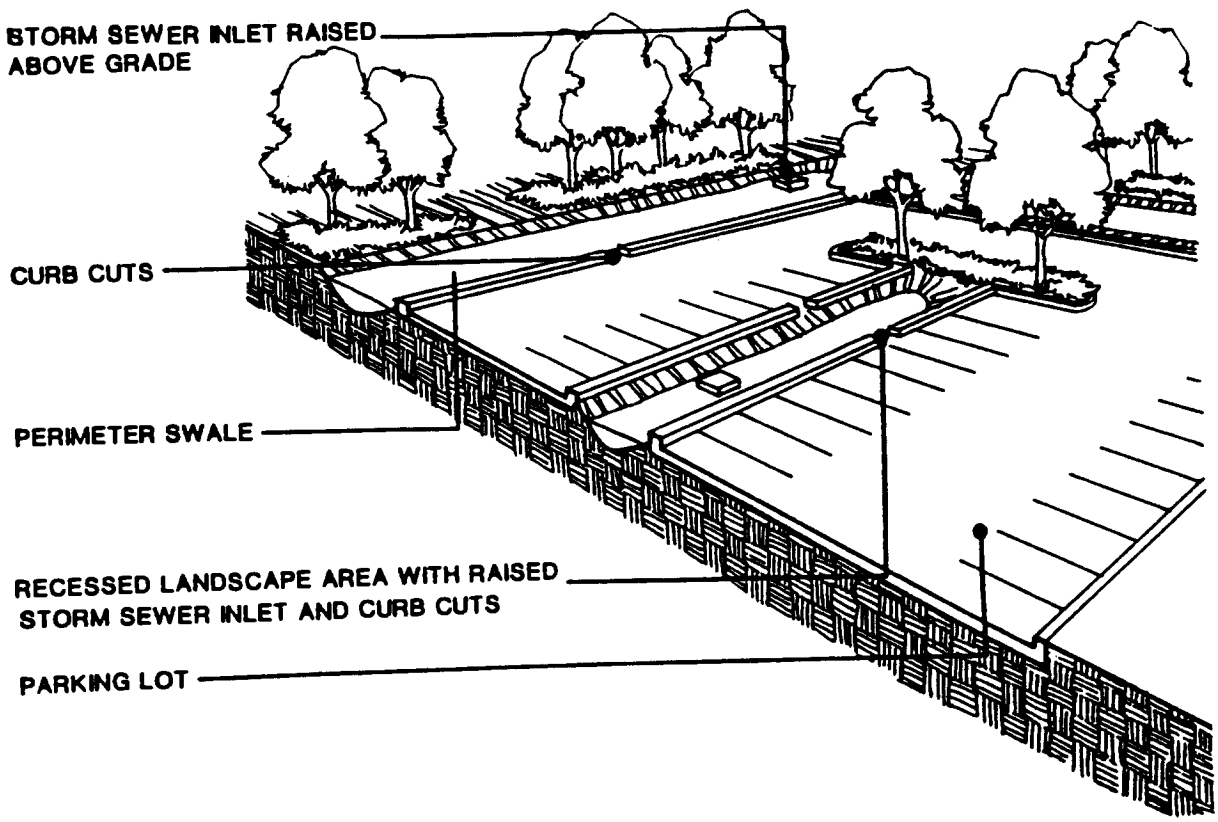
The effectiveness of parking lot storage for nonpoint source pollution control can be increased by routing ponded water over infiltration areas and/or trenches. An easy way of promoting infiltraiton is to place raised storm sewer inlets within recessed landscaped areas. Curb cuts will allow runoff to enter the mini-retention/detention area where infiltration can occur before the stormwater rises to the elevation of the inlet. Infiltration allows a certain amount of the ponded water to be purified by the soil. Before using infiltration techniques in conjunction with parking lot storage a determination must be made as to the possible effect upon groundwater. The Exfiltration Section (SW BMP 3.03) contains relevant information on this topic. Other infiltration practices such as porous pavement, concrete grid and modular pavement, grassed waterways, filter strips and seepage areas can also be used in conjunction with parking lot storage to reduce nonpoint source pollution.

Design Criteria

Wherever they exist, local criteria for the design of parking lot storage systems should be followed. If no local criteria exist, the following may be used as design guidelines:



Storage Volume and Release Rate: Design of the storage volume and release rate is dependent upon the purpose of the system. In parking lot detention systems, the storage volume is usually limited by the size and grade of the parking lot and the proximity of ponding areas to structures and traffic routes. There will seldom be enough storage volume to control moderate or major flooding downstream unless additional storage volume is provided.



For nonpoint source pollution reduction, a slow release rate is needed (i.e., 0.1 inch per day to 1 inch per day). Detention times in excess of 30-40 hours are most effective. Unfortunately, stormwater detention for such long

R0071193

FIGURE 6-24

Parking Lot Detention Configurations

R0071194

periods of time is not desirable on a parking surface. A good alternative is to design the parking lot storage system in conjunction with a subsurface retention/detention system such as infiltration trenches and/or pits. The subsurface system can be designed to collect a small initial volume of runoff while the surface ponding system can be designed to control a specific design storm at a pre-development level.

Minimum Slope: The storage area should have at least 0.5 to 1 percent slope toward the outlet to assure complete drainage following a storm.

Maximum Depth: The maximum depth of water within the pond area is not recommended to exceed 7 inches.

Location: The portion of the parking lot where runoff storage is planned should be located so that there will be minimum interference with pedestrian and vehicular traffic during a storm. Remote perimeter areas of large parking lots are usually best suited.

Overflow: The parking lot storage system should be designed so that overflow from storms larger than the design storm will not cause excessive damage or inconvenience. Specifically, there should be no potential for flooding of nearby buildings, major throughfares or other important facilities.

Warning Signs: Ponding areas should be well marked with signs or pavement markings advising users to avoid these areas during storms in order to protect their vehicle brake linings from wetting and to prevent inconvenience to themselves.

Maintenance

Discharge control structures should be inspected periodically and following each storm. Accumulated debris and litter should be removed as necessary to assure proper functioning.

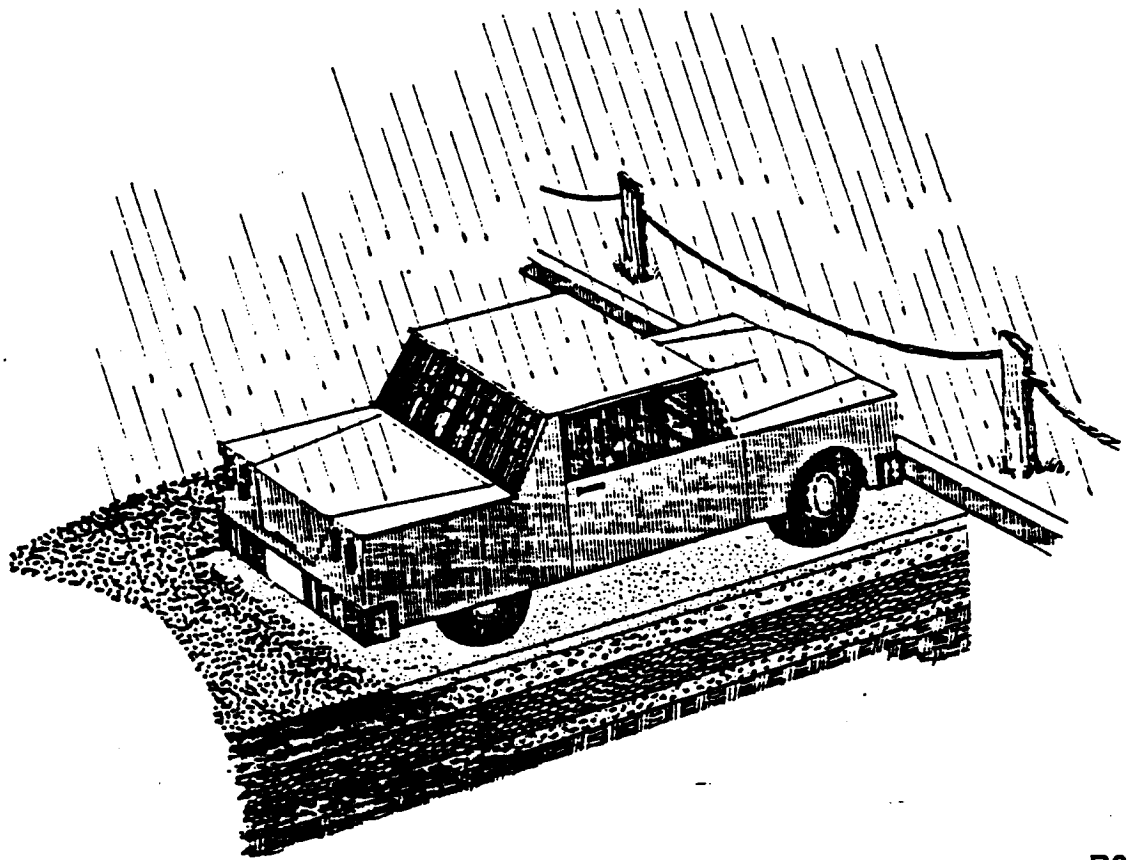
Parking lot surfaces must be cleaned following storms to provide a reasonable level of pollution control and reduce accumulation of litter, debris, traffic-generated residues and other nonpoint source pollutants. Sweeping or vacuuming is recommended.

R0071195

SW BMP 3.06

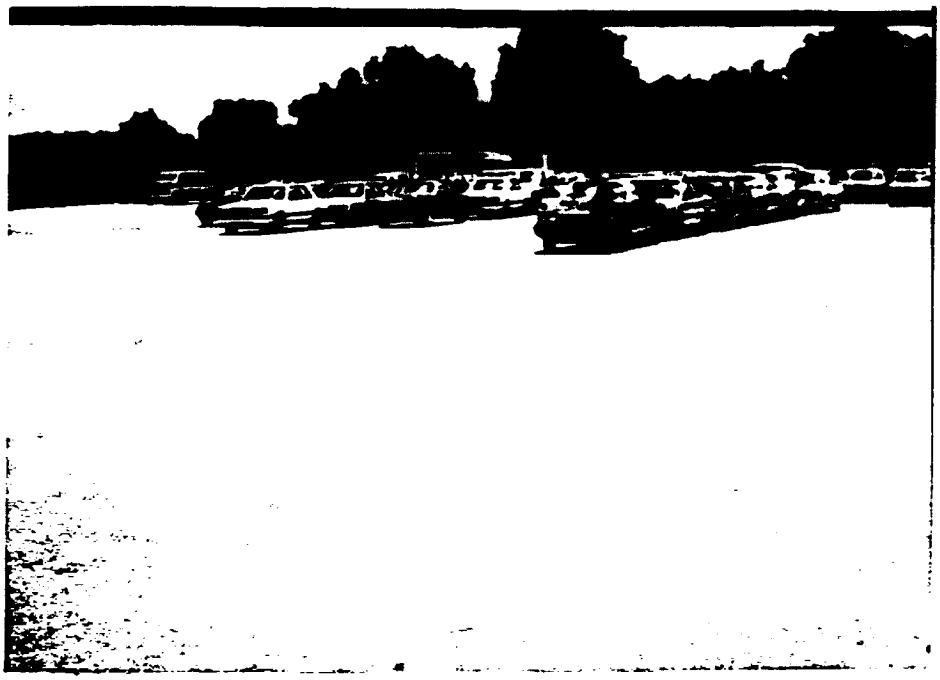
POROUS PAVEMENT

Definitions



The use of a porous asphaltic paving material and a high-void aggregate base that allows for rapid infiltration and temporary storage of rain falling on or runoff delivered to paved surfaces. As described herein, porous asphaltic paving material consists of an open graded coarse aggregate cemented together by asphalt cement into a coherent mass, with sufficient interconnected voids to provide a high rate of permeability to water.

Pervious concrete consists of specially formulated mixtures of Portland Cement, uniform open graded coarse aggregate (FDOT #8 or #89, 3/8 inch to no. 16 or no. 50 recommended), and potable water. This material may be combined with certain water reducing and retarding or accelerating admixtures along with air entraining agents. When properly handled, and installed pervious concrete has a high percentage of void space which allows rapid percolation of liquids through the pavement.



Purpose

1) To reduce volumes and peak rates of runoff normally associated with urban-type development, thereby reducing the potential for combined sewer overflows and for downstream channel erosion and subsequent sediment pollution.

2) To improve water quality by filtration and bacterial action.

R0071196

Parking Lot of Pervious Concrete Near Tampa International Airport

Conditions Where Practice Applies

Theoretically, applicable as a direct substitute for conventional asphalt and concrete pavements wherever on-site detention is necessary to control runoff rates, volumes, and/or quality. However, this practice is most popular for low-volume traffic areas such as parking areas, where stable subgrade soils having at least moderate permeability exist. The practice should have a wider range of application in areas with very sandy soils.

Planning Considerations

The use of porous pavement in place of conventional impervious paving material is quite new and represents a significant departure from conventional pavement design. Extensive laboratory testing and some limited field testing and experience seem to indicate that this practice has good potential for a wide variety of applications. However, a number of

R0071197

questions have been raised concerning the potential benefits verses possible shortcomings of these materials which require further consideration and analysis. The following is a discussion of some of the major factors which should be considered in determining the applicability of this practice.

Possible Problems

1) Wet Subgrade: A wet subgrade is inherent to porous pavement. If the subgrade soil cannot support the design load under saturated conditions, this practice would not be applicable without first replacing the subgrade with a suitable material.

2) Water Stripping (Asphalt): Generally, open-graded mixtures may be considered more prone to water stripping than conventional dense aggregate mixtures because of water access. However, tests have shown that if the aggregate is dried adequately and the asphalt is properly designed and mixed, stripping should not be a problem. Stripping prevention is discussed later under Construction and Materials Specifications.

3) Pressure Head on Slopes: Rapid subsurface drainage on steep slopes may create water pressure at low points of the pavement. This problem can be alleviated through the use of spaced collection pipes which can capture subsurface flow on slopes and direct it away from the pavement.

4) Pore Clogging: On pavements with high-volume traffic and heavy use or those located in particularly dirty environments, such as near a sandy beach, particulate matter as well as grease and oil may clog void spaces quite readily, thus reducing the infiltration capacity of the pavement and restricting its intended function. Clogging can be prevented through periodic vacuum cleaning. This problem is not as evident on low-volume, light use pavements. To preclude premature clogging porous pavement should not be placed into service until all areas that contribute stormwater runoff to the on-pavement retention system have been effectively stabilized.

5) Groundwater Pollution: The asphaltic oils that could be leached from hot-mix asphalt pavements during the first several weeks following placement as well as motor oil drippings and gasoline spillage have the potential to pollute groundwater. However, these systems may be less prone to problems than more conventional retention ponds or trenches since the pollutants are not collected in a small area for treatment. Stormwater along with the pollutants it carries should wash through to nature's own treatment plant, the soil.

Organic materials and any other biodegradable waste should then be metabolized by soil bacteria.

Possible Benefits

1) Reduced Stormwater Management Requirements: Under most conditions, porous pavement can significantly reduce or eliminate surface runoff from the areas it covers. Where separate storm sewers already exist or are to be installed, use of porous pavement could produce substantial cost savings. With existing separate sewers, the use of porous pavement could alleviate the need to install additional capacity when the present storm sewer capacity is fully utilized. For future installations, the use of porous pavement would allow reduction in the design capacity of the storm drainage collection system installed. Catch basins could be reduced in size or number. Consequently, the volume of septic sludge which builds up in them would be reduced, lowering the cost of having them cleaned periodically.

2) Safety Improvement:

   a) Skid Resistance: Porous pavement overlays (friction courses) on conventional surfaces have been found successful in preventing wet skidding or hydroplaning. Other research has shown that conventional dense paving material consistently exhibits dry skid resistance better than or equal to that of porous pavement installation, but porous pavements are clearly superior under wet conditions. In fact, conventional pavements exhibit a decline in their coefficients of friction when wet, while porous pavements seem to exhibit an increase in their coefficients of friction when wet.

   b) Enchanced Visibility: Visibility of pavement markings during rain is expected to be improved because of rapid removal of water and because of the marking material penetrating the voids to present an oblique view. Research has shown white marking paint slightly superior to yellow paint on these surfaces. Enhanced visibility of pavement markings could be an important factor in accident mitigation during storms.

3) Water Quality Improvement: A permeable subgrade and a sufficiently deep water table below the pavement surface provide an opportunity for a significant amount of infiltration to occur. Depending upon soil type and water table depth, this increased infiltration can lead to a significant reduction in the annual pollutant load associated with these surfaces versus non-porous pavement.

4) Preservation of Vegetation: Plants and vegetation along conventional roads, particularly in areas of high pavement densities, are often starved for water because the dry soil under the road tends

to rob their supply. Porous pavement would restore natural moisture, to the benefit of roadside vegetation.

5) Reduced Puddling: Use of porous pavement eliminates inconvenient surface puddling and provides for pavement drainage with no crown slope necessary. The pavement can be laid perfectly level, presenting a pleasing appearance.

6) Color Infusion: Porous pavement is adaptable to color infusion through the use of colored aggregate or colored roofing granules applied to the surface.

7) Noise Reduction: Porous pavements have been found to be slightly less noisy than conventional pavements.

Potential Regulatory Conflicts

The sizing of storm sewerage systems is determined by ordinance in most municipalities. However, porous paving is a relatively new development, and few local regulations contemplate its use. Consequently, flood control authorities may not permit any reduction in the size of storm drains or other drainage structures. Such restrictions eliminate the economic advantage of porous pavement. Local regulations may need to be revised to permit the use of practices like porous pavement that may have wide-ranging environmental benefits.

General Design Criteria

Porous pavement installations should be designed and constructed according to applicable standards and specifications of local, state or national standard-setting agencies or organizations such as the Federal Highway Administration, the Florida Department of Transportation, the local Water Management District, the City or County Public Works Department, the Asphalt Institute, the National Crushed Stone Association, the National Sand and Gravel Association and the Florida Concrete and Products Association. The following guidelines should also be used.

Retention Storage Volume Needed to Satisfy State Stormwater Quality Regulations

In order to provide a level of pollutant removal equivalent with other practices recommended for use in Florida the pavement must have the necessary reservoir capacity to store and percolate the first half-inch of untreated runoff from the parking lot or roadway and any other contributing area within a 72-hour time period. The ability to store and percolate at least 80% of the runoff from a three year one-hour design storm may also be used to demonstrate equivalency in lieu fo the former criteria.

R0071200

To satisfy state criteria the storage volume required (Vr) may be calculated in the same manner as other retention devices. The mathematical expression is:

$$Vr = (1/2 \text{ inch} \times A \times 43{,}560 \text{ sq.ft./ac} \times 1 \text{ ft}/12 \text{ in.}) \text{ or,}$$
$$Vr = 1815\ A$$

where:

Vr = Volume of Storage Required (cu.ft.)
A = Size of the facility plus any additional contributing area (Ac)

The nature of each individual site will determine the design of the porous pavement to be placed on it. A thorough prior examination of the site is of primary importance to the proper functioning of the pavement. Each case is different depending upon site and particularly soil conditions, the wear expected on the surface itself, and the objectives of the designer in regard to the particular use for the porous surface.

Estimating Available Storage

Calculation of Void Space: Void space should be calculated according to the testing procedure recommended in Federal Highway Administration Report No. FHWA-RD-74-2. The volume of the sample should be measured mechanically rather than calculated from a water displacement method because a great deal of water is absorbed. This error might affect the computation of reservoir capacity.

As of this printing a consistent statewide policy has not been established in reference to credit for storage volume within the voids in the pavement and the coarse aggregate base (when used). The Department (FDER) normally allows an applicant to consider storage within the pore spaces of both. This policy is consistent with that for other subsurface retention facilities supported by open graded material (e.g. exfiltration trench storage criteria). The agency will also count the capacity to hold water over the pavement if the facility is curbed and all potential outlets are elevated for storage.

Most other local, regional and state permitting authorities will also allow up to 6 inches of available surface storage credit for flat parking areas ringed with curb and gutters under similar circumstances. However, most agencies differ in their opinion as to the appropriate percentage of credit to be given for storage below the surface. The level may range from 0% to 100% depending on jurisdiction.

When designing these facilities the engineer is urged to contact the appropriate agency for a determination. FDER or the appropriate local Water

R0071201

Management District with delegated stormwater permitting autnority should be contacted for water quality treatment purposes. Tne city, county, water management district or FDOT snould be consulted for drainage connection purposes.

In defense of the various agencies that have failed to reach a concensus regarding this technology, the designer should realize that the major concern with porous pavement is that its' quality, and permeability appear to be very sensitive to batching and installation techniques. Among other factors, the water to cement ratio which is used in the mixing operation and how carefully the material is placed by the contractor will impact the available void space associated with the pavement. Consequently, it is difficult for the designer or review authority to predict the exact amount of storage space which will be available within the matrix of the material.

Couple these uncertainties with a tendency for the void space to become filled over time with sand, silt and clay carried and deposited on the pavement by automobiles, and one can begin to understand the reason for the divergence of opinions that the designer must currently cope with. Counting only storage which can be achieved on top of the pavement alleviates this problem.

However, the storage available (Vs) would be calculated in the following manner presuming that the designer were to be given credit for storage available within the pavement and the open graded aggregate subgrade material (if used):

$$Vs = A \times d_1 \times p_1/100 + A \times d_2 \times p_2/100$$

where:

Vs = Available storage in the pavement and subgrade matrix (ft^3)
A = Area of the pavement (sq.ft.)
d_1 = Thickness of pavement (ft.)
d_2 = Thickness of subgrade base if used (ft.)
P_1 = Percentage pore space or voids in pavement
P_2 = Percentage pore space or voids associated with the subgrade if used.

Example:

Suppose a developer is building a 20 acre shopping center. The soils are fine sand and the topography is flat. Assume that project is 85% buildings and parking lot and that 10 acres or 50% of the project is paved with porous pavement. How much storage is available within a six inch thickness of pavement plus an open graded subgrade course of equal dimension?

R0071202

Assume that field testing of the pavement mix to be used had been performed and were available from the supplier. The results indicate that the void space could be expected to range from 12% - 22%. Presume that the subgrade was estimated to have 40% pore volume.

The storage volume may be determined as follows:

A = 10 ac x 43,560 sq.ft./ac or $\boxed{A = 435,600 \text{ sq.ft.}}$

The pavement depth and subgrade depth are said to be equal. Each is noted to be six inches thick. Therefore, $\boxed{d_1 = d_2 = .5 \text{ ft.}}$
The pore space or percentage voids in the pavement (p_1) ranges from 12% to 22%. Be conservative, use $\boxed{P_1 = 12\%}$

The subgrade coarse is presumed to contain 40% voids by volume in this problem. Consequently the value of (p_2) is known

$\boxed{P_2 = 40\%}$

Substituting these values into the equation:

$$Vs = 435,600 \times .5 \times 12/100 + 435,600 \times .5 \times 40/100$$

$\boxed{Vs = 113,256 \text{ cu.ft.}}$

This value (Vs) would be compared with the 1/2" storage volume required (Vr). Should the relationship (Vs - Vr) be a negative number the designer would need to provide on pavement storage for the remainder or increase the pavement or coarse aggregate base thickness to provide the additional storage.

In this instance, presume the entire 20 acre project contributed runoff via the parking lot. The storage required may be determined as noted earlier [Vr = 1815A = 36,300 cu.ft.]. The value (Vs - Vr) is not negative. Therefore, the facility would have much more capacity than needed.

Storage Volume Recovery

In accordance with state criteria these facilities must be capable of recovering their storage volume (primarily through percolation) within 72 hours following a storm.

This capacity is evaluated in the same manner as other retention facilities by a simultaneous solution of "Darcys" and the "Continuity Equation".

$$Q = KiA$$

where:

Q = Rate of recovery (cfs)
K = Hydraulic conductivity or percolation rate of the soil (in/hr)
i = Hydraulic gradient (usually assumed = 1, conservatively)
A = Area of the pavement (Ac)
[NOTE: 1 Ac in/hr = 1 cfs]

The value determined for (Vr) is subsequently divided by the value of (Q) from the preceding equation to determine the recovery period (Td) in seconds.

$$[Td = Vr/Q]$$

Assuming that $Td/3600 \leq 72$, the design would be acceptable.

SITE SURVEYS AND INFORMATION REQUIRED

The type of surveys and information required is similar to other retention facilities. At a minimum a soil survey and drainage area map should be prepared. The topography of the site before development and after construction is completed will be of interest and should be provided. Similar to other retention areas the location should be examined to provide permitting authorities with an estimate of the seasonal high groundwater elevation as well as any sensitive geologic conditions that could result in groundwater contamination due to inadequate treatment. The latter is discussed more thoroughly in RETENTION (SW BMP 3.07).

Survey and Investigations

Soil Borings: Test borings should be taken to determine the character and permeability of the soil. The ability to transmit the water passing through the pavement is crucial to the treatment efficiency of these systems. In some cases, where soil permeability is poor, an alternative approach to the removal of water from the base reservoir is required.

Percolation Tests: The double ring infiltrometer test would normally be the method of choice for this type of installation. However, when substantial excavation is contemplated, the testing procedure that is used should be capable of characterizing the infiltration capacity of the appropriate soil layer on which the pavement will actually rest when completed.

DESIGN AND PLANNING CONSIDERATIONS

Subgrade: Water continually in contact with silty or clay types of subgrade soils will saturate and decrease the strength of the subgrade and, in turn, lower the load-carrying capability of the roadway. Therefore an ideal soil for use as a subgrade must have adequate load-bearing capacity wet and dry. The ideal soil must be well-drained; that is, the water table must be so far below the surface that the rise of water by capillary action will not come close to the surface. The soil must be permeable to water so that water is transmitted relatively quickly down through it. Finally, it must be quite porous so that it has the capacity to imbibe large quantities of water in its surface layers.

Likely soils to meet these requirements would be a sand to sandy clay loam some distance above the water table. Soil types classified under the Soil Conservation Service hydrologic soil group (HSG) category A or B are recommended for consideration. The particles for this type of soil ranges from sand to clay, but the clay content must be low enough to leave good void size and permit capillary flow downward at a suitable rate. If too clayey, the soil compacts very well and carries the load when dry, but porosity is lacking and transmission of water through the clay is very slow. Likewise, clays may also absorb more than enough water to fill their voids, thereby swelling and becoming very low in load support value. This situation is relatively common following excavation into HSG-B soils in North Florida.

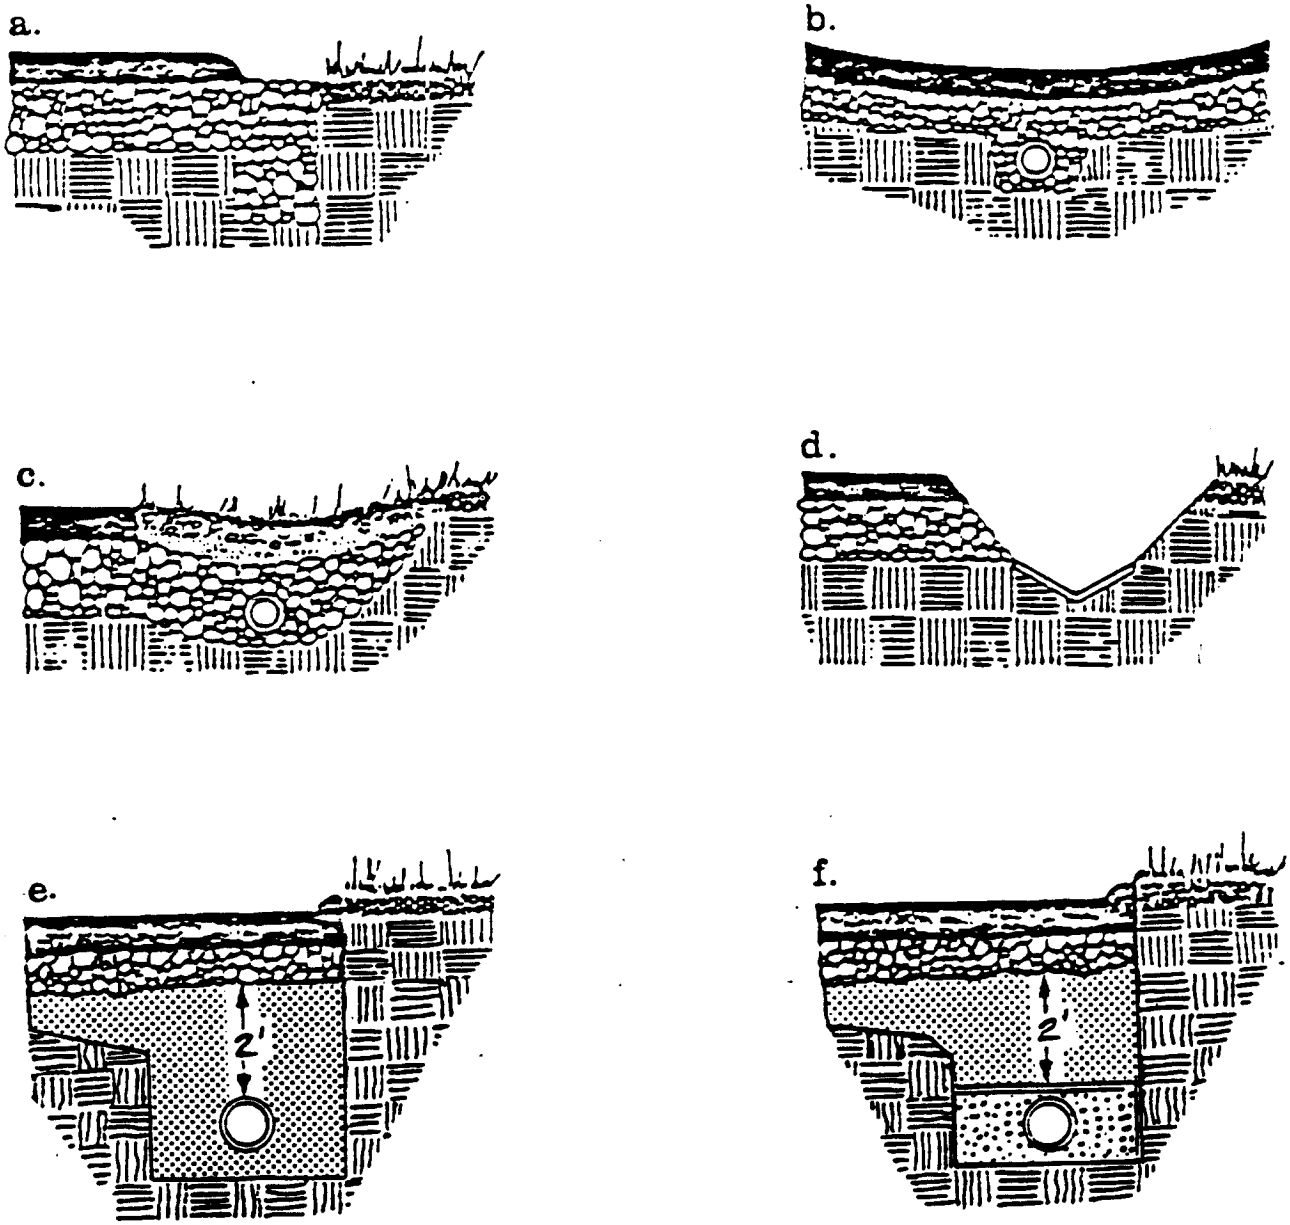
Drainage: If tests indicate that the subgrade is too impermeable to drain the base course reservoir within a reasonable amount of time, it will be advisable to provide a supplementary stormwater system. There are a number of popular stormwater practices capable of adequately removing the water remaining in the base course. These include:

1) **Rock Filled Trench:** This system uses coarse open-grade rock in trenches that are interconnected with the base (reservoir) course which supports the pavement (see Figure 6-25(a,b,c). Drains are located along the edges or in laterals spaced evenly beneath pervious parking areas or roads. The subgrade (soil) is sloped toward the trench such that excess water is conducted

laterally through the coarse aggregate base and possibly via the pavement surface to the collection system.

Although not illustrated in Figure 6-25(a), these appurtenances would usually be directly connected to the primary drainage system (e.g., drainage ditch, canal or stormsewer) by a positive outfall pipe covered with hardware cloth or other type wire mesh screen. The screen is intended to prevent the coarse aggregate from washing into the pipe. A perforated underdrain pipe (Figure 6-25b, c) sometimes covered with a filter fabric sock is another popular means to provide for recovery of the base reservoir storage capactiy within the time frame desired by the designer.

The latter would usually be sized by using techniques for estimating the diameter of tile drains required given a specified rate of removal (see UNDERDRAIN, SW BMP 3.10). The former may be sized in the same manner as estimating orifice area required for drawdown (see DETENTION SW BMP 3.05).



In either instance, the designer should be aware that these systems only provide for temporary attenuation of runoff. **These positive drainage systems will not provide a substantial improvement in the quality of water discharged versus conventional pavement. Consequently, these systems must be emptied into a properly designed wet detention pond or other suitable treatment system prior to discharge off-site.**

2) V-Trench Water Removal to Pond: Another positive method of removing water from the base reservoir is to use the base material as a drain for transport to a relatively shallow V-trench at a low point in the cross-section of the roadway. If a heavy volume of water is expected or an appreciable gradient is involved, it would be advisable to pave the trench or size the facility such that the erosive velocity for the soil and cover is not exceeded. (See SWALE SW BMP 3.04). The V-trench shown in Figure 6-25(d) must also be emptied into a wet detention pond or other suitable treatment system prior to off-site discharge.

3) Sand Underdrain: With this type system a sub-base is provided as a filter medium. The coarse open rock drain layer (base) is underlain by a suitable filter layer (sub-base) such as clean concrete sand, approximately 6 inches in depth. The subgrade (soil) is sloped toward a single peripheral or a series of evenly spaced trenches beneath the pavement. Water is collected by a perforated pipe installed near the bottom of the trench. Provided that the minimum distance that water must travel through the sand before reaching the perforated pipe (Figure 6-25e) or reaching

FIGURE 6-25

Examples of Porous Pavement Drainage Systems

Source: Investigation of Porous Pavements for Urban Runoff Control, Thelen et al

(after Virginia State Water Control Board, 1979. "Urban Best Management Practices Handbook")

R0071207

the gravel envelope surrounding the underdrain (Figure 6-25f) is 2-feet or more, these systems currently would not require additional treatment. Methods for sizing underdrain systems and the state criteria pertaining to sand filters are discussed in SW BMP 3.10. The designer should be thoroughly familiar with the requirements and drawbacks associated with stormwater filtration devices before making the decision to use this type of system for stormwater management.

Aggregate Gradation and Quality: The gradation required to obtain a porous asphalt or concrete pavement is of the "open" graded type as contrasted to the "dense" graded type which is capable of close packing. However, not just any coarse aggregate of suitable grade will work well. Experience with some locally available material consisting of crushed limestone has not been completely satisfactory.

Designers should avoid using relatively "soft" aggregate especially in pervious concrete applications. The capacity of this material to absorb substantial quantities of water seems to result in difficulties obtaining an acceptable and consistent water to cement ratio. As a consequence several applications experienced raveling that was so severe that the original treatment scheme was abandoned in favor of a more conventional approach.

The aggregates selected for porous pavement construction should be of the recrystalized type which will not hydrate. It should be hard and durable. The material should not contain phosphate or calcium florappatite within its matrix. The appropriate (ASTM) testing standards for these purposes are listed in the section entitled "Construction and Materials".

Factor of Safety in Design: Some pavement designers have suggested that because open graded mixes are not as strong as dense graded mixes, the pavement thickness needs to be increased. However, with normal and proper construction practices, sufficient subgrade compaction should be achieved so that with a well-drained subgrade a California Bearing Ratio (CBR) of six or seven could be used quite safely. These CBR values would permit pavements to be considerably thinner than normally specified.

The design of porous pavement roadways equivalent to conventionally constructed roads has been found to depend primarily on the load-bearing capacity of the subgrade, the expected traffic volume and the reservoir capacity of surface and base. Specifications of the Asphalt Institute have been used to design the porous pavement roadways illustrated in Table 6-10. Most, if not all, applications in Florida thus far have been for "light" duty service as mentioned earlier.

Because of the low load-bearing capacity of a wet subgrade, a very poor subgrade (CBR = 2) has been assumed in establishing these designs. Traffic volumes are indicated by the Design Traffic Number (DTN), which is the average number of equivalent 18,000 pound single-axle loads per day expected in the heaviest traffic lane during the design period (normally 20 years). The method of calculating the DTN is given in detail in

the Asphalt Institute Manual Series No. 1, "Thickness Design." The classifications are as follows:

DTN	TRAFFIC CLASSIFICATION
1 - 10	Light (parking lots, residential streets)
10 - 100	Medium (city business streets)
100 - 10,000	Heavy (highways)

TABLE 6-10

THICKNESS REQUIREMENTS FOR SURFACE AND BASE COURSE FOR POROUS PAVEMENT

CBR[a]	DTN[b]	SURFACE THICKNESS (INCHES)[c]	BASE THICKNESS (INCHES)[c]	RESERVOIR CAPACITY (INCHES OF RAINFALL) SURFACE	BASE	TOTAL
2	1	4	6	.60	1.80	2.40
2	10	4	12	.60	3.60	4.20
2	20	4-1/2	13	.66	3.90	4.56
2	50	5	14	.75	4.20	4.95

[a] California Bearing Ratio, a measure of the soil support value.

[b] Design Traffic Number, a measure of traffic volume.

[c] Asphalt Institute specifications assume a dense graded mix.

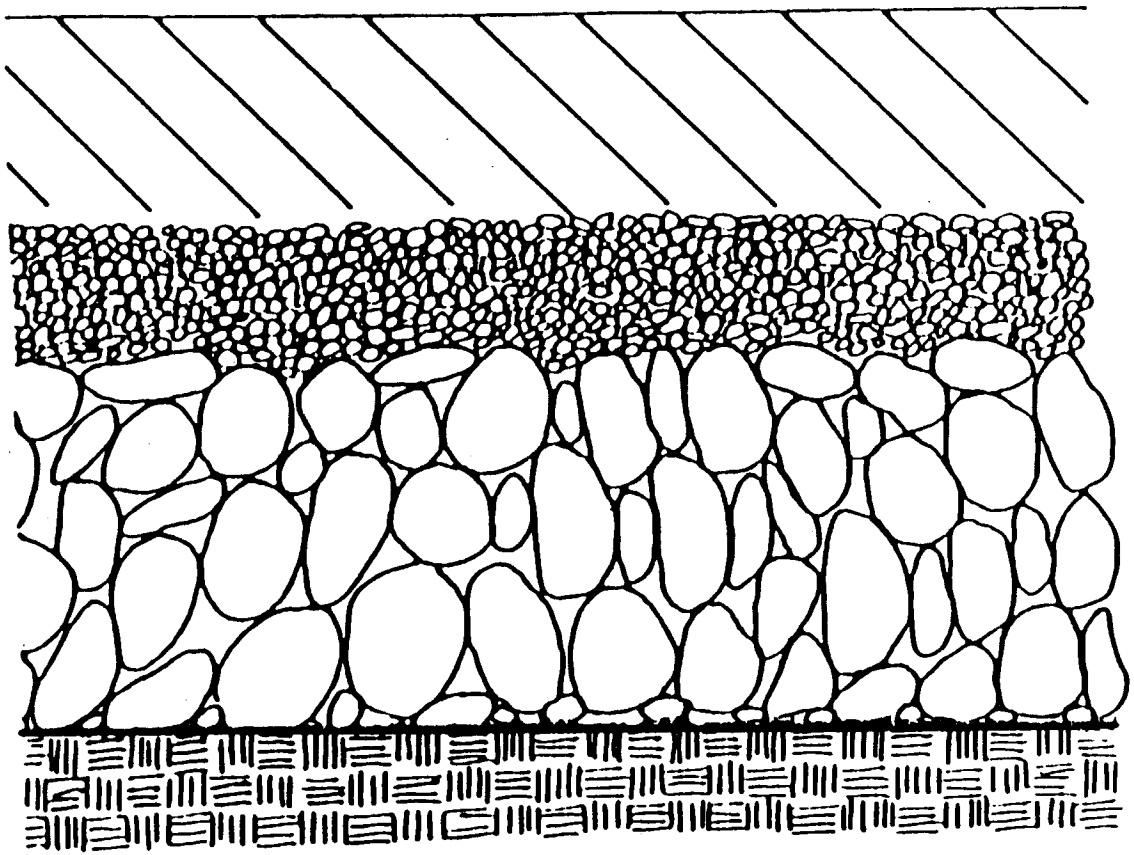
Source: Investigation of Porous Pavements for Urban Runoff Control, Thelen, et,al.

Porous pavement must be designed and built to support the heaviest traffic volumes and loads for a particular application. By increasing the depth of the base course, loads are spread conically over large areas, thus reducing the loading intensity until the subgrade will support the load without undue deformation.

R0071209

Volume of Retention Storage Available

The base course depth can and will provide for the load and also act as a water reservoir. The reservoir capacity figures given in Table 6-10 are based upon an assumed average void space of 15% for the surface course and 30% for the base course. These are average values from a number of test results. The percent pore space and the resultant reservoir capacity can be quite variable as mentioned earlier. Consequently, when estimating available storage the engineer should use the lowest percentage voids associated with any particular pervious cement or asphalt and aggregate mixture offered by the supplier.



The owner or manufacturer should retain an independent testing laboratory. The testing laboratory shall conform to the applicable requirements of ASTM E-329 "Standard Recommended Practice for Inspection and Testing Agencies for Concrete, Steel, and Bituminous Materials as Used In Construction" and ASTM C-1077 "Standard Practice for Testing Concrete and Concrete Aggregates for Use in Construction, and Criteria for Laboratory Evaluation". A minimum frequency of one test for each day of placement is recommended to verify the rodded weight of material as delivered. The test shall be conducted in accordance with ASTM C172 and C-29. The mix shall be within (±5) five pcf of design unit weight. If outside this range, mix proportions shall be modified to comply.

CONSTRUCTION AND MATERIALS SPECIFICATIONS

General: The following section provides construction standards and materials specification associated with each of the two basic categories of porous pavement currently being used in Florida. The section begins by presenting information associated with the installation of porous asphaltic paving material. These standards are followed by recommendations associated with the manufacture and placement of pervious concrete. Requirements associated with other forms of pervious pavements (e.g., turf block) may be found by referring to CONCRETE GRID AND MODULAR PAVEMENT (SW BMP 301).

Porous Asphalt

Thus far the application of porous asphaltic paving material has been minimal in Florida. Only a very limited number of installations have been reported to date. The technology remains predominantly untried, therefore, the standard discussed herein represent suggestions obtained from other regions of the United States where the procedure has had more popularity. This technique has been most extensively used in Maryland. The following discussions and recommended standards were established by the state of Maryland to help ensure the longest possible function of these facilities. The reader should refer to (Figure 6-26) for an illustration

POROUS ASPHALT PAVING TYPICAL SECTION

Modified after Diniz, 1980 and City of Rockville, Maryland, 1982

showing the types of materials used in these installations, their relative location within the matrix and the thickness associated with a typical cross-section of porous asphalt pavement.

The design shown is typical of most installations permitted by the City of Rockville, Maryland. The material is composed of four layers as described below:

1) Minimally compacted subbase consisting of undisturbed existing soil. Auxiliary drainage structures (French drains, pipe drains, etc.) may also be required for soils with slower infiltration rates.

2) Reservoir base course consisting of one to two inch diameter stone aggregate. The thickness of this reservoir layer is determined from runoff storage needs, the soil load bearing strength and the traffic load.

3) Two inches of 1/2-inch aggregate to stablilize and fair the reservoir base course surface.

4) Porous asphalt concrete surface course with a thickness that is based on bearing strength and pavement design requirements. For most applications, light duty applications 2-1/2 to 4 inches have been found to be sufficient.

In addition, a layer of engineering filter fabric is recommended between the soil and the reservoir base course, as shown in the typical porous asphalt pavement cross-section presented in the figure.

Porous asphalt paving is used to recharge groundwater supplies and reduce stormwater runoff and water pollution from paved, low-volume traffic areas by providing a bearing surface having adequate strength to accommodate vehicles while allowing infiltration of surface water and filtration of pollutants.

Subgrade Preparation

1) Alter and refine the grades as necessary to bring subgrade (soil profile) to required grades and sections as shown in the drawings.

2) The type of equipment used in subgrade preparation construction shall not cause undue subgrade compaction. Use tracked equipment or oversized rubber tire equipment - DO NOT use standard rubber tired equipment. Traffic over subgrade shall be kept at a minimum. Where fill is required, it shall be compacted to a density equal to the undisturbed subgrade, and inherent soft spots shall be corrected.

Aggregate Base Course (Reservoir Course)

1) All stone used shall be clean, washed, crushed stone, meeting Florida Department of Transportation specifications.

2) The aggregate shall be of two sizes. The reservoir base course shall be to depth as noted on drawings of 2-inch to 1-inch aggregate (FDOT No.3) or equivalent. A two inches deep top course of 1/2" aggregate (FDOT No. 7) is also recommended.

3) Aggregate base course shall be laid over a dry subgrade covered with engineering filter fabric to a depth shown in drawings, in lifts to lay naturally compacted. The stone base course shall be compacted lightly. Keep the base course clean from debris, and sediment.

Porous Asphalt Surface Course

1) The surface course shall be laid directly over the 1/2" aggregate base course and shall be laid in one lift.

2) The aggregate selected for porous asphaltic pavement construction should meet requirements of the standard specification for "Crushed Stone, Crushed Slag, and Crushed Gravel for Bituminous Macadam Base and Surface Courses of Pavements", ASTM D-693-71, with one exception and one addition. The exception requires the gradation to be of the open graded type for the reasons described previously. The addition should be a requirement for a soundness test as specified in ASTM D-694-62, "Crushed Stone, Crushed Slag, and Crushed Gravel for Dry-Bound or Water-Bound Macadama Base Courses." This is required to determine if the aggregate is susceptible to disintegration by water.

   The aggregate grading shall be of a type (FDOT No. 7 or similar) wherein the majority (60% by weight) of material is concentrated in the 1/2" to 3/8" size range. All stone used shall be clean washed crushed stone containing less than 2% silt clay and organic matter. Any material finer than No. 4 shall be of uniform distribution.

3) The asphalt grade shall meet AASHTO Specification M-20 for 50 to 65 penetration road asphalt as a binder in the southern United States. The suggested viscosity grade of asphalt cement to be used is AC-20 of AASHO M-226-73 I. This grade is to be considered a tentative starting point because test results obtained from the design process may indicate an advantage or a necessity to alter the asphalt grade.

R0071213

4) For road paving durability and to prevent too rapid hardening of the asphalt, it is desirable to have the highest asphalt content possible in the mix. Too much aspnalt would separate out under traffic, so that maximum asphalt content is generally limited by that factor. Experience has shown that 5.5% by weight is the minimum recommended aspnalt content. Asphalt content should be determined according to the testing procedure recommended in Federal Highway Administration Report No. FHWA, RD-74-2, Design of Open-Graded Asphalt Friction Courses.

5) The mixing plant shall certify the aggregate and the asphalt content in the mix. The asphaltic mix shall be tested for its resistance to stripping by water using ASTM D 1664. The asphalt-coated aggregate should retain an estimated 95% of the coated area after water immersion of the mix for 16 to 18 hours at 77°F (25°C). If this standard is not met, then anti-stripping agents are added to the asphalt. Many designers, however, feel that this specific testing procedure is not very reliable. Federal Highway Administration Report No. FHWA-RD-74-2 includes a test for resistance to water (Immersion Compression Test) which may also be used for determining whether stripping might be a problem. However, the best insurance for avoiding stripping problems is the use of aggregates and asphalts that are compatible with one another.

6) To ensure that the individual aggregate particles are completely surrounded by asphalt, and that the asphalt is tightly bound to each particle, temperature of mixing at the hot mix plant must be rigidly controlled. Too low a mixing temperature will result in inadequate asphalt binding and coverage of the aggregate, while too high a mixing temperature will allow asphalt to drain from the mix, resulting in a lower asphalt content and decreased strength. Suitable mixing temperatures range from 230° - 260°F, with the recommended temperatures at the lower end of that range (230° - 240°F).

   The minimum air temperature of 50°F, is recommended to make sure that the surface does not cool prior to compaction.

7) Compaction of surface course shall be done while the surface is cool enough to resist a 10-ton roller. One or two passes by the roller is all that is required for proper compaction. More rolling could cause a reduction in the surface course porosity, damage the aggregate, and break the bonding between particles which would shorten the pavement life.

8) Transporting of mix to site shall be in a clean vehicle with smooth dump beds that have been sprayed with a non-petroleum release

agent. The mix shall be covered during transportation to control cooling.

9) Experience has shown the need for close control of contractor vehicles on newly installed areas or porous pavement. Damage to pavement porosity results chiefly from abuse during the early life of the pavement. Normally, paving is done while heavy construction or earth moving is continuing in an area. The new pavement is thus subjected to mud and dirt from contractor vehicles for up to several months, and the continual passage of these vehicles compacts the dirt into the pores. Only if caked mud is cleaned from vehicle wheels and the pavement is cleaned daily by sweeping and high-pressure water washing can porosity be retained. Clogging can be further minimized by proper use of curbing to prevent surrounding soils from washing onto the pavement surface.

CONSTRUCTION AND MATERIAL SPECIFICATION (CONTINUED)

Pervious Concrete

Introduction: Pervious concrete contains a large percentage by weight of aggregate larger than the number four sieve (0.185 inches). Pervious concrete is also referred to by several other names such as open graded mix, gap graded mix, draincrete, popcorn mix, no fines mix or porous concrete. Pervious concrete has a high void space, at least 15% is required and a coarse surface texture. The water-cement ratio is low, 0.20 - 0.40, and the slump is extremely low, often zero.

Excessive amounts of water yield a paste which is too fluid and flows off the aggregate particles, reducing cohesion and filling the voids in the lower part. Too little water results in a paste which does not adhere to the aggregate particles, leading to insufficient cohesion. The quantity of cement paste and water is considered sufficient when it coats the coarse aggregate with a shiny film, giving it a metallic gleam. A typical mix provides a permeability of about 2.3 gallons per minute per square foot. Higher percolation rates are possible with higher void contents, but higher void contents also produce lower strengths.

Compressive and flexural strengths of pervious concrete are somewhat lower than those of conventional portland cement concrete, due to the higher void content and lower unit weight. Compressive and flexural strengths are dependent on the water-cement ratio, aggregate-cement ratio, unit weight, void content and aggregate shape and size. The flexible nature of this pavement means that the subgrade condition is extremely important to the performance of the pavement.

The method of handling and placing are different from other types of concrete. Only concrete firms and contractors familiar with the intricacies of porous concrete should be used and then only if a Professional Engineer,

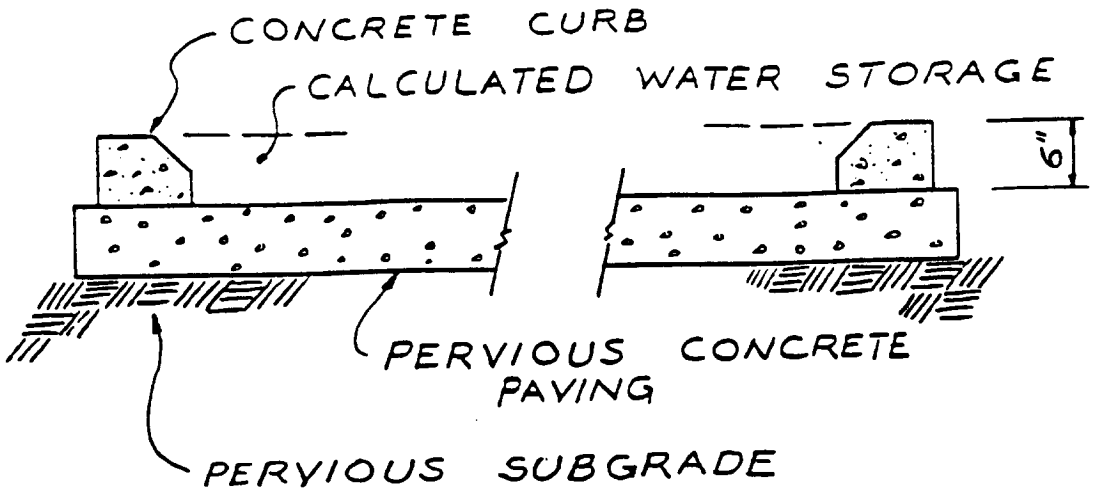
with training and experience in porous concrete, is present during tne time of paving. Pervious concrete is placed into location and not poured as is conventional concrete. Tne time lapse between batching and placement should be kept as short as possible. Due to its low water-cement ratio, hydration of the cement will proceed faster and strengths may be impaired from delays in placement. Pervious concrete is placed with a minimum of handling. Best results have been obtained by using a vibratory screed, or vibratory bullfloat for small jobs. These may have to be modified by adding extra weight. For uniform compaction it is advisable to have an inch of material along the base of the screed, while moving it over the concrete surface. Hand troweling or finishing is neither required nor desirable, as this will close up the voids and impair the drainage characteristics.

When a vibratory screed is used, its forward movement over the concrete should not be stopped unless the vibrating mechanism is also stopped. Otherwise, there will be variations in the surface texture of the concrete. A straightedge for manual screeding should be available on jobs using a vibratory screed. In the event of machine breakdown, this will permit uninterrupted unloading of the mixer trucks and avoid extended mixing with attendant loss in voids and change in consistency.

The screeding operation must be followed by two passes with a garden roller. This is to assure that any loose particles are becoming well embedded in the pavement surface.

Curing is a very important factor with pervious concrete. With the high void percentage, rapid drying is a far more serious problem because the dry paste fails to bond the aggregate particles together. Therefore, adequate moist curing is essential. The pervious concrete should be sprayed shortly after screeding, with a light mist so as not to wash the cement paste off the aggregate. It is then covered with impervious sheets for at least the first three days, and preferably for a longer period.

A typical cross-section of porous concrete as installed in south Florida is illustrated by Figure 6-27. These installations are different from pervious asphaltic pavement, primarily due to the type of cementing agent that is used in the surface course (e.g., portland cement as opposed to asphalt). However, it is also noticeable that the pavement is placed direclty on the shaped and graded existing sandy soil (pervious subgrade).



Retention storage of up to six inches maximum depth is provided on the surface of the pavement as well as within the voids in the concrete. The load bearing 1/2-inch aggregate base, the open graded coarse aggregate subbase, and filter fabric that were shown with the pervious asphalt cross-section (Figure 6-26) are often not used. When a subbase is required for stability, up to six inches of clean durable quartz sand (FDOT 902 Fine Aggregate) or equivalent is substituted for crushed stone. The concrete is then placed directly on this lightly compacted subbase.

However, the manufacturer of the patented porous concrete paving process includes both the 1/2-inch bearing course and the open graded subbase in

R0071216

FIGURE 6-27

PERVIOUS CONCRETE PAVEMENT
TYPICAL SECTION

A close-up view of no-fines concrete

R0071217

their design. A layer of compacted sand is used between the subbase and the existing soil to prevent the migration of fine material in the surrounding media from migration into the subbase. Certainly this design would provide for more strength and stability and would be preferred in anything exceeding light duty applications.

A manual relating to mixing, hauling, placing, testing and suggested design procedures for use of pervious concrete is available through the Florida Concrete and Products Association at a nominal fee. This comprehensive Manual will assist material suppliers, contractors, specifying agencies and design professionals in the proper procedures used to place portland cement pervious pavements.

At a minimum the following interim specifications should be followed for the manufacture and placement of pervious concrete pavement.

1) Materials:

Locally available materials having a record of satisfactory performance are recommended.

a) The cement used for these facilities shall be Portland Cement Type I or II conforming to ASTM C-150 or Portland Cement Type IP or IS conforming to ASTM C-595. Fly ash conforming to ASTM C-618 may be used in amounts not to exceed 20% of total cementitious material. Ground iron blast-furnace slag conforming to ASTM C-989 may be used in amounts not to exceed 50% by weight of total cementitious material.

b) Use Florida Department of Transportation (FDOT) No. 8 coarse aggregate (3/8 inch to No. 16) ASTM C-33 or No.89 coarse aggregate (3/8 inch to No. 50) ASTM D-448. For designs incorporating fine aggregate, it shall conform to FDOT Specifications 902. Other gradation of aggregate may be used, subject to approval.

c) Air Entraining Agent: Shall comply with ASTM C-260.

d) Admixture: Type A water reducing

Type D water reducing and retarding
Type E water reducing and accelerating
In accordance to ASTM C-494

e) Water: Potable or shall comply with FDOT Standard Specifications, Section 923.

2) Proportions:

a) For pavements subjected to other than light vehicular traffic, the total cementitious material shall not be less than 600 lbs. per unit.

b) The volume of aggregate per unit shall be equal to 27 cu.ft. when calculated as a function of the rodded unit weight determined in accordance with ASTM C-29.

Fine aggregate, if used, should not exceed 3 cu.ft. (rodded unit weight in accordance with ASTM C-29) and shall be included in total aggregate volume.

c) Admixtures shall be used in accordance with the manufacturer's instructions and recommendations.

d) The quantity of mix water shall be such that the cement paste displays a "wet-metallic" sheen, without causing the paste to flow from the aggregate. Insufficient water will result in a dull appearing paste of inadequate consistency.

3) Subgrade Preparation and Formwork:

a) The top six inches of the subgrade shall be composed of granular or gravely soil that is predominantly sandy with no more than a moderate amount of silt or clay.

b) Prior to placement of Portland Cement Pervious Pavement, the subgrade shall be tested for rate of permeability by double ring infiltrometer, or other suitable test of subgrade soil permeability.

c) Subgrade Support: Material shall be placed and compacted in layers of a thickness that can be compacted to a minimum density of 94 ± 2% of maximum density as determined by AASHTOT-180. A minimum Limerock Bearing Ratio (LBR) of 20 ± 2 shall be obtained in the top six inches of the subgrade.

d) Subgrade Moisture: The subgrade shall be in a moist condition with no free standing water prior to pavement placement.

e) Forms: Forms may be of wood or steel and shall be the depth of the pavement. Forms shall be of sufficient strength and stability to support mechanical equipment without deformation of plan profiles following spreading, strike-off and compaction operations.

f) If required, control (contraction) joints shall be installed at 60 foot intervals to a depth of 1/4 the pavement thickness. No raveling of the surface will be permitted during the joint installation procedure. Isolation (expansion) joints will not be used, except when pavement is abutting building slabs or other adjoining structures.

5) Testing and Inspection:

a) It is strongly suggested that the owner retain an independent testing laboratory. The testing laboratory shall conform to the applicable requirements of ASTM E-329 "Standard Recommended Practice for Inspection and Testing Agencies for Concrete, Steel, and Bituminous Materials as Used in Construction" and ASTM C-1077 "Standard Practice for Testing Concrete and Conrete Aggregates for Use in Construction, and Criteria for Laboratory Evaluation" and shall be inspected and accredited by the Concrete Materials Engineering Council, Inc., or by an equivalent recognized national authority.

The agent of the testing laboratory performing field sampling and testing of concrete shall be certified by the American Concrete Institute as a concrete field testing technician Grade I or by a recognized state or national authority for an equivalent level of competence.

b) A minimum frequency of one (1) test for each day of placement shall be conducted to verify the rodded weight of material as delivered. The test shall be conducted in accordance with ASTM C-172 and C-29. The mix shall be within (±5) five pcf of design unit weight. If outside this range, mix proportions shall be modified to comply.

c) At seven (7) days from placement, a minimum of three (3) cores for each placement shall be taken in accordance with ASTM C-42. The cores shall be used for verification of pavement thickness. Subsequent to thickness verification, core ends shall be trimmed to facilitate volume determination. Core unit weight shall be calculated based on weight results when tested in accordance with ASTM C-140 paragraph 14.1 (disregard suspended weight).

Pavement acceptance shall be based on the average unit weight of cores being within ±5 pcf of design weight. The thickness of the pavement recommended is five (5) inches for light traffic loadings. Additional thickness will be required for pavement subjected to frequent heavy axle loadings.

4) Mixing, Hauling and Placing:

a) Truck mixers shall be operated at the speed designed as mixing speed by the manufacturer for 75 to 100 revolutions of the drum.

b) The portland cement aggregate mixture may be transported or mixed on site and should be used within one (1) hour of the introduction of mix water, unless otherwise approved by an engineer.

c) Each mixer truck should be inspected for appearance of concrete uniformity according to preceding Section (2d). Water may be added to obtain the required mix consistency. A minimum of 20 revolutions at the manufacturer's designated mixing speed shall be required following any addition of water to the mix. Discharge shall be a continuous operation and shall be completed as quickly as possible.

d) Placing and Finishing Equipment: Unless otherwise approved by the Owner or Engineer in writing, the Contractor shall provide mechanical equipment of either slipform or form riding with a following compactive unit that will provide a minimum of 10 psi vertical force. The pervious concrete pavement will be placed to the required cross-section and shall not deviate more than $\pm$ 1/4-inch in 10 feet from profile grade. If placing equipment does not provide minimum specified unit weight, a full width roller or other compaction device that will provide a compactive effort to meet unit weight requirement will be used immediately following strike-off operations. After mechanical or other approved strike-off and compaction operation, no other finishing operation will be allowed. If vibration, internal or surface applied, is used, it shall be shut off immediately when forward progress is halted for any reason. The Contractor will be restricted to pavement placement widths of a maximum of fifteen (15') feet unless Contractor can demonstrate competence to provide pavement placement widths greater than the maximum specified to the satisfaction of the Engineer.

e) Curing procedures shall begin within twenty minutes after final placement operations. A fog mist shall be applied prior to covering all surfaces and exposed edges with a 6-mil thick polyethylene sheet for a period of five days. Covering shall be held down securely to prevent dislocation due to high winds or adjacent traffic conditions.

Maintenance

Routine maintenance involves removal of debris that is too coarse to be washed through the pavement system. Vacuuming pavements is required to remove particulates that are fine enough to be carried into the pavement but too large to pass through, thus clogging the void space. Porous pavements require no more repair maintenance than conventional pavements, so maintenance problems can generally be reduced to better "housekeeping" practices on the part of area residents and more efficient street cleaning procedure in municipalities.

To preserve the high filtration rate of the pervious paving, routine inspection and maintenance is required. The surface should be routinely visually checked (preferably after a prolonged storm event) for evidence of debris, ponding of water, clogging of pores and other damage. Any debris should be immediately removed. An annual cleaning program should be instituted that requires a street sweeper with a vacuum to thoroughly cleanse the surface.

Cleaning: It has long been recognized that maintenance and cleaning of porous pavements to prevent or alleviate clogging would be a factor in the application of such pavements. Sections of porous pavement which have been clogged have been cleaned by various methods. No method has been satisfactory on fully clogged pavements, however, and, only a superficially clogged section showing a water penetration rate of 0.1 inches per second compared to a normal water penetration of 0.38 inches per second can be restored to normal operation. The best method for cleaning is brush and vacuum sweeping followed by high pressure water washing of the pavement. In Maryland it has been determined that vacuum cleaning alone, once the pavement is clogged, will be largely ineffective. The oils, especially in porous asphalt, bind dirt, and, only an abrading and washing technique can be effective in its removal. Clogging to a depth of 0.5 inch is sufficient to prevent water penetration.

If, during visual inspection, any ponding or clogging is noticed, the following program should be followed to correct the problem. First, a street sweeper with a vacuum would be used. If ponding persists, steam cleaning with a biodegradable substance can be applied, then vacuum. If the clogging is at a depth greater than 1/2-inch, holes, 1/4-inch in diameter and one (1) foot on-center, can be drilled through concrete pavement. Hand drilling or tandem drill rigs may be used. All drilling debris should be vacuumed from the pavement.

Replacing Clogged Pavement: Once a large area of porous pavement is fully clogged and it cannot be adequately cleaned, the paving must be removed to a depth where the clogging is not evident and new porous paving filled in. In extreme cases, the affected area must be removed and new topping put down. Since these materials are relatively new, obtaining a patching mix suitable

to match the installed pavement may be difficult. Available patching material is usually dense graded at present. If the subbase becomes clogged, the pavement must also be saw cut and removed. Six to twelve inches of the subbase will usually need to be replaced with clean sand, then proof rolled. Pervious paving will then need to be filled in.

SW BMP 3.07

STORMWATER RETENTION BASINS

Definition

The use of infiltration basins (usually dry) to retain stormwater on site thus reducing pollution and improving downstream water quality.

Purpose

To incorporate pollution control and groundwater recharge concepts into the design and construction of storage areas for the percolation of stormwater runoff so that the adverse impact of urban type development on receiving waters can be reduced.

R0071224

Conditions Where Practice Applies

Applicability of this practice is primarily dependent upon the availability of an adequate site for a retention area or for modifications of an existing system. Geologic, topographic and soils conditions must be considered in determining site suitability. The most significant limiting factor in many cases is the availability of sufficient land area to provide the necessary storage volume. This is particularly true in densely urbanized areas where land is scarce and property values are high.

The soil and water table conditions must also be such that the system can, in a maximum of 72 hours following a stormwater event, provide for a new volume of storage through percolation and/or evapotranspiration. Retention systems do not release stored waters for surface discharge.

Planning Considerations

Retention ponds are often designed and constructed for a number of purposes other than nonpoint source pollution control. The purpose may be recreation, water supply, recharge, flood protection, aesthetic improvement or any combination. Incorporating pollution control concepts into the design and construction of such impoundments or in modifying existing impoundments can provide added benefits in improved downstream water quality. All elements of any impounding structure must be designed, modified, and/or constructed and operated in conformance with good engineering practice.

Basins are generally open excavated depressions of varying size. They can be located in excess land areas within a road right-of-way, within open land areas of developments, within recreational sites such as playgrounds or athletic fields and within natural or landscaped depressions. Designed for storage and infiltration, these basins can be a practical and economical means of disposing of road or subdivision surface water. Their principle drawback is that they require considerable space. However, where space is available, they may be the least expensive recharge system to construct per unit of water handled.

Retention systems are suitable over much of Florida, but they are particularly desirable in areas with deep sandy soils. Areas in which impermeable or semi-impermeable lenses protect underlying sources of groundwaters may be equally suitable locations. Tests performed as a part of the statewide and regional nonpoint source management programs during the late 1970's show that a substantial amount of the pollutants carried in stormwater including suspended solids, oxygen demanding materials, heavy metals, bacteria, some varieties of pesticides and nutrients such as phosphorus are removed as runoff percolates through the vegetation and soil profile.

R0071225

Recently, the percolation of stormwater using on-site retention systems has gathered acceptance. Their appeal is heightened by a widely recognized need to promote the recharge of groundwater to prevent salt water intrusion in the rapidly urbanizing coastal areas of the state. The impact on the quality of underlying groundwaters is a prime concern of the Department. This potential impact must be fully considered in planning a retention system to prevent groundwater contamination. While only a handful of studies have found measurable effects on groundwater quality from infiltration systems, few if any studies have been conducted to evaluate the full range of constituents that may be found in stormwater runoff. Therefore, protection of groundwater remains a primary consideration in the design of retention systems.

As stormwater percolates through the soil into underlying geologic formations, the form and concentration of pollutants will be subject to alteration by a variety of physical, chemical and biological processes. Unless these interactions are well understood and considered in the design of infiltration and seepage facilities, the possibility of groundwater contamination and/or surface water degradation through lateral transmission is always a threat.

The following recommendations should be followed when planning and designing a retention system:

1) Lateral distances between seepage structures and surface waters should be maintained as large as possible (e.g., at least 100 ft. or more) depending upon site conditions.

2) Treatment practices should take greater advantage of the unsaturated zone for attenuation of pollutants. Where feasible, swale conveyances are preferable to curb and gutter systems.

3) "Source controls" of stormwater runoff and its associated pollutants should be used whenever possible. These are easier to maintain and have less potential for problems than do large structural treatment and storage devices which concentrate runoff at the downstream end of a project prior to discharge. As the name implies, source controls are designed to control pollutants before they enter the storm sewer or other conveyance system. To ensure adequately diffused pollutant concentrations once they enter an aquifer it is wise to avoid configurations which concentrate pollutants. A number of small retention facilities would be preferable to a single large facility in areas where the aquifer is shallow and relatively unprotected from materials which can percolate down from the land's surface.

4) When possible, the bottom of retention facilities should be at least three feet above the mean high water table elevation and any limestone or other water conducting strata. This will ensure sufficient vegetation and soil to promote pollutant removal and improve the hydraulic capacity of the system.

5) Seepage systems should not be located in close proximity to drinking water supply wells. Chapter 17-22, F.A.C. requires stormwater treatment facilities to be at least 100 feet from any public water supply well.

6) Industrial and commercial land uses may have unusual contaminants in the stormwater runoff. This can lead to uncertainities about the amount and type of constituents this water is likely to contain and the control practices that may be necessary. Stormwater discharges that include synthetic organic compounds such as solvents (e.g., from marine maintenance areas, airport, etc.) should be monitored for several storms before final stormwater management plans are made. This is particularly important in any areas where the aquifer is shallow and must be protected. The presence or absence of pollutants that might not be treatable via filtration through the soil, sand or limerock should be established prior to designing a treatment system. In such instances the physical, chemical and hydrologic properties of the pollutant may be known and an effective scheme could be devised to increase the effectiveness of the system to treat it. For example, pollutants that may be soluble but volatilize rather quickly in aerobic conditions could be prevented from entering the groundwater system by increasing the turbulence associated with the conveyance system prior to reaching the retention facility.

7) The use of sinkhole depressions to provide stormwater treatment should be avoided. There are several areas in Florida where active subsurface erosion of the underlying geological formations is common. Experience shows that large deep impoundments may experience problems with sudden and unexpected collapse. The result is a direct discharge of stormwater pollutants directly to the aquifer. Therefore, using areas which are showing signs of Karst activity for stormwater disposal would be unwise. The state groundwater rule (Chapter 17-4.245, F.A.C.) specifies that stormwater must be treated to primary and secondary drinking water standards prior to direct discharge to groundwater.

Special Planning Considerations for Karst Sensitive Areas

The Floridian aquifer is the drinking water source for much of the population of Florida. In parts of the state the limestone that contains this aquifer is near the land surface, only a few inches or feet away from potential pollutant sources and possible contamination from stormwater containing metals, bacteria, and petroleum products.

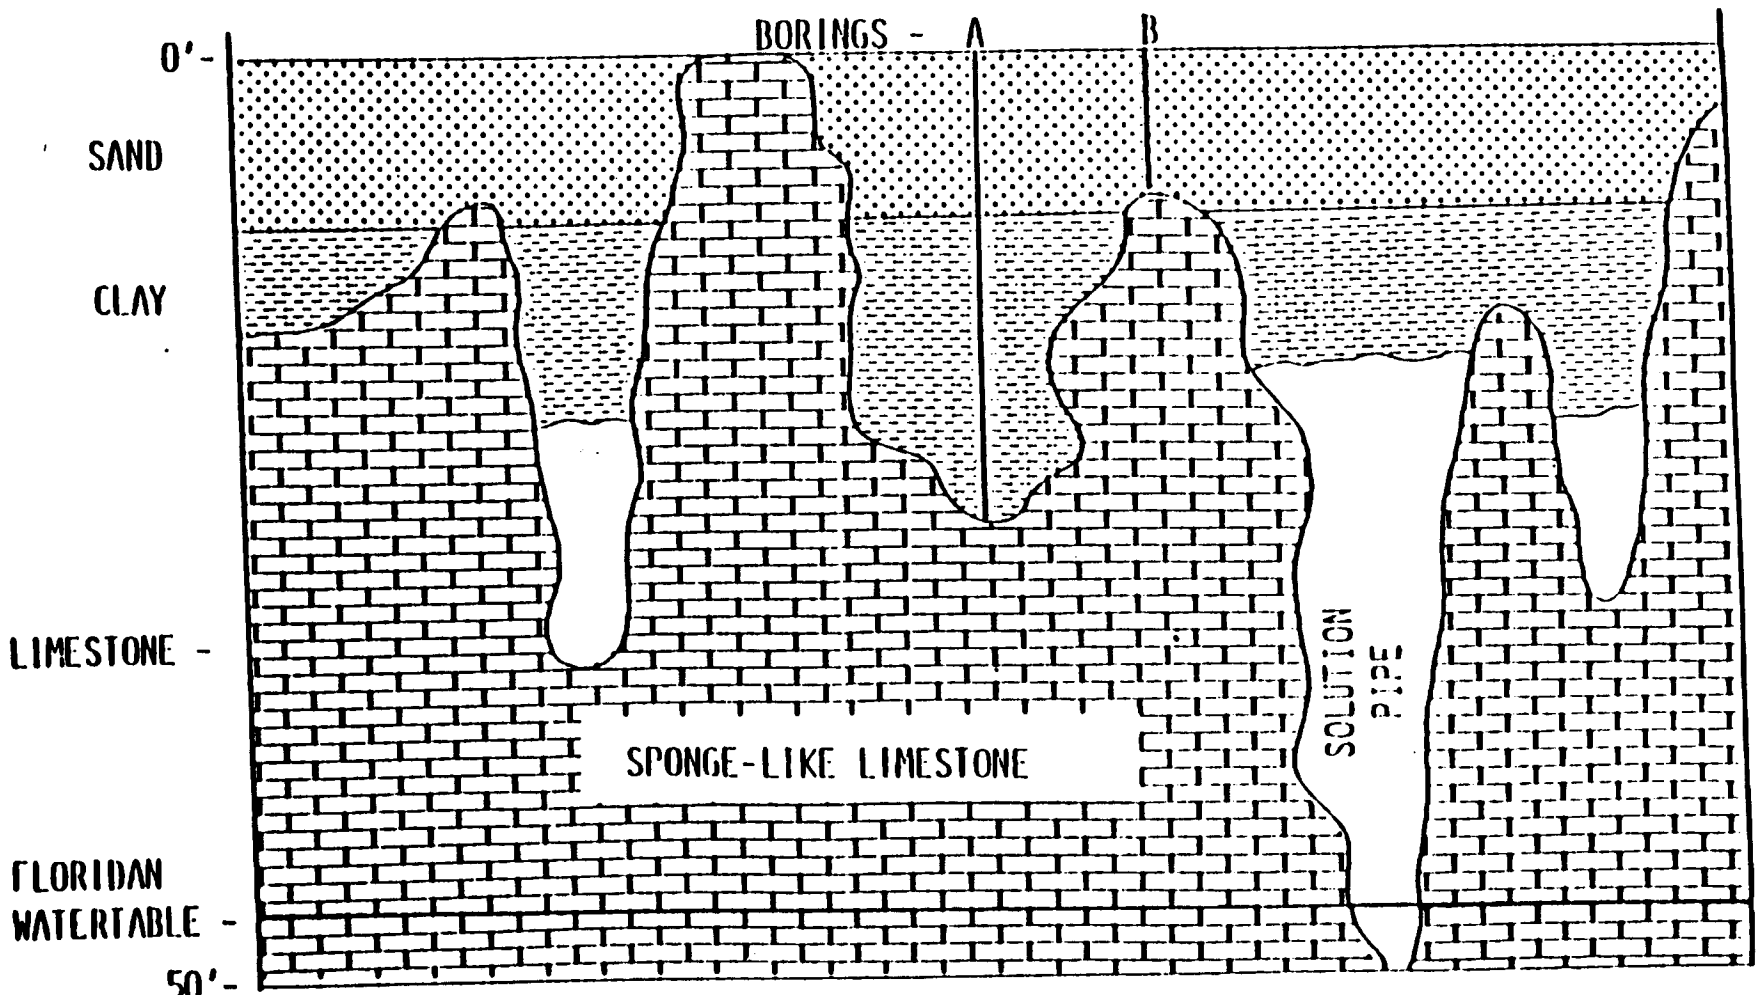
The Floridian aquifer has a greater potential for contamination from surface pollutant sources in portions of some counties than within the rest of the state. The hydrogeology and geology is the basis of this sensitivity. These areas are sometimes referred to as "Karst Sensitive Areas". Karst is a geologic term used to describe areas where sinkhole formation is common and

the landscape or topography is strongly influenced by the solution of limestone.

The highly porous limestone formations which make up the Floridian aquifer are usually overlain by tens to hundreds of feet of sands, clays, and other material. This cover acts as a buffer, isolating the Floridian aquifer from surface pollutants. Surface water seeps through this material slowly which allows filtration, adsorption and biological removal of contaminants.

However, in the "Karst Sensitive Areas" the limestone which contains the Floridian aquifer exists at, or very near the land surface (Figure 6-28). The absence of cover material allows rapid movement of surface water into the aquifer with little treatment. These regions are areas of high recharge for the Floridian aquifer.

A factor which makes the "Karst Sensitive Areas" particularly prone to stormwater contamination is the formation of a unique type of geologic condition called a solution pipe sinkhole. Solution pipes are common in Florida and they form due to the collapse of surficial material into existing long, vertical cavities that have been dissolved in the upper portion of the limestone. In most cases, the solution pipes are capped by a natural plug of sands and clays as illustrated in Figures 6-28 and 6-29. However, if the cap is washed out or it collapses, the resulting solution pipe sinkhole (Figure 6-30) can act as a direct avenue for the movement of stormwater into the Floridian aquifer.



Solution pipe sinkholes often form in the bottom of stormwater retention basins where the capping plug is thinner due to partial removal. The storage of large quantities of stormwater in the basins can also cause a greater hydraulic pressure which can promote washing out the plug in the solution pipe. The resulting cavity acts as a natural drainage well capable of evacuating large stormwater basins within a few minutes to several hours following a storm.

Experience has shown that the installation of stormwater facilities in Karst areas requires special site information and design features to assure protection of the groundwater system. Additional site survey information recommended is discussed later in this write-up (see "Surveys and Investigations Required"). Special design considerations that should be followed are listed below:

1) A minimum of three feet of unconsolidated soil should be provided between the surface of the limestone bedrock and the bottom and sides of a retention basin. As a substitute the designer may wish to use an impermeable liner or excavate and backfill with suitable soil. These provisions can give reasonable assurance of adequate

R0071231

treatment of the stormwater before it enters the aquifer or ensure that the stormwater is isolated from the groundwater.

2) The basin depth should be as shallow as possible with a flat bottom (no deep spots). The maximum depth recommended is ten feet. This reduces the potential for solution pipe sinkhole formation caused by a large hydraulic head. If limestone bedrock is within thirteen feet of land surface the requirement listed in #1 above will apply. This criteria (#1) will restrict maximum basin depth to less than ten feet in many cases.

   In areas where peak discharge controls are also in effect to reduce the potential for down gradient flooding, a dual pond system is preferred. The first flush of runoff should be treated in shallow (generally less than two feet deep), grassed retention areas. These retention areas should be incorporated into a project's open space/landscaping. Rather than concentrating the runoff into one large retention area, several small retention areas should be used.

3) The side slopes and bottoms of all dry retention basins must be fully vegetated. Vegetation plays a critical role in the removal of contaminants from stormwater and stabilization of side slopes. However, in the "Karst Sensitive Areas" droughty, highly alkaline soils are common. These conditions may prevent successful establishment of commonly used grasses such as bahia.

   Saint Augustine grass can tolerate high alkalinity and brief inundation. However, it is <u>not</u> drought resistant and irrigation will be required to foster a healthy cover during dry periods between storms.

   Bermuda grass can grow in alkaline conditions, is drought tolerant, and can stand brief inundation. It is also a low maintenance species which provides excellent cover and soil stablilization. Bermuda grass grows in a thick mat, eventually covering all exposed soil. It recovers quickly after extended periods of low rainfall. Mowing is rarely required because bermuda creeps laterally rather than growing vertically. Seed is available commercially and is inexpensive.

4) Pretreatment for stormwater prior to entering the retention basin should be designed into the system whenever possible. Pretreatment of stormwater by using sheet flow, swales, off-line landscape infiltration areas, or other measures can remove a large percentage of the pollutants (up to 90%) that are contained in stormwater.

5) Projects in areas zoned for industrial land uses shall assure that industrial pollutants do not enter the stormwater system or come in contact with groundwater. Developments permitted in areas zoned for industrial land use should receive more detailed review to assure that they comply with these requirements.

Design Criteria

General: All facilities which either temporarily or permanently impound runoff waters shall be designed to be stable during construction, and operation. The facility should be safe against overtopping during the appropriate design flood (including consideration of wind and wave action) established according to the damage potential classification, size, height of embankment and so forth. The design procedures, criteria, and manuals currently used by the United States Army Corps of Engineers, the USDA Soil Conservation Service, the U.S. Department of Interior Bureau of Reclamation, or others approved by the Department or local Water Management District may be used for appropriate references in performing these analyses. Seepage forces through the embankment foundation and abutments should be evaluated to ensure against internal erosion and sloughing. Likewise, the design should include provisions to protect the upstream slope, crest and downstream slope of earth embankments from erosion due to rain, wind and wave action.

Calculating Retention Volume

Retention facilities built in accordance with Chapter 17-25, F.A.C. must have the capacity to store and percolate either the runoff from the first inch of rainfall or (a minimum of) the first one-half inch of runoff within 72 hours. Small watershed areas (e.g., those of 100 acres or less) are only required by the department to provide for the minimum first one-half inch level of retention. However, some local review agencies may require greater retention levels.

a) Storage and Treatment of the First One-Half Inch of Runoff: The use of a retention facility is usually associated with some sort of diversion system, usually controlled by hydraulic techniques, thus requiring no energy consumption. Since retention depends primarily on soil percolation rates, the soils in the vicinity of the pond must be tested to determine infiltration rates and to locate the water table depth. Procedures to determine the infiltration rate are discussed in Appendix 6-2.

Most often, the design of retention systems is based on a specified diversion volume. Based on extensive field investigations and simulations using 20 years of rainfall data, average yearly pollutant removal efficiencies were estimated for fixed diversion volumes for on-site (small) watersheds as presented in Table 6-11. The diversion depth is the depth of runoff water which must be stored and percolated from the total watershed (contributory

area) to achieve the treatment level.

Table 6-11
Efficiency Percent Vs Retention Volume

% Eff/Ret	Diversion Depth (DI) in.
99	1.25
97	1.00
95	0.75
90	0.50
80	0.25

Assuming that a retention basin will percolate stormwater before the next storm event, a volume of storage can be calculated using the following formulas:

$$V_m = \frac{A \times DI}{12}$$

where:

V_m = minimum basin volume (acre-feet)
A = contributing watershed area (acre)
DI = diversion volume from Table 6-11 (.5 inches as specified by 17-25 F.A.C.)
12 = conversion factor (in/ft)

Example Problem: What is the minimum retention volume in acre-feet for a watershed of 24 acres if the diversion depth is one-half inch?

The Volume is:

$$V_m = \frac{(0.5)\ (24)}{12}$$

V_m = 1 Ac.Ft.

b) Storage and Treatment of the Runoff From the First Inch of Rainfall (Rational Method): The previous procedure is used for small projects less than 100 acres in size where the value of DI required to satisfy state retention storage requirements is one-half inch. Larger projects with a runoff coefficient greater than (C=0.5) would calculate storage volume a

little differently. In tnese instances, the volume of storage may be computed from a modified form of the basic rational formula:

$$V_m = \frac{CAR}{12}$$

where:

V_m is the required volume of basin (acre-feet)
C is the rational runoff coefficient as defined in Chapter 5
A is the contributing drainage area (acres)
R is the total rainfall (inches)

To meet state stormwater rule requirements, the value of R is equal to one inch.

The two sizing procedures discussed above are simplistic, easy to use procedures. They provide the engineer with the minimum basin volume that is required to satisfy the intentions of state stormwater treatment standards. However, it should be noted that the procedures were developed quite sometime ago (1977-1978) during the initial phases of the state nonpoint source pollution control program. The initial evaluation of pollutant removal efficiency and diversion volume required to achieve water quality objectives was based primarily on statistical analyses of rainfall event magnitude and duration. The results, summarized and illustrated in Table 6-11, were viewed as a first indication that high efficiencies of pollutant removal were possible by diversion and retention of the first one-half inch of runoff or the runoff from the first inch of rainfall.

While it may outwardly appear that this high degree of treatment can be ensured by simply providing storage for the first inch of rainfall, it should be recognized that these efficiencies and criteria are valid only to the extent that all storms equal to or less than the stated amount will be stored and treated. Likewise, a facility must treat the initial runoff volume from those events exceeding the treatment level and only that amount in excess of this first flush may be discharged without treatment. A number of factors including the method of calculating runoff, antecedent moisture condition, the infiltration rate, the time variability between rainfall events, the size of the watershed and the basin depth (deep basins require a longer time to drain) affect the actual treatment efficiency and thus the storage volume required for a basin to actually achieve 80% treatment. Consequently, Dr. Wanielista, of the University of Central Florida later developed a series of design equations, based on water quality and quantity research actually conducted in the field. These procedures are suitable to estimate storage volumes needed to achieve 80 to 90% pollutant removal for a wider range of watershed sizes and conditions.

R0071235

c) Storage Volumes Based on Wanielista Design Equations: The following design equations were developed for shallow basins (5 ft. deep) and two removal efficiencies.

TYPE A SOILS

80% efficiency $V_I = 0.016\ A^{1.28}$ for impervious watershed

90% efficiency $V_I = 0.046\ A^{1.18}$ for impervious watershed

$V_5 = V_I(0.59 + 0.37\ CN/100)$ for composite land use

Volume requirements can be reduced for basins less than five deep. The following equation is based on values of V_5 for composite land use areas or V_I for totally impervious projects. It should be noted that the value of V_m for the appropriate treatment efficiency or diversion volume as determined from Tabel 6-11 must also be calculated when using the following equation:

$$V_D = V_m + \left(\frac{V_5 - V_m}{4}\right)(D-1) \text{ when } 1 \leq D \leq 5$$

$$V_D = V_m \text{ when } D < 1$$

where:

V_I = basin volume at 5 foot depth for impervious areas (acre-feet)
V_D = basin volume at depth D (acre-feet)
V_m = minimum basin volume (acre-feet)
V_5 = basin volume at 5 foot depth for composite land use area (acre-feet)
D = basin water depth (feet)
A = drainage area (acres)
CN = average curve number (soil moisture II condition).

Example Problem:

A project has 30 acres of watershed area and a composite CN number of 80. Using the Wanielista Design Equations, calculate the size (acre-feet) of a 5 foot deep retention pond necessary to provide up to 90% treatment.

Step #1: Determine the value of (V_I)
90%: $V_I = 0.046\ (30)^{1.18} = 2.55$ ac.ft.

R0071236

Step #2: Calculate (V_5) for tne composite land use situation

90%: $V_5 = 2.55\ (0.59 + 0.37\ (80/100)) =$ 2.26 ac.ft.

Similar equations were developed for Class D soils. However, tne data base used to derive this formula was severely restricted due to the inherent unpopularity these systems enjoy in areas where percolation is restrictive. In such circumstances, land area required to stay within drawdown limits usually will render such systems non-cost effective. Soil replacement with more permeable material, underdrains or stormwater filtration facilities, or wet detention systems are economically more feasible in most urbanizing situations with such soil conditions. As a result, the equations for this circumstance are not included in this write-up.

Dr. Wanielista's design equations for low runoff potential (Type A) soil conditions were used to evaluate how the "rational method" and "SCS CN Method" and the one-half inch treatment criteria compare in respect to providing the storage volume estimates needed to ensure 80 to 90% treatment capacity. The results are illustrated in the following table. The analysis was based on the assumption that a rational coefficient of .64 is equivalent to curve number (CN) of 75, AMC-II.

Storage Volume (Acre - Feet)

Area	(1) 80%	(2) 90%	(3) Rational Formula	(4) SCS CN Method	(5) V_m 1/2"
10	0.26	0.60	0.53	0.025	0.42
50	2.08	4.03	2.67	0.125	2.08
100	5.04	9.14	5.33	0.25	4.17

1) Vol. (Ac. Ft.) for 5' deep pond, composite land use, 80% efficiency Design Equation

2) Vol. (Ac. Ft.) 5' deep pond, composite land use, 90% efficiency Design Equation

3) Volume with Rational Formula (e.g., 0.64 x 10 ac. x 1 in. rain x 1 ft/12 in. = .53 Ac.Ft.)

4) Vol. = Runoff depth for 1 in. rainfall (R) x Area (Ac) x 1/12; where, $[R=(P-.2S')^2/P+.8S']$ & [S' = (1000/CN)-10] & [P = 1 inch] (e.g., .03 in. x 10 Ac. x 1 Ft/12 in. = .025 Ac.Ft.)

5) V_m = Retention volume associated with the first 1/2-inch of runoff (minimum basin volume)

R0071237

As can be seen, both the rational method and the half inch diversion criteria generally work to ensure 80 to 90% removal. However, as the watershed increases in size to the 100 acre cutoff, the half inch diversion requirement gradually begins to fall short on providing sufficient storage volume to satisfy the 80 to 90% treatment intended by Chapter 17-25 F.A.C.. Therefore, the half inch diversion volume procedure for sizing retention areas is allowable for drainage areas up to and including 100 acres in magnitude. Larger areas with (C) values in excess of (.5) must provide storage for the runoff from the first inch of rainfall as calculated with the rational method.

Use of the SCS composite curve number method for sizing these systems results in a greatly undersized basin as illustrated in the table. Therefore, this procedure is not allowable for these purposes.

The Wanielista Design Equations can be used for watershed sizes up to 500 acres in size. Beyond 500 acres a linear relationship can be used which relates size of retention in multiples of those calculated for 500 acres. The designer should also be advised that whenever the value of V_m, based on 90% treatment (e.g., DI = 1/2" from Table 6-11) exceed the value of V_I calculated using the design equation, the designer should consider V_m equivalent to the minimum basin volume allowed for any depth and abandon use of the equation in favor of the more simplified approach.

The Wanielista design formulas and the rational formula do not consider the shape or the time of concentration of a watershed. However, the spatial variation of time of concentration can be an important parameter in the routings of stormwater runoff, and the level of treatment expected given a specified diversion volume, especially for larger watershed areas. As the first flush of stormwater pollution from the upper reaches of a watershed mixes with runoff from the longer reaches, it is generally diluted. This is because the first flush from the lower reaches has already passed by and the runoff from the lower watershed area is now relatively "clean". The design of a stormwater drainage system should take into account the implications of routing of the first flush to the retention pond. This evaluation can also be beneficial in the site selection process of the pond itself.

Large narrow watersheds can be expected to have a long time of concentration compared to more compact drainage areas. They may also be expected to produce long, drawn out hydrographs. Due to the extended time it takes water from the upper reaches of the drainage area to reach the outlet, only a small percentage of the runoff waters are contributing to flow at any point in time. During a storm, such watersheds display the unit hydrograph characteristics illustrated for the curve marked K = 0.1 in (Figure 6-31).

Other watersheds are more effective in their delivery processes. At any point in time during a storm, the ratio of flow at the point of interest when compared to the total instantaneous runoff from the entire watershed or contributing area will be much higher than in the first instance. These

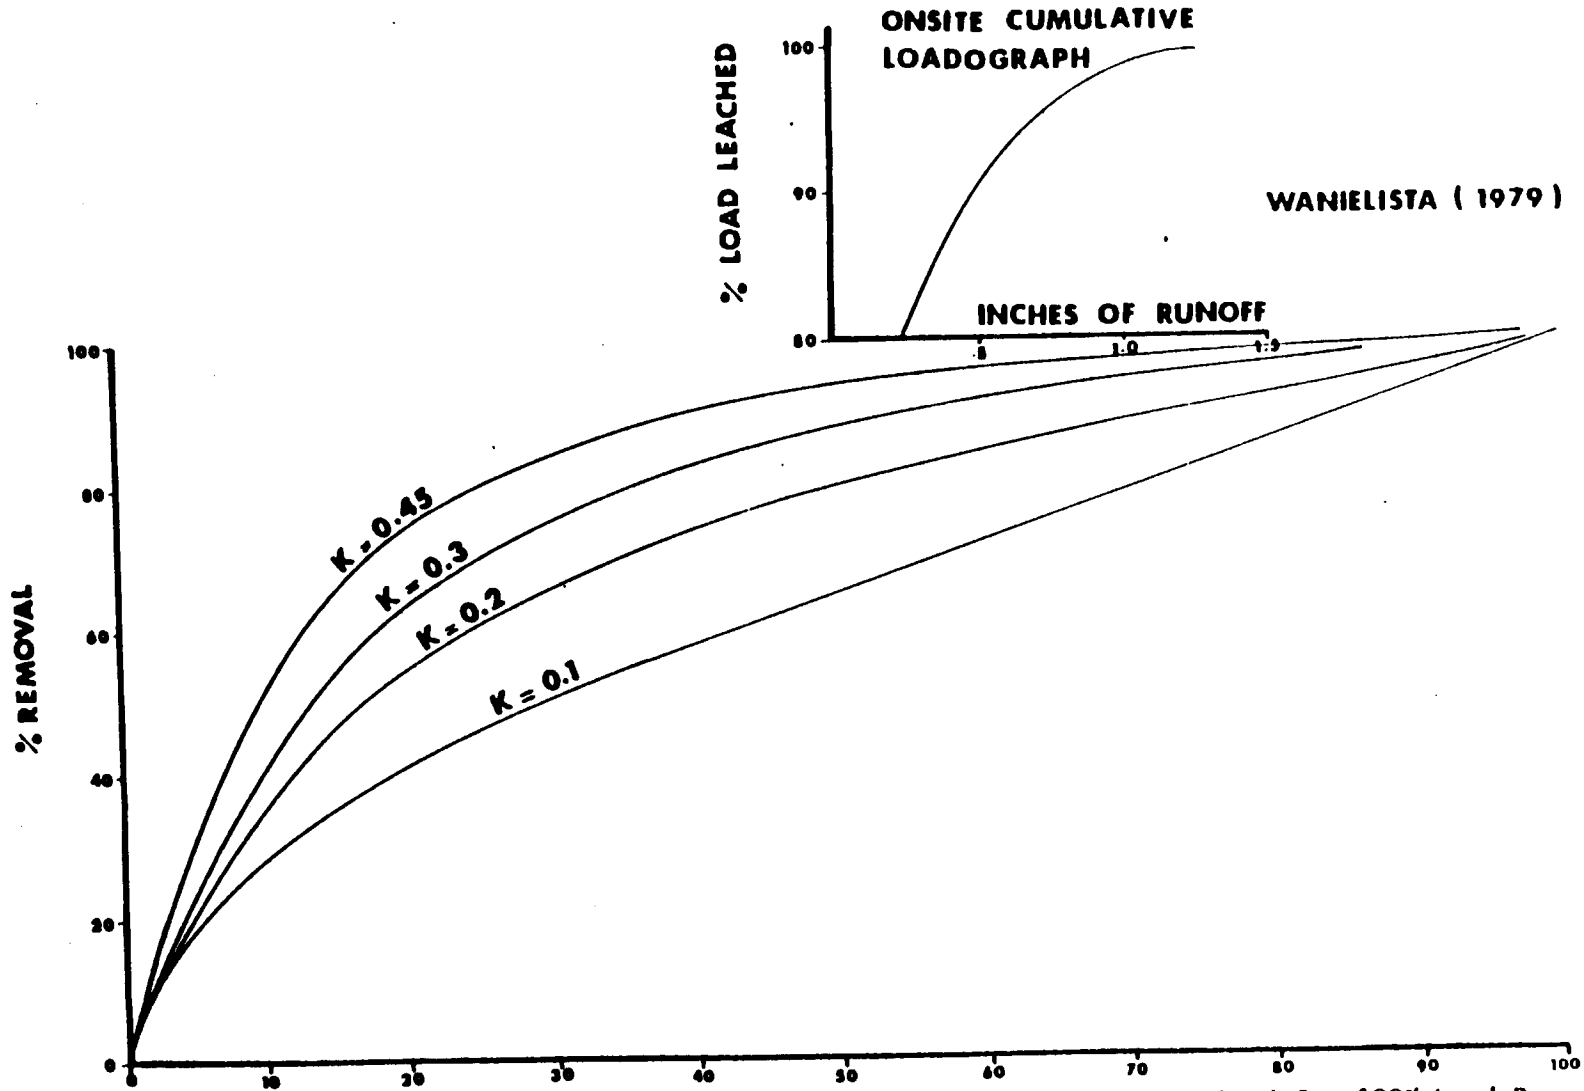

FIGURE 6-31

Variation in Potential Pollutant Removal Associated with Watershed Response and Unit Hydrograph Shape Factor (K)
(after Wanielista, 1981. "Stormwater Management Manual")

R0071239

watersheds have hydrograph shape characteristics similar to curve K = 0.45. Nearly 90% of the runoff from the entire watersned may be observed at the outlet during the first flush producing period.

The important point to consider in this discussion is the following:

> If it is determined that 80% pollutant removal must be acheived, then 75% of the first 1.25 inches of runoff (0.94 inches) must be retained for the watershed with the unit hydrograph described by K = 0.1 (Figure 6-31). However, for the watershed with a unit hydrograph described by K = 0.45 only 25% of the runoff (0.31 inches) must be retained to yield the same pollutant removal efficiency. This analysis is based on the assumption that nearly 100% of the pollutant mass will be removed by retaining 1.25 inches of runoff as illustrated in the small graph at the top of Figure 6-31.

Research is needed to develop design aids that will enable the engineer to easily determine the probable inflow unit hydrograph shape associated with any individual retention facility. In this manner, more detailed information similar to that illustrated with this figure may be developed for various land use types and regions of the state. Such data could be used to obtain a better estimate of storage requirements needed to accomplish an intended level of treatment.

Estimating and Evaluating Drawdown Time Requirements

The state regulation specifies that retention facilities must be capable of providing a new volume of storage within 72 hours following a storm. For facilities designed for multiple purposes (recreation, open space, etc.) this time should be a maximum of 24 to 36 hours, however.

For systems in which the water table elevation is below the bottom of the retention basin the drawdown time (T) may be estimated very simply. Percolation or infiltration in a retention basin produces an infiltration hydrograph (time-variable) which describes the draining of the basin. The rate of outflow will be in accordance with Darcy's Equation which is discussed in more detail in the FILTERS AND UNDERDRAINS (SW BMP 3.20). The equation may be written as follows:

$$Q = KiA$$

where:

Q = rate of seepage or percolation from the facility
K = hydraulic conductivity or percolation rate associated with the soil in the vicinity of the facility
i = hydraulic gradient or the loss of hydraulic head per unit distance of flow
A = area of the soil profile through which infiltration is occurring

When the water table is below the bottom of the basin, the entire surface area of the facility is available for percolation. The average area (A) may be determined by dividing the volume by the depth of the holding area. Assuming a hydraulic gradient of unity (e.g., i = 1), which is a conservative assumption, the rate of outflow may be calculated once the permeability (K) is established using appropriate field testing procedures. A discussion of these tests is included in Appendix 6-2. The final or constant rate established from these testing procedures must be used, not the initial rate encountered shortly after the beginning of a test run.

Subsequently, drawdown time (T) may be determined by dividing the storage volume required for the facility (e.g., one-half inch runoff volume or other appropriate value) by the rate of percolation (Q) from the facility as established from Darcy's formula. The appropriate expression is shown below where all terms are as previously discussed in this paragraph.

$$T = Vm/Q$$

Special Procedures for Estimating Drawdown Time in High Water Table Areas

There are many areas in Florida where retention is not an economically feasible alternative. The most common limitations are restrictive soil layers in combination with flat terrain, poorly defined surficial drainage systems, and limited elevation differences which severely restrict the movement of water. In most instances, designers elect to use wet detention systems or filters and underdrains to provide the prescribed level of stormwater quality treatment. However, there are always those who, for one reason or another, wish to try anything including retention in high water table areas. The following excerpts and figures from the document titled "Underground Disposal of Stormwater Runoff, Design Guidelines Manual," (FHWA, 1980) will serve to illustrate a method for evaluating outflow for lateral flow cases. It also, very vividly, demonstrates some of the problems one may expect to encounter in these situations.

> Darcy's Law and flow nets are two useful methods for analyzing potential infiltration rates when the permeabilities of the formations are reasonably well known. Some theoretical solutions to seepage problems may be too rigorous for the assumptions that are made in the derivations and may fit actual cases only approximately. Most engineers experienced in seepage calculation feel that it is far better to make use of an approximate method than to rely on a rigorous theoretical formula that is not easily understood and which represent only a crude approximation of true conditions due to questionable assumptions. Some simplified procedures illustrated in Figure 6-32 are discussed in the following paragraphs.

a. Vertical Flow Case

In Figure 6-32a an infiltration basin is shown in soil formations having a vertical permeability (K) of 1 ft/day (3.5×10^{-4} cm/sec). An impervious stratum is located at 20 ft. depth (6.1 m), and a natural water table at 10 ft. (3.05 m). What is the capability of the site for vertical discharge of water? From Darcy's Law, Q = KiA, the flow can be estimated from the vertical permeability of 1 ft/day (3.5×10^{-4} cm/sec) and a downward hydraulic gradient of 1.0 (conservative assumption). Hence; Q = 1.0 ft/day (1.0) = 1.0 ft/day/sq ft (3.28 m/day/m^2). For a 300-ft (91.5 m) wide basin, the possible Q is 300 cu ft/day/linear foot (27.54 m^3/day/m).

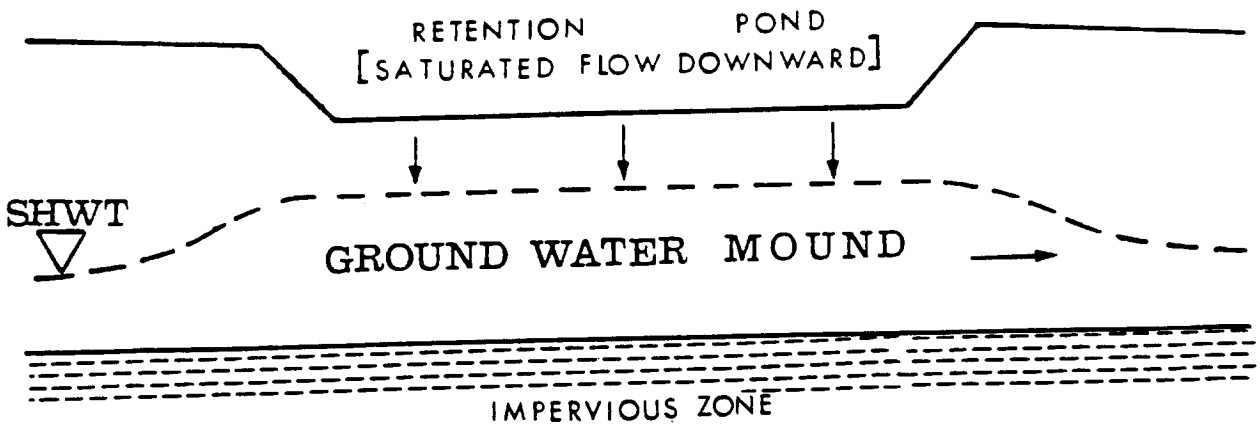
b. Lateral Flow Case

Many sites that are capable of relatively large disposal rates when the underlying water table is low, become relatively useless if the water table is high and flow is lateral. Figure 6-32b illustrates the flow conditions at the edge of a basin where the groundwater mound has risen to the bottom of the basin. The flow net gives the shape factor, n_f/n_d, which is used in the following expression to estimate lateral seepage:

$$q = kh(n_f/n_d)$$

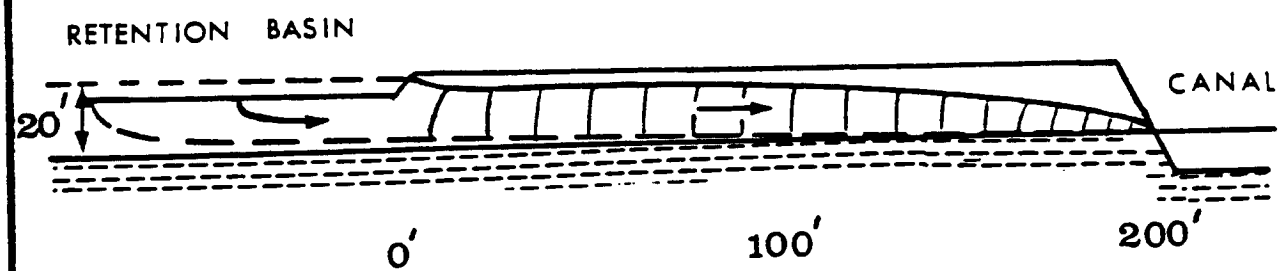
The equation is the conventional formula for estimating seepage quantities with flow nets. The seepage quantity per linear foot is q, under net head h, while n_f is the number of flow channels in the flow net, and n_d is the number of equipotential drops. In this example, assuming a horizontal k = 5 ft/day (1.53 m/day), and a head of 20 ft (6.1 m), with the shape factor of n_f/n_d = 1.1/20, the seepage quantity is:

$$q = kh(n_f/n_d) = (5 \text{ ft/day})(20 \text{ ft})(1.1/20)$$
$$= 5.5 \text{ cu ft/day/foot } (0.50 \text{ m}^3\text{/day/m})$$



The potential for lateral flow from this basin is only about 2% of the vertical flow capability; even though the assumed lateral k is 5 times the vertical k. When estimates of infiltration are made, designers should recognize that they are only approximate and should try to use conservative assumptions so as not to overestimate the capabilities of infiltration systems.

Surveys and Investigations Required



At a minimum it will be necessary to determine the infiltration rate of local soils using procedures defined in the Appendix 6-2 of this chapter. This

FIGURE 6-32

R0071243

information is needed to evaluate drawdown time. Provided the location of the treatment facility is flexible, this type of data is also valuable for situating the facility where it may function the most advantageously.

For large watersheds, it is advisable to develop a discharge time relationship for the drainage area. In order for this task to be accomplished, sufficient topographic information and data pertaining to the type and condition of the vegetative cover at the site must be available in order to estimate the time of concentration of the watershed. This information is required in order to evaluate the effect which hydrograph shape may have on treatment efficiency as discussed in the preceding section of this write-up.

In areas of active sinkhole formation natural depressions should be used for stormwater management only when hydrogeologic evidence shows that the subgeologic structure and soils are stable and unlikely to form a conduit that creates a direct connection to the groundwater. Soil boring information and/or supplemental data such as ground penetrating radar may be required to verify the geologic stability.

A complete hydrogeologic survey is recommended for the entire site with emphasis on potential locations of swales and especially excavated basins. A map depicting limestone outcroppings, sinkholes, solution pipes, and general depth of soil to limerock can help to avoid problem areas when locating the components of the stormwater treatment system. Borings taken in potential locations of swales and basins should be made to the limestone and then an additional ten feet deep. The overburden material shall be characterized and this information should be used to site swales and retention areas in locations with the most protective soil profile and the "strongest" limestone.

The site survey should be in sufficient detail to allow the permitting authority to be able to fully assess the potential for groundwater contamination that may be associated with a proposed project. In most cases the applicant should be prepared to submit:

1) Geologic sections describing the substrate through the retention basin area.

2) A description of any existing limestone outcrops and any Karst features, (i.e., sinkholes or solution pipes) at the project site.

3) A description of all groundwater levels and flow at the site.

4) A description of the site's topography before and after the project construction including information on any surface water drainage features.

5) An inventory of existing wells within a 1000 foot radius of the stormwater basin.

R0071244

Construction and Design Considerations

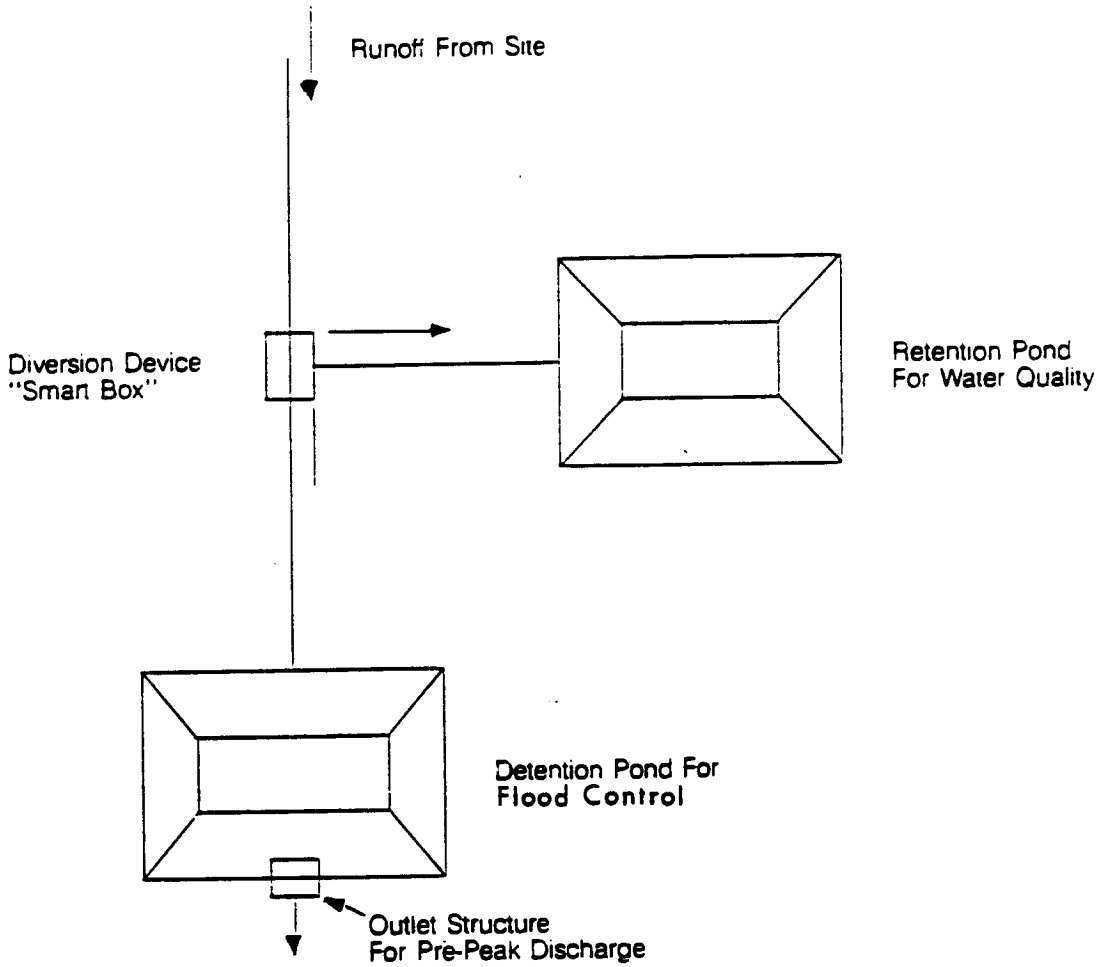
General

Both surface and below ground retention systems are common in Florida. A schematic of an off-line retention pond with a diversion is shown in Figure 6-33. Exfiltration trenches (SW BMP 3.03) are the most common subsurface retention device currently used in various regions of the state.

Regardless of the type of infiltration system to be constructed, careful consideration should be given to the effects that the design work sequence, construction techniques, and equipment employed will have on future operation and maintenance of the system. Serious problems can be averted, or in large part mitigated, by the adoption of relatively simple measures during the design and construction phase.

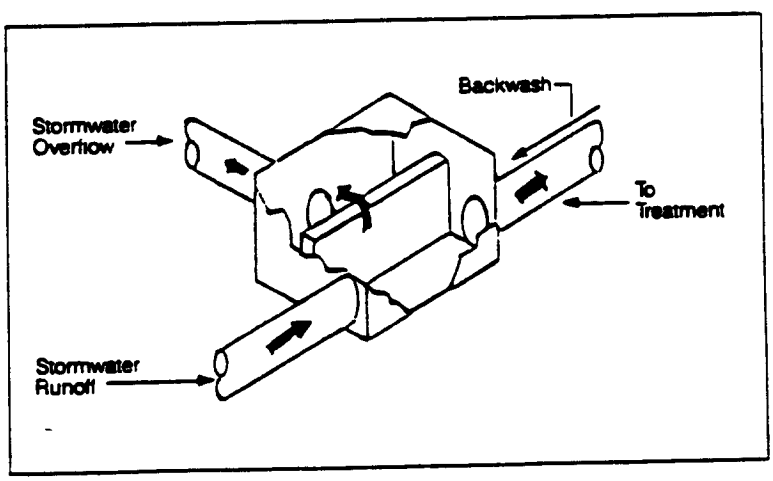
Surface Percolation (Retention Pond) Construction and Design Considerations

The sequence of various phases of basin construction has an identifiable relationship to the overall project construction schedule. An ideal program would schedule rough excavation of the basin for the rough grading phase of the project to permit use of the material as fill in earthwork areas. The partially excavated basin may serve as a sedimentation basin to assist in erosion control during construction. However, basins near final stages of construction should never be used prematurely for runoff disposal. Stormwater from untreated, freshly constructed slopes within the watershed area will load the newly formed basin with a heavy concentration of fine sediment. Such circumstances seriously impair the natural infiltration characteristics of the site. Specifications for basin construction should state the earliest time that stormwater may be directed to the basin, and the means by which this delay in use is to be accomplished.



Runoff from surrounding land should be intercepted to prevent erosion of the side slopes. Establishment of turf on the basin sides and floor is recommended. A dense stand of turf will not only prevent erosion and sloughing, but will also provide a natural means of maintaining relatively high infiltration rates through the surface. When the basin is adequately maintained, removal of accumulated sediment is a problem only at the basin floor. Little, if any, additional maintenance is normally required to maintain the infiltration capacity of the slope areas.

In design, prevention of scour at the inlet is mandatory as it reduces maintenance problems and aids in establishing a cover crop. Reduction in water energy by providing hydraulic structures and an apron on which water can flow into the pond are effective in reducing scour. A paved stilling basin before discharge into the pond is also effective. If possible, after excavation or earth moving for pond construction, runoff waters should not be permitted to flow into the pond until a cover crop has been established.



R0071245

Off-Line Treatment System

Figure 6-33

"Smart" Box Schematic

R0071246

Maintenance of side slopes is important. Slopes greater than 2 horizontal to 1 vertical are time consuming, expensive, and dangerous to maintain.

Initial basin excavation should be carried to within 1 ft. (0.3 m) of the final elevation of the basin floor. Final excavation to the finished grade should be deferred until all slopes in the watershed have been seeded and protected with an interim treatment. The final phase excavation should be performed carefully to remove all accumulated sediment. Relatively light equipment is recommended for this operation to avoid deep compaction of the basin floor. After the final grading is completed, the basin floor should be deeply tilled with rotary tillers or disc harrows to open the soil pores and provide a well-aerated, highly porous surface texture for seeding or sodding.

Basin shape depends largely on the configuration of the available site. The shape providing the greatest area will infiltrate water most rapidly. However, an increase in basin floor area may not necessarily bring about a corresponding increase in the rate of infiltration. After operation begins, lateral drainage through the basin wall may become more rapid than vertical percolation should the bottom become less pervious as silt deposits build up.

Some designers tend to compensate by proposing to use deeper facilities since increased depth can provide greater lateral infiltration area. However, basin side slopes should be 3:1 or flatter to prevent erosion, improve appearance and promote easy maintenance. Moreover, deep installations in residential areas should be fenced, and the bank slope should be 4:1 or flatter to allow a point where exit would not be difficult should someone fall into the basin by accident.

As noted earlier, detention or sedimentation basins can be used prior to infiltration basins so that suspended solids will settle out before the water is released into the infiltration basin. These ponds must be large enough to hold storm runoff for a sufficient settlement time. This could vary from one or two hours to a day or more depending on soil type and particle size. In north Florida, where the soil contains considerable amounts of fine textured material of low settling velocity, a sedimentation pond may be larger and shallower than the actual infiltration basin.

Landscaping of infiltration basin facilities creates a pleasing appearance that should always be considered when ponds are located near residential areas. Without landscaping and maintenance, these devices will accumulate the inevitable old tires, shopping carts, broken glass, and trash thus becoming a community nuisance. The landscaped basin can be used as a park or recreation area. However, such a project requires plants, trees and shrubs capable of withstanding temporary inundation. Basin sides should be gently sloped to giave a park-like appearance.

R0071247

FIGURE 6-34

Typical Inline Landscaped Retention Area
Used in Conjunction with a Pond for Flood Control

A typical park-type installation is shown in Figure 6-34. It consists of a very shallow well landscaped basin for infiltration of stormwater followed by a detention pond for peak discharge control. During summer months, the grass in these park basins may need to be sprinkled and additional inflow may occur from domestic watering or irrigation.

Infiltration basins are sometimes lined with material to help prevent the build-up in impervious silt deposits on the soil surface. A 6-inch (0.15 m) layer of pea gravel on the basin floor can serve to effectively screen out suspended solids and keep infiltration rates high. The gravel layer can be replaced or cleaned when it becomes clogged. However, planting of grass is probably a more economical alternative. This practice has been shown to extend infiltration efficiency, keep the soil pervious, reduce maintenance due to clogging and prevent erosion.

R0071248

Grass serves as a good filter material, particularly the Bermuda variety which is extremely hardy and can withstand several days of submergence. Well established Bermuda on a basin floor will grow up through silt deposits forming a porous turf and thus preventing the formation of an impermeable layer. Bermuda grass infiltration works well with long narrow basins along the fringes of parking areas and highways. Bermuda requires little attention besides summer irrigation during the period of establishment.

Coarse organic material (such as cotton boll hulls, leaves, stems, etc.) is sometimes specified for discing or spading into the basin floor to increase the permeability of clayey soils. The basin floor should be soaked or inundated for a brief period then allowed to dry subsequent to this operation. This is thought to induce the organic material to decay rapidly, loosening the upper soil layer.

Maintenance and Inspection

General

All stormwater systems should be inspected on a routine basis to ensure that they are functioning properly. Major inspections can be on an annual or semi-annual basis, but brief inspections should always be conducted following major storms. Systems that incorporate infiltration are most critical since poor maintenance practices can soon render them inefficient. Procedures for maintenance of these systems are discussed in this section. It should be stressed that good records should be kept on all maintenance operations to help plan future work and identify facilities requiring attention.
In areas of active sinkhole activity a site inspection should be performed by field personnel when the retention basins is excavated to final grade. The objective is to visually inspect for exposed limerock or solution pipes. It is also advisable to follow up with a site visit to assure that vegetation (sod) is growing well and that all construction is according to approved design.

Retention Basins

Infiltration basin surfaces are sometimes scarified to break up silt deposits and restore topsoil porosity. This should be accomplished after all sediment has been removed from the basin floor. However, this operation can be eliminated or minimized by the establishment of grass cover on the basin floor and slopes. Such cover helps maintain soil permeability.

Algae or bacterial growth can also inhibit infiltration. While chlorination of the runoff water can solve this problem, it is more practical to make certain that the basin is permitted to dry out between storms and during summer months.

Holding ponds or sedimentation basins can be used to reduce maintenance in conjunction with infiltration basins by settling out suspended solids or removing oil and grease before the water is released into the infiltration basin.

Chemical flocculants can also be used to speed up settlement in tnese holding or sedimentation ponds. Flocculants should be added to the runoff water within the settlement pond inlet pipe or culvert where turbulence will ensure more thorough mixing. After suspended matter has flocculated and settled in the settling pond, the water may be released into the infiltration basin for disposal. Although chemical flocculants may be impractical for general use, they might well be considered in special cases.

Cleanout frequency of infiltration basins will depend on whether they are vegetated or non-vegetated and will be a function of their storage capacity, infiltration characteristics, volume of inflow and amount and type of sediment load. Infiltration basins should be thoroughly inspected at least once a year. Sedimentation basins and traps may require more frequent inspections and cleanout. These structures should have a prescribed sediment level at which they are cleaned.

Non-vegetated basins can be scarified on an annual basis following removal of all accumulated sediments. Rotary tillers or disc harrows with light tractors are recommended for maintenance of retention basins. Use of heavy equipment should be discouraged to prevent excessive compaction of surface soils. The basin floor should be left level and smooth after the tilling operation to ease future removal of sediment and minimize the amount of material to be removed during future cleaning operations. A leveling drag, towed behind the equipment on the last pass, will accomplish this.

Special Operation/Maintenance Conditions for Karst Sensitive Areas

To mitigate the potential for direct connections from on-site stormwater basins to the groundwater, the following recommendations are provided:

- Stormwater swales and retention basins should be monitored by visual observations following significant storm events. If open solutions or pipes and/or sinkhole-like depressions are noted, this information should be relayed to permitting authorities and appropriate corrective action should be taken.

- Where small, shallow depressions are noted, these may be filled to pre-existing grade with clayey sand materials, graded and vegetated.

- When, and if, chimney-type solution pipes are exposed within the retention basins, these may be plugged in accordance with acceptable water well plugging and abandonment procedures. Where

these features are small in diameter and of a limited vertical deptn, bridging of the pipe with indigenous limestone boulders is recommended. Once the bridge is in place, the pipe may be filled with clay and/or clayey sand back to the land surface and then vegetated.

- Remedial plugging activities should employ methodologies acceptable to the applicable regulatory agency.

SW BMP 3.08

ROOFTOP RUNOFF DISPOSAL

Definition

The disposal of rooftop runoff by systems and techniques that avoid or replace direct connections of roof drainage systems to storm or sanitary sewer systems.

Purpose

To reduce the adverse impact of rooftop runoff on receiving waters. When applied on an areawide basis this practice can:

1) Reduce the frequency and magnitude of combined sewer overflows in areas where such systems are used.

2) Reduce peak runoff rates and volume, thus contributing to decreased flooding frequency and lessened stream channel degradation downstream.

3) Reduce the amount of airborne pollutants which reach stormwater conveyance systems via direct connection to building drain spouts.

Conditions Where Practice Applies

Wherever direct connection of roof drainage systems to public sewer, storm sewer or stormwater management systems exists or is planned.

Planning Considerations

The rooftop runoff disposal techniques described are for application to individual structures. In order for these techniques to achieve the purposes stated, they must be applied on an areawide basis. Their use on one or just a few buildings will not have any measurable downstream effect.

In many urban areas, roof drainage systems are connected directly to sewer systems to reduce the inconvenience to property owners of excess surface runoff. Such connections may be permitted, or they may be illicit connections made for the convenience of property owners without consideration of the effects on public sewer systems. Water discharged from these connections takes up flow capacity in the sewers, especially in combined sanitary/stormwater sewers that are often subject to illicit connections.

R0071252

Flooding of street and road areas may result with accompanying hazards to health and safety.

Three techniques are described for handling rooftop runoff without direct connections. Depending upon the size of rooftops and local rainfall conditions, these techniques can be used singly or in combination to achieve desired results. The three are:

1) Surface Drainage

The simplest and most widely used technique for disposing of rooftop runoff is to allow it to disperse over the surface of the land. This technique is especially applicable where there is sufficient open space and permeable soils to allow infiltration of surface runoff to occur. This practice is often avoided where property owners fear flooding, excessive surface ponding, or erosion from concentrated runoff. However, if proper precautions are taken, the practice can usually be used without significant problems. Such precautions include:

a) Erosion Protection -- The use of properly designed splash blocks that spread the water at downspout outlet and other points of high velocity flow can reduce erosion potential. Also wherever possible, flow should be made to spread out over wide gently sloping areas instead of being allowed to concentrate. The dispersion can be accomplished by the use of energy dissipators and level spreaders. Surface drainage may cause erosion if the ground slopes quickly away from the downspout. Areas where flow is allowed to concentrate should be stabilized with sod, riprap, or other suitable means as necessary.

b) Flooding Protection -- Adequate drainage should be provided away from the base of the structure as specified in local building codes. As an extra precaution, flow from the rooftop gutters can be carried away from the house in tile drains before it is allowed to outlet to the land surface. Flow should always be directed to areas sloping away from the structure.

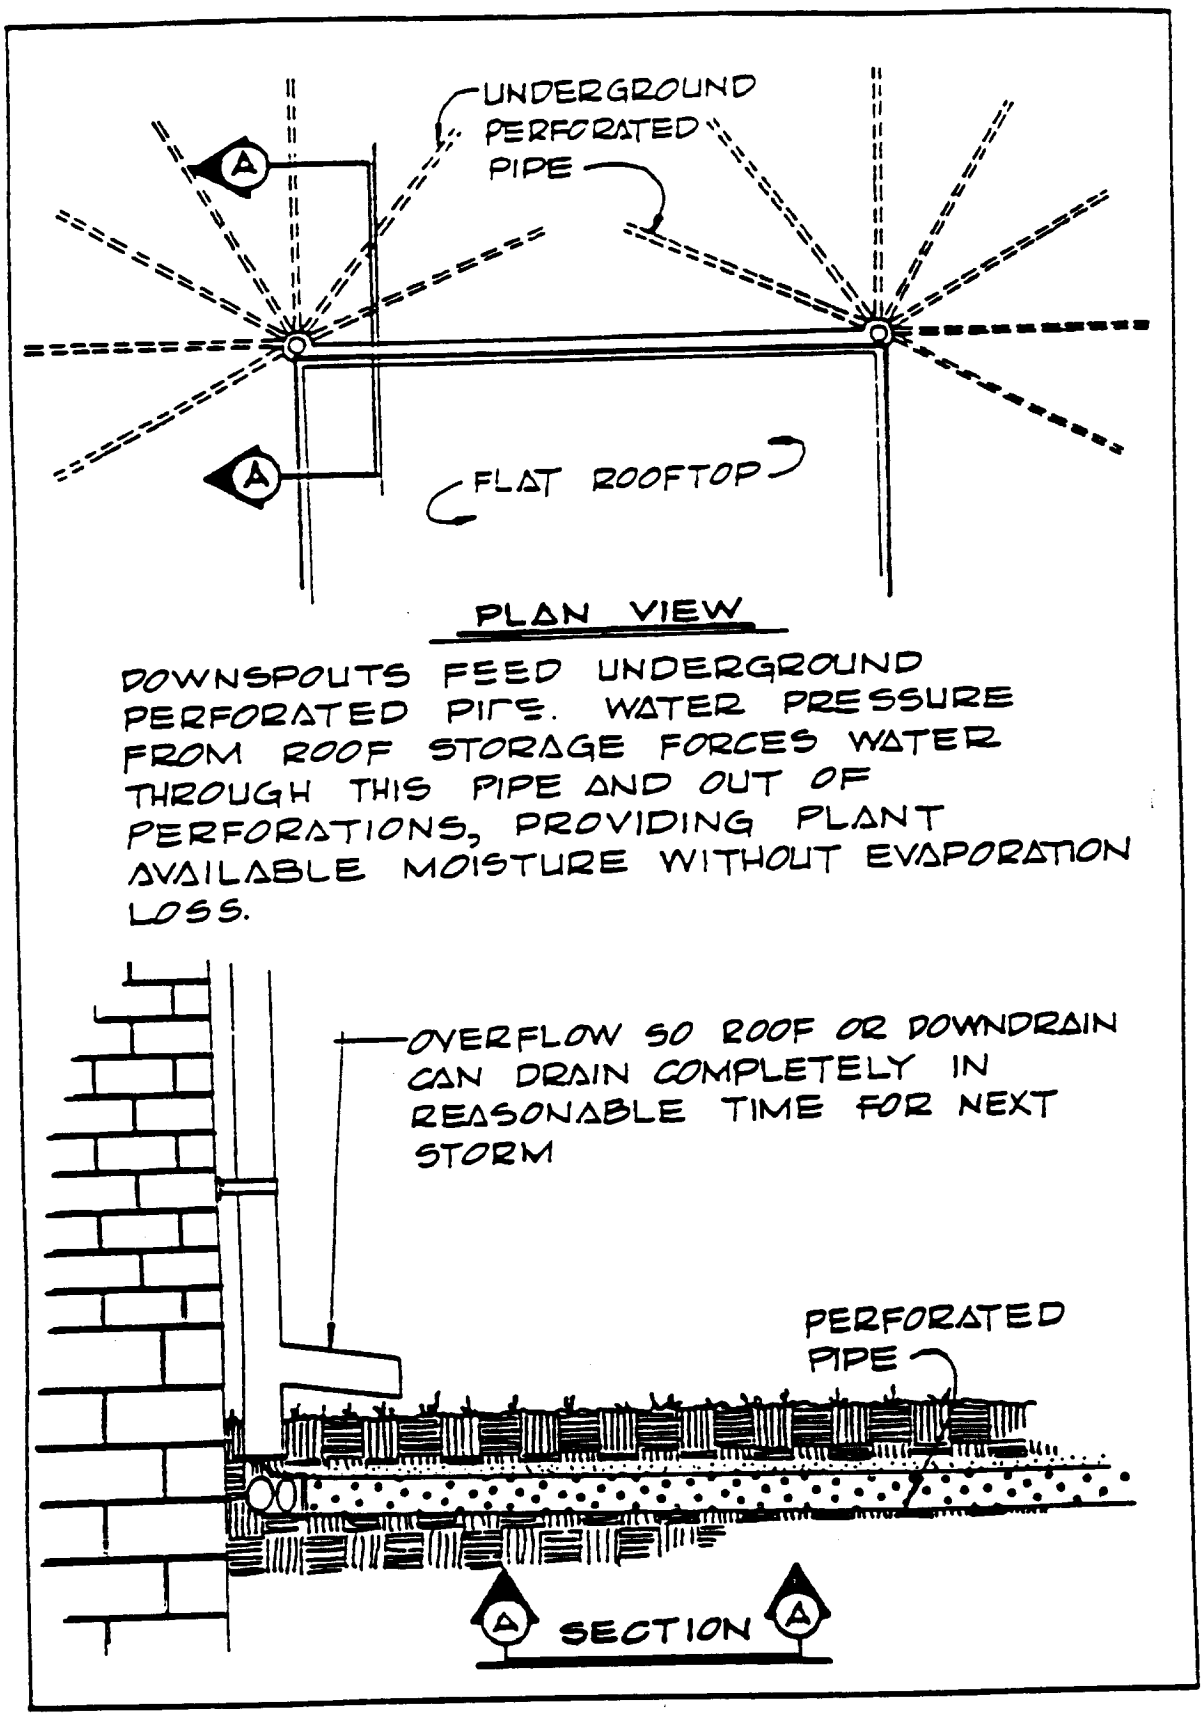
c) Minimizing Surface Ponding -- Surface ponding of runoff can best be minimized by using good landscaping techniques. Smooth even slopes will generally drain well. Permeable soils and water-absorbing vegetation or mulch are also key factors in preventing surface ponding.

2) Subsurface Infiltration

Where surface drainage of rooftop runoff is not feasible, the use of subsurface infiltration practices may become a suitable alternative.

Devices such as exfiltration trenches may be installed to dispose of rooftop runoff beneath the land surface. Of course, soils must have a relatively high permeability in order for these systems to function properly. As with surface drainage, adequate precautions should be taken to prevent flooding. Design, construction and maintenance criteria for subsurface retention devices can also be found in this manual (see SW BMP 3.03). Typical applications of subsurface infiltration techniques for rooftop runoff disposal are illustrated in Figure 6-35 and 6-36.

3) Runoff Collection and Storage



In certain circumstances, neither surface drainage nor subsurface infiltration techniques would be feasible because of poor soils or other site conditions. A suitable alternative may be to collect and store rooftop runoff for later release or use. Rain barrels at downspout outlets are an example of how this technique has been applied in the past. Above-ground storage facilities such as rain barrels, however, are generally not desirable in densely urbanized areas. One solution may be to install cisterns underground to collect the water. The stored water can be utilized for some purpose which does not require treated water, such as garden or lawn watering. A typical application of a cistern for rooftop runoff collection is illustrated in Figure 6-37.

Maintenance

Erosion prevention is important if one is directing the runoff onto the ground surface. Maintenance for infiltration and storage of runoff is covered in the discussion of EXFILTRATION TRENCHES (SW BMP 3.03).

SW BMP 3.09

STORAGE/TREATMENT

Definition

Unit operations that provide treatment of urban stormwater but are less involved and costly than treatment plant technology and can be either used independently or interfaced with other best management practices.

Purpose

To remove contaminants from collected stormwater.

Conditions Where Practice Applies

Where a level of contaminant removal greater than that achieved by other best management practices is desirable or necessary, but where treatment plant construction or use is not feasible. These techniques are particularly well-adapted for use in conjunction with stormwater detention and some conveyance systems.

Planning Considerations

There are several methods of physical and chemical treatment that have potential for increasing contaminant removal from stormwater. The physical treatment processes are particularly effective for removing flotable and settleable solids and are generally effective for BOD and COD removal. Physical processes are less effective for the removal of nutrients and organics than the more advanced treatment processes. The physical processes described herein are settling (sedimentation tanks) and screening. Swirl regulator/concentrators would also fall into this category. They will not be discussed here. This practice has not been used to any degree for stormwater treatment in Florida. However, designers should be aware that this technique is available and may be adapted for stormwater control.

Chemical treatment processes are seldom used by themselves but are generally used in combination with some physical process, especially to enhance settling. The process of chemical clarification through flocculation and settling is considered a potential best management practice in conjunction with sediment ponds and tanks preceding final polishing of the stormwater effluent, usually via a larger detention, filtration, or retention facility. Chemical clarification can provide increased removal of BOD, suspended solids

R0071258

and phosphorous. Chemical flocs can also provide effective removal of heavy metals.

Land application for the treatment of stormwater runoff can also be considered if an appropriate site is available for application of the runoff.

Sedimentation Tanks

Whenever liquid containing solids in suspension is placed in a relatively quiescent state, those solids having a higher specific gravity than the liquid will tend to settle, and those with a lower specific gravity will tend to rise. These principles are used in the design of sedimentation tanks for treatment of stormwater. The objective of treatment by sedi- mentation is to remove readily settleable solids and floating material and thus to reduce the suspended solids content and associated pollutant load.

Sedimentation tanks can be used as stormwater storage tanks, which are designed to provide a moderate detention period (10 to 30 minutes) for overflows from either combined sewers or storm sewers. The purpose is to remove a substantial portion of the organic solids which otherwise would be discharged directly to multiple purpose detention or retention facilities and could form offensive sludge banks. Short-period sedimentation in a tank produces a mixture of grit and organic solids called detritus. Sludge removal equipment may be provided or cleaning by hand may be employed. Such tanks have also been used to provide sufficient detention periods for effective chlorination of such overflows.

The physical construction of a sedimentation facility may vary from an excavation in the ground (often used for presedimentation of extremely turbid waters) to a basin or tank structure of concrete or steel. Such basins are constructed in a variety of sizes and shapes. Depths range from 7 to 15 feet, but 8 to 12-foot depths are most common. Circular tanks run from about 35 to 150 feet in diameter, although some are as large as 200 feet. Square tanks usually have sides less than 100 feet long while rectangular basins are normally 100 feet or more in length. The length-to-width ratio of rectangular tanks varies from about 3:1 to 5:1, the width being controlled in many instances by the size of the sludge-removal apparatus. Bottom slopes are from approximately 1% in rectangular tanks to about 8% for circular or square basins.

To minimize the effects of short-circuiting and turbulent flow, considerable attention has been directed toward effective hydraulic design of inlets and outlets. Inlets are expected to 1) uniformly distribute the influent over the cross-section of the settling zone; 2) initiate parallel or radial flow; 3) minimize large-scale turbulence; and 4) preclude excessive velocities near the sludge zone. Generally, the influent is dispersed across the width or radially from the center of the tank through entrance ports or pipes. Various methods of employing baffles or deflectors to dissipate the velocity

of influent jets have been devised. Considerable large-scale turbulence is often developed by inlet structures; however, by controlling overall tank dimensions, inflow distribution can be confined to a relatively minor volume of the tank.

Part of the volume in a sedimentation tank is ineffective for settling purposes because particles entering this zone become entrained in the effluent. To minimize this effect, a relatively long flow path is desirable. Long, narrow tanks are especially effective under such circumstances.

Outflows are normally controlled by weirs placed along the sides of outlet troughs located beside the walls of rectangular tanks or extending toward the center. In circular basins, weirs are conventionally located on the periphery of the tank. Various types of outlets are of little importance compared with inlet types for control of dispersion characteristics.

The use of flocculating agents may add as many as three ancillary functions to settling units by requiring 1) rapid distribution of the agent through the water to be treated; 2) adequate reaction time or time for floc growth; and 3) return of floc to the influent for the sake of promoting flocculation. These functions are best performed separately in units designed to meet the key purposes. Nevertheless, this is not always done. Large, open basins, constructed by diking off a low-lying area or cut-and-fill methods, for example, may not require refinements in design and separation of functions.

Screening

Screening consists of passing polluted water through devices with openings (generally of uniform size) so that coarse solid material is separated from the water. The screening element may consist of parallel bars, rods or wires, grating, wire mesh, or a perforated plate, and the openings may be of any shape (generally circular or rectangular slots). A screen composed of parallel bars or rods is called a rack. Although a rack is a screening device and its function is referred to as screening, the application of the term "screen" should be limited to elements employing wire mesh or perforated plates. The material removed from screening elements is referred to as screenings, although solids removed from racks are often called rakings. According to the method of cleaning, racks and screens are designated as hand cleaned or mechanically cleaned. According to the size of openings, screens are designated as coarse or fine. Coarse screens have openings of 1/4-inch or more, and fine screens have openings of less than 1/4-inch.

Screening is very effective in removal of coarse and medium grain solids. The efficiency of screens treating stormwater with a normal distribution of sizes will increase as the size of the mesh decreases and as the thickness of the screen mat increases. Screening facilities are not effective in reducing organic or oxygen-demaning material.

R0071260

Flocculation

The process of chemical clarification through flocculation and settling can provide a major portion of pollutant removal from urban stormwater runoff. Through the use of lime, iron or aluminium salts, polyelectrolytes, or combinations thereof, flocs or coagulated particles form and settle due to their increased weight relative to the liquid medium within which they are suspended. In the future it may become necessary to use flocculation in sediment ponds and tanks as well as at treatment plants. It is possible to adapt this process to automatic operation. It is feasible to consider recovering the flocculants for reuse.

Because stormwaters vary and fluctuate widely in quality, needed coagulation and flocculation are best determined in practice by trial. Required coagulant dosage is usually found by jar tests performed in a laboratory stirring device. Because coagulation depends on so many variables that are themselves interdependent, as many testing parameters as possible should be kept constant. The importance of pH in governing the nature of the coagulant or flocculent through the extent of hydrolysis and ionization and in determining the charge of colloidal impurities suggests that the pH also be kept constant. In this connection it is well to remember that pH is changed implicitly when a coagulant is added.

Coagulation may be improved by coagulant aids which are substances that increase the critical mass of colloids and speed up coagulation. Kinetically, for example, water with little turbidity may not coagulate as easily and as well as water of moderate turbidity. Coagulation may then be improved by adding turbidity or, more specifically, by adding colloids that carry a charge of the same sign as the natural turbidity of the water. Examples are bentonite, anionic polyelectrolytes, and activated silica. Because the critical mass of colloids interacting with coagulants is increased by additives of this kind, the coagulation process is accelerated. Occasionally, coagulant aids may reduce coagulant dosage by speeding the kinetics of the process. They may also improve the physical character of the flocs. In solutions containing metal ion coagulants, for instance, some anions, polysilicates, and other anionic polyelectrolytes may produce dense flocs that settle fast and respond well to filtration.

Disinfection

Disinfection refers to the selective destruction of pathogenic micro-organisms. Generally, not all of the organisms are destroyed during the process. Viruses, cysts, and bacterial spores are the most hardy. Disinfection may have some marginal application as a best management practice used in conjunction with sedimentation tanks, especially if the process can be adapted to automatic operation.

In applying the disinfectic agents or means, tne following factors must be considered: 1) contact tir 2) concentration and type of chemical agent, 3) intensity and nature of sical agent, 4) temperature, 5) numbers of organisms, 6) type of organisms, 7) nature of the suspending liquid and 8) feeder operation--manual or automatic.

Disinfection through the use of some form of chlorine is 98 to 99% effective in destroying pathogenic organisms with a contact time of only 2 to 4 minutes at 5 mg/l for combined sewage. Some authorities suggest that stormwater may need a dose of 20 to 30 mg/l with 15-minute contact time to make it safe for full-body recreation uses and that perhaps 50 mg/l is required to remove viruses.

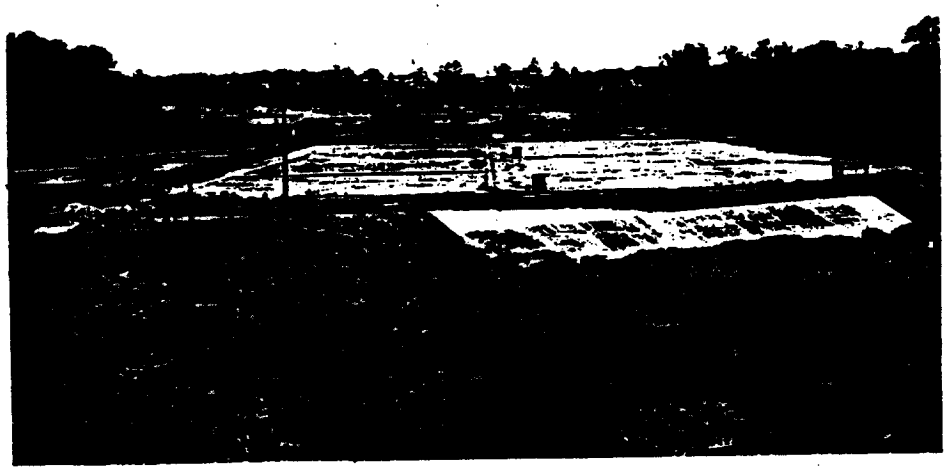
Experimental work is being done with other disinfectants. Bromine and iodine can be considered in place of chlorine. Ozone is a highly effective disinfectant, but because it is a relatively unstable gas it must be generated on-site from air or pure oxygen.

SW BMP 3.10

UNDERDRAINS AND STORMWATER FILTRATION SYSTEMS

Definition

Stormwater underdrain and filtration systems usually consists of a conduit, such as a pipe and/or a gravel filled trench, which intercepts, collects, and conveys stormwater following infiltration and percolation through the soil, suitable aggregate, and/or filter fabric. Many of the principles established for "subsurface drains" discussed earlier in the chapter may also apply.



Purpose

In Florida, these systems serve one or more of the following purposes:

1) To filter a portion (normally 0.5 to 1-inch) of the stormwater runoff contained in detention facilities prior to discharge to surface waters or other receiving waters of the state.

2) To alter the soil environment in treatment areas when not suitable for desired vegetation; usually by regulating the period of inundation, the water table elevation, and/or the inflow of shallow groundwater.

3) To improve the infiltration and percolation characteristics of the soil in stormwater management facilities when permeability is restricted due to soil texture or high water table conditions.

R0071263

Conditions Where Practice Applies

Underdrain systems and filters are used in combination with a variety of stormwater management measures where space, soil permeability, and/or water table conditions dictate that sufficient pollutant removal cannot normally be achieved through natural percolation, sedimentation, or other means. A gravity outlet must be available or pumping must be provided. A pumped discharge will usually require a permit from the Department and/or Water Management District.

Planning Considerations

Underdrains and filter systems are very similar in design. They differ slightly in their function however.

An underdrain system is intended to improve the percolation rate of the soil and/or control the water table elevation over the entire area of a stormwater treatment facility. Examples include the installation of a tile drainage system in the bottom and along the banks of a detention pond, in the bottom of a grassed waterway, or under a site used for overland flow or landspreading of stormwater. Such a system would be needed when the soil has a good capacity for percolation but has high water table conditions that otherwise prevent the infiltration of the prescribed amount of stormwater through the soil profile of the treatment facility.

A filtration system may also function to lower the water table in its immediate vicinity to some extent; however, the system is not usually designed with this in mind. Filters are normally installed in the bottom or along the banks of detention ponds above the water table elevation. The trench or bed where conduits are installed represent only a small part of the area of the storage facility. The trench is usually backfilled to the surface with aggregate material that is much more permeable than the surrounding soil. Pollutant removal primarily occurs as the prescribed volume of stormwater passes through the sand, gravel, and filter cloth which usually surrounds the conduit.

Filter systems may be used in situations where underdrains are not suitable. For example, filtration is often used in combination with wet detention facilities. Likewise, filtration may be used in situations where the natural soil permeability is restrictive to percolation even when underdrained due to a high percentage of clay or other fine material.

The selection of suitable filter material is critical to the pollutant removal capacity of filter systems. When selecting backfill material the designer should consider its pollution abatement capability not just its hydraulic efficiency. Research has shown that a high percentage of the pollutants associated with urban stormwater may be absorbed on the fine and very fine solids portion of the sediment carried by runoff waters. Generally the more porous and highly permeable the filter fill material, the less efficient the system will be in removing many stormwater contaminants.

R0071264

In most cases percolation through the soil profile will provide better pollutant removal rates than filter material. However, in some poorly graded, very sandy soils, or in areas where facilities are excavated into highly porous limestone formations, a filter may be capable of providing more treatment than the natural base material. In these circumstances, detention ponds should be lined with impermeable material and the first one-half to one-inch of runoff filtered before discharge to surface water or percolation to groundwater.

Design Criteria

The design of underdrains and stormwater filtration systems involves several steps. The procedures are illustrated below through the use of several example situations.

PART-I

Conventional Underdrain System Design Using Spacing Equations (Normally Used in Conjunction with Dry Detention Facilities)

Suppose the designer has a project in which the area contributing runoff is a 10-acre office complex. Six acres are impervious and 4 acres are lawn. Based on the initial site survey and published soil survey information, the permeability (e.g., hydraulic conductivity) of the soil is estimated to be 10.0 inches per hour. The site has slow internal drainage due a restrictive layer of finer textured materials which occurs at approximately 80 inches below the surface. The slope of the project averages 0 to 2%. The soils are classified as sandy.

The task of the engineer is to determine the length of underdrain required to drain and filter the water from a detention pond within 72 hours as specified by state regulations. Assume the facility was designed to store the runoff from the first inch of rainfall prior to any direct discharge to surface waters. No additional local water quantity regulations have been adopted. The designer would like the holding area to be no more than 3 feet deep. The steps in sizing an underdrain system to satisfy the provisions discussed above are:

1) Calculate Storage Volume and Area of the Facility

Due to the small size of the project the detention volume (e.g. the amount of runoff to be temporarily stored for filtration through the soil and/or underdrain system) can be most appropriately estimated using a modified form of the Rational Formula.

R0071265

Volume of Rainfall Excess (Runoff)= CAR
where: C = Runoff or Rational Coefficient
A = Contributory Area in Acres
R = Rainfall

Converting the volume of runoff to cubic feet we find:
Runoff = C (A acres) (R inches) $\frac{1 \text{ ft}}{12 \text{ in}}$ (43,560 ft^2/Ac) or,

$$\text{Runoff} = CAR\ (3{,}630) ft^3$$

The contributory area (A) is 10 acres and the amount of rainfall (R) with which we are concerned is equal to one inch. However, the runoff coefficient (C) must be established in order to calculate the volume to be treated.

Runoff coefficients have been estimated for various land uses with some typical values shown in Table 6-12. The selection of the appropriate value is at the discretion of the designer and should be based upon experience. Designers generally use average values for pollution control and larger, more conservative values when sizing flood abatement structures.

In this instance the project will be composed of 4 acres of lawns and 6 acres impervious area with flat (0 - 2%) slopes and sandy soil. The procedure used to determine the average value of (C) for this project is illustrated in Table 6-13. The preparation of such a table is useful to the designer to help explain the basis for the coefficient used in runoff calculations. Such foresight may speed up approval from officials responsible for reviewing design plans to determine compliance with various water management regulations.

Substituting C = 0.60 into the equation:
Runoff = CAR (3,630 ft^3) = (0.60) (10) (1) (3,630) ft^3; or, 21,780 ft^3.

Therefore, in order to satisfy the requirements of the example problem the detention area must be capable of detaining and filtering approximately 21,800 ft^3 of runoff prior to discharge.

Since the holding area is being designed for a maximum depth of 3 feet, it will average approximately 7260 ft^2 in area (21,780 ft^3 volume divided by the 3 ft depth of the facility).

2) Determine Drain Spacing

The area over which a subsurface drain can be expected to function must first be estimated in order to determine the length of underdrain needed to lower the water level in the holding area to the desired elevation within a specified time interval. In humid areas such as Florida, both the depth and spacing of drains have been determined largely by experience and judgement

TABLE 6-12

Runoff Coefficients[a,b]

DESCRIPTION OF AREA	RUNOFF COEFFICIENTS	CHARACTER OF SURFACE	RUNOFF COEFFICIENTS
Business		Pavement	
Downtown	0.70 to 0.95	Asphalt or concrete	0.70 to 0.95
Neighborhood	0.50 to 0.70	Brick	0.70 to 0.85
Residential		Roofs	0.70 to 0.95
Single Family	0.30 to 0.50	Lawns, Sandy Soil	
Multiunits, detached	0.40 to 0.60	Flat, 0-2%	0.05 to 0.10
Multiunits, attached	0.60 to 0.75	Average, 2-7%	0.10 to 0.15
Residential, suburban	0.25 to 0.40	Steep, 7% or more	0.15 to 0.20
Apartment	0.50 to 0.70	Lawns, Heavy Soil	
Industrial		Flat, 2%	0.13 to 0.17
Light	0.50 to 0.80	Average, 2-7%	0.18 to 0.22
Heavy	0.60 to 0.90	Steep, 7% or more	0.25 to 0.35
Parks, Cemeteries	0.10 to 0.25		
Railroad Yard	0.20 to 0.35		
Unimproved	0.10 to 0.30		

[a]The coefficients in these two tabulations are only applicable for storms of 5 to 10 year return frequencies and were originally developed when many streets were uncurbed and drainage was conveyed in roadside swales.

For recurrence intervals longer than 10 years, the indicated runoff coefficients should be increased, assuming that nearly all of the rainfall in excess of that expected from the 10 year recurrence interval rainfall will become runoff and should be accommodated by an increased runoff coefficient.

The runoff coefficients indicated for different soil conditions reflect runoff behavior shortly after initial construction. With the passage of time, the runoff behavior of sandy soil areas will tend to approach that of heavy soil areas. If the designer's interest is long term, the reduced response indicated for sandy soil areas should be disregarded.

R0071268

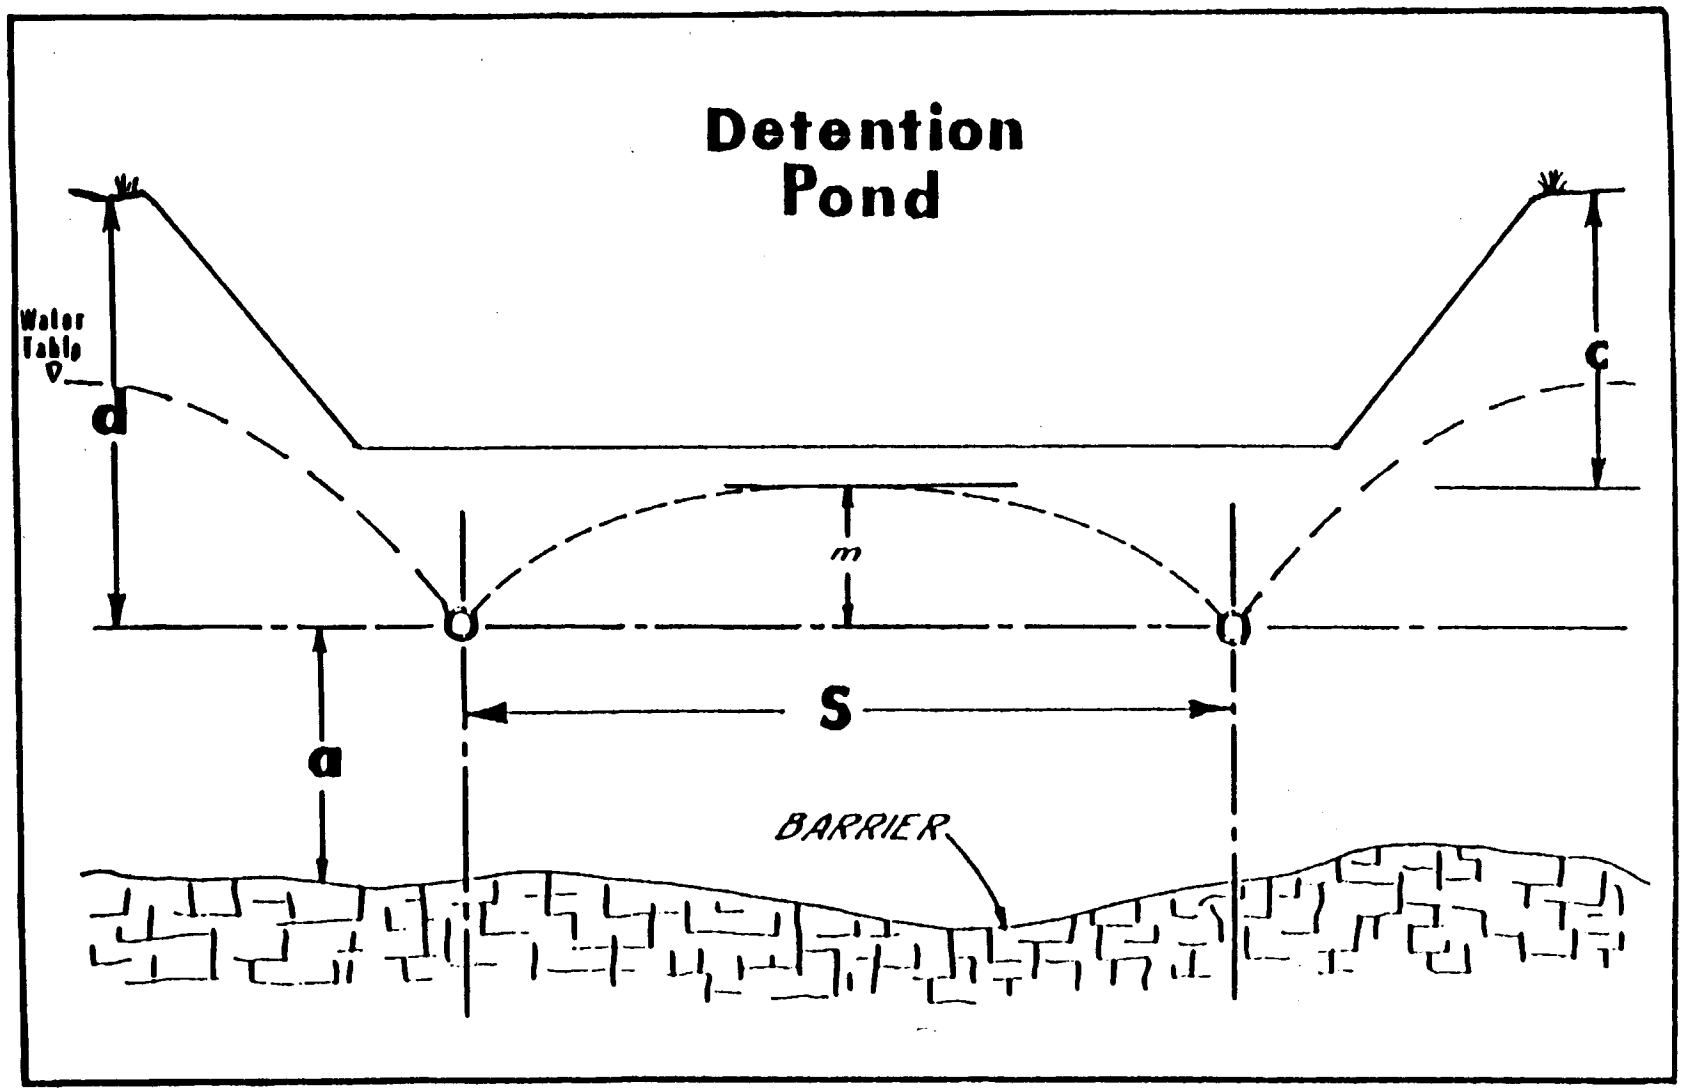
for specific soil conditions. Optimum drain spacing for laterals is influenced by soil permeability, drain depth, optimum depth of water table desired after drainage, cover crops, depth to impervious strata, and the outlet elevation of the system. The minimum cover over the drain should be 2 feet in mineral soils and 2.5 feet in organic soils. The drain trench depth usually varies from 30 to 60 inches. Where practical, increasing the depth of the drain will permit the use of wider spacing and minimize the length of underdrain required for the facility.

In areas where drainage installations and knowledge of effective spacings are limited, the ellipse equation or other similar procedures may be used to determine underdrain spacing. As noted earlier, the procedures used to design the underdrain systems presented in this manual are largely based on techniques commonly used to design agricultural subsurface drainage systems by the Soil Conservation Service (SCS).

The "Ellipse Equation" is expressed as:

$$S = \sqrt{4K\ \frac{(m^2+2am)}{q}}$$

Where:
S = drain spacing (feet)
K = average hydraulic conductivity (in./hr.)
m = vertical distance, after drawdown, of water table above drain at midpoint between lines (feet)
a = depth of barrier below drain (feet)
q = drainage coefficient (in./hr.)
d = depth of drain (feet)
c = depth to water table desired (feet)
(refer to Figure 6-38)



NOTE: The units of K and q may be in "inches removed in 24 hours" or "gallons per square foot per day" but both must be in the same units in this equation. Where there is no barrier stratum present, a barrier should be assumed at a depth equal to twice the drain depth.

Underdrains are designed to remove a certain quantity of groundwater from a given area subject to a high water table due to poor internal drainage. They are used where lateral groundwater flow or movement toward the treatment area is expected to be insignificant. The quantity of water to be removed by the drain is equal to the storage volume which must be percolated within that given area. The objective of the system is to remove a quantity of water that will lower the water table to some predetermined level during the required period of time. The design is based on the spacing and depth required to maintain a certain minimum water level at the midpoint between drains. This is illustrated in Figure 6-38 which shows the configuration of the new water table established after drainage.

R0071269

FIGURE 6-38

Cross-Section of Detention Facility with Underdrain System Illustrating Symbols Used in the Ellipse Equation

R0071270

The ellipse equation is based on the assumption that groundwater accretion from outside the given area is slight. Although it is known that this assumption is only approximate, it may approach actual conditions very closely under certain site conditions. For this reason use of the formula should be limited to the following conditions:

1) Where the hydraulic gradient of the undisturbed water table is one percent (0.01 feet per foot) or less. Under these conditions there is likely to be very little groundwater flow or movement from outside the facility.

2) Where soil and subsoil materials are underlain by a barrier at relatively shallow depths (twice the depth of the drain or less) which restricts vertical flow and forces the percolating water to flow horizontally toward the drain.

3) Where a gravel envelope or porous sandy backfill materials are used such that there is a minimum of restriction to flow into the drain itself.

The depth of the drain must be determined before the spacing may be computed by formula. As noted above, a minimum depth of 2 feet should be maintained for mineral soils such as those described for this example project. This is especially important for facilities where heavy mowing equipment or other large vehicles are likely to be used for maintenance.

The following illustrates the use of the equation. (NOTE: Variable (a) should not exceed the value of variable (d) to be within the limits of the assumptions associated with the use of the formula). Working through the various factors of the equation:

1) Assuming 6-inch diameter underdrains are to be installed at the minimum depth recommended for mineral soils (2 ft), the depth to the flow line of each drain would equal 5.25 ft. (d), since the desired pond depth is 3 feet and the radius of the pipe is 3 inches or 0.25 ft.

2) As specified earlier the soils information indicates a restrictive layer at a depth of 80" or six and one-half feet. Therefore, $a = (6.5 - d) = 1.25$ ft.

3) The system should be capable of lowering the water level to the pond bottom within 24 hours following storm events if improved grass varieties are to be used as a cover crop or if the storage area is to serve other purposes such as parks and recreation. Assuming the storage area is to be sodded with lawn grass, the depth to water table after drawdown in the vicinity of facility would be equal to the depth of the pond, therefore $c = 3.0$ ft and $m = (d-c) = 2.25$ ft.

4) The average hydraulic conductivity was specified earlier. (K = 10 in/hr).

5) The applicable drainage coefficient is:

$$q = c/t = \frac{3.0 \text{ ft.}}{da} = 1.50 \text{ in/hr.}$$

Substituting the values specified above into the Ellipse Equation:

$$S = \frac{[4(10)(2.25^2 + 2(1.25)(2.25)]}{1.5}$$

$$S = \underline{16.9 \text{ or } 17.0 \text{ ft.}}$$

In actual practice this value may be adjusted slightly to conform with tract dimensions. Suppose the dimension of the facility perpendicular to the direction of the underdrains is limited to 100 feet. Five drains equally spaced (20 ft) would slightly exceed the recommended spacing however, this spacing is within adjustment limits.

Based on the Ellipse Equation, Table 6-14 presents values of (S) or the width in feet over which a subsurface drain would be estimated to be functional given a number of drain depths, soil permeability rates (k) and drainage coefficients (q).

TABLE 6-14

Underdrain Spacing Chart
(based on Ellipse Equation)

q* (in/hr)	k (in/hr)	Drain Burial Depths(ft) 1 2 3
		(S) Spacing (ft)**
0.5	1	4.9 9.8 14.7
	10	15.5 31.0 46.5
0.33	1	6.0 12.1 18.1
	10	19.1 38.1 57.2
0.167	1	8.5 17.0 25.4
	10	26.8 53.6 80.4

*Drainage rates required respectively to drawdown 3-feet, 2-feet, and 1-foot

** $S = \left[\frac{4K\ (m^2 + 2\ am)}{q}\right]^{1/2}$ where:

S = spacing (ft.)
q = drainage rate from column #1 (in/hr.)
k = soil permeability rate from column 2 (in/hr.)
m = drain burial depth (ft.)
a = depth of barrier below drain equal to drain burial depth (ft.) (e.g., a = m)

R0071272

It should be noted that the values of (q) listed in Table 6-14 from top to bottom represent the drainage rates which would be needed to drain 3-feet, 2-feet, and 1-foot of water from the holding area over a 72-hour period. This is the maximum time frame allowed according to specifications adopted by the state. Such limitations are needed primarily for mosquito control purposes, and to ensure a high level of treatment of the average annual rainfall volume based on storm frequency analysis. As can be seen from the table, the deeper the drain, the greater the space over which it can be expected to remove the required amount of water. Likewise the spacing increases as the depth in the holding area is reduced and/or as the permeability of the surrounding base material (soil) increases.

3) Calculate the Length of Underdrain Required

A quick estimate of the length of underdrain can be determined by dividing the value of spacing (S) into the average area of the storage facility. The area was specified in step one of the design procedure ($A = 7260\ ft^2$). There- fore, the length of the underdrain system would equal 7260 square feet divided by the 20.0 foot spacing or 363 ft.

To prevent damage to the cover crop due to erosion and/or seepage, it is usually desirable to keep both the bottom and sides of the detention area dry. Using the top dimensions to determine the configuration of the underdrain can help ensure this function. Suppose the installation in the direction perpendicular to the underdrains is limited to 100 feet and the designer wants the pond to be a maximum of 3-feet deep. Assuming the slope of the sides and shape of the storage area are known, it is possible to determine the top width of the facility and the exact length of drain tile needed.

For example, suppose that the basin is to be rectangular shaped, 3-feet deep, 100 feet along the top, with 3:1 side slopes. A detention area with a top width equal to 88.8 feet, would be capable of storing the required volume of runoff ($21{,}780\ ft^3$). The area served by each lateral in the system would equal the spacing (S) times the length of the drain (L) plus one-half the spacing at each end 2(S/2). In equation form, $A = S(L+S)$. As illustrated in Figure 6-39 the length of each lateral (L) would be equivalent to the top width of the facility (88.8 ft) minus two times one-half the spacing (2)(S/2) or (20.0 ft) which gives **L = 68.8 ft/lateral.** Since five laterals will be needed as specified earlier, the total length of underdrain laterals (L) would equal 344 feet. In mathematical terms

Total Length of Laterals = Lx5 = 344 ft

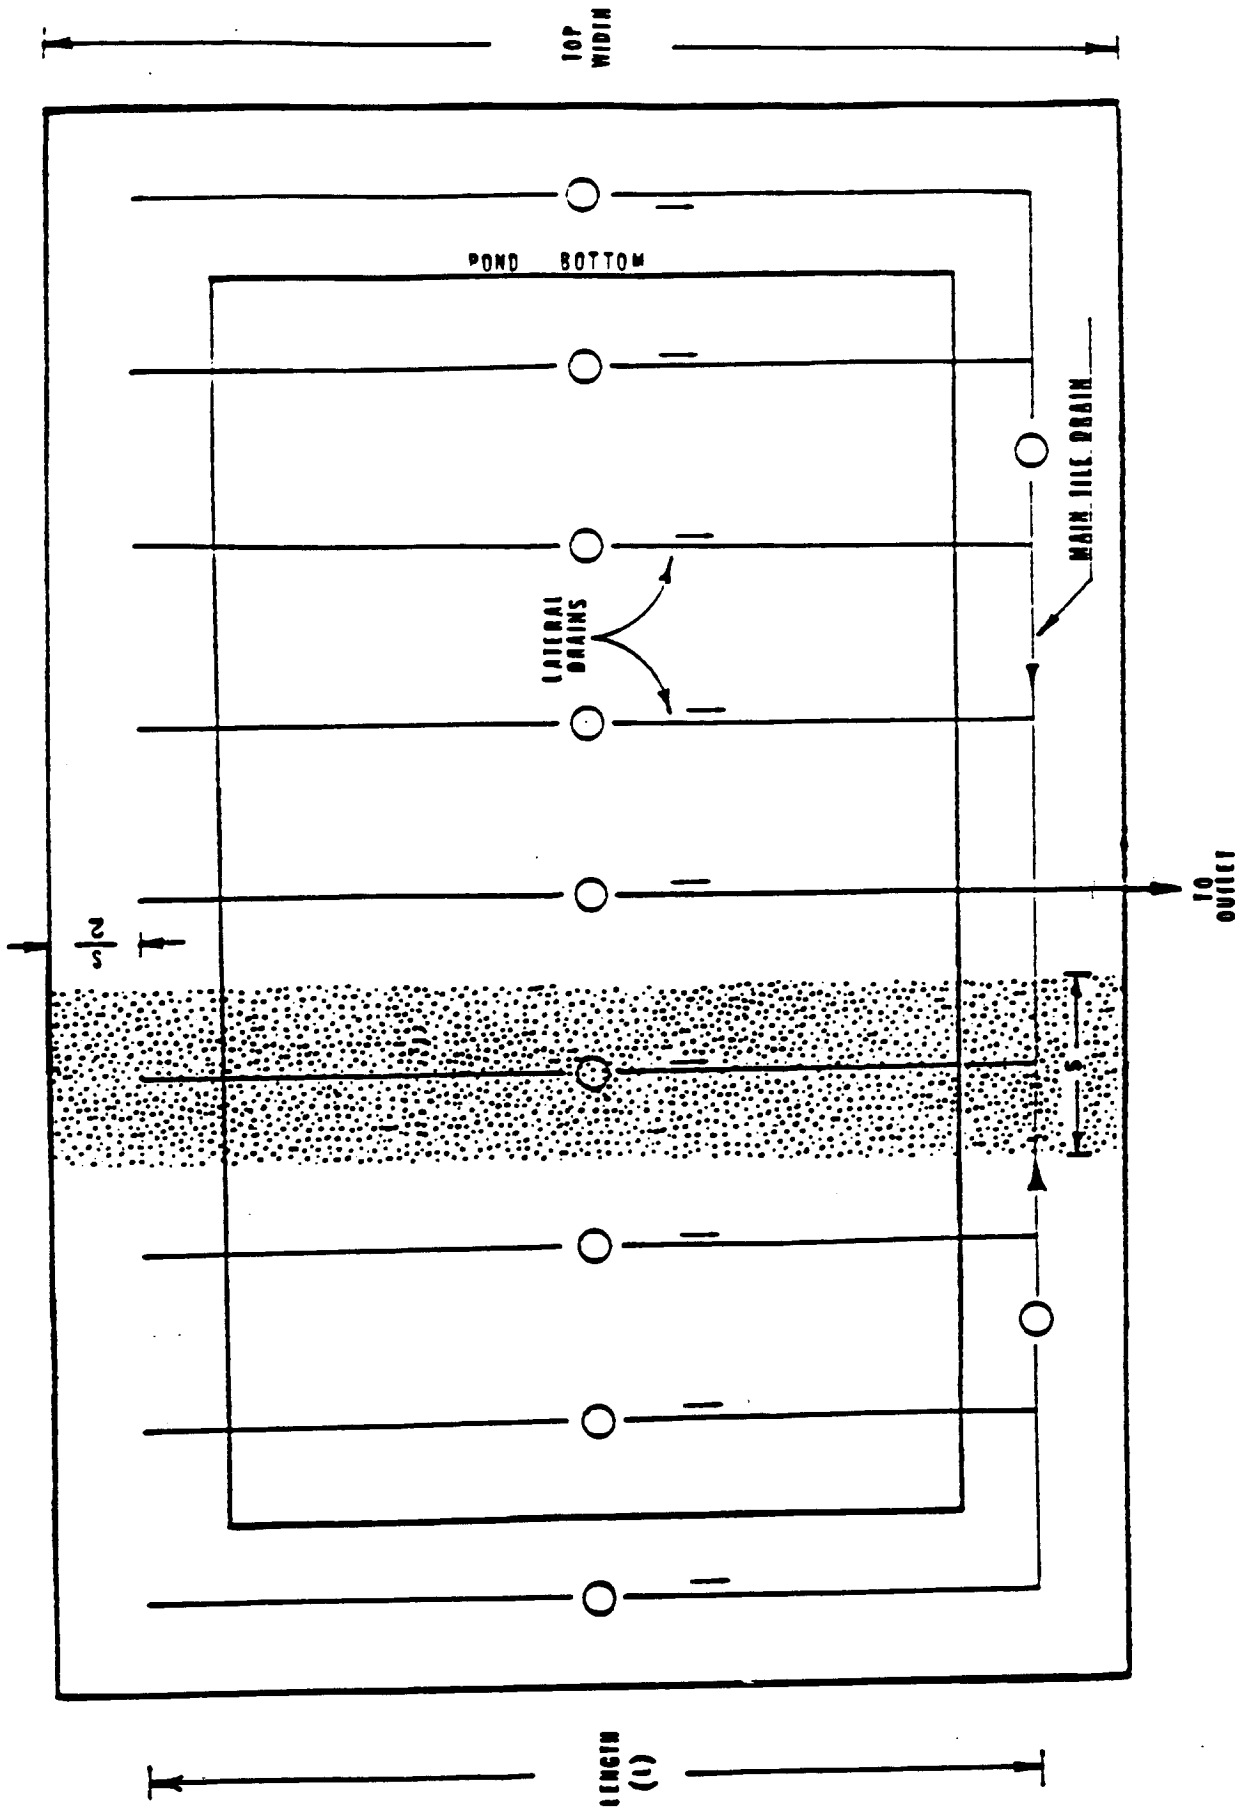


FIGURE 6-39
Sketch of Typical Underdrain System
Illustrating the Area Served by Laterals

R0071274

4) Estimate Design Capacity

The size of the drain may be found by determining the discharge using the following formula.

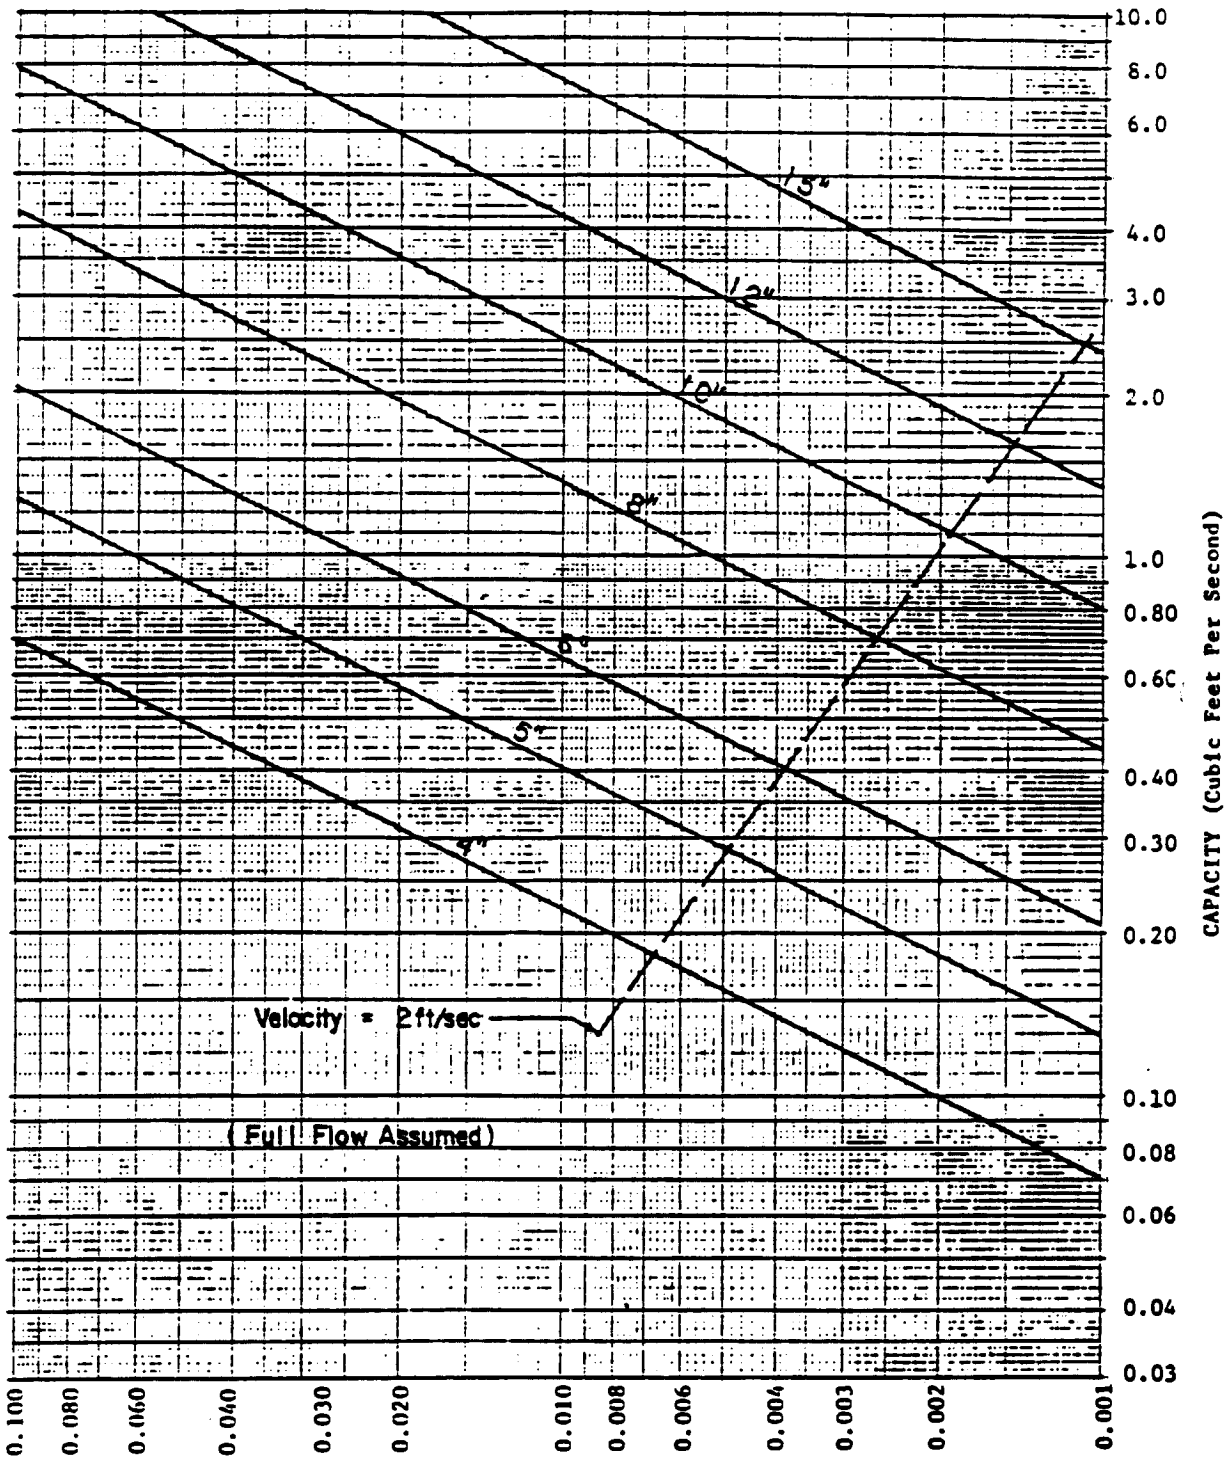
$$Q_r = \frac{q\ S(L + S)}{43{,}200}$$

Where:
Q_r = Relief drain discharge (c.f.s.)
q = Drainage coefficient (in/hr.)
S = Drain spacing (feet)
L = Drain length (feet)

In this example: (Assuming a 3' deep pond)
Drain spacing = 20.0 feet (S)
Drain length = 344 feet (L)
Drain coefficient = 1.50 in/hr (q)

$$Q_r = \frac{1.50 \times 20.0\ (344 + 20)}{43{,}200} = \boxed{0.25 \text{ cfs.}}$$

5) Determine Drain Diameter, Sizing Underdrains



Subsurface drains ordinarily are not designed to flow under pressure. The hydraulic gradient is considered to be parallel with the grade line of the underdrain. The flow in the drain is considered to be open-channel flow. The size conduit required for a given capacity is dependent on the hydraulic gradient and the roughness coefficient--"n" value--of the drain. Commonly used materials have "n" values ranging from about 0.011 for good quality smooth plastic pipe to about 0.025 for corrugated metal. When determining the size of drain required for a particular situation the "n" value of the product to be used must be known. This information will normally be available from the manufacturer. The diameter pipe required for a given capacity, hydraulic gradient, and four different "n" values may be determined from Figures 6-40, 41, 42 and 43.

Example: **Assume an underdrain on a 0.2% grade (s = 0.002) is to discharge 0.25 cubic feet per second. What size drain will be required if the material to be used has a roughness coefficient of 0.015?** Find the hydraulic gradient 0.002 on the horizontal scale in Figure 6-40 then follow vertically upward to intersect the line representing the design discharge of 0.25 cubic feet per second. This point falls in the space between the lines marked 6 to 8 inches in diameter therefore, an 8-inch drain is required. Since the point of intersection is below the line marked 8 inches, the drain will not flow full. The full capacity of the drain is 0.47 cfs therefore, the drain will flow about 50% full for the design discharge. The same procedure is followed when using Figures 6-40, 41 and 43 for roughness coefficients of 0.011, 0.013, and 0.025, respectively.

R0071279

Most filtration and underdrain systems currently being installed throughout the state use a minimum of 6" pipe. Smaller diameters may be used, however, it is presently recommended that the pipes be no smaller than 4-inch material. The area to the right of the broken line in the charts indicates conditions where the velocity of flow is expected to be less than 2.0 feet per second. For a field scale, agricultural subsurface drainage system lower velocities may present a problem with siltation in areas of fine soils. Underdrain and filter beds for urban stormwater treatment should be designed to remove much of the fine solids portion of the particulates being carried in the runoff. Due to the sandy nature of the soils over much of Florida, maintaining velocities greater than 2.0 ft/sec is usually not critical. However, a filter or underdrain system must be designed with this in mind in order to be effective. A layer or combination of layers of pervious materials must be used and installed in a manner to provide for water movement yet prevent the migration of soil particles due to flowing water. In most cases, it is felt that systems designed to the specification contained in the Stormwater Rule should be capable of meeting this goal.

6) Sizing of drains within the drainage system

The previous discussion on drain size deals with the problem of selecting the proper size for a drain at a specific point in the stormwater system (the outlet). In drainage systems with laterals and mains, the variation of flow within a single line may be great enough to warrant changing size in the line. This is often the case in long drains or systems with numerous laterals. The following example illustrates a method for such a design.

Example:

Assume that the total discharge from 344 feet of smooth perforated plastic underdrain is to be .25 cfs, that no surface water is admitted, and that the accretion to the drain is uniform throughout its length. Also assume a constant grade of 0.20%. The accretion per 100 feet of drain would be $\frac{0.25}{3.4}$ = .07 cfs. The "n" value of the pipe to be used is listed as 0.011. Use Figure 6-40 to determine the sizes of tile required. Start the design process at the upper end of the drain using a minimum size of 4 inches. First compute the distance that the drain would carry the flow on the assumed grade. Let (L) equal the distance (in 100-foot sections) down gradient that a 4-inch drain would be adequate. Referring to Figure 6-40, a 4-inch tile with a slope of 0.20% or .002 feet per foot has a maximum capacity of 0.10 cfs and:

$$L = \frac{0.10}{.07} = 1.4 \text{ (100-foot sections)}$$

The 4-inch drain is adequate for 140 feet of line. Continue these calculations for the next size pipe (5-inch) which has a maximum capacity of 0.18 cfs.

$$L = \frac{0.180}{0.070} = 2.60 \text{ (100-foot sections)}$$

R0071280

The 5-inch drain would be adequate for 260 feet. Of this 260 feet, 140 feet would be 4-inch drain; and the remaining 120 feet would be 5-inch drain. These computations should be continued progressively for the total length of the system. The following tabulation shows the complete problem:

Tile Size	Maximum Capacity .20% Grade	Accretion per 100' Line	L-Value Number of 100 Foot	Length of Tile Required
inches	c.f.s.	c.f.s.	stations	feet
4	0.10	0.07	1.4	140
5	0.18	0.07	2.6	120
6	0.29	0.07	4.1	$\frac{84}{344}$[1]

[1]Total length of the drain desired is 344 feet. Although the 6-inch tile would be adequate for 150 feet, only 84 feet are needed.

The example assumes a single line with uniform accretion throughout its length. If investigations indicate a variation in permeability, the accretion rate per 100 foot station may be varied. The same procedure is applicable for mains in a system where laterals join at regular intervals. In this case the accretion to the main would be the accumulative discharges of each of the laterals at intervals equal to the drain spacing.

Example:

Assume that the configuration of the underdrain system being considered is similar to the design illustrated in Figure 6-39 but it has only five lateral drains. One drain line connects into the main drain at the middle, opposite the outlet, followed by two laterals of equal size spaced 20 feet apart on each side. In other words, the total length of the main tile drain runs 40 feet in each direction from its midpoint at the outlet. Further assume that the total discharge expected from the system is 0.25 c.f.s. and that all the other presumptions made in the preceding example also pertain.

Begin by estimating the accretion per lateral. Since each line is of equal length this may be accomplished simply by dividing the total discharge by the total number of lines which feed into the main tile drain. In this case, 0.25 c.f.s./5 laterals = 0.050 c.f.s. per lateral. From Figure 6-40, 4-inch drain tile with a grade of .002 feet per foot has a discharge capacity of 0.10 c.f.s. Therefore, 4-inch pipe is adequate to handle the accretion expected per lateral. Each line would function at 50% of total capacity (e.g., .050 c.f.s. compared to the 0.10 c.f.s. maximum discharge ability).

R0071281

Given the "T" snaped configuration of the outlet pipe and main tile drains as shown in Figure 6-39 the accretion in each 20-foot section of main tile drain would be .050 c.f.s. at the first lateral plus .050 c.f.s. for each additional lateral or 20.0 foot station. Use Figure 6-40 to determine the sizes of pipe required for the main tile drain. Start computation at the upper end of each main with a minimum size equivalent to the diameter of the laterals. In this instance begin with 4-inch pipe. Compute the distance down drain that it would carry the flow on the assumed grade. Let (L) equal the distance that a 4-inch tile would be adequate. This number must be reduced by the number of laterals which enter at the upper end or head of each main (in this case, one). As noted earlier, a 4-inch drain on a grade of 0.20% has a maximum capacity of 0.10 c.f.s. and:

$$L = \frac{0.10}{.05} - 1 = 1.00 \text{ (20 ft. sections)}$$

The 4-inch pipe size is adequate for the first 20 feet on each side of the main tile drain. Continue these calculations for the next size tile (5-inch). From Figure 6-40 the 5-inch plastic pipe has the capacity to carry 0.18 c.f.s. assuming a constant grade of 0.20%. Therefore;

$$L = \frac{0.18}{0.05} - 1 = 2.6 \text{ (20 ft. sections)}$$

The 5-inch drain would be adequate for 52 feet (2.6 x 20 ft. per section). Of this 52 feet, the first 20 feet would be 4-inch pipe. Given the configuration of this system the remaining 20 feet must be increased to 5-inch drain. These computations should be continued for the total length of main drain. However, in this example each main tile line is designed to be 40 feet long in each direction. The following tabulation illustrates the complete problem.

Tile Size	Maximum Capacity .20% Grade	Accretion per 20' Line	L-Value Number of 20 Feet	Length of Tile Required
inches	c.f.s.	c.f.s.	stations	feet
4	0.10	0.050	1.0	20
5	0.18	0.050	2.6	$\frac{20}{40}$

Continue calculations to determine the size of the outlet pipe required. Once again refer to Figure 6-40 to determine the size of smooth plastic drain pipe required. Procedures for selecting the proper size for a drain

at a specific point in a system were discussed earlier. In this example the designer must estimate the discharge capacity for plastic pipe (n value = 0.011).

Find the hydraulic grade 0.002 ft/ft. or .2% on the horizontal scale in Figure 6-40 and follow vertically upward to intersect the line representing the total design discharge from the five laterals (e.g., 0.25 c.f.s.). This point falls in the space between the lines marked 5 to 6 inches in diameter. Therefore, a 6-inch diameter pipe is required. The pipe will not flow full since the capacity of the drain is 0.29 c.f.s.

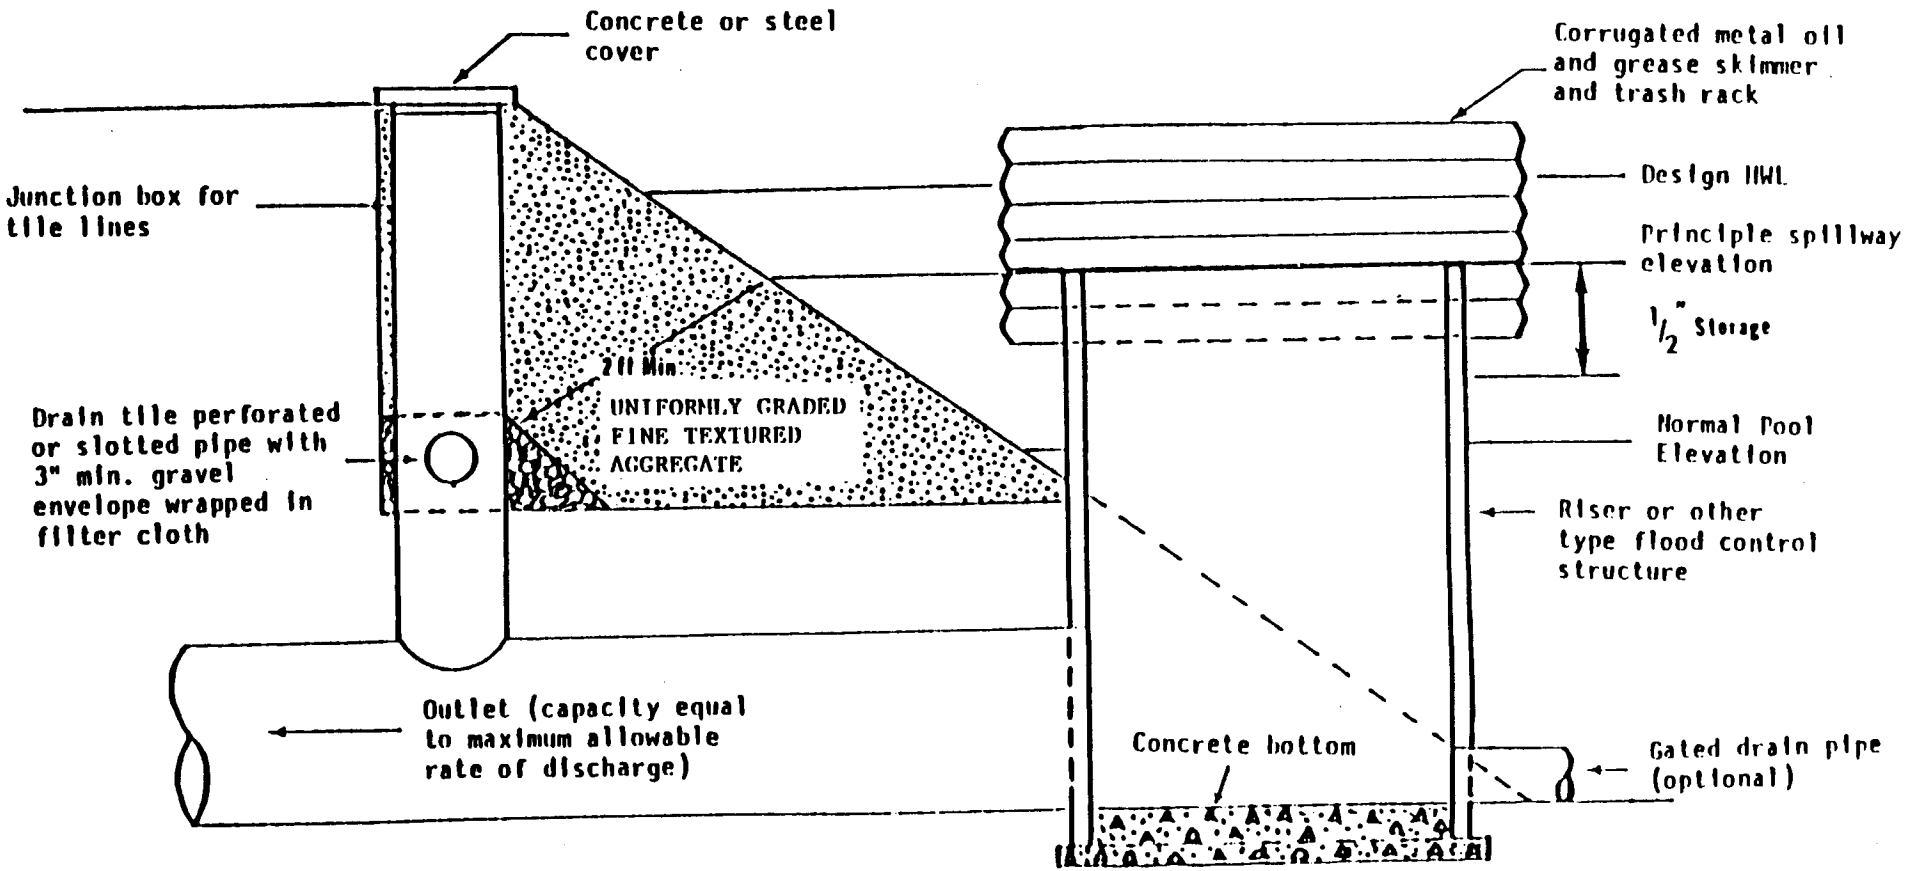
The final design for the underdrain system would consist of five laterals each 4 inches in diameter spaced equally at 20 feet apart. Each of the main tile drains would be 40 feet long. The first 20 feet would be 4-inch diameter pipe and the final 20 feet to the outlet must be five-inch diameter drain. The outlet must be sized to handle 0.25 c.f.s. therefore six-inch diameter pipe is required.

PART-II

Design Criteria for Stormwater Filtration Facilities

Filter systems for stormwater quality renovation may be used in conjunction with either wet or dry detention facilities. The bottom elevation of the former is below the grade line of the underdrain pipe. Conversely, subsurface drains are normally located in the lowest portion and below the bottom of dry detention facilities.

Examples of stormwater filtration systems include:



1) Filter systems in the banks of wet detention facilities. A typical cross section is illustrated in Figure 6-44. A slightly modified version of this particular style of discharge control structure is shown in Figure 6-45. The major difference between the two consists of a "flash board" type riser for adjustable depths of detention and flood control. Also notice that underdrains enter at the base of the riser pipe in the system shown in Figure 6-45 as opposed to entering somewhere along the outlet pipe as shown in Figure 6-44.

2) Bank filter systems used in conjunction with online or offline wet detention facilities which use the natural in place soils for filtration in conjunction with underdrain pipe for drainage. (See Figure 6-46).

3) Raised filtration beds projecting outward toward the center or extending along the sides of wet or dry detention facilities. (See Figures 6-47, 48, 49 and 50).

R0071291

4) Sand filter systems installed in the bottom of swales to improve percolation. (See Figure 6-51).

How does the Stormwater Rule standards listed in Chapter 17-25, F.A.C., affect these systems?

Underdrain systems and bank filters which use natural soil for filtration do not have to meet the requirements in section 17-25.025(2), F.A.C. pertaining to effective grain size, uniformity coefficient, etc.

However, these systems must be designed to prevent piping both within and through the filter. They are also subject to the 2 feet minimum flow requirements specified in Section 17-25.02(8), F.A.C.

Filter systems which use an aggregate other than natural soil for filtration must satisfy the standards listed in Section 17-25.025(2), F.A.C. The current standards for filter media are summarized and noted at the bottom of Figure 6-48.

Material with effective sizes less than .20 millimeters are acceptable to the Department for pollution control purposes. However, applicants may find the permeability to be restrictive.

Likewise, material mixed with organic matter or colloidal material may improve pollutant removal. However, anything more than slight amounts of material less than 0.074 millimeters in size has the potential to reduce hydraulic capacity quite substantially. The improvement in removal efficiency of such practices is still being tested by Dr. Wanielista and others at this time.

Design Procedures for Sizing Stormwater Filtration Systems

Underdrain design procedures will often involve the use of "spacing equations" to determine the area over which the drainage network can be expected to function to drain the proper amount of water in the required time frame.

Filter systems are usually designed by trial and error. In this procedure drainage capacity is checked for compliance with various regulations until a suitable configuration (e.g., trench area, depth, pipe diameter, and hydraulic conductivity of filter media) is achieved to meet drawdown time and grain size requirements. In terms of stormwater treatment, the Department is interested in the various design procedures from the standpoint that underdesign will result in reduced hydraulic capacity. This, in turn, will result in a reduction in storage between subsequent rainfall events and an associated decrease in the annual average volume of stormwater treated resulting in a reduction of pollutant removal. Such circumstances also reduce the aesthetic value of the system and may promote mosquito production.

R0071292

In most cases, various forms of the Darcy Equation for saturated flow through porous media are used to design filters. The equation is written:

$$Q = K\ i\ A$$

Where:

Q = Flow in ft^3/hr
K = Permeability rate of filter media (ft/hr)
i = Hydraulic gradient (ft/ft)
A = Area of the aquifer or water bearing strata intersected (ft^2)

The basic equation is applied in a number of different ways.

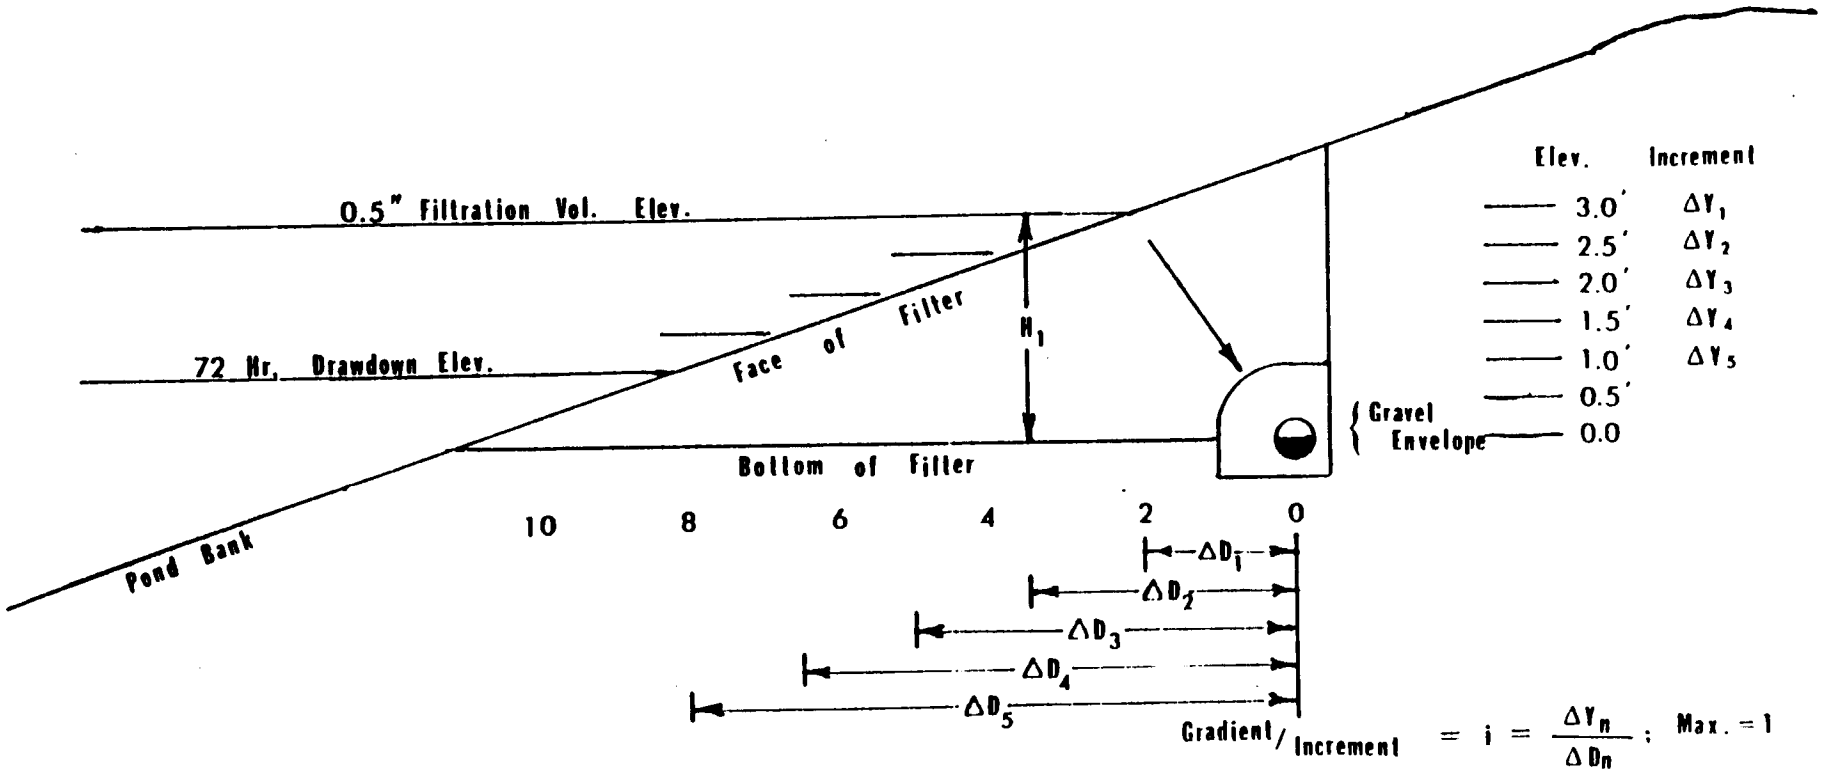
1) Calculating the length of a bottom filter and determining drain pipe size.

a) Possibly the most simplistic application of the Darcy Equation involves a slight manipulation in the formula such that the designer may determine the length (L) of a bottom filter, as illustrated in Figure 6-52, to treat and dewater an area sized to hold either the first one-half inch of runoff or the runoff from the first inch of rainfall. The flow (Q) of water reaching the underdrain pipe is assumed equal to its average velocity as it moves through the filter profile multiplied by the cross sectional area of the aquifer or filter trench intersected.

The velocity of flow is assumed proportional to the soil hydraulic conductivity (K) at a hydraulic gradient of unity (i.e. i=1).

The cross-sectional area intersected (A) is usually assumed equal to the average width of the drain field or trench (W) times the length of the drain (L). In mathematical form:

$$A = WL \text{ and therefore, } Q = KiWL.$$



The drain length is unknown but can be determined by rearranging the equation if the width of the trench is known:

$$L = \frac{Q}{KiW}$$

The flow (Q) is based on the storage volume which must be removed in the time frame desired. (K) is determined based on field permeability test or other information. The value of (W) is determined at the discretion of the designer. Its value normally will vary depending on the depth of the drain and the size pipe required.

FIGURE 6-52

Cross-Section of Bank Filter Illustrating Parameters Used in Calculating Drawdown Time with Darcy's Equation for Lateral Flow Situations

Example:

Suppose a facility is required to store one-half inch of runoff water per acre of project area as per state design criteria. Further, suppose the project is twenty acres in size with the hydraulic conductivity or permeability of the filter media (K) equal to ten inches per hour. The design calls for a three feet wide filter trench with the underdrain system installed two and one-half feet below the bottom of the detention facility for drawdown.

The length of filter and underdrain pipe needed to satisfy FDER criteria may be derived using the equation:

$$L = \frac{Q}{KiW}$$

Based on information presented in the paragraph above the one-half inch volume of runoff which must be temporarily stored and treated would equal ten acre-inches or 36,300 cu. ft. To drain the entire amount (36,300 cu. ft.) in three days (72 hrs.) would require an average rate of outflow equal to 504 cu. ft./hour. The length (L) of underdrain needed to satisfy the three day requirement is:

$$L = \frac{Q}{KiW} = \frac{504 \text{ cu. ft./hr.}}{(.833 \text{ ft./hr.})(1)(3 \text{ ft.})}$$

$$L = \underline{202 \text{ ft.}}$$

However, let's suppose the detention area was also planned for use as open space such as a park or recreation facility. In this instance it would be desirable to discharge the stored water within a day. The length (L) needed to provide sufficient drawdown in 24 hours would be:

$$L = \frac{1513 \text{ cu. ft./hr.}}{(.833 \text{ ft./hr.})\ (1)\ (3 \text{ ft.})}$$

$$L = \underline{606 \text{ ft.}}$$

In either instance, the discharge capacity of the underdrain pipe must be equal to or greater than the flow intercepted (Q). Given the latter circumstances, the pipe should be sized to carry at least a flow equal to 1513 cu. ft./hr. Converting this value to 0.42 cfs., the pipe size may be determined in accordance with procedures mentioned earlier (see Part I). Using the SCS Drain Capacity Charts included in this section, 8" corrugated polyethylene pipe (CPEP) with a roughness coefficient (n = 0.015) at a grade of 0.5% or .005 ft./ft. would be capable of conducting the proper amount of water.

The results of this analysis are based on several simplifying assumptions that would rarely, if ever, occur. The hydraulic gradient (i), for example, does

not remain constant. The value will change as the water level in the facility rises and falls. A more detailed assessment procedure capable of ascertaining the difference in drainage capacity under variable head conditions would reduce the amount of drain required.

Likewise, the assessment also presumes there are no other contributions from sources such as groundwater. Artesian type conditions would be expected to occur should high water table elevations surround the treatment area during any portion of the year. The size of the underdrain pipe would need to be increased. An increase of 1.5 to 2 times should be used in these situations.

b) A more complex method to determine if a specific design will satisfy the drawdown requirement under various head conditions is currently used by several engineering companies. The procedure combines Darcy's Law and the Falling Head Equation into a form similar to that used to determine the hydraulic conductivity (K) from falling head permeability testing techniques. The equations may be rearranged to solve for either drawdown time (t) or filter area (A) if the hydraulic conductivity (K) is known, and certain simplifying assumptions are made.

$$K = \frac{2.3\ aL}{A\ dt}\ \text{Log}_{10}\ \frac{h_0}{h_i}$$

$$dt = \frac{2.3\ aL}{AK}\ \text{Log}\ \frac{h_0}{h_i}\ \text{and,}$$

$$A = \frac{2.3\ aL}{Kdt}\ \text{Log}\ \frac{h_0}{h_i}$$

In these equations a is the average cross-sectional area of the pond or reservoir; A is the cross-sectional area of the soil profile or filter served by the drain tube; L is the length or depth of the soil profile (filter media) through which the water must travel to reach the gravel envelope or perforated pipe; in most cases that value will be a minimum or two feet; and dt is the time interval (hrs.) during which the elevation drops from its initial value (h_0) to some lower value (h_i) as the water approaches the pond bottom.

Example: Assume our objective is to estimate the time to remove the 36,300 ft^3 of runoff discussed in the previous problem. The area of the facility is assumed to remain constant as the water receeds. The head (h_0) at the time when the facility was full would equal 5.0 feet. The average area (a) may be calculated by dividing the pond volume by the depth. In this case presume the pond was designed 3 feet deep.

Working through the equation when the facility was full to determine the area (A) of filter needed:

a = 12,100 square ft.
L = 2.0 ft. (average length of travel)
K = 10 in/hr. or .833 ft. hr.
h_o = 5.0 ft.
h_i = 2.0 ft.
dt = 24 hrs.

Therefore:

$$A = \frac{2.3\ a\ L}{Kdt} \quad \text{Log} \quad \frac{h_o}{h_i}$$

$$A = \frac{2.3\ (12{,}100)(2.0)}{.833\ (24)} \quad \text{Log} \quad \frac{5.0}{2.0}$$

$$A = \frac{55{,}660}{20} \times 0.40$$

$$A = \underline{1{,}113\ ft^2}$$

Given no accretion from other sources, a filter three ft. wide by 371 ft. long should be capable of draining the facility. As may be seen, the results using this procedure will be much more favorable to the applicant since the drain length is reduced. This is because the previous assumption relative to a hydraulic gradient of unity (i = 1) is not used in this procedure. The procedure is much less conservative than the former.

The designer should also notice that this analysis is dependent on the presumption that the size and slope of the drain tube as well as the number and size of pipe orifices or openings will not restrict the maximum peak flow delivered to the drain tube via the filter media.

In using the equation above, pipe size must be checked using the pipe flow capacity charts mentioned previously. Likewise, orifice area must be checked using the orifice equation which may be written:

$$Q = C_d A\ (2gh)^{1/2}$$

Where:
Q = Orifice discharge (cfs)
C_d = Coefficient of discharge (usually assumed to be 0.6)
A = Orifice cross-sectional area ($ft.^2$)
g = Gravitational acceleration (32.2 $ft./sec.^2$)
h = Hydraulic head above the orifice (ft.)

The maximum peak flow expected from the filter system must first be calculated once again using Darcy's Law.

$$Q = KiA = K \frac{Y}{D} A$$

Where:

K = Coefficient of soil permeability (ft./hr.)
i = $\frac{Y}{D}$ = Instantaneous hydraulic gradient
A = Area of trench or filter ($ft.^2$)
Y = Head difference between water level elevation behind the structure at any point in time and the flow line of the underdrain pipe or top or gravel envelope if used
D = Depth of soil column or filter to flow line of underdrain or top of envelope material
Q = Instantaneous rate of discharge ($ft.^3$/hr.)

Continuing to work through this example problem:

K = 0.83 ft./hr.
Y = 5.0 ft. (when the detention area is full)
D = 2.0 ft.
A = 1113 $ft.^2$

Therefore:

$$Qmax = K \frac{Y}{D} A = 0.833(2.5)(1113)$$

$$= 2318 \text{ ft.}^3\text{/hr.}$$

$$Qmax = 0.64 \text{ cfs.}$$

Checking this rate of flow with the SCS pipe capacity charts mentioned previously for n = 0.015 and hydraulic grade (0.005 ft./ft.) indicates that an 8-inch pipe will remain adequate to handle the maximum peak flow.

The minimum orifice area required is then determined using the following equation:

$$A = \frac{Q}{C_d\sqrt{2gh}}$$

Where:
A = total orifice area required
Q = .64 cfs
C_d = .6
g = 32.2 $ft./sec.^2$
h = 5.0 ft.

R0071298

$$A = \frac{.64}{.6\sqrt{64.4 \times 5}} = .059 \text{ ft.}^2/371 \text{ ft. of pipe}$$

$$= 1.6 \times 10^{-4} \text{ ft.}^2/\text{ft. of pipe}$$

$$A = \underline{.023 \text{ in}^2} \text{ ft. of underdrain pipe}$$

Therefore, a pipe is required that contains at least eight or more 1/16 inch diameter holes per foot.

2) Calculating the length of a bank filter and determining pipe size required.

Either of the two basic procedures discussed above may also be used to determine the length of a bank filter system. However, the designer should notice that both the cross-sectional area of the filter media intersected by the drain and the hydraulic gradient which was presumed to be unity or larger in the previous analysis decrease with time in these systems. These factors must be taken into account and act to complicate the more simplistic procedures discussed previously. The length of bank filters is usually established by trial and error. The designer chooses the underdrain length desired and subsequently checks drawdown time against state regulations or land use requirements until a suitable configuration is reached.

a) Procedure for sizing bank filters based on Darcy's Equation

The most simple and easily understood method for sizing bank filters is primarily applicable to conditions wherein lateral flow is predominant (see Figure 6-52).

Once again, the rate of flow should be in accordance with Darcy's Law which states that the flow velocity of water through porous media media is proportional to the hydraulic conductivity and the hydraulic gradient. The relationship may be stated:

$$V = Ki$$

Where: V = velocity of flow
K = the hydraulic conductivity
i = the hydraulic gradient $\frac{\Delta Y}{\Delta D}$

Y = the change in elevation between the free water surface in the reservoir and a horizontal reference plane usually passing through the flow line of the underdrain pipe.

D = the horizontal distance from the edge of the free water surface to the verticle reference plane (usually chosen passing through the center of the underdrain pipe).

Tne flow of water delivered to the drain is equal to the velocity (Ki) as it moves through the media, multiplied by the cross sectional area (A) of the filter. Contrary to the more simplistic situations analyzed earlier, this area changes not only in relation to the depth of the free water surface but also decreases in relation to the upper line of seepage as it moves toward the underdrain.

Hence, Darcy's Law is usually applied in the design of bank filters in much the same way as it is for determining seepage through an embankment. The media is assumed to be homogenous throughout and located on an impervious foundation (e.g., the bottom and sides of filter trenches are presumed impermeable). Since the depth of the saturated zone varies as it approaches the drain, the mean width is used to calculate the area factor used in these determinations.

When the bottom of the filter and the horizontal reference plane coincide, (A) is assumed to equal one-half the vertical distance (H) shown in Figure 6-52 multiplied by the length of the filter (L). Stated in mathematical form:

$$A = \frac{H\,L}{2}$$

Where: A = Mean cross sectional area of the saturated zone (ft^2)
H = Change in elevation or depth of the filter from the free water surface to the bottom of the filter (ft)
L = Length of the filter (ft)

The instantaneous rate of discharge (Q) is subsequently calculated at the various stages of drawdown or storage elevations in the pond. The greater the number of increments the more accurate the assessment is likely to be.

The formula for expressing the discharge through a unit length of filter media for each increment is:

$$q = K\,(\frac{\Delta Yn}{\Delta Dn})(\frac{Hn}{2})$$

When the elevation of the free water surface does not exceed the top of the filter, the value of (Hn) is equivalent to the change in elevation per increment of rise or fall in the storage area (i.e., $Hn = \Delta Yn$). The equation subsequently may be written:

$$q = \frac{K}{2}\,(\frac{Hn^2}{\Delta Dn})$$

R0071300

Where: q = discharge rate per unit length
K = hydraulic conductivity of the filter material comprising the least permeable section
Hn = change in elevation from the flow line of the drain or other reference point to the water level in the reservoir
Dn = horizontal distance measured from the edge of the free water surface to the vertical plane of reference (in this instance, the middle of the perforated pipe).

Values of (q) are multipled by the total length (L) of the filter system to determine the total discharge capacity (Q) of the facility. In equation form the relationship may be stated:

$$Q = (q)(L)$$

In some situations, the bottom of the filter is located below the flow-line of the pipe. In these instances, the value of (H) will exceed (Yn). The mean discharge area may be determined as follows:

$$A = \frac{(H - \Delta Y) + H}{2} L = (H - \frac{\Delta Y}{2})L$$

In either case, the instantaneous discharge is averaged between each increment. The drawdown time is then determined by dividing the volume of storage available in the reservoir between stages by the mean rate of outflow projected through the filter.

Similar to previous examples presented in this section, Table 6-15 shows how the drawdown time would be calculated for a project designed to treat approximately 36,300 ft^3 or 10 acre inches of runoff. By comparison, it may be seen that bank filtration is not nearly as hydraulically efficient as a means of treatment as bottom filters or underdrains. Earlier it was shown that only 200 ft. of bottom filter would be needed to drain an equivalent amount of water within 72 hours. However, a 75% increase in length (350 ft.) of bank filter is required to accomplish the same task even though the hydraulic conductivity of the media is presumed to be more than five times greater than the earlier example.

The designer should be aware that the configuration of the system itself can have substantial influence on the hydraulic efficiency of these facilities. Most of these systems are relatively low head since they are normally designed with little more than 2 feet of elevation difference between the maximum stage in the facility and the bottom of the filter. Consequently, there is often only a very slight energy gradient to move water toward the drain. In such situations elongated envelopes (see Figure 6-53) are often used to provide higher internal gradients and improve the flow of water through these structures. The higher discharge capacity decreases the length of filter needed to satisfy drawdown requirements.

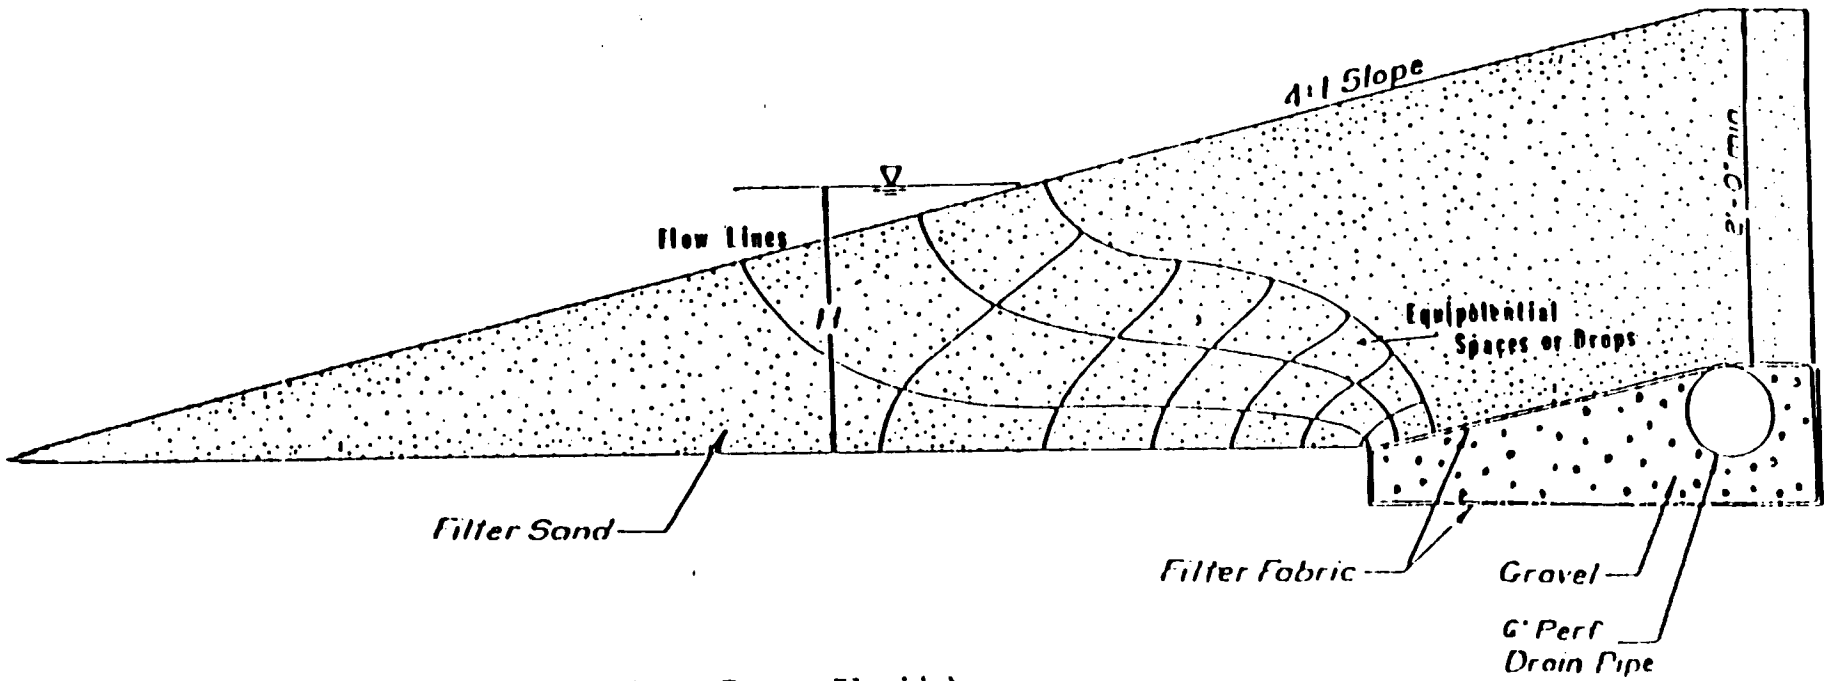
b) Flow Nets

Another commonly used method for evaluating problems related to seepage through porous media involves the construction of flow nets. This type of analysis can also prove to be a valuable tool for the design of stormwater filtration systems. A diagram of a flow net constructed for a rather commonly used bank filter design is illustrated in Figure 6-54. Those interested in developing skills in flow net analyses for this and other configurations of bank filters may find Seepage, Drainage, and Flow Nets by H.R. Cedergren to be a vaulable reference.

Flow nets may be applied in sizing a bank filter in the same manner as Darcy's Law was used earlier. A number of diagrams are constructed, each correlating to various stages within the reservoir. The individual diagrams are then used to determine the discharge relationship per linear foot of filter. The flow net equation may be written:

$$q = KH \frac{nf}{nd}$$

Where: q = seepage quantity ($L^3/T/ft.$ of filter)
K = permeability of the media (L/T)
H = net head (L) as illustrated in Figure 6-54
nf = number of flow channels
nd = number of equipotential drops



The ratio nf/nd is otherwise known as the shape factor. As noted by Cedergren, the number of flow channels and the corresponding number of equipotential spaces depends on the shape of the cross section, and will not necessarily be a whole number. A different shape will produce a different number of spaces and channels. He goes on to warn those who are just learning by stating that novices "sometimes overlook one or more of the basic rules. The resulting flow net can be so filled with errors that a grossly distorted picture of a seepage pattern will be given". However, he also points out that any number of flow nets for a given problem will agree when the work has been done correctly. There is but one solution to a given problem. Consequently, although this work may be quite cumbersome at first, once flow nets have been constructed for a given configuration of filter they will continue to apply to the specific design or shape as long as they are not changed.

Once the unit rate of discharge (q) is established at each increment of drawdown the total stage discharge relationship may be determined by multiplying the value of (q) at each stage by the length of the filter (L). The instantaneous discharge Q is averaged between each increment. Assuming the volume of storage between increments is known, the drawdown time (t) may be calculated by dividing the volume by the average rate of outflow in the same manner as illustrated in Table 6-15. Here again, the preparation of such a table is an aid to any reviewing agency and can help speed up project approval. Preliminary evaluations seem to show that flow net analyses may

R0071304

(Not to scale, for illustration only)

R0071305

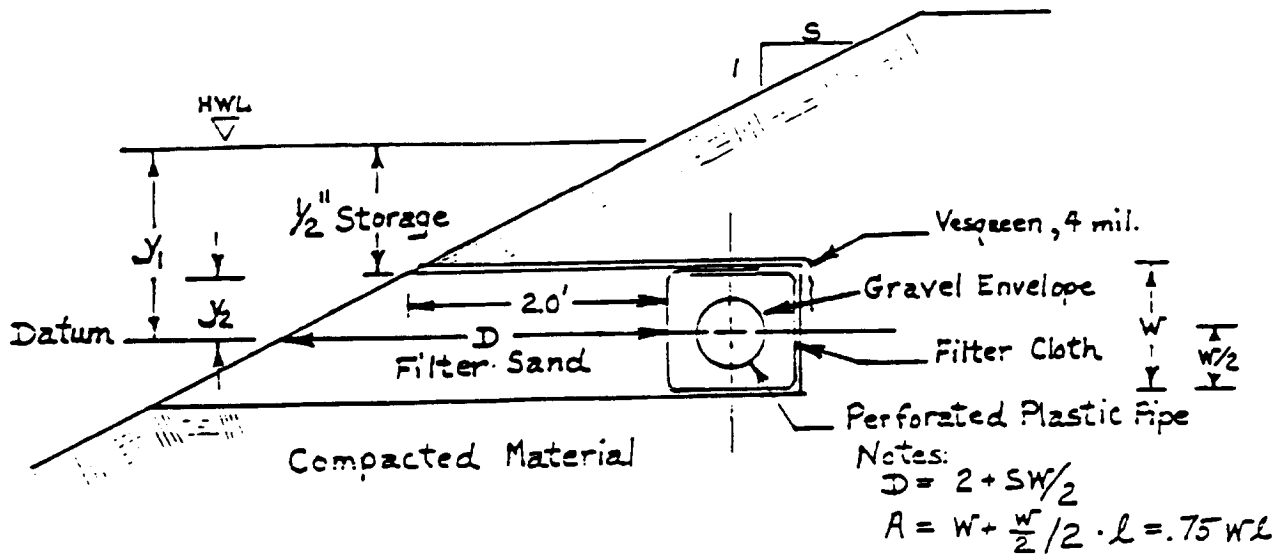
offer benefits over the procedure described in section 2(a) when gradients of 100% or more are likely to occur over much of each filtration cycle.

c. Other Analytic Approaches

Currently several other methodologies being used to design underdrains that are not incremental in nature. In these instances several designers have modified the designs illustrated previously. This has enabled the use of equations in which drawdown time (t) or filter length (L) may be calculated in one step based on a single formula. Figure 6-55 illustrates the general design and important dimensions of two such systems.

The form of the expression used to estimate the length of filter trench (L) required to accomplish drawdown in the time desired is written as follows:

$$L = \frac{1.33\ Ar\ D}{KtW} \ln (Y_1/Y_2) \text{ for system (a), and;}$$



$$L = \frac{Ar\ D}{KtW} \ln (Y_1/Y_2) \text{ for system (b) Figure 6-55.}$$

A_r = Average area of reservoir between elevation Y_1 and Y_2 (ft^2)

Where: L = length of filter required (ft)
K = hydraulic conductivity of the filter media (ft/hr)
t = allotted drawdown time (hrs)
W = trench width as illustrated in Figure 6-55 (ft)
D = average distance which water must travel through the filter profile as shown in Figure 6-55 (ft)
Y_1= Difference in elevation between the flow-line of the underdrain pipe and the water level in the reservoir at the appropriate volume of storage (ft)
Y_2= Difference in elevation between the flow-line of the underdrain and the stage in the reservoir following discharge of the treatment volume required (ft)

It should be noted that the mean distance (D) traveled is used for calculations involving systems similar to that illustrated in Figure 6-55(a) while for the system shown in Figure 6-55(b) the distance is equal to 2.0 feet. However, the difference in the form of each equation is primarily due to differences in the magnitude of the cross section visualized to be intersected by the drain in each situation. In Figure 6-55(b) the trench is perpendicular to the face of the bank. Flow through the filter, toward the drain is predominantly vertical. The entire cross-section or width (W) of the filter is intersected by the drain and its surrounding gravel envelope. Flow is primarily normal to the plane of reference. In these circumstances, the discharge area remains relatively constant as water moves toward the drain. The phreatic surface will be parallel to the upper trench wall, intersecting nearly the entire width of the drain before curving toward the drain tube itself. The presumption that A = WL is primarily correct in this circumstance.

(a) Reduced Head System

(b) Side-of-the-Bank System

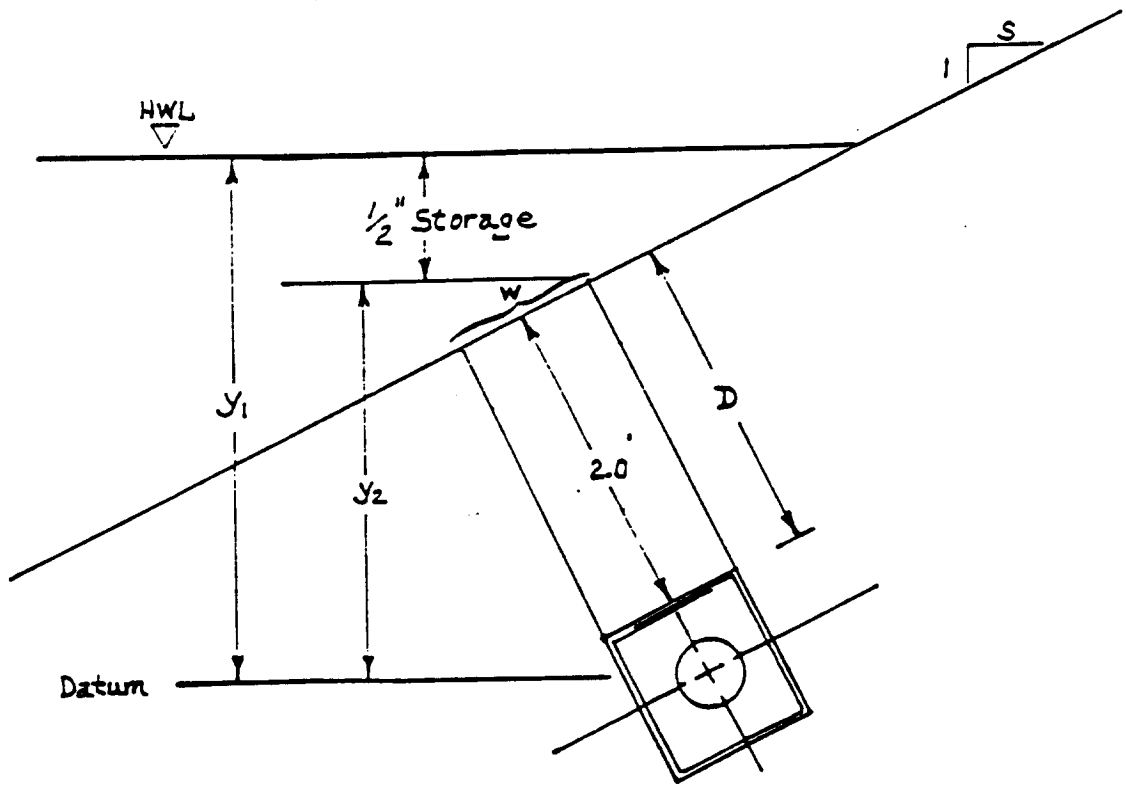


FIGURE 6-55

Sketch of Bank Filter Designs Illustrating Symbols for Use With Single Step Evaluation of Trench Length and Drawdown Time

(Courtesy of Post, Buckley, Schuh and Jernigan Engineers, Clearwater, Florida)

R0071307

On the other hand, this assumption does not pertain in the horizontal flow situation shown in Figure 6-55(a). The reference plane (passing through the flow line of the pipe when full flow is assumed) does not intersect the entire cross-section or width of the filter. Flow is primarily parallel to the plane of reference. In these circumstances the width of the saturated zones is reduced as water moves toward the drain. The average discharge area (see notation with figure) should be used in this situation. The presumption that the discharge area (A) is equal to the entire width (W) of the drain times its length (L) would be correct only in the event that the water level was expected to be at the top of the trench during operation. This assumption is pertinent to submerged drains only. The latter situation would not be recommended because of added difficulties in the design, installation, operation and maintenance of these systems due to constant anaerobic conditions.

When the length of the system is known, the equations may be rearranged to solve for the drawdown time associated with the system as follows:

$$t = \frac{1.33\ Ar\ D}{K\ W\ L} \ln Y_1/Y_2 \text{ for system (a)}$$

$$t = \frac{Ar\ D}{K\ W\ L} \ln Y_1/Y_2 \text{ for system (b)}$$

Similar to using other forms of Darcy's Law when the length and drawdown constraints are predetermined, the equation may be used to establish the required permeability. In this instance the designer would establish a trial thickness of the filter and calculate the hydraulic conductivity needed to satisfy these requirements. Likewise, the designer may select one or more permeabilities that represent commercially available filter materials within acceptable degrees of uniformity and effective size (as outlined in 17-25.025(2) F.A.C.) and calculate their required thickness.

3) Other Design Considerations

a) Pipe Size, Orifice Area, and Filter Cloth

The design procedures discussed in section 1 and 2 of this BMP are all primarily associated with the capability of the filter media to transmit water. The permeability associated with filter cloth (when used), the size and number of orifices or perforations in the drain pipe, and the capacity of the pipe itself can also limit the rate of discharge. Each of these factors must be checked as described in section 1(a) and (b) of the design criteria to also ensure that these factors will not effect drain requirements.

b) Safety Factors

Permeability is crucial to all of the design procedures. However, as noted by Cedergren, "Permeability can vary so widely that its physical significance is often difficult to comprehend,..." In this instance, the author was referring

R0071308

to the differences in the properties of various aggregates (sand, clay, gravel, etc). However, tests of similar types of materials show that even these percolation rates may vary by 100% or more. In the light of the large margin of discrepancy associated with most design techniques and rest results, safety factors on the order of at least two are appropriate. Drawdown time on the order of one-half of what is required should be encouraged.

c) Pollution Control

Filters for stormwater treatment are designed to remove particulates and their associated pollutants from the runoff waters as they percolate through the fine textured aggregate on its way to the drain tube. According to preliminary indications based on information published by Dr. Y.H. Chen et.al (1981) "a layer of soil can stop the passage of a particle if the size of this particle is larger than one-fifth of the size of particles establishing the soil layer". Using the effective size (D_{10}) requirements specified for filters in Chapter 17-25 F.A.C. it is expected that particles on the order of .04 to .10 mm. may be removed. According to grain size distribution data for pollutants associated with street surface contaminants (Sartor and Boyd, 1972), more than 90% of the suspended and oxygen demanding materials found in urban stormwater should be removed. Preliminary information reported from an in-line filter system installed on a tributary to Lake Jackson near Tallahassee supports this conclusion.

Soluble pollutants are not removed so readily. However, in general, the more fine textured the media, the better the pollutant removal expected. When designing a filter system, these considerations, as well as, the form of contaminants to be removed from the stormwater, should be balanced with the improved hydraulic capacities which are concommittent with more coarse grained, even-graded filter media.

d) Filter Fabric and Piping Control

Filter cloth must also contain pore spaces which will not permit the filter media (sand) to be carried away by the water. The Corps of Engineers and Yung Hal Chen, Daryl B. Simons, and Phillip M. Demery in "Hydraulic Testing of Plastic Filter Fabrics" discuss valuable information pertaining to the proper selection of these materials. Several important guidelines are summarized as below:

1) In order for filter fabric to work as a permeable constraint to stop adjacent particles of filter material from washing through the fabric, the EOS (equivalent opening size of the fabric) divided by the D_{85} of the sand should be less than or equal to two.

$$EOS/D_{85} \leq 2$$

2) To avoid clogging by fine particles requires that the EOS of the fabric must be equal to or greater than twice the D_{15} of the filter material.

$$EOS \geq 2D_{15}$$

Planning an Underdrain or Filter System

Analyzing Information and Data from Surveys and Investigations

In most humid areas, many years of experience with subsurface drainage installation have provided the main basis for determining drainage requirements for various soil types and problem areas. Special investigations are necessary for drainage of soils where experience is lacking. One of the most important phases of planning either an underdrain or stormwater filtration system is to compile and analyze the field data collected through various surveys, investigations and studies. These investigations are difficult because subsoil and groundwater conditions are not evident through visual inspection. Various methods and techniques have been developed whereby these conditions can be determined and made evident through a graphical or statistical presentation. The following is a discussion of some of the methods and procedures commonly used.

1) Water Table Contour Maps - The elevation of the water table at selected points covering the area are plotted on the base map. By interpolation and extrapolation lines of equal water table elevation are drawn. The completed map represents the surface configuration of the water table at a specific time.

   To be of greatest use as a tool in planning, groundwater contour maps should be superimposed on topographic maps to give the relationship between surface configuration and water table configuration. An example of this type of map is shown in Figure 6-56. The completed map will show areal delineation of depth to groundwater which is usually the criteria for determining maximum allowable depth of stormwater filters.

2) Observation Well Hydrographs - On profile paper, cross-section paper or printed hydrograph sheets, plot water table elevation against time. Well hydrographs may be compiled for all observation wells or for a few selected wells at key locations. The time scale, which is usually on the abscissa (horizontal), is in days by months for one year's time. The ordinate (vertical) is used for water table elevation and is in feet and tenths. The completed hydrograph shows water table fluctuation by seasons: the high level and the low level for the season.

R0071310

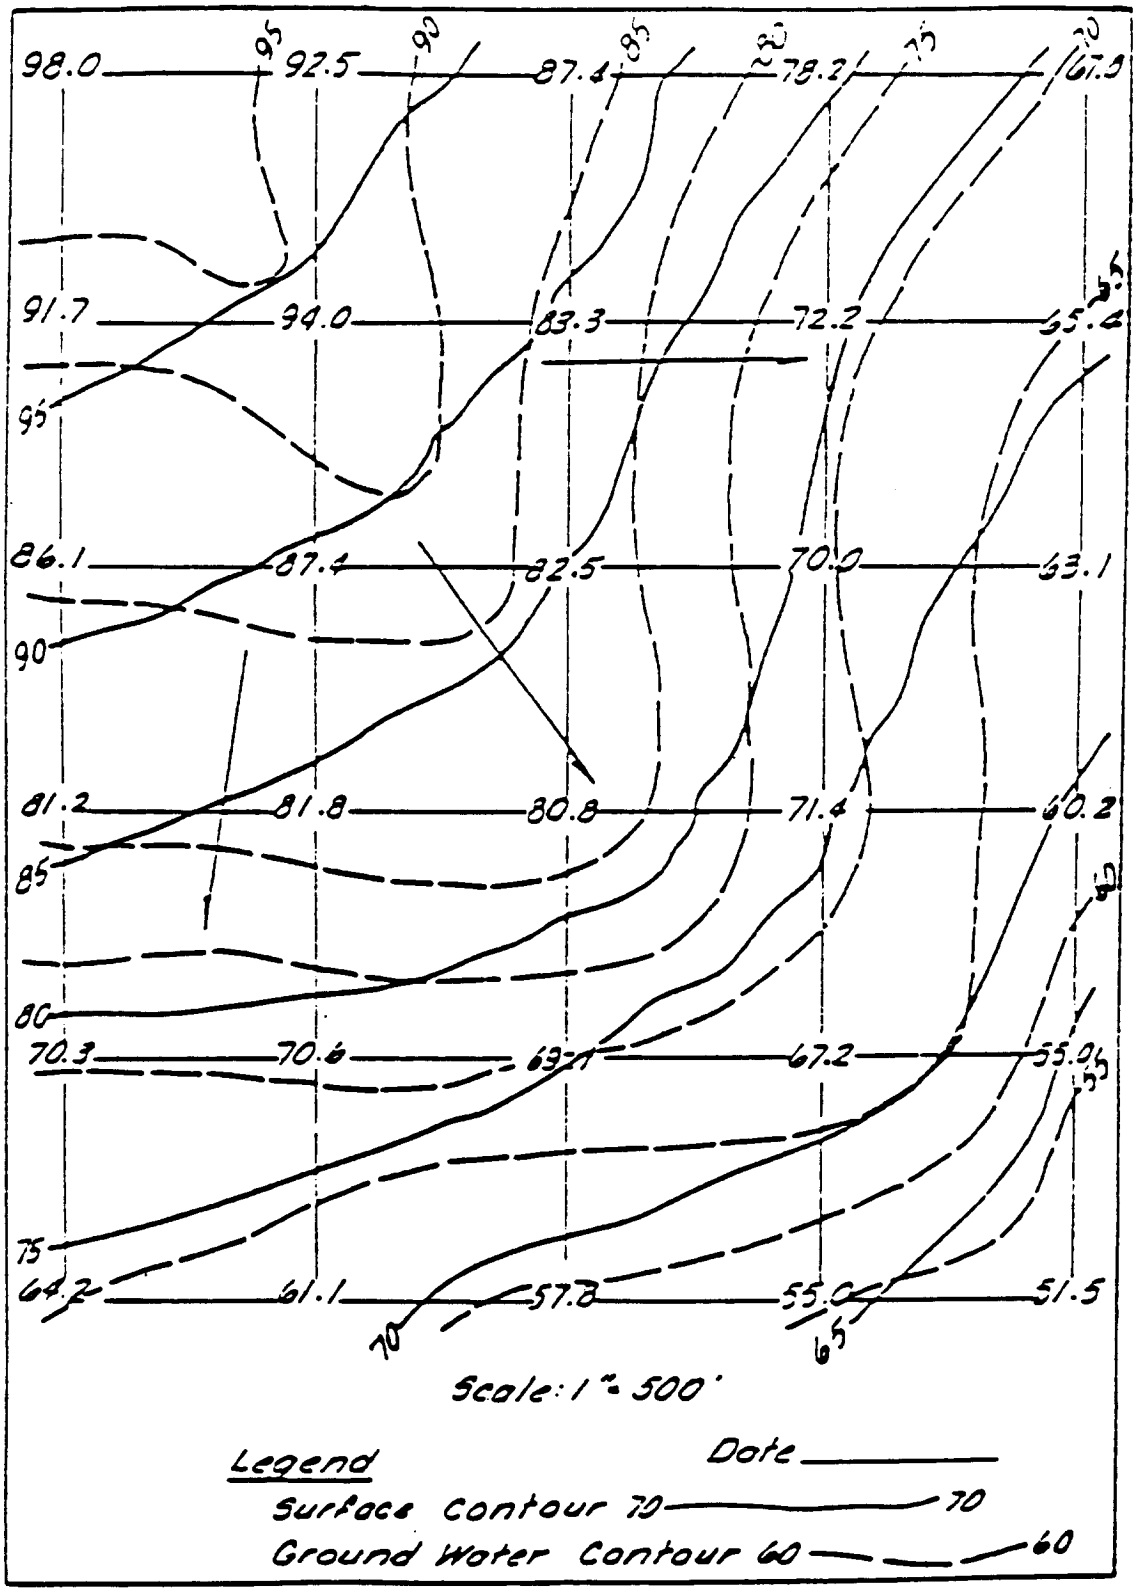

FIGURE 6-56

Typical Water Table Contour Map

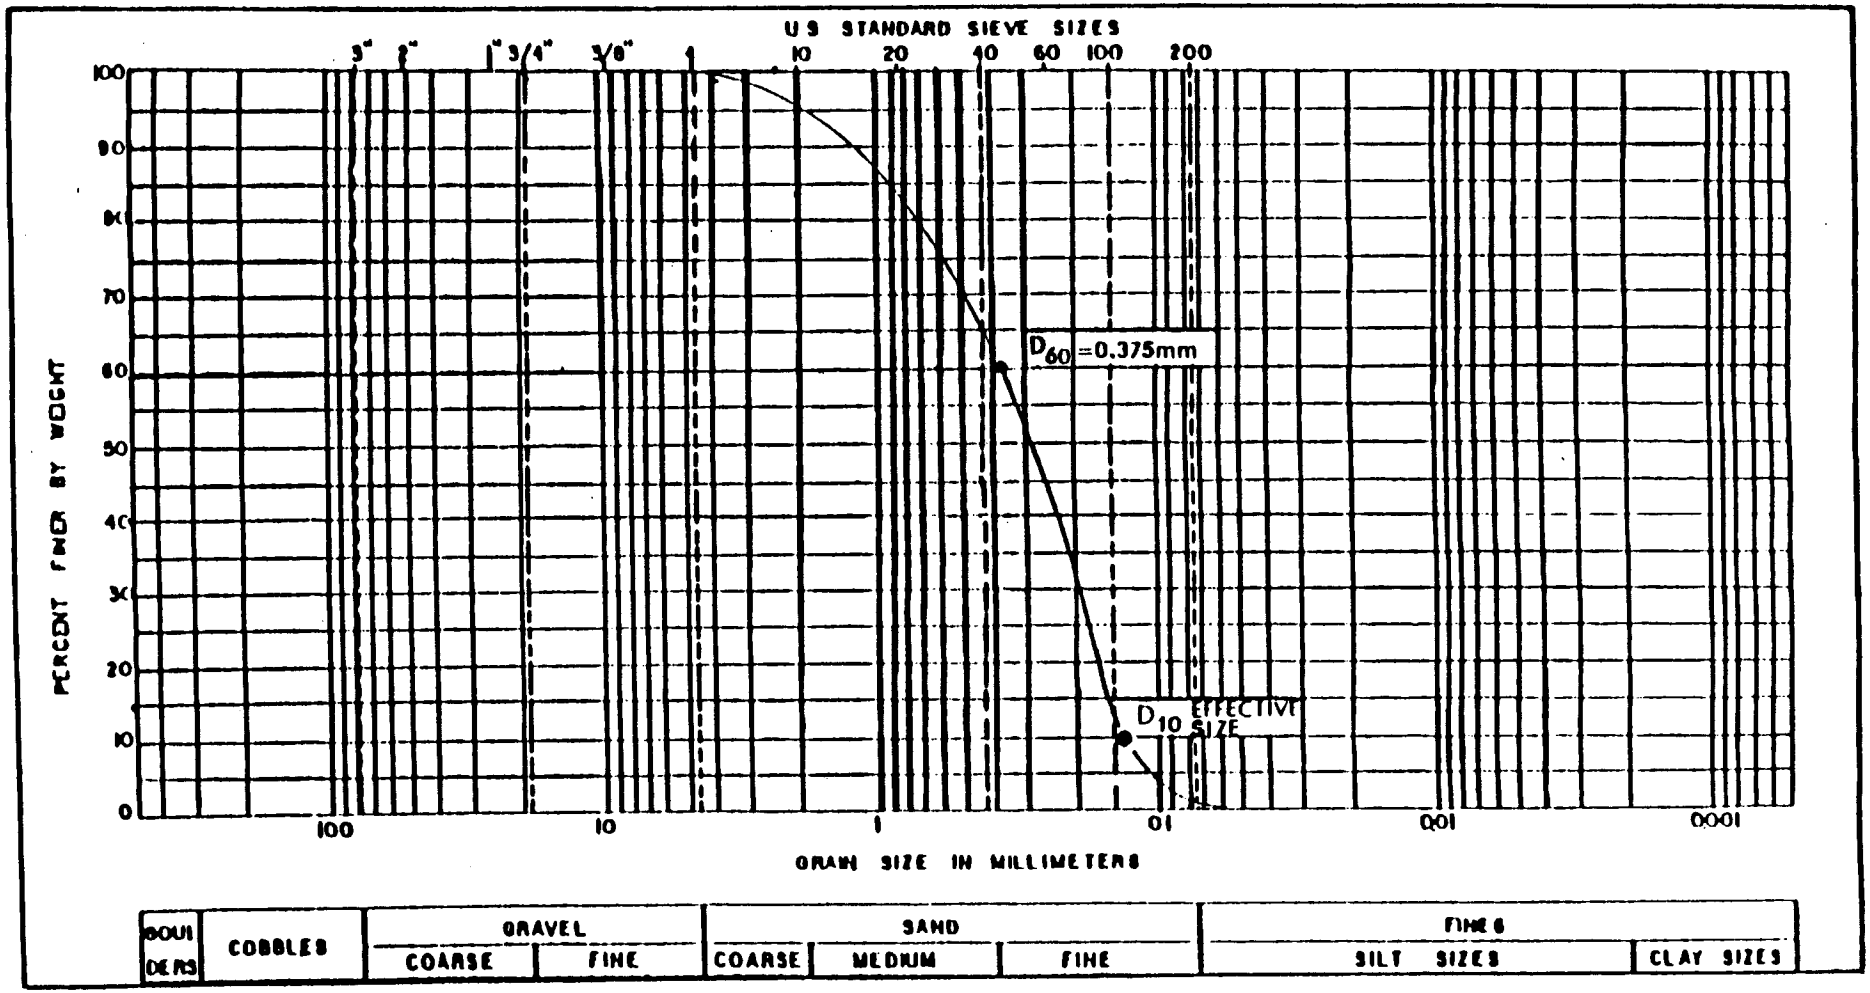
R0071311

It is often very helpful in determining the source of groundwater.

Even when compiled from wells not exactly located on the immediate grounds, this data may aide in the interpretation of more short term instantaneous water table elevation mapping information. Knowledge related to seasonal fluctuations of high water table conditions can help prevent the under design and consequential bypassing of these stormwater treatment systems due to an influx of water not normally expected to occur and left unaccounted for in drain size analyses.

3) Profile Flow Patterns - Profile flow patterns may be shown by plotting the surface of the ground, information on subsoil materials, and hydraulic-head values at points where measurements have been made with piezometers. Lines should be drawn to connect points of equal hydraulic head. Convenient hydraulic-head intervals may be selected extending over the range of measured values for hydraulic head. Usually an interval is selected that allows a number of equal hydraulic-head lines to be sketched on the same profile. The component of flow in the plane of the profile is normal to lines of equal hydraulic head if the profile section is plotted on a one to one scale. Using this scale, flow lines can be sketched in at right angles to the equal hydraulic-head lines, with arrows to show the direction of flow.

A vertical component of flow is indicated where the hydraulic-head changes. This component may be either up or down. Profile flow patterns are very helpful in detecting artesian conditions, which is particularly an important consideration in determining the size, shape, and spacing of laterals in underdrain system design.



4) Gradation and Permeability Tests Results - Mechanical analysis (sieve size) is important for both filter and underdrain design. The results of tests run on the soils to be underdrained or the sand or other fine textured aggregate used for filtration are recorded and plotted on a grain size distribution chart as illustrated in Figure 6-57. Shown on the vertical scale at the left of the graph is the percentage of a soil or sand sample passing each of a number of increasingly smaller (in opening size) screens or sieves. A curved line connecting the points is shown for easy interpretation of percentages related to sizes in between the size separates.

This data is subsequently used to verify that the filter media conforms to state requirements listed in Section 17-25.025(2) pertaining to effective size and coefficient of uniformity. In both underdrain and filter design such information is also useful to help evaluate the capacity of a given configuration and to avoid potential piping of the filter sand or soil into the drain.

R0071312

FIGURE 6-57

Typical Grain Size Distribution Chart

D_{10} = 0.15

$C_u = 2.5\ (D_{60}/D_{10})$

R0071313

Likewise, information pertinent to the capacity of a particular soil or filter sand to conduct or transmit water is quite important. There are a number of ways in which the permeability rate may be determined. Discussions of the applicable techniques are included in most soil mechanics texts. In this manual several of the more common field testing procedures are discussed in more detail in Appendix 6-2. Field testing is usually preferred for underdrain design while laboratory methods are most often used for establishing the hydraulic conductivity (K) of filter media.

Salt-water Intrusion in Coastal Areas

When planning a filter or underdrain design system in areas in close proximity to sea coasts, certain precautions must be considered in regard to salt-water intrusion. Beneath coastal areas, the normal movement of fresh ground water toward the sea usually prevents landward intrusion of the denser sea water; however, pumped well drains or pumped surface and subsurface drainage can reverse this situation. If this happens, the consequences can be serious since land once subjected to salt-water intrusion is difficult to reclaim.

Guidelines for Prevention - In coastal areas salt-water is present in underground strata at a depth equal to about forty times the height of fresh water above sea level. This is given by the Ghyben-Herzberg relation.

This relationship is only approximate because the density of sea water varies with temperature and the salts present. However, the ratio of 40.0 to 1.0 is adequate, as a general rule, for the purposes discussed here. In coastal areas, lowering of the water table one foot will cause a 40-foot rise in the fresh water-salt water interface. Lowering of the water table to mean sea level will bring the interface up to mean sea level which will in most cases render the land salty and unfit for many uses.

As a general guide for use in planning pumped stormwater systems near the coast, sumps should not extend below mean sea level. Filters and underdrains should be designed and developed for minimum drawdown of the water table and be located so that drawdown is distributed as widely as possible and not concentrated in specific areas.

Outlets for Underdrains and Filters - An outlet for the stormwater system must be available for gravity flow or by pumping. The outlet must be adequate for the quantity and quality of the effluent to be disposed of without causing damage to other areas and with minimum deterioration of the water quality in the outlet.

An open-ditch outlet for gravity flow from a buried drain should permit discharge from the drain above the elevation of normal flow in the outlet. Interruption of flow from the drain due to storm runoff in the outlet should

not occur so often and with such duration that the rate of drawdown by the buried drain would fail to meet the design requirements specified in Chapter 17-25 F.A.C. during most situations.

Construction and Materials Specifications for Underdrains and Stormwater Filtration Facilities

General

The location of the main drain and laterals should be planned to obtain the most efficient and economical drainage system. A few general rules to follow are:

1) Provide the minimum number of outlets.

2) When practical lay out the system with a short main and long laterals.

3) Orient the laterals to use the available slope to the best advantage.

4) Follow the general direction of natural waterways with mains and submains.

5) Avoid locations that result in excessive cut.

6) Avoid crossing waterways wherever feasible. If waterways must be crossed, use as near a right-angle crossing as the situation will permit.

7) Where feasible, avoid soil conditions that increase installation and maintenance cost.

Laterals should be located in the direction for the most effective collection of excess water, with due regard to the grade required for prevention of sedimentation, and following the rule of long laterals with short mains where feasible. Where it is desirable for main drains to be located parallel to a ditch deeper than the drain, enough distance should be maintained between ditch and drain to prevent washouts in the drain. Submains may be used to eliminate crossing waterways and to reduce the number of lateral connections to the main.

Inspection and Handling of Materials

Material for drains shall be given a rigid inspection before installation. Bituminized fiber and plastic pipe and tubing shall be protected from hazards causing deformation or warping. All material shall be satisfactory for its intended use and shall meet applicable specifications and requirements.

Placement and Coarse Aggregate Bedding Requirements

All drains, both flexible as plastic tubing and non-flexible as clay and concrete tile, shall be laid to line and grade and covered with approved blinding, or filter material. A minimum 3-inch thick gravel envelope wrapped in filter cloth is suggested to improve flow into the drain. Either of the two methods below may be used.

1) Except as provided in Metnod 2 below, the bottom of the excavated trench shall be shaped or grooved. Flexible type drains, when placed, shall be embedded in undisturbed soil for approximately 60 degrees of their circumference. After placement of all types of drains, friable material taken from the trench spoil or cut from the trench side walls shall be placed around the drain in such a manner that it will completely surround and support the drain and fill the trench to a depth of 3 inches over the top of the drain. To be suitable, materials surrounding the drain must contain no hard clods, rocks, or fine materials which would cause a silting hazard in the drain.

2) When special shaping or grooving of the trench bottom is not provided to embed the drain when placed, the drain shall be laid directly upon the envelope material. A sufficient quantity shall be used to fill the trench to a depth of 3 inches surrounding the drain. Envelope material shall consist of coarse material, all of which shall pass a one and one-half inch sieve. FDOT No. 57 or equivalent is recommended. The material should be washed and contain no more than 1% silt, clay or organic matter. The aggregate should be hard, durable, and comply with the requirements for soundness specified in ASTM D-694-62. This provision is to determine that the aggregate is not susceptible to disintegration by water. The loss when subject to the Los Angeles abrasion test should not exceed 40%. Pre-Cenozoic limestones, dolomites, nor stone containing phosphate shall not be used.

The gap between tile or other drain pipe joints shall not exceed 1/4-inch for mineral soils or one-half inch for organic soils. Openings wider than these, occurring on the outer side of a curve in a tile line or due to tile irregularity, shall be permitted if they are covered with broken tile, fiber glass, or other suitable material.

The upper end of each drain line shall be capped with concrete or other durable material unless connected to a clean out structure or other facility.

Earth backfill or filter material shall be placed in the trench in such a manner that displacement of the drain will not occur after backfilling.

No reversals in grade of the conduit shall be permitted.

R0071316

Where the conduit is to be laid in a rock trench, or where rock is exposed at the bottom of the trench, the rock shall be removed below grade enough that the trench may be backfilled, compacted, and bedded; and when completed, the conduit shall be not less than 3 inches from rock.

Alignment

When change in horizontal alignment is required, one of the following methods should be used to minimize head losses in the line:

1) Use of manufactured fittings, such as ells, T's, and Y's.

2) Use of a gradual curve of the drain trench to prevent excessive gap-space.

3) Use of junction boxes or manholes where more than two mains or laterals join.

Connections

Manufactured connections or junctions for joining two lines should be used. It is good practice to lay a submain parallel to a large tile main (usually 10 inches or larger) to prevent tapping the large main for each lateral. Tapping a large tile is difficult, costly, and is frequently the cause of failure. Savings, through the elimination of large connections, usually will offset the extra cost of a submain. Smooth curves in tile lines and manufactured tile connections or junctions of less than 90° have been recommended in the past on the assumption that energy losses at the junction of tile lines would be reduced. Investigations show that the variation in energy loss for different angles of entry are insignificant from a practical standpoint when the main and lateral are of the same size and the drains are flowing full.

Loads on Drains

General

Drains installed in the ground must have sufficient strength to withstand the loads placed upon them. In underdrains, the load which usually governs the strength required is the weight of the earth covering the drain. The magnitude of the load which the drain can safely support depends upon the unit weight of the soil, or sand, the width and depth of the trench, and the method of bedding and installation of the drain. Where the drain is at shallow depths (3 feet or less) there is danger from impact loads from heavy equipment. All installations should be checked to ensure adequate loadbearing strength.

Frequently drain installations are made in wide trenches and at greater depths than is possible with the average trenching machine. Draglines, backhoes, and other equipment may be used for deep trenches. Trenches excavated by this equipment are wide and the greater loads to be placed upon the drain must be determined so that a drain of adequate strength may be selected.

Underground Conduits

Research on loads on underground conduits (including tile) has been carried on by Marston, Schlick and Spangler at Iowa State University. The results of their work are used in determining the loads on underground conduits and their supporting strength. Information regarding loads on conduits may be found in the following publications.

"The Structural Design of Underground Conduits," SCS Engineering Division, Technical Release No. 5.

Engineering Handbook, Section 6, "Structural Design," U.S. Department of Agriculture, Soil Conservation Service.

"Soil Engineering," by Merlin Grant Spangler, International Textbook Company, Scranton, Pennsylvania.

"Design Data - Loads and Supporting Strengths," American Concrete Pipe Association, Arlington, Virginia.

"Handbook of Drainage and Construction Products," Armco Drainage and Metal Products, Inc., Middletown, Ohio.

Classification of Conduits as to Rigidity

Conduits used for subsurface drains may be of several kinds of materials. One characteristic of these various conduits important in determining the load-bearing strength is the degree of flexibility. Two classes of conduits according to their flexibility are as follows:

1) Rigid conduits, such as concrete or clay, fail by rupture of the pipe walls. Their principal load supporting ability lies in the inherent strength or stiffness of the pipe.

2) Flexible conduits, such as corrugated metal pipes and certain types of plastic pipe, fail by deflection. Flexible conduits rely only partly on their inherent strength to resist external loads. When the pipe deflects the horizontal diameter increases which compresses the soil at the sides and thereby builds up passive resistance which in turn helps support the vertically applied load.

Bedding Conditions for Rigid Ditch Conduits

The supporting strength of a conduit will vary with bedding conditions. Two types of bedding are generally used in drainage work and each has a load factor which, when multiplied by the three-edge bearing strength, will give the safe supporting strength of the conduit.

1) Impermissible bedding is that method of bedding a ditch conduit in which little or no care is given to shape the foundation to fit the lower part of the conduit or to refill all the spaces under and around the conduit with granular material. The load factor for this type of installation is 1.1.

2) Ordinary Bedding is that method of bedding a ditch conduit in which the conduit is bedded with ordinary care in an earth foundation shaped to fit the lower part of the conduit for a width of at least 50% of the conduit breadth, and in which the remainder of the conduit is surrounded to a height of at least 0.5 foot above its top by granular materials that are shovel-placed and shovel-tamped to completely fill all spaces under and adjacent to the conduit. The load factor for this type of installation is 1.5.

When sand and gravel filter or envelopes are used, the foundation need not be shaped since the filter and envelope material are placed entirely around the conduit and provide for lateral pressures on the conduit. With this type of installation the supporting strength of the conduit is increased above the three-edge bearing strength. Depending on its gradation and the care used in placing the sand-gravel filter or envelope, the load factor will be in the range of 1.2 for a poorly graded envelope of irregular thickness to 1.5 for a well-graded material of uniform thickness around the drain. To be effective the gravel envelope should have a minimum thickness of 3 inches.

Bedding Conditions for Flexible Drainage Tubing

A flexible conduit has relatively little inherent load-bearing strength, and its ability to support soil loadings in a trench must be derived from pressures induced as the sides of the conduit deflect and move against the soil. This ability of a flexible conduit to deform and use the soil pressure to support it is the main reason that light-weight plastic drainage tubing can support soil loadings imposed in drainage trenches.

A flexible tubing must be installed in a trench in a way which insures good soil support from all sides. There must be no voids remaining which would permit the soil pressure from backfill to cause deflection of the tubing to the point of buckling. Most installations will be made with machinery, without requiring a man in the trench to position the tubing or place the bedding. Some modification of machinery designed for installation of rigid

R0071319

conduits usually is necessary to install flexible conduits efficiently. See tne section on installation of corrugated plastic drainage tubing.

Drain Grades and Velocities

Underdrains and filters are placed at rather uniform depths, therefore, the topography of the land may dictate the range of grades available. There is often an opportunity, however, to orient the drains within tne site in order to obtain a desirable grade. The selected grades should, if possible, be sufficient to result in a nonsilting velocity which experience has shown is about 1.4 feet per second.

The recommended minimum grades are as follows:

	Precent
4" drain	.10
5" drain	.07
6" drain	.05

On sites where topographic conditions require the use of drains on steep grades which will result in velocities greater than shown in the following table, special measures should be used to protect the line from undermining.

Maximum Permissible Velocity in Drains Without Protective Measures

Soil Texture	Velocity-ft./sec.
Sand and Sandy Loam	3.5
Silt and Silt Loam	5.0
Silty Clay Loam	6.0
Clay and Clay Loam	7.0
Coarse Sand or Gravel	9.0

The protective measures may include one or more of the following:

1) Use only drains that are uniform in size and shape and with smooth ends.

2) Lay the drains so as to secure a tight fit with the inside diameter of one section matching that of the adjoining sections.

3) Wrap open joints with tar impregnated paper, burlap, or special filter material such as plastic or fiberglass fabrics.

4) Select the least erodible soil available for blinding.

5) Use long sections of perforated pipe or tubing. (Bituminized fiber, plastic, asbestos cement, etc.).

R0071320

Materials for Drains

"Drains" include conduits of clay, concrete, bituminized fiber, metal, plastic, or other materials of acceptable quality.

The conduit shall meet strength and durability requirements of the site. Current specifications as listed below or as included in the specifications guide shall be used in determining the quality of the conduit.

The following specifications cover the products currently acceptable for use as drains or for use in determining quality of materials used in drainage installations: (Source USDA, SCS-FL).

Type	Specification
Clay drain tile	ASTM[1] C 4
Clay drain tile, perforated	ASTM C 498
Clay sewer pipe, standard strength	ASTM C 13
Clay pipe, extra strength	ASTM C 200
Clay pipe, perforated, standard and extra strength	ASTM C 211
Clay pipe, testing	ASTM C 301
Concrete drain tile	ASTM C 412
Concrete pipe for irrigation or drainage	ASTM C 118
Concrete pipe or tile, determining physical properties of	ASTM C 497
Concrete sewer, storm drain, and culvert pipe	ASTM C 14
Reinforced concrete culvert, storm drain, and sewer pipe	ASTM C 76
Perforated concrete pipe	ASTM C 444
Portland Cement	ASTM C 150
Asbestos-cement nonpressure sewer pipe	ASTM C 428
Asbestos-cement perforated underdrain pipe	ASTM C 508
Asbestos-cement pipe, testing	ASTM C 500
Bituminized fiber, perforated drainage pipe	Federal Spec.[2] SS-P-358a
Homogeneous perforated bituminized fiber pipe for general drainage	ASTM D 2311
Homogeneous bituminized fiber pipe, testing	ASTM D 2314
Laminated-wall bituminized fiber perforated pipe for agricultural, land, and general drainage	ASTM D 2417
Laminated-wall bituminized fiber pipe, physical testing of	ASTM D 2315
Plastic drain and sewer pipe, styrene rubber Perforations, if needed, are to be as specified in Fed. Spec. SS-P-358a	Commercial Standard[2] CS-228
Corrugated Polyethylene Pipe Small diameter through 6" Large diameter through 24"	ASTM F 405 ASTM F 667
Pipe, corrugated, aluminum alloy	Federal Spec. WW-P-402a
Pipe, corrugated, iron or steel, zinc coated	Federal Spec. WW-P-00405

Clay Tile - These specifications may be modified as follows: the freezing and thawing and absorption tests may be modified or waived.
Corrugated Polyethylene Pipe - SCS standards and specifications for perforated corrugated plastic pipe may be found under standard 606.

[1]American Society for Testing and Materials, 1916 Race Street, Philadelphia, Pa. 19103

[2]Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402

R0071321

Other Clay and Concrete Pipe

Bell and spigot, tongue and groove, and other pipe which meets the strength, absorption, and other requirements of clay or concrete tile as covered above, except for minor imperfections in the bell, the spigot tongue or the groove, and ordinarily classed by the industry as "seconds," may be used for drainage conduits provided the pipe is otherwise adequate for the job.

Foundation Requirements

Soft or yielding foundations shall be stabilized where required and lines protected from settlement by adding gravel or other material to the trench, placing the conduit on plank or other rigid supports, or using long sections of perforated or watertight pipe.

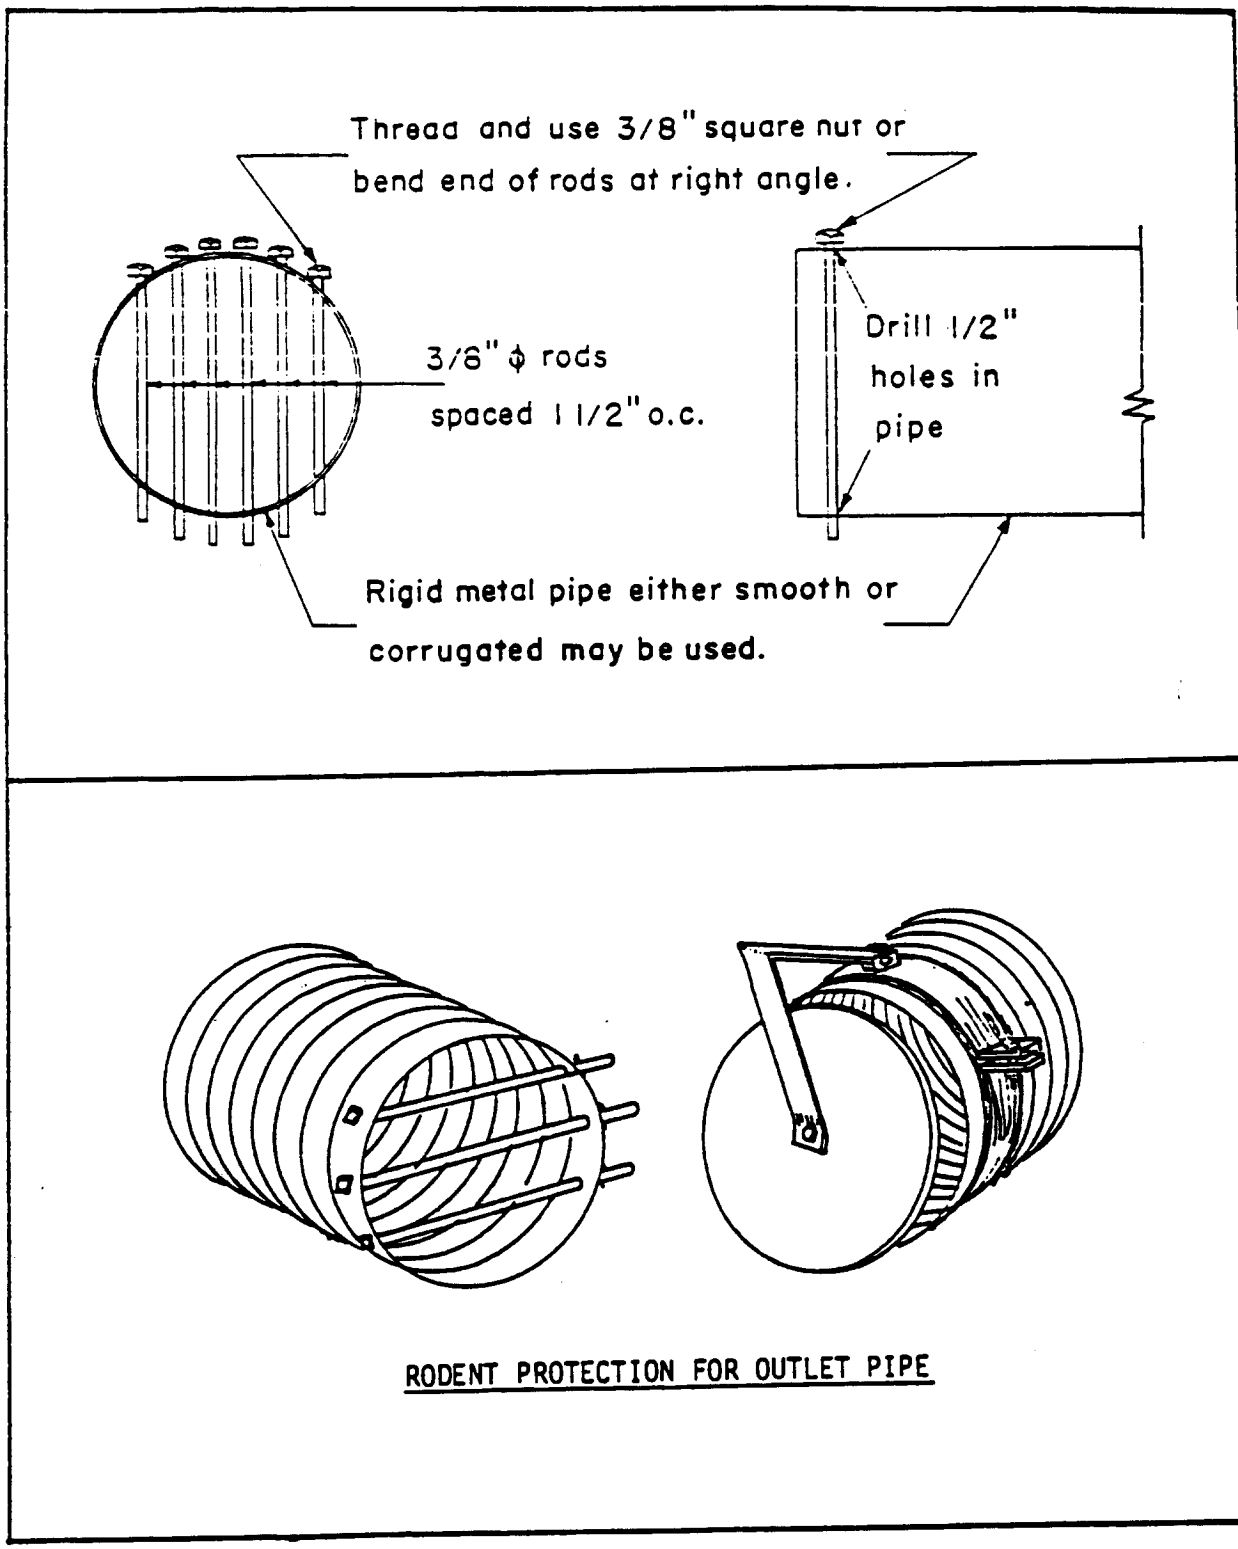
Envelopes and Envelope Material

Envelopes shall be used around drains where required for proper bedding of the conduit, or where necessary to improve the characteristics of flow of groundwater into the conduit.

Materials used for envelopes do not need to meet the gradation requirements of filters, but they shall not contain materials which will cause an accumulation of sediment in the conduit or render the envelope unsuitable for bedding of the conduit.

Auxiliary Structures and Drain Protection

The outlet shall be protected against erosion and undermining of the drain, against damaging periods of submergence, and against entry of rodents or other animals into the drain as shown in Figure 6-58. A continuous section of pipe without open joints or perforations (Figure 6-59) shall be used at the outlet end of the line and shall outlet above the normal elevation of flow in the outlet ditch.

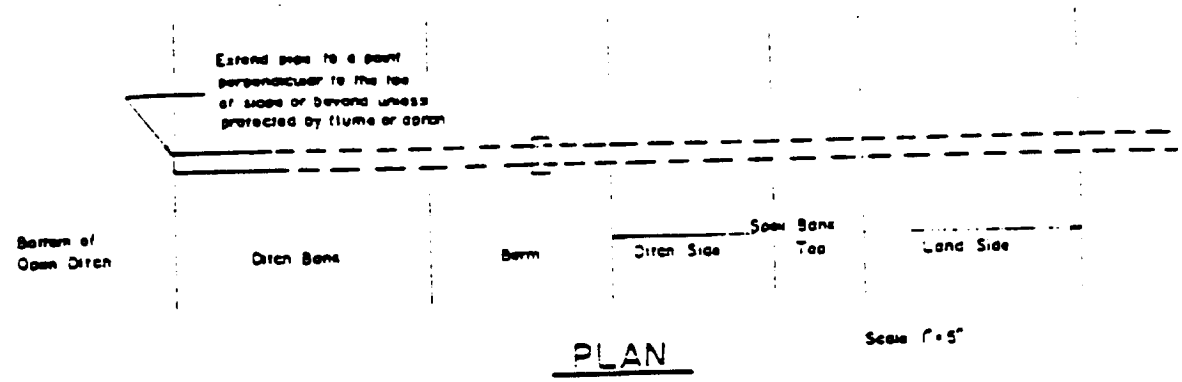


The pipe and its installation shall conform to the following requirements:

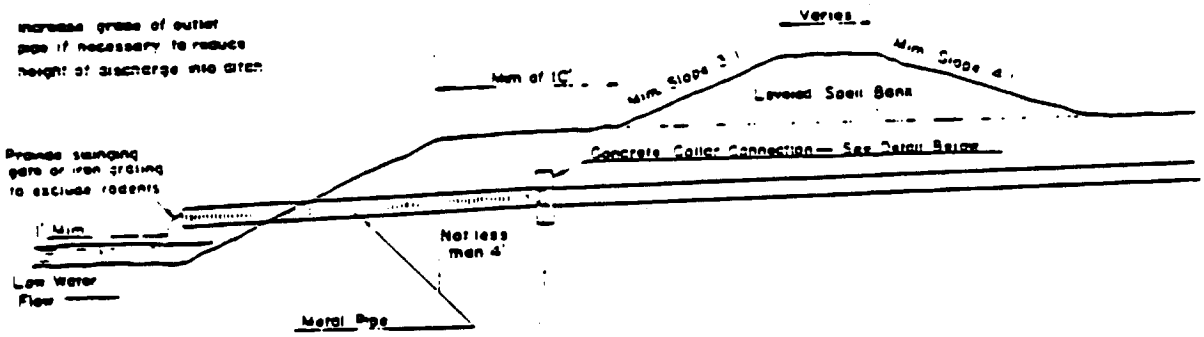
1) Where there is a hazard of burning to vegetation on the outlet ditch bank, the material from which the outlet pipe is fabricated shall be fire resistant. Where the hazard of burning is high, the outlet pipe shall be fireproof.

2) Two-thirds of the pipe shall be buried in the ditch bank and the cantilevered section shall extend beyond the toe of the ditch side slope or the side slope shall be protected from erosion. The minimum length of pipe shall be eight feet.

FIGURE 6-58



Rodent Protection for Outlet Pipe



RODENT PROTECTION FOR OUTLET PIPE

R0071323

PLAN

SECTION

DETAIL-CONCRETE COLLAR

NOTE:
Rigid metal pipe either smooth or corrugated may be used.

If metal pipe is placed on a steeper slope than tile, same size may be used. Use pipe 2" larger than tile if on same slope.

If floating debris is a problem the metal pipe should be placed at approx. 30 degree angle facing downstream instead of as shown.

FIGURE 6-59

Metal Pipe Outlet and Concrete Collar

(USDA-SCS-FL)

R0071324

3) Where floating debris may damage the outlet pipe, the outlet shall be recessed to the extent that the cantilevered portion of the pipe will be protected from the current in the ditch.

4) Headwalls which are used for tile outlets shall be adequate in strength and design to avoid washouts and other failures.

Watertight conduit strong enough to withstand the loads upon it shall be used where subsurface drains cross under irrigation canals or other ditches. Conduits under roadways shall be designed to withstand the expected loads. Shallow drains through depressional areas and near outlets shall be protected against hazards of maintenance equipment.

Junction boxes shall be used where more than two main lines join.

Where surface water is to be admitted to drains, inlets shall be designed to exclude debris and prevent sediment from entering the conduit. Drain lines flowing under pressure shall be designed to withstand the resulting pressures and velocity of flow. Auxiliary surface waterways shall be used where feasible.

Headwalls

Headwalls shall be constructed on compact foundation and shall be of long lasting, durable materials such as steel piling, reinforced concrete, concrete block and sand cement riprap. The structures shall be designed to safely withstand expected loads.

Structure Capacity

Structures installed in tile lines must not unduly impede the flow of water in the system. They shall have a capacity no less than that of the line or lines feeding into or through them.

Where the tile system will carry surface waterflow, surface water inlets shall have a capacity no more than that required to provide the maximum allowable design flow in the tile line or lines.

Size of Structures

Junction boxes, manholes, catch basins, and sand traps shall be accessible for maintenance. A clear opening of not less than 2 feet shall be provided in either circular or rectangular structures.

Velocities in Structures

The tile system shall be protected against turbulence created near outlets, surface inlets, or similar structures. Continuous or closed-joint pipe shall

be used in tile lines adjoining the structure where excessive velocities will occur.

Screens and Trash Racks

Surface water inlet structures shall be equipped with screens, trash racks, or gratings to exclude debris.

Junction Boxes

Junction boxes shall be installed where more than two mains join, or where two mains join at different elevations.

Vents

Vents will be located at changes in grade, sharp changes in direction and at intervals along tile lines as needed. They shall be constructed as a tee with the riser pipe extending to ground surface or above. The riser pipe shall not be less than 4 inches in diameter. Each riser pipe shall be provided with a wire mesh or grating cover to prevent trash from entering the lines.

Maintenance of Filter and Underdrain Facilities

An underdrain filter system of adequate design and proper installation, using good material, still requires maintenance to keep it operating. Inspection of the drains, especially after heavy rains, should be made to see if they are working and if maintenance is required. Pore spaces in stormwater filters can be expected to seal with time following the beginning of operation. The duration of a filter's effectiveness before the hydraulic capacity is reduced to the point that drawdown requirements can no longer be met will depend on a number of factors including the initial permeability of filter material used, the degree of pretreatment (sedimentation) prior to entering the filtration facility, and the nature of the pollutants being removed.

Preliminary indication show that these systems can function for up to one year with only minor maintenance. However, periodic discing or scrapping the surface layers of the soil may be required following heavy events that carry heavy sediment loads.

Coarse grained systems may require complete replacement of the filter media to restore their function following clogging since pollutants would be expected to further penetrate these systems than their more close-grained counterparts. Most of the particulates will be trapped in the first 2 or 3 inches of the latter while suspended substances can be expected to penetrate up to a foot or more into the coarse-grained filter. Semi-annual restoration

efforts are likely to involve complete removal and cleaning and or replacement of the top 12 inches or more of the filter material. While major maintenance of this type may not have to be done as often, when it is required, the operation will involve a significant amount of labor and material. Heavy machinery may be needed if the facility is large and care will be needed to prevent damage to the underdrain pipes. There may be some problems associated with the ability of these more coarse-grained, evenly graded materials to support machinery needed to perform maintenance activities, such as scrapping without getting equipment stuck and/or damaging the filter bed.

Common causes of subsurface drainage system failures include the following:

1) Drains installed with insufficient capacity.

2) Drains placed too shallow and lack of auxiliary structures necessary for the installation.

3) Drains of insufficient strength or lacking in other qualities necessary for the installation.

4) Poor construction resulting in such inadequacies as too wide or too small a joint spacing, improper bedding, poor grade and alignment and improper backfilling.

5) Failure due to mineral deposits such as iron oxide. These deposits do not seriously affect the operation of the drain unless the perforations or joints become sealed. Usually indications of deposits may be observed at the outlets, junction boxes and inspection holes.

Hydraulic Cleaning - High pressure hydraulic nozzles have been used with success to clean tile drains in Florida that have evidence of iron oxide.

Silt and Vegetation - One of the most common maintenance problems that we have with tile drains in Florida is to get landowners to keep the outlets free of silt and vegetation where they empty into open ditches. The outlet end of the system must be kept clean if the maximum benefits from the tile are to be obtained. Sediment and fast growing aquatic vegetation might cause the outlets to become entirely plugged within one year after installation, consequently frequent inspections must be made.

Rodent Guards - Landowners often do not maintain the rodent guards. These appurtenances are sometimes removed, become rusted or plugged, and may never be replaced. These actions invite damage that can lead to the failure of the entire system. The outlet must be inspected periodically to make sure that it is clear, and that these guards are in place and functional.

R0071327

Trees - If trees near the drain are not removed at the time of construction, the tile may become plugged by roots. If it is found that the tile line is not functioning and the outlet is open, the lines should be checked near trees.

Auxiliary Structures - The life and value of a tile system many times depends on the repair of auxiliary structures. These structures are to protect the tile system as well as to aid in determining when maintenance is needed. If they are not maintained, the value of the installation will decrease. Regular inspection is required.

As-Built Plans - Upon completing a subsurface drainage installation and after all checks and inspection have been made, a set of "As-Built" plans, showing location, depths and sizes of all drains should be preserved and made available to those that will be maintaining the system.

R0071328

GUIDELINES FOR USING

EROSION AND SEDIMENT CONTROL PRACTICES

ES BMP 1.01

TEMPORARY GRAVEL CONSTRUCTION ENTRANCE

Definition

A stone stabilized pad located at points of vehicular ingress and egress on a construction site.

Purpose

To reduce the amount of sediment transported onto public roads by motor vehicles or runoff.

Conditions Where Practice Applies

Wherever traffic will be leaving a construction site and moves directly onto a public road or other paved area.

R0071330

Planning Considerations

Construction entrances provide an area where mud can be removed from constructio vehicle tires before they enter a public road. If the action of the vehicle traveling over the gravel pad is not sufficient to remove the majority of the mud, then the tires must be washed before the vehicle enters a public road. If washing is used, provisions must be made to intercept the wash water and trap the sediment before it is carried off-site. Construction entrances should be used in conjunction with the stabilization of construction roads to reduce the amount of mud picked up by construction vehicles.

Design Criteria

Aggregate Size

FDOT aggregate No. 1 (1.5 - 3.5 inch stone) should be used.

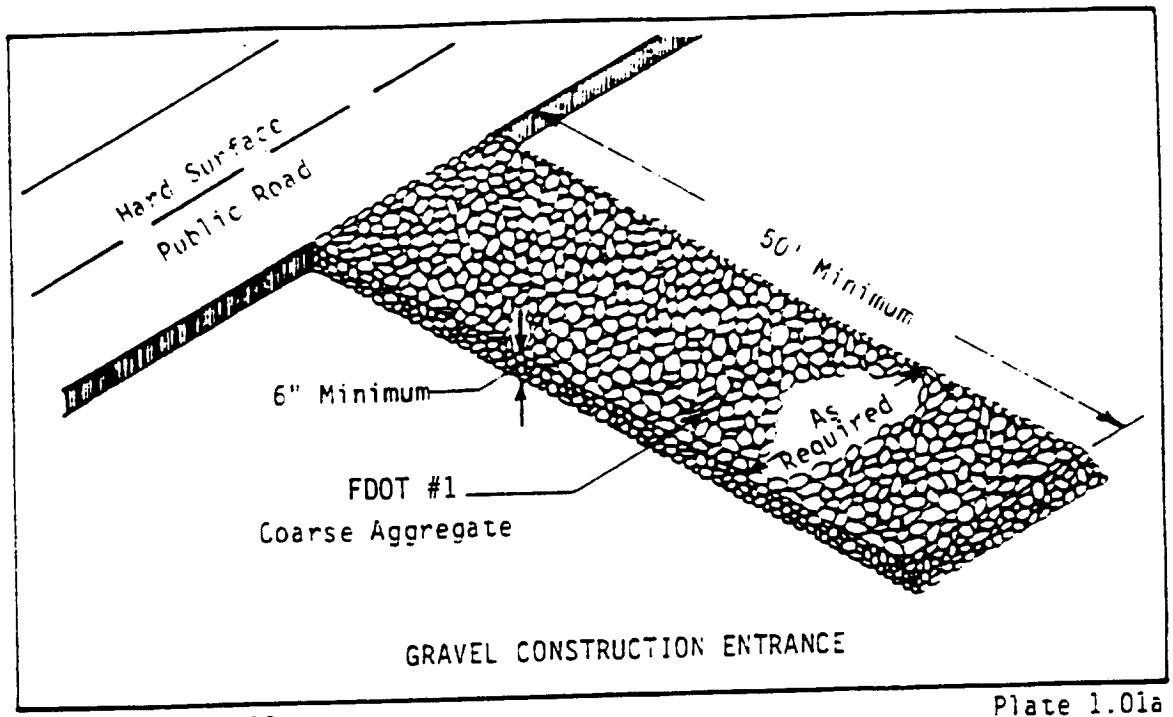
Entrance Dimensions

The aggregate layer must be at least 6 inches thick. It must extend the full width of the vehicular ingress and egress area. The length of the entrance must be at least 50 feet. (See Plate 1.01a).

Washing

If conditions on the site are such that the majority of the mud is not removed by the vehicles traveling over the gravel, then the tires of the vehicles must be washed before entering a public road. Wash water must be carried away from the entrance to a settling area to remove sediment. A wash rack may also be used to make washing more convenient and effective. (See Plate 1.01b).

Location



The entrance should be located to provide for maximum utility by all construction vehicles.

Construction Specifications

The area of the entrance should be cleared of all vegetation, roots, and other objectionable material. The gravel shall be placed to the specified dimensions. Any drainage facilities required because of washing should be constructed according to specifications. If wash racks are used, they should be installed according to manufacturer's specifications.

Maintenance

The entrance shall be maintained in a condition which will prevent tracking or flow of mud onto public rights-of-way. This may require periodic top dressing with 2-inch stone, as conditions demand, and repair and/or cleanout of any structures used to trap sediment. All materials spilled, dropped, washed, or tracked from vehicles onto roadways or into storm drains must be removed immediately.

R0071332

ES BMP 1.02

CONSTRUCTION ROAD STABILIZATION

Definition

The temporary stabilization of access roads, subdivision roads, parking areas, and other on-site vehicle transportation routes with stone immediately after grading.

Purposes

1. To reduce the erosion of temporary roadbeds by construction traffic during wet weather.

2. To reduce the erosion and therefore regrading of permanent roadbeds between the time of initial grading and final stabilization.

Conditions Where Practice Applies

Wherever stone-base roads or parking areas are constructed, whether permanent or temporary, for use by construction traffic.

R0071333

Planning Considerations

Areas which are graded for construction vehicle transport and parking purposes are especially susceptible to erosion. The exposed soil surface is continually disturbed, leaving no opportunity for vegetative stabilization. Such areas also tend to collect and transport runoff waters along their surfaces. During wet weather, they often become muddy quagmires which generate significant quantities of sediment that may pollute nearby streams or be transported off-site on the wheels of construction vehicles. Dirt roads can become so unstable during wet weather that they are virtually unusable.

Immediate stabilization of such areas with stone may cost money at the outset, but it may actually save money in the long run by increasing the usefulness of the road during wet weather.

Permanent roads and parking areas should be paved as soon as possible after grading. However, it is understandable that funds for this purpose may not be available in the early phases of the development project. As an alternative, the early application of stone may solve potential erosion and stability problems and eliminate later regrading costs. Some of the stone will also probably remain in place for use as part of the final base course of the road.

Specifications

Temporary Access Roads and Parking Areas

1. Temporary roads shall follow the contour of the natural terrain to the extent possible. Slopes should not exceed 10 percent.

2. Temporary parking areas should be located on naturally flat areas to minimize grading. Grades should be sufficient to provide drainage but should not exceed 4 percent.

3. Roadbeds shall be at least 14 feet wide for one-way traffic and 20 feet wide for two-way traffic.

4. All cuts and fills shall have side slopes that are stable for the particular soil. Slopes of 2:1 or flatter are recommended for clay soils and slopes of 3:1 or flatter are recommended for sandy soils.

5. Stormwater system shall be provided as needed and shall be designed and constructed in accordance with applicable regulations.

6. The roadbed or parking surface shall be cleared of all vegetation, roots and other objectionable material.

7. A 6-inch course of FDOT No. 1 aggregate shall be applied immediately after grading or the completion of utility installation within the right-of-way. Filter fabric may be applied to the roadbed for additional stability in accordance with fabric manufacturer's specifications.

Permanent Roads and Parking Areas

Permanent roads and parking areas shall be designed and constructed in accordance with applicable Florida Department of Transportation (FDOT) or local criteria except that an initial base course of gravel of at least 6 inches shall be applied immediately following grading.

Vegetation

All roadside ditches, cuts, fills and disturbed areas adjacent to parking areas and roads shall be stabilized with appropriate temporary or permanent vegetation according to the applicable ES BMPs contained in this handbook.

Maintenance

Both temporary and permanent roads and parking areas may require periodic top dressing with new gravel. Seeded areas adjacent to the roads and parking areas should be checked periodically to insure that a vigorous stand of vegetation is maintained. Roadside ditches and other drainage structures should be checked regularly to insure that they do not become clogged with silt or other debris.

ES BMP 1.05

STRAW BALE BARRIER

Definition

A temporary sediment barrier consisting of a row of entrenched and anchored straw bales.

Purposes

1. To intercept and detain small amounts of sediment from disturbed areas of limited extent in order to prevent sediment from leaving the site.

2. To decrease the velocity of sheet flows and low-to-moderate level channel flows.

Conditions Where Practice Applies

1. Below disturbed areas subject to sheet and rill erosion.

2. Where the size of the drainage area is no greater than 1/4 acre per 100 feet of barrier length; the maximum slope length behind the barrier is 100 feet; and the maximum slope gradient behind the barrier is 50 percent (2:1).

R0071336

3. In minor swales or ditch lines where the maximum contributing drainage area is no greater than 2 acres.

4. Where effectiveness is required for less than 3 months.

5. Under no circumstances should straw bale barriers be constructed in live streams or in swales where there is the possibility of a washout.

Planning Considerations

Based on observations made in Virginia, Pennsylvania, Maryland, and other parts of the nation, straw bale barriers have not been as effective as many users had hoped they would be. There are three major reasons for this.

Improper use of straw bale barriers has been a major problem. Straw bale barriers have been used in streams and drainageways where high water velocities and volumes have destroyed or impaired their effectiveness. Improper placement and installation of the barriers, such as staking the bales directly to the ground with no soil seal or entrenchment, has allowed undercutting and end flow. This has resulted in additions instead of removal of sediment from runoff waters (Plate 1.05a). Finally, inadequate maintenance lowers the effectiveness of these barriers. Trapping efficiencies of carefully installed straw bale barriers on one project in Virginia dropped from 57 percent to 16 percent in one month due to lack of maintenance.

There are serious questions about the continued use of straw bale barriers as they are presently installed and maintained. Averaging approximately $1.00 per linear foot, the thousands of straw bale barriers used annually in Florida represent sufficient expense that optimum installation procedures should be emphasized. If such procedures are carefully followed, straw bale barriers can be quite effective.

Design Criteria

A formal design is not required.

Construction Specifications

Sheet Flow Applications

1. Bales shall be placed in a single row, lengthwise on the contour, with ends of adjacent bales tightly abutting one another.

R0071337

Plate 1.05a

FAILURE POINTS OF A POORLY CONSTRUCTED STRAW BALE BARRIER

R0071338

2. All bales shall be either wire-bound or string-tied. Straw bales shall be installed so that bindings are oriented around the sides rather than along the tops and bottoms of the bales (in order to prevent deterioration of the bindings). See Plate 1.05b.

3. The barrier shall be entrenched and backfilled. A trench shall be excavated the width of a bale and the length of the proposed barrier to a minimum depth of 4 inches. After the bales are staked and chinked, the excavated soil shall be backfilled against the barrier. Backfill soil shall conform to the ground level on the downhill side and shall be built up to 4 inches against the uphill side of the barrier (Plate 1.05c).

4. Each bale shall be securely anchored by at least two stakes or rebars driven through the bale. The first stake in each bale shall be driven toward the previously laid bale to force the bales together. Stakes or rebars shall be driven deep enough into the ground to securely anchor the bales.

5. The gaps between bales shall be chinked (filled by wedging) with straw to prevent water from escaping between the bales. (Loose straw scattered over the area immediately uphill from a straw bale barrier tends to increase barrier efficiency).

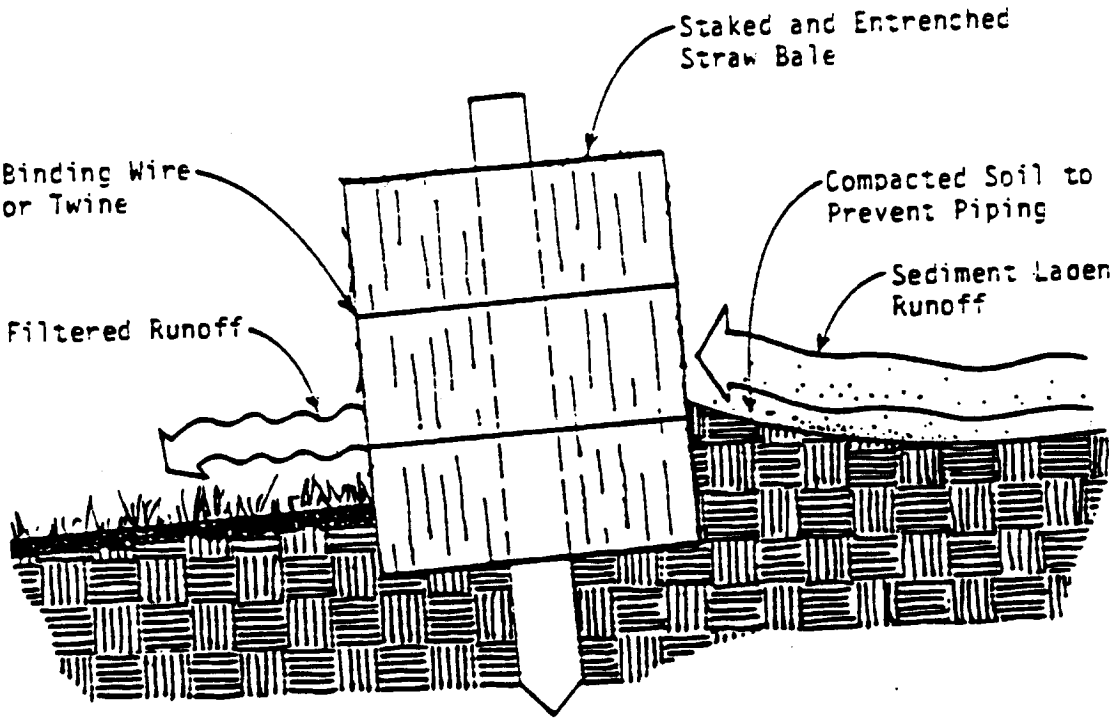
6. Inspection shall be frequent and repair or replacement shall be made promptly as needed.

7. Straw bale barriers shall be removed when they have served their usefulness, but not before the upslope areas have been permanently stabilized.

Channel Flow Applications

1. Bales shall be placed in a single row, lengthwise, oriented perpendicular to the contour, with ends of adjacent bales tightly abutting one another.

2. The remaining steps for installing a straw bale barrier for sheet flow applications apply here, with the following addition.



3. The barrier shall be extended to such a length that the bottoms of the end bales are higher in elevation than the top of the lowest middle bale (Plate 1.05d) to assure that sediment-laden runoff will flow either through or over the barrier but not around it.

Maintenance

1. Straw bale barriers shall be inspected immediately after each rainfall and at least daily during prolonged rainfall.

2. Close attention shall be paid to the repair of damaged bales, end runds and undercutting beneath bales.

R0071339

CROSS-SECTION OF A PROPERLY INSTALLED STRAW BALE

Plate 1.05d

R0071341

3. Necessary repairs to barriers or replacement of bales shall be accomplished promptly.

4. Sediment deposits should be removed after each rainfall. They must be removed when the level of deposition reaches approximately one-half the height of the barrier.

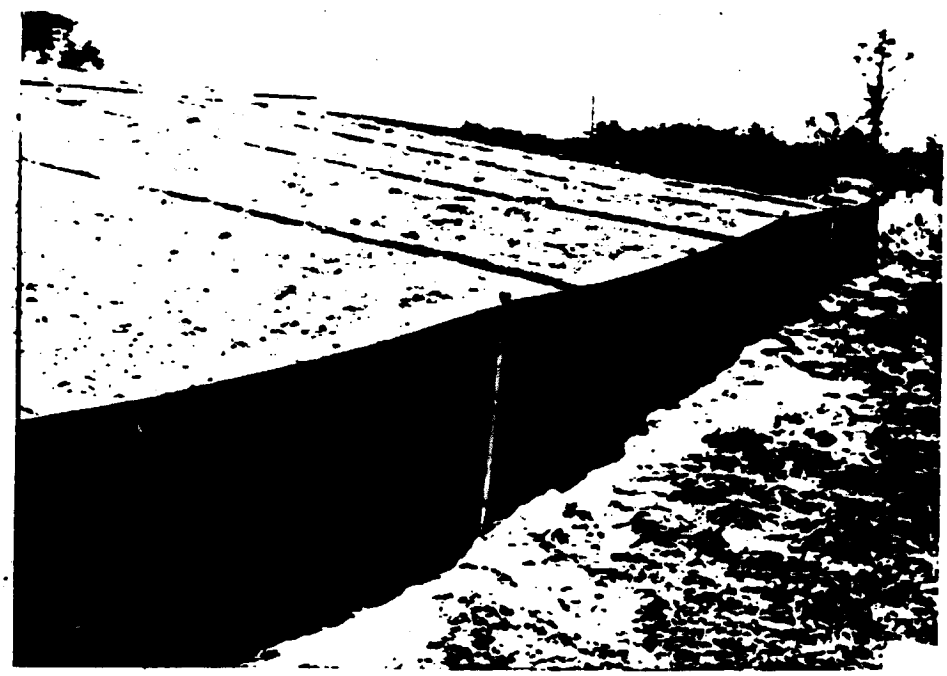
5. Any sediment deposits remaining in place after the straw bale barrier is no longer required shall be dressed to conform to the existing grade, prepared and seeded.

ES BMP 1.06

SILT FENCE

Definition

A temporary sediment barrier consisting of a filter fabric stretched across and attached to supporting posts and entrenched. There are two types. The Silt Fence is a temporary linear filter barrier constructed of synthetic filter fabric, posts, and, depending upon the strength of the fabric used, wire fence for support. The Filter Barrier is constructed of stakes and burlap or synthetic filter fabric.



Purposes

1. To intercept and detain small amounts of sediment from disturbed areas during construction operations in order to prevent sediment from leaving the site.

2. To decrease the velocity of sheet flows and low-to-moderate level channel floods.

Conditions When Practice Applies

1. Below disturbed areas where erosion would occur in the form of sheet and rill erosion.

R0071343

2. Where the size of the drainage area is no more than 1/4 acre per 100 feet of silt fence length; the maximum slope length behind the barrier is 100 feet; and the maximum gradient behind the barrier is 50 percent (2:1).

3. In minor swales or ditch lines where the maximum contributing drainage area is no greater than 2 acres.

4. Under no circumstances should silt fences be constructed in live streams or in swales or ditch lines where flows are likely to exceed 1 cubic foot per second (cfs). See Design Criteria for further clarification.

Planning Considerations

Laboratory work at the Virginia Highway and Transportation Research Council (VH & TRC) has shown that silt fences can trap a much higher percentage of suspended sediments than can straw bales. Silt fences may be preferable to straw barriers in many cases. While the failure rate of silt fences is lower than that of straw barriers, there have been instances in which silt fences were improperly installed. The installation methods outlined here can improve performance.

Filter barriers are inexpensive structures composed of burlap or standard weight synthetic filter fabric stapled to wooden stakes. Flow rates through burlap filter barriers are slightly slower and filtering efficiency is significantly higher than for straw bale barriers (see Table 1.06a).

Table 1.06a

FLOW RATES AND FILTERING EFFICIENCIES OF VARIOUS SEDIMENT FILTER MATERIALS

Material	Flow Rate (gal./sq. ft./min.)	Filter Efficiency (%)
Straw	5.6	67
Burlap (10 oz. fabric)	2.4	84
Synthetic Fabric	0.3 (Avg.)	97 (Avg.)

Source: Va. Highway and Transportation Research Council

Silt fences composed of a wire support fence and an attached synthetic filter fabric slow the flow rate significantly but have a higher filtering efficiency than burlap. Both woven and non-woven synthetic fabrics are commercially available. The woven fabrics generally display higher strength than the non-woven fabrics. When tested under acid and alkaline water conditions, most of the woven fabrics increase in strength. There is a variety of reactions among the non-woven fabrics. The same is true of testing under extensive ultraviolet radiation. Permeability rates vary regardless of fabric type. While all of the fabrics demonstrate very high

filtering efficiencies for sandy sediments, there is considerable variation among both woven and non-woven fabrics when filtering the finer silt and clay particles.

Design Criteria

1. No formal design is required.

2. Filter barriers shall have an expected usable life of 3 months. They are applicable in ditch lines, around drop inlets, and at temporary locations where continuous construction changes the earth contour and runoff characteristics and where low or moderate flows (not exceeding 1 cfs) are expected.

3. Silt fences, because they have a much lower permeability than burlap filter barriers, have their applicability limited to situations in which only sheet or overland flows are expected. They normally cannot filter the volumes of water generated by channel flows, and many of the fabrics do not have sufficient structural strength to support the weight of water ponded behind the fence line. Their expected usable life is 6 months.

Construction Specifications

Materials

1. Synthetic filter fabric shall be a pervious sheet of propylene, nylon, polyester or ethylene yarn and shall be certified by the manufacturer or supplier as conforming to the following requirements:

PHYSICAL PROPERTY	TEST	REQUIREMENTS
Filtering Efficiency	VTM-51	75% (minimum)
Tensile Strength at 20% (max.) Elongation*	VTM-52	Extra Strength- 50 lbs./lin. in. (minimum) Standard Strength- 30 lbs./lin. in. (minimum)
Flow Rate	VTM-51	0.3 gal./sq. ft./min. (minimum)

*Requirements reduced by 50 percent after 6 months of installation.

Synthetic filter fabric shall contain ultraviolet ray inhibitors and stabilizers to provide a minimum of 6 months of expected usable construction life at a temperature range of 0° F to 120° F.

2. Burlap shall be 10 ounces per square yard fabric.

3. Posts for Silt Fences shall be either 4-inch diameter wood or 1.33 pounds per linear foot steel with a minimum length of 5 feet. Steel posts shall have projections for fastening wire to them.

R0071345

4. Stakes for Filter Barriers shall be 1" x 2" wood (preferred) or equivalent metal with a minimum length of 3 feet.

5. Wire fence reinforcement for silt fences using standard strength filter cloth shall be a minimum of 36 inches in height, a minimum of 14 gauge and shall have a maximum mesh spacing of 6 inches.

Filter Barrier: This sediment barrier may be constructed using burlap or standard strength synthetic filter fabric. It is designed for low or moderate flows not exceeding 1 cfs. See Plate 1.06a.

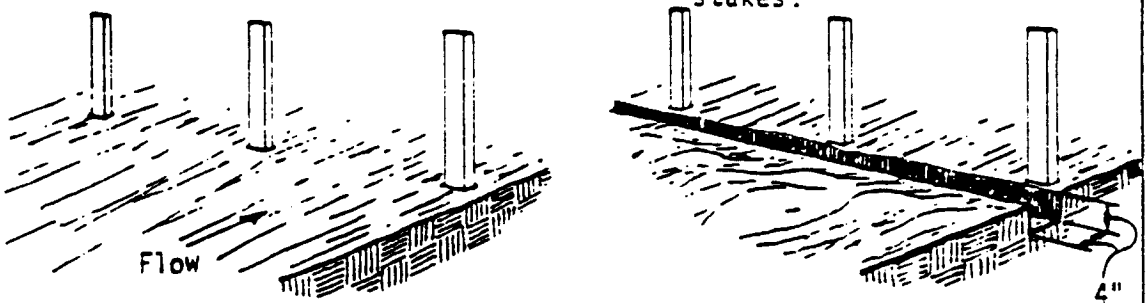
1. The height of a filter barrier shall be a minimum of 15 inches and shall not exceed 18 inches.

2. Burlap or standard strength synthetic filter fabric shall be purchased in a continuous roll and cut to the length of the barrier to avoid the use of joints (and thus improve the strength and efficiency of the barrier).

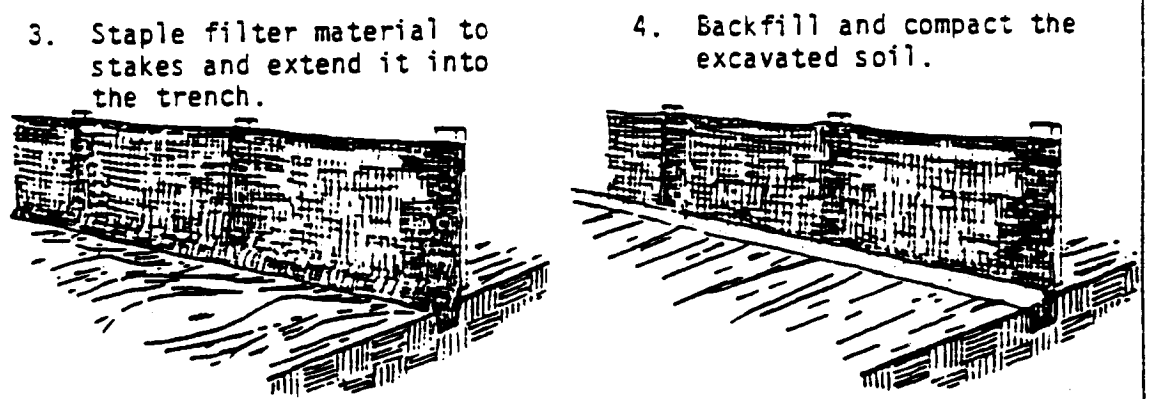
3. The stakes shall be spaced a maximum of 3 feet apart at the barrier location and driven securely into the ground (minimum of 8 inches).

4. A trench shall be excavated approximately 4 inches wide and 4 inches deep along the line of stakes and upslope from the barrier.

5. The filter material shall be stapled to the wooden stakes, and 8 inches of the fabric shall be extended into the trench. Heavy duty wire staples at least 1/2-inch long shall be used. Filter material shall not be stapled to existing trees.



6. The trench shall be backfilled and the soil compacted over the filter material.

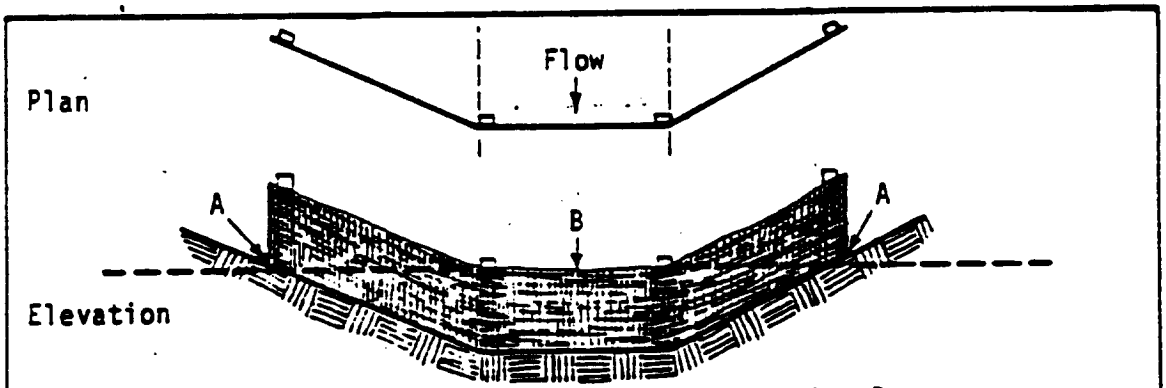


7. If a filter barrier is to be constructed across a ditch line or swale, the barrier shall be of sufficient length to eliminate end flow, and the plan configuration shall resemble an arc or horseshoe with the ends oriented upslope (Plate 1.06b).

8. Filter barriers shall be removed when they have served their useful purpose, but not before the upslope area has been permanently stabilized.

Silt Fence: This sediment barrier utilizes standard strength or extra strength synthetic filter fabrics. It is designed for situations in which only sheet or overland flows are expected. See Plate 1.06c.

1. The height of a silt fence shall not exceed 36 inches (higher fences may impound volumes of water sufficient to cause failure of the structure).



CONSTRUCTION OF A FILTER BARRIER

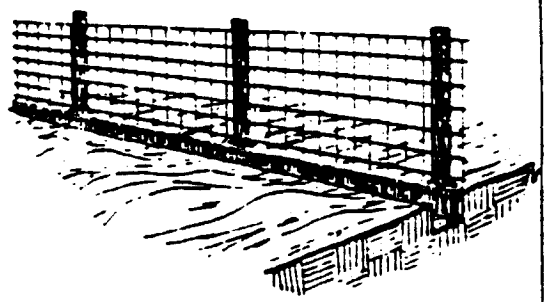

Plate 1.06b

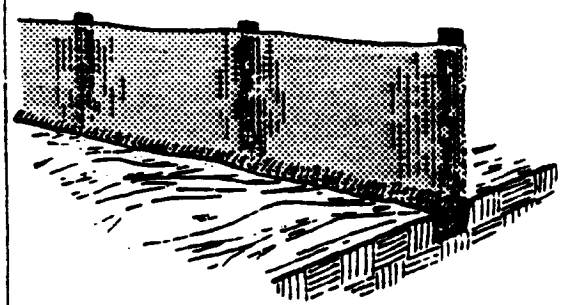
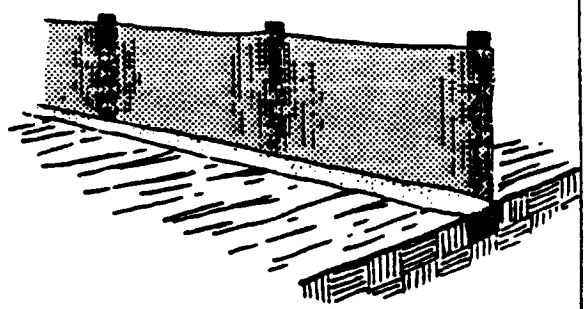
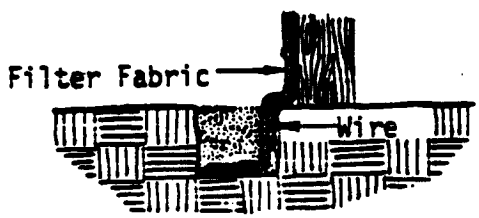
R0071347



1. Set posts and excavate a 4"x4" trench upslope along the line of posts.



2. Staple wire fencing to the posts.



3. Attach the filter fabric to the wire fence and extend it into the trench.

4. Backfill and compact the excavated soil.

Extension of fabric and wire into the trench.

CONSTRUCTION OF A SILT FENCE

Source: Adapted from Installation of Straw and Fabric Filter Barriers for Sediment Control, Sherwood and Wyant

Plate 1.06c

R0071348

2. The filter fabric shall be purchased in a continous roll cut to the length of the barrier to avoid the use of joints. When joints are necessary, filter cloth shall be spliced together only at a support post, with a minimum 6-inch overlap, and securely sealed.

3. Posts shall be spaced a maximum of 10 feet apart at the barrier location and driven securely into the ground (minimum of 12 inches). When extra strength fabric is used without the wire support fence, post spacing shall not exceed 6 feet.

4. A trench shall be excavated approximately 4 inches wide and 4 inches deep along the line of posts and upslope from the barrier.

5. When standard strength filter fabric is used, a wire mesh support fence fence shall be fastened securely to the upslope side of the posts using heavy duty wire staples at least 1 inch long, tie wires or hog rings. The wire shall extend into the trench a minimum of 2 inches and shall not extend more than 36 inches above the original ground surface.

6. The Standard Strength filter fabric shall be stapled or wired to the fence, and 8 inches of the fabric shall be extended into the trench. The fabric shall not extend more than 36 inches above the original ground surface.

7. When extra strength filter fabric and closer post spacing are used, the wire mesh support fence may be eliminated. In such a case, the filter fabric is stapled or wired directly to the posts with all other provisions of item No. 6 applying.

8. The trench shall be backfilled and the soil compacted over the filter fabric.

9. Silt fences shall be removed when they have served their useful purpose, but not before the upslope area has been permanently stabilized.

Maintenance

1. Silt fences and filter barriers shall be inspected immediately after each rainfall and at least daily during prolonged rainfall. Any required repairs shall be made immediately.

2. Should the fabric on a silt fence or filter barrier decompose or become ineffective prior to the end of the expected usable life and the barrier still be necessary, the fabric shall be replaced promptly.

3. Sediment deposits should be removed after each storm event. They must be removed when deposits reach approximatley one-half the height of the barrier.

4. Any sediment deposits remaining in place after the silt fence or filter barrier is no longer required shall be dressed to conform with the existing grade, prepared and seeded.

ES BMP 1.07

BRUSH BARRIER

Definition

A temporary sediment barrier constructed at the perimeter of a disturbed area from the residue materials available from clearing and grubbing the site.

Purpose

To intercept and retain sediment from disturbed areas of limited extent, preventing sediment from leaving the site.

Conditions Where Practice Applies

Below disturbed areas subject to sheet and rill erosion, where enough residue material is available for construction of such a barrier.

Planning Considerations

Organic litter and spoil material from site clearing operations is usually burned or hauled away to be dumped elsewhere. Much of this material can be used effectively on the construction site itself. During clearing and grubbing operations, equipment can push or dump the mixture of limbs, small vegetation and root mat along with minor amounts of soil and rock into windrows along the toe of a slope where erosion and accelerated runoff are expected. Anchoring a filter fabric over the berm enhances the filtration ability of the barrier. Because brush barriers are fairly stable and composed of natural materials, maintenance requirements are small.

Design Criteria

A formal design is not required.

Construction Specifications

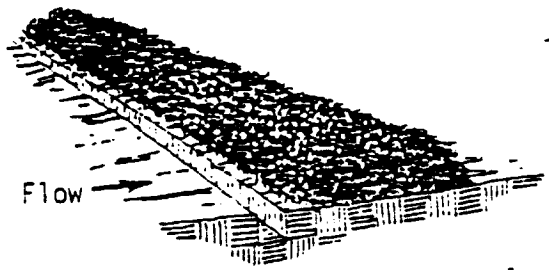
1. The height of a brush barrier shall be a minimum of 3 feet.

2. The width of a brush barrier shall be a minimum of 5 feet at its base. (The sizes of brush barriers may vary considerably based upon the amount of material available and the judgment of the design engineer.)

3. The barrier shall be constructed by piling brush, stone, root mat and other material from the clearing process into a mounded row on the contour.

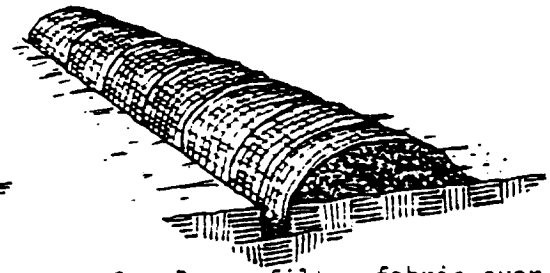
If a filter fabric is used (Plate 1.07a):

4. The filter fabric shall be cut into lengths sufficient to lay across the barrier from its upslope base to just beyond its peak. Where joints are necessary, the fabric shall be spliced together with a minimum 6-inch overlap and securely sealed.



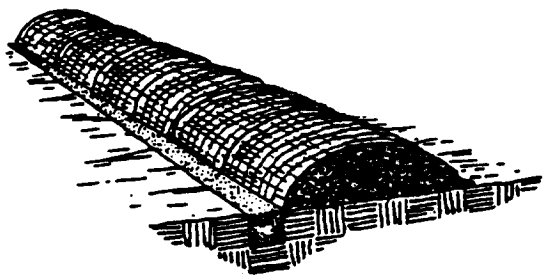
5. A trench shall be excavated 6 inches wide and 4 inches deep along the length of the barrier and immediately uphill from the barrier.

6. The lengths of filter fabric shall be draped across the width of the barrier with the uphill edge placed in the trench and the edges of adjacent pieces overlapping each other.

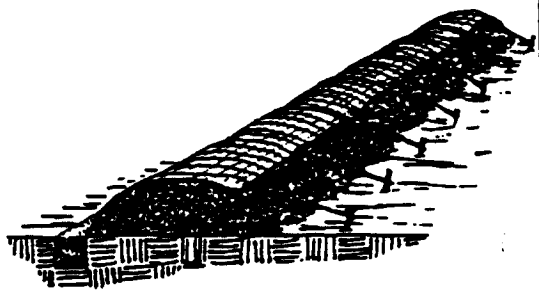


7. The filter fabric shall be secured in the trench with stakes set approximately 36 inches on center.

8. The trench shall be backfilled and the soil compacted over the filter fabric.



9. Set stakes into the ground along the downhill edge of the brush barrier, and anchor the fabric by tying twine from the fabric to the stakes.



1. Excavate a 4" x 4" trench along the uphill edge of the brush barrier.

2. Drape filter fabric over the brush barrier and into the trench. Fabric should be secured in the trench with stakes set approximately 36" o.c.

3. Backfill and compact the excavated soil.

4. Set stakes along the downhill edge of the brush barrier, and anchor by tying twine from the fabric to the stakes.

CONSTRUCTION OF A BRUSH BARRIER
COVERED BY FILTER FABRIC

Plate 1.07a

Source: Adapted from Installation of Straw and Fabric Filter Barriers for Sediment Control, Sherwood and Wyant

Maintenance

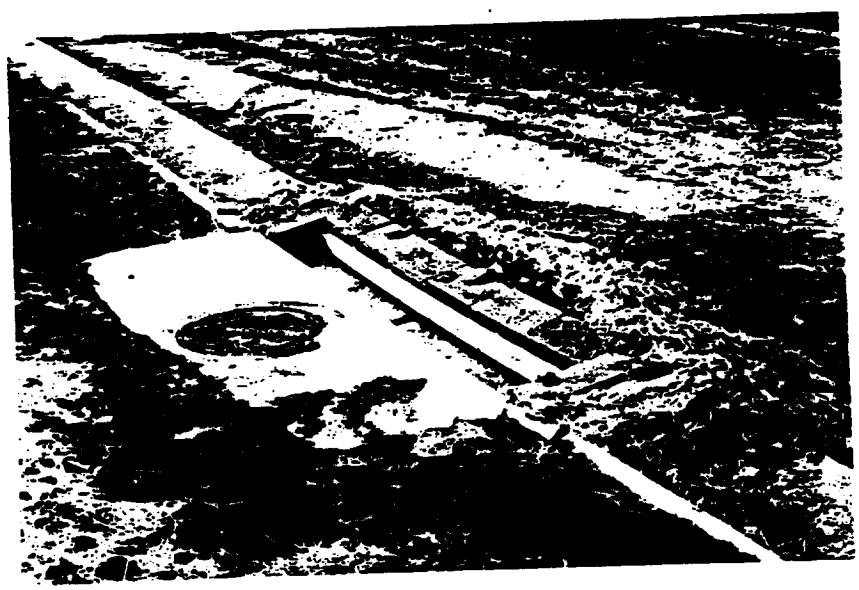
1. Brush barriers shall be inspected after each rainfall and necessary repairs shall be made promptly.

2. Sediment deposits must be removed when they reach approximately one-half the height of the barrier.

ES BMP 1.08

STORM DRAIN INLET PROTECTION

Definition



A sediment filter or an excavated impounding area around a storm drain drop inlet or curb inlet.

Purpose

To prevent sediment from entering storm drainage systems prior to permanent stabilization of the disturbed area.

Condition Where Practice Applies

Where storm drain inlets are to be made operational before permanent stabilization of the disturbed drainage area. Different types of structures are applicable to different conditions (see Plates 1.08a through 1.08h).

R0071353

Planning Considerations

Storm sewers which are made operational before their drainage area is stabilized can convey large amounts of sediment to natural drainageways. In case of extreme sediment loading, the storm sewer itself may clog and lose a major portion of its capacity. To avoid these problems, it is necessary to prevent sediment from entering the system at the inlets.

This practice contains several types of inlet filters and traps which have different applications dependent upon site conditions and type of inlet. Other innovative techniques for accomplishing the same purpose are encouraged, but only after specific plans and details are submitted to and approved by the stormwater permitting agency.

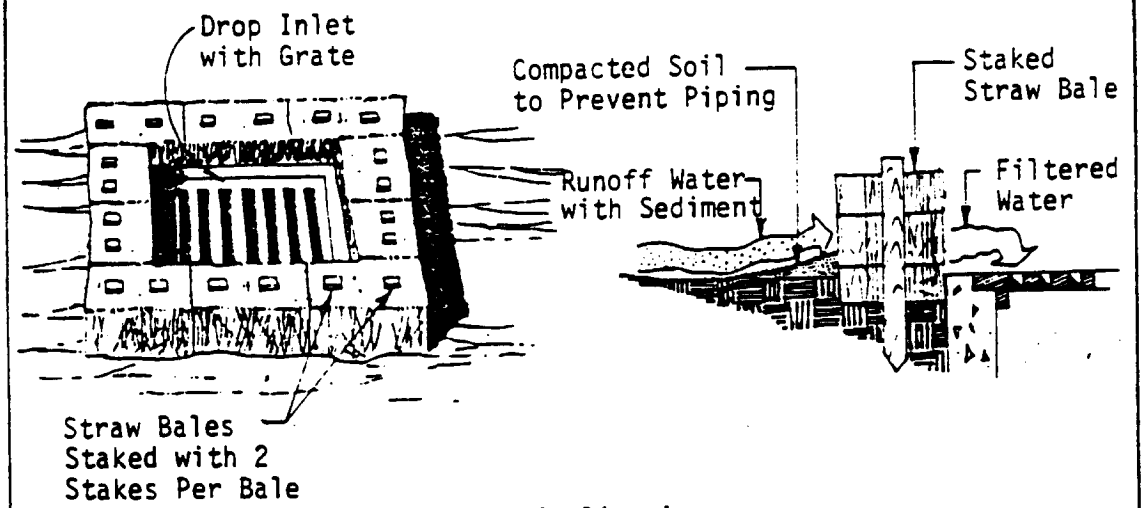
Note that these various inlet protection devices are for drainage areas of less than one acre. Runoff from large disturbed areas should be routed through a TEMPORARY SEDIMENT TRAP (ES BMP 1.25).

Design Criteria

1. The drainage area shall be no greater than 1 acre.

2. The inlet protection device shall be constructed in such a manner that will facilitate cleanout and disposal of trapped sediment and minimize interference with construction activities.

3. The inlet protection devices shall be constructed in such a manner that any resultant ponding or stormwater will not cause excessive inconvenience or damage to adjacent areas or structures.



4. Design criteria more specific to each particular inlet protection device will be found on Plates 1.08a-h.

Construction Specifications

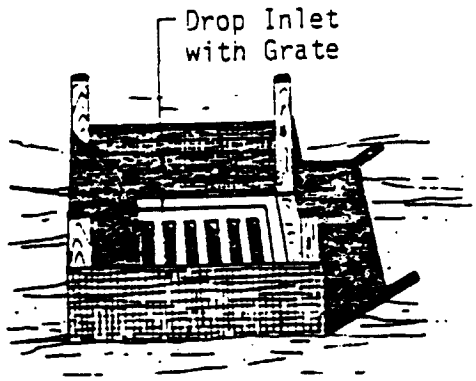
1. **STRAW BALE DROP INLET STRUCTURE**

   a. Bales shall be either wire-bound or string-tied with the bindings oriented around the sides rather than over and under the bales.
   b. Bales shall be placed lengthwise in a single row surrounding the inlet, with the ends of adjacent bales pressed together.
   c. The filter barrier shall be entrenched and backfilled. A trench shall be excavated around the inlet the width of a bale to a minimum depth of 4 inches. After the bales are staked, the excavated soil shall be backfilled and compacted against the filter barrier.

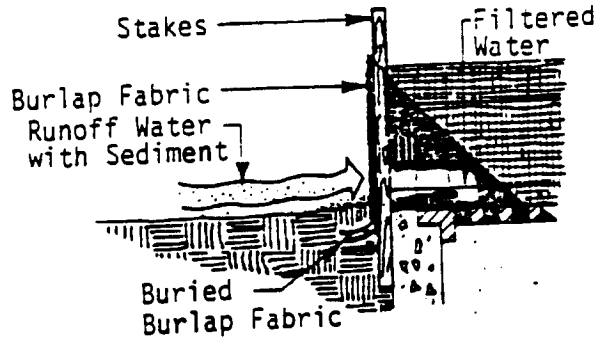
d. Each bale shall be securely anchored and held in place by at least two stakes or rebars driven through the bale.
e. Loose straw should be wedged between bales to prevent water from entering between bales.

Specific Application

This method of inlet protection is applicable where the inlet drains a relatively flat area (slopes no greater than 5 percent) where sheet or overland flows (not exceeding 0.5 cfs) are typical. The method shall not apply to inlets receiving concentrated flows, such as in street or highway medians.



STRAW BALE DROP INLET SEDIMENT FILTER



Source: Michigan Soil Erosion and Sedimentation Control Guidebook, 1975

Plate 1.08a

2. **BURLAP DROP INLET SEDIMENT FILTER**

a. Burlap shall be 10 ounce per square yard fabric and shall be cut from a continuous roll to avoid joints.
b. Stakes shall be 1" x 2" wood (preferred) or equivalent metal with a minimum length of 3 feet.
c. Staples shall be of heavy duty wire at least 1/2-inch long.
d. Stakes shall be spaced around the perimeter of the inlet a maximum of 3 feet apart and securely driven into the ground (minimum of 8 inches).
e. A trench shall be excavated approximately 4 inches wide and 4 inches deep around the outside perimeter of the stakes.
f. The burlap shall be stapled to the wooden stakes, and 8 inches of the fabric shall be extended into the trench. The height of the filter barrier shall be a minimum of 15 inches and shall not exceed 18 inches (Plate 1.08b).
g. The trench shall be backfilled and the soil compacted over the burlap.

Specific Application

This method of inlet protection is applicable where the inlet drains a relatively flat area (slopes no greater than 5 percent) where sheet or overland flows (not exceeding 0.5 cfs) are typical. The method shall not apply to inlets receiving concentrated flows, such as in street or highway medians.

BURLAP DROP INLET SEDIMENT FILTER

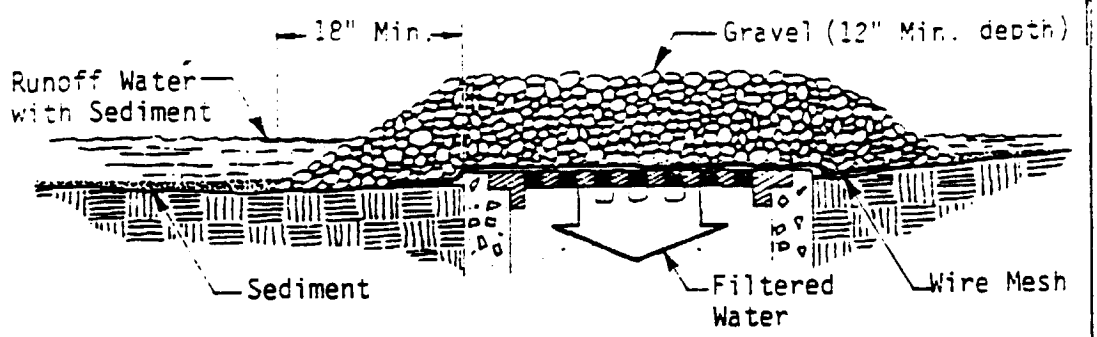


Plate 1.08b

Source: Va SWCC

3. **GRAVEL AND WIRE MESH DROP INLET SEDIMENT FILTER**

   a. Wire mesh shall be laid over the drop inlet so that the wire extends a minimum of 1 foot beyond each side of the inlet structure. Hardware cloth or comparable wire mesh with 1/2-inch openings shall be used. If more than one strip of mesh is necessary, the strips shall be overlapped.
   b. FDOT No. 1 Coarse Aggregate shall be placed over the wire mesh as indicated on Plate 1.08c. The depth of stone shall be at least 12 inches over the entire inlet opening. The stone shall extend beyond the inlet opening at least 18 inches on all sides.
   c. If the stone filter becomes clogged with sediment so that it no longer adequately performs its function, the stones must be pulled away from the inlet, cleaned and replaced.

NOTE: This filtering device has no overflow mechanism. Therefore, ponding is likely especially if sediment is not removed regularly. This type of device must never be used where overflow may endanger an exposed fill slope. Consideration should also be given to the possible effects of ponding on traffic movement, nearby structures, working areas, adjacent property, etc.

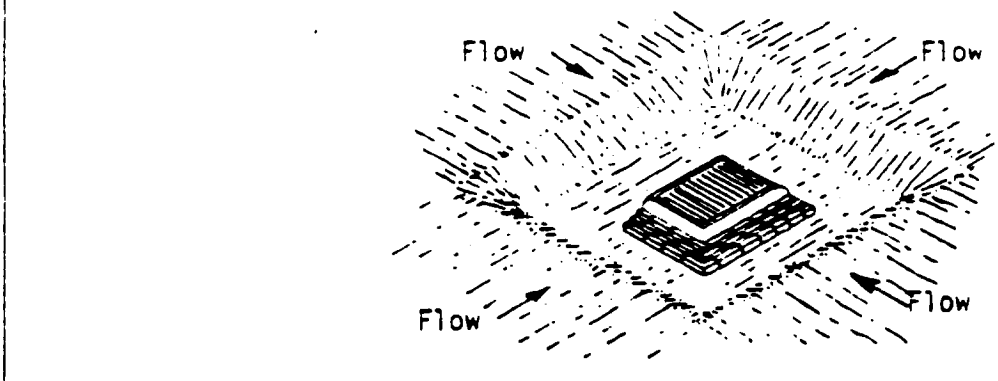
Specific Application

This method of inlet protection is applicable where heavy concentrated flows are expected, but not where ponding around the structure might cause excessive inconvenience or damage to adjacent structures and unprotected areas.

GRAVEL AND WIRE MESH DROP INLET SEDIMENT FILTER

Source: Va SWCC

Plate 1.08c



4. **BLOCK AND GRAVEL DROP INLET SEDIMENT FILTER**

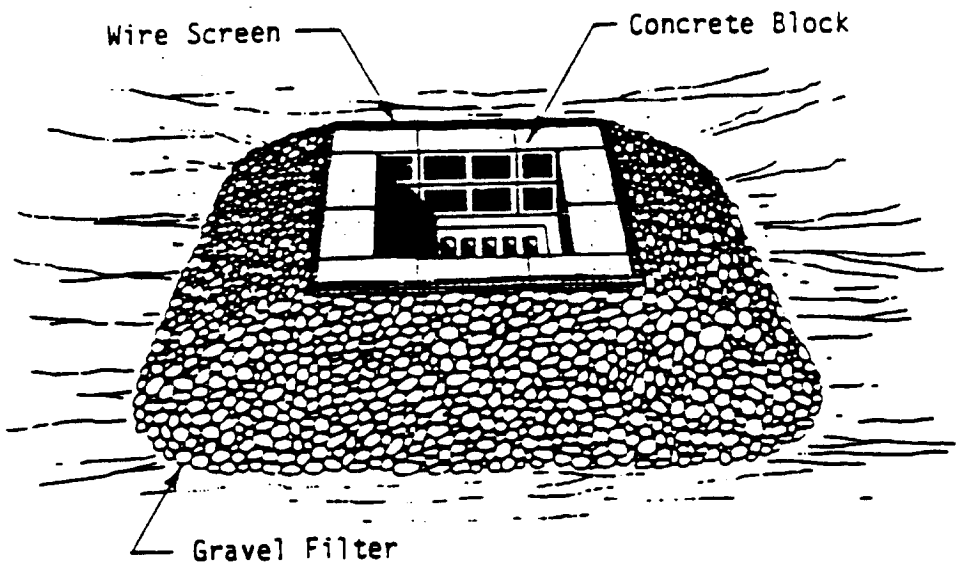
   a. Place concrete blocks lengthwise on their sides in a single row around the perimeter of the inlet, with the ends of adjacent blocks abutting. The height of the barrier can be varied, depending on design needs, by stacking combinations of 4-inch, 8-inch and 12-inch wide blocks. The barrier of blocks shall be at least 12 inches high and no greater than 24 inches high.
   b. Wire mesh shall be placed over the outside vertical face (webbing) of the concrete blocks to prevent stone from being washed through the holes in the blocks. Hardware cloth or comparable wire mesh with 1/2-inch openings shall be used.
   c. Stone shall be piled against the wire to the top of the block barrier, as shown in Plate 1.08d. FDOT No. 1 Coarse Aggregate shall be used.
   d. If the stone filter becomes clogged with sediment so that it no longer adequately performs its function, the stone must be pulled away from the blocks, cleaned and replaced.

5. **EXCAVATED DROP INLET SEDIMENT TRAP**

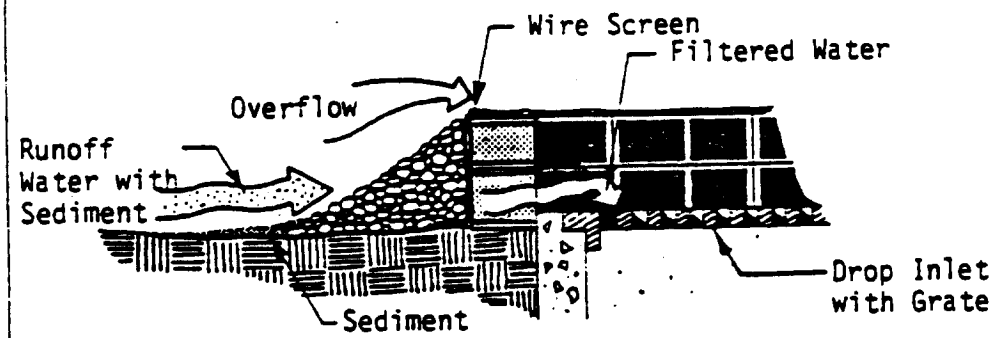
   a. The excavated trap shall be sized to provide a minimum storage capacity calculated at the rate of 67 cubic yards for 1 acre of drainage area. A trap shall be no less than 1 foot nor more than 2 feet deep measured from the top of the inlet structure. Side slopes shall not be steeper than 3:1 (Plate 1.08e).
   b. The slope of the basin may vary to fit the drainage area and terrain. Observations must be made to check trap efficiency and modifications shall be made as necessary to insure satisfactory trapping of sediment. Where an inlet is located so as to receive concentrated flows, such as in a highway median, it is recommended that the basin have a rectangular shape in 2:1 ratio, with the length oriented in the direction of the flow.

R0071357

Specific Application



This method of inlet protection is applicable where heavy flows are expected and where an overflow capability and ease of maintenance are desirable.



EXCAVATED DROP INLET SEDIMENT TRAP

Source: Michigan Soil Erosion and Sedimentation Control Guidebook, 1975, and USDA-SCS

Plate 1.08e

R0071358

Specific Application

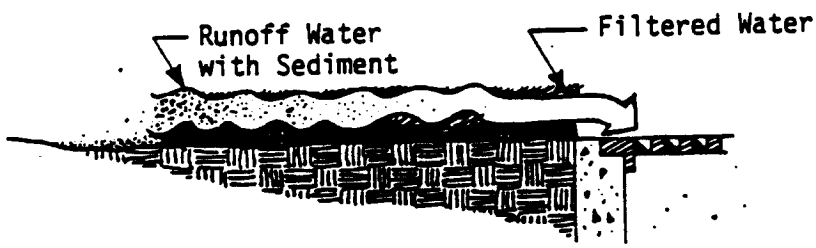
This method of inlet protection is applicable where heavy flows are expected and where an overflow capacity is necessary to prevent excessive ponding around the structure.

BLOCK AND GRAVEL DROP INLET SEDIMENT FILTER

Source: Va SWCC

Plate 1.08d

R0071359



c. Sediment shall be removed and the trap restored to its original dimensions when the sediment has accumulated to 1/2 the design depth of the trap. Removed sediment shall be deposited in a suitable area and in a manner such that it will not erode.

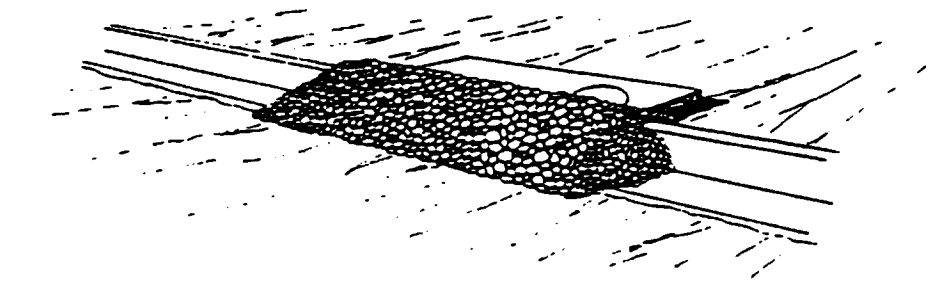
6. SOD DROP INLET SEDIMENT FILTER

a. Soil shall be prepared and sod installed according to the specifications in ES BMP 1.67 entitled SODDING.
b. Sod shall be placed to form a turf map covering the soil for a distance of 4 feet from each side of the inlet structure, as illustrated in Plate 1.08f.

Four 1-foot Wide Strips of Sod on Each Side of the Drop Inlet

Specific Application

This method of inlet protection is applicable only at the time of permanent seeding, to protect the inlet from sediment and mulch materials until permanent vegetation has become established.



SOD DROP INLET SEDIMENT FILTER

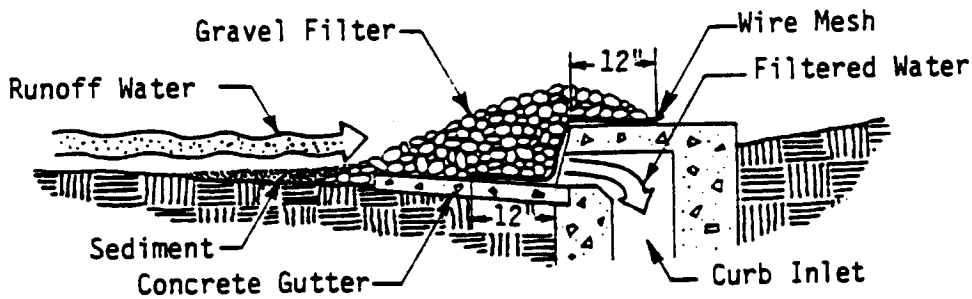


Plate 1.08f

Source: Va SWCC

a. Hardware cloth or comparable wire mesh with 1/2-inch openings shall be placed over the curb inlet opening so that at least 12 inches of wire extends across the inlet cover and at least 12 inches of wire extends across the concrete gutter from the inlet opening, as illustrated in Plate 1.08g.

b. Stone shall be piled against the wire so as to anchor it against the gutter and inlet cover and to cover the inlet opening completely. FDOT No. 1 Coarse Aggregate shall be used.
c. If the stone filter becomes clogged with sediment so that it no longer adequately performs its function, the stone must be pulled away from the block, cleaned and replaced.

Specific Application

This method of inlet protection is applicable at curb inlets where ponding in front of the structure is not likely to cause inconvenience or damage to adjacent structures and unprotected areas.

GRAVEL CURB INLET SEDIMENT FILTER

Source: Va SWCC

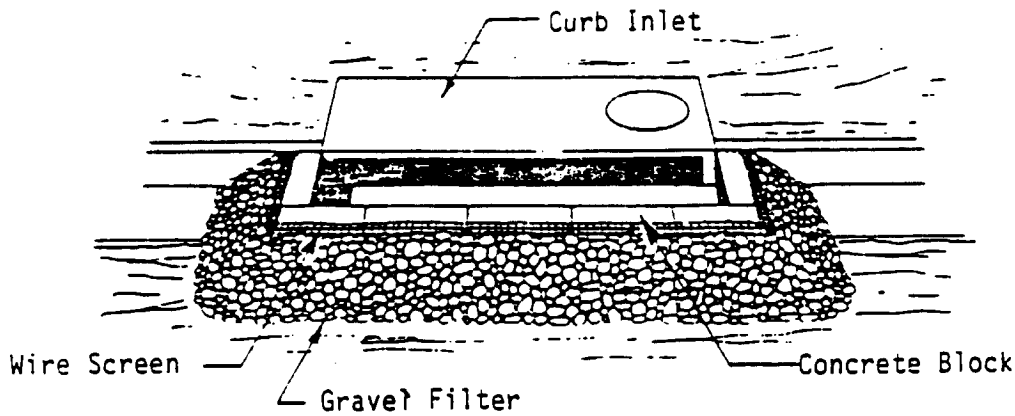

Plate 1.08g

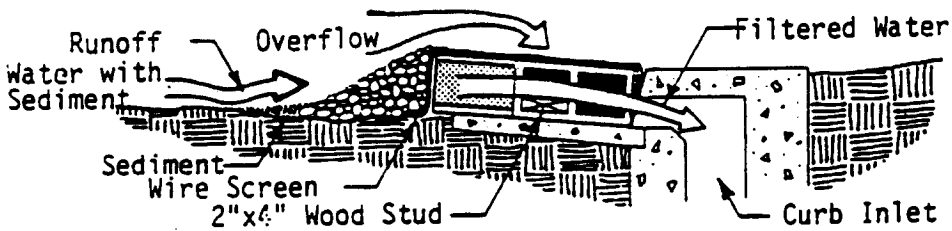


8. **BLOCK AND GRAVEL CURB INLET SEDIMENT FILTER**

a. Two concrete blocks shall be placed on their sides abutting the curb at either side of the inlet opening.
b. A 2-inch by 4-inch stud shall be cut and placed through the outer holes of each spacer block to help keep the front blocks in place.
c. Concrete blocks shall be placed on their sides across the front of the inlet and abutting the spacer blocks as illustrated in Plate 1.08h.
d. Wire mesh shall be placed over the outside vertical face (webbing) of the concrete blocks to prevent stone from being washed through the holes in the blocks. Chicken wire or hardware cloth with 1/2-inch openings shall be used.
e. FDOT No. 1 Coarse Aggregate shall be piled against the wire to the top of the barrier as shown in Plate 1.08h.

R0071361

f. If the stone filter becomes clogged with sediment so that it no longer adequately performs its function, the stone must be pulled away from the block, cleaned and replaced.

Specific Application

This method of inlet protection is applicable at curb inlets where an overflow capability is necessary to prevent excessive ponding in front of the structure.

BLOCK AND GRAVEL CURB INLET SEDIMENT FILTER

Source: Va SWCC

Plate 1.08h

Maintenance

1. The structure shall be inspected after each rain and repairs made as needed.

2. Sediment shall be removed and the trap restored to its original dimensions when the sediment has accumulated to 1/2 the design depth of the trap. Removed sediment shall be deposited in a suitable area and in such a manner that it will not erode.

3. Structures shall be removed and the area stabilized when the remaining drainage area has been properly stabilized.

ES BMP 1.15

TEMPORARY DIVERSION DIKE

Definition

A temporary ridge of compacted soil located at the top or base of a sloping disturbed area.

Purposes

1. To divert storm runoff from higher drainage areas away from unprotected slopes to a stabilized outlet;

or

2. To divert sediment-laden runoff from a disturbed area to a sediment trapping facility.

Condition Where Practice Applies

Wherever stormwater runoff must be temporarily diverted to protect disturbed slopes or retain sediments on site during construction. These structures generally have a life expectancy of 18 months or less.

Planning Considerations

A temporary diversion dike is intended to divert overland sheet flow to a stabilized outlet or a sediment trapping facility during establishment of permanent stabilization on sloping, disturbed areas. When used at the top of a slope, the structure protects exposed slopes by keeping upland runoff away. When used at the base of a slope, the structure protects adjacent and downstream areas by diverting sediment-laden runoff to a sediment trapping facility.

If the dike is going to remain in place for longer than 30 days, it is very important that it be established with temporary or permanent vegetation. The slope behind the dike is also an important consideration. The dike must have a positive grade to assure drainage, but if the slope is too great, precautions must be taken to prevent erosion due to high velocity flow behind the dike.

This practice is considered an economical one because it uses material available on the site and can usually be constructed with equipment needed for site grading. The useful life of the practice can be extended by stabilizing the dike with vegetation.

As specified herein, this practice is intended to be temporary. However, with more stringent design criteria, it can be made permanent in accordance with DIVERSIONS (ES BMP 1.18).

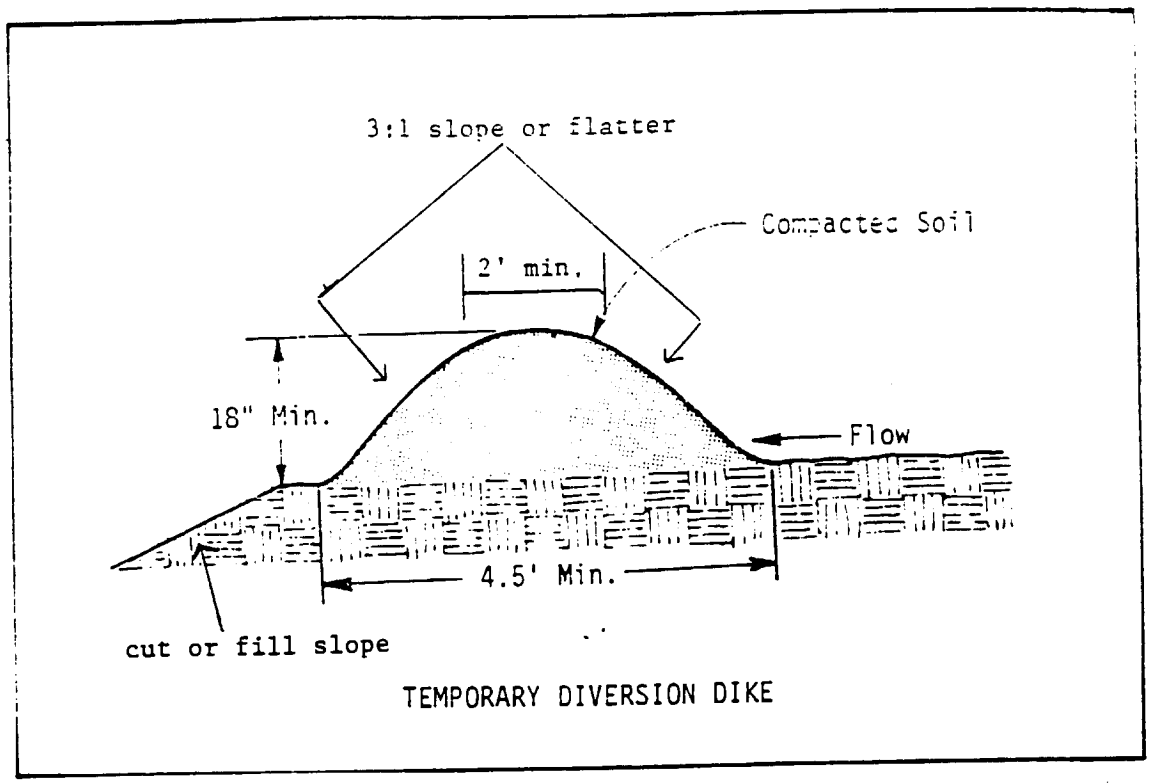
Design Criteria

No formal design is required. The following criteria shall be met:

Drainage Area

The maximum allowable drainage area is 5 acres.

Dimensions



The minimum allowable height measured from the upslope side of the dike is 18 inches. Top width shall be a minimum of 2 feet with a minimum base width of 4.5 feet. (See Plate 1.15a)

Side Slopes

3:1 or flatter.

Grade

The channel behind the dike shall have a positive grade to a stabilized outlet. If the channel slope is less than or equal to 2%, no stabilization is usually required. If the slope is greater than 2%, the channel shall be stabilized in accordance with ES BMP 1.35 (STORMWATER CONVEYANCE CHANNEL).

TEMPORARY DIVERSION DIKE

Source: Va SWCC

Plate 1.15a

Outlet

1. The diverted runoff, if free of sediment, must be released through a stabilized outlet or channel.

2. Sediment-laden runoff must be diverted and released through a sediment trapping facility.

Construction Specifications

1. Whenever feasible, the dike should be built before construction begins on the project.

2. The dike should be adequately compacted to prevent failure.

3. Temporary or permanent seeding and mulch shall be applied to the dike within 15 days of construction.

4. The dike should be located to minimize damages by construction operations and traffic.

Maintenance

The measure shall be inspected after every storm and repairs made to the dike, flow channel and outlet, as necessary. Approximately once every week, whether a storm has occurred or not, the measure shall be inspected and repairs made if needed. Damages caused by construction traffic or other activity must be repaired before the end of each working day.

ES BMP 1.16

TEMPORARY FILL DIVERSION

Definition

A channel with a supporting ridge on the lower side cut along the top of an active earth fill.

Purpose

To divert storm runoff away from the unprotected slope of the fill to a stabilized outlet or sediment trapping facility.

Conditions Where Practice Applies

Where the drainage area at the top of an active earth fill slopes toward the exposed slope and where continuous fill operations make the use of a DIVERSION (ES BMP 1.18) unfeasible. This temporary structure should remain in place for less than one week.

R0071367

Planning Considerations

One important principle of erosion and sediment control is to keep stormwater runoff away from exposed slopes. This is often accomplished by installing a dike, diversion or paved ditch at the top of a slope to carry the runoff away from the slope to a stabilized outlet or downdrain. In general, these measures are installed after the final grade has been reached. On cuts, the measures may be installed at the beginning since the work proceeds from the top and the measures have little chance of being covered or damaged. On fills, the work proceeds from the bottom to the top and the elevation changes daily. It is therefore not feasible to construct a compacted dike or permanent diversion which may be covered by the next day's activity.

The temporary fill diversion is intended to provide some slope protection on a daily basis until final elevations are reached and a more permanent measure can be constructed. This practice can be constructed by the use of a motor grader or one of the smaller dozers. To shape the diversion, the piece of machinery used may run near the edge of the fill with its blade tilted to form the channel as described in Plate 1.16a. This work would be done at the end of the working day and provide a channel with a berm on the lower side to protect the slope. Wherever possible, the temporary diversion should be sloped to direct water to a stabilized outlet. If the runoff is diverted over the fill itself, the practice may cause more problems than it solves by concentrating water at a single point.

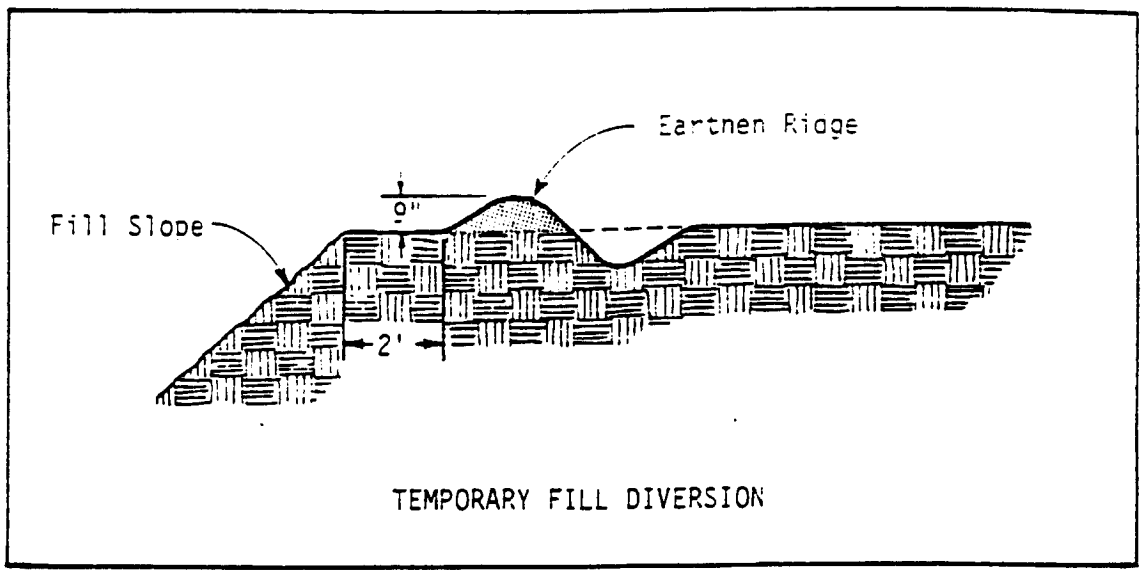
Good timing is essential to fill construction. The filling operation should be completed as quickly as possible and the permanent slope protection measures and slope stabilization measures installed as soon after completion as possible. With quick and proper construction, the developer or contractor will save both time and money in building, repairing and stabilizing the fill area. The longer the time period for construction and stabilization, the more prone the fill operation is to damages by erosion. Repairing the damages adds additional time and expense to the project.

Design Criteria

No formal design is required. The following criteria shall be met:

Drainage Area

The maximum allowable drainage area is 5 acres.



Height

The minimum height of the supporting ridge shall be 9 inches. (See Plate 1.16a).

Grade

The channel shall have a positive grade to a stabilized outlet.

R0071368

TEMPORARY FILL DIVERSION

Source: Va SWCC

Plate 1.16a

Outlet

The diverted runoff should be released through a stabilized outlet, slope drain or sediment trapping measure.

Construction Specifications

1. The diversion shall be constructed at the top of the fill at the end of each work day as needed.

2. The diversion shall be located at least 2 feet inside the top edge of the fill. (See Plate 1.16a).

3. The supporting ridge of the lower side shall be constructed with a uniform height along its entire length.

Maintenance

Since the practice is temporary and under most situations will be covered the next work day, the maintenance required should be low. If the practice is to remain in use for more than one day, an inspection will be made at the end of each work day and repairs made to the measure if needed. The contractor should avoid the placement of any material over the structure while it is in use. Construction traffic should not be permitted to cross the diversion.

R0071369

ES BMP 1.17

TEMPORARY
RIGHT-OF-WAY DIVERSION

Definition

A ridge of compacted soil or loose rock or gravel constructed across disturbed rights-of-way and similar sloping areas.

Purpose

To shorten the flow length within a long sloping right-of-way, thereby reducing the erosion potential by diverting storm runoff to a stabilized outlet or sediment trapping device.

Conditions Where Practice Applies

Generally, earthen diversions are applicable where there will be little or no construction traffic within the right-of-way. Gravel structures are more applicable to roads and other rights-of-way which accommodate vehicular traffic.

R0071370

Planning Considerations

Construction of utility lines and roads often requires the clearing of long strips of right-of-way over sloping terrain. Tne volume and velocity of stormwater runoff tend to increase in these cleared strips and the potential for erosion is much greater since the vegetative cover is diminished or removed. To compensate for the loss of vegetation, it is usually a good practice to break up the flow length within tne cleared strip so that runoff does not have a chance to concentrate and cause erosion. At proper spacing intervals, Temporary Right-of-Way Diversions can significantly reduce the amount of erosion which will occur until the area is permanently stabilized.

Design Criteria

No formal design is required. The following criteria shall be met:

Drainage Area - Less than 5 acres (for larger drainage areas use a DIVERSION, ES BMP 1.18).

Dimensions

The minimum allowable height measured from the upslope side of the diversion is 18 inches. The minimum top width shall be 2 feet and the base width minimum is 6 feet.

Side Slopes

3:1 or flatter to allow the passage of construction traffic. (See Plate 1.17a).

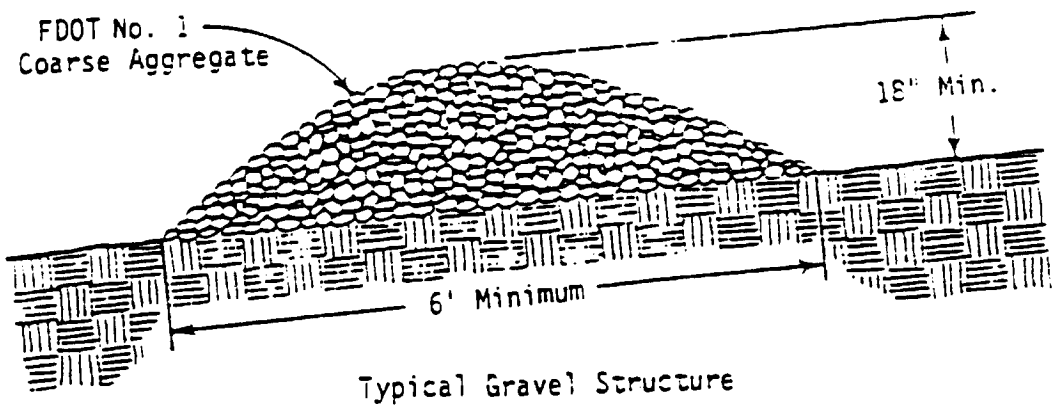
Width

The measure should be constructed completely across the disturbed portion of the right-of-way.

Spacing

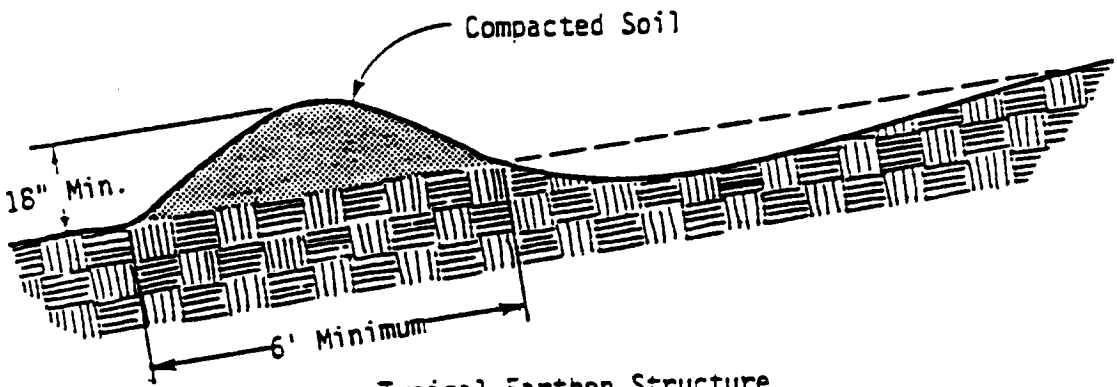
The following table will be used to determine the spacing of right-of-way diversions:

% Slope	Spacing (ft.)
Less than 5%	300
Between 5% and 10%	200
Greater than 10%	100



Grade

Positive drainage, with less than 2% slope, should be provided to a stabilized outlet or sediment trapping facility.



Outlet

Interceptor dikes must have an outlet which is not subject to erosion.

R0071371

Typical Gravel Structure

Typical Earthen Structure

TEMPORARY RIGHT-OF-WAY DIVERSIONS

Plate 1.17a

Source: Va SWCC

R0071372

The on-site location may need to be adjusted to meet field conditions in order to utilize the most suitable outlet. Concentrated flows should spread over the widest possible area after release. Flows with high sediment concentrations should pass through a sediment trapping measure.

Construction Specifications

1. The diversion shall be installed as soon as the right-of-way has been cleared and/or graded.

2. All earthen diversions shall be machine- or hand-compacted in 8-inch lifts.

3. The outlet of the diversion shall be located on an undisturbed and stabilized area when at all possible. The field location should be adjusted as needed to utilize a stabilized outlet. Sediment laden flows shall be conveyed to a sediment trapping device.

4. Earthen diversions which will not be subject to construction traffic should be stabilized in accordance with TEMPORARY SEEDING (ES BMP 1.65).

Maintenance

The practice shall be inspected after every rainfall and repairs made if necessary. Approximately once every week, whether a storm has occurred or not, the measure shall be inspected and repairs made if needed. Diversions which are subject to damage by vehicular traffic should be re-shaped at the end of each working day.

R0071373

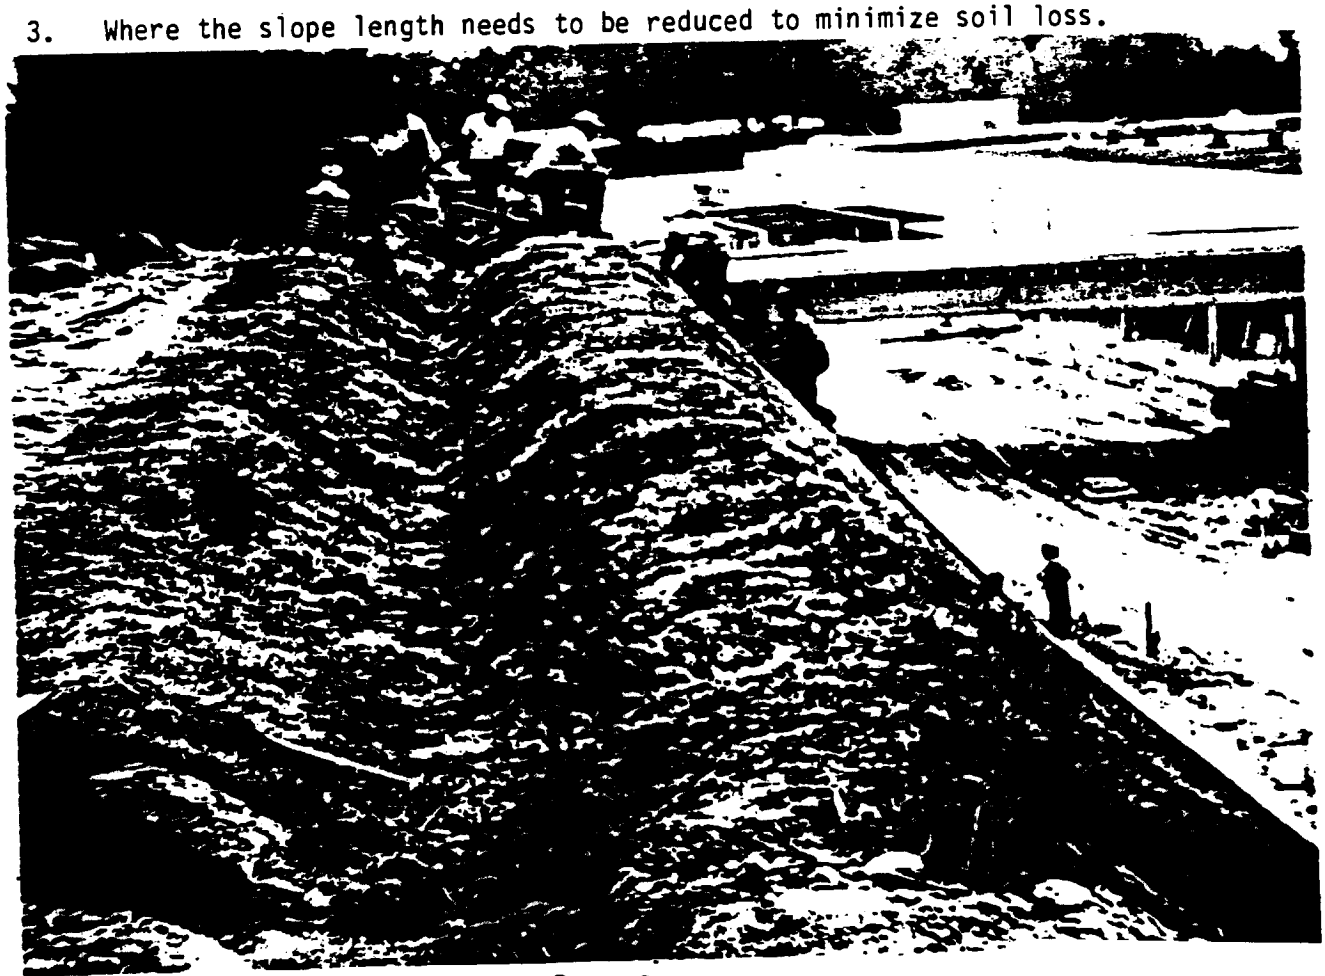
ES BMP 1.18

DIVERSION

Definition

A channel constructed across a slope with a supporting ridge on the lower side.

Purpose



To reduce slope length and to intercept and divert stormwater runoff to stabilized outlets at non-erosive velocities.

Conditions Where Practice Applies

1. Where runoff from higher areas may damage property, cause erosion, or interfere with the establishment of vegetation on lower areas.

2. Where surface and/or shallow subsurface flow is damaging upland slopes.

3. Where the slope length needs to be reduced to minimize soil loss.

R0071374

4. Diversions are applicable only below stabilized or protected areas. They should not be used below high sediment producing areas unless land treatment practices or structural measures, designed to prevent damaging accumulations of sediment in the channels, are installed with or before the diversions.

5. Diversions should not be placed on slopes greater than fifteen percent.

Planning Considerations

Diversions can be useful tools for managing surface water flows and preventing soil erosion. On moderately sloping areas, they may be placed at intervals to trap and divert sheet flow before it has a chance to concentrate and cause rill and gully erosion. They may be placed at the top of cut or fill slopes to keep runoff from upland drainage areas off the slope. They can also be used to protect structures, parking lots, adjacent properties, and other special areas from flooding.

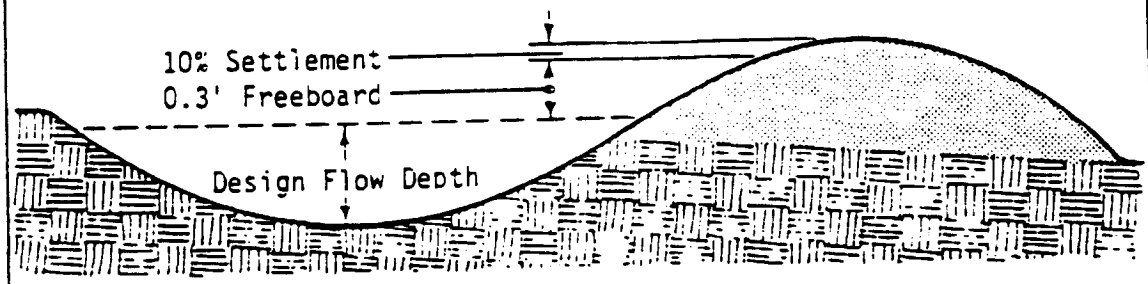
Diversions are preferable to other types of man-made stormwater conveyance systems because they more closely simulate natural flow patterns and characteristics. Flow velocities are generally kept to a minimum. When properly coordinated into the landscape design of a site, diversions can be visually pleasing as well as functional.

As with any earthen structure, it is very important to establish adequate vegetation as soon as possible after installation. It is equally important to stabilize the drainage area above the diversion so that sediment will not enter and accumulate in the diversion channel.

Diversions should be constructed before clearing and grading operations begin. If used to protect a flat, exposed area, a diversion might be constructed as a dike or berm. Berms made of gravel or story can be crossed by construction equipment.

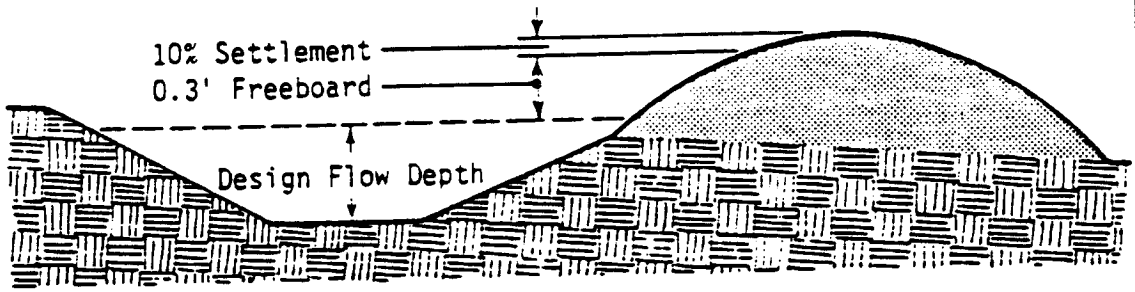
Design Criteria

Location



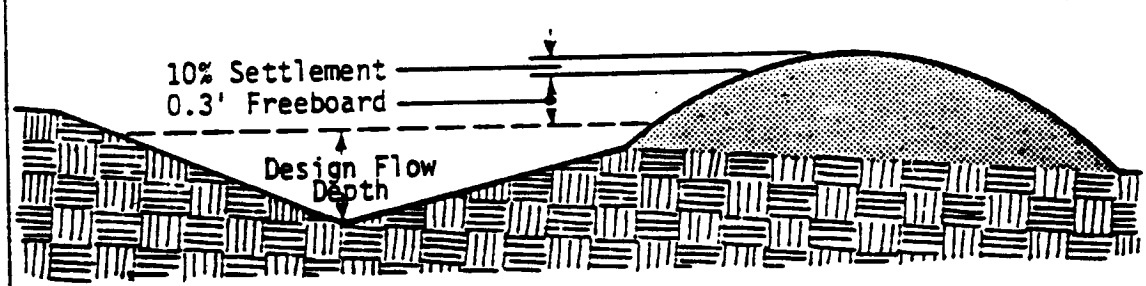
Diversion location shall be determined by considering outlet conditions, topography, land use, soil type, length of slope, seepage planes (where seepage is a problem) and the development layout.

Capacity



1. The diversion channel must have a minimum capacity to carry the runoff expected from a 10-year frequency storm with a freeboard of at least 0.3 foot. (Plate 1.18a).

2. Diversions designed to protect homes, schools, industrial buildings, roads, parking lots, and comparable high-risk areas, and those designed to function in connection with other structures, shall have sufficient capacity to carry peak runoff expected from a storm frequency consistent with the hazard involved.



R0071375

Typical Parabolic Diversion

Typical Trapezoidal Diversion

Typical Vee-Shaped Diversion

DIVERSIONS

Source: Va SWCC

Plate 1.18a

R0071376

3. Peak rates of runoff used in determining the capacity requirements shall be as outlined in Chapter 5 of this manual or by other accepted methods.

Channel Design

The diversion channel may be parabolic, trapezoidal or Vee-shaped and shall be designed and constructed according to ES BMP 1.35 (STORMWATER CONVEYANCE CHANNELS).

Ridge Design

The supporting ridge cross-section shall meet the following criteria (Plate 1.18a).

1. The side slopes shall be no steeper than 2:1 and shall be flat enough to insure ease of maintenance of the structure and its protective vegetative cover.

2. The width at the design water elevation shall be a minimum of 4 feet.

3. The minimum freeboard shall be 0.3 foot.

4. The design shall include a 10 percent settlement factor.

Outlet

Diversions shall be stabilized outlets which will convey concentrated runoff without erosion. Acceptable outlets include STORMWATER CONVEYANCE CHANNELS (ES BMP 1.35); LEVEL SPREADERS (ES BMP 1.40); OUTLET PROTECTION (ES BMP 1.36); and PAVED FLUMES (ES BMP 1.31).

Outlets shall be constructed and stabilized prior to the operation of the diversion.

Stabilization

1. Unless otherwise stabilized, the ridge and channel shall be seeded and mulched within 15 days of installation in accordance with ES BMP 1.66 (PERMANENT SEEDING).

2. Disturbed areas draining into the diversion shall be seeded and mulched prior to or at the time the diversion is constructed.

3. Permanent diversions should include a filter strip of close growing grass maintained above the channel. The width of the filter, measured from the center of the channel, shall be one-half the channel width plus 15 feet.

Construction Specifications

1. All trees, brush, stumps, debris, and other obstructions shall be removed and disposed of so as not to interfere with the proper functioning of the diversion.

2. The diversion shall be excavated or shaped to line, grade, and cross-section as required to meet the criteria specified herein, free of irregularities which will impede flow.

3. Fills shall be compacted as needed to prevent unequal settlement that would cause damage in the complete diversion.

4. All earth removed and not needed in construction shall be spread or disposed of so that it will not interfere with the functioning of the diversion.

5. Permanent stabilization of disturbed areas shall be done in accordance with the applicable standard and specification contained in this handbook. Permanent stabilization techniques include PERMANENT SEEDING (ES BMP 1.66) and SODDING (ES BMP 1.67).

Maintenance

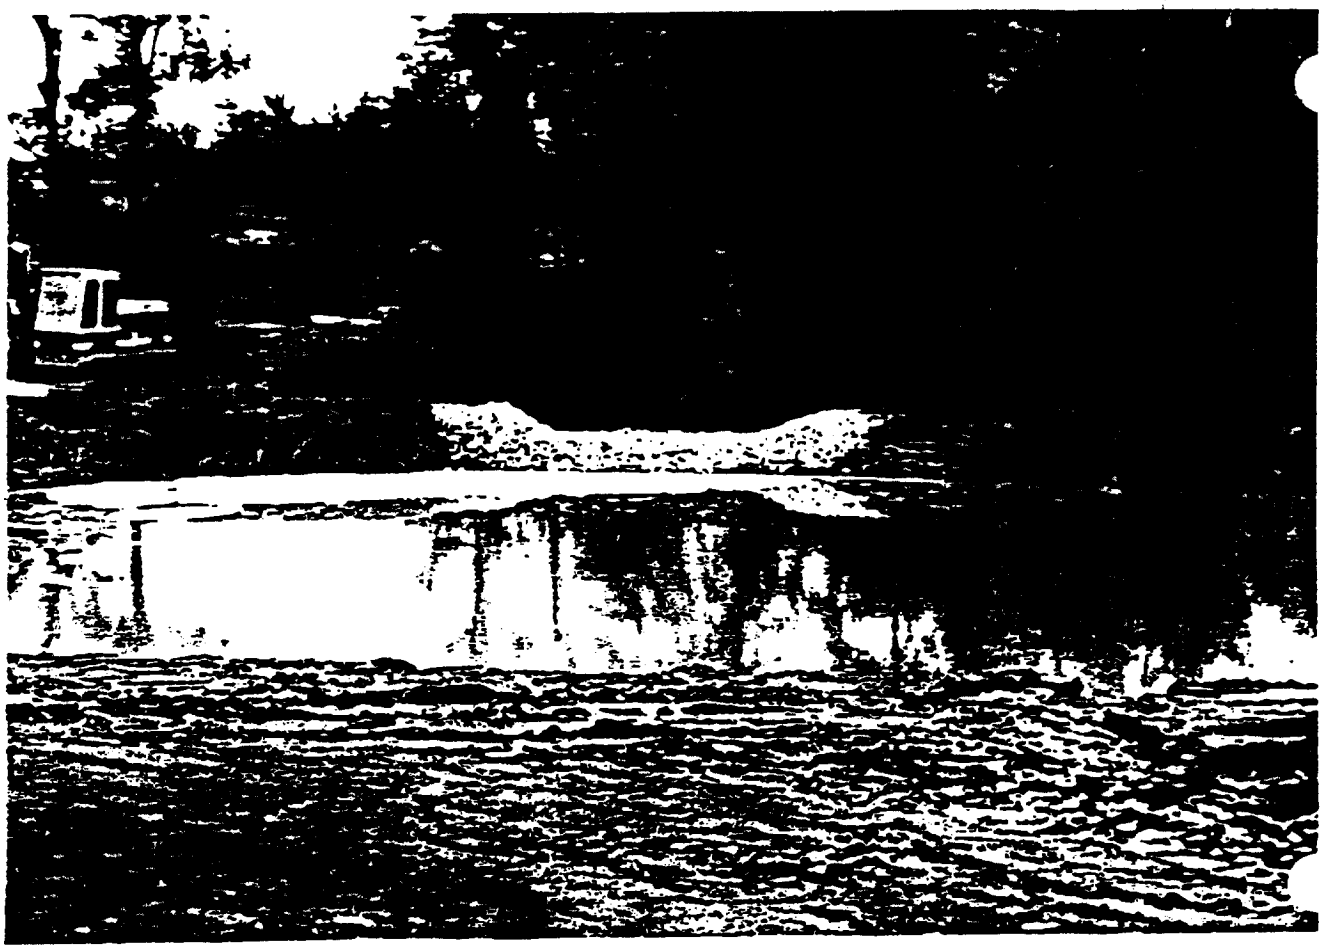
Before final stabilization, the diversion should be inspected after every rainfall. Sediment shall be removed from the ditchline and repairs made as necessary. Seeded areas which fail to establish a vegetative cover shall be reseeded as necessary.

R0071378

ES BMP 1.25

TEMPORARY SEDIMENT TRAP

Definition



A small temporary ponding area formed by excavation and/or an embankment across a drainageway.

Purpose

To detain sediment-laden runoff from small disturbed areas long enough to allow the majority of the sediment to settle out thereby protecting drainageways, properties and rights-of-way from sedimentation.

Conditions Where Practice Applies

1. A sediment trap is usually installed in a drainageway, at a storm drain inlet or at other points of discharge from a disturbed area.

R0071379

2. Below drainage areas of 5 acres or less.

3. Where the sediment trap will be used less than 18 months.

4. The sediment trap may be constructed either independently or in conjunction with a TEMPORARY DIVERSION DIKE (ES BMP 1.15).

Planning Considerations

The sediment trap should be located to obtain the maximum storage benefit from the terrain, for ease of cleanout and disposal of the trapped sediment and to minimize interference with construction activities.

Sediment traps should be used only for small drainage areas. If the contributing drainage area is greater than 5 acres, refer to SEDIMENT BASINS (ES BMP 1.26).

Sediment must be periodically removed from the trap. Plans should detail how this sediment is to be disposed of, such as by use in fill areas on site or removal to an approved off-site dump.

Sediment traps, along with other perimeter controls, shall be installed before any land disturbance takes place in the drainage area.

Design Criteria

Trap Capacity

The sediment trap must have an initial storage volume of 67 cubic yards per acre of drainage area, measured from the low point of the ground to the crest of the gravel outlet. Sediment should be removed from the basin when the volume is reduced by one-half.

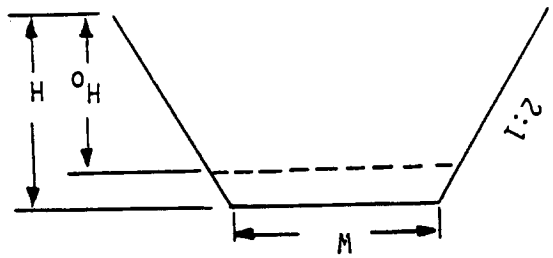
For a natural basin, the volume may be approximated as follows:

$V = 0.4 \times A \times D$

where,

V = the storage volume in $ft.^3$
A = the surface area of the flood area at the crest of the outlet, in $ft.^2$
D = the maximum depth, measured from the low point in the trap to the crest of the outlet, in ft.

Excavation



If excavation is necessary to attain the required storage volume, side slopes should be no steeper than 2:1.

R0071380

Embankment Cross-Section

The maximum height of the sediment trap embankment shall be 5 feet as measured from the low point. Minimum top widths (W) and outlet heights (H_o) for various embankment heights (H) are shown in Table 1.25a. Side slopes of the embankment shall be 2:1 or flatter.

Table 1.25a
MINIMUM TOP WIDTH (W) AND OUTLET HEIGHT (H_o)REQUIRED FOR SEDIMENT TRAP EMBANKMENTS ACCORDING TO HEIGHT OF EMBANKMENT (feet)

H	H_o	W
1.5	0.5	2.0
2.0	1.0	2.0

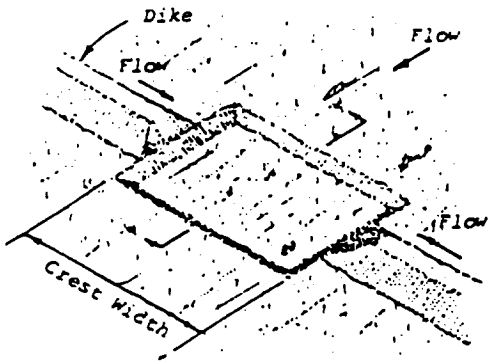
4.0	3.0	3.0
4.5	3.5	4.0
5.0	4.0	4.5

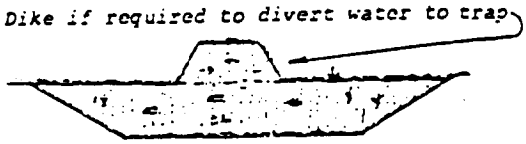
Source: Va SWCC

Outlet

The outlets shall be designed, constructed and maintained in such a manner that sediment does not leave the trap and that erosion of the outlet does not occur. A trap may have several different outlets with each outlet conveying part of the flow based on the criteria below and the combined outlet capacity shall meet that criteria. For example, a 12 foot earth outlet (adequate for 2 acres) and a 12 inch pipe outlet (adequate for 1 acre) could be used for a three acre drainage area.



There are four types of outlets for sediment traps. Each sediment trap is named according to the type of outlet that it has. Each type has different design criteria and will be discussed separately.



1. An Earth Outlet Sediment Trap (Plate 1.25a) consists of a basin formed by excavation and/or an embankment. The trap has a discharge point over or cut into natural ground. The outlet width (feet) shall be equal to 6 times the drainage area (acres). If an embankment is used the outlet crest shall be at least one foot below the top of the embankment. The outlet shall be free of any restriction to flow. The earthen embankment shall be seeded with temporary or permanent vegetation (see ES BMP 1.65 and 1.66) within 15 days of construction.

2. A Pipe Outlet Sediment Trap (Plate 1.25b) consists of a basin formed by an embankment of excavation and an embankment. The outlet for the trap is through a perforated riser and a pipe through the embankment. The outlet pipe and riser shall be made of corrugated metal. The riser diameter shall be of the same or larger diameter than the pipe. The top of the embankment shall be at least 1.5 feet above the crest of the riser. At least the top 2/3 of the riser shall be perforated with 1/2 inch diameter holes spaced 8 inches vertically and 10-12 inches horizontally. All pipe connections shall be watertight.

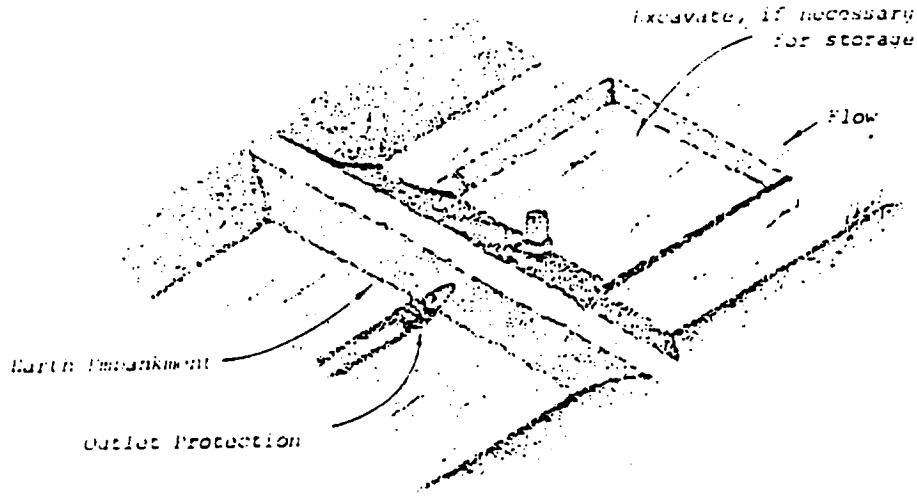
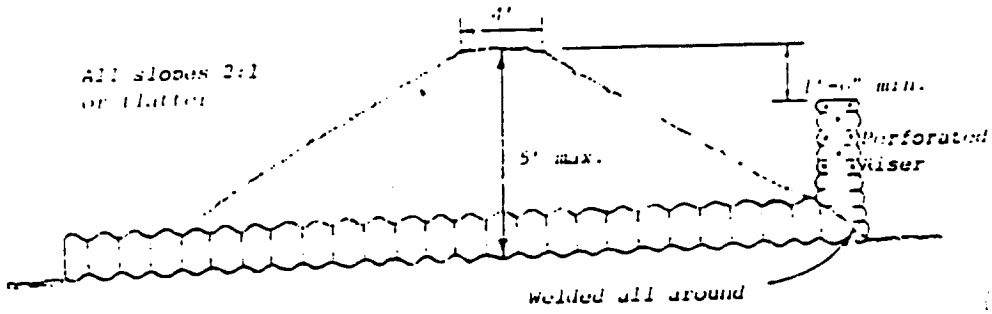
Construction Specifications



1. Area under embankment shall be cleared, grubbed and stripped of any vegetation and root mat. The pool area shall be cleared.
2. The fill material for the embankment shall be free of roots or other woody vegetation as well as oversized stones, rocks, organic material, or other objectionable material. The embankment shall be compacted by traversing with equipment while it is being constructed.
3. Sediment shall be removed and trap restored to its original dimensions when the sediment has accumulated to 1/2 the design depth of the trap. Removed sediment shall be deposited in a suitable area and in such a manner that it will not erode.
4. The structure shall be inspected after each rain and repairs made as needed.
5. Construction operations shall be carried out in such a manner that erosion and water pollution are minimized.
6. The structure shall be removed and area stabilized when the drainage area has been properly stabilized.
7. All cut and fill slopes shall be 2:1 or flatter.
8. Outlet crest elevation shall be at least one foot below the top of the embankment.



* Drainage area less than 5 acres

Select pipe diameter from the following table:

Min. Pipe Diameter	Max. Drainage Area (acres)
12"	1
18"	2
21"	3
24"	4
30"	5

3. A Stone Outlet Sediment Trap (Plate 1.25c) consists of a basin formed by an embankment or excavation and an embankment. The outlet for the sediment trap shall consist of a crushed stone section of the embankment located at the low point in the basin. The minimum length of the outlet shall be 6 feet times the acreage of the drainage area. The crest of the outlet must be at least 1.0 foot below the top of the embankment, to insure that the flow will travel over the stone and not the embankment. The outlet shall be constructed of FDOT No. 1 size crushed stone.

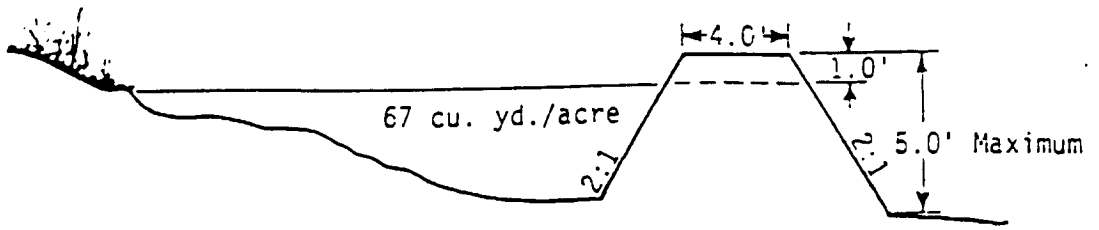
4. A Storm Inlet Sediment Trap (Plate 1.25d) consists of a basin formed by excavation or natural ground that discharges through an opening in a storm drain inlet structure. This opening can either be the inlet opening or a temporary opening made by omitting bricks or blocks in the inlet. A yard drain inlet or an inlet in the median strip of a dual highway would use the inlet opening for an outlet. A curb inlet would require a temporary opening. The trap should be out of the roadway to avoid interference with construction. Placing the trap on the opposite side of the opening and diverting water from the roadway to the trap is one means of accomplishing this.

Removal

Sediment traps must be removed after the contributing drainage area is stabilized. Plans should show how the site of the sediment trap is to be graded and stabilized after removal.

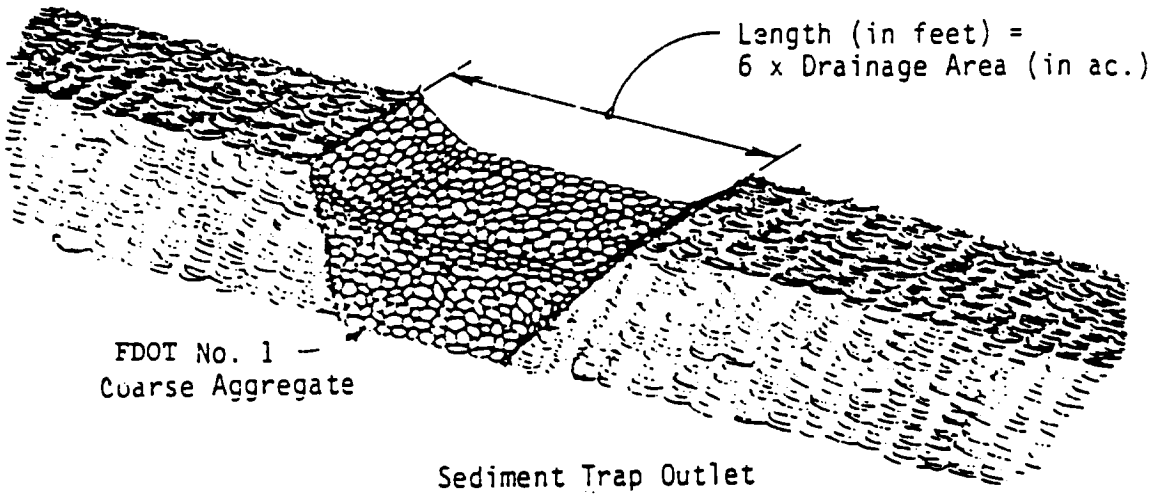
Construction Specifications

1. The area under the embankment shall be cleared, grubbed, and stripped of any vegetation and root mat. To facilitate cleanout, the pool area should be cleared.



2. Fill material for the embankment shall be free of roots or other woody vegetation, organic material, large stones, and other objectionable material. The embankment should be compacted in 8-inch layers by traversing with construction equipment.

3. The earthen embankment shall be seeded with temporary or permanent vegetation (see ES BMP 1.65 and 1.66) within 15 days of construction.



4. Construction operations shall be carried out in such a manner that erosion and water pollution are minimized.

5. The structure shall be removed and the area stabilized when the upslope drainage area has been stabilized.

Maintenance

1. Sediment shall be removed and the trap restored to its original dimensions when the sediment has accumulated to 1/2 the design volume of the trap. Sediment removed from the basin shall be desposited in a suitable area and in such a manner that it will not erode.

2. The structure should be checked regularly to insure that it is structurally sound and has not been damaged by erosion or construction equipment. The height of the outlet should be checked to ensure that its center is at least one foot below the top of the embankment.

R0071387

ES BMP 1.26

TEMPORARY SEDIMENT BASIN

Definition

A temporary basin with a controlled stormwater release structure, formed by constructing an embankment of compacted soil across a drainageway.

Purpose

To detain sediment-laden runoff from disturbed areas long enough for the majority of the sediment to settle out.

Conditions Where Practice Applies

Below disturbed areas greater than 5 acres. There must be sufficient space and appropriate topography for the construction of a temporary impoundment. These structures are limited to a useful life of 18 months unless they are designed as permanent ponds by a qualified professional engineer.

R0071388

Planning Considerations

Effectiveness

Sediment basins are at best only 70-80% effective in trapping sediment which flows into them. Therefore, they should be used in conjunction with erosion control practices such as temporary seeding, mulching, diversion dikes, etc. to reduce the amount of sediment flowing into the basin.

Location

To improve the effectiveness of the basin, it should be located so as to intercept the largest possible amount of runoff from the disturbed area. The best locations are generally low areas and natural drainageways below disturbed areas. Drainage into the basin can be improved by the use of diversion dikes and ditches. The basin must not be located in a live stream but should be located to trap sediment-laden runoff before it enters the stream. The basin should not be located where its failure would result in the loss of life or interruption of the use or service of public utilities or roads.

Multiple Use

Sediment basins may be designed as permanent structures to remain in place after construction is completed. The Stormwater Rule (Ch. 17-25, F.A.C.) makes the use of these structures desirable for stormwater detention purposes. Wherever these structures are to become permanent, or if they exceed the size limitations of the design criteria, they must be designed as permanent ponds by a qualified professional engineer. Permanent ponds are beyond the scope of these ES BMP.

Design Criteria

Maximum Drainage Area

Unless the structure is designed as a permanent pond by a qualified professional engineer, the maximum allowable drainage area into the basin shall be 150 acres.

Basin Capacity

The design capacity of the basin must be at least 67 cubic yards per acre of drainage area, measured from the bottom of the basin to the crest of the principal spillway (riser pipe). Sediment should be removed from the basin when the volume of the basin has been reduced to 27 cubic yards per acre of drainage area. In no case shall the sediment cleanout level be higher than one foot below the top of the riser. The elevation of the sediment cleanout level should be calculated and clearly marked on the riser. (See Plate 1.26a).

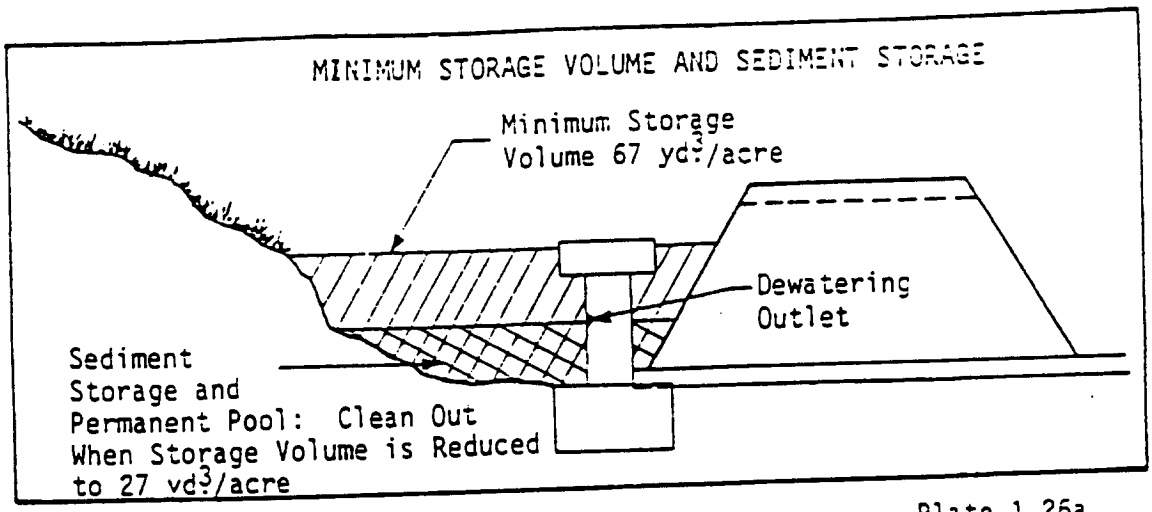

Plate 1.26a

Source: VaSWCC

Basin Shape

To improve sediment trapping efficiency of the basin, the effective flow length must be twice the effective flow width. This basin shape may be attained by properly selecting the site of the basin, by excavation, or by the use of baffles. See Appendix 1.26A for design details.

Embankment Cross-Section

The embankment must have a minimum top width of 8 feet. The side slopes must be 2:1 or flatter. The embankment may have a maximum height of 10 feet if the side slopes are 2:1. If the side slopes are 2.5:1 or flatter, the embankment may have a maximum height of 15 feet.

Spillway Design

The outlets for the basin may consist of a combination of principal and emergency spillways or a principal spillway alone. In either case, the outlet(s) must pass the peak runoff expected from the drainage area for a 10-year storm without damage to the embankment of the basin. Runoff computations shall be based upon the soil cover conditions which are expected to prevail during the life of the basin. Refer to Chapter 5 of this manual for calculation of the peak rate of runoff.

The spillways designed by the procedures contained in this ES BMP will not necessarily result in any reduction in the peak rate of runoff. If a reduction in peak runoff is desired, the appropriate hydrographs should be generated to choose the basin and outlet sizes.

To increase the efficiency of the basin, the spillway(s) must be designed to maintain a permanent pool of water between storm events.

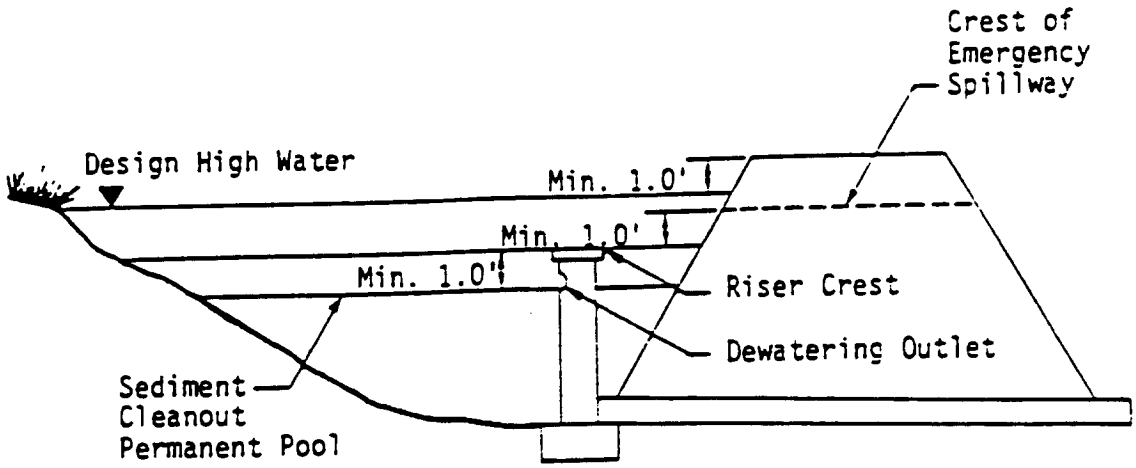
Principal Spillway

The principal spillway shall consist of a solid (non-perforated), vertical pipe or box of corrugated metal or reinforced concrete joined by a watertight connection to a horizontal pipe (barrel) extending through the embankment and outletting beyond the downstream toe of the fill. If the principal spillway is used in conjunction with an emergency spillway, the principal spillway shall have a minimum capacity of 0.2 cfs per acre of drainage area when the water surface is at the crest of the emergency spillway. If no emergency spillway is used, the principal spillway must be designed to pass the entire peak flow expected from a 10-year storm. See Appendix 1.26A for design details.

Design Elevations - If the principal spillway is used in conjunction with an emergency spillway, the crest of the principal spillway shall be a minimum of 1.0 foot below the crest of the emergency spillway. If no emergency spillway is used, the crest of the principal spillway shall be a minimum of 3 feet below the top of the embankment. (See Plate 1.26b.) In either case, a minimum freeboard of 1.0 foot shall be provided between the design high water and the top of the embankment.

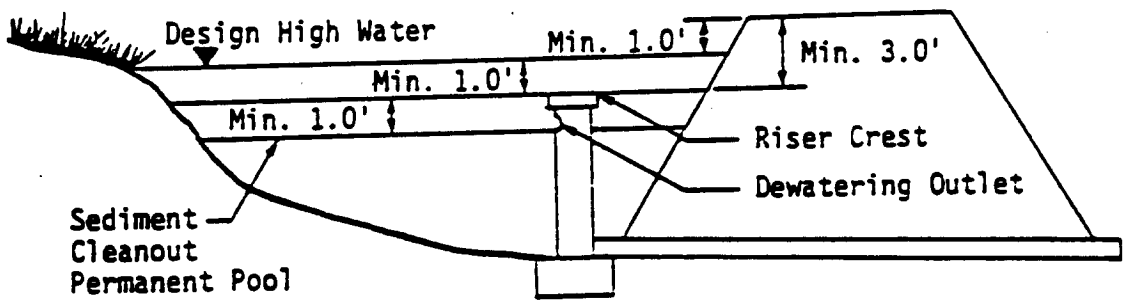
Anti-vortex device and trash rack - An anti-vortex device and trash rack shall be attached to the top of the principal spillway to improve the flow of water into the spillway and prevent floating debris from being carried out of the basin. The anti-vortex device shall be of the concentric type as shown in Plate 1.26j. See Appendix 1.26A for design procedures for the anti-vortex device and trash rack.

Dewatering - Shall be done in such a manner as to remove the relatively clean water without removing any of the sediment that has settled out and without removing any appreciable quantities of floating debris. As a minimum, provisions shall be made to dewater the basin down to the sediment cleanout elevation. This can be accomplished by providing a hole at the maximum sediment retention elevation (See Plate 1.26o). The dewatering hole shall be no larger than 4 inches in diameter. Other means of automatic dewatering are detailed in Appendix 1.26A.



It is also advantageous (but not required) to provide for dewatering of trapped sediment before cleanout. Basin underdrains are generally installed for this purpose. Appendix 1.26A contains details for the design of an underdrain system.

Base - The base of the principal spillway must be firmly anchored to prevent its floating. If the riser of the spillway is greater than 10 feet in height, computations must be made to determine the anchoring requirements. As a minimum, a factor of safety of 1.25 shall be used (downward forces = 1.25 x upward forces).

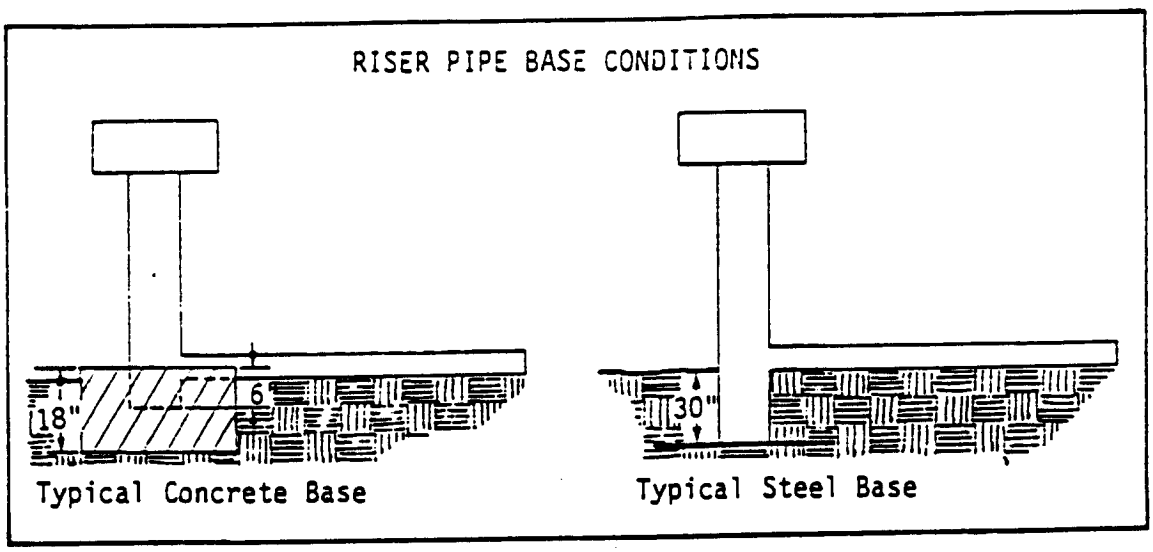


For risers 10 feet or less in height, the anchoring may be done in one of the two following ways:

1. A concrete base 18 inches thick and twice the width of riser diameter shall be used and the riser embedded 6 inches into the concrete. See Plate 1.26c and Appendix 1.26A for design details.

SEDIMENT BASIN SCHEMATIC ELEVATIONS

Design Elevations With Emergency Spillway



Design Elevations Without Emergency Spillway

Source: Va SWCC

Plate 1.26b

R0071392

2. A square steel plate, a minimum of 1/4 inch thick and having a width equal to twice the diameter of the riser, shall be welded to the base of the riser. The plate shall then be covered with 2.5 feet of stone, gravel, or compacted soil to prevent floatation. See Plate 1.26c and Appendix 1.26A for design details.

Source: Va SWCC

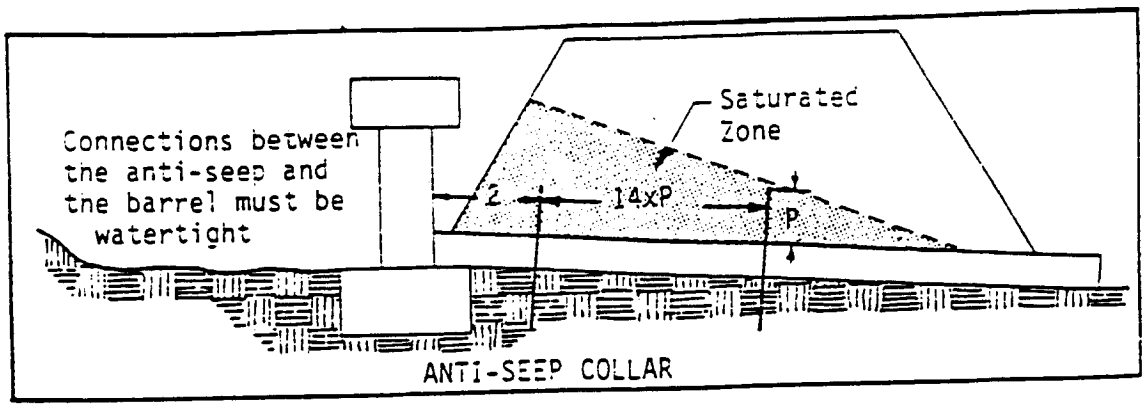


Plate 1.26c

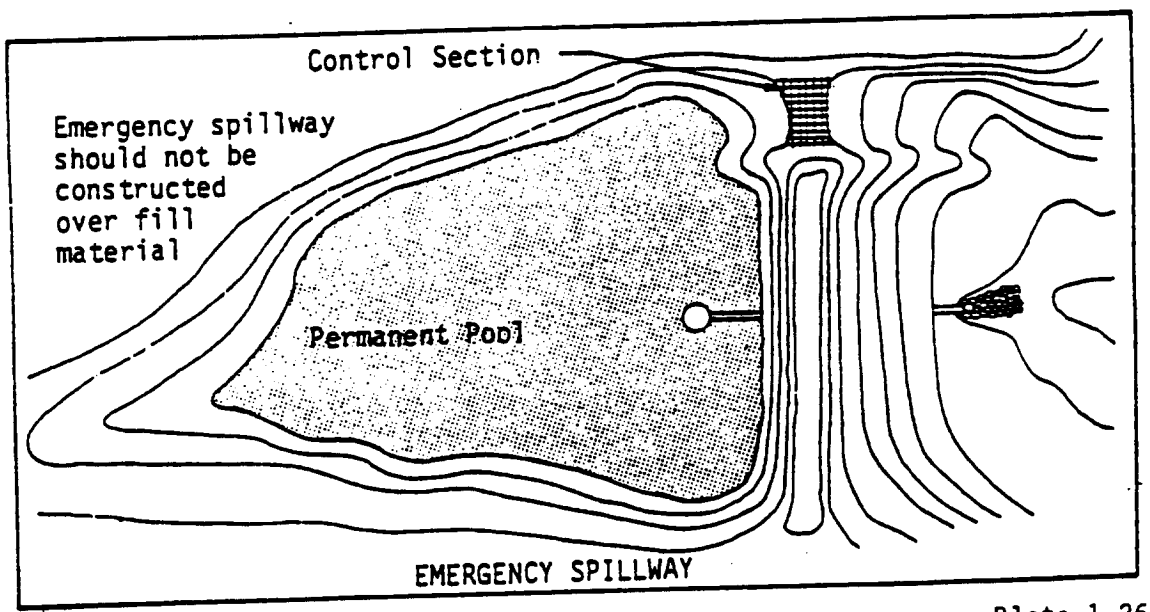
Barrel - The barrel of the principal spillway, which extends through the embankment, shall be designed to carry the flow provided by the riser of the principal spillway with the water level at the crest of the emergency spillway. The connection between the riser and the barrel must be watertight. The outlet of the barrel must be protected to prevent erosion or scour of downstream areas. See Appendix 1.26A for design details.

Anti-seep collars - Anti-seep collars shall be used on the barrel of the principal spillway within the normal saturation zone of the embankment to increase the seepage length by at least 10%, if either of the following two conditions is met:

1. The settled height of the embankment exceeds 10 feet.
2. The embankment has a low silt-clay content (Unified Soil Classes SM or GM) and the barrel is greater than 10 inches in diameter.

The anti-seep collars shall be installed within the saturated zone. The maximum spacing between collars shall be 14 times the projection of the collar above the barrel. Collars shall not be closer than 2 feet to a pipe joint. Collars should be placed sufficiently far apart to allow space for hauling and compacting equipment. Connections between the collars and the barrel shall be watertight. See Plate 1.26d and Appendix 1.26A for design procedure and details.



Source: VA SWCC

Plate 1.26d

Emergency Spillway

The emergency spillway shall consist of an open channel constructed adjacent to the embankment over undisturbed material (not fill). The spillway shall have a control section at least 20 feet in length. The control section is a level portion of the spillway channel at the highest elevation in the channel. See Appendix 1.26A and Plate 1.26e.

Source: Va SWCC

Plate 1.26e

Capacity - The emergency spillway shall be designed to carry the peak rate of runoff expected from a 10-year storm, less any reduction due to the flow through the principal spillway. See Appendix 1.26A for design details.

Design elevations - The design high water through the emergency spillway shall be at least 1.0 foot below the top of the embankment. The crest of the emergency spillway channel shall be at least 1.0 foot above the crest of the principal spillway.

Location - The emergency spillway channel shall be located so that it will not be constructed over fill material. The channel shall be located so as to avoid sharp turns or bends. The channel shall return the flow of water to a defined channel downstream from the embankment.

Maximum velocities - The maximum allowable velocity in the emergency spillway channel will depend upon the type of lining used. For vegetated linings, allowable velocities are listed in Table 1.35a (STORMWATER CONVEYANCE CHANNEL, ES BMP 1.35). For non-erodible linings, such as concrete or asphalt paving and riprap, design velocities may be increased. However, the emergency spillway channel shall return the flow to the natural channel at a non-eroding velocity. See Appendix 1.26A for design details.

Stabilization of the Embankment and Basin

The embankment of the sediment basin shall be temporarily seeded within 15 days after its completion (see TEMPORARY SEEDING, ES BMP 1.65). If excavation is required in the basin, side slopes should not be steeper than 2:1.

Disposal

Cleanout - Sediment shall be removed from the basin when the capacity is reduced to 27 cubic yards per acre of drainage area. Plans for the sediment basin shall indicate the methods for disposing of sediment removed from the basin. Possible alternatives are the use of the material in fill areas on-site or removal to an approved off-site dump.

Final removal - Sediment basin plans shall indicate the final disposition of the sediment basin after the upstream drainage area is stabilized. The plans shall indicate methods for the removal of excess water lying over the sediment, stabilization of the basin site, and the disposal of any excess material. Sediment shall not be flushed into the stream or drainageway.

Safety

Sediment basins are attractive to children and can be very dangerous. Therefore, they should be fenced or otherwise made inaccessible to persons or animals unless this is deemed unnecessary due to the remoteness of the site or other circumstances. Strategically placed signs around the impoundment reading "DANGER-QUICKSAND" should also be installed. In any case, local ordinances and regulations regarding health and safety must be adhered to.

Construction Specifications

Site Preparation

Areas under the embankment and any structural works shall be cleared, grubbed, and stripped of topsoil to remove trees, vegetation, roots, or other objectionable material. In order to facilitate cleanout and restoration, the pool area (measured at the top of the principal spillway) will be cleared of all brush and trees.

Cutoff Trench

For earth fill embankments, a cutoff trench shall be excavated along the centerline of the dam. The minimum depth shall be 2 feet. The cutoff trench shall extend up both abutments to the riser crest elevation. The minimum bottom width shall be 4 feet, but wide enough to permit operation of compaction equipment. The side slopes shall be no steeper than 1:1.

Compaction requirements shall be the same as those for the embankment. The trench shall be drained during the backfilling-compacting operations.

Embankment

The fill material shall be taken from approved borrow areas. It shall be clean mineral soil, free of roots, woody vegetation, oversized stones, rocks, or other objectionable material. Areas on which fill is to be placed shall be scarified prior to placement of fill. The fill material should contain sufficient moisture so that it can be formed by hand into a ball without crumbling. If water can be squeezed out of the ball, it is too wet for proper compaction. Fill material will be placed in 6-to-8-inch continuous layers over the entire length of the fill. Compaction shall be obtained by routing the hauling equipment over the fill so that the entire surface of the fill is traversed by at least one wheel or tread track of the equipment, or by using a compactor. The embankment shall be constructed to an elevation 10% higher than the design height to allow for settlement if compaction is obtained with hauling equipment. If compactors are used for compaction, the overbuild may be reduced to not less than 5%.

Principal Spillway

The riser of the principal spillway shall be securely attached to the barrel by a watertight connection. The barrel and riser shall be placed on a firm compacted soil foundation. The base of the riser shall be firmly anchored according to design criteria to prevent its floating. Pervious material such as sand, gravel or crushed stone shall not be used as backfill around the barrel or anti-seep collars. Fill material shall be placed around the pipe in 4-inch layers and compacted by hand at least to the same density as the embankment. A minimum of two feet of fill shall be hand-compacted over the barrel before crossing it with construction equipment.

Emergency Spillway

The emergency spillway should not be constructed over fill material. Design elevations, widths, entrance and exit channel slopes are critical to the successful operation of the spillway and should be adhered to closely during construction.

Vegetative Stabilization

The embankment and emergency spillway of the sediment basin shall be stabilized with temporary vegetation within 15 days of completion of the basin (see TEMPORARY SEEDING, ES BMP 1.65).

Erosion and Sediment Control

The construction of the sediment basin shall be carried out in a manner such that erosion and water pollution are minimized downstream.

Safety

All state and local requirements shall be met concerning fencing and signs warning the public of the hazards of soft sediment and flood waters.

Final Disposal

When temporary structures have served their intended purpose and the contributing drainage area has been properly stabilized, the embankment and resulting sediment deposits are to be leveled or otherwise disposed of in accordance with the approved pollution control plan.

Maintenance

The embankment of the basin should be checked regularly to ensure that it is structurally sound and has not been damaged by erosion or construction equipment.

The emergency spillway should be checked regularly to ensure that its lining is well established and erosion-resistant.

The basin should be checked after each runoff-producing rainfall for sediment cleanout. When the sediment reaches the cleanout level, it shall be removed and properly disposed of.

Information to be Submitted for Approval

Sediment Basin designs and construction plans submitted for review to the appropriate regulatory agency shall include:

A. Specific location of the dam.
B. Plan view of dam, storage basin and emergency spillway.
C. Cross section of dam, principal spillway and emergency spillway; profile of emergency spillway.
D. Details of pipe connections, riser to pipe connection, riser base, anti-seep collars, trash rack and anti-vortex device.
E. Runoff calculations for 10-year frequency storm.
F. Storage Computations
    1. Total required
    2. Total available
    3. Level of sediment at which cleanout shall be required; to be stated as a distance from the riser crest to the sediment surface.
G. Calculations showing design of pipe and emergency spillway.

NOTE: Items E through G above may be submitted using the design data sheet in the Appendix.

APPENDIX 1.26A

Design Procedure for Temporary Sediment Basin

The following design procedure provides a step-by-step method for the design of a temporary sediment basin. The data sheet found in the back of this Appendix should be used in the erosion and sediment control plan to outline design values calculated.

I. Basin Volume

A. Determine the required basin volume. A volume of 67 $yd.^3$, measured from the ground surface to the crest of the principal spillway, is required for each acre draining into the basin. The volume of a naturally shaped basin may be approximated by the equation:

$$V = 0.4 \times A \times D$$

where,

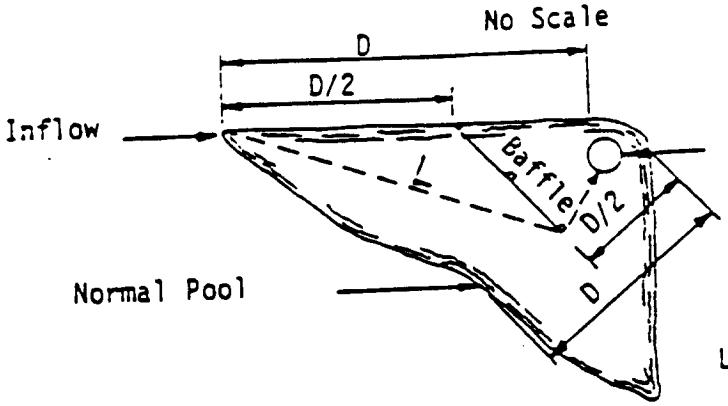
V = the storage volume in $ft.^3$
A = the surface area flooded, with the water level at the crest of the principal spillway.
D = the depth of the basin measured from the ground surface to the crest of the principal spillway.

The volume may also be computed from contour information or other suitable methods.

B. If the volume of the basin is inadequate, excavate to obtain the required volume.

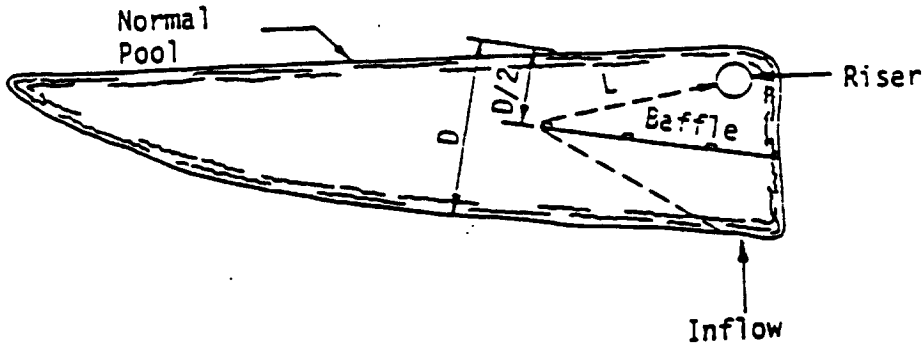
II. Basin Shape

A. The shape of the basin must be such that the length-to-width ratio is at least 2 to 1 according to the following equation:

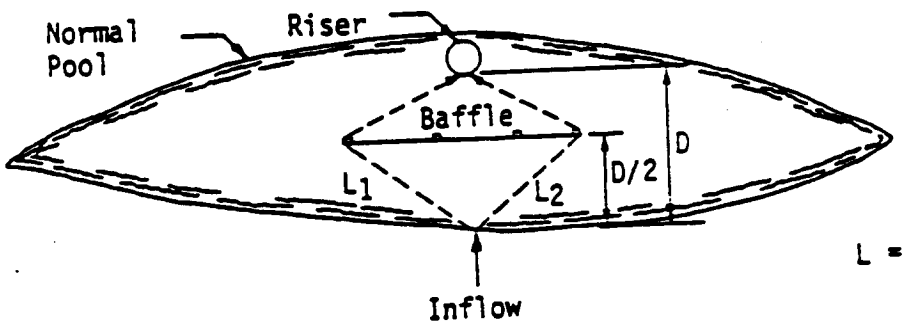


$$\text{Length-to-width ratio} = \frac{L}{We}$$

where,



We = the effective width (A/L).
A = the surface area of the normal pool.
L = the length of the flow path from the inflow to the outflow. If there is more than one inflow point, any inflow which carries more than 30% of the peak rate of inflow must meet these criteria.



EXAMPLE PLAN VIEWS OF BAFFLE LOCATIONS IN SEDIMENT BASINS

No Scale

L = Total distance from the point of inflow around the baffle to the riser.

$L = L_1 + L_2$

Baffle Detail

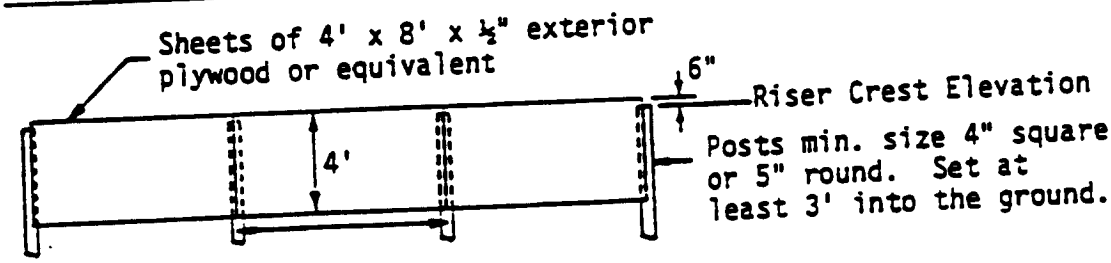


Plate 1.26f

Source: USDA-SCS

B. The correct basin shape can be obtained by proper site selection, excavation, or the use of baffles. Baffles increase the flow length by deflecting the flow. The baffles should be placed halfway between the inflow point and the outflow. Plate 1.26f shows the detail for baffle construction and three situations where baffles might be used.

III. Determine whether the basin will have an emergency spillway.

IV. Determine the elevation of the crest of the principal spillway for the required volume.

V. Estimate the elevation of the design high water and the required height of the dam.

A. If an emergency spillway is included, the crest of the principal spillway must be at least 1.0 foot below the crest of the emergency spillway.

B. The elevation of the flow through the emergency spillway (which will be the design high water) must be at least 1.0 foot below the top of the embankment.

C. If an emergency spillway is not included, the crest of the principal spillway must be at least 3 feet below the top of the embankment.

D. The elevation of the design high water must be 1.0 foot below the top of the embankment.

VI. From Chapter 5 of this manual determine the peak rate of runoff expected from the drainage area of the basin for a ten-year storm.

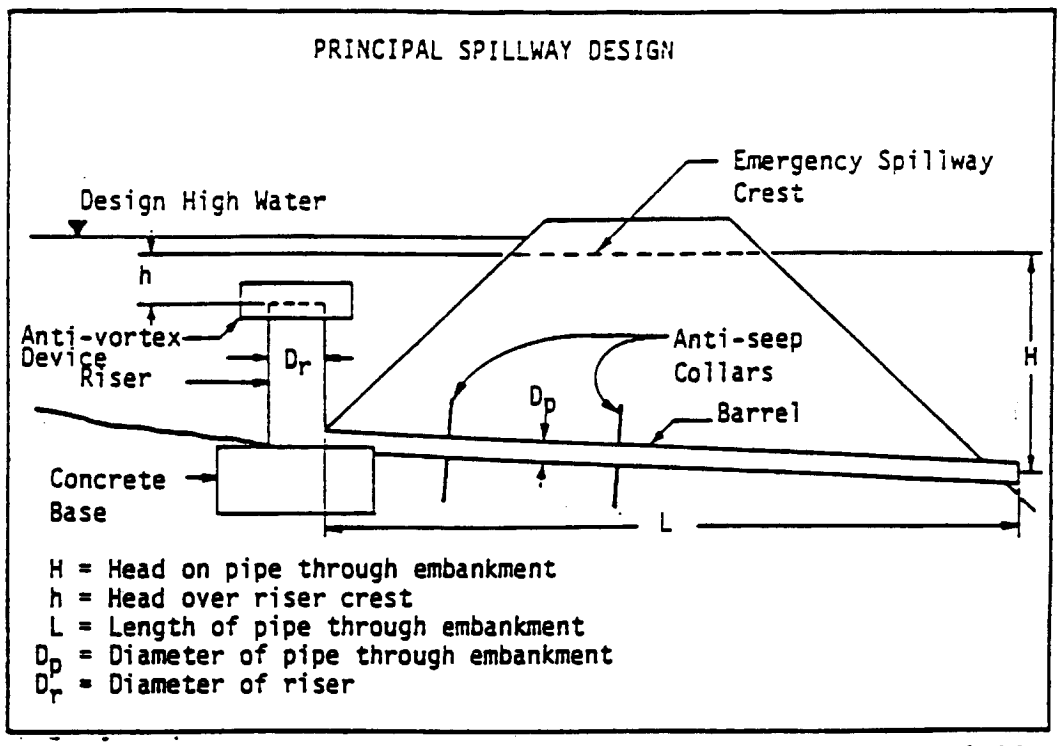
VII. Principal Spillway Design

A. If an emergency spillway is included, the principal spillway must pass a minimum of 0.2 cfs/acre of drainage area.

1. Compute, Q_p = 0.2 x drainage area, the peak rate of runoff the principal spillway must pass.

B. If an emergency spillway is not included, the principal spillway must pass the peak rate of runoff from the basin drainage area for a 10-year storm.

1. Q_p = the 10-year peak rate of runoff.



C. Refer to Plate 1.26g, where h is the difference between the elevation of the crest of the principal spillway and the elevation of the crest of the emergency spillway.

R0071400

D. Enter Plate 1.26h with Q_p. Choose the smallest riser which will pass the required flow with the available head, h.

E. Refer to Plate 1.26g, where H is the difference in elevation of the centerline of the outlet of the barrel and the crest of the emergency spillway. L is the length of the barrel through the embankment.

F. Enter Table 1.26a or Table 1.26b with H. Choose the smallest-size barrel which will pass the flow provided by the riser. If L is other than 70 ft., make the necessary correction.

Source: Va SWCC Plate 1.26g

VIII. Emergency Spillway Design

A. The emergency spillway must pass the remainder of the 10-year peak runoff not carried by the principal spillway.

B. Compute, $Q_e = Q_{10} - Q_p$.

C. Refer to Plate 1.26i and Table 1.26c.

D. Determine approximate permissible values for b, the bottom width; s, the slope of the exit channel; and X, minimum length of the exit channel.

E. Enter Table 1.26c and choose a channel cross-section which passes the required flow and meets the other constraints of the site.

Source: USDA-SCS

Plate 1.26i

R0071405

F. Note:

1. Maximum permissible velocity for vegetated waterways is 6 ft./sec.
2. For a given H_p, a decrease in the exit slope from S as given in the table decreases spillway discharge but increasing the exit slope from S does not increase discharge. If an exit slope (S_e) steeper than S is used, the velocity (V_e) in the exit channel will increase according to the following relationship:

$$V_e = \frac{V(S_e)^{0.3}}{S}$$

3. Data to right of heavy vertical lines should be used with caution, as the resulting sections will be either poorly proportioned or have velocities in excess of 6 ft./sec.

IX. Re-estimate the elevation of the design high water and the top of the dam based upon the design of the principal spillway and the emergency spillway.

X. Anti-vortex device and trash rack.

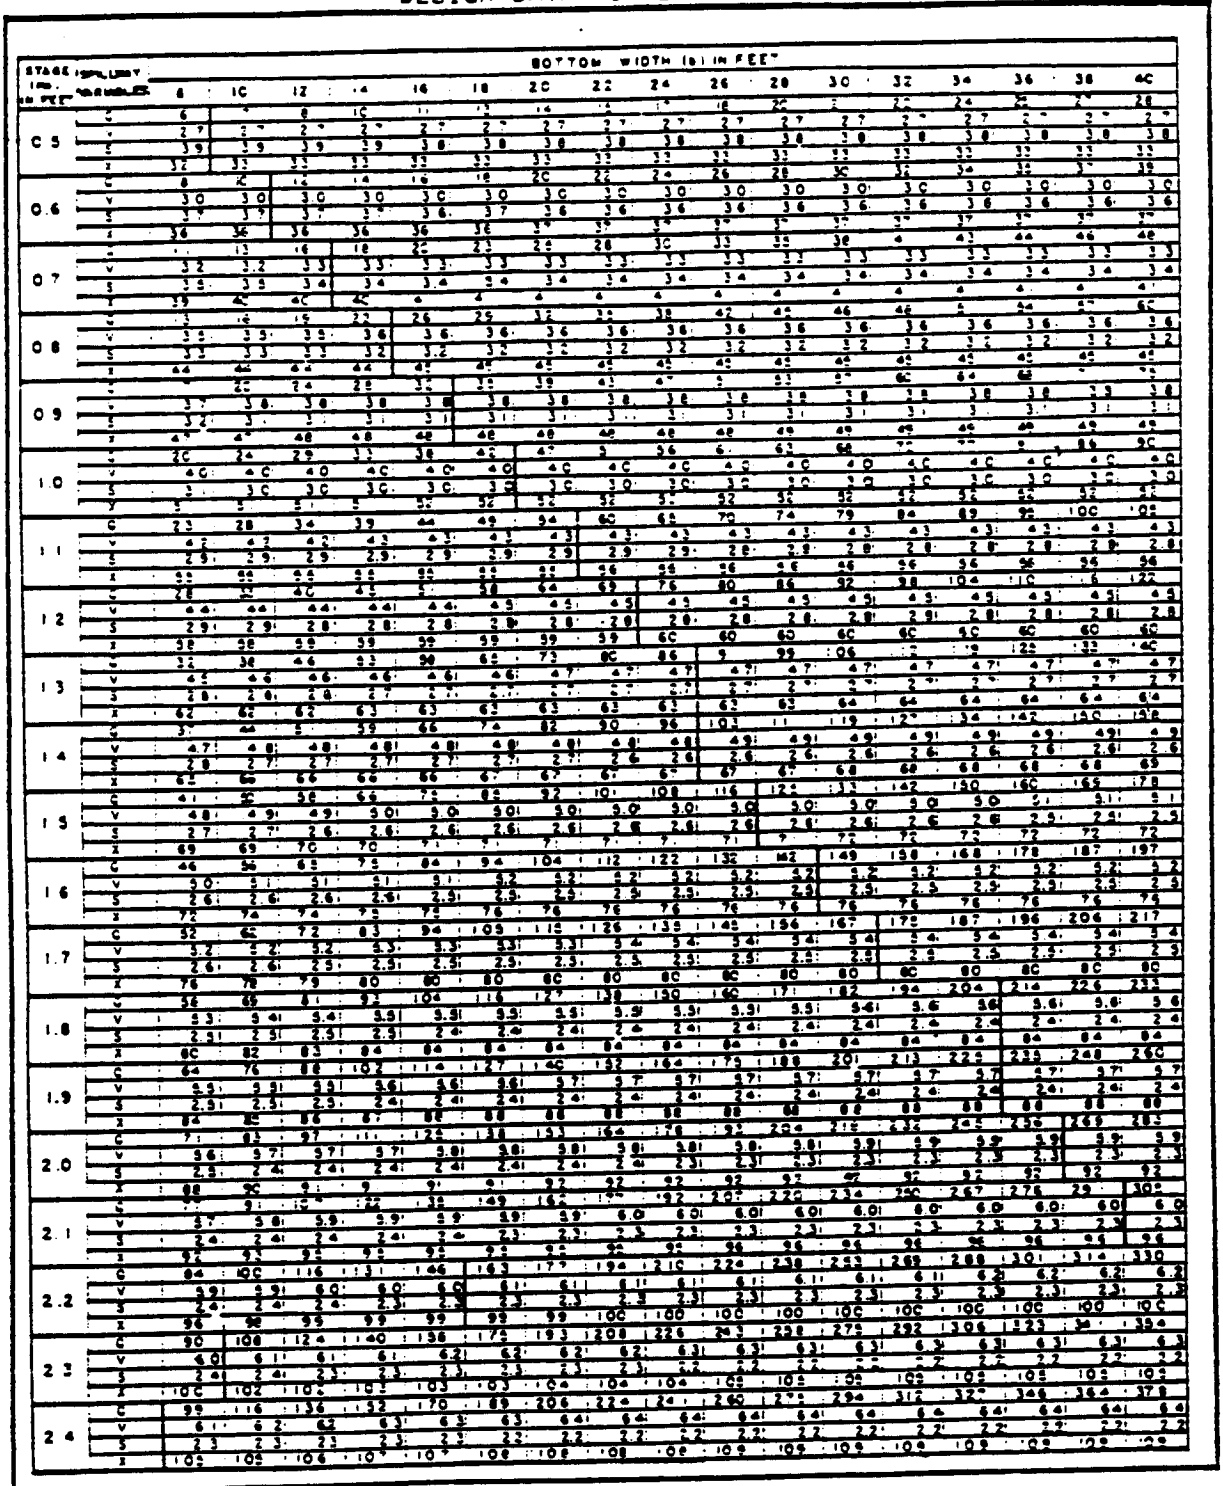
A. This design procedure refers only to riser pipes of corrugated metal.

B. Refer to Plate 1.26j and Table 1.26d. Choose cylinder size, support bars, and top requirements from Plate 1.26p based on the diameter of the riser pipe.

XI. Anti-seep collars.

A. Anti-seep collars must be used under the conditions specified in the Design Criteria.

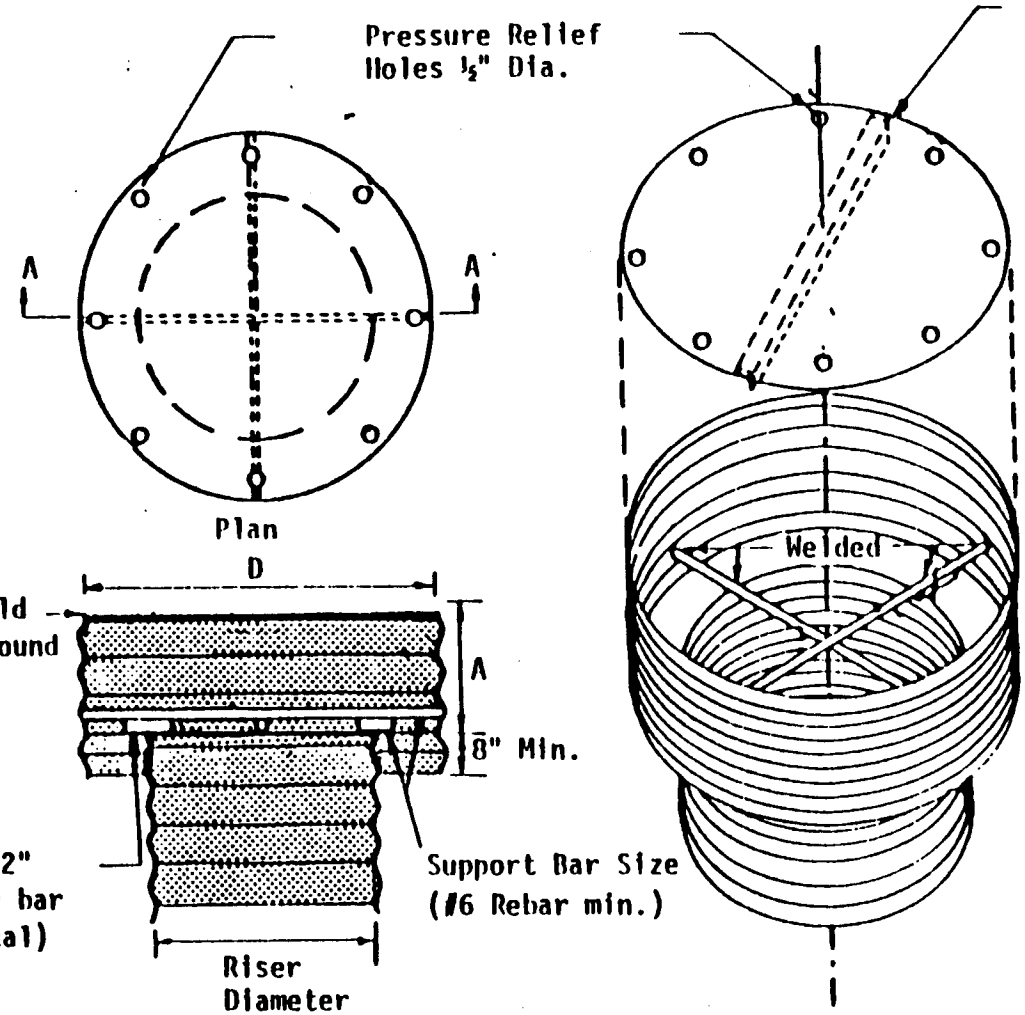
B. Anti-seep collars are used to increase the seepage length along the barrel by 10%.



C. Determine the length of the barrel within the saturated zone. This may be done graphically as in Plate 1.26k or by solving the following equation:

$$L_S = Y\ (Z + 4)\ \left(1 + \frac{S}{0.25 - S}\right)$$

where,



L_S = length of barrel in the saturated zone, feet.
Y = the depth of water at the principal spillway crest, feet.
Z = slope of the upstream face of the embankment in Z feet horizontal to one vertical.
S = slope of the barrel in feet per foot.

Table 1.26c
DESIGN DATA FOR EARTH SPILLWAYS

Source: USDA-SCS

Source: USDA-SCS

Top stiffener (if required) is ___x___x___ angle welded to top and oriented perpendicular to corrugations.

Top is ___ gage corrugated metal or 1/8" steel plate. Pressure relief holes may be omitted, if ends of corrugations are left fully open when the top is attached.

Cylinder is ___gage corrugated metal pipe or fabricated from 1/8" steel plate.

Notes:
1. The cylinder must be firmly fastened to the top of the riser.
2. Support bars are welded to the top of the riser or attached by straps bolted to top of riser

ANTI - VORTEX DEVICE DESIGN

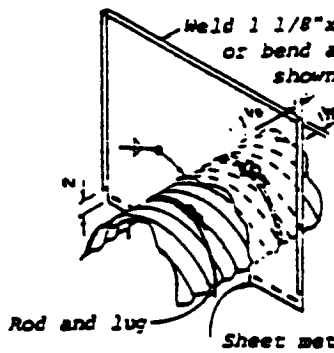
ELEVATION OF UNASSEMBLED COLLAR

SECTION E-E

NOTES FOR COLLARS:

1. All materials to be in accordance with construction and construction material specifications.
2. When specified on the plans, coating of collars shall be in accordance with construction and construction material specifications.
3. Unassembled collars shall be marked by painting or tagging to identify matching pairs.
4. The lap between the two half sections and between the pipe and connecting band shall be caulked with asphalt mastic at time of installation.
5. Each collar shall be furnished with two 1/2" diameter rods with standard tank lugs for connecting collars to pipe.



DETAILS OF CORRUGATED METAL ANTI-SEEP COLLAR

Size and spacing of slotted openings shall be the same as shown for CM collar

Use rods and lugs to clamp bands securely to pipe

PARTIAL ELEVATION

NOTE FOR BANDS AND COLLARS: Modifications of the details shown may be used providing equal watertightness is maintained and detailed drawings are submitted and approved by the Engineer prior to delivery.

Sheet metal collar shall be cut to fit corrugations of helical band, and welded with a continuous weld.

ISOMETRIC VIEW

NOTE: For details of fabrication dimensions, minimum gages, slotted holes, and notes, see detail above.

DETAILS OF HELICAL PIPE ANTI-SEEP COLLAR

NOTE: Two other types of anti-seep collars are:

1. Corrugated metal, similar to upper detail, except shop welded to a short (4 ft.) section of the pipe and connected with connecting bands to the pipe.
2. Concrete, six inches thick formed around the pipe with #3 rebar spaced 15" horizontally and vertically.

Ref: Engr. Field Manual

Source: USDA-SCS

Plate 1.26m

R0071412

D. Enter Plate 1.26l with L_s. Move horizontally right until one of the lines is intersected. Move vertically until the correct line for barrel diameter is intersected. Move horizontally right to read P, the size of the anti-seep collar.

E. If more than one collar is used, the spacing between collars should be 14 times the projection of the collar above the barrel.

F. Collars should not be located closer than 2 feet to a pipe joint.

G. See Plate 1.26m for details of the anti-seep collar.

XII. Anchoring the Principal Spillway

A. The principal spillway must be firmly anchored to prevent its floating.

B. If the riser is over 10 feet in height, the forces acting on the spillway must be calculated. A method of anchoring the spillway which provides a safety factor of 1.25 must be used (downward forces = 1.25 x upward forces).

C. If the riser is 10 feet or less in height, choose one of the two methods in Plate 1.25n to anchor the principal spillway.

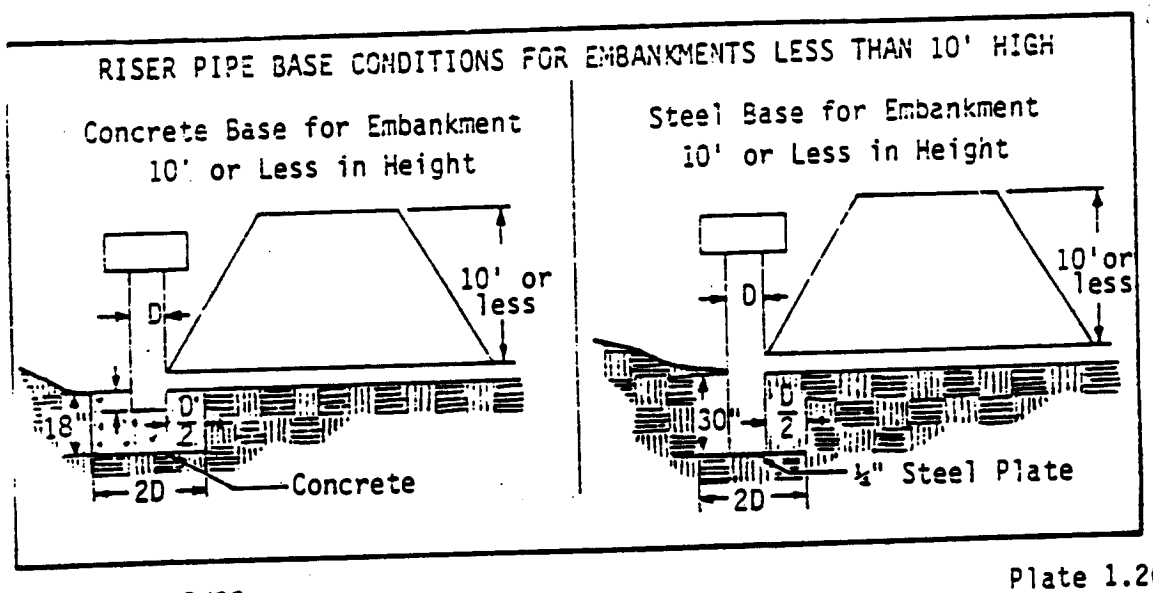


Plate 1.26n

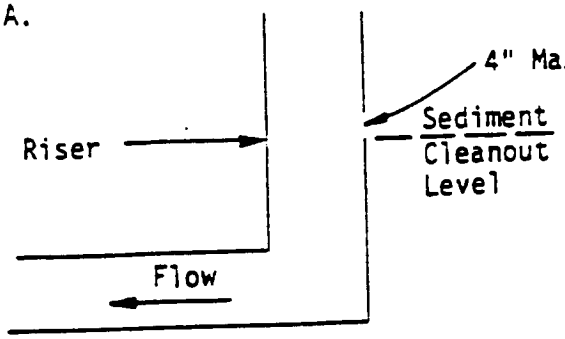
Source: Va SWCC

XIII. Dewatering

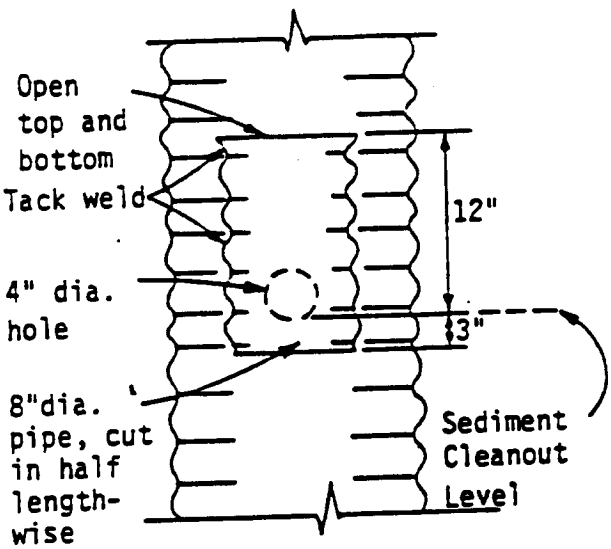


A. Refer to Plates 1.26o-1.26p. Choose one method to dewater the basin. Plate 1.26o shows methods to dewater the basin down to the sediment cleanout level. Plate 1.26p shows a method to dewater the sediment.

METHODS OF DEWATERING SEDIMENT BASIN DETENTION POOLS

Methods

Comments



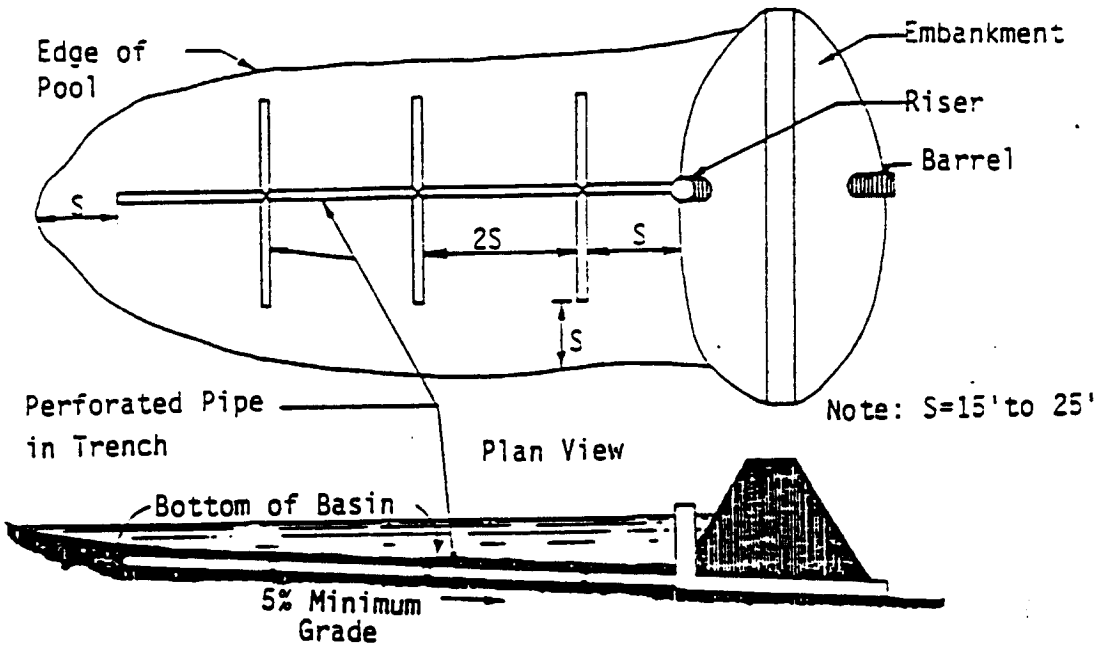
A.

Cross-Section

Easy to construct
May clog with trash
Non-skimming
Capable of draining down to sediment clean-out level
Passes base flow with-out storage of water

B. Same as "A" except for skimming device, detailed below:

Elevation



Efficient skimmer
Non-clogging
Fairly easy to construct
Capable of draining down to sediment clean-out level
Passes base flow without storage of water

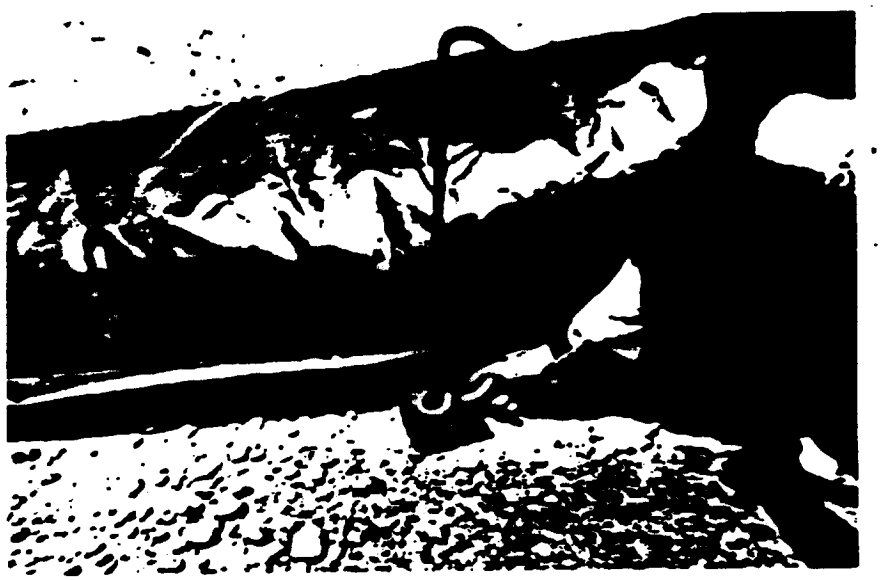
R0071416

ES BMP 1.30

TEMPORARY SLOPE DRAIN

Definition



A flexible tubing or conduit extending from the top to the bottom of a cut or fill slope.

Purpose

To temporarily conduct concentrated stormwater runoff safely down the face of a cut or fill slope without causing erosion problems on or below the slope.

Conditions Where Practice Applies

On cut or fill slopes before permanent stormwater drainage structures are installed.

R0071417

Planning Considerations

There is often a significant lag between the time a cut or fill slope is completed and the time a permanent drainage system can be installed. During this period, the slope is usually not stabilized and is particularly vulnerable to erosion. This situation also occurs on slope construction which is temporarily delayed before final grade is reached. Temporary slope drains can provide valuable protection of exposed slopes until permanent drainage structures can be installed.

When used in conjunction with diversion dikes, temporary slope drains can be used to convey stormwater from the entire drainage area above a slope to the base of the slope without erosion. It is very important that these temporary structures be installed properly since their failure will often result in severe gully erosion. The entrance section must be securely entrenched, all connections must be watertight, and the conduit must be staked securely.

Design Criteria

Drainage Area

The maximum allowable drainage area per drain is 5 acres.

Flexible Conduit

1. The slope drain shall consist of heavy duty flexible material designed for this purpose. The diameter of the slope drain shall be equal over its entire length. Reinforced hold-down grommets shall be spaced at 10-foot (or less) intervals.

2. Slope drains shall be sized according to the following table:

Table 1.30a

SIZE OF SLOPE DRAIN

Maximum Drainage Area (Acres)	Pipe Diameter, D (in.)
0.5	12
1.5	18
2.5	21
3.5	24
5.0	30

Source: Va SWCC

Entrance Sections

The entrance to the slope drain shall consist of a Standard FDOT "Flared End- Section for Metal Pipe Culverts." Extension collars shall consist of 12-inch long corrugated metal pipe. Watertight fittings shall be provided. (See Plate 1.30b).

Dike Design

1. An earthen dike shall be used to direct stormwater runoff into the temporary slope drain and shall be constructed according to the practice entitled DIVERSION (ES BMP 1.18). (Plate 1.30a).

2. The height of the dike at the centerline of the inlet shall be equal to the diameter of the pipe (D) plus 6 inches. Where the dike height is greater than 18 inches at the inlet, it shall be sloped at the rate of 3:1 or flatter to connect with the remainder of the dike. (Plate 1.30a).

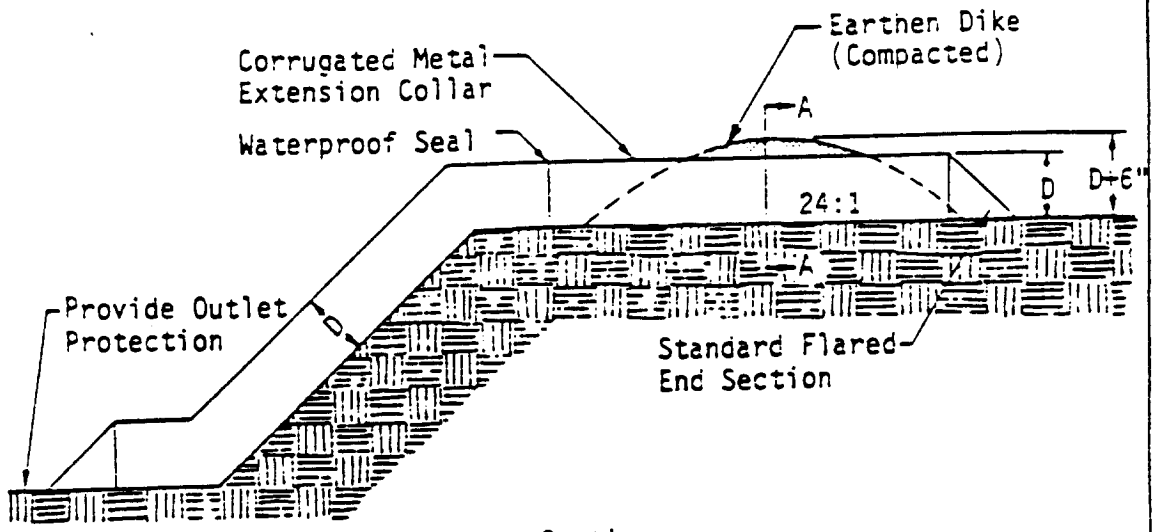
Outlet Protection

The outlet of the slope drain shall be protected from erosion according to the practice entitled OUTLET PROTECTION (ES BMP 1.36).

Construction Specifications

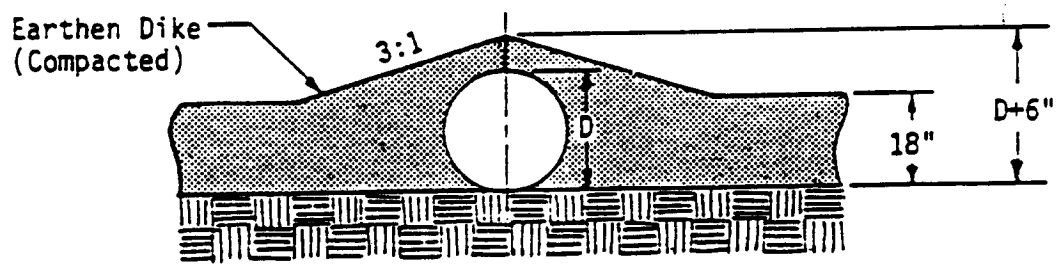
1. The measure shall be placed on undisturbed soil or well-compacted fill.

2. The entrance section shall slope toward the slope drain at the minimum rate of 1/2-inch per foot.



3. The soil around and under the entrance section shall be hand-tamped in 8-inch lifts to the top of the dike to prevent piping failure around the inlet.

4. The slope drain shall be securely staked to the slope at the grommets provided.



5. The slope drain sections shall be securely fastened together and have watertight fittings.

Maintenance

The slope drain structure shall be inspected weekly and after every storm and repairs made if necessary. The contractor should avoid the placement of any material on and prevent construction traffic across the slope drain.

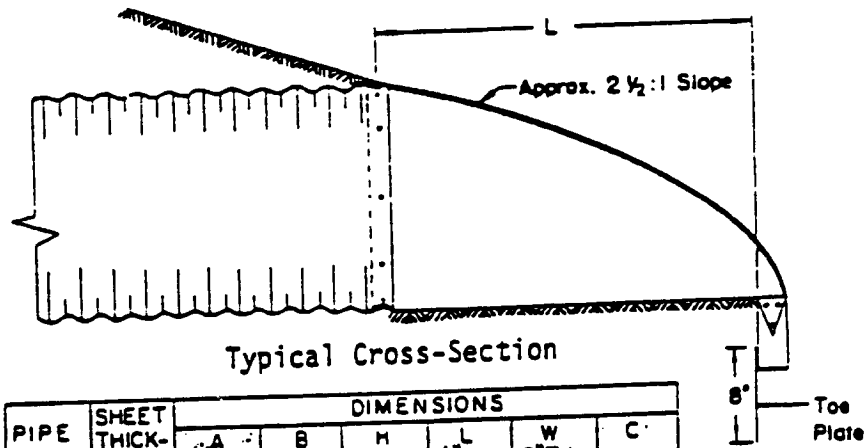
Alternate Connection



Toe plate, where needed, to be punched to match holes in skirt lip. 3/8" galv bolts to be furnished. Length of toe plate is W + 10" for 12" to 30" dia. pipe and W + 22" for 36" to 60" dia. pipe.

Skirt Section for 12" to 30" dia pipe to be made in one piece.

Skirt Section for 36" to 54" dia pipe may be made from two sheets joined by riveting or bolting on center line. 60" may be constructed in 3 pieces.

Connector Section, Corner Plate and Toe Plate to be same sheet thickness as skirt.

End-sections and fittings are to be galvanized steel or aluminum alloy for use with like pipe.

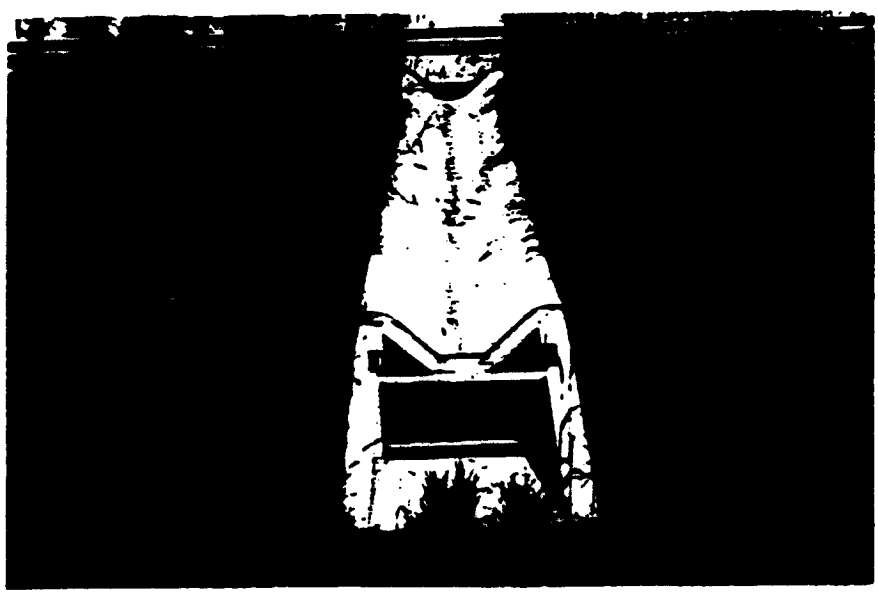
ES BMP 1.31

PAVED FLUME

Definition



A permanent concrete-lined channel constructed on a slope.

Purpose

To conduct stormwater runoff safely down the face of a slope without causing erosion problems on or below the slope.

Conditions Where Practice Applies

Wherever concentrated stormwater runoff must be conveyed from the top to the bottom of cut or fill slopes on a permanent basis.

R0071423

Planning Considerations

Paved flumes are used routinely on highway cuts and fills to convey concentrated stormwater runoff from the top to the bottom of a slope without erosion. The Virginia Department of Highways and Transportation (VDH&T) has developed standards and specifications for these structures. Fortunately these structures have equal applicability to cut and fill slopes for construction projects other than highways.

Design Criteria

Design criteria and construction specifications contained herein are extracted and summarized from the following VDH&T publications:

Road Designs and Standards (76)
Road and Bridge Specifications (75)
Drainage Manual (73)

Handbook users should refer to the above publications for additional information or clarification if needed.

Capacity

Paved flumes shall be capable of passing the peak flow expected from a 10-year frequency storm.

Cross-Sections

Plate 1.31a illustrates a typical trapezoidal cross-section of a VDH&T "Standard Paved Flume (PG-4)." Where additional flow capacity is required, larger trapezoidal cross-sections may be designed. The following criteria apply to all trapezoidal flume designs:

1. The maximum slope of the structure shall be 1.5:1 (67%).

2. Curtain Walls shall be provided at the beginning and end of all paved flumes not abutted to another structure. The curtain wall shall be as wide as the flume channel, extend at least 18 inches into the soil below the channel, and have a thickness of 6 inches. Curtain walls shall be reinforced with #4 reinforcing steel bars placed on 6-inch centers. (See Plate 1.31a).

R0071424

3. Anchor Lugs shall be spaced at a maximum of 10 feet on center for the length of the flume. Where no curtain wall is required, an anchor lug shall be constructed within 2 feet of the end of the flume. Anchor lugs are to be as wide as the bottom of the flume channel, extend at least 1 foot into the soil below the channel, and have a thickness of 6 inches. Anchor lugs shall be reinforced with #4 reinforcing steel bars placed on 4-inch centers. (See Plate 1.31a).

4. The flume channel shall have at least a 4-inch thickness of class A-3 concrete with welded wire fabric (6 x 6 - W2.1 x W2.1) in the center for reinforcement. (See Plate 1.31a).

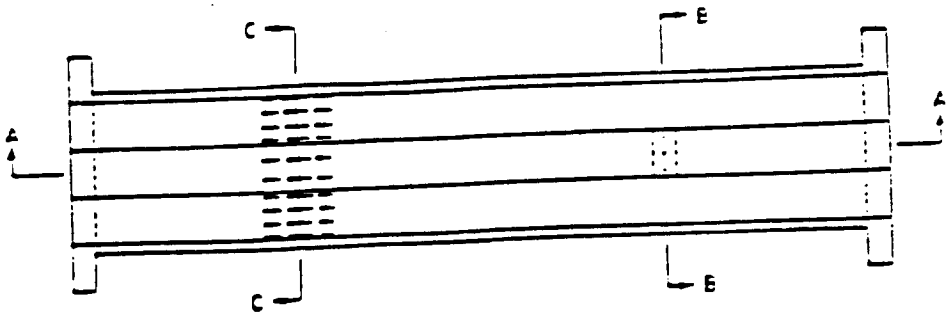
5. Expansion Joints shall be provided approximately every 90 feet. Eighteen-inch dowels of #4 reinforcing steel placed on 5-inch centers shall be located at all required joints. (See Plate 1.31a).

Outlet

Outlets of paved flumes shall be protected from erosion. In addition to OUTLET PROTECTION (ES BMP 1.36), each paved flume should be provided with a VDH&T "Standard Energy Dissipator." Plates 1.31b and 1.31c show a "Standard Energy Dissipator (EG-1)" which is designed for use in conjunction with a "Standard Paved Flume (PG-4)." Larger energy dissipators may be similarly designed for larger flume cross-sections.

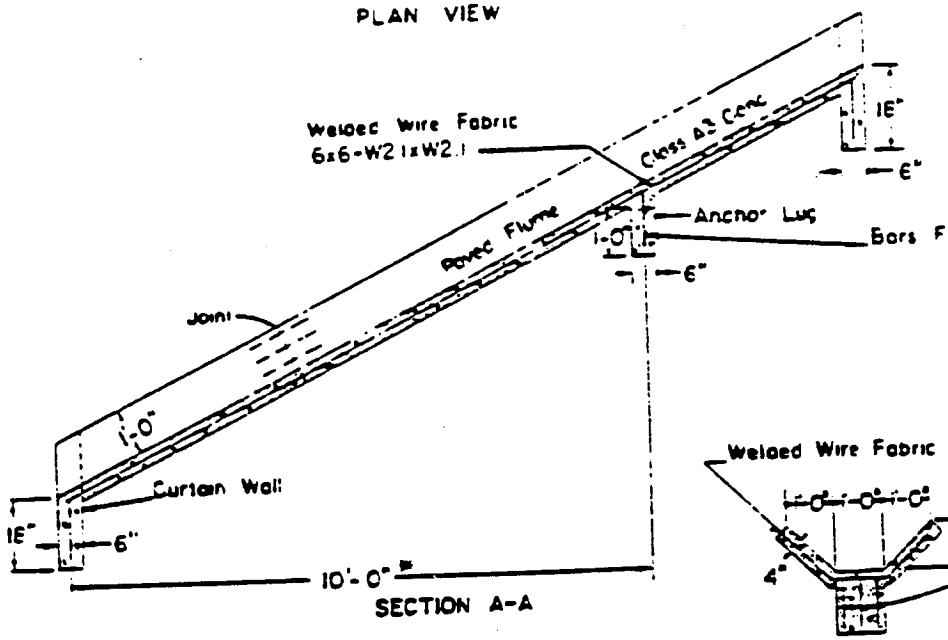
Construction Specifications

1. The subgrade shall be constructed to the required elevations. All soft sections and unsuitable material shall be removed and replaced with suitable material. The subgrade shall be thoroughly compacted and shaped to a smooth, uniform surface. For Portland cement, the subgrade shall be moist at the time the concrete is poured.



2. Anchor lugs and curtain walls shall be formed to be continuous with the channel lining.

3. Traverse joints for crack control should be provided at approximately 20-foot intervals and when more than 45 minutes elapses between consecutive concrete placements. All sections should be at least 6 feet long. Crack control joints may be formed by using a 1/8-inch thick removable template, by scoring or sawing to a depth of at least 3/4 inch or by an approved "leave-in" type insert.



Maintenance

Before permanent stabilization of the slope, the structure should be inspected after each rainfall and damages to the slope or paved flume repaired immediately. After the slope is stabilized, little maintenance should be required.

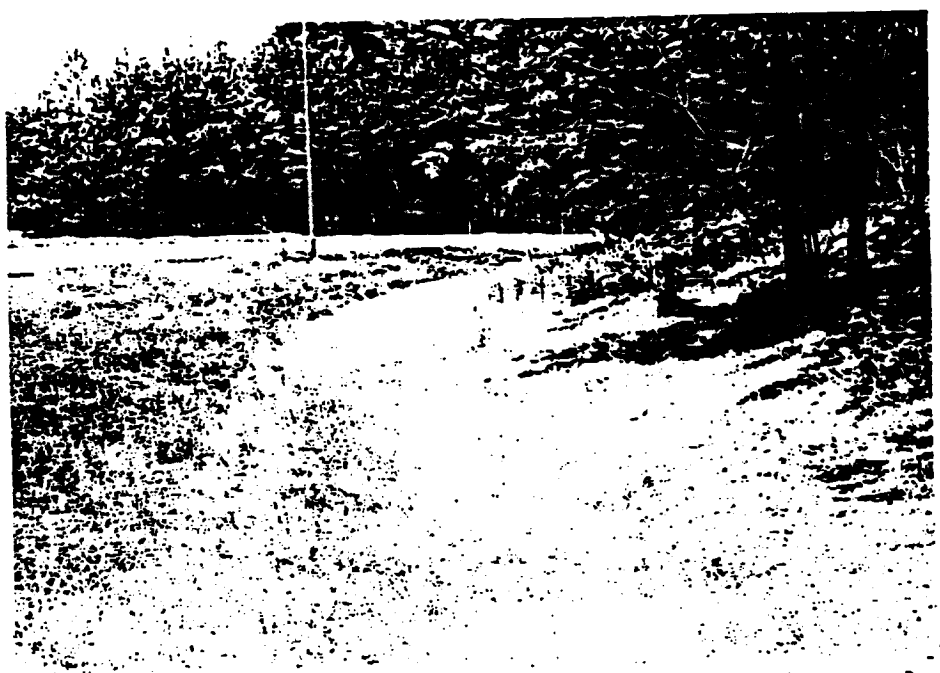
Plate 1.31c

R0071428

ES BMP 1.35

STORMWATER CONVEYANCE CHANNEL

Definition



A permanent, designed waterway, shaped and lined with appropriate vegetation or structural material to safely convey excess stormwater runoff away from a developing area.

Purpose

To provide for the conveyance of concentrated surface runoff water without damage from erosion.

Conditions Where Practice Applies

Generally applicable to man-made channels, including roadside ditches, and intermittent natural channels that are modified to accommodate increased flows generated by land development. This practice is not applicable to major, continuous flowing natural streams.

Grass Lined Channel Transition to Concrete Lined Channel

R0071429

Planning Considerations

The design of a channel cross-section and lining is based primarily upon the volume and velocity of flow expected in the channel. If conditions are appropriate, vegetated or riprap channels are generally preferred over concrete. While concrete channels are efficient and easy to maintain, they remove runoff so quickly that channel erosion, flooding and pollution often result downstream. Stormwater conveyance channels that do not provide treatment as required by Chapter 17-25, F.A.C. will require treatment facilities before discharging to state waters.

Besides the primary design considerations of capacity and velocity, a number of other important factors should be taken into account when selecting a cross-section and lining. These factors include land availability, compatibility with land use and surrounding environment, safety, maintenance requirements, outlet conditions and stormwater treatment capability. For these reasons SWALES (see SW BMP 3.04) are the preferred means of conveying stormwater since they provide treatment of pollutants and allow infiltration.

Vee-Shaped ditches are generally used where the quantity of water to be handled is relatively small, such as along roadsides. A grass or sod lining will suffice where velocities in the ditch are low. For steeper slopes where high velocities are encountered, a concrete or bituminous concrete lining may be appropriate.

Parabolic channels are often used where the quantity of water to be handled is larger and where space is available for a wide, shallow channel with low velocity flow. Riprap should be used where higher velocities are expected and where some dissipation of energy (velocity) is desired. Combinations of grass and riprap are also useful where there is a continuous low flow in the channel.

Trapezoidal channels are often used where the quantity of water to be carried is large and conditions require that it be carried at a relatively high velocity. Trapezoidal ditches are generally lined with concrete or riprap.

Outlet conditions for all channels should be considered. This is particularly important for the transition from a man-made lining such as concrete to a vegetative lining. Appropriate measures must be taken to dissipate the energy of the flow to prevent scour of the receiving channel. (See OUTLET PROTECTION, ES BMP 1.36).

Design Criteria

Capacity

Unless otherwise specified in local or state stormwater criteria, all channels shall be designed to contain at least the peak flow from a 10 year frequency storm. If channel flooding will cause inconvenience or property damage, the minimum channel capacity should be increased to carry at least 25 year frequency storm. Where the consequences of channel flooding are "severe", the capacity of the channel should be increased accordingly.

Velocity

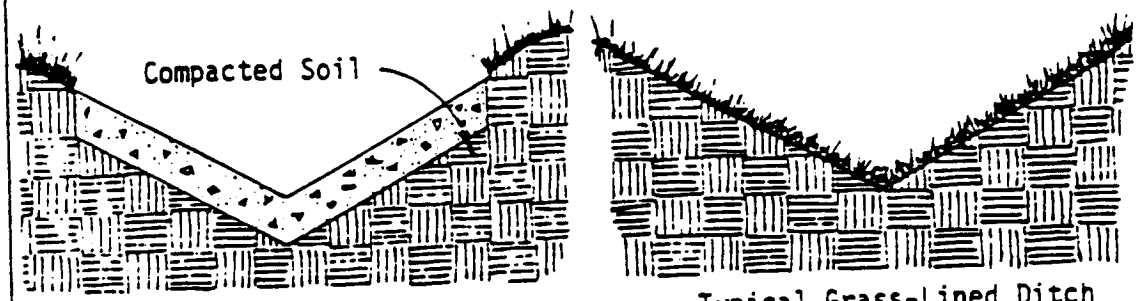
Channels shall be designed so that the velocity of flow expected from a 10 year frequency storm shall not exceed the permissible velocity for the type of lining used.

Grass-lined channels: Permissible velocities for grass-lined channels are shown in Table I.35a.

Riprap-lined channels: Riprap linings can be designed to withstand most flow velocities by choosing a stable stone size. The procedure for selecting a stable stone size for channels is contained in ES BMP 1.37, RIPRAP.

Concrete-lined channels: Velocity is usually not a limiting factor in the design of concrete-lined channels; however, it should be kept in mind that the flow velocity at the outlet of the paved section must not exceed the permissible velocity of the receiving channel. The outlet must also be stabilized to prevent erosion and scour. It may require energy dissipaters.

Depth



The design water surface elevation of a channel receiving water from diversions or other tributary channels shall be equal to or less than the design water surface elevation of the diversion or other tributary channel at the point of intersection.

Cross-Sections

1) Channel cross-sections may be vee-shaped, parabolic or trapezoidal. Typical vee-shaped, parabolic and trapezoidal cross-sections are shown in Plate 1.35a. Parabolic cross-sections are closest to that of natural channels. Trapezoidal cross-sections tend to revert to the parabolic shape with time.

2) The top width of parabolic and vee-shaped, grass-lined channels shall not exceed 30 feet, and the bottom width of trapezoidal, grass-lined channels shall not exceed 15 feet unless multiple or divided waterways, riprap center, or other means are provided to control meandering of low flows.

R0071432

Table 1.35a

PERMISSIBLE VELOCITIES GRASS-LINED CHANNELS

CHANNEL SLOPE	LINING	PERMISSIBLE VELOCITY*
0-5%	Bermudagrass	6 ft/sec
	Bahia	5 ft/sec
	Bluestem (broomsedges)	5 ft/sec
	Grass-legume mixture	4 ft/sec
	Sericea lespedeza	2.5 ft/sec
	Annual lespedeza	2.5 ft/sec
	Small grains (temporary)	2.5 ft/sec
5-10%	Bermudagrass	5 ft/sec
	Bahia	4 ft/sec
	Bluestem (broomsedges)	4 ft/sec
	Grass-legume mixture	3 ft/sec

For highly erodible soils, permissible velocities should be decreased 25%. An erodibility factor (K) greater than 35 would indicate a highly erodible soil. Erodibility factors (K-factors) for many Florida soils are listed in Appendix 2-4 of this manual.

Channel Linings

Grass: The type of grass chosen shall be appropriate for the site conditions; i.e., drainage tolerance, shade tolerance, maintenance requirements, permissible velocities, slope and soil type. (See PERMANENT SEEDING, ES BMP 1.66).

Riprap: Riprap shall meet the design criteria set forth in RIPRAP, ES BMP 1.37.

Concrete: Concrete channels shall be at least four inches thick and meet applicable FDOT criteria.

R0071433

Drainage (grass-lined channels)

Where there will be a base flow in grass-lined channels, a stone center, a subsurface, or other suitable means of handle the base flow shall be provided. Plate 1.35b shows typical cross-sections for stone center channels. Refer to RIPRAP, ES BMP 1.37 to choose the correct stone size.

Outlet

The outlets of all channels shall be protected from erosion. (See OUTLET PROTECTION, ES BMP 1.36).

Calculations

1) Peak runoff shall be calculated in accordance with the guidelines contained in Chapter 5 of this manual.

2) Channel dimensions for roadside ditches and median channels shall be determined in accordance with applicable design procedures outlined in the FDOT Drainage Manual. Helpful design charts are also included in that publication to aid in the design of concrete-lined channels for many cross-sectional shapes.

3) Channel dimensions for parabolic, grass-lined channels may be determined from the tables in Appendix 6-4.

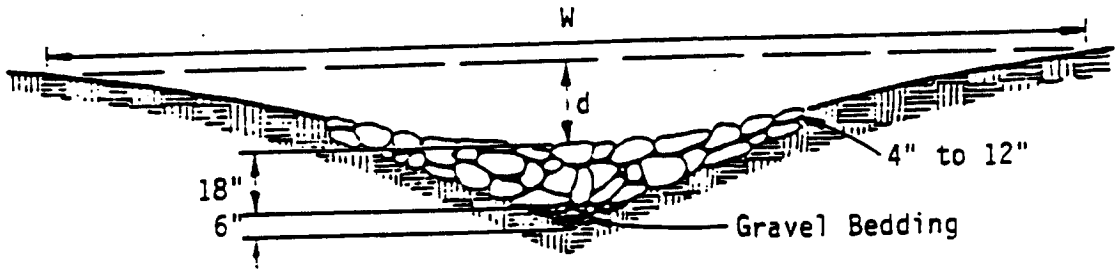
4) A general "trial and error" procedure for designing channels using the Manning's Equation and Continuity Equation is contained in SWALES (SW BMP 3.04).

Construction Specifications

General

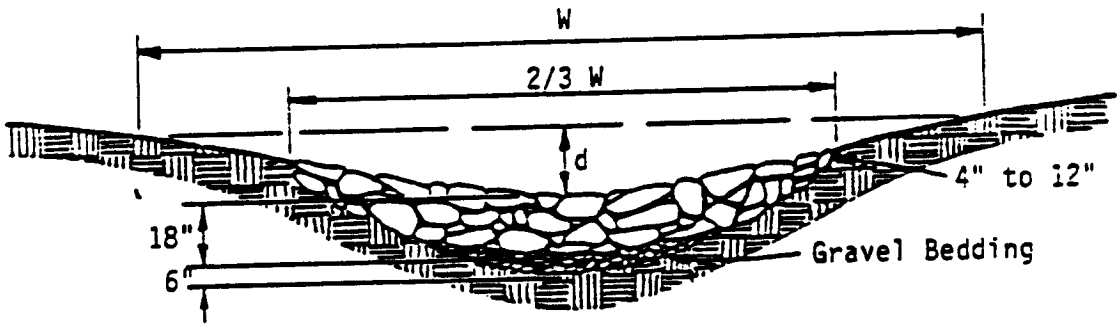
1) All trees, brush, stumps, roots, obstructions and other unsuitable materials shall be removed and properly disposed of.

2) The channel shall be excavated or shaped to the proper grade and cross-section.



3) All fills shall be well compacted to prevent unequal settlement.

4) Any excess soil shall be removed and properly disposed of.



Grass-lined channels

The method used to establish grass in the ditch or channel will depend upon the severity of the conditions encountered. The methods available for grass establishment are:

STONE-LINED WATERWAYS

V-Shaped Waterway with Stone Center Drain
(Shaped by Motor Patrol)

Parabolic-Shaped Waterway with Stone Center Drain
(Shaped by Bulldozer)

Source: USDA-SCS

Plate 1.35b

R0071435

1a) Seeding with straw mulch and tack coat.
b) Sprigging with bermudagrass.
2) Seeding with straw mulch and jute mesh or erosion netting.
3) Sodding.

Consult Table 1.35b to choose the correct grass establishment technique. For each establishment technique, if any one of the four conditions is exceeded, the next establishment technique below must be used.

TABLE 1.35b

GRASS ESTABLISHMENT ALTERNATIVES

Establishment Technique	Conditions
1a) Seeding with straw mulch and tack coat. 1b) Establishing bermudagrass by sprigging.	1) Slopes less than 5%. 2) Velocity less than 3 feet per second. 3) Majority of drainage can be diverted away from channel during germination and establishment. 4) Erosion-resistant soils.
2) Seeding with straw mulch and jute mesh or erosion netting.	1) Slopes less than 5%. 2) Velocity less than 5 feet per second. 3) Majority of drainage can not be diverted away from channel during germination and establishment. 4) Moderate erodible soil.
3) Sodding	1) Slopes greater than 5%. 2) Velocity between 5 feet per second and 6 feet per second. 3) Majority of drainage can not be diverted away from channel during germination. 4) Highly erodible soil.

1a) Seeding with straw mulch and tack coat. All seeding shall be done in accordance with PERMANENT SEEDING. ES BMP 1.66. When mulching, use 2 tons/acre small grain straw with an acceptable tacking agent. Refer to MULCHING, ES BMP 1.75.

b) Bermudagrass establishment by sprigging. Establish bermudagrass in accordance with BERMUDAGRASS ESTABLISHMENT, ES BMP 1.68. Irrigation water must be available during the first 4 weeks. Divert drainage away from the channel during the first 3 weeks of the establishment period by using temporary dikes, silt fencing, or straw bale barriers.

2) Seeding with straw mulch and jute mesh or erosion netting. In addition to 1A) above, straw mulch will be secured with netting. If using jute mesh, use only 1 ton/acre small grain straw, evenly distributed. If using a light plastic or paper erosion netting, 1-1/2 to 2 tons/acre of straw is appropriate. Care should be taken to staple the mesh or netting according to specifications in MULCHING, ES BMP 1.75, Nets and Mats. Excelsior blankets, used alone, are also acceptable mulches for waterways.

3) Sodding. Sod shall be installed in accordance with SODDING, ES BMP 1.67.

Concrete-lined channels

Concrete-lined channels must be constructed in accordance with all applicable FDOT specifications. Following is a summary of those specifications provided as a guide only:

1) The subgrade should be moist at the time the concrete is poured.

2) Traverse joints for crack control should be provided at approximately 20-feet intervals and when more than 45 minutes elapses between the times of consecutive concrete placements. All sections should be at least 6 feet long. Crack control joints may be formed by using a 1/8-inch thick removable template, by scoring or sawing to a depth of at least 3/4 inch or by an approved "leave in" type insert.

3) Expansion joints shall be installed every 100 feet.

Riprap-lined channels

Riprap shall be installed in accordance with RIPRAP, ES BMP 1.37.

Maintenance

Grass-lined channels

During the initial establishment, grass-lined channels should be repaired immediately and grass re-established if necessary. After grass has become established, the channel should be checked periodically to determine if the grass is staying in place. If the channel is to be mowed, it should be done in a manner that will not damage the grass.

Riprap-lined channels

Riprap-lined channels should be checked periodically to ensure that scour does not occur beneath the riprap layer. The channel should also be checked to determine that the stones are not dislodged by the flow.

Concrete-lined channels

Concrete-lined channels should be checked periodically to ensure that there is no undermining of the channel. Particular attention should be paid to the outlet of the channel. If scour is occurring at the outlet, appropriate energy dissipation measures shall be taken.

Sediment deposition

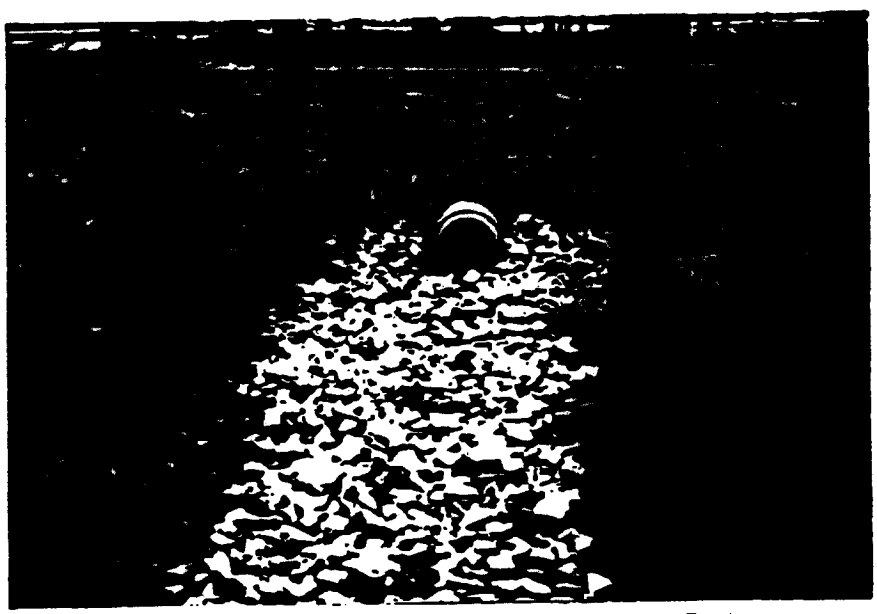
If the channel is below a high sediment-producing area, sediment should be trapped before it enters the channel. If sediment is deposited in grass-lined channels, it should be removed promptly to prevent damage to the grass. Sediment deposited in riprap and concrete-lined channels should be removed when it reduces the capacity of the channel.

R0071438

ES BMP 1.36

OUTLET PROTECTION

Definition



Structurally lined aprons or other acceptable energy dissipating devices placed at the outlets of pipes or paved channel sections.

Purpose

To prevent scour at stormwater outlets and to minimize the potential for downstream erosion by reducing the velocity of concentrated stormwater flows.

Conditions Where Practice Applies

Applicable to the outlets of all pipes and paved channel sections where the velocity of flow at design capacity of the outlet will exceed the permissible velocity of the receiving channel or area. (See Table 1.36a).

R0071439

Planning Considerations

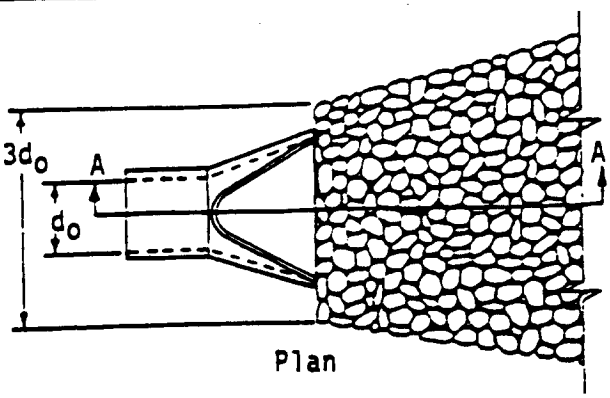
The outlets of pipes and structurally lined channels are points of critical erosion potential. Stormwater which is transported through man-made conveyance systems at design capacity generally reaches a velocity which exceeds the capacity of the receiving channel or area to resist erosion. To prevent scour at stormwater outlets, a flow transition structure is needed which will absorb the initial impact of the flow and reduce the flow velocity to a level which will not erode the receiving channel or area.

The most commonly used device for outlet protection is a structurally lined apron. These aprons are generally lined with riprap, grouted riprap or concrete. They are constructed at a zero grade for a distance which is related to the outlet flow rate and the tailwater level. Criteria for designing such an apron are contained in this practice. Sample problems of outlet protection design are contained in Appendix 1.36A.

1. Hydraulic Design of Energy Dissipators for Culverts and Channels, Hydraulic Engineering Circular No. 14, U.S. Department of Transportation, Federal Highway Administration (70).

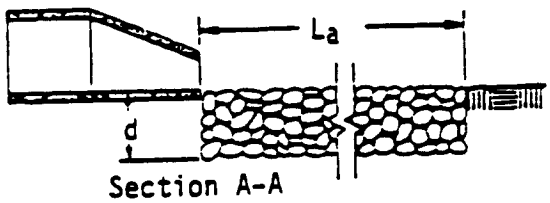
2. Hydraulic Design of Stilling Basins and Energy Dissipators, Engineering Monograph No. 25, U.S. Department of the Interior - Bureau of Reclamation (61).

3. Road Designs and Standards, Virginia Department of Highways and Transportation (76).



Design Criteria

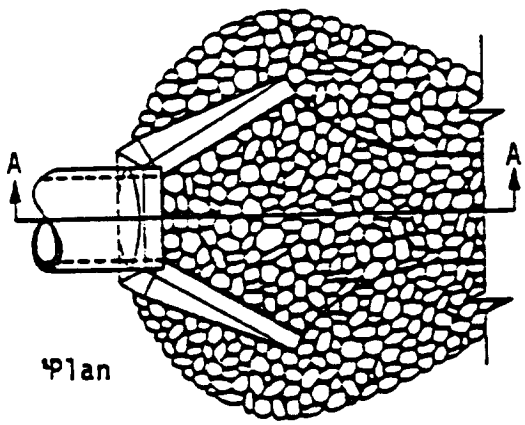
Structurally lined aprons at the outlets of pipes and paved channel sections shall be designed according to the following criteria:



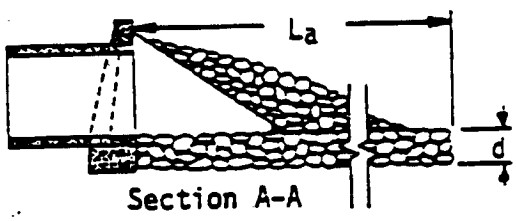
PIPE OUTLETS

1. Tailwater depth: The depth of tailwater immediately below the pipe outlet must be determined for the design capacity of the pipe. Manning's Equation may be used to determine tailwater depth (see Chapter 5 of this manual). If the tailwater depth is less than half the diameter of the outlet pipe, it shall be classified as a Minimum Tailwater Condition. If the tailwater depth is greater than half the pipe diameter, it shall be classified as a Maximum Tailwater Condition. Pipes which outlet onto flat areas with no defined channel may be assumed to have a Minimum Tailwater Condition.

R0071440



Plan



Section A-A

Pipe Outlet To Flat Area
With No Defined Channel

Plan

Section A-A

Pipe Outlet To Well-Defined Channel

Notes

1. Apron lining may be riprap, grouted riprap, or concrete.
2. L_a is the length of the riprap apron as calculated using Plates 1.36d and 1.36e.
3. d = 1.5 times the maximum stone diameter but not less than 6 inches.

PIPE OUTLET CONDITIONS

Source: Va SWCC

Plate 1.36a

R0071441

2. Apron length: The apron length shall be determined from the curves according to the tailwater condition:

   Minimum Tailwater - Use Plate 1.36c.

   Maximum Tailwater - Use Plate 1.36d.

3. Apron width: If the pipe discharges directly into a well-defined channel, the apron shall extend across the channel bottom and up the channel banks to an elevation one foot above the maximum tailwater depth or to the top of the bank (whichever is less).

   If the pipe discharges onto a flat area with no defined channel, the width of the apron shall be determined as follows:

   a. The upstream end of the apron, adjacent to the pipe, shall have a width three times the diameter of the outlet pipe.

   b. For a Minimum Tailwater Condition, the downstream end shall have a width equal to the pipe diameter plus the length of the apron.

   c. For a Maximum Tailwater Condition, the downstream end shall have a width equal to the pipe diameter plus 0.4 times the length of the apron.

4. Bottom grade: The apron shall be constructed with no slope along its length (0.0% grade). The invert elevation of the downstream end of the apron shall be equal to the elevation of the invert of the receiving channel. There shall be no overfall at the end of the apron.

5. Side slopes: If the pipe discharges into a well-defined channel, the side slopes of the channel shall not be steeper than 2:1 (Horizontal: Vertical).

6. Alignment: The apron shall be located so that there are no bends in the horizontal alignment.

7. Materials: The apron may be lined with riprap, grouted riprap, or concrete. The median size stone for riprap shall be determined from the curves in Appendix 1.36A (Plates 1.36c and 1.36d) according to the tailwater condition. The gradation, quality and placement of riprap shall conform to ES BMP 1.37, RIPRAP.

R0071442

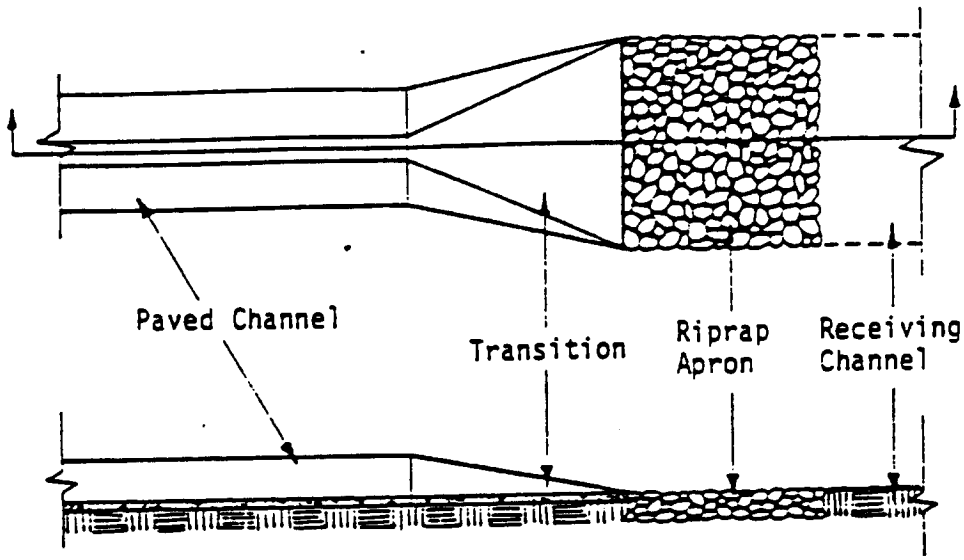
R0071443

PAVED CHANNEL OUTLETS
(See Plate 1.36b)

1. The flow velocity at the outlet of paved channels flowing at design capacity must not exceed the permissible velocity of the receiving channel. (See Table 1.36a).



2. The end of the paved channel shall merge smoothly with the receiving channel section. There shall be no overfall at the end of the paved section. Where the bottom width of the paved channel is narrower than the bottom width of the receiving channel, a transition section shall be provided (see Plate 1.36b). The maximum side divergence of the transition shall be 1 in 3F where:

$$F = \frac{V}{\sqrt{gd}}, \text{ and}$$

F = Froude number
V = Velocity at beginning of transition (ft./sec.)
d = depth of flow at beginning of transition (ft.)
g = 32.2 ft./sec.

3. Bends or curves in the horizontal alignment of the transition are not allowed unless the Froude number (F) is 1.0 or less, or the section is specifically designed for turbulent flow.

R0071444

Notes

1. Riprap apron reduces the flow velocity below the permissible velocity of the natural receiving channel.
2. Transition side divergence is 1 in 3F, where

   F = Froude Number = $\frac{V}{\sqrt{gd}}$, where

   V = Velocity at the beginning of the transition

   d = Depth of flow at the beginning of the transition

   g = 32.2 ft./sec.^{2}

PAVED CHANNEL OUTLET

Source: Va SWCC

Plate 1.36b

R0071445

APPENDIX 1.36A

Sample Problems
Outlet Protection Design

Example 1

Given: An 18-inch pipe discharge 24 ft.^{3}/sec. at design capacity onto a grassy slope (no defined channel).

Find: The required length, width and median stone size (d_{50}) for a riprap-lined apron.

Solution:
1. Since the pipe discharges onto a grassy slope with no defined channel, a Minimum Tailwater Condition may be assumed.
2. From Plate 1.36c, an apron length (L_a) of 20 feet and a median stone size (d_{50}) of 0.8 ft are determined.
3. The upstream apron width equals three times the pipe diameter; 3 x 1.5 ft. = 4.5 ft.
4. The downstream apron width equals the apron length plus the pipe diameter; 20 ft. + 1.5 ft. = 21.5 ft.

Example 2

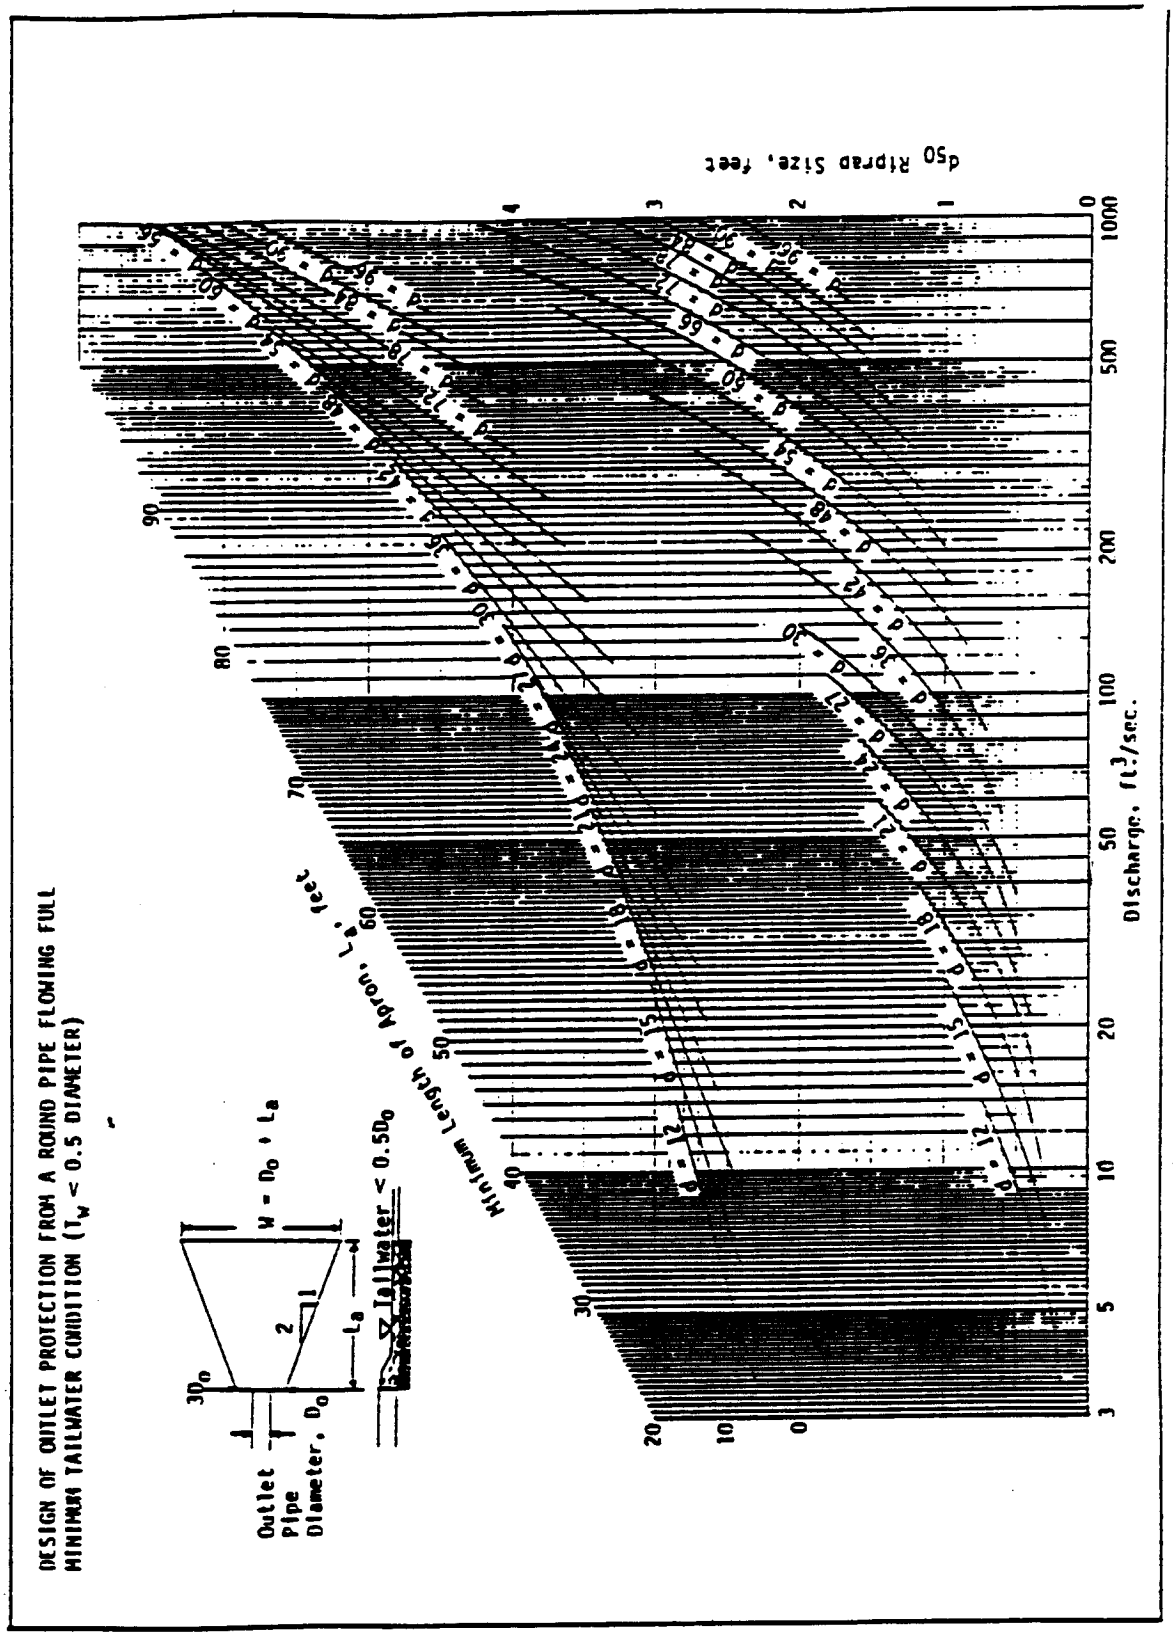
Given: The pipe in example No. 1 discharges into a channel with a triangular cross-section, 2 feet deep and 2:1 side slopes. The channel has a 2% slope and an "n" factor of .045.

Find: The required length, width and the median stone size (d_{50}) for a riprap lining.

Solution:
1. Determine the tailwater depth using Manning's Equation.

$$Q = \frac{1.49}{n} R^{2/3} S^{1/2} A$$

$$24 = \frac{1.49}{.045} \left(\frac{2d}{2\sqrt{2^2 + 1}} \right)^{2/3} (.02)^{1/2} (2d^2)$$

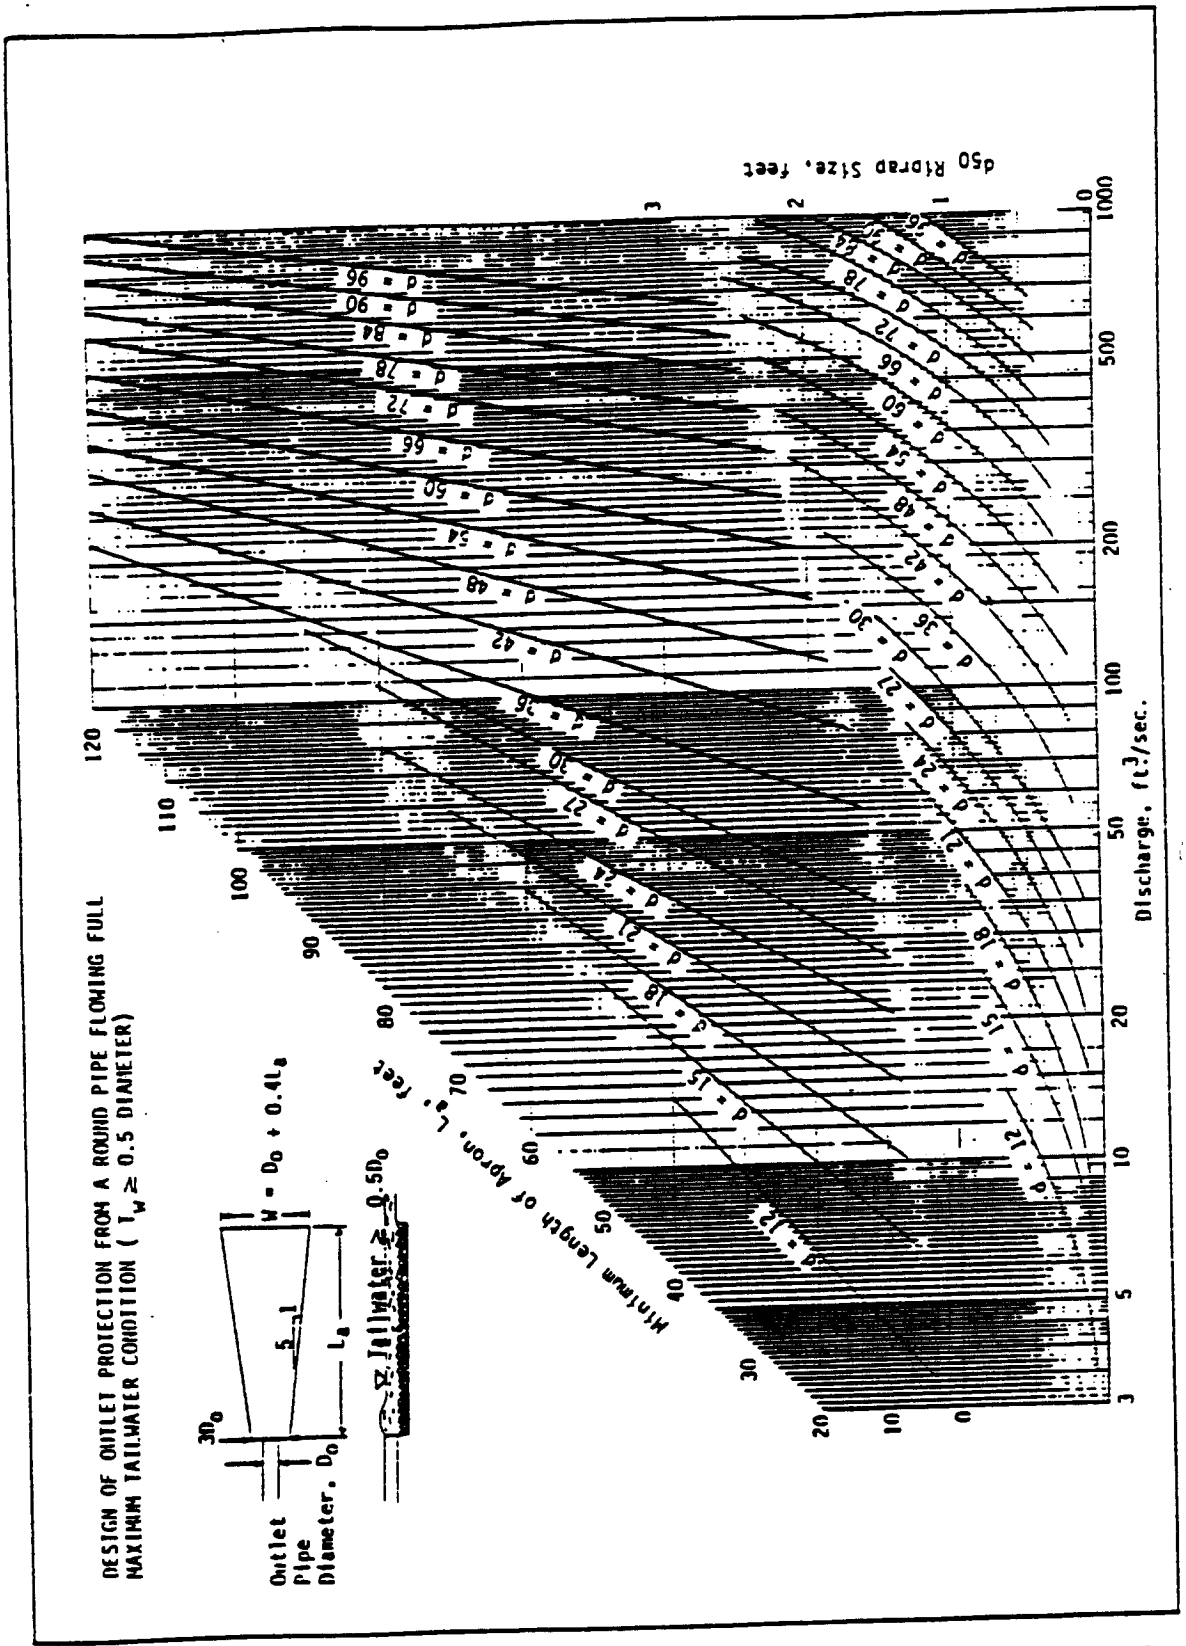


where,

d = depth of tailwater
d = 1.74 ft.*

*Since d is greater than half the pipe diameter, a Maximum Tailwater Condition exists.

2. From Plate 1.36d, a median stone size (d_{50}) of 0.5 ft. and an apron length of (L_a) of 41 ft. is determined.



3. The entire channel cross-section should be lined, since the maximum tailwater depth is within one foot of the top of the channel.

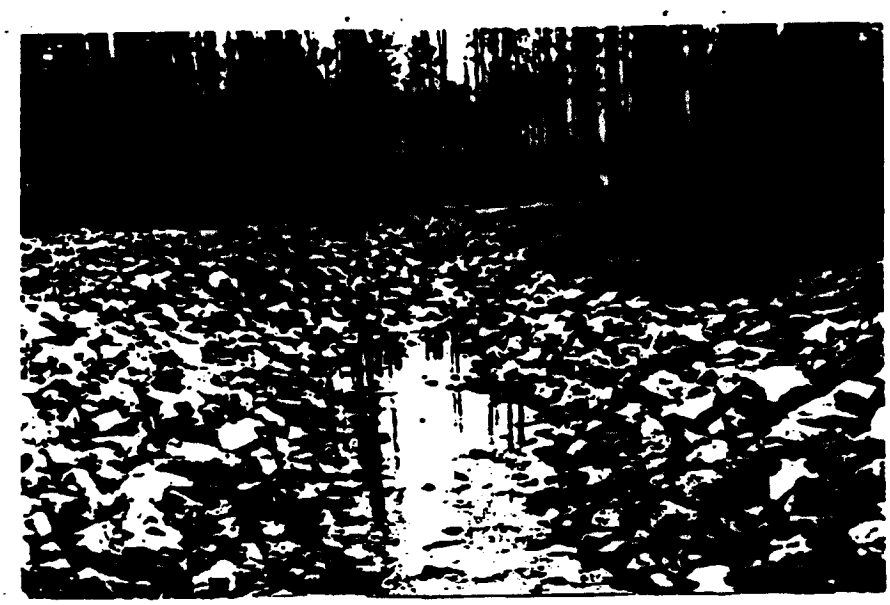
R0071448

ES BMP 1.37

RIPRAP

Definition



A permanent erosion-resistant ground cover of large, loose, angular stone.

Purposes

1. To protect the soil surface from the erosive forces of concentrated runoff.
2. To slow the velocity of concentrated runoff while enhancing the potential for infiltration.
3. To stabilize slopes with seepage problems and/or non-cohesive soils.

Conditions Where Practice Applies

To soil-water interfaces where the soil conditions, water turbulence and velocity, expected vegetative cover, etc., are such that the soil may erode under the design flow conditions. Riprap may be used, as appropriate, at stormdrain outlets, on channel banks and/or bottoms, roadside ditches, drop structures, at the toe of slopes, etc.

R0071449

Graded vs. Uniform Riprap

Riprap is classified as either graded or uniform. A sample of graded riprap would contain a mixture of stones which vary in size from small to large. A sample of uniform riprap would contain stones which are all fairly close in size.

For most applications, graded riprap is preferred to uniform riprap. Graded riprap forms a flexible self-healing cover, while uniform riprap is more rigid and cannot withstand movement of the stones. Graded riprap is cheaper to install, requiring only that the stones be dumped so that they remain in a well-graded mass. Hand or mechanical placement of individual stones is limited to that necessary to achieve the proper thickness and line. Uniform riprap requires placement in a more or less uniform pattern, requiring more hand or mechanical labor.

Riprap sizes can be designated by either the diameter or the weight of the stones. It is often misleading to think of riprap in terms of diameter, since the stones should be rectangular instead of spherical. However, it is simpler to specify the diameter of an equivalent size of spherical stone. Table 1.37a lists some typical stones by weight, spherical diameter and the corresponding rectangular dimensions. These stone sizes are based upon an assumed specific weight of 165 lbs./ft.^{3}.

Table 1.37a

SIZE OF RIPRAP STONES

Weight (lbs.)	Mean Spherical Diameter (ft.)	Rectangular Shape	
		Length (ft.)	Width, Height (ft.)
50	0.8	1.4	0.5
100	1.1	1.75	0.6
150	1.3	2.0	0.67
300	1.6	2.6	0.9
500	1.9	3.0	1.0
1000	2.2	3.7	1.25
1500	2.6	4.7	1.5
2000	2.75	5.4	1.8
4000	3.6	6.0	2.0
6000	4.0	6.9	2.3
8000	4.5	7.6	2.5
20000	6.1	10.0	3.3

Since graded riprap consists of a variety of stone sizes, a method is needed to specify the size range of the mixture of stone. This is done by specifying a diameter of stone in the mixture for which some percentage, by weight will be smaller. For example, d_{85} refers to a mixture of stones in which 85% of the stone by weight would be smaller than the diameter specified. Most designs are based on d_{50}. In other words, the design is based on the average size of stone in the mixture. Table 1.37b lists Virginia Department of Highways and Transportation (VDH&T) standard graded riprap sizes by diameter and weight of the stone.

R0071450

Table 1.37b

GRADED RIPRAP

Riprap Class	D_{15} Weight (lbs)	D_{15} Spherical Diameter (ft.)	Mean D_{50} Spherical Diameter (ft.)
Class I	50	0.8	1.1
Class II	150	1.3	1.6
Class III	500	1.9	2.2
Type I	1500	2.6	2.8
Type II	6000	4.0	4.5

Sequence of Construction

Since riprap is used where erosion potential is high, construction must be sequenced so that the riprap is put in place with the minimum possible delay. Disturbance of areas where riprap is to be placed should be undertaken only when final preparation and placement of the riprap can follow immediately behind the initial disturbance. Where riprap is used for outlet protection, the riprap should be placed before or in conjunction with the construction of the pipe or channel so that it is in place when the pipe or channel begins to operate.

Design Criteria

Gradation

The riprap shall be composed of a well-graded mixture down to the one-inch size particle such that 50% of the mixture by weight shall be larger than the d_{50} size as determined from the design procedure. A well-graded mixture as used herein is defined as a mixture composed primarily of the larger stone sizes but with a sufficient mixture of other sizes to fill the progressively smaller voids between the stones. The diameter of the largest stone size in such a mixture shall be 1.5 times the d_{50} size.

The designer, after determining the riprap size that will be stable under the flow conditions, shall consider that size to be a minimum size and then, based on riprap gradations actually available in the area, select the size or sizes that equal or exceed the minimum size. The possibility of damage by children shall be considered in selecting a riprap size, especially if there is nearby water to toss the stones into.

Thickness

The minimum thickness of the riprap layer shall be 1.5 times the maximum stone diameter but not less than 6 inches.

R0071451

Quality of Stone

Stone for riprap shall consist of field stone or rough unhewn quarry stone of approximately rectangular shape. The stone shall be hard and angular and of such quality that it will not disintegrate on exposure to water or weathering and it shall be suitable in all other respects for the purpose intended. The specific gravity of the individual stones shall be at least 2.5.

Rubble concrete may be used provided it has a density of at least 150 pounds per cubic foot, and otherwise meets the requirements of this ES BMP Section.

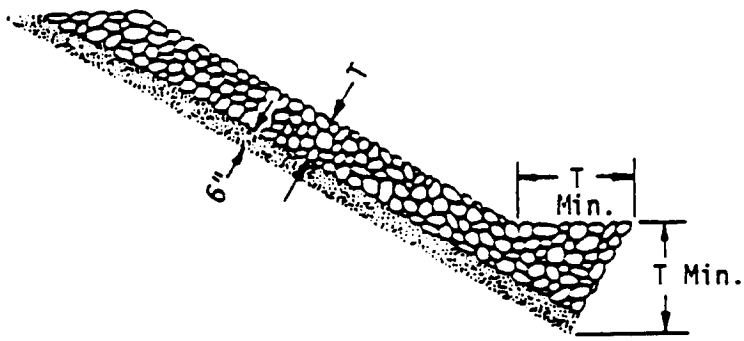
Riprap at Outlets

Design criteria for sizing the stone and determining the dimensions of riprap pads at the outlet of drainage structures are contained in STORMDRAIN OUTLET PROTECTION (ES BMP 1.36).

Riprap for Channel Stabilization

Riprap for channel stabilization shall be designed to be stable for the condition of bank-full flow in the reach of channel being stabilized. The design procedure in Appendix 1.37A, which is extracted from the Federal Highway Administration's Design of Stable Channels with Flexible Linings (69) shall be used.

Riprap size to be used in a channel bend shall extend upstream from the point of curvature and downstream from the point of tangency a distance of at least 5 times the channel bottom width. The riprap shall extend across the bottom and up both sides of the channel.



Where riprap is used only for bank protection and does not extend across the bottom of the channel, riprap shall be keyed into the bottom of the channel to a minimum depth equal to the thickness of the blanket and shall extend across the bottom of the channel the same distance. (See Plate 1.37a).

Riprap for Slope Stabilization

Riprap for slope stabilization shall be designed so that the natural angle of repose of the stone mixture is greater than the gradient of the slope being stabilized (see Plate 1.37d).

R0071452

TOE REQUIREMENTS FOR RIPRAP BANK PROTECTION

Source: VDH&T

Plate 1.37a

Filter Blankets

A filter blanket is a layer of material placed between the riprap and the underlying soil surface to prevent soil movement into or through the riprap.

A filter blanket can be of two general forms: a gravel layer or a plastic filter cloth. A determination of the need for a filter blanket is made by comparing particle sizes of the overlying material and the base material in accordance with the criteria below:

Gravel filter blanket: The following relationships must exist:

$$\frac{d_{15}\ \text{filter}}{d_{85}\ \text{base}} < 5 < \frac{d_{15}\ \text{filter}}{d_{15}\ \text{base}} < 40$$

and,

$$\frac{d_{50}\ \text{filter}}{d_{50}\ \text{base}} < 40$$

In these relationships, filter refers to the overlying material and base refers to the underlying material. The relationships must hold between the filter material and the base material and between the riprap and the filter material. In same cases, more than one layer of filter material may be needed. Each layer of filter material should be approximately 6 inches thick.

Plastic filter cloth: Plastic filter cloth may be used in place of or in conjunction with gravel filters. The following particle size relationships must exist:

R0071453

1. For filter cloth adjacent to granular materials containing 50 percent or less (by weight), of fine particles (less than 0.074 mm):

   a. $\frac{d_{85} \text{ base (mm)}}{\text{EOS* filter cloth (mm)}} > 1$

   b. Total open area of filter is less than 36 percent.

2. For filter cloth adjacent to all other soils:

   a. EOS* less than U.S. Standard Sieve No. 70.
   b. Total open area of filter is less than 10 percent.

No filter cloth should be used with less than 4 percent open area or an EOS* less than U.S. Standard Sieve No. 100.

*EOS - Equivalent Opening Size to a U.S. Standard Sieve Size.

Filter blankets should always be provided where seepage from underground sources threatens the stability of the riprap. No filter blanket is required for riprap used for storm drain outlet protection.

Construction Specifications

Subgrade Preparation: The subgrade for the riprap or filter shall be prepared to the required lines and grades. Any fill required in the subgrade shall be compacted to a density approximating that of the surrounding undisturbed material. Brush, trees, stumps and other objectionable material shall be removed.

Filter Blanket: Placement of the filter blanket should be done immediately after slope preparation. For granular filters the stone should be spread in a uniform layer to the specified depth. Where more than one layer of filter material is used, the layers should be spread so that there is minimal mixing of the layers.

For plastic filter clothes, the cloth should be placed directly on the prepared slope. The edges of the sheets should overlap by at least 12 inches. Anchor pins, 15 inches long, should be spaced every 3 feet along the overlap. The upper and lower ends of the cloth should be buried a minimum of 12 inches deep. Care should be taken not to damage the cloth when placing the riprap. If damage occurs, that sheet should be removed and replaced. For large stone (12 inches or greater), a 4-inch layer of gravel may be necessary to prevent damage to the cloth.

Stone Placement: Placement of riprap should follow immediately after placement of the filter. The riprap should be placed so that it produces a dense well-graded mass of stone with a minimum of voids. The desired

R0071454

distribution of stones throughout the mass may be obtained by selective loading at the quarry, controlled dumping of successive loads during final placing, or by a combination of these methods. The riprap should be placed to its full thickness in one operation. The riprap should not be placed in layers. The riprap should not be placed by dumping into chutes or similar methods which are likely to cause segregation of the various stone sizes. Care should be taken not to dislodge the underlying material when placing the stones.

The finished slope should be free of pockets of small stone or clusters of large stones. Hand placing may be necessary to achieve the required grades and a good distribution of stone sizes. Final thickness of the riprap blanket should be within plus or minus 1/4 of the specified thickness.

Maintenance

Once a riprap installation has been completed, it should require very little maintenance. It should, however, be inspected periodically to determine if high flows have caused scour beneath the riprap or dislodged any of the stone. If repairs are needed, they should be accomplished immediately.

APPENDIX 1.37A

RIPRAP DESIGN IN CHANNEL

The design method described below is adapted from Hydraulic Engineering Circular No. 15 of the Federal Highway Administration. It is applicable to both straight and curved sections of channel where the flow is tangent to the bank of the channel.

Tangent Flow - Federal Highway Administration Method

This design method determines a stable rock size for straight and curved sections of channels. It is assumed that the shape, depth of flow, and slope of the channel are known. A stone size is chosen for the maximum depth of flow. If the sides of the channel are steeper than 3:1, the stone size must be modified accordingly. The final design size will be stable on both the sides of the channel and the bottom.

1. Enter Plate 1.37b with the maximum depth of flow (feet) and channel slope (feet/foot). Where the two lines intersect, choose the d_{50} size of stone. (Select the d_{50} for the diagonal line above the point of intersection.)

2. If channel side slopes are steeper than 3:1, continue with step 3; if not, the procedure is complete.

3. Enter Plate 1.37c with the side slope and the base width to maximum depth ratio (B/d). Where the two lines intersect, move horizontally left to read K_1.

4. Determine from Plate 1.37d the angle of repose for the d_{50} size of stone and the side slope of the channel. (Use 42° for d_{50} greater than 1.0'±. Do not use riprap on slopes steeper than the angle of repose for the size of stone.)

5. Enter Plate 1.37e with the side slope of the channel and the angle of repose for the d_{50} size of stone. Where the two lines intersect, move vertically down to read K_2.

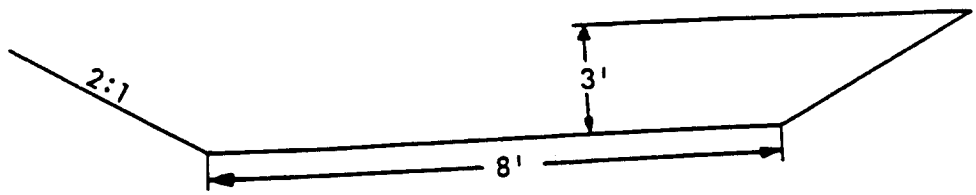
6. Compute $d_{50} \times K_1/K_2 = d'_{50}$ to determine the correct size stone for the bottom and side slopes of straight sections of channel.

For Curved Sections of Channel

1. Compute the radius of the curve (Ro), measured at the outside edge of the bottom.

2. Compute the ratio of the top width of the water surface (Bs) to the radius of the curve (Ro), Bs/Ro.

3. Enter Plate 1.37f with the ratio Bs/Ro. Move vertically until the curve is intersected. Move horizontally left to read K_3.



R0071456

4. Compute $d'_{50} \times K_3 = d_{50c}$ to determine the correct size stone for bottom and side slopes of curved sections of channel.

Example Problem

Given:

A trapezoidal channel 3 feet deep, 8 feet bottom, 2:1 side slopes, and a 2% slope.

Calculate:

A stable riprap size for the bottom and side slopes of the channel.

Solution:

1. From Plate 1.37b, for a 3-foot-deep channel on a 2% grade, d_{50} = 0.75 feet or 9 inches.
2. Since the side slopes are steeper than 3:1, continue with step 3.
3. From Plate 1.37c, B/d = 8/3 = 2.67, Z = 2, K_1 = 0.82.
4. From Plate 1.37d, for d_{50} = 9 inches, θ = 41°.
5. From Plate 1.37e, for Z = 2 and θ = 41°, K_2 = 0.73.
6. $d_{50} \times K_1/K_2 = d'_{50} = 0.75 \times 0.82/0.73 = 0.84$ feet.

   $0.84 \text{ feet} \times \frac{12 \text{ inches}}{1 \text{ foot}} = 10.08$. Use d'_{50} = 10 inches.

Given:

The preceding channel has a curved section with a radius of 50 feet.

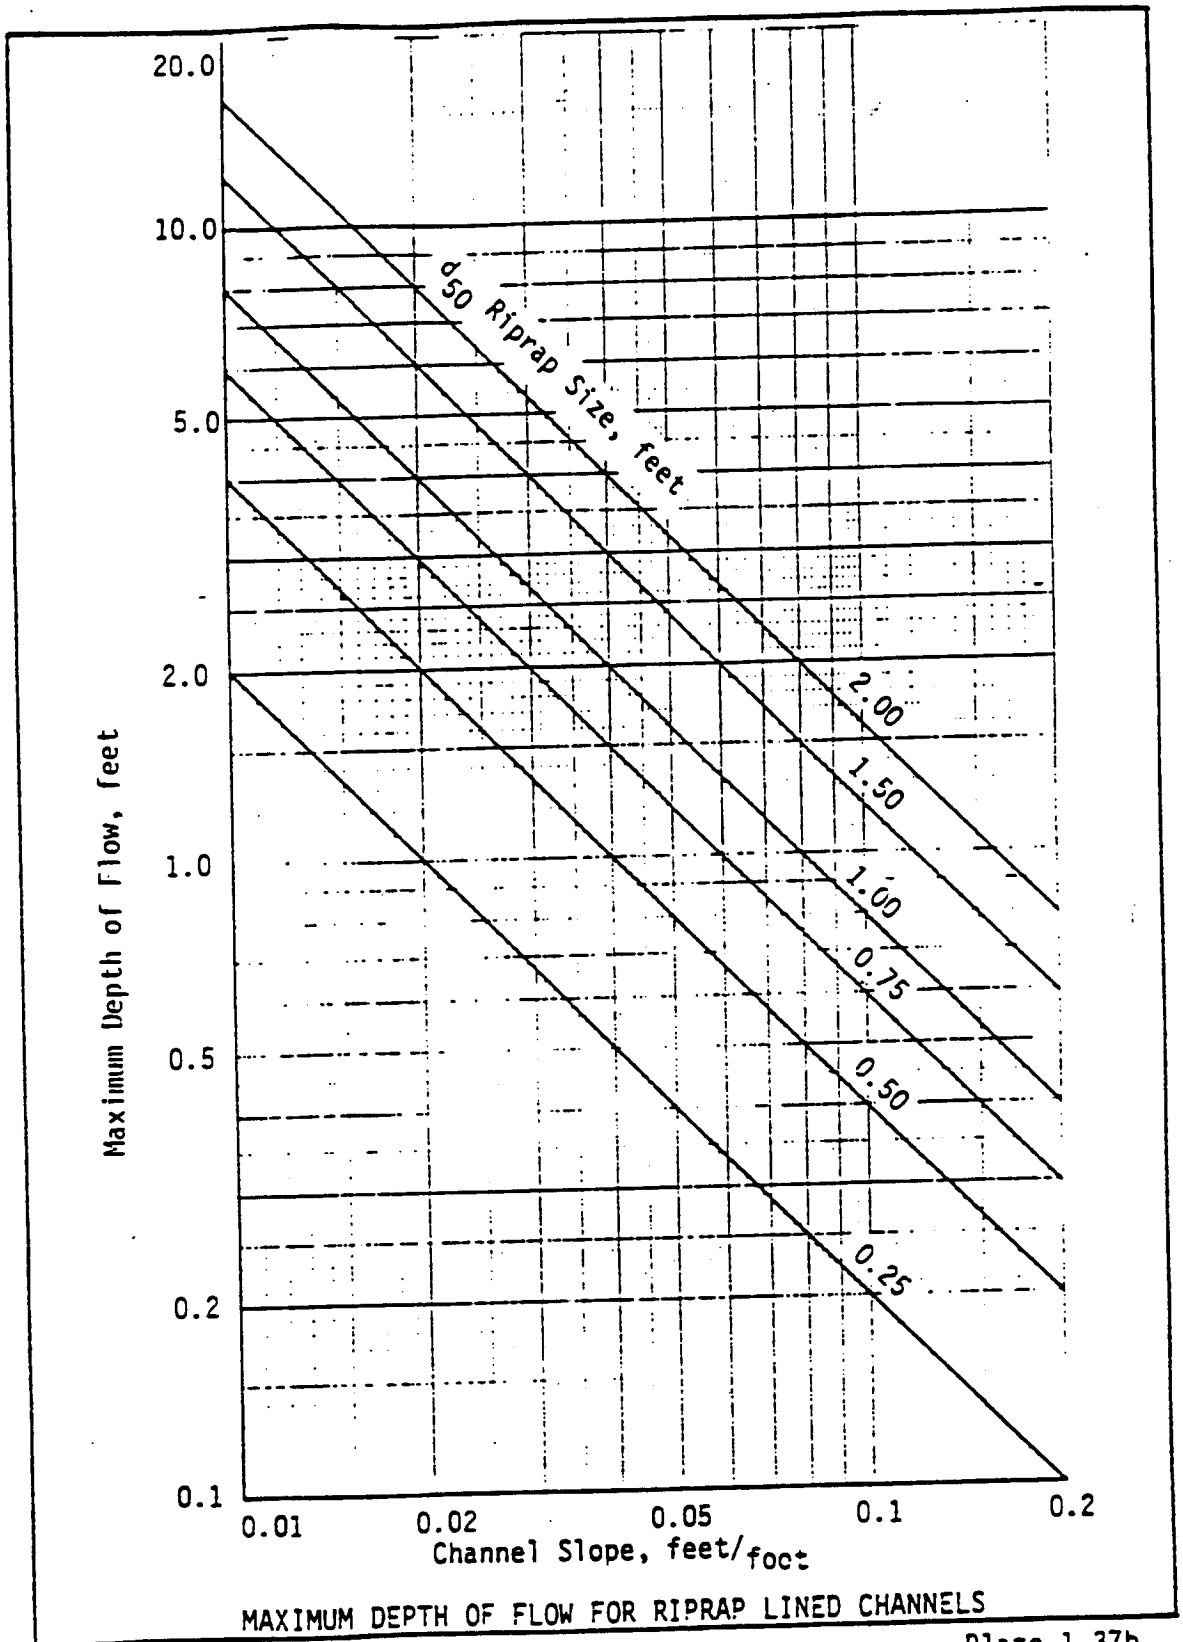
Calculate:

A stable riprap size for the bottom and side slopes of the curved section of channel.

R0071457

Solution:

1. R_o = 30 inches.



2. B_s/R_o = 20/30 = 0.67

3. From Plate 1.37f, for B_s/R_o = 0.67, K_3 = 1.4

4. $d'_{50} \times K_3 = d_{50c}$ = 0.84 x 1.4 = 1.2 feet

   $$1.2 \text{ feet} \times \frac{12 \text{ inches}}{1 \text{ foot}} = 14.4 \text{ inches}$$

CHECK DAMS

Definition

Small temporary dams constructed across a swale or drainage ditch.

Purpose

To reduce the velocity of concentrated stormwater flows, thereby reducing erosion of the swale or ditch. This practice also traps small amounts of sediment generated in the ditch itself. However, this is not a sediment trapping practice and should not be used as such.

Conditions Where Practice Applies

This practice is limited to use in small open channels which drain 10 acres or less. It should not be used in a live stream. They are especially applicable to sloping sides where the gradient of waterways is close to the maximum for a grass lining. Some specific applications include:

1. Temporary ditches or swales which, because of their short length of service, cannot receive a non-erodible lining but still need some protection to reduce erosion.

1. Permanent ditches or swales which for some reason cannot receive a permanent non-erodible lining for an extended period of time.

2. Either temporary or permanent ditches or swales which need protection during the establishment of grass linings.

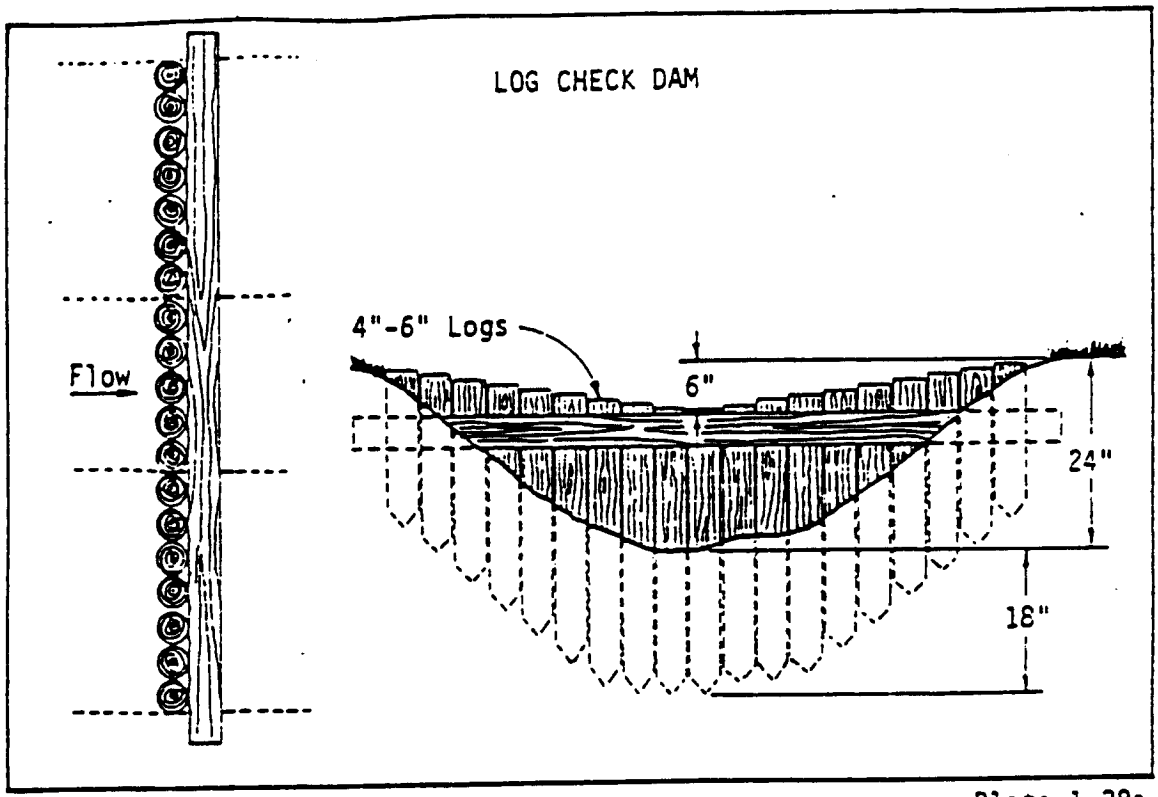
Planning Considerations

Check dams can be constructed of either stone or logs. Log check dams are more economical from the standpoint of material costs, since logs can usually be salvaged from clearing operations. However, log check dams require more time and hand labor to install. Stone for check dams, on the other hand, must generally be purchased. However, this cost is offset somewhat by the ease of installation.

If stone check dams are used in grass-lined channels which will be mowed, care should be taken to remove all the stone from the dam when the dam is removed. This should immediately include any stone which has washed downstream.

Since log check dams are embedded in the soil, their removal will result in more disturbance of the soil than will removal of stone check dams. Consequently, extra care should be taken to stabilize the area when log dams are used in permanent ditches or swales.

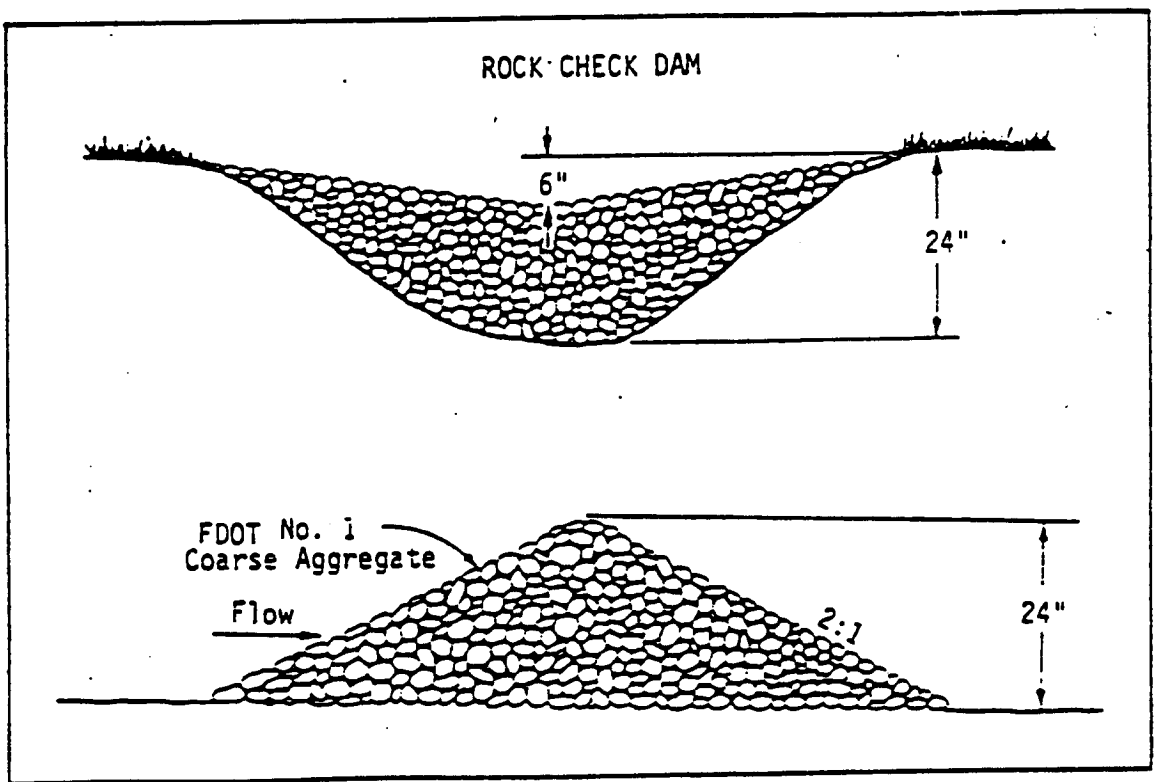
Specifications



No formal design is required for a check dam; however, the following criteria should be adhered to when specifying check dams.

The drainage area of the ditch or swale being protected should not exceed 10 acres. The maximum height of the check dam should be 2 feet. The center of the check dam must be at least 6 inches lower than the outer edges (see Plate 1.38a). The cross-sections of the dams should be as shown in Plates 1.38a and 1.38b, respectively, for logs and stone. The maximum spacing between the dams should be such that the toe of the upstream dam is at the same elevation as the top of the downstream dam. (See Plate 1.38c).

Stone check dams should be constructed of FDOT Aggregate No. 1 (2- to 3-inch stone). The stone should be placed according to the configuration in Plate 1.38b. Hand or mechanical placement will be necessary to achieve complete coverage of the ditch or swale and to insure that the center of the dam is lower than the edges.



Log check dams should be constructed of 4- to 6-inch logs salvaged from clearing operation site, if possible. The logs should be embedded into the soil at least 18 inches. The 6-inch lower height required at the center can be achieved either by careful placement of the logs or by cutting the logs after they are in place.

R0071464

Source: Va SWCC

Plate 1.38a

Source: Va SWCC

Plate 1.38b

R0071465

Logs and/or brush should be placed on the downstream side of the dam to prevent scour during high flows.

Sediment Removal

While this practice is not intended to be used primarily for sediment trapping, some sediment will accumulate behind the check dams. Sediment should be removed from behind the check dams when it has accumulated to one half of the original height of the dam.

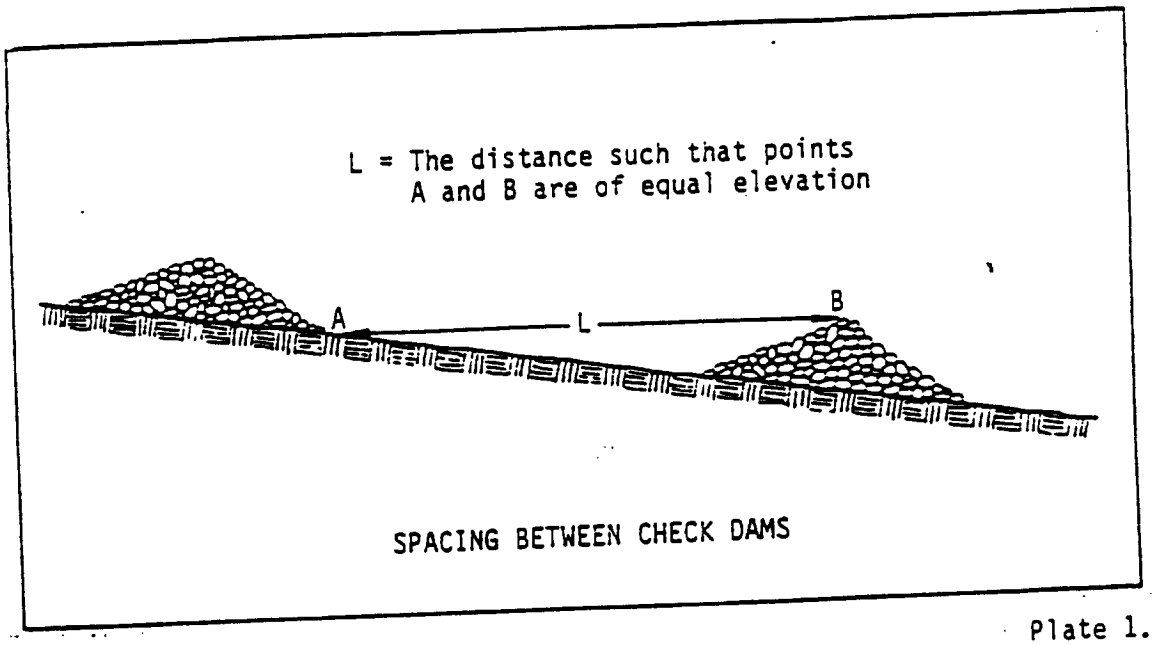


Plate 1.38c

Source: Va SWCC

Removal

Check dams must be removed when their useful life has been completed. In temporary ditches and swales, check dams should be removed and the ditch filled in when it is no longer needed. In permanent structures, check dams should be removed when a permanent lining can be installed. In the case of grass-lined ditches, check dams should be removed when the grass has matured sufficiently to protect the ditch or swale. The area beneath the check dams should be seeded and mulched or sodded (depending upon velocity) immediately after they are removed.

Maintenance

Check dams should be checked for sediment accumulation after each significant rainfall. Sediment should be removed when it reaches one-half of the original height or before.

Regular inspections should be made to insure that the center of the dam is lower than the edges. Erosion caused by high flows around the edges of the dam should be corrected immediately.

R0071466

ES BMP 1.39

WATERWAY DROP STRUCTURE

Definition

A permanent structure or series of structures designed to set up the flow of water down a slope without causing erosion of the channel.

Purpose

To prevent channel erosion of waterways by preventing high velocity flows in moderately steep channels.

Conditions Where Practice Applies

1. In man-made channels which must traverse long, relatively steep slopes without large increases in the flow velocity.

2. In natural channels which have long or relatively steep sections and which, as a result of construction activities, are expected to experience channel erosion problems.

Planning Considerations

Waterway drop structures are expensive permanent structures and consequently should be designed by a qualified engineer.

When locating the structure, attention should be given to changed water elevations which will result and their effect upon adjacent areas.

Waterway drop structures of this type are most cost-effective where the design flow is 100 cfs or greater and the drop in elevation across the structure is less than 10 feet.

Chapter 6 of the SCS Engineering Field Manual contains criteria for selecting the type of structure.

Design Criteria

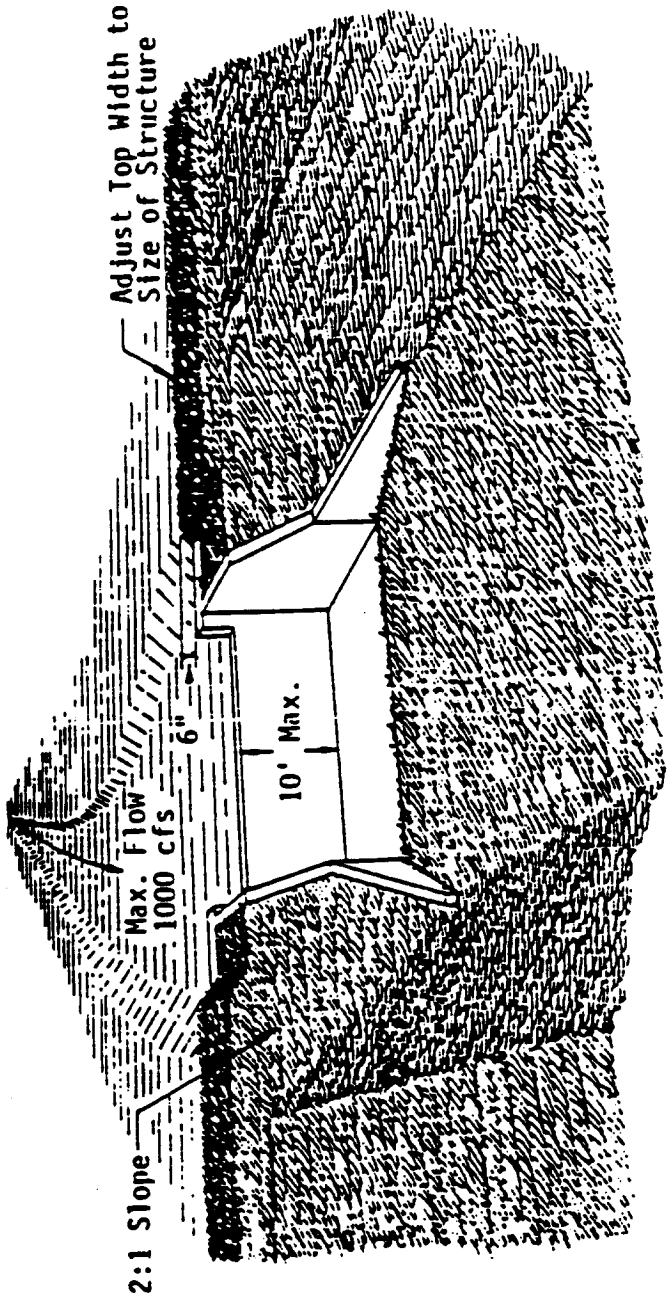
Waterway drop structures should either be designed on an individual basis by a qualified engineer or constructed from standard plans which may be obtained, for structures with a drop of up to 9 feet, from USDA-Soil Conservation Service. In general, however, the structure should adhere to the following criteria:

Location

Waterway drop structures should be located on reasonably straight sections of channel, with no upstream or downstream curves within 100 feet of the structure. It is often necessary to straighten the channel alignment so that it merges smoothly with the existing channel. This will lessen the likelihood of scour in channel.

The site of the structure should be one that provides a stable foundation. The foundation material should have sufficient strength to support the structure and to resist sliding and piping. The foundation material should also be relatively homogeneous to prevent uneven settling.

Capacity



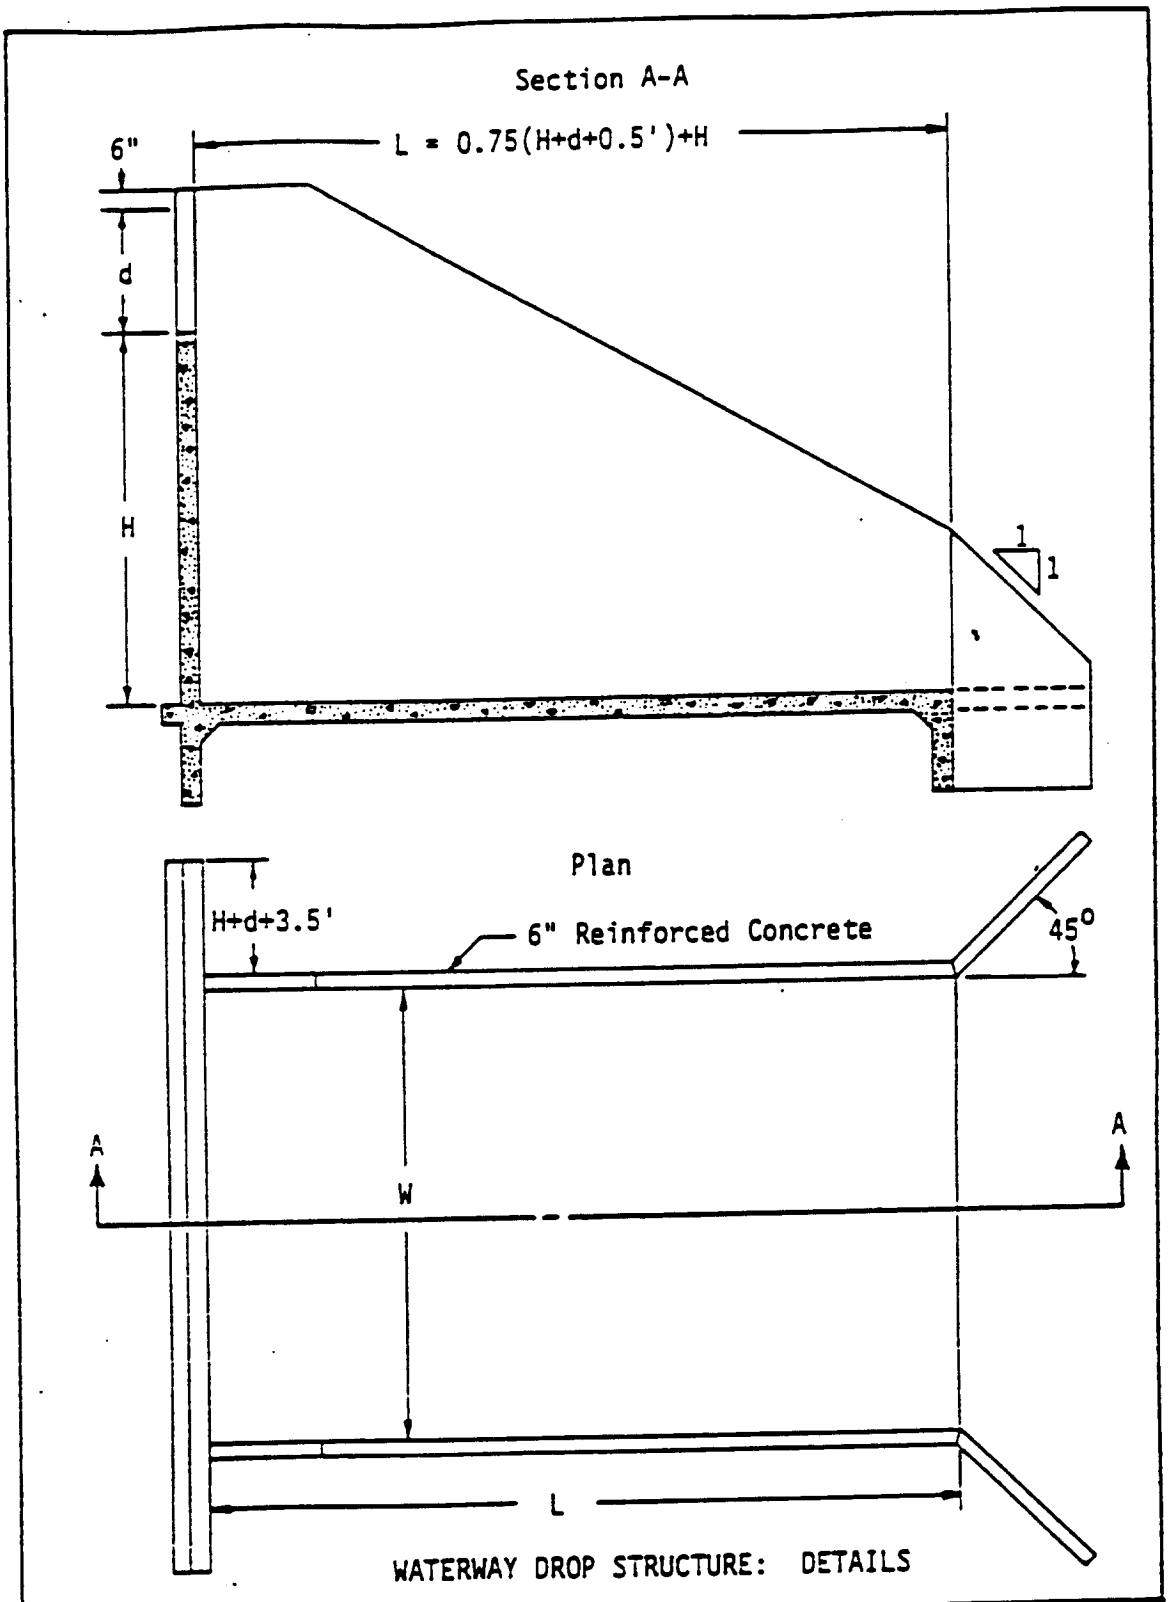
The structure should be designed to pass the peak rate of runoff from a 10-year storm. If the consequences from the failure of the structure will be severe, the design rate of flow should be increased accordingly. The maximum design flow should not exceed 1000 cfs (see Plate 1.39a).

Dimensions

Refer to Plate 1.39b. The width W, and the depth of flow d, over the weir, should be those necessary to achieve the design flow. A minimum freeboard of 6 inches should be allowed between the design high water and the top of the structure. The maximum drop H should not exceed 10 feet.

The downstream apron of the structure should extend at zero grade far enough downstream to prevent scour of the channel. The length of the apron can be calculated by the following equation:

R0071468



WATERWAY DROP STRUCTURE

Source: USDA-SCS

Plate 1.39a

R0071469

WATERWAY DROP STRUCTURE: DETAILS

Source: Soil and Water Conservation Engineering, Schwab et. al.

Plate 1.39b

R0071470

$$L = 0.75 (H + d) + H$$

where,

L = the length of the apron
H = the drop in elevation across the structure
d = the depth of flow across the weir plus 7 inches

The headwall extensions should extend a distance of (H + d + 3') on either side of the weir. The wing walls should project out from the channel at a 45° angle at a distance of 2.25d. (See Plate 1.39b).

Embankment

Depending upon the topography, an earthen embankment may need to be constructed in conjunction with the waterway drop structure to direct the flow of water to the spillway of the structure. The embankment should be a minimum of 6 inches higher than the top of the structure. The top width of the embankment should correspond to the width of the structure. (See Plate 1.39a). Side slopes of the embankment should not be steeper than 2:1.

Materials

The waterway drop structure shall be constructed of 6-inch thick reinforced concrete. Reinforcing of the structure shall be in accordance with accepted engineering practice. Standard plans for reinforcing can be obtained from the USDA-Soil Conservation Service.

Construction Specifications

1. All runoff should be diverted away from the swale, if possible, during construction.

2. The foundation of the structure shall be well compacted and free of roots, rocks, organic matter and other objectionable material.

3. Pouring of concrete for the structure shall be done in a continuous operation.

4. Backfill around the structure shall be hand-compacted in 4-inch layers.

5. The embankment shall be constructed according to the specifications for sediment basin embankments (Std. & Spec. 1.26).

6. The embankment and all other disturbed areas shall be seeded within 15 days of construction.

7. All necessary precautions shall be taken to prevent excess erosion and sedimentation during construction of the structure.

R0071471

Maintenance

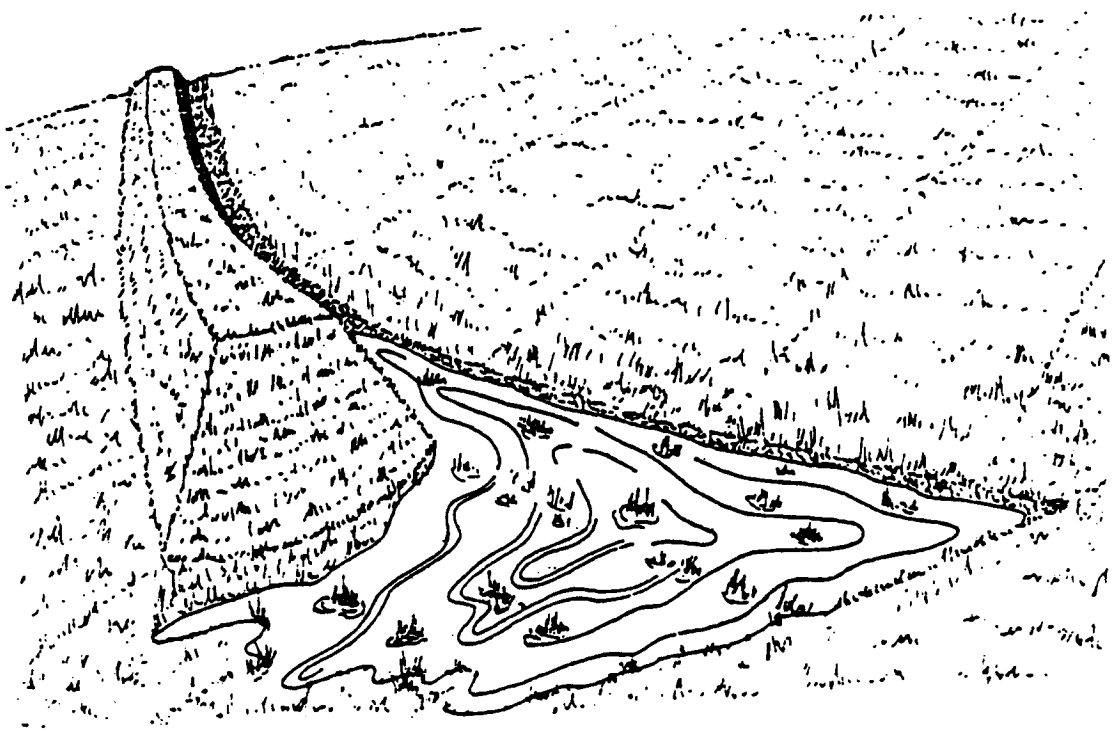
Once the waterway drop structure has been established and the area around it stabilized, maintenance should be minimal. Immediately after construction, however, the channel should be checked for scour above and below the structure. The embankment should be checked to insure that vegetation is well established. The structure itself should be checked for cracking of the concrete, uneven settlement, and piping around the structure.

R0071472

ES BMP 1.40

LEVEL SPREADER

Definition



An outlet for dikes and diversions consisting of an excavated depression constructed at zero grade across a slope whereby concentrated runoff may be discharged at non-erosive velocities onto undisturbed area stabilized by existing vegetation.

Purpose

To convert concentrated runoff to sheet flow and release it onto area stabilized by existing vegetation.

Conditions Where Practice Applies

Where sediment-free storm runoff is intercepted and diverted away from graded areas onto undisturbed stabilized areas. This practice applies only in those situations where the spreader can be constructed on undisturbed soil and the area below the level lip is stabilized by natural vegetation. The water should not be allowed to reconcentrate after release.

R0071473

Planning Considerations

The TEMPORARY DIVERSION DIKE (ES BMP 1.15) and the TEMPORARY RIGHT-OF- WAY DIVERSION (ES BMP 1.17) each call for a stable outlet for concentrated stormwater flows. The Level Spreader can be used for this purpose provided the runoff is relatively free of sediment. If properly constructed, the Level Spreader will significantly reduce the velocity of concentrated stormwater and spread it uniformly over a stable undisturbed area.

This practice is relatively easy and inexpensive to install. However, particular care must be taken during construction to insure that the lower lip of the structure is level. If there are any depressions in the lip, flow will tend to concentrate at these points and erosion will occur, resulting in failure of the outlet. Regular maintenance is essential for this practice.

Design Criteria

No formal design is required. The following criteria must be met:

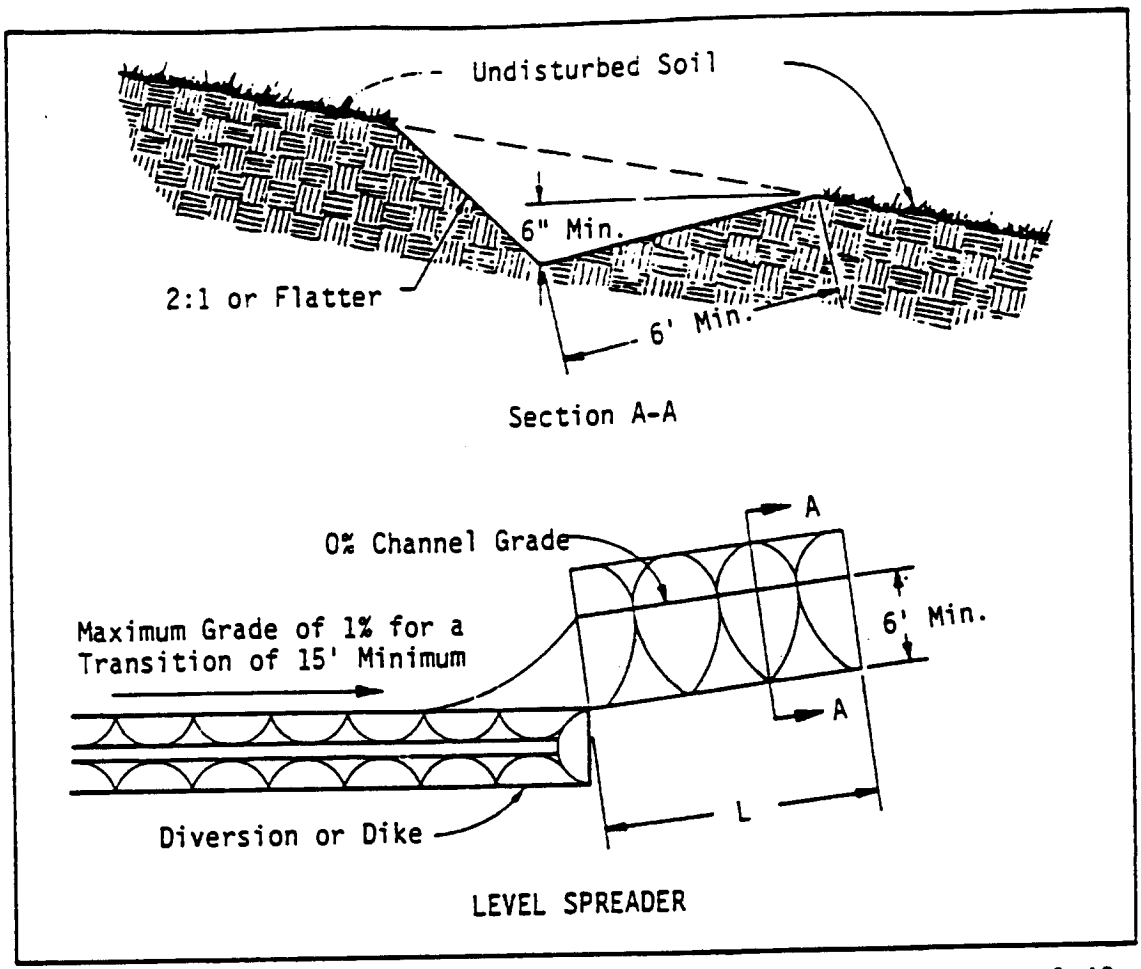
Length

Spreader Length will be determined by estimating the flow expected from a 10-year storm (Q_{10}), and selecting the appropriate length from the following table:

Design Flow, Q_{10} (CFS)	Minimum Length (FEET)
0 - 10	10
10 - 20	20
20 - 30	30
30 - 40	40
40 - 50	50

Width

The minimum acceptable width shall be 6 feet. (See Plate 1.40a).



Depth

The depth of the level spreader as measured from the lip shall be at least 6 inches. The depth shall be uniform across the entire length of the measure.
(See Plate 1.40a).

Grade

1. The grade of the channel for the last 20 feet of the dike or diversion entering the level spreader shall be less than or equal to 1%. (See Plate 1.40a).

2. The grade of the level spreader shall be 0%.

Source: Va SWCC

Plate 1.40a

Outlet

The release of the stormwater will be over the level lip onto an undisturbed stabilized area. The level lip should be of uniform height and zero grade over the length of the spreader.

Construction Specifications

1. Level spreaders must be constructed on undisturbed soil (not fill material).

2. The entrance to the spreader must be shaped in such a manner as to insure that runoff enters directly onto the 0% channel.

3. The level lip shall be constructed on zero percent grade to insure uniform spreading of storm runoff.

4. The released runoff must outlet onto undisturbed stabilized areas in sheet flow and not be allowed to reconcentrate below the structure.

Maintenance

The measure shall be inspected after every rainfall and repairs made if required. The contractor should avoid the placement of any material on and prevent construction traffic across the structure. If the measure is damaged by construction traffic, it shall be repaired immediately.

R0071476

ES BMP 1.50

SUBSURFACE DRAIN

Definition

A perforated conduit such as pipe, tubing or tile installed beneath the ground to intercept and convey ground water.

Purposes

1. To prevent sloping soils from becoming excessively wet and subject to sloughing.

2. To improve the quality of the growth medium in excessively wet areas by lowering the water table.

3. To drain stormwater detention areas or structures.

Conditions Where Practice Applies

Wherever excess water must be removed from the soil. The soil must be deep and permeable enough to allow an effective system to be installed. Either a gravity outlet must be available or pumping must be provided. These standards do not apply to foundation drains.

R0071477

Planning Considerations

Subsurface drainage systems are of two types: relief drains and interceptor drains. Relief drains are used either to lower the water table in order to improve the growth of vegetation, or to remove surface water. They are installed along a slope and drain in the direction of the slope. They can be installed in a gridiron pattern, a herringbone pattern, or a random pattern (see Plate 1.50a).

Interceptor drains are used to remove water as it seeps down a slope, to prevent the soil from becoming saturated and subject to slippage. They are installed across a slope and drain to the side of the slope. They usually consist of a single pipe or series of single pipes instead of a patterned layout (see Plate 1.50b).

Design Criteria

Location

Tree roots can often clog subsurface drain systems. Consequently, subsurface drains should be located such that there are no trees within 50 feet of the drain.

Relief drains - Relief drains should be located through the center of wet areas. They should drain in the same direction as the slope.

Interceptor drains - Interceptor drains should be located on the uphill side of wet areas. They should be installed across the slope and drain to the side of the slope.

Capacity of Drains

The required capacity of a subsurface drain depends upon its use.

Relief drains - Relief drains installed in a uniform pattern should remove a minimum of 1 inch of groundwater in 24 hours (0.042 cfs/acre). The design capacity must be increased accordingly to accommodate any surface water which enters directly into the system (Plate 1.50d).

Interceptor drains or relief drains in a random pattern - Interceptor drains or relief drains installed in a random pattern should remove a minimum of 1.5 cfs/1000 feet of length. This value should be increased for sloping land according to the values in Table 1.50a. In addition, if a flowing spring or surface water enters directly into the system, this flow must be accommodated and the design capacity must be increased accordingly to take care of this flow (Plate 1.50d).

R0071478

Table 1.50a

WATER REMOVAL RATES FOR SLOPING LAND

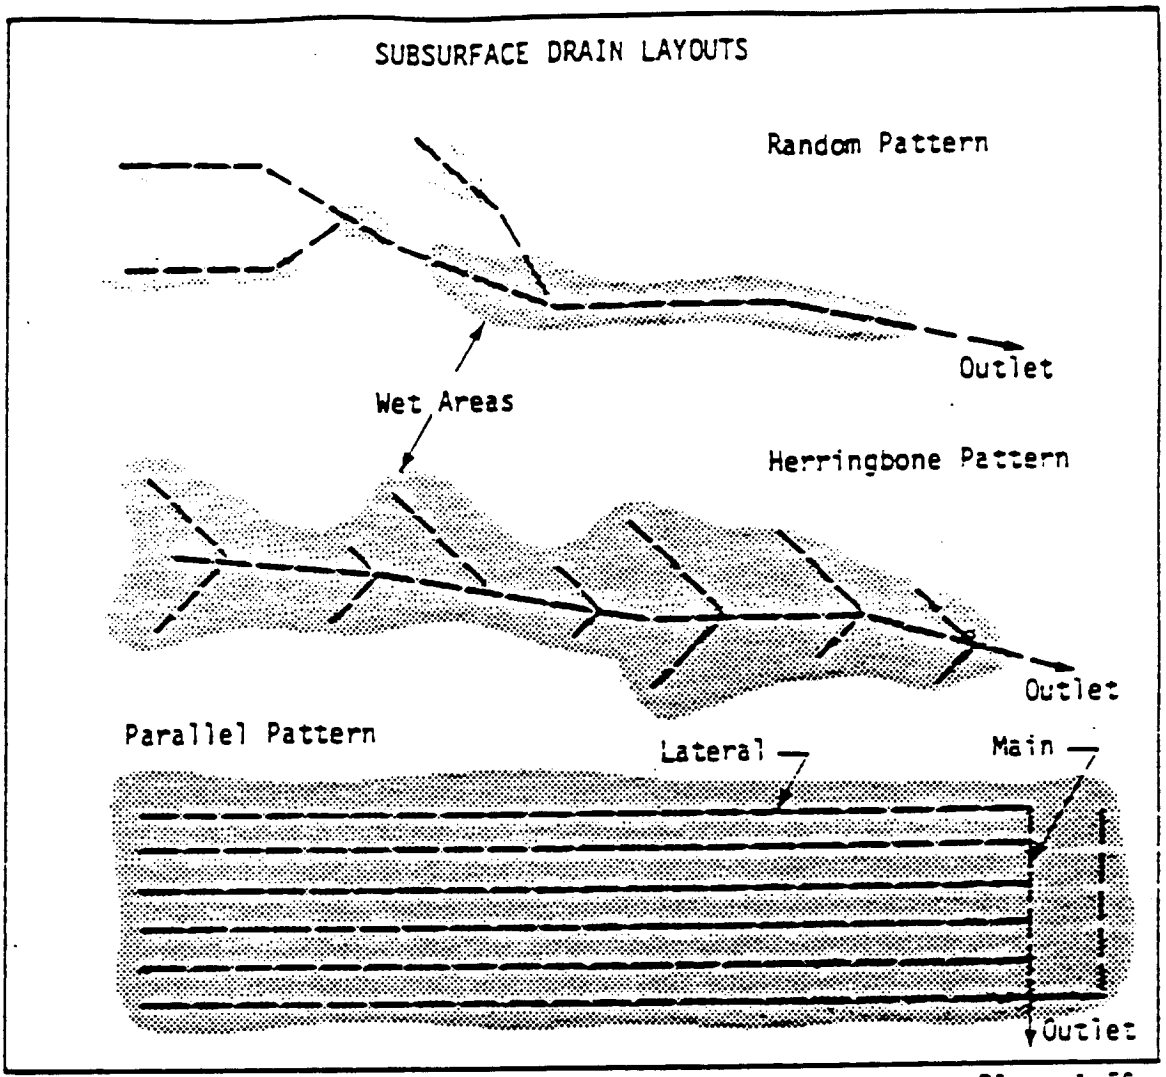
Land Slope	Water Removal Rate
2 - 5%	1.65 cfs/1000 ft.
6 - 12%	1.80 cfs/1000 ft.
> 12%	1.95 cfs/1000 ft.

Size of Drains

Subsurface drains should be sized for the required capacity using Plates 1.50f to 1.50h in Appendix 1.50A. The minimum diameter for a subsurface drain shall be 4 inches.

Depth and Spacing

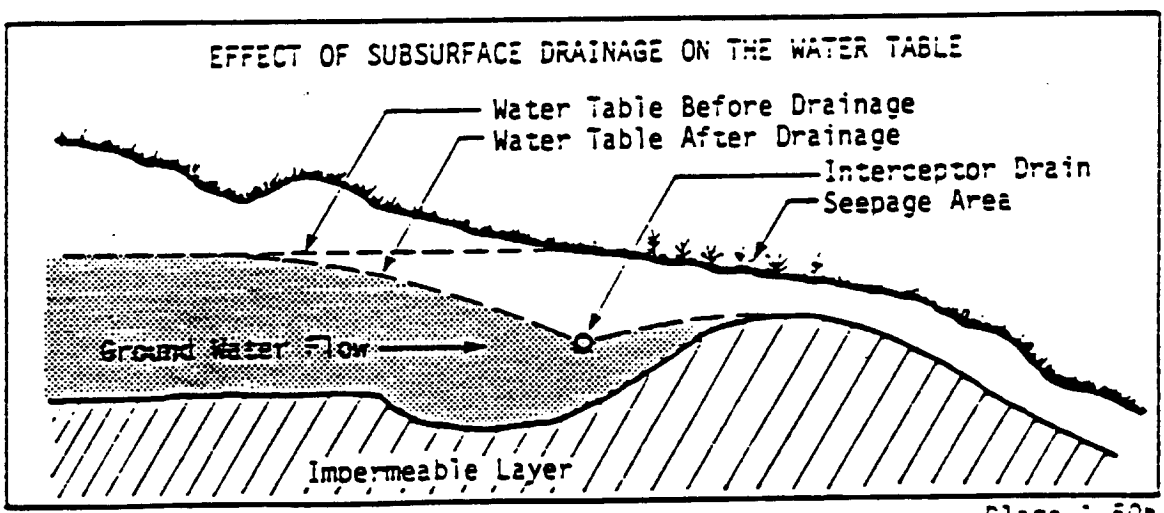
Relief drains - Relief drains installed in a uniform pattern should have equal spacing between drains and the drains should be at the same depth. Maximum depth is limited by the allowable load on the pipe, depth to impermeable layers in the soil, and outlet requirements. The minimum depth is 24 inches under normal conditions. Twelve inches is acceptable where the drain will not be subject to equipment loading or frost action. Spacing between drains is dependent on soil permeability and the depth of the drain. In general, however, a depth of 3 feet and a spacing of 50 feet will be adequate. A more economical system may be designed, if the necessary information is available, by using the equations found in Appendix 1.50A.



Interceptor drain - The depth of installation of an interceptor drain is influenced mainly by the depth to which the water table is to be lowered. The maximum depth is limited by the allowable load on the pipe and the depth to an impermeable layer. Minimum depth should be the same as for relief drains.

One interceptor drain is usually sufficient. However, if multiple drains are to be used, determining the required spacing can be difficult. The best approach is to install the first drain--then if seepage or high water table problems occur downslope, install an additional drain a suitable distance downslope. This distance can be calculated from equations found in Appendix 1.50A.

Velocity and Grade



The minimum velocity required to prevent silting is 1.4 ft./sec. The line should be graded to achieve at least this velocity. Steep grades should be avoided, however. Table 1.50b lists maximum velocities for various soil textures.

R0071479

Source: USDA-SCS

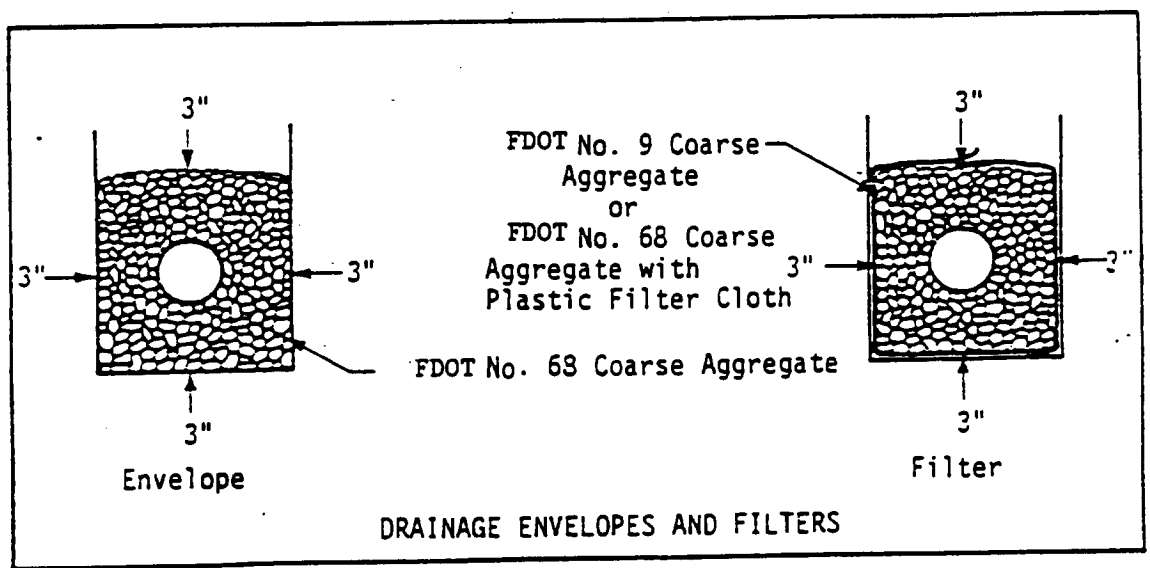
Plate 1.50a

Source: USDA-SCS

Plate 1.50b

Table 1.50b

MAXIMUM VELOCITIES FOR VARIOUS SOIL TEXTURES



Soil Texture	Maximum Velocity - ft./sec.
Sandy and Sandy Loam	3.5
Silt and Silt Loam	5.0
Silty Clay Loam	6.0
Clay and Clay Loam	7.0
Coarse Sand or Gravel	9.0

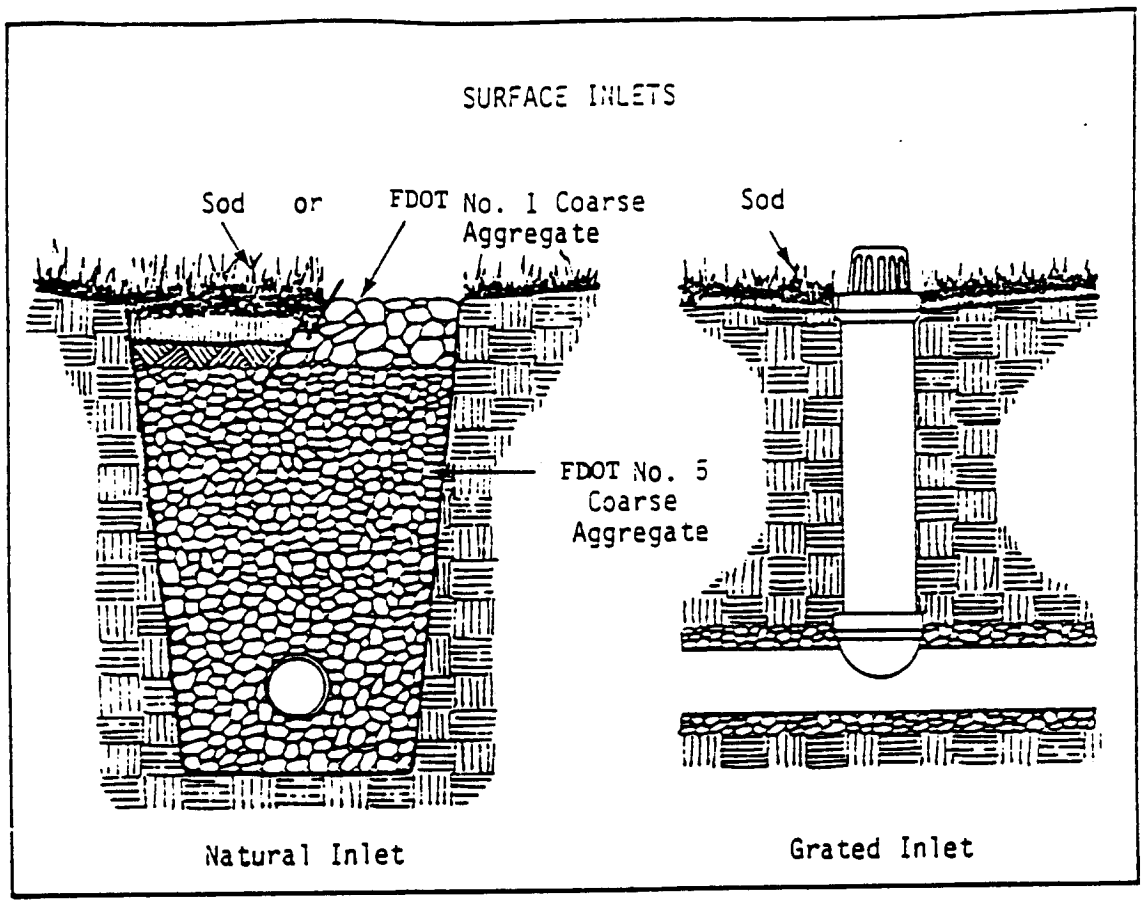
Envelopes and Filters

Envelopes or filters shall be used around all drains for proper bedding and improved flow of groundwater into the drain. The envelope shall consist of 3 inches of FDOT No. 68 aggregate placed completely around the drain (see Plate 1.50c).

Where high concentrations of silt and fine sand are encountered, a filter should be used instead of an envelope. The filter shall consist of 3 inches of FDOT No. 9 aggregate placed completely around the drain.

Plastic filter clothes can be used instead of granular filters. Filter cloths should be used with a gravel envelope as shown in Plate 1.50c.

DRAINAGE ENVELOPES AND FILTERS



Source: USDA-SCS

Plate 1.50c

Surface Water

Plate 1.50d shows two types of surface water inlets. The grated inlet should not be used where sediment might be a problem.

R0071481

Source: USDA-SCS

Plate 1.50d

Outlet

The outlet of the subsurface drain shall empty into a stabilized channel or other watercourse which will remove the water from the outlet. It shall be above the mean water level in the receiving channel. It shall be protected from erosion, undermining, damage from periods of submergence, and the entry of small animals into the drain.

The outlet shall consist of a 10-foot section of corrugated metal, cast iron, or steel pipe without perforations. No envelope material shall be used around the pipe. At least two-thirds of the outlet pipe length shall be buried.

Materials

Acceptable materials for subsurface drains include perforated, continuous closed-joint conduits of corrugated plastic, concrete, corrugated metal, asbestos cement, and bituminized fiber. The strength and durability of the pipe shall meet the requirements of the site in accordance with the manufacturer's specifications.

R0071482

Construction Specifications

1. The trench shall be constructed on a continuous grade with no reverse grades or low spots.

2. Soft or yielding soils under the drain shall be stabilized with gravel or suitable material.

3. Deformed, warped, or otherwise unsuitable pipe shall not be used.

4. Envelopes or filter material shall be placed as specified with at least 3 inches of material on all sides of the pipe.

5. Backfilling shall be done immediately after placement of the pipe. No sections of pipe should remain uncovered overnight or during a rainstorm. Backfill material shall be placed in the trench in such a manner that the drain pipe is not displaced or damaged.

6. The outlet section of the drain shall consist of at least 10 feet of non-perforated corrugated metal, cast iron or steel pipe. At least two-thirds of its length shall be buried.

Maintenance

1. Subsurface drains should be checked periodically to insure that they are free-flowing and not clogged with sediment.

2. The outlet should be kept clean and free of debris.

3. Surface inlets should be kept open and free of sediment and other debris.

4. Trees located too close to a subsurface drain often clog the system with their roots. If a drain becomes clogged, relocate the drain or remove the trees.

5. Where drains are crossed by heavy vehicles, the line should be checked to insure that it is not crushed.

R0071483

APPENDIX 1.50A

Subsurface drains are not generally designed to flow under pressure and the hydraulic gradient is parallel with the grade line. Consequently, the flow is considered to be open channel and Manning's Equation can be used. The required drain size can be determined by the following procedure:

1. Determine the flow the drain must carry.
2. Determine the gradient of the drain.
3. From Table 1.50c, determine n for the type of drain pipe to be used. Choose the correct Plate 1.50e-1.50g for the n just determined.
4. Enter the appropriate plate with the gradient of the pipe and the flow in the pipe. The intersection of the two lines must be to the right of the line for 1.4 ft./sec. If it is not, increase the gradient or flow capacity or both.

Example 1

Given:

A random subsurface drain is to be installed on a 1.0% grade, 700 feet in length, and using corrugated plastic pipe.

Calculate:

The required size of the drain pipe.

Solution:

From the Std. and Spec., the required capacity of the pipe is 1.5 $ft.^3/sec.$ 1000 ft.

$$\text{Capacity} = \frac{700}{1000} \times 1.5\ ft.^3/sec.\quad 1.05\ ft.^3/sec.$$

From Table 1.50c, n = 0.015 for corrugated plastic pipe.

From Plate 1.50f, choose an 8-inch pipe.

Example 2

Given:

A relief drain installed in a gridiron pattern, of 8 laterals, 500 feet long, 0.5% grade, and 50 feet on centers. A main 400 feet in length on a 0.5% grade will connect to the laterals. Use bituminized fiber pipe for the main and laterals.

Calculate:

The required size of the drain pipe.

R0071484

Solution:

The drainage area for each lateral is 25 feet on either side of the pipe times the length, therefore,

$$\frac{50 \text{ ft.} \times 500 \text{ ft.}}{43{,}560 \text{ ft.}^2/\text{acre}} = 0.57 \text{ acre}$$

From the Std. & Spec., the drains must remove 1 inch of water in 24 hours or 0.042 $ft.^3/sec./acre$.

$$0.042 \text{ ft.}^3/\text{sec./acre} \times 0.57 \text{ acre} = 0.02 \text{ ft.}^3/\text{sec.}$$

From Table 1.50c, n = 0.013 for bituminized fiber pipe.

From Plate 1.50e, a 4-inch pipe must be used for the laterals.

The first 25 feet of the main will drain 25 feet on either side of the pipe. The remaining 375 feet will drain only 25 feet on the side opposite from the laterals. In addition, the main will drain the laterals.

Drainage from the main:

$$\frac{25 \text{ ft.} \times 50 \text{ ft.}}{43{,}560 \text{ ft.}^2/\text{acre}} + \frac{375 \text{ ft.} \times 25 \text{ ft.}}{43{,}560 \text{ ft.}^2/\text{acre}} = 0.24 \text{ acre}$$

Drainage from laterals:

$$8 \times 0.57 \text{ acre} = 4.56 \text{ acre}$$

$$\text{Total} = 0.24 + 4.56 = 4.8 \text{ acre}$$

Required capacity:

$$0.042 \text{ ft.}^3/\text{sec./acre} \times 4.8 \text{ acre} = 0.20 \text{ ft.}^3/\text{sec.}$$

From Plate 1.50e, choose a 5-inch pipe for the main.

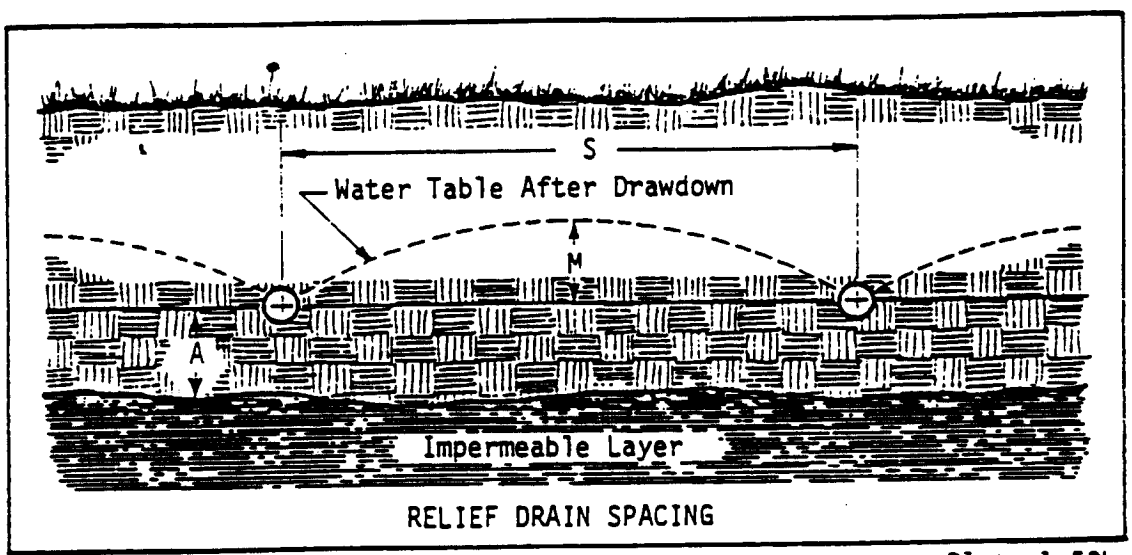
Spacing of Relief Drains

If the necessary information is known, the following equation can be used to calculate drain spacing in lieu of the recommended standard:



$$S = \sqrt{\frac{4k\ (M^2 + 2\ AM)}{q}}$$

where,

S = drain spacing, feet.
k = average hydraulic conductivity, in./hr. (For practical purposes, hydraulic conductivity is equal to permeability).
M = vertical distance, after drawdown, of water table above drain at mid-point between lines, feet.
A = depth of barrier below drain, feet.
q = drainage coefficient, rate of water removal, in./hr.

Also, see Plate 1.50h.

Limitations of the equation are listed in the SCS National Engineering Handbook, Section 16, Drainage of Agricultural Land (53).

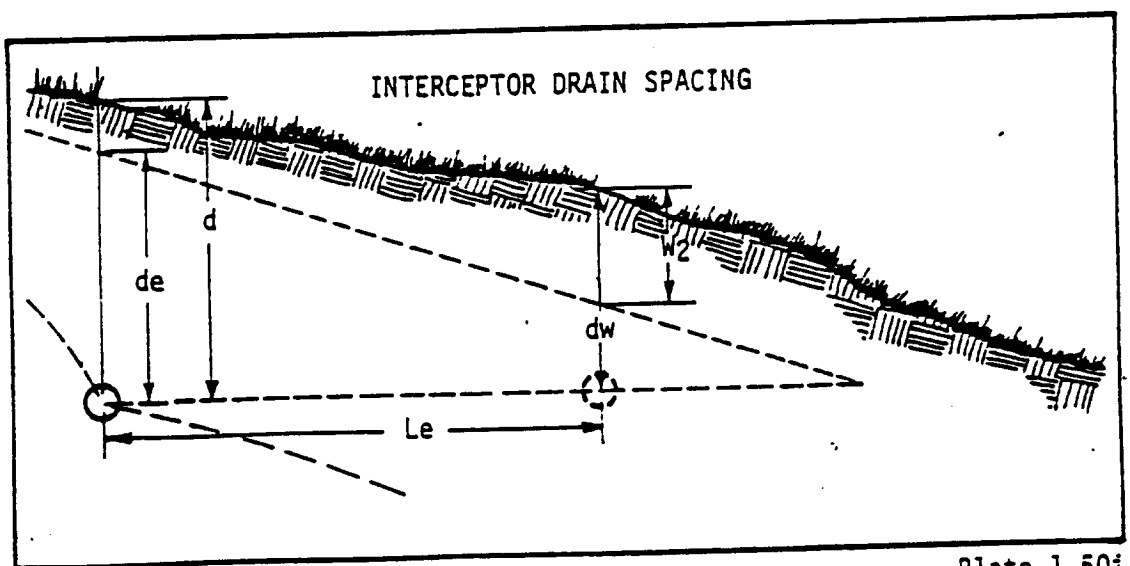
RELIEF DRAIN SPACING

Source: USDA-SCS

Plate 1.50h

Spacing of Interceptor Drains

If one interceptor drain is not sufficient, the spacing of multiple drains can be calculated by the following equation:



$$Le = \frac{ki}{q} (de - dw + W_2)$$

where,

Le = the distance downslope from the drain to the point where the water table is at the desired depth after drainage, feet. The second drain should be located at this point.
k = the average hydraulic conductivity of the subsurface profile to the depth of the drain, in./hr.
q = drainage coefficient, rate of water removal, in./hr.
i = the hydraulic gradient of the water table before drainage, feet/foot.
de = the effective depth of the drain, feet.
dw = the desired minimum depth to water table after drainage, feet.
W_2 = the distance from the ground surface to the water table, before table, before drainage, at the distance (Le) downslope from the drain, feet.

Also see Plate 1.50i.

Further information on this equation can be obtained from the SCS National Engineering Handbook, Section 16, Drainage of Agricultural Land (53).

R0071490

ES BMP 1.60

SURFACE ROUGHENING

Definition

Providing a rough soil surface with horizontal depressions created by operating a tillage or other suitable implement on the contour, or by leaving slopes in a roughened condition by not fine-grading them.

Purposes

1. To aid in establishment of vegetative cover with seed.
2. To reduce runoff velocity and increase infiltration.
3. To reduce erosion and provide for sediment trapping.

R0071491

Conditions Where Practice Applies

1. All slopes steeper than 3:1 require surface roughening, either stair-step grading, grooving, furrowing, or tracking if they are to be stabilized with vegetation.

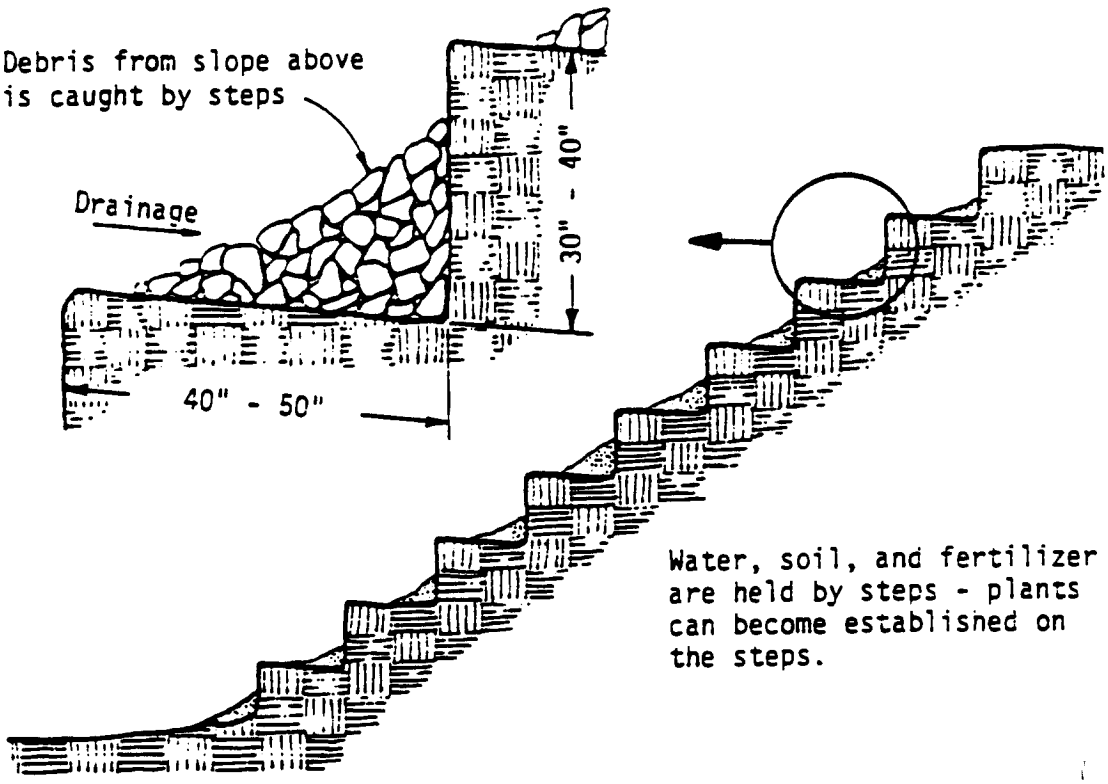
2. Areas with grades less steep than 3:1 should have the soil surface lightly roughened and loose to a depth of 2 to 4 inches prior to seeding.

3. Areas which have been graded and will not be stabilized immediately may be roughened to reduce runoff velocity until seeding takes place.

4. Slopes with a stable rock face do not require roughening or stabilization.

Planning Considerations

Grades areas with smooth, hard surfaces give a false impression of "finished grading" and a job well done. It is difficult to establish vegetation on such surfaces due to reduced water infiltration and the potential for erosion. Rough slope surfaces with uneven soil and rocks left in place may appear unattractive or unfinished at first, but encourage water infiltration, speed the establishment of vegetation, and decrease runoff velocity.

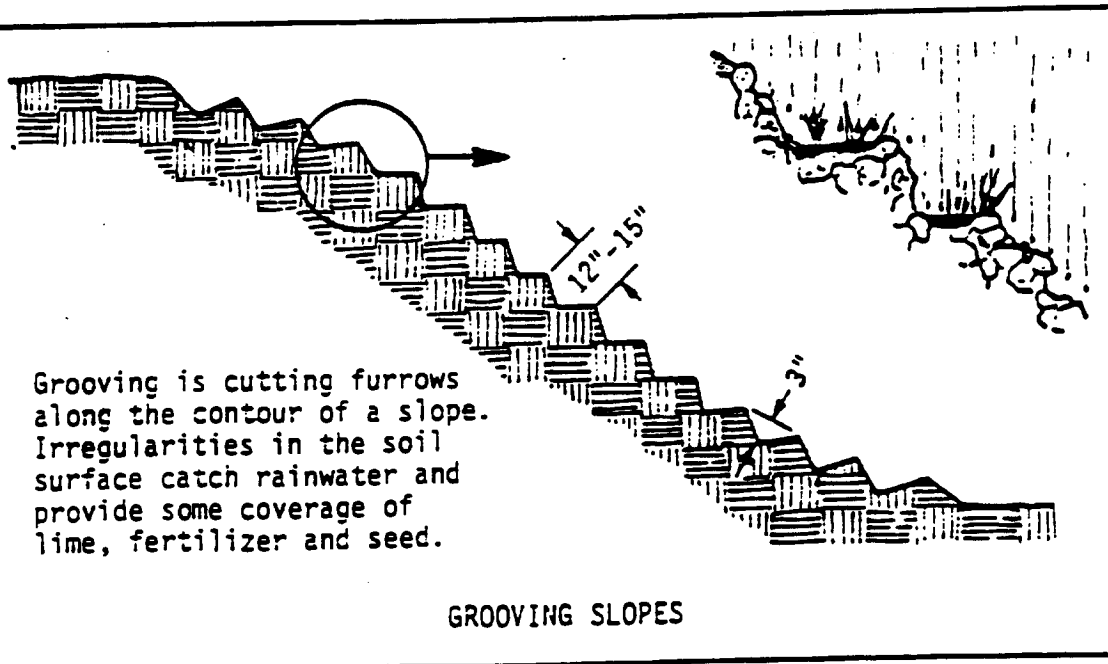


Rough, loose soil surfaces give lime, fertilizer and seed some natural coverage. Niches in the surface provide microclimates which generally provide a cooler and more favorable moisture level than hard flat surfaces; this aids seed germination.

There are different methods for achieving a roughened soil surface on a slope, and the selection of an appropriate methods depends upon the type of slope. Roughening methods include stair-step grading, grooving, and tracking. Factors to be considered in choosing a method are slope steepness, mowing requirements, and whether the slope is formed by cutting or filling.

1. Disturbed areas which will not require mowing may be stair-step graded, grooved, or left rough after filling.

2. Stair-step grading is particularly appropriate in soils containing large amounts of soft rock. Each "step" catches material which sloughs from above, and provides a level site where vegetation can become established.



R0071492

STAIR STEPPING CUT SLOPES

Source: Va SWCC

Plate 1.60a

GROOVING SLOPES

Source: Va SWCC

Plate 1.60b

R0071493

3. Areas which will be mowed (these areas should have slopes less steep than 3:1) may have small furrows left by discing, harrowing, raking or seed-planting machinery operated on the contour.

4. It is important to avoid excessive compacting of the soil surface when scarifying. Tracking with bulldozer treads is preferable to not roughening at all, but is not as effective as other forms of roughening, as the soil surface is severely compacted and runoff is increased.

Specifications

Cut Slope Applications for Areas Which Will Not Be Mowed

Cut slopes with a gradient steeper than 3:1 shall be stair-step graded or grooved (Plate 1.60a and 1.60b).

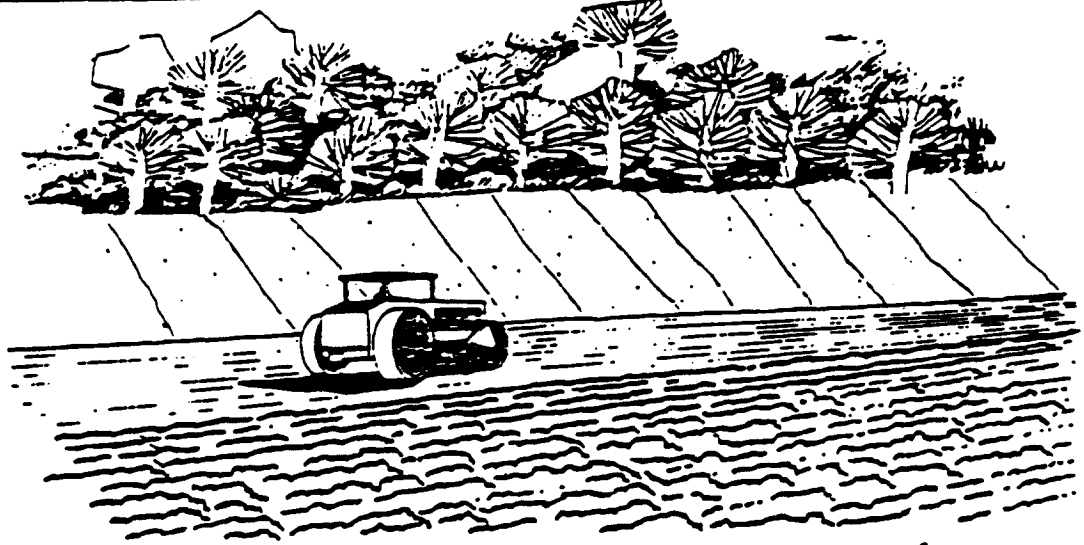
1. Stair-step grading may be carried out on any material soft enough to be ripped with a bulldozer. Slopes consisting of soft rock with some subsoil are particularly suited to stair-step grading.

   The ratio of the vertical cut distance to the horizontal distance shall be less than 1:1 and the horizontal portion of the "step" shall slope toward the vertical wall.

   Individual vertical cuts shall not be more than thirty inches on soft soil materials and not more than forty inches in rocky materials.

2. Grooving consists of using machinery to create a series of ridges and depressions which run perpendicular to the slope (on the contour).

   Grooves may be made with an appropriate implement which can be safely operated on the slope and which will not cause undue compaction. Suggested implements include discs, tillers, spring harrows, and the teeth on a front-end loader bucket. Such grooves shall not be less than three inches deep nor further than fifteen inches apart.



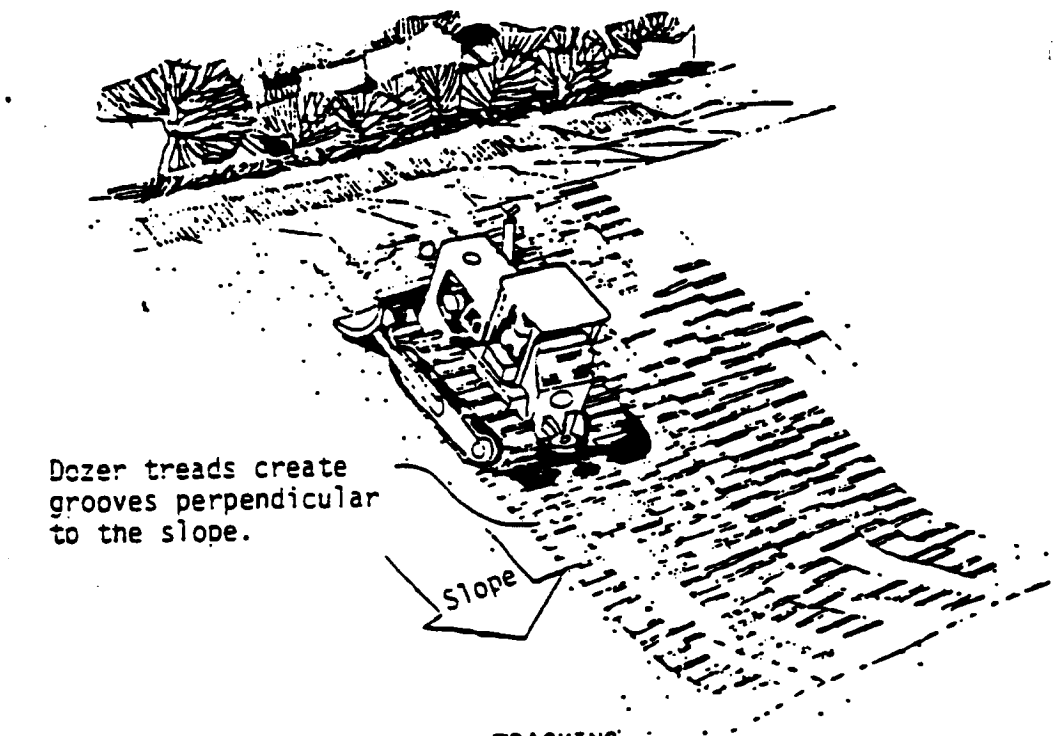
Fill Slope Applications For Areas Which Will Not Be Mowed

Fill slopes with a gradient steeper than 3:1 shall be grooved or allowed to remain rough as they are constructed. Method (1) or (2) below may be used:

1. Groove according to #2, above.

2. As lists of the fill are constructed, soil and rock materials may be allowed to fall naturally onto the slope surface (Plate 1.60c).

Colluvial materials (soil deposits at the base of slopes or from old stream beds) shall not be used in fills as they flow when saturated.



Each lift of the fill is compacted, but the outer face of the slope is allowed to remain loose so that the rocks, clods, etc. reach the natural angle of repose.

FILL SLOPE TREATMENT

Source: Va SWCC

Plate 1.60c

TRACKING

Source: Michigan Soil Erosion and Sedimentation Control Guidebook

Plate 1.60d

R0071495

At no time shall slopes be bladed or scraped to produce a smooth, hard surface.

Cuts, Fills, and Graded Areas Which Will Be Mowed

Mowed slopes should not be steeper than 3:1. Excessive roughness is undesirable where mowing is planned.

These areas may be roughened with shallow grooves such as remain after tilling, discing harrowing, raking, or use of a cultipacker-seeder. The final pass of any such tillage implement shall be on the contour (perpendicular to the slope).

Grooves formed by such implements shall not be less than one inch deep and not further than twelve inches apart.

Fill slopes which are left rough as constructed may be smoothed with a dragline or pickchain to facilitate mowing.

Roughening With Tracked Machinery (Plate 1.60d)

Roughening with tracked machinery on clayed soils is not recommended unless no alternatives are available. Undue compaction of surface soil results from this practice. Sandy soils do not compact severely, and may be tracked. In no case is tracking as effective as the other roughening methods described.

When tracking is the chosen surface roughening technique, it shall be done by operating tracked machinery up and down the slope to leave horizontal depressions in the soil. As few passes of the machinery should be made as possible to minimize compaction.

Seeding

Roughened areas shall be seeded and mulched as soon as possible to obtain optimum seed germination and seedling growth.

R0071496

ES BMP 1.61

TOPSOILING

Definition

Methods of preserving and using topsoil to enhance final site stabilization with vegetation.

Purpose

To provide a suitable growth medium for final site stabilization with vegetation.

Conditions Where Practice Applies

1. Where the preservation or importation of topsoil is determined to be the most effective method of providing a suitable growth medium.

2. Where the subsoil or existing soil presents the following problems:

   a. The texture, pH, or nutrient balance of the available soil cannot be modified by reasonable means to provide an adequate growth medium.
   b. The soil material is too shallow to provide an adequate root zone and to supply necessary moisture and nutrients for plant growth.
   c. The soil contains substances potentially toxic to plant growth.

R0071497

3. Where high-quality turf is desirable to withstand intense use or meet aesthetic requirements.

4. Where ornamental plants will be established.

5. Only on slopes that are 2:1 or flatter.

Planning Considerations

Topsoil is the surface layer of the soil profile, generally characterized as being darker than the subsoil due to the presence of organic matter. It is the major zone of root development, carrying much of the nutrients available to plants, and supplying a large share of the water used by plants.

Although topsoil provides an excellent growth medium, there are disadvantages to its use. Stripping, stockpiling, and reapplying topsoil, or importing topsoil, may not always be cost-effective. Topsoiling can delay seeding or sodding operations, increasing the exposure time of denuded areas. Most topsoil contains weed seeds, and weeds may compete with desirable species.

Advantages of topsoil include its high organic matter content and friable consistence, water-holding capacity, and nutrient content.

In site planning, the option of topsoiling should be compared with that of preparing a seedbed in subsoil. The clay content of subsoils does provide high moisture availability and deter leaching of nutrients, and when properly limed and fertilized, subsoils may provide a good growth medium which is generally free of weed seeds.

Topsoiling is strongly recommended where ornamental plants or high-maintenance turf will be grown. Topsoiling is a required procedure when establishing vegetation on shallow soils, soils containing potentially toxic materials, and soils of critically low pH (high acid) levels.

If topsoiling is to be done, the following items should be considered:

1. Whether an adequate volume of topsoil exists on the site. Topsoil will be spread at a compacted depth of 2-4 inches.

2. Location of the topsoil stockpile so that it meets specifications and does not interfere with work on the site.

3. Allow sufficient time in scheduling for topsoil to be spread and bonded prior to seeding, sodding, or planting.

4. Care must be taken not to apply topsoil to subsoil if the two soils have contrasting textures. Clayey topsoil over sandy subsoil is a particularly poor combination, as water creeps along the junction between the soil layers and causes the topsoil to slough.

5. If topsoil and subsoil are not properly bonded, water will not infiltrate the soil profile evenly and it will be difficult to establish vegetation.

R0071498

Specifications

Materials

Field exploration of the site should be made to determine if there is sufficient surface soil of good quality to justify stripping. Topsoil should be friable and loamy (loam, sandy loam, silt loam, sandy clay loam, clay loam). It should be free of debris, trash, stumps, rocks, roots, and noxious weeds, and should give evidence of being able to support healthy plant growth.

Stripping

Stripping should be confined to the immediate construction area. A 4- to 6- inch stripping depth is common, but depth may vary depending on the particular soil. All perimeter dikes, basins, and other sediment controls shall be in place prior to stripping.

Stockpiling

Topsoil shall be stockpiled in such a manner that natural drainage is not obstructed and no off-site sedimentation occurs. Stockpiles should be planned so as not to interfere with any of the construction operations. Stockpiles can also act as barriers to shield the construction site from the neighborhood and adjacent landowners. They will also help to reduce the amount of dust and noise coming from the site.

Side slopes of the stockpile shall not exceed 2:1.

A perimeter dike with gravel outlet, silt fence, or straw bale barrier shall surround all topsoil stockpiles.

Temporary seeding of stockpiles shall be completed within 15 days of the formation of the stockpile, in accordance with TEMPORARY SEEDING (ES BMP 1.65).

Site Preparation Prior to and Maintenance During Topsoiling

Before topsoiling, establish needed erosion and sediment control practices such as diversions, grade stabilization structures, berms, dikes, level spreaders, waterways, sediment basins, etc. These practices must be maintained during topsoiling.

Grading: Previously established grades on the areas to be topsoiled shall be maintained according to the approved plan.

Liming: Where the pH of the subsoil is 6.0 or less, or the soil is composed of heavy clays, agricultural limestone shall be spread in accordance with the soil test or the vegetative establishment practice being used.

R0071499

Bonding: After the areas to be topsoiled have been brought to grade, and immediately prior to dumping and spreading the topsoil, the subgrade shall be loosened by discing or scarifying to a depth of at least 2 inches to insure bonding of the topsoil and subsoil.

Applying Topsoil

Topsoil shall not be placed while in a muddy condition, when the subgrade is excessively wet, or in a condition that may otherwise be detrimental to proper grading or proposed sodding or seeding. The topsoil shall be uniformly distributed to a minimum compacted depth of 2 inches on 3:1 or steeper slopes and 4 inches on flatter slopes. (See Table 1.61a to determine volume of topsoil required for application to various depths). Any irregularities in the surface, resulting from topsoiling or other operations, shall be corrected in order to prevent the formation of depressions or water pockets.

It is necessary to compact the topsoil enough to ensure good contact with the underlying soil and to obtain a level seedbed for the establishment of high maintenance turf. However, undue compaction is to be avoided as it increases runoff velocity and volume, and deters seed germination. In areas which are not going to be mowed, the surface should be left rough in accordance with SURFACE ROUGHENING (ES BMP 1.60).

Soil Sterilants

No sod or seed shall be placed on soil which has been treated with soil sterilants until sufficient time has elapsed to permit dissipation of toxic materials.

Table 1.61a

CUBIC YARDS OF TOPSOIL REQUIRED FOR APPLICATION TO VARIOUS DEPTHS

Depth (inches)	Per 1,000 Square Feet	Per Acre
1	3.1	134
2	6.2	268
3	9.3	403
4	12.4	537
5	15.5	672
6	18.6	806

R0071500

ES BMP 1.65

TEMPORARY SEEDING

Definition

The establishment of a temporary vegetative cover on disturbed areas by seeding with appropriate rapidly growing annual plants.

Purposes

1. To reduce erosion and sedimentation by stabilizing disturbed areas that will not be brought to final grade for a year or less.

2. To reduce problems associated with mud and dust production from bare soil surfaces during construction.

Conditions Where Practice Applies

Where exposed soil surfaces are not to be fine-graded for periods from 30 days to one year. Such areas include denuded areas, soil stockpiles, dikes, dams, sides of sediment basins, temporary roadbanks, etc.

R0071501

Planning Considerations

Sheet erosion, caused by the impact of rain on bare soil, is the source of most fine particles in sediment. To reduce this sediment load in runoff, the soil surface itself should be protected. The most efficient and economical means of controlling sheet and rill erosion is to establish vegetative cover. Annual plants which sprout rapidly and survive for only one growing season are suitable for establishing temporary vegetative cover.

Temporary seeding may prevent costly maintenance operations on other erosion control systems. For example, sediment basin clean-outs will be reduced if the drainage area of the basin is seeded where grading and construction are not taking place. Perimeter dikes will be more effective if not choked with sediment.

Temporary seeding is essential to preserve the integrity of earthen structures used to control sediment, such as dikes, diversions, and the banks and dams of sediment basins.

Proper seedbed preparation and the use of quality seed are important in this practice just as in permanent seeding. Failure to carefully follow sound agronomic recommendations will often result in an inadequate stand of vegetation that provides little or no erosion control. Temporary measures should be coordinated with permanent vegetation to assure the most economical and efficient control.

Specifications

Prior to seeding, install necessary erosion control practices such as dikes, waterways, and basins.

Plant Selection

Select plants appropriate to the season and site conditions from Table 1.65a.

Seedbed Preparation

To control erosion on bare soil surfaces, plants must be able to germinate and grow. Seedbed preparation is essential. A soil test should be taken to determine liming and fertilization requirements. In the absence of a soil test the following guidelines should be followed:

1. Liming: Where soils are known to be highly acid (pH 5.5 and lower), lime should be applied at the rate of two tons of pulverized agricultural limestone per acre.

2. Fertilizer: Shall be applied as 450 lbs./acre of 10-20-20 (10 lbs./1,000 sq. ft.) or equivalent. Lime and fertilizer shall be incorporated into the top 2 to 4 inches of the soil.

3. Surface Roughening: If the area has been recently loosened or disturbed, no further roughening is required.

R0071502

TABLE 1.65 A

TEMPORARY SEEDING PLANT MATERIALS

Common Name (Botanical Name)	Seeding Rate Acre	Seeding Rate 1000 ft²	Planting Dates NORTH	Planting Dates CENTRAL	Planting Dates SOUTH	Comments
OATS (Avena sativa)	3 Bu (125 lbs)	3 lbs	September-February	September-February	October-February	Will not tolerate flooding, high water table soils.
RYE (Secale cereale)	3 Bu (170 lbs)	4 lbs	September-February	October-February	October-February	Tolerates cold and drought.
WHEAT (Triticum sp)	3 Bu (120 lbs)	3 lbs	September-February	October-February	October-February	
ANNUAL RYEGRASS (Lolium multiflorum)	60 lbs	1.5 lbs	September-February	October-February	October-January	Volunteers may return.
CRIMSON CLOVER (Trifolium incarnatum)	25 lbs	9 oz	September-November	October-November		Annual winter legume. Innoculate seed at 5 times recommended rate. Does poorly on deep dry sands, will not tolerate flooding.
RED CLOVER (Trifolium pratense)	15 lbs	6 oz	September-December	October-December	October-December	Annual winter legume. Innoculate seed at 5 times recommended rate. Grows best on moist soils, will not tolerate flooding. Easily hurt by drought.
WHITE CLOVER (Trifolium repens)	6 lbs	2.5 oz	September-December	October-December	October-December	Annual winter legume. Innoculate seed at 5 times recommended rate. Grows best on moist-wet soils, tolerates some flooding.
ANNUAL SWEETCLOVER (Melilotus altissima)	15 lbs	6 oz	September-December	October-December	October-December	Annual winter legume. Innoculate seed at 3-5 times recommended rate. Grows well on both flatwoods and upland soils. Will not tolerate flooding.
ARROWLEAF CLOVER (Trifolium vesiculosum)	15 lbs	6 oz	September-December	October-December	November-December	Annual winter legume. Innoculate seed at 3-5 times recommended rate. Grow on soil too wet for crimson, tolerates some flooding. Use scarified seed.
LUPINE CLOVER (Lupinus sp.)	60 lbs	1.5 lbs	September-December	October-December	October-December	Annual winter legume. Innoculate seed at 3 times recommended rate. Susceptible to freeze damage at time of emergence. Use scarified seed.
ALFALFA (Medicago sativa)	22 lbs	8 oz	September-December	October-December	October-December	Short lived perennial. Some drought resistance. Grows best on well-drained, fertile soils. Will not tolerate wet soils.
AUSTRIAN WINTER PEAS	45 lbs	1 lb	September-December	October-December	October-December	Grows best on well-drained soils with high clay content.
HAIRY VETCH (Vicia villosa)	25 lbs	9 oz	September-December	October-December	October-December	Grows best on well-drained, loamy soils.
ALYCECLOVER (Alysicarpus vaginalis)	15 lbs	6 ozs	April-July	March-July	March-July	Warm season annual legume. Grows best on well-drained sandy soils.
COMMON LESPEDEZA (Lespideza striata)	30 lbs	11 ozs	March-July	February-July	February-July	Warm season annual. Needs innoculation on eroded soils. Grows best on sandy loams. Fairly drought resistant.
HAIRY INDIGO (Indigofera hirsuta)	8 lbs (120 lbs)	3 ozs	March-July	February-July	February-July	
JOINT VETCH (Aeschynomera americana)	8 lbs	3 ozs	March-August	February-August	February-August	Warm season annual legume. Most suitable of summer legumes for use in low, wet areas.
MILLET (Setaria sp)	30 lbs	11 oz	March-August	March-August	February-August	Warm season annual. Does not tolerate flooding. Grows best in fertile, moist soils. Pearl and Browntop are good varieties to use.
SESBANIA (Sesban macrocarpa)	30 lbs	11 oz	March-July	March-July	February-July	Warm season annual legume. Does well under extremely wet conditions.
SORGHAH-SUDANGRASS HYBRID	30 lbs	11 oz	March-July	March-July	February-July	Warm season annual. Rapid grower. Tolerates dryer soils than millet. Grows best on well-drained soils. Can also use Sudangrass alone.
WEEPING LOVEGRASS (Eragrostis curvula)	5 lbs	2 oz	March-August	March-August	February-August	Short-lived perennial, 2-3 years. Tolerates hot, dry slopes and acid, infertile soils.

Usually mixtures of the above plant materials are better than a single plant alone. Each of the legumes discussed above can be grown in mixture with annual ryegrass and/or the small grains. In a two-crop mixture cut the seeding rate of each crop to one-half of the recommended planting rate when grown alone. Simply three plant types in a mixture requires approximately one-third of the normal seeding rate for each plant. In a three plant mixture containing a single legume, the legume should be planted at one-half of the pure stand seeding rate.

R0071503

When the area is compacted, crusted, or hardened, the soil surface shall be loosened by discing, raking, harrowing, or other acceptable means. (See SURFACE ROUGHENING, ES BMP 1.60).

4. Tracking: Tracking with bulldozer cleats is most effective on sandy soils. This practice often causes undue compaction of the soil surface, especially in clayey soils, and does not aid plant growth as effectively as other methods of surface roughening.

Seeding

Seed shall be evenly applied with a cyclone seeder, drill, cultipacker seeder or hydroseeder. Small grains shall be planted no more than one inch deep. Grasses and legumes shall be planted no more than 1/4 inch deep.

Mulching

1. Mulching should usually be used to reduce damage from water runoff or wind erosion, and to improve moisture conditions for seedlings. Mulching without seeding should be considered for very short term protection. The use of mulch is a judgment decision based on time of seeding and conditions of individual sites. When used, mulch shall be applied according to MULCHING, ES BMP 1.75.

2. Seedings made on slopes in excess of 3:1, or on adverse soil conditions, or during excessively hot or dry weather, shall be mulched according to MULCHING, ES BMP 1.75.

3. Seedings made during optimum spring and summer seeding dates, with favorable soil and site conditions, may not require mulch.

Re-seeding

Areas which fail to establish vegetative cover adequate to prevent rill erosion will be re-seeded as soon as such areas are identified.

R0071504

ES BMP 1.66

PERMANENT SEEDING

Definition

The establishment of perennial vegetative cover on disturbed areas by planting seed.

Purposes

1. To reduce erosion and decrease sediment yield from disturbed areas.
2. To permanently stabilize disturbed areas in a manner that is economical, adaptable to site conditions, and allows selection of the most appropriate plant materials.

Conditions Where Practice Applies

1. Disturbed areas where permanent, long-lived vegetative cover is needed to stabilize the soil.
2. Rough-graded areas which will not be brought to final grade for a year or more.

R0071505

Planning Considerations

Vegetation controls erosion by reducing the velocity and the volume of overland flow and protecting the bare soil surface from raindrop impact.

Areas which must be stabilized after the land has been disturbed require vegetative cover. The most common and economical means of establishing this cover is by seeding grasses and legumes.

Advantages of seeding over other means of establishing plants include the small initial establishment cost, the wide variety of grasses and legumes available, low labor requirement, and ease of establishment in difficult areas.

Disadvantages which must be dealt with are the potential for erosion during the establishment stage, a need to reseed areas that fail to establish, limited periods during the year suitable for seeding, and a need for water and appropriate climatic conditions during germination.

There are so many variables in plant growth that an end product cannot be guaranteed. Much can be done in the planning stages to increase the chances for successful seeding. Selection of the right plant materials for the site, good seedbed preparation, and conscientious maintenance are important.

SELECTING PLANT MATERIALS: The factors affecting plant growth are climate, soils, and topography. In Florida, there are four major physiographic regions that reflect changes in soil and topography. In selecting appropriate plant materials, one should take into account the characteristics of the physiographic region in which the project is located. (See Plate 1.66a).

PHYSIOGRAPHIC REGIONS:

Coastal Plain--Gently to strongly sloping rolling plain underlain by unconsolidated sands, silts and clays. Dominant soils are acid, well drained, finely textured and low in nutrients. Rainfall, perennial streams and groundwater provide an abundance of water although summer droughts occur on sandy soils.

Central Florida Ridge--A gently sloping to rolling sandy ridge underlain by limestone. Land surface is very irregular because of numerous sinkholes and lakes. Dominant soils are acid, well drained, coarse textured and low in nutrients. Rainfall, groundwater, lakes and sinkholes provide ample water although deep sands can become droughty.

Flatwoods--A nearly level plain characterized by swamps, marshes, wetlands and generally high groundwater levels. Dominant soils are acid, poorly drained, coarse textured and low in nutrients. Rainfall, surface water and groundwater provide an abundance of water although drainage activities and urbanization have caused salt water intrusion and water shortages.

R0071506

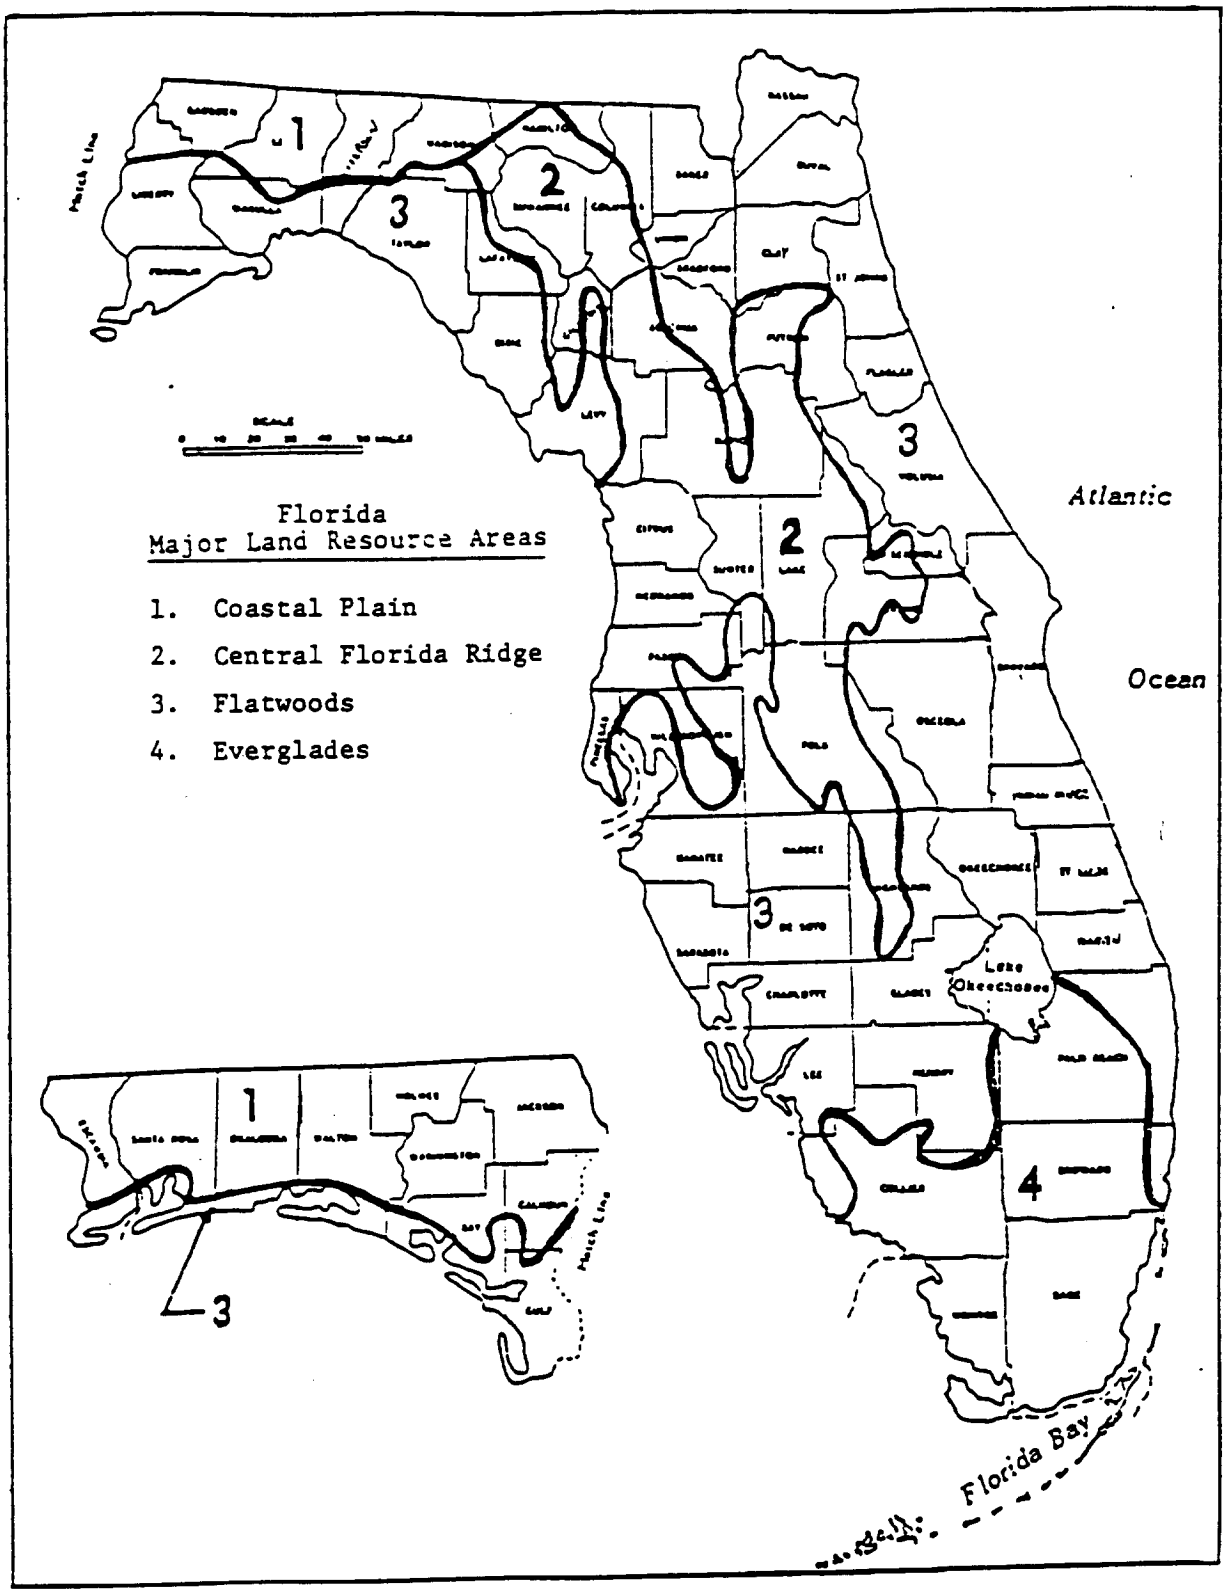


Plate 1.66a

R0071507

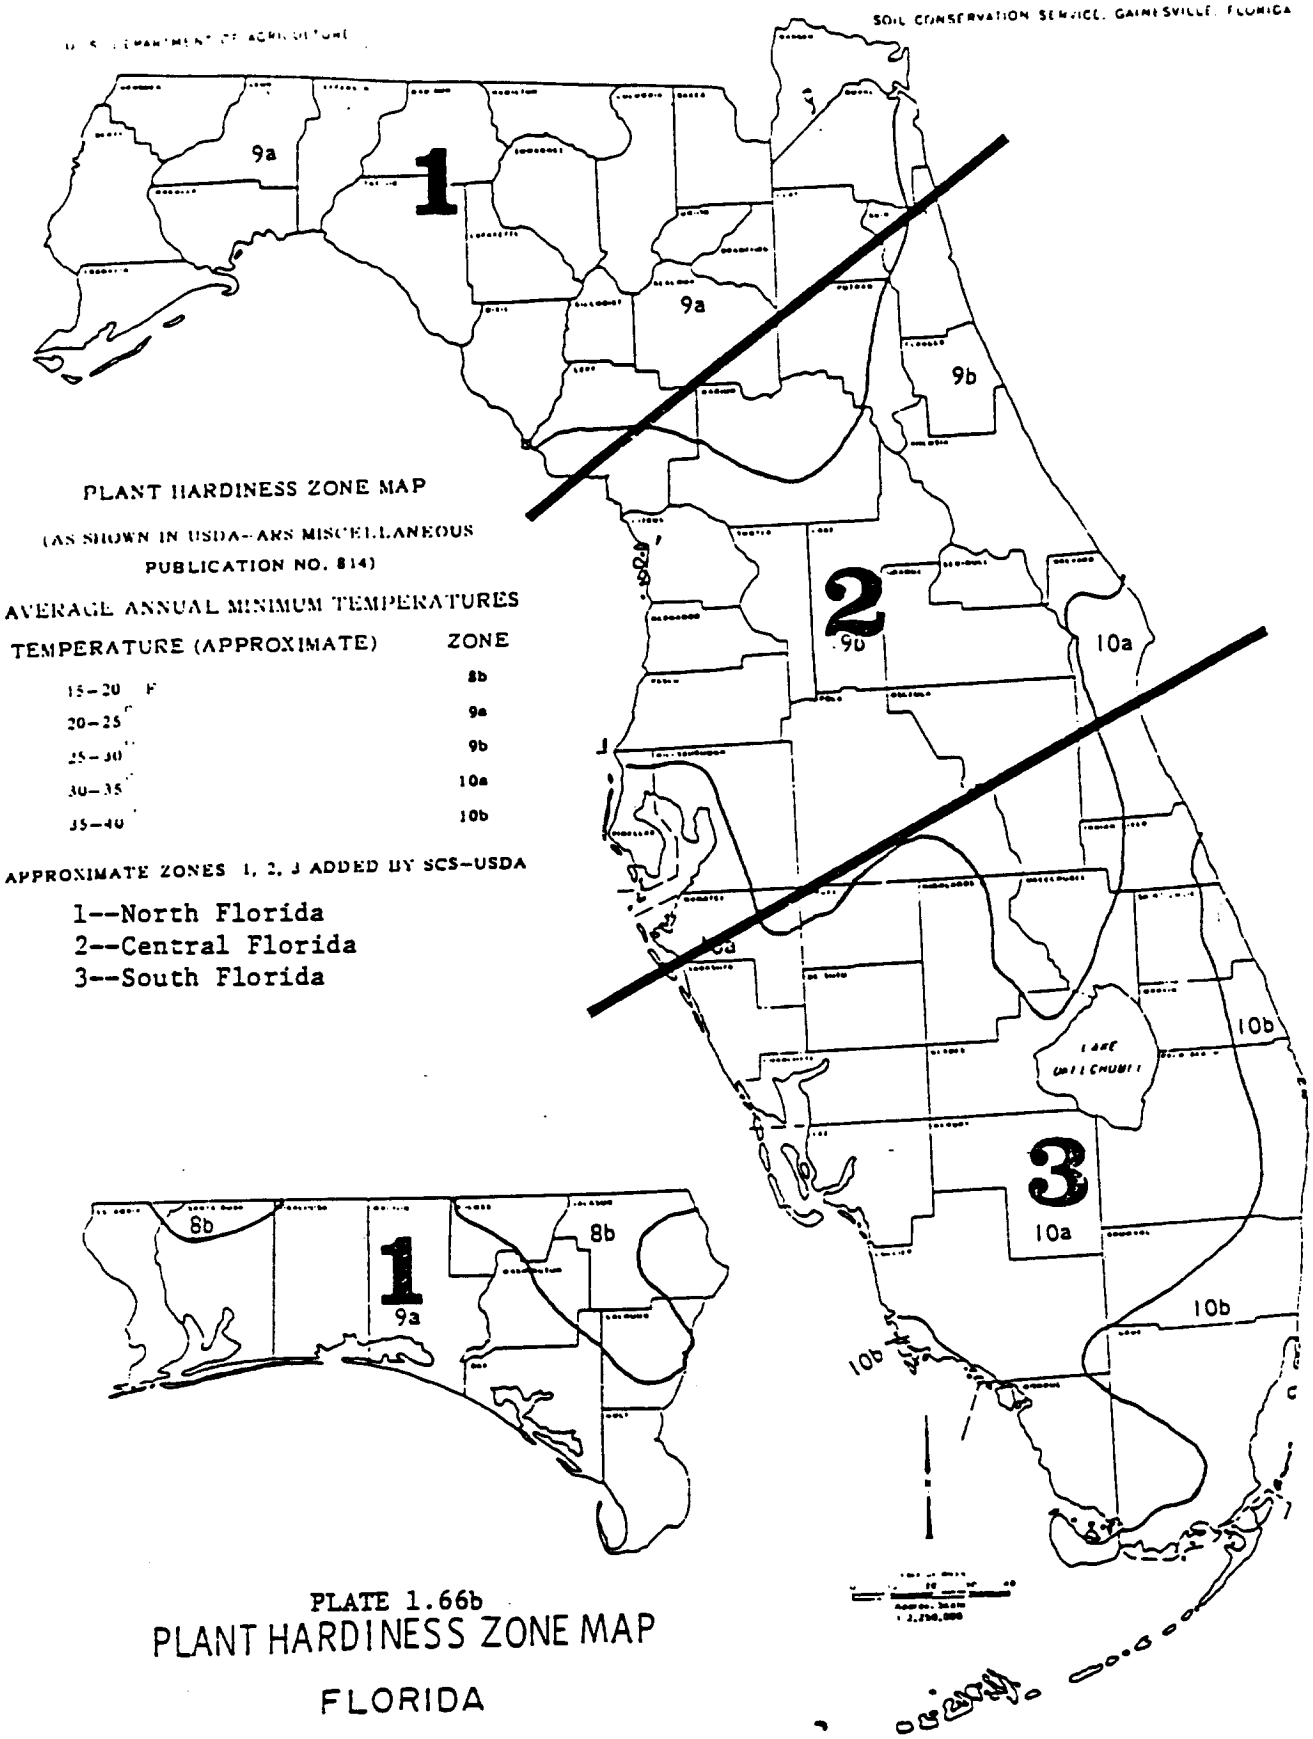
Everglades--A level, low coastal primarily composed of swamps, marshes and other wetlands. Dominant soils are poorly drained and range from organic mucks and peats to rockland. Water is abundant and extensive ditching and draining are required to control the groundwater levels. Urbanization and draining of wetlands has created seasonal water shortages and salt water intrusion along the coast.

SOILS: On the whole, soils in Florida always require some nitrogen (N) fertilization to establish plants. Phosphorus (P) and potassium (K) are usually needed. Except for some small pockets of shallow limestone soils, lime is universally needed.

Soils can be modified with lime and fertilizer, but climate cannot be controlled. For this reason, the State has been divided into three major (or five minor) climatic regions for plant selection. (See map, Plate 1.66b).

Microclimate, or localized climate conditions, can affect plant growth. A south-facing slope is drier and hotter than a north-facing slope, and may require drought-tolerant plants. Shaded areas require shade-tolerant plants; the windward side of a ridge will be drier than the leeward, etc.

LAND USE: A prime consideration in selecting which plants to establish is the intended use of land. All of these uses--residential, industrial, commercial, recreational--can be separated into two categories: High-maintenance and low-maintenance.



High-maintenance areas will be mowed frequently, limed and fertilized regularly, and will either receive intense use (e.g., athletics) or require maintaining to an aesthetic standard (home lawns). Grasses used for these situations must be fine-leaved and attractive in appearance, able to form tight sod, and be long-lived perennials. They must be well-adapted to the geographic area where they are planted, because constant mowing puts turf under great stress. Sites where high-maintenance vegetative cover is desirable include homes, industrial parks, schools, churches, and some recreational areas.

Low-maintenance areas will be mowed infrequently or not at all; lime and fertilizer may be applied on a regular basis; the areas will not be subjected to intense use, nor required to have a uniform appearance. These plants must be able to persist with little maintenance over long periods of time. Grass and legume mixtures are favored for these sites because legumes are capable of fixing nitrogen from the air for their own use, and the use of the plants around them. Such mixed stands are better able to withstand adverse conditions. Sites that would be suitable for low-maintenance vegetation include steep slopes, stream or channel banks, some commercial properties, and "utility turf" areas such as roadbanks.

SEEDBED PREPARATION - The soil on a disturbed site must be modified to provide an optimum environment for seed germination and seedling growth. The surface soil must be loose enough for water infiltration and root penetration. The pH (acidity and alkalinity) of the soil must be such that it is not toxic and nutrients are available, usually between pH 6.0-7.0. Sufficient nutrients--added as fertilizer--must be present.

R0071509

After seed is in place, it must be protected with a mulch to hold moisture and modify temperature extremes, and to prevent erosion while seedlings are growing.

The addition of lime is equally as important as applying fertilizer. Lime is best known as a pH, or acidity, modifier, but it also supplies calcium and magnesium which are plant nutrients. Its effect on pH makes other nutrients more available to the plant. It can also prevent aluminum toxicity by making aluminum less soluble in the soil.

MAINTENANCE - Even with careful, well planned seeding operations, failures can occur. When it is clear that plants have not germinated on an area or have died, these areas must be reseeded immediately to prevent erosion damage. Healthy vegetation is the most effective erosion preventive available.

Specifications

Selection of Plant Materials

1. Selection of plant materials is based on climate, topography, soils, land use, and planting season. To determine which plant materials are best adapted to a specific site, use Tables 1.66b and 1.66c, which describe plant characteristics and list recommended varieties.

2. Appropriate seeding mixtures for various site conditions in Florida are given in Table 1.66a. These mixtures are designed for general use, and are known to perform well on the sites described. Adhere to these mixtures whenever feasible. Check Tables 1.66b and 1.66c for recommended varieties.

Seedbed Requirements

Vegetation should not be established on slopes that are unsuitable due to inappropriate soil texture, poor internal structure or internal drainage, volume of overland flow, or excessive steepness, until measures have been taken to correct these problems.

To maintain a good stand of vegetation, the soil must meet certain minimum requirements as a growth medium. The existing soil must have these criteria:

1. Enough fine-grained material to maintain adequate moisture and nutrient supply.

2. Sufficient pore space to permit root penetration. A bulk density of 1.2 to 1.5 indicates that sufficient pore space is present. A fine granular or crumb-like structure is also favorable.

3. Sufficient depth of soil to provide an adequate root zone. The depth to rock or impermeable layers such as hardpans shall be 12 inches or more, except on slopes steeper than 2:1 where the addition of soil is not feasible.

R0071510

4. A favorable pH range for plant growth. If the soil is so acid that a pH range of 6.0-7.0 cannot be attained by addition of pH-modifying materials, then the soil is considered an unsuitable environment for plant roots.

5. Freedom from toxic amounts of materials harmful to plant growth.

6. Freedom from excessive quantities of roots, branches, large stones, large clods of earth, or trash of any kind. Clods and stones may be left on slopes steeper than 3:1 if they are to be hydroseeded.

If any of the above criteria cannot be met, i.e., if the existing soil is too coarse, dense, shallow, acid, or contaminated to foster vegetation, then topsoil should be applied in accordance with TOPSOILING, ES BMP 1.61.

Necessary mechanical erosion and sediment control practices will be installed prior to seeding. Grading will be carried out according to the approved plan.

Surfaces will be roughened in accordance with SURFACE ROUGHENING, ES BMP 1.60.

Soil Conditioners

In order to modify the texture, structure, or drainage characteristics of a soil, the following materials may be added to the soil:

1. Peat shall be sphagnum moss peat, hypnum moss peat, reed-sedge peat or peat humus, from fresh-water sources. Peat shall be shredded and conditioned in storage piles for at least six months after excavation.

2. Sand shall be clean and free of toxic materials.

3. Vermiculite shall be horizontal grade and free of toxic substances.

4. Rotted manure shall be stable or cattle manure not containing undue amounts of straw or other bedding materials or toxic chemicals.

5. Thoroughly rotted sawdust shall be 6 lbs. of nitrogen added to each cubic yard and shall be free of stones, sticks, and toxic substances.

6. Where local ordinances permit, treated sewage sludge may be used in accordance with local, state, and federal regulations.

Lime and Fertilizer

Lime and fertilizer needs should be determined by soil tests. Soil tests may be performed by the Cooperative Extension Service Soil Testing Laboratory at the U.F., or by a reputable commercial laboratory. Information concerning the State Soil Testing Laboratory is available from county extension agents.

R0071511

Under unusual conditions where it is not possible to obtain a soil test, the following soil amendments will be applied:

LIME: 2 tons/acre finely ground agricultural or dolomitic limestone (90 lbs./1000 $ft.^2$).

FERTILIZER: Mixed grasses and legumes: 1000 lbs./acre 5-20-10 (25 lbs./1000 $ft.^2$).

Legume stands only: 1000 lbs./acre 5-20-10 (25 lbs./1000 $ft.^2$).

Grass stands only: 1000 lbs./acre 5-20-10 and 300 lbs. of 38-0-0 in spring (7 lbs./1000 $ft.^2$).

1000 lbs./acre 10-20-10 and 300 lbs. of 38-0-0 in fall (7 lbs./1000 $ft.^2$).

Other fertilizer formulations may be used, provided they can supply the same amounts and proportions of plant nutrients.

Incorporation - Lime and fertilizer shall be incorporated into the top 4-6 inches of the soil by discing or other means. When applying lime and fertilizer with a hydroseeder, apply to a rough, loose surface.

Seeding

1. Certified seed should be used for all permanent seeding whenever possible.

2. Legume seed - Legume seed should be inoculated with the inoculant appropriate to the species. Seed of lespendezas, crown vetch, and clovers should be scarified to promote uniform germination.

3. Apply seed uniformly with a cyclone seeder, drill, cultipacker seeder, or hydroseeder on a firm, friable seedbed. Maximum seeding depth should be 1/4 inch.

4. Hydroseeding - To avoid seed damage, it is recommended that if a machinery breakdown of 30 minutes to 2 hours occurs, 50% more seed be added to the tank, based on the proportion of the slurry remaining in the tank. Beyond 2 hours, a full rate of new seed may be necessary.

   Often hydroseeding contractors prefer not to apply lime in their rigs as it is abrasive. In inaccessible areas, lime may have to be applied in pelletized or liquid form, separately. Rates of wood fiber should be at least 2000 lbs. per acre. Surface roughening is particularly important when hydroseeding, as a roughened slope will provide some natural coverage of lime, fertilier and seed.

5. Legume inoculants should be used by the date indicated on the container. When dry seeding use four times the manufacturer's recommended rate and use ten times the recommended rate of inoculant when hydroseeding.

R0071512

Mulching

All permanent seeding must be mulched immediately upon completion of seed application. Refer to MULCHING, ES BMP 1.75.

Maintenance of New Seedings

Irrigation: New seedings should be supplied with adequate moisture. Supply water as needed, especially late in the season, in abnormally hot or dry weather, or on adverse sites. Water application rates should be controlled to prevent runoff. Inadequate amounts of water may be more harmful than no water.

Re-seeding: Inspect seeded areas for failure and make necessary repairs and reseedings within the same season, if possible.

1. If vegetative cover is inadequate to prevent rill erosion, overseed and fertilize in accordance with soil test results.

2. If a stand has less than 40% cover, re-evaluate choice of plant materials and quantities of lime and fertilizer. Re-establish the stand following seedbed preparation and seeding recommendations, omitting lime and fertilizer in the absence of soil test results. NOTE: if vegetation has failed to grow, soil must be tested to determine if acidity or nutrient imbalances are responsible.

Fertilization: Seedlings should be fertilized one year after planting to insure proper stand density.

1. To established all-grass stands, apply 500 lbs./acre of 10-20-10 (12 lbs./1000 $ft.^2$) between August 15 and November 15. (The first fall following seeding.)

2. To legume-and-grass stands or pure legume stands, apply 500 lbs./acre of 0-20-20 (12 lbs./1000 $ft.^2$) in early May or between August 15-October 15.

GENERALLY, A STAND OF VEGETATION CANNOT BE DETERMINED TO BE FULLY ESTABLISHED UNTIL SOIL COVER HAS BEEN MAINTAINED FOR ONE FULL YEAR FROM PLANTING. DISTURBED AREAS WHICH ARE TO BE STABILIZED WITH PERMANENT VEGETATION MUST BE SEEDED OR PLANTED WITHIN 15 DAYS AFTER FINAL GRADE IS REACHED UNLESS TEMPORARY STABILIZATION IS APPLIED.

R0071513

TABLE 1.66 A

SEEDING MIXTURES, RATES AND DATES

Site Conditions	Seeding Mixtures	Seeding Rate		Seeding Dates			Comments
		Per Acre	Per 1000 Ft^2	North	Central	South	
High Maintenance Lawns	See Table 1.67A						
General Use	1. Bahiagrass	40-60 lbs	1 lb	2/15-8/15	2/1-8/31	1/15-9/15	Use 50% scarified seed.
	2. Bahiagrass	40-60 lbs	1 lb	2/15-8/15	2/1-8/31	1/15-9/15	Use 50% scarified Bahia seed.
	Bermudagrass (Hulled)	8-12 lbs	4 oz				
	3. Bahiagrass with one of the following:	20-30 lbs	.5 lb				Use 50% scarified Bahia seed.
	Southern White Clover	3 lbs	1.2 oz	9/1-1/1	9/15-1/1	10/1 -12/15	Innoculate legumes.
	Annual White Sweetclover	8 lbs	3 oz	9/1-1/1	9/15-1/1	10/1-12/15	
	Crimson Clover	12 lbs	4.5 oz	9/1-1/1	9/15-1/1	10/1-12/15	
	Arrowleaf Clover	8 lbs	3 oz	9/1-1/1	9/15-1/1	10/1-12/15	
	Alyce Clover	8 lbs	3 oz	2/15-7/15	2/1-7/15	1/15-7/15	
	Hairy Indigo	4 lbs	1.5 oz	2/15-7/15	2/1-7/15	1/15-7/15	
	Aeschynomene	12 lbs	4.5 oz	2/15-7/15	2/1-7/15	1/15-7/15	
Slopes	1. Sericea lespedeza	a.40-50 lbs	1.2 lbs	1/1-7/15	1/15-7/15	1/15-7/1	For scarified seed.
		b. 75 lbs	1.7 lbs	7/15-1/1	7/15-1/15	7/1-1/15	For unhulled seed.
	2. Sericea lespedeza with one of the following:						Use seeding rate specified above.
	Bahiagrass	15 lbs	7 oz	2/15-8/15	2/1-8/31	1/15-9/15	
	Tall Fescue	20 lbs	8 oz	10/1-11/15	10/15-11/30		Best adapted to N. Florida.
	Weeping Lovegrass	3 lbs	1.2 oz	2/15-8/15	2/1-8/31	1/15-9/15	
Droughty Areas	1. Weeping lovegrass	5 lbs	2 oz	2/15-8/15	2/1-8/31	1/15-9/15	Gives quick summer cover.
	2. Weeping lovegrass with one of the following:	5 lbs	2 oz	2/15-8/15	2/1-8/31	1/15-9/15	
	a. Bahiagrass (50% scarified seed)	30-40 lbs	12 oz	2/15-8/15	2/1-8/31	1/15-9/15	
	b. Bermudagrass (Hulled)	8-12 lbs	4 oz	2/15-8/15	2/1-8/31	1/15-9/15	
	c. Hairy panicum	8-12 lbs	4 oz	2/15-8/15	2/1-8/31	1/15-9/15	
	d. Sericea lespedeza						Use seeding rate and dates specified above.

CHARACTERISTICS OF GRASSES APPROPRIATE FOR EROSION CONTROL

Common Name (Botanical Name)	Life Cycle	Season	Sod-Former	Bunch Grass	Prop Method (2)	Salt Tolerance	Drainage Tolerance						Maintenance Requirements	Comments	Suggested Varieties for Florida
							D	WD	MWD	SPD	PD	FT			
BAHIAGRASS (Paspalum notatum)	P	W	X		S Sd	L	X	X	X	X	X		Low. Requires good, moisture for germination, first growth.	Use scarified seed. Widely used on highways for stabilizing shoulders.	Pensacola Argentine Paraguay 22
BERMUDAGRASS (Cynodon sp)	P	W	X		S Sd Sp	H		X	X	X			High. Requires fertilization.	Common can be seeded. Coastal does not do well on poorly drained flatwood soils. Callie tolerates very droughty soils.	Common Callie Coastal
BUSHYBEARD BLUESTEM (Andropogon glomeratus)	P	W		X	S T	L		X	X				Very low. Does well on soils of low fertility.	Good cover for old fields or vacant lots. Native grass.	
CARPETGRASS (Axonopus affinis)	P	W	X		S Sp	L				X	X	X	Low. Responds little to fertilization.	Poor cold hardiness and drought tolerance.	
COMMON REEDGRASS (Phragmites communis)	P	W		X	R T	M				X	X	X	Low. Requires water.	Grows in marshes, swamps, on banks of streams of streams and lakes. Excellent erosion control plant in such areas.	
CREEPING BLUESTEM (Andropogon stolonifer)	P	W		X	R T	M		X	X	X	X		Low.	Grows best in open spaces, tolerates some shade Excellent cover for vacant lots.	
EASTERN GAMAGRASS (Tripsacum dactyloides)	P	W		X	R T	L				X	X	X	Low. Very robust growth.	Flood tolerant for short periods only. Excellent erosion control along streams and lakes.	
GIANT REEDGRASS (Arundo donax)	P	W		X	R T	L				X	X	X	Low.	Excellent erosion control plant along streams and lakes. Good screening plant.	
HAIRY PANICUM (Panicum rhizomatum)	P	W		X	R S	L	X	X					Low.	Good cover on dry sandy soils. Good wildlife plant food.	
LIMPO GRASS (Hemarthria altissima	P	W		X	Sp T	L				X	X	X	Low. Grows well with moderate fertilization	Continuous growth during cool season. Some varieties do well under freezing temperatures.	
LONGLEAF UNIOLA (Uniola sessiliflora)	P	C		X	S	L				X	X	X	Low. Grows on soils of low fertility.	Good cover plant for shaded areas. Not suited to wet soils or sand hills.	
LOPSIDED INDIANGRASS (Sorghastrum secundum	P	W		X	S	L	X	X	X				Low.	In S. Florida, growth starts by mid-January. In N. Florida, growth starts by April.

CHARACTERISTICS OF GRASSES APPROPRIATE FOR EROSION CONTROL

Common Name (Botanical Name)	Life Cycle	Season	Sod-Former	Bunch Grass	Prop Method	Salt Tolerance	Drainage Tolerance (1)						Maintenance Requirements	Comments	Suggested Varieties for Florida
							D	WD	MWD	SPD	PD	PT			
MAIDENCANE (Panicum hemitomon)	P	W		X	RT	L				X	X	X	Low.	Grows best if water level fluctuates from two (2) inches above soil to four (4) inches below. Erosion control plant for marshes, swamps, stream banks.	
MARSHHAY CORDGRASS (Spartina patens)	P	W		X	ST	H		X	X	X	X	X	Low.	Good for sand dune stabilization as well as coastal marshes.	
PANGOLAGRASS (Digitaria decumbens)	P	W	X		SSp	L				X	X	X	Moderate. Plant with legumes to provide nitrogen.	Use in S. Florida only.	
SEA OATS (Uniola paniculata)	P	W		X	ST	H	X	X	X				Low. Once established thrive with little help.	Excellent for sand dune stabilization. Protected by Florida laws.	
SEASHORE SALTGRASS (Distichlis spicata)	P	W		X	RT	H				X	X	X	Low.	Does best if water level fluctuates between two (2) two inches above soil surface to six (6) inches below.	
SHOREDUNE PANICUM (Panicum amarulum)	P	W		X	ST	H	X	X	X				Low.	Native to coastal dunes. Excellent for stabilizing dunes.	
SHOREGRASS (Monanthochloe littoralis)	P	W			T	H					X	X	Low.	Good ground cover on tidal flats and extremely salty areas.	
SMOOTH CORDGRASS (Spartina alterniflora)	P	W		X	ST	H				X	X	X		Native to salt marshes and tidal flats. Seedheads produced in October-November.	
SWITCHGRASS (Panicum virgatum)	P	W		X	ST	H				X	X	X	Low.	Excellent for streambank, marsh stabilization.	
TALL FESCUE (Festuca pratensis)	P	C	X		S	L		X	X	X			Moderate. Needs nitrogen supplements.	Use in N. and N.W. Florida only.	
WEEPING LOVEGRASS (Eragrostis curvula)	P	W				L	X	X	X	X			Mow yearly to encourage persistence.	Tolerates acid, infertile soils and steep, droughty slopes.	
ANNUAL RYEGRASS (Lolium multiflorum)	A	C		X	S	L		X	X	X	X	X		Cool season companion grass. Use as temporary cover when permanent cover is being established in fall, winter.

TABLE 1.66 C

CHARACTERISTICS OF LEGUMES APPROPRIATE FOR EROSION CONTROL

Common Name (Botanical Name)	Life Cycle	Season	Germ Time Days	Drainage Tolerance					Remarks	Suggested Varieties for Florida
				D	WD	MWD	SPD	PD		
ALYCECLOVER (Alysicarpus vaginalis)	A	W	7-21		X	X				
ARROWLEAF CLOVER (Trifolium vesiculosum)	A	C	7-21		X	X	X		Well adapted to well-drained loamy sands and clays in N. Florida. Does not germinate well at high temperatures or dry conditions. If planted with permanent grassess, do not use Meechee variety. Reseeds itself.	AMCLO YUCHI MEECHEE
CRIMSON CLOVER (Trifolium incarnatum)	A	C	7-21		X	X			Does poorly on deep dry sands, will not tolerate flooding. Adapted to N. Florida. Widely used in N. Florida along highways. Do not mow before seed heads mature if it is to serve as a perennial.	DIXIE AUTAUGA AUBURN
RED CLOVER (Trifolium pratense)	A	C	7-21		X	X	X		Has soil requirements similar to white clover but is more easily damaged by excess water. Does not seed abundantly in Florida. Useful with tall fescue in low maintenance stands.	TENSAS NOLIN'S
SWEET CLOVER (Melilotus altissima	A	C	7-21			X	X		Productive on both flatwoods (which do not flood) and upland soils. Produces seed but needs to be reseeded to maintain stand.	HUBAM FLORANNA ISRAEL
WHITE CLOVER (Trifolium repens)	A	C	7-21				X	X	Best cool season legume for flatwoods and other high moisture fertile soils. Requires continuous and abundant moisture, tolerates short-term flooding.	LOUISIANA S-1 NOLIN'S - IMPROVED
LUPINE (Lupinus sp.)	A	C	7-21		X	X			Very susceptible to freeze damage at time of emergence. An excellent cover plant.	SWEETBLUE FROST RANCHER
AUSTRIAN WINTER PEAS	A	C	7-21		X	X				COMMON ROMAIC DIXIE WONDER
ALFALFA (Medicago sativa)	sP	W	10-21	X	X				Develop deep root system which makes it drought-tolerant. Will not tolerate flooding Plant in early fall to insure establishment before first frost. Requires good, fertile soil and has relatively high maintenance needs.	FLORIDA 77
HAIRY INDIGO (Indigofera hirsuta)	A	W	7-21		X	X			Sensitive to cold, killed by first frost. To assure reseeding, mow after seed matures in fall before first frost.	EARLY LATE
CROWN VETCH (Coronilla varia)	sP	C	14-21	X	X	X			Needs high lime or calcareous soil, high phosphorus. Does not tolerate wet soil. Useful on steep slopes and rocky areas.	
JOINT VETCH (Aeschynomene americana)	A	W	7-21				X	X	Widely used in Central and South Florida especially in low, wet areas.	
ANNUAL LESPEDEZA (Lespedeza striata)	A	W	14-21	X	X	X			Fairly drought resistant. Use with cool season companion plant for year-round soil protection. Grows in thick stands.	KOBE COMMON

R0071518

TABLE 1.66 C (Continued)

CHARACTERISTICS OF LEGUMES APPROPRIATE FOR EROSION CONTROL

Common Name (Botanical Name)	Life Cycle	Season	Germ Time Days	Drainage Tolerance[1]					Remarks	Suggested Varieties for Florida
				D	WD	MWD	SPD	PD		
SERICEA LESPEDEZA (Lespedeza cuneata)	P	W		X	X	X			Deep rooted and drought tolerant. Very useful on infertile slopes. Will tolerate short term flooding, particularly in winter. If used alone, use scarified seed (50 lbs/acre) from Dec. to July; unhulled seed (75 lbs/acre) other times.	INTERSTATE SERALA
PERENNIAL PEANUT (Arachis glabrata)	P	W		X	X	X			Not adapted to flatwoods soils or high-water table soils. Drought resistance once established. Establish by planting rhizomes.	FLORIGRAZE
SESBANIA (Sesban macrocarpa)	A	W	7-21				X	X	Tolerates extremely wet conditions.	

1 D = Droughty

C = Cool season plant, grows in fall, winter, spring

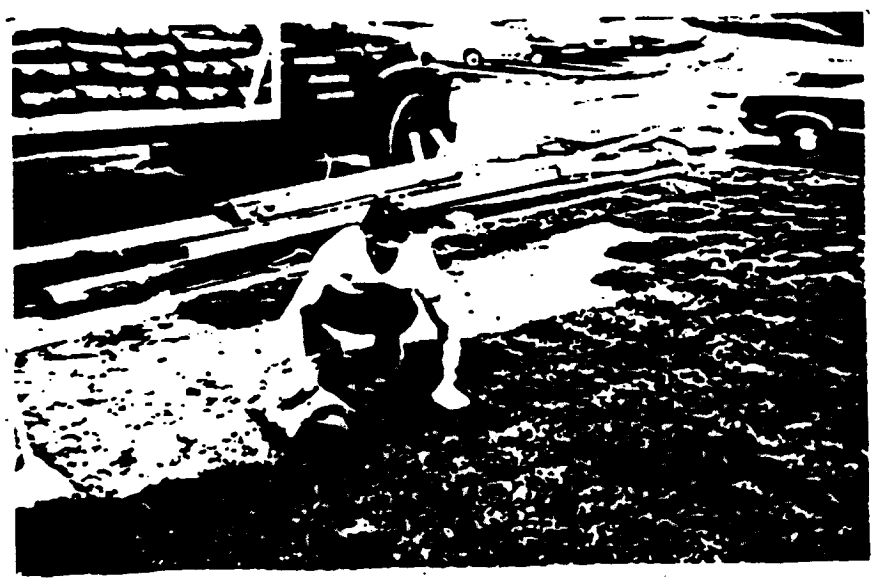
NOTE: Seed of all legumes must be innoculated with the correct strain of bacteria.

R0071519

ES BMP 1.67

SODDING

Definition



Stabilizing fine-graded disturbed areas by establishing permanent grass stands with sod.

Purposes

1. To establish permanent turf immediately.
2. To prevent erosion and damage from sediment and runoff by stabilizing the soil surface.
3. To reduce the production of dust and mud associated with bare soil surfaces.
4. To stabilize drainageways where concentrated overland flow will occur.

Conditions Where Practice Applies

1. Disturbed areas which require immediate vegetative covers, or where sodding is preferred to other means of grass establishment.

R0071520

2. Locations particularly suited to stabilization with sod are:
   --waterways carrying intermittant flow
   --area around drop inlets in grassed swales
   --residential or commercial lawns where quick use or aesthetics are factors.

Planning Specifications

The successful establishment of quality turfgrass is relatively easy in Florida. Sod is relatively inexpensive and fairly easy to obtain throughout the state.

A quality turf containing the recommended mixtures and species can be established with either seed or sod. Soil preparation for the two methods is the same.

The advantages of properly installed sod include:

1. immediate erosion control
2. an instant green surface with no dust or mud
3. nearly year-round establishment capability
4. less chance of failure than with seed
5. freedom from weeds
6. quick use of the sodded surface
7. the option of buying a quality-controlled product with predictable results.

It is initially more costly to install sod than to seed. However, this cost is justified in places where sod can perform better than seed in controlling erosion.

In swales and waterways where concentrated flow will occur, properly pegged sod is preferable to seed because there is no lag time between installation and the time when the channel is protected by vegetation.

Drop inlets which will be placed in grassed areas can be kept free of mulch, seed, and mud, and the grade immediately around the inlet can be maintained, by framing the inlet with sod strings.

Sod can be laid during any time of the year so long as there is adequate water available to meet the moisture requirements of the grass.

Ground preparation and proper maintenance are as important with sod as with seed. Sod is composed of living plants and those plants must receive adequate care in order to provide vegetative stabilization on a disturbed area. Sod cannot be expected to provide erosion control and prevent soil slippage on a slope that is not stable because of its structure, water movement or excessive gradient.

R0071521

Specifications

Soil Preparation

1. Prior to soil preparation, areas to be sodded shall be brought to final grade in accordance with the approval plan. These operations should leave as much topsoil as possible or replace the topsoil to a depth of four inches.

2. Soil tests should be made to determine the exact requirements for lime and fertilizer. Soil tests may be conducted by the State Laboratory at the University of Florida or a reputable commercial laboratory. Information on state soil tests is available from county agricultural extension agents.

   When a soil test is not made the following soil amendments should be made:

   Pulverized agricultural limestone at 100 lbs./1000 ft.^{2} (2 tons/acre).

   Fertilizer at 25 lbs./1000 ft.^{2} (1000 lbs./acre) of 10-10-10 in fall or 25 lbs./1000 ft.^{2} of 5-10-10 in spring. NOTE: Equivalent nutrients may be applied with other fertilizer formulations.

   These amendments shall be spread evenly over the area to be sodded, and incorporated into the top 3-6 inches of the soil by discing, harrowing or other acceptable means.

3. Prior to laying sod, the soil surface shall be clear of trash, debris, roots, branches, stones and clods in excess of 2 inches in length or diameter. Sod shall not be applied to gravel or other non-soil surfaces.

4. Any irregularities in the soil surface resulting from topsoil or other operations shall be filled or leveled in order to prevent the formation of depressions or water pockets.

5. Areas to be topsoiled and topsoil used shall fulfill the requirements of TOPSOILING, ES BMP 1.61. No sod shall be spread on soil which has been treated with soil sterilants until enough time has elapsed to permit dissipation of toxic materials.

Sod Quality

1. Sod should be free of weeds and undesirable coarse weedy grasses. If possible, Certified or Approved turfgrass sod should be used.

2. Sod shall be machine cut at a uniform soil thickness of 3/4 inch, plus or minus 1/4 inch, at the time of cutting. This thickness shall exclude shoot growth and thatch.

3. Pieces of sod shall be cut to the supplier's standard width and length, with a maximum allowable deviation in any dimension of 5%. Torn or uneven pads will not be acceptable.

4. Standard size sections of sod shall be strong enough to support their own weight and retain their size and shape when suspended from a firm grasp on one end of the section.

5. Sod shall be not cut or laid in excessively wet or dry weather.

6. Sod shall be harvested, delivered, and installed within a period of 36 hours.

Choosing Appropriate Types of Sod

The type of sod used must be composed of plants adapted to the locality. Use Table 1.67a to select the type of sod best suited to your area.

Sod Installation

A. Solid Sodding (Plate 1.67a)

1. Irrigate areas to be sodded with a minimum of 1/2-inch of water unless recent rains have provided equivalent moisture.

2. The first row of sod shall be laid in a straight line with subsequent rows placed parallel to and butting tightly against each other. Lateral joints shall be staggered to promote more uniform growth and strength. Care shall be exercised to insure that sod is not stretched or overlapped and that all joints are butted tight in order to prevent voids which would cause drying of the roots.

3. On slopes 3:1 or greater, or wherever erosion may be a problem, sod shall be laid with staggered joints and secured by pegging or other approved methods. Sod shall be installed with the length perpendicular to the slope (on the contour). Begin laying sod at the bottom of the slope and work uphill. On very steep slopes, the use of ladders will facilitate the work and prevent damage to the sod.

4. Surface water cannot always be diverted from flowing over the face of the slope, but a capping strip of heavy jute or erosion netting, properly secured, along the crown of the slope will provide extra protection against lifting and undercutting of sod. This same technique can be used to fortify sod in water-carrying channels and other critical areas. Use wire staples to anchor heavy jute or erosion netting in channels.

5. As sodding of clearly defined areas is completed, sod shall be rolled or tamped to provide firm contact between roots and soil.

6. After rolling, sod shall be irrigated to a depth sufficient that the underside of the sod pad and the soil 4 inches below the sod is thoroughly wet.

7. During the first week, in the absence of adequate rainfall, watering shall be performed as often as necessary to maintain moist soil to a depth of at least 4 inches.

R0071523

8. The first mowing shall not be attempted until the sod is firmly rooted, usually after 2-3 weeks. Not more than 1/3 of the grass leaf should be removed at any one cutting.

B. **Spot Sodding**

1. Spot sodding is the planting of plugs or blocks, a minimum of four inches in diameter or square, of sod at measured intervals. The plugs or blocks should be placed one foot apart.

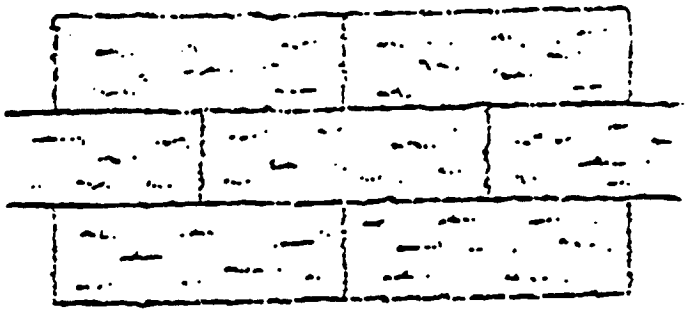
2. Sod spots within a row should be placed alternately and not directly opposite sod spots in adjacent rows.

3. Fit the plugs or blocks tightly into prepared holes and tamp them firmly into place.

4. Irrigate to a depth sufficient that the underside of the sod spot and the soil 4 inches below the sod is thoroughly wet.

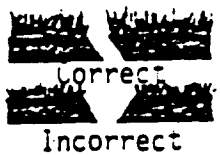
C. **Strip Sodding**

1. Areas to be strip sodded should be fertilized, limed, prepared and smoothed as in solid sodding.



2. Lay the strips end to end in rows that are from 1 to 1-1/2 feet apart with the stripe a minimum of 2 to 4 inches wide.

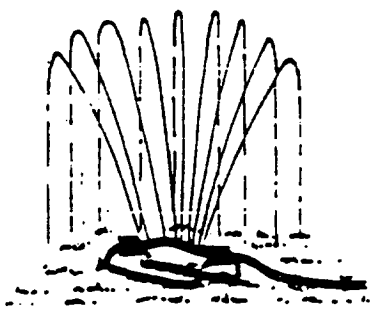
3. Roll or tamp the strips thoroughly to provide firm contact between roots and soil.



4. Irrigate to a depth sufficient that the underside of the strips and the soil 4 inches below the strips are wet.

R0071524

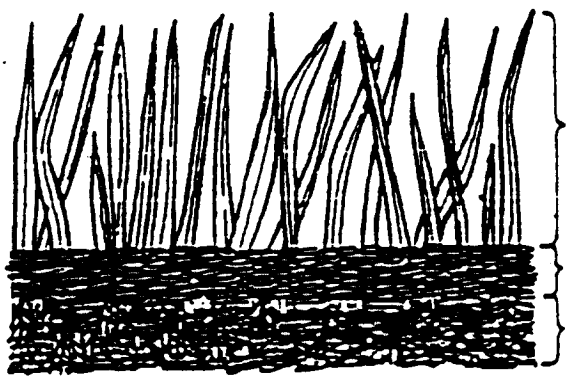
SODDING



Lay sod in a staggered pattern. Butt the strips tightly against each other. Do not leave spaces and do not overlap. A sharpened mason's trowel is a handy tool for tucking down the ends and trimming pieces.

Butting - angled ends caused by the automatic sod cutter must be matched correctly.

ROLL sod immediately to achieve firm contact with the soil.



WATER to a depth of 4" as needed. Water well as soon as the sod is laid.

MOW when the sod is established - in 2-3 weeks. Set the mower high (2"-3").

APPEARANCE OF GOOD SOD

Shoots or grass blades. Grass should be green and healthy, mowed at a 2"-3" cutting height.

Thatch - grass clippings and dead leaves, up to 1/2" thick.

Root Zone - soil and roots. Should be 1/2"-3/4" thick, with dense root mat for strength.

Source: Va SWCC

Plate 1.67a

R0071525

Sodded Waterways (Plate 1.67b)

1. Care should be taken to prepare the soil adequately in accordance with this specification. The sod type shall consist of plant materials able to withstand tne designed velocity. (See STORMWATER CONVEYANCE CHANNELS, ES BMP 1.35).

2. Sod strips in waterways shall be laid perpendicular to the direction of flow. Care should be taken to butt ends of strips tightly.

3. After rolling or tamping, sod shall be pegged or stapled to resist washout during the establishment period. Chicken wire, jute or other netting may be pegged over the sod for extra protection in critical areas.

4. All other specifications for this practice shall be adhered to when sodding a waterway.

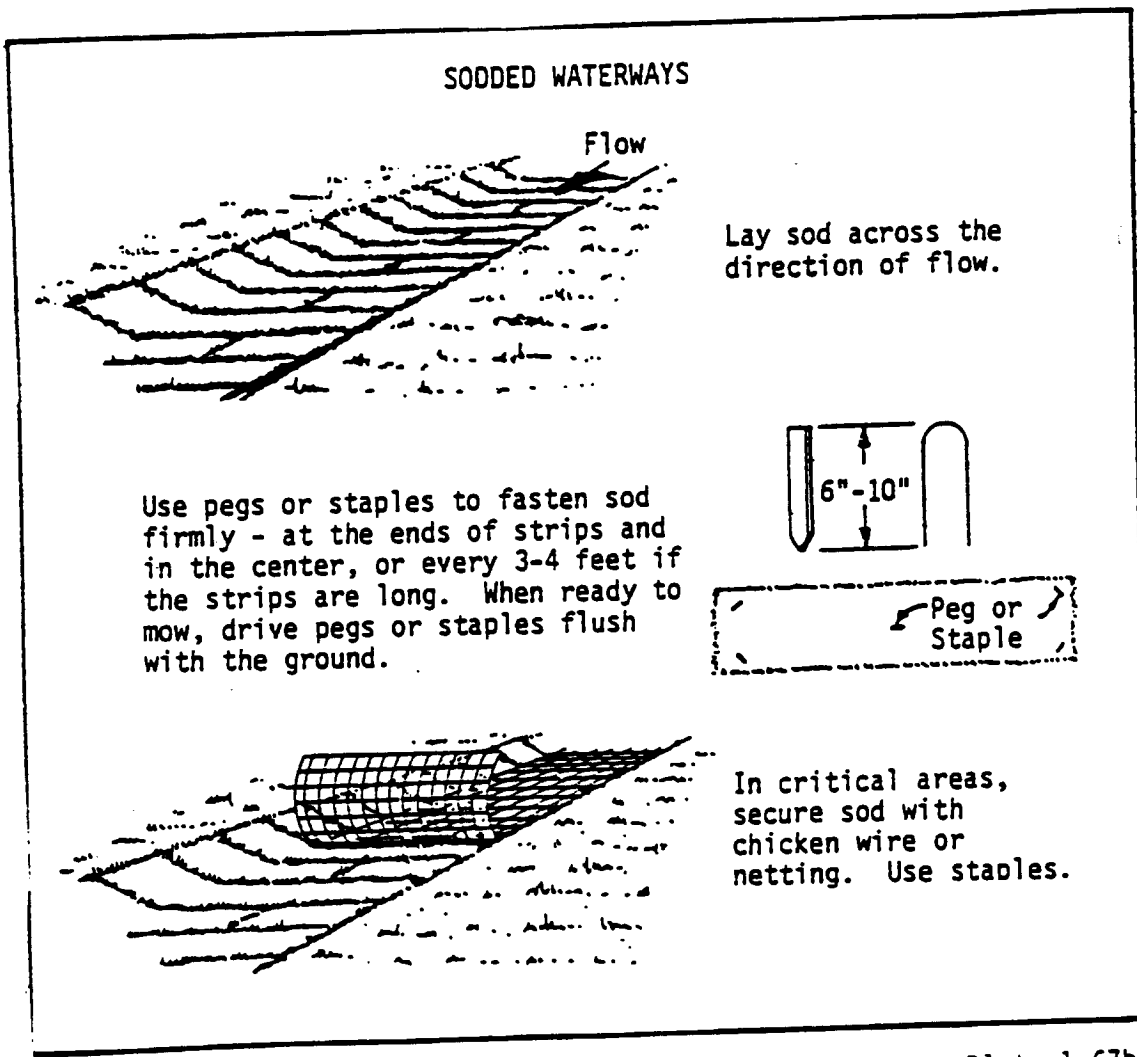


Plate 1.67b

R0071526

Maintenance of Established Sod

1. After the first week, sod shall be watered as necessary to maintain adequate moisture in the root zone and prevent dormancy.

2. Apply lime and fertilizer under a regular program based on soil tests and on the use and general appearance of the vegetative cover. In the absence of a soil test apply 1-2 tons/acre (45-90 lbs./1000 $ft.^2$) of finely ground agricultural limestone every three years. Apply 400-500 lbs./acre (9-18 lbs./1000 $ft.^2$) of 10-10-10 fertilizer. To obtain better vegetative cover, topdress with 150-300 lbs./acre (6-12 lbs./1000 $ft.^2$) of 16-4-4 fertilizer during the growing season, but at least six weeks before the end of the growing season.

   If Centipede or St. Augustine grass is used, do not apply more than 1 pound of actual nitrogen per 1000 $ft.^2$ (20-40 lbs./acre).

3. Mow to control weeds, improve the appearance of the vegetative cover, and to reduce fire hazard, as necessary. In general, the coarser the leaf texture of the grass, the higher it should be cut. Continuous close mowing will result in loss of vigor and reduced stand. No more than 1/3 of the grass leaf should be removed in any mowing.

R0071527

TABLE 1.67a

Comparison of Florida Lawn Grasses

Grass	Texture	Soil Adaptability	Tolerances*			Minimum Fertilization/yr.
			Shade	Salt	Drought	
A. HIGH MAINTENANCE						
St. Augustine	Coarse	Wide Range	E	E	G	1-4
Bermuda	Fine	Wide Range	VP	F-G	F	4-6
Zoysia	Intermediate to Fine	Wide Range	G	G	F	2-4
B. LOW MAINTENANCE						
Bahia	Intermediate to Coarse	Acid Soils	E	P-F	E	1-2
Centipede	Intermediate	Acid Soils	G	VP	F-G	1
Carpet	Intermediate	Wet, Acid Soils	F-G	VP	P	1

*Tolerances:

G = Good
F = Fair
P = Poor
VP = Very Poor

R0071528

ES BMP 1.68

BERMUDAGRASS ESTABLISHMENT

Definition

The establishment of vegetative cover with hybrid bermudagrass by planting sprigs, stolons, or plugs.

Purposes

1. To reduce erosion and decrease sediment yield from disturbed areas.
2. To stabilize disturbed areas with a specific plant material suited to the site which cannot be established by seed.
3. To establish vegetative cover more rapidly than would be possible using seed.

Conditions Where Practice Applies

1. In areas where hybrid bermudagrass is the desired plant material, and establishment with sod is not preferred.
2. Bermudagrass is particularly suited to droughty, sandy sites or situations where high salt content is a problem. It should not be used in shaded areas or on poorly drained sites.
3. Irrigation must be available during the establishment phase.

R0071529

Planning Considerations

Bermudagrasses are warm-season permanent grasses which are well suited to erosion control, as they have vigorous rhizomes and stolons (runners). There are two main types of bermudagrass in Florida, common and hybrid. Common bermudagrass produces seed and may be established with seeds. However, it has the potential to become a weed problem because it spreads vigorously; it is also coarse and not suitable for fine turf. Common bermuda has little cold tolerance and winterkills frequently.

Hybrid bermudagrasses do not produce seed and must be established by sodding, sprigging or plugging. These grasses produce a fine, tight turf, do not spread as virorously as common bermudagrass, exhibit good cold tolerance, and can withstand many adverse conditions. For these reasons, hybrid bermudagrass produces the finest lawns in Florida, however they require extensive maintenance.

Turf may be established most rapidly and efficiently with sod. Where speed is essential and cost is not an overriding constraint, sod should be used. (See SODDING, ES BMP 1.67).

> Sprigging: A bermudagrass sprig is a small section of rhizome (underground stem) 3 to 5 inches long, with at least one node or joint. Leaves should be present at the nodes. Stolons (runners) are above-ground stems that spread by creeping on the soil surface. A mixture of sprigs and stolons is usually used in "sprigging". Sprigs may be planted by machine or by hand.
>
> Plugging: Plugs are small sections of sod which are expressed into precut holes in the soil so that topgrowth is flush to the surface and leaves are exposed. Plugs are usually planted by hand.

Bermudagrass is particularly suited to use in grassland waterways. Depending upon the soil type, an established stand of bermudagrass can tolerate intermittent concentrated flows of water on slopes up to 10%. It is important to divert runoff from the waterway during the first three weeks of establishment to permit bermudagrass to take root. If this cannot be done, the center of the waterway should be sodded to prevent washout.

Bermudagrass is drought-tolerant, salt-tolerant, and tolerates floods of short duration. It prefers a pH range from 6.0-7.0 with high nitrogen fertilization during the growing season. In northern and parts of central Florida, bermudagrass will be dormant in winter and will turn brown at that time.

The Bermudagrass hybrids most frequently used in Florida differ in appearance, texture, growth rate, susceptibility to pests and suitability for turf use. The following varieties are suggested for rough and fine-turf areas:

For Rough Areas

Common: A low growing variety that produces dense sod. It is very coarse and typically used for forage or erosion control in critical areas.

Coastal: Also a forage type used in low maintenance areas.

For Fine-turf Areas

Ormond: A medium-textured, dense type with good drought and cold tolerance. Very susceptible to dollar spot disease and the stunt mite.

Tiflawn: Also called Tifton-57. Similar to Ormond but less susceptible to dollar spot and mites.

Tifway: Also called Tifton-419. Often used on golf course fairways.

Tifgreen and Tifdwarf: Both are used on golf greens. Very fine textured, textured, dense sod but requires very high maintenance.

Specifications

Soil Preparation

Procedures for preparing the soil are the same for sprigging and plugging.

1. Bermudagrass requires soil which is well drained, loose enough for root penetration, has a pH range between 6.0-7.0, and is free of toxic amounts of materials harmful to plant growth. If any of these criteria cannot be met, topsoil shall be applied in accordance with TOPSOILING, ES BMP 1.61.

2. Necessary erosion and sediment control practices will be installed prior to establishment of bermudagrass. Final grading will be carried out according to the approved plan.

3. Surfaces will be roughened in accordance with SURFACE ROUGHENING, ES BMP 1.60.

4. The soil shall be free of debris, trash, roots, and weeds.

Lime and Fertilizer

Soil tests should be made to determine the exact requirements for lime and fertilizer. Soil tests may be conducted by the State Laboratory at the University of Florida or at a reputable commercial laboratory. Information on low cost state soil tests is available from county or city agricultural extension agents.

R0071531

Under difficult circumstances where it is not possible to obtain a soil test the following soil amendments shall be made:

Pulverized agricultural limestone: 100 lbs./1000 ft.^{2} (2 tons/acre).
NOTE: Only carbonate forms of lime may be used. Dolomitic limestone shall be used on the Coastal Plain.

Fertilizer: 800 lbs. 10-10-10/acre (20 lbs./1000 ft.^{2}).
NOTE: Equivalent nutrients may be applied with other fertilizer formulations.

These amendments shall be spread evenly over the area to be sprigged, and incorporated into the top 3-6 inches of the soil by discing, harrowing or other acceptable means.

Any irregularities in the soil surface resulting from topsoiling or other operations shall be filled or leveled in order to prevent the formation of water pockets.

SPRIGGING AND PLUGGING

Sources

Sprigs can be purchased as sod and then shredded or can often be purchased by the bushel. For turf-type bermudagrasses, Certified or Approved sod sources (bearing the label of the Florida Crop Improvement Association) should be used. Coastal and Common bermudagrasses are available through agricultural sources. Contact the county or city agricultural extension agent or the Soil Conservation Service district office for information on where these materials may be obtained. Plugs may be cut from sod as needed or purchased pre-cut.

Sprigs shall be 3 to 5 inches long, having several nodes (joints). Plugs shall be a minimum diameter of 2 inches.

Quantities of Materials Needed

Sprigging: 2-7 bushels per 1000 ft.^{2}, or 80-300 bushels per acre. Use of the maximum recommended amount when broadcast sprigging. One bushel of sprigs is approximately equal to 1 yard^2 of sod.

Plugging: About 12 square yards of sod for 1000 ft.^{2}, or 530 square yards of sod per acre.

When to Plant

To establish quickly, bermudagrass should not be in a dormant state (leaves should b egreen) and the material should be fresh and moist. Bermudagrassess may be planted from mid-March until mid-September except in

southern Florida where it can be planted at any time if soil mixture conditions are favorable.

How to Plant

SPRIGGING: Sprigs may be broadcast over the surface by hand, planted in rows by machine, or applied with a hydroseeder. Machines are available which will insert sprigs properly and firm the soil over them. When sprigs are broadcast or hydrosprigged, they should be partially covered with soil by light discing or topdressing with good soil. Ideally, half of the sprig should be covered with soil, and half (including some leaves) should be exposed. Soil should be firmed over the sprigs by using a cultipacker, or by rolling or tamping. Spacing - When planted in row, sprigs should be placed no more than 12 inches apart. Closer spacing is recommended for slopes, waterways, and highly erodible soils.

PLUGGING: Plugs should be inserted in the soil surface so that leaf tips are above the surrounding soil, and tamped firmly in place. Spacing - Plugs should be placed in a grid pattern on 12 inch centers. Close spacing is recommended on critical areas. Plugs are usually placed by hand, but machines are available which can plug automatically.

Weed Control

In order to become effectively established, bermudagrass must not have to compete with weeds or excessive nurse crop growth. These can be controlled by mowing, hand cultivation or the use of herbicides. When herbicides are used, follow current Florida Institute of Food and Agricultural Sciences chemical weed control recommendations and adhere strictly to the instructions on the label.

Maintenance

Bermudagrass sprigs and plugs can be expected to root in 5 to 10 days under optimum conditions. Full coverage of the soil by spreading plants can be effected in 4 to 8 weeks with good growing conditions. The following maintenance activities should be followed to retain effective vegetative cover:

1. Adequate moisture. Water immediately after planting, and water enough to keep soil moist to a depth of 4 inches during the first 4 weeks and as needed thereafter to sustain growth.

2. Sunlight. Do not permit mulches, weeds, or other plantings to shade new bermudagrass stands.

3. Freedom from erosive forces. Keep concentrated flows of water off of new plantings for 2 weeks to one month depending upon growth.

R0071533

4. Repairs. Inspect all areas for planting failures and make necessary repairs, replacements and reseeding within the planting season, if possible.

5. Lime and fertilizer. Apply lime and fertilizer under a regular program based on soil tests, and on the use and general appearance of the vegetative cover. In the absence of a soil test, apply lime and fertilizer as follows:

   a. Apply 1 to 2 tons of finely ground dolomite or agricultural limestone per acre or 45 to 90 lbs. per 100 square feet every 3 to 5 years.

   b. Apply 40 to 50 lbs. per acre or one pound per 1000 square feet of nitrogen, phosphate and potash annually in the spring. This can be supplied with 400 to 500 pounds per acre or 9 to 12 pounds per 1000 square feet of 10-10-10. To obtain better vegetative cover, topdress with 30 to 60 pounds per acre or 1 to 2 pounds per 1000 square feet of nitrogen during the growing season, but at least six weeks before the end of the growing season.

6. Mowing. As necessary, mow to control weeds and as growth requires. Common and Coastal may be left unmowed except for an occasional trimming to about six inches in height. Turf-type bermudagrasses should be cut to a height of 1 to 1.5 inches.

R0071534

ES BMP 1.75

MULCHING

Definition

Application of plant residues or other suitable materials to the soil surface.

Purposes

1. To prevent erosion by protecting the soil surface from raindrop impact and reducing the velocity of overland flow.

2. To foster the growth of vegetation by increasing available moisture and providing insulation against extreme heat and cold.

Conditions Where Practice Applies

1. Areas which have been permanently seeded should be mulched immediately following seeding.

2. Areas which cannot be seeded because of the season should be mulched to provide some protection to the soil surface. An organic mulch (not wood fiber alone) shall be used, and the area then seeded as soon as feasible in spring.

R0071535

3. Mulch shall be used together with plantings of trees, shrubs, or certain ground covers which do not provide adequate soil stabilization by themselves.

4. Mulch shall be used in conjunction with temporary seeding operations specified in TEMPORARY SEEDING, ES BMP 1.65.

Planning Considerations

Mulches are applied to the soil surface to conserve a desirable soil property or to promote plant growth. A surface mulch is one of the most effective means of controlling runoff on disturbed land.

Mulches can increase the infiltration rate of the soil, reduce soil moisture loss by evaporation, prevent crusting and sealing of the soil surface, modify soil temperatures, and provide a suitable microclimate for seed germination.

Organic mulch materials, such as straw, wood chips, bark, and wood fiber, have been found to be the most effective.

Chemical soil stabilizers are less effective mulches when used alone. These materials are useful to bind organic mulches together.

A variety of nets and mats have been developed for erosion control in recent years, and these are also used as mulches, particularly in critical areas such as waterways. They may be used to hold other mulches to the soil surface.

The choice of materials for mulching will be based on the type of soil to be protected, site conditions, season, and economics. It is especially important to mulch liberally in mid-summer and prior to winter, and on cut slopes and southern slope exposures.

Organic Mulches

Straw - The mulch most commonly used in conjunction with seeding. The straw should come from wheat or oats, and may be spread by hand or machine. Straw can be windblown and must be tacked down.

Corn Stalks - These should be shredded into 4 to 6-inch lengths. Stalks decompose slowly and are resistent to windblow.

Wood Chips - Suitable for areas that will not be closely mowed, and around ornamental plantings. Chips decompose slowly, do not require tacking. Must be treated with 12 pounds nitrogen per ton to prevent nutrient deficiency in plants. Can be a very inexpensive mulch if chips are obtained from trees cleared on the site.

Bark Chips, Shredded Bark - By-products of timber processing. Used in landscaping plantings. Bark is also a suitable mulch for areas planted to

R0071536

grasses and not closely mowed; may be applied by hand or mechanically. Bark is not usually toxic to grasses or legumes, and additional nitrogen fertilizer is not required.

Wood Fiber - Used in hydroseeding operations, applied as part of the slurry. These short cellulose fibers do not require tacking, although tacking agent or soil binders are sometimes used with wood fiber. This form of mulch does not provide sufficient protection to erodible soils to be used alone during the severe heat of summer or for late fall seedings. Wood fiber hydroseeder slurries may be used to tack straw mulch. This combination treatment is well suited to steep slopes and critical areas, and severe climate conditions.

There are other organic materials which make excellent mulches but are only available locally or seasonally. Creative use of these materials can reduce costs.

Chemical Mulches and Soil Binders

A wide range of synthetic, spray-on materials are marketed to stabilize and protect the soil surface. These are emulsion or dispersions of vinyl compounds, asphalt, rubber or other substances which are mixed with water and applied to the soil. They may be used alone or or may be used to tack wood fiber hydromulches or straw.

When used alone, chemical mulches do not have the capability to insulate the soil or retain soil moisture that organic mulches have. This soil protection is also damaged by traffic. Application of these mulches is usually more expensive than organic mulching, and the mulches decompose in 60-90 days.

Nets and Mats

Used alone, netting does not retain soil moisture or modify soil temperature. It stabilizes the soil surface while grasses are being established, and is useful in grassed waterways and on slopes. Light netting may also be used to hold other mulches in place.

The most critical aspect of installing nets and mats is obtaining firm, continuous contact between material and the soil. Without such contact, the material is useless and erosion occurs. It is important to use an adequate number of staples and to roll the material after laying it to insure that the soil is protected.

Specifications

ORGANIC MULCHES

Organic mulches may be used in any area where mulch is required, subject to the restrictions noted in Table 1.75a.

R0071537

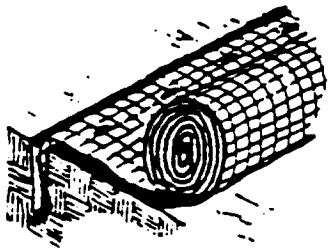

Table 1.75a

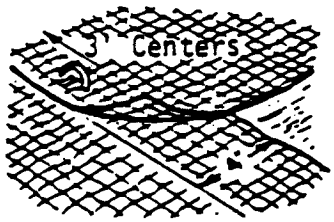
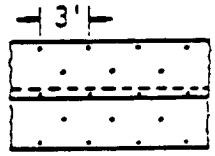
ORGANIC MULCH MATERIALS AND APPLICATION RATES

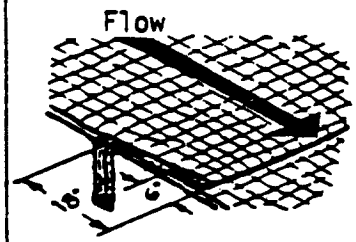


MULCHES	RATES		NOTES
	Per Acre	Per 1000 ft.^{2}	
Straw	1-1/2-2 Tons	70-90 lbs.	Free from weeds and coarse matter. Must be anchored. Spread with mulch blower or by hand.
Wood Fibers	1000-2000 lbs.	25-50 lbs.	Fibers 4 mm or longer. Do not use alone in winter or during hot, dry weather. Apply as slurry.
Corn Stalks	4-6 tons	185-275 lbs.	Cut or shrredded in 4-6" lengths. Air-dried. Do not use in fine turf areas. Apply with mulch blower or by hand.
Wood Chips	4-6 tons	185-275 lbs.	Free of coarse matter. Air-dried. Treat with 12 lbs. nitrogen per ton. Do not use in fine turf areas. Apply with mulch blower, chip handler, or by hand.
Bark Chips Shredded	50-70 cu. yds.	1-2 cu. yds.	Free of coarse matter. Air-dried. Do not use in fine turf areas. Apply with mulch blower, chip handler, or by hand.

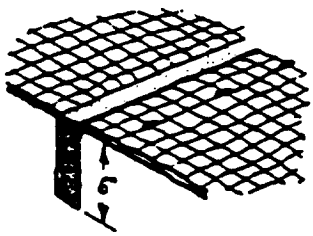
Source: Va SWCC



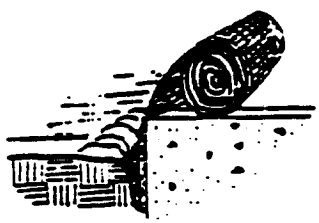
INSTALLATION OF NETTING AND MATTING

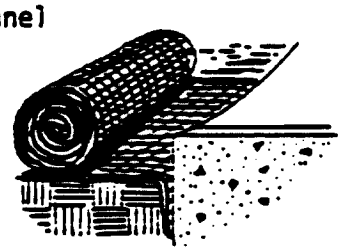


Anchor Slot: Bury the up-channel end of the net in a 6" deep trench. Tamp the soil firmly. Staple at 12" intervals across the net.



Overlap: Overlap edges of the strips at least 4". Staple every 3 feet down the center of the strip.

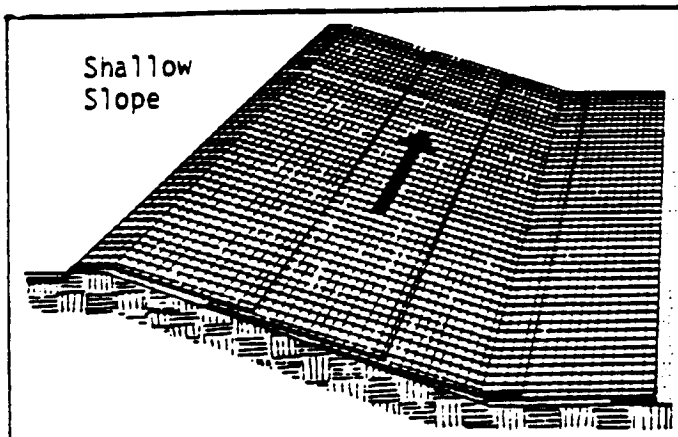




Joining Strips: Insert the new roll of net in a trench, as with the Anchor Slot. Overlap the up-channel end of the previous roll 18" and turn the end under 6". Staple the end of the previous roll just below the anchor slot and at the end at 12" intervals.

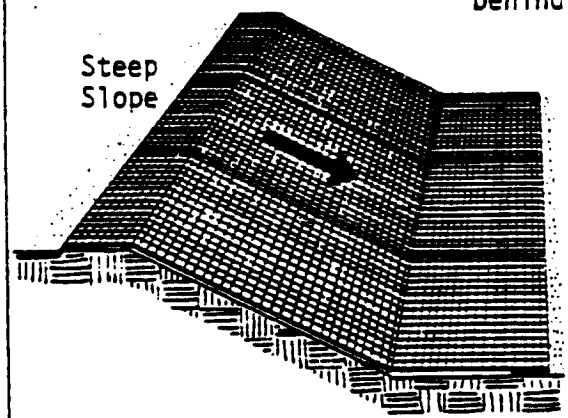
Check Slots: On erodible soils or steep slopes, check slots should be made every 15 feet. Insert a fold of the net into a 6" trench and tamp firmly. Staple at 12" intervals across the net. Lay the net smoothly on the surface of the soil - do not stretch the net, and do not allow wrinkles.

Anchoring Ends At Structures: Place the end of the net in a 6" slot on the up-channel side of the structure. Fill the trench and tamp firmly. Roll the net up the channel. Place staples at 12" intervals along the anchor end of the net.



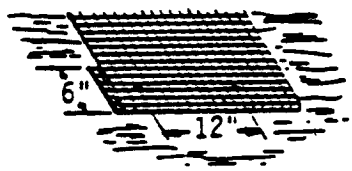
Source: Adapted from Conwed Products Brochure

Plate 1.75a

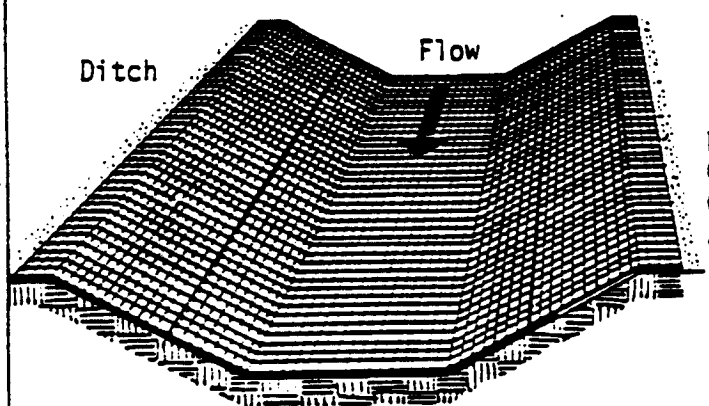


R0071539

On shallow slopes, strips of netting may be applied across the slope.



Where there is a berm at the top of the slope, bring the netting over the berm and anchor it behind the berm.



On steep slopes, apply strips of netting parallel to the direction of flow and anchor securely.

Bring netting down to a level area before terminating the installation. Turn the end under 6" and staple at 12" intervals.

In ditches, apply netting parallel to the direction of flow. Use check slots every 15 feet. Do not join strips in the center of the ditch.

ORIENTATION OF NETTING AND MATTING

Source: Adapted from Ludlow Products Brochure

Plate 1.75b

Materials: Select mulch material based on site requirements, availability of materials, and availability of labor and equipment. Table 1.75a lists the most commonly used organic mulches. Other materials, such as peanut hulls and cotton burs, may be used.

Prior to mulching: Complete the required grading and install needed sediment control practice.

Lime and fertilizer should be incorporated and surface roughening accomplished as needed. Seed should be applied prior to mulching except in the following cases: (a) Where seed is to be applied as part of a hydro-seeder slurry containing wood fiber mulch. (b) Where seed is to be applied following a straw mulch spread during winter months. (c) Where a hydro-seeder slurry is applied over straw.

Application: Mulch materials shall be spread uniformly, by hand or machine.

When spreading straw by hand, divide the area to be mulched into approximately 1000 sq. ft. sections and place 70-90 lbs. (1-1/2 to 2 bales) of straw in each section to facilitate uniform distribution.

Mulch Anchoring: Straw mulch must be anchored immediately after spreading to prevent windblow. Other organic mulches listed in Table 1.75a do not require anchoring. The following methods of anchoring straw may be used:

1. Mulch anchoring tool: This is a tractor-drawn implement designed to punch mulch into the soil surface. This method provides maximum erosion control with straw. It is limited to use on slopes no steeper than 3:1, where equipment can operate safely. Machinery shall be operated on the contour.

2. Liquid mulch binders: Application of liquid mulch binders and tackifiers should be heaviest at edges of areas and at crests of ridges and banks, to prevent windblow. The remainder of the area should have binder applied uniformly. Binders may be applied after mulch is spread or may be sprayed into the mulch as it is being blown onto the soil. Applying straw and binder together is the most effective method.

The following types of binders may be used:

   a. Asphalt - Any type of asphalt thin enough to be blown from spray equipment is satisfactory. Recommended for use are rapid curing (RC-70, RC-250, RC-800), medium curing (MC-250, MC-800) and emulsified asphalt (SS-1, CSS-1, CMS-2, MS-2, RS-1, RS-2, CRS-1, and CRS-2).

      Apply asphalt at 0.10 gallon per square yard (10 gal./1000 ft.^{2}, 480 gal./acre). Do not use heavier applications as it may cause the straw to "perch" over rills. All asphalt designations are from the Asphalt Institute Specifications.

R0071541

b. Synthetic binders - Chemical binders such as Petroset, Terratack and Aerospray may be used as recommended by the manufacturer to anchor mulch. These are expensive and therefore usually used in small areas or in residential areas where asphalt may be a problem. (Use of trade names do not constitute an endorsement by the Commission).

3. Mulch nettings - Lightweight plastic, cotton, or paper nets may be stapled over the mulch according to manufacturer's recommendations. (See NETS AND MATS, below).

4. Peg and twine - Because it is labor intensive, this method is feasible only in small areas where other methods cannot be used. Drive 8 - 10 inch wooden pegs to within 3 inches of the soil surface, every 4 feet in all directions. Stakes may be driven before or after straw is spread. Secure mulch by stretching twine between pegs in a criss-cross-within-a- square pattern. Turn twine 2 or more times around each peg.

CHEMICAL MULCHES

Chemical mulches may be used alone only in the following situations:

a. Where no other mulching material is available.

b. In conjunction with temporary seeding during the times when mulch is not required for that practice.

c. From May 1 to June 15 and September 15 to October 15, provided that they are used on areas with slopes no steeper than 4:1, which have been roughened in accordance with SURFACE ROUGHENING ES BMP 1.60. If rill erosion occurs, another mulch material shall be applied immediately.

NETS AND MATS

Nets may be used alone on level areas, on slopes no steeper than 3:1, and in waterways (as specified in STORMWATER CONVEYANCE CHANNELS, ES BMP 1.35).

When mulching is done in late fall or during June, July, or August, or where soil is highly erodible, net should only be used in conjunction with an organic mulch such as straw.

When net and organic mulch are used together, the net should be installed over the mulch except when the mulch is wood fiber. Wood fiber may be sprayed on top of the installed net.

Excelsior binders are considered protective mulches and may be used alone on erodible soils and during all times of year.

Materials: Jute net shall be heavy, uniform cloth woven of single jute yarn, which if 36 to 48 inches wide shall weigh an average of 1.2 pounds per linear yard.

Other products designed to control erosion shall conform to manufacturer's specification and should be applied in accordance with manufacturer's instructions provided those instructions are at least as stringent as this specification. Examples of these products are Erosionet, Holdgro, Weedchek, and Curlex. (Use of trade names does not indicate an endorsement of products by the department). In no case shall these products cover less than 30% of the soil surface.

Staples will be made of plain iron wire, No. 8 gauge or heavier, and will be 6 inches or more in length.

Prior to installation:

1. Shape and grade as require the waterway, channel, slope or other area to be protected.

2. Remove all rocks, clods, or debris larger than 2 inches in diameter that will prevent contact betwen the net and the soil surface.

3. When open-weave nets are used, lime fertilizer and seed may be applied either before or after laying the net. When excelsior netting is used, they must be applied before the the mat is laid.

Laying the Net

1. Start laying net from top of channel or top of slope and unroll downgrade.

2. Allow to lay loosely on soil--do not stretch.

3. To secure net: Upslope ends of net should be buried in a slot or trench no less than 6 inches deep. Tamp earth firmly over net. Staple the net every 12 inches across the top end.

   Edges of net shall be stapled every 3 feet. Where 2 strips of net are laid side by side, the adjacent edges shall be overlapped 3 inches and stapled together.

Staples shall be placed down the center of net strips at 3-foot intervals. DO NOT STRETCH net when applying staples.

Joining strips: Insert new roll of net in trench, as with upslope ends of net. Overlap the end of the previous roll 18 inches, turn under 6 inches, and staple across end of roll just below anchor slot and at the end of the turned-under net every 12 inches.

At bottom of slopes: Lead net out onto a level area before anchoring. Turn ends under 6 inches, and staple across end every 12 inches.

Check slots: On highly erodible soils and on slopes steeper than 4:1, erosion check slots should be made every 15 feet. Insert a fold of net into a 6-inch trench and tamp firmly. Staple at 12-inch intervals across the downstream portion of the net.

Rolling: After installation, stapling, and seeding, net should be rolled to ensure firm contact between net and soil.

Maintenance

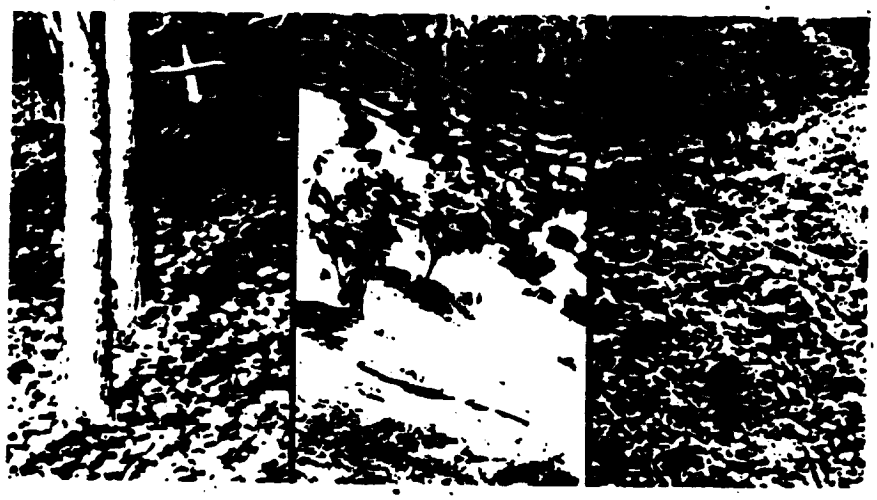
All mulches should be inspected periodically, in particular after rainstorms, to check for rill erosion. Where erosion is observed additional mulch should be applied. Net should be inspected after rainstorms for dislocation or failure. If washouts or breakage occur, re-install net as necessary after repairing damage to the slope. Inspections should take place up until grasses are firmly established. Where mulch is used in conjunction with ornamental plantings, inspect periodically throughout the year to determine if mulch is maintaining coverage of the soil surface; repair as needed.

R0071544

ES BMP 1.80

TREES, SHRUBS, VINES AND GROUND COVERS

Definition



Stabilizing disturbed areas by establishing vegetative cover with trees, shrubs, vines, or ground covers.

Purposes

1. To aid in stabilizing soil in areas where vegetation other than turf is preferred.
2. To provide food and shelter for wildlife where wildlife habitat is desirable.

Conditions Where Practice Applies

1. On steep or rocky slopes, where mowing is not feasible.
2. Where ornamentals are desirable for landscaping purposes.
3. In shady areas where turf maintenance is difficult.
4. Where woody plants are desirable for soil conservation, or to establish wildlife habitats.

Planning Considerations

Disturbed areas may be stabilized in many different ways. Most frequently, a permanent vegetative cover of grasses and legumes is established. There are locations, however, where other types of vegetation are preferred. The following situations are examples of ways in which trees, shrubs, vines, and ground covers may be used:

1. On cut and fill slopes adjacent to paved areas of shopping centers, schools, industrial parks, or other non-residential projects: woody plants and ground covers can be used on these slopes to control erosion. They will also help to control foot traffic, will not require as much maintenance as mowed lawns, and will be more attractive than unmowed grass cover.

2. In residential areas, slopes too steep to be mowed and areas along rights-of-way or easements may be planted in trees, shrubs, vines, or ground covers to reduce maintenance and improve appearance.

3. The interested homeowner or small project developer may choose to use ornamental plants in problem areas--shade, steep slopes, inaccessible places--as alternatives to grass. Ground covers may be used to reduce or eliminate the need for mowing grass on level areas.

There are vast numbers of plants that may be used for these purposes. The plants discussed in this practice are those which are known to be adapted to Florida, fairly easy to grow, and commonly available from commercial nurseries. Many plants suitable for use are not mentioned here. Information on such plants can be obtained from nurserymen, landscape architects, and extension agents.

Because many types of woody plants and ground covers are discussed, and because site conditions and land use vary so widely, it is not practical to give specific requirements for the establishment of every plant mentioned. This practice consists, instead, of a set of general guidelines for growing trees, shrubs, vines, and ground covers on disturbed land.

Guidelines

Disturbed soil between trees and shrubs must be mulched or planted with permanent vegetation to prevent erosion. Refer to the other practices to select a method for stabilizing these areas.

TREES

Selecting the Right Trees - In the urban and suburban environments, trees may be exposed to insufficient light and water; high velocity winds; salt spray in coastal locations; heat radiation from roads and buildings; pollutants from cars and industry; root amputation for water, power, sewer, and gas lines; topping to prevent interference with power lines; and covering of roots by pavement. New species and varieties of trees are

being selected for the modern environment on the basis of their ability to withstand those difficult conditions and still provide the benefits associated with having trees (see Plate 1.80a).

Selection of trees depends on the desired function of the tree, whether it be shade, privacy screening, noise screening, appearance, enhancement of wildlife habitat, or a combination of these. The following characteristics of the tree should be considered when making choices:

1. Hardiness - "Hardiness zones" are based on average annual minimum temperature. Florida contains 3 such zones (Plate 1.66b) to which different trees are adapted.

2. Mature height and spread - The eventual height of a tree must be considered in relation to planting location to avoid future problems with power lines and buildings. (See Plate 1.80b).

3. Growth rate - Some trees attain mature height at an early age, others take many years. If "instant shade" is desired, rapid growth is needed. Slow-growing trees are usually less brittle and live longer.

4. Root system - Some trees obstruct underground pipelines with fibrous roots.

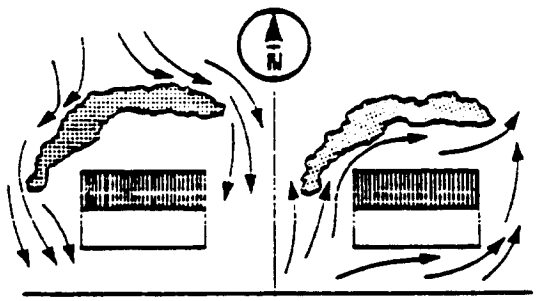
5. Cleanliness - Maintenance problems can be avoided by not selecting trees that drop seedpods, flowers, or twigs in large amounts.

6. Moisture and fertility requirements - If good soil and drainage are not available, trees tolerant of poor growing conditions must be planted.

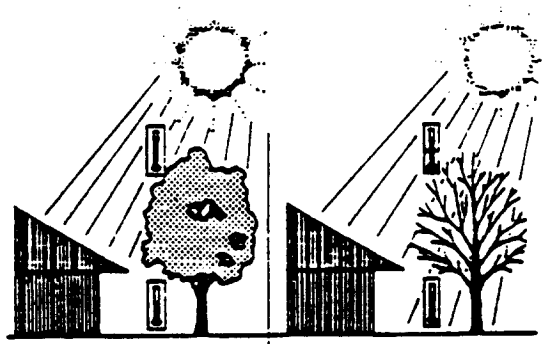
7. Ornamental effects - If a tree is unusually attractive in appearance, some other shortcomings may be overlooked.

8. Evergreen vs. deciduous - Evergreens retain their leaves throughout the year, and so are useful for privacy screens and noise screens. Deciduous trees drop their leaves in fall. They are preferable for shade trees.

Some of these characteristics are given in Table 1.80a (at the end of this ES BMP) for trees commonly grown in Florida.



At the same time as trees are being selected, the site where they will be planted should be evaluated. Consider the prior use of the land; adverse soil conditions, such as poor drainage or acidity; exposure to wind; temperature extremes; location of utilities, paved areas, and security lighting; and traffic patterns.



Sources of trees and how they may be bought - The trees listed in Table 1.80a are usually available at commercial nurseries as container-grown trees or as balled and burlapped trees. Container-grown trees can be planted at any time of year if sufficient water is provided. They should be purchased and planted when quite young (less than 2" diameter trunk) to avoid dealing with root-bound plants.

R0071547

Temperature Modification

Trees affect wind speed and direction, and thus temperature. For example, an evergreen planting on the northwest side of a building will reduce the effects of harsh winter winds and direct cool summer breezes through the area. Trees protect the soil from drying sun and wind, reducing evaporation and maintaining cooler temperatures under trees. When properly placed near buildings, trees of proper size will insulate buildings from extreme temperature changes in winter and summer, helping reduce costs of heating and cooling. Deciduous trees block out the hot summer sun, keeping the home cooler, and allow warmth of winter sun to pass through.

Sound Control

Noises from nearby sources can be reduced through proper placement of trees. The degree of control depends on the density of the planting and intensity and direction of sound waves. Both deciduous and evergreen trees should be used for best effect.

Erosion Control

Coarse leaf textures, horizontal branching habits, fibrous root systems, and rough bark are tree characteristics most effective in slowing water movement and wind speed, thus reducing erosion problems.

BENEFITS OF TREES

Source: Va SWCC

Plate 1.80a

R0071548

SPACING TREES FOR SAFETY AND EFFECTIVE LANDSCAPING

Small Trees

Plant small trees a minimum of 12 feet from structures or utility wires. In rows, plant them 25 feet apart.

Medium Trees

Plant medium trees a minimum of 25 feet from structures and utility wires, and 30-50 feet apart in rows.

Large Trees

Plant large trees a minimum of 35 feet from structures and utility wires, and 50-75 feet apart when planted in rows.

Source: Va SWCC

Plate 1.80b

Balled and burlapped trees are usually larger; check to be sure that soil around roots was dug with the tree and not just packed around bare roots. The soil should have been kept moist.

Tree seedlings are available commercially and are also sold by the State Division of Forestry which has nurseries located in Munson, Chiefland and Lake Placid. About 40 species of trees are usually available at nominal prices. The minimum price is for an order of 500 trees although any number of seedlings may be ordered. Seedlings are available as bare root, containerized or potted trees with the latter two categories usually utilized in the urban environment. Orders for bare root seedlings are accepted between July 1 and March 1 with delivery occurring between late November and early March. Containerized and potted seedlings may be ordered and delivered throughout the year although high demand for these type of seedlings creates occasional delays in delivery. More information about this program is available from the Florida Division of Forestry.

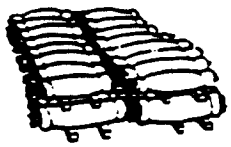
PLANTING BARE-ROOTED TREE SEEDLINGS

When - Trees to be planted as bare-rooted seedlings should be handled only while dormant in spring, or after leaf fall in autumn. Refer to Plate 1.80c for planting instructions.

When stabilizing the disturbed areas between tree plantings, do not use grasses or legumes which will overshade the new seedlings. Where possible, a circle of mulch around seedlings will help them to compete successfully with herbaceous plants.

TRANSPLANTING TREES (Planting Balled-and-Burlapped and Container-grown Trees)
When - Late fall through winter (November to February) is the preferred time for planting both deciduous and evergreen trees throughout Florida.

Tree preparation - Proper digging of a tree includes the conservation of as much of the root system as possible, particularly the fine roots. Soil adhering to the roots should be damp when the tree is dug, and kept moist until planting. The soil ball should be 12 inches in diameter for each inch of diameter of the trunk. The tree should be carefully excavated and the soil ball wrapped in burlap and tied with rope. Use of a mechanical tree spade is also acceptable.



Evergreens, or any trees which are to be transplanted for a distance, should have the branches bound in with soft rope to prevent damage.

Site preparation - The planting hole should be dug deep and wide enough to allow proper placement of the root ball. The final level of the root ball's top should be level with the ground surface. (Plate 1.80d).

As the hole is dug, topsoil should be kept separate from subsoil. If possible, discard subsoil and replace with good topsoil. If topsoil is unavailable, improve subsoil by mixing in 1/3 by volume of peat moss or well-rotted manure.

R0071550

Care of Seedlings Until Planted

Seedlings should be planted immediately. If it is necessary to store moss-packed seedlings for more than 2 weeks, one pint of water per pkg. should be added. If clay-treated, do not add water to pkg. Packages must be separated to provide ventilation to prevent "heating". Separate packages with wood strips and store out of the wind in a shaded, cool (not freezing) location.

Care of Seedlings During Planting

When planting, roots must be kept moist until trees are in the ground. Do not carry seedlings in your hand exposed to the air and sun. Keep moss-packed seedlings in a container packed with wet moss or filled with thick muddy water. Cover clay-treated seedlings with wet burlap only.

Hand Planting

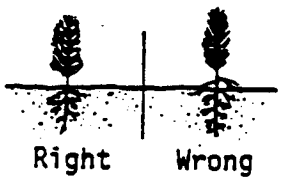
Insert bar at angle shown and push forward to upright position.

Remove bar and place seedling at correct depth.

Insert bar two inches toward planter from seedling.

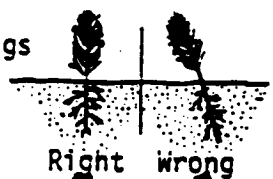
Pull bar toward planter firming soil at bottom of roots.

Push bar forward from planter firming soil at top of roots.



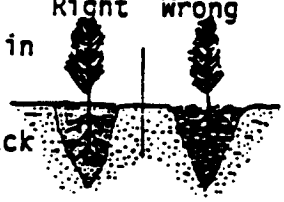
Fill in last hole by stamping with heel.

Firm soil around seedling with feet.



Test planting by pulling lightly on seedling.

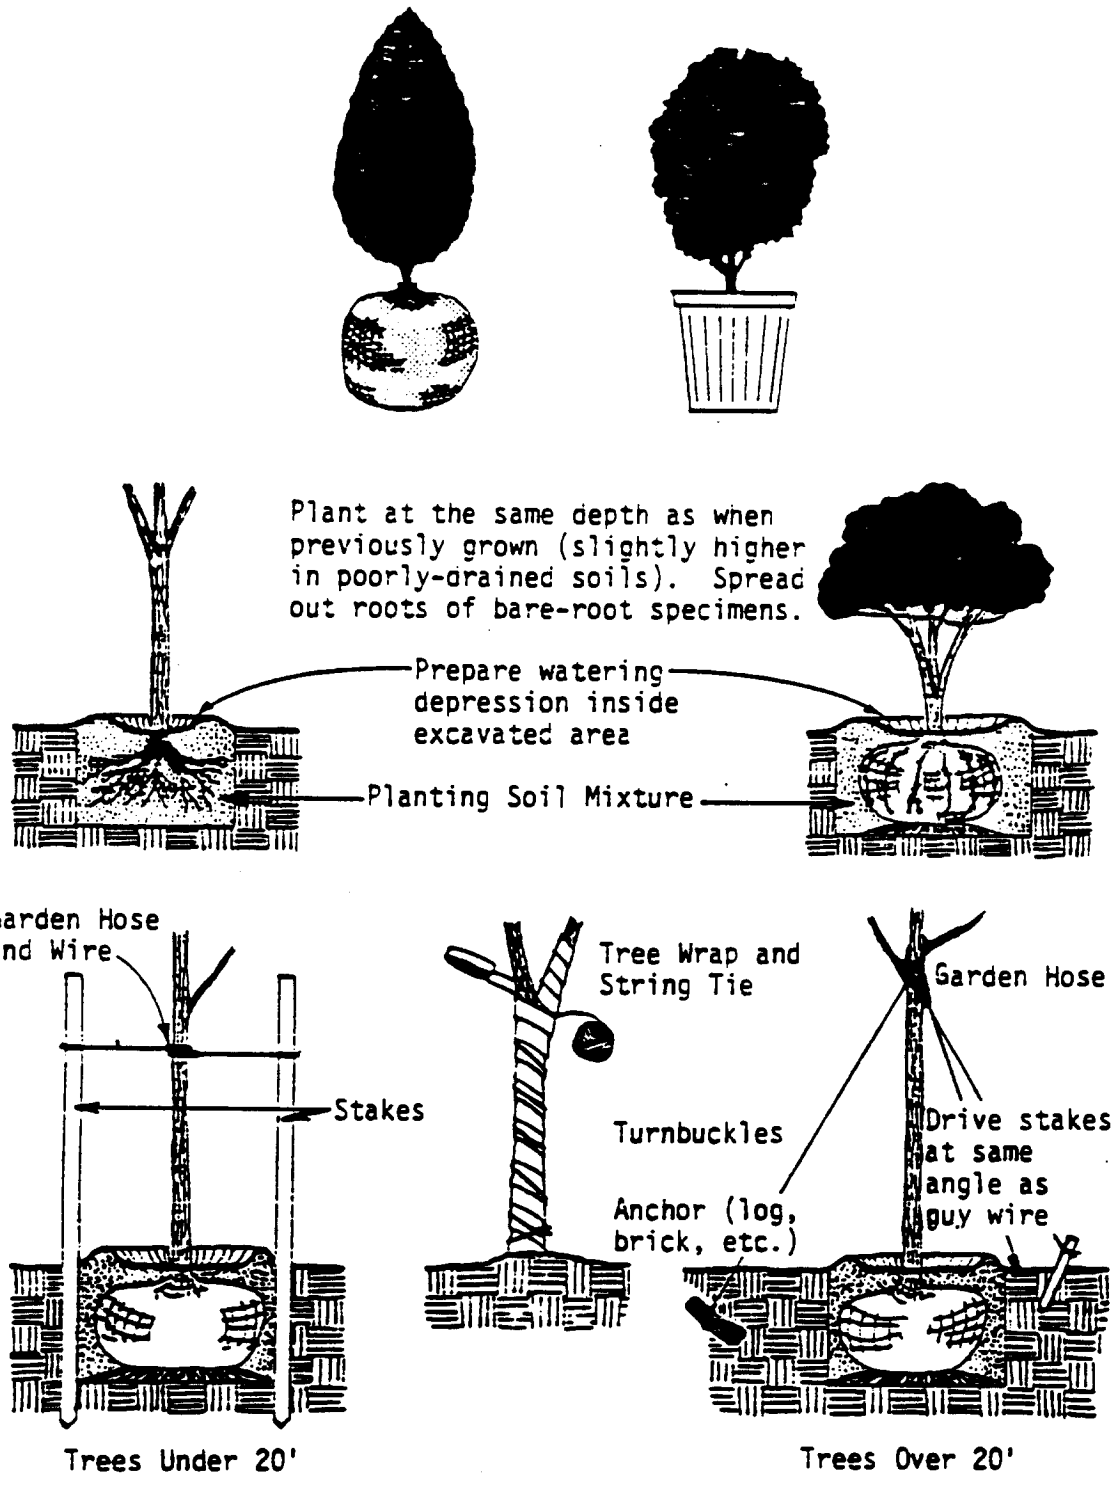
Don't expose roots to air during freeze or plant in frozen ground.



Plant seedlings upright - not at an angle.

Do not bend roots so that they grow upwards out of the ground.

Always plant in soil - never loose leaves or debris. Pack soil tightly.



PLANTING BARE-ROOTED SEEDLINGS

PLANTING BALLED-AND-BURLAPPED AND CONTAINER-GROWN TREES

Source: Virginia Division of Forestry

Plate 1.80d

R0071552

Heavy or poorly drained soils are not good growth media for trees. When it is necessary to transplant trees into such soils, extra care should be taken. Properly installed drain tile will improve drainage.

Setting the tree - Depth of planting must be close to the original depth. The tree may be set just a few inches higher than in its former location, especially if soil is poorly drained. DO NOT set the tree lower than before. Soil to be placed around the root ball should be moist but not wet.

Set the tree in the hole and remove the rope which holds the burlap. Loosen the burlap; remove completely if that is practical. Do not break the soil of the root ball. Fill the hole with soil half-way, and tamp firmly around the root ball. Add water to settle the soil and eliminate air pockets. When the water has drained off, fill the hole the remainder of the way and tamp as before.

Use extra soil to form a shallow basin around the tree, somewhat smaller than the diameter of the root ball (Plate 1.80d). This will be for holding water when the tree is irrigated. Note: Level the ground and eliminate these basins when winter sets in, as ice forming in the basin might injure the trunk.

Supporting the tree - Newly planted trees need artificial support to prevent excessive swaying. Stakes or guy wires may be used (see Plate 1.80d).

Watering - Soil around the tree should be thoroughly watered after the tree is set in place. When the soil becomes dry, the tree should be watered deeply but not too often. Mulching around the base of the tree is helpful in preventing roots from drying out.

Maintenance of Tree Plantings

Like all plants, trees require water and fertilizer to grow. Ideally, young trees should receive an inch of water each week for the first two years after planting. When rain does not supply this need, the tree should be watered deeply but not more often than once per week.

Transplanted trees should be fertilized one year or so after planting. There are many sophisticated ways to supply fertilizer to trees, but some simple methods are adequate. The best material for small trees is well-rotted stable manure, if it can be obtained. Add it annually as a 2-inch layer of mulch around the tree. If chemical fertilizers are to be used, a formulation such as 10-8-6 or 10-6-4 is preferred. Use about 2 lbs. per inch of trunk diameter measured 4 feet from the ground. Thus, if the trunk diameter at 4 feet was 5 inches, 10 lbs. of fertilizer would be applied.

NOTE: Evergreens use 1/2 the recommended amount of chemical fertilizer or use only organic fertilizers such as cottonseed meal, bone meal, or manure.

R0071553

Fertilizer must come in contact with the roots to benefit the tree. A simple way to insure this is to make holes in the tree's root area with a punchbar, crowbar, or auger. Holes should be 18 inches deep, spaced about 2 feet apart, and located around the drip line of the tree. Distribute the necessary fertilizer evenly into these holes, and close the holes with the heel of the shoe or by filling with topsoil or peat moss.

Fertilize trees in late fall or in early spring, before leaves emerge.

SHRUBS

Much of what has been said about trees also applies to shrubs. A shrub is an erect woody plant less than 15 feet tall, usually with several trunks rising from a common base. Some have the appearance of small trees, and some lie close to the ground.

Selecting appropriate shrubs - There are so many ornamental shrubs available that advising on the choice of any one is difficult. Table 1.80c gives the basic characteristics of shrubs commonly available at commercial nurseries in Florida, which are recommended for conservation planting because they enrich or hold the soil or encourage development of wildlife habitat. Information on other shrubs is available from nurserymen and extension agents.

Follow the general procedure for tree planting when planting shrubs.

Maintenance

Proper pruning, watering, and application of fertilizer every 3 years or so will keep shrubs healthy. Maintain the mulch cover or turf cover surrounding the shrubs. A heavy layer of mulch reduces weeds and retains moisture.

VINES AND GROUND COVERS

Low-growing plants that sprawl, trail, spread, or send out runners come in many leaf types, colors and growth habits. Some are suitable only as part of a maintained landscape, and some can stabilize large areas with little care.

In addition to stabilizing disturbed soil, vines and ground covers can perform the following functions:

1. Maintain cover in heavily shaded areas where turf will not thrive.

2. Provide attractive cover that does not need mowing.

3. Help to define traffic areas and control pedestrian movement. People are more likely to walk on the grass than on a thick bed of ivy or a prickly planting of juniper.

R0071554

Table 1.80c gives the characteristics of some commonly used vines and ground covers suitable for Florida. Information on others is available from nurserymen.

Like shrubs and trees, ground covers are best planted in spring. Containergrown plants can be planted throughout the growing season if adequate water is provided.

Site preparation - Ground covers are plants that naturally grow very close together, causing severe competition for space, nutrients, and water. Soil for ground covers should be well prepared. A well-drained soil high in organic matter is best.

The entire area should be spaded, disced or roto-tilled to a depth of six to eight inches. Two to three inches of organic material such as good topsoil, peat or well composted manure should be spread over the entire area. Apply 9-18 lbs./1000 ft^2 of 10-10-10 fertilizer and incorporate the organic material and fertilizer into the soil before planting.

If the area to be planted is very large or it is impractical to prepare the entire area, individual planting holes 1/3 larger and deeper than the plant root ball should be dug. If the soil is not suitable for plant growth, it is best to batch blend a planting medium. A mixture of 1:1 of 2:1 sandy loam soil and peat, composted manure or other well-rotted organic material with 10 pounds of 10-10-10 fertilizer and 20 lbs. lime per cubic yard of soil mix. Lime should not be used for acid loving plants such as camellias, azaleas or blueberries.

Planting - Plants such as ivy, pachysandra and periwinkle should be planted on one-foot centers; large plants such as juniper can be spaced on 3-foot centers. The following steps will help insure good plant growth:

1. Make the plantings on the contour.
2. Dig the holes 1/3 larger that the plant root ball.
3. Plant at the same level that the plants grew.
4. Use good topsoil or soil mixture with a lot of organics.
5. Fill hole 1/3 to 1/2 full, shake plants to settle soil among roots, then water. Finish filling hole, firm slightly and again settle with water.
6. Leave saucer-shaped depression around plant to hold water.
7. Water thoroughly and regularly.
8. Space plants according to the type of plant and the extent of covering desired. Set small plants as close as 4 to 6 inches apart and large plants as much as 4 feet apart. The following chart shows the area that approximately 100 plants will cover when set at various distances apart:

Planting Distance inches	Area Covered sq. ft.	Planting Distance inches	Area Covered sq. ft.
4	11	18	225
6	25	24	400
8	44	36	900
10	70	48	1600
12	100		

R0071555

Mulching - The soil between trees and shrubs must be planted with cover vegetation or must be mulched. When establishing ground covers, it is not desirable to plant species that will compete strongly with the ground cover or will make maintenance difficult. A thick durable mulch such as shredded bark or wood chips is recommended to prevent erosion and reduce weed problems. Pre-emergent herbicides may be necessary where weeding is not practical.

On slopes where erosion may be a problem, jute net or excelsior blankets may be installed prior to planting, and plants tucked into the soil through slits in the net. Such plants should be put in a staggered pattern to minimize erosion.

Maintenance

Trim old growth as needed to improve the appearance of ground covers. Most covers need once-a-year trimming to promote growth. Maintain mulch cover with additions of mulch where needed. Fertilize as described above, every 3-4 years.

ES BMP 1.85

TREE PRESERVATION AND PROTECTION

Definition

Protection of desirable trees from mechanical and other injury during land disturbing and construction activity.

Purpose

To ensure the survival of desirable trees where they will be effective for erosion and sediment control, watershed protection, landscape beautification, dust and pollution control, noise reduction, shade and other environmental benefits while the land is being converted from forest to urban-type uses.

Conditions Where Practice Applies

Tree-inhabited areas subject to land disturbing activities.

R0071572

Planning Considerations

New development often takes place on tracts of forested land. In fact, building sites are often selected because of the presence of mature trees. However, unless sufficient care is taken and planning done, in the interval between buying the property and completing construction much of this resource is likely to be destroyed. The property owner is ultimately responsible for protecting as many trees as possible, with their understory and ground cover. This responsibility is usually exercised by agents--the planners, designers and contractors. It takes 20 to 30 years for newly planted trees to provide the benefits for which we value trees so highly. Trees may perform the following functions on a site:

1. Assist in stabilizing the soil and preventing erosion.

2. Help to decrease stormwater runoff through canopy interception and root zone absorption.

3. Moderate temperature changes and provide shade.

4. Moderate the effects of sun and wind.

5. Provide buffers and screens against noise.

6. Filter pollutants from the air.

7. Help to remove carbon dioxide from the air and release oxygen.

8. Provide a haven for animals and birds, which help to control insect populations.

9. Conserve and increase property values.

10. Provide physiological and aesthetic counterpoints to a man-made urban setting.

Stresses of Construction

Trees may appear to be inanimate objects, but they are living organisms that are constantly involved in the process of respiration, food processing and growth. Construction activities expose trees to a variety of stresses resulting in injury ranging from superficial wounds to death. An understanding of these stresses is helpful in planning for tree protection.

1. Surface Impacts: Natural and man-related forces exerted on the tree above the ground can cause significant damage to trees.

    a. Wind damage - Removal of some trees from groups will expose the survivors to greater wind velocities. Trees tend to develop anchorage where it is most needed. Isolated trees develop anchorage rather equally all around, with stronger root development on the side of the prevailing winds.

Tne more a tree is protected from the wind, the less secure is its anchorage. The result of improper thinning is often windthrown trees. Selective removal in favor of a single tall tree may also create a lightning hazard.

b. Excessive pruning - Unprotected trees are often "topped" or carelessly pruned to prevent interference with utility wires or buildings. If too many branches are cut, the tree may not be able to sustain itself. If the pruning is done without considering the growth habit, the tree may lose all visual appeal. If the branches are not pruned correctly, decay may set in.

c. Trunk damage - Tree trunks are often nicked or scarred by trucks and construction equipment. Such superficial wounds provide access to insects and disease.

2. Root Zone Impacts: Disturbing the delicate relationship between soil, roots and the rest of the tree can damage or kill a tree. The roots of an existing tree are established in an area where essential materials--water, oxygen and nutrients--are present. The mass of the root system is the correct size to balance the intake of water from the soil with the transpiration of water from the leaves.

a. Raising the grade as little as 6 inches can retard the normal exchange of air and gases. Roots may suffocate due to lack of oxygen, or be damaged by toxic gases and chemicals released by soil bacteria.

b. Raising the grade may also elevate the water table. This can cause drowning of the deeper roots.

c. Lowering the grade is not usually as damaging as raising it. However, even shallow cuts of 6 to 8 inches will remove most of the topsoil, removing some feeder roots and exposing the rest to drying and freezing.

d. Deep cuts may sever a large portion of the root system, depriving the tree of water and increasing the chance of wind-throw.

e. Lowering the grade may lower the water table, inducing drought. This is a problem in large roadway cuts or underdrain installations.

f. Trenching or excavating through a tree's root zone can eliminate as much as 40 percent of the root system. Trees suffering such damage usually die within 2 to 5 years.

g. Compaction of the soil within the drip line of a tree by equipment operation, materials storage, or paving can block off air and water from roots.

h. Construction chemicals or refuse disposed of in the soil can change soil chemistry or be toxic to trees.

R0071574

Most damage to trees from construction activities is due to the invisible root zone stresses.

Design Criteria

No formal design is required. However, in planning for the development of a wooded site where some trees will be preserved, a number of criteria must be considered.

Selecting Trees to be Retained

The proper development of a wooded site requires completion of a plan for tree preservation before clearing and construction begins. Trees should be identified by species, and located on a topographical map, either as stands or as individuals, depending on the density and value of the trees. The following factors should be considered when deciding which trees to retain:

1. Life expectancy and present age: Preference should be given to trees with a long life span, such as white oak, beech, and maple. Long-lived specimens that are past their prime may succumb to the stresses of construction, so smaller, younger trees of desirable species are preferred; they are more resilient and will last longer. However, if the cost of preservation is greater than the cost of replacement with a specimen of the same age and size, replacement may be preferred.

2. Health and disease susceptibility: Check for scarring caused by fire or lightning, insect or disease damage, and rotted or broken trunks or limbs. Pest- and pollution-resistant trees are preferred.

3. Structure: Check for structural defects that indicate weakness or reduce the aesthetic value of a tree: trees growing from old stumps, large trees with overhanging limbs that endanger property, trees with brittle wood, misshapen trunks or crowns, and small crowns at the top of tall trunks. Open grown trees often have better form than those grown in the woods. Trees with strong tap or fibrous root systems are preferred to trees with weak rooting habits.

4. Cleanliness: Some trees such as elm and black locust are notoriously "dirty," dropping twigs, bark, fruit, or plant exudates. A clean tree is worth more than a dirty one. Trees which seed prolifically or sucker profusely are generally less desirable in urban areas. Thornless varieties are preferred.

5. Aesthetic values: Handsome bark and leaves, net growth habits, fine fall color, and attractive flowers and fruit are desirable characteristics. Trees that provide interest during several seasons of the year enhance the value of the site.

6. Comfort: Trees relieve the heat of summer and buffer strong winds throughout the year. Summer temperatures may be 10 degrees cooler under hardwoods than under conifers. Deciduous trees drop their leaves in winter, allowing the sun to warm buildings and soil. Evergreens are more effective wind buffers.

R0071575

7. Wildlife: Preference should be given to trees that provide food, cover, and nesting sites for birds and game.

8. Adaptability to the proposed development:

   a. Consider the mature height and spread of trees; they may interfere with proposed structures and overhead utilities. Roots may interfere with walls, walks, driveways, patios, and other paved surfaces; or water lines, septic tanks, and underground drainage.

   b. Trees must be appropriate to the proposed use of the development; select trees which are pollution-tolerant for high traffic and industrial areas, screen and buffer trees for noise or objectionable views, salt-tolerant species exposed to ocean spray.

   c. Consider location of landfills. Gases generated in them can travel long distances underground, to injure distant trees. Choose species tolerant of anaerobic soil conditions.

   d. Determine the effect of proposed grading on the water table. Grading should not take place within the drip line of any trees to be saved.

9. Survival needs of the tree: Chosen trees must have enough room to develop naturally. They will be subject to injury from increased exposure to sunlight, heat radiated from buildings and pavement, and wind. It is best to retain groups of trees rather than individuals. As trees mature, they can be thinned gradually.

10. Relationship to other trees: Individual species should be evaluated in relation to other species on the site. A species with low value when growing among hardwoods will increase in value if it is the only species present. Trees standing alone generally have higher landscape value than those in a wooded situation. However, tree groups are much more effective in preventing erosion and excess stormwater runoff.

Site Planning for Tree Protection

1. If lot size allows, select tree to be saved before siting the building. No tree should be destroyed or altered until the design of the buildings and utility systems is final.

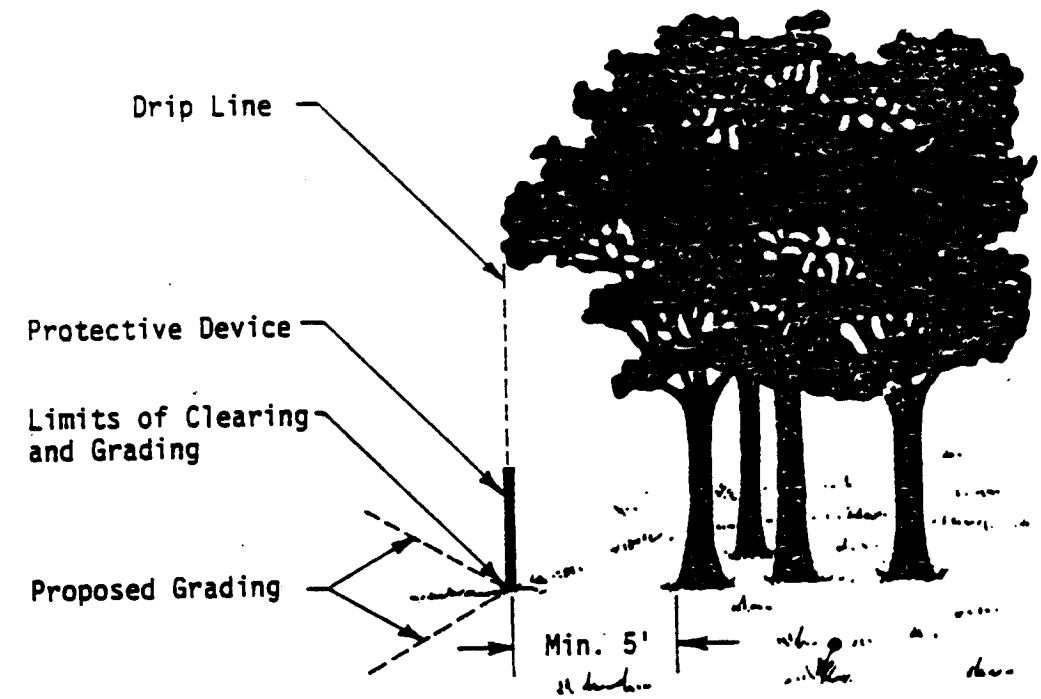
2. Critical areas, such as flood plains, steep slopes, and wetlands, should be left in their natural condition or only partially developed as open space.

3. Locate roadways to cause the least damage to valuable stands. Follow original contours, where feasible, to minimize cuts and fills.

4. Minimize trenching by locating several utilities in the same trench. Excavations for basements and utilities should be kept away from the drip line of trees.

R0071576

5. Construction material storage areas and worker parking should be noted on the site plan, and located where they will not cause compaction over roots.



6. When retaining existing trees in parking areas, leave enough ground ungraded around the tree to allow for its survival.

7. Locate erosion and sediment control measures at the limits of clearing and not in wooded areas, to prevent deposition of sediment within the drip line of trees being preserved. Sediment basins should be constructed in the natural terrain, if possible, rather than in locations where extensive grading and tree removal will be required.

Specifications

1. Groups of trees and individual trees selected for retention shall be accurately located on the plan and designated as "tree(s) to be saved." Individual specimens that are not part of a tree group shall also have their species and diameter noted on the plan.

2. The limits of clearing shall be located outside the drip line of any tree to be retained, and in no case closer than 5 feet to the trunk of such a tree (Plate 1.85a).

CONSTRUCTION OPERATIONS RELATIVE TO THE LOCATION OF PROTECTED TREES

Source: Public Facilities Manual, Vol. III, Fairfax County, Virginia 1976

Plate 1.85a

R0071577

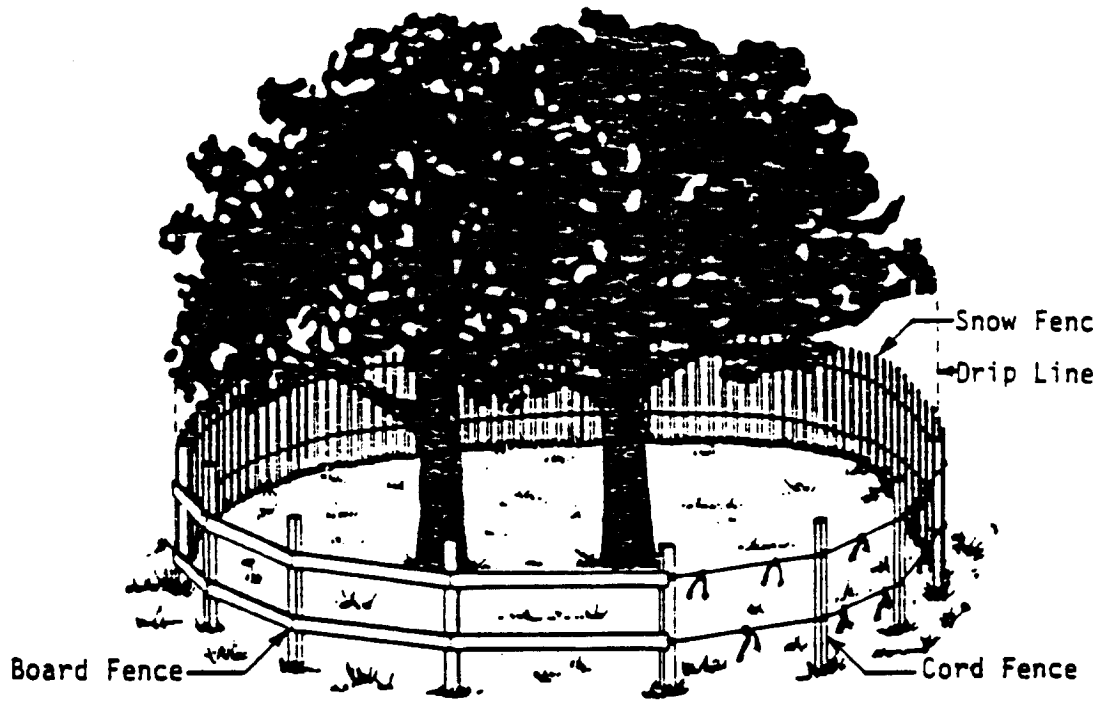
3. Marking: Prior to construction and before the preconstruction conference, individual trees and stands of trees to be retained within the limits of clearing shall be visibly marked with a bright color paint or surveyor's ribbon applied in a band circling the tree at a height visible to equipment operators.

4. Pre-Construction Conference: During any preconstruction conference, tree preservation and protection measures should be reviewed with the contractor as they apply to that specific project.

5. Equipment Operation and Storage: Heavy equipment, vehicular traffic or stockpiles of any construction material including topsoil shall not be permitted within the drip line of any tree to be retained. Trees being removed shall not be felled, pushed or pulled into trees being retained. Equipment operators shall not clean any part of their equipment by slamming it against the trunks of trees to be retained.

6. Fires: Fires shall not be permitted within 100 feet from the drip line of any trees to be retained. Fires shall be limited in size to prevent adverse effects on trees, and kept under surveillance.

7. Storage and Disposal of Toxic Materials: No toxic materials shall be stored closer than 100 feet to the drip line of any trees to be retained. Paint, acid, nails, gypsum board, wire, chemicals, fuels, and lubricants shall not be disposed of in such a way as to injure vegetation.

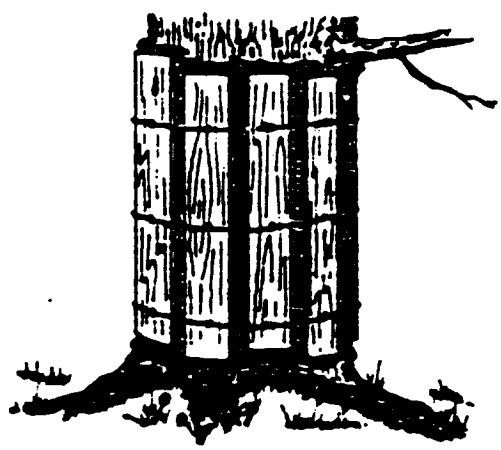


8. Fencing and Armoring: (Plate 1.85b): Any device may be used which will effectively protect the roots, trunk and tops of trees retained on the site. However, trees to be retained within 40 feet of a proposed building or excavation shall be protected by fencing. Personnel must be instructed to honor protective devices. The devices described are suggested only, and are not intended to exclude the use of other devices which will protect the trees to be retained.

   a. Field fence - Standard 48 inch high field fence shall be placed at the limits of the clearing on standard steel posts set 6 feet apart.

   b. Board Fence - Board fencing consisting of 4 inch square posts set securely in the ground and protruding at least 4 feet above the ground shall be placed at the limits of clearing with a minimum of two horizontal boards between posts. If it is not practical to erect a fence at the drip line, construct a triangular fence nearer the trunk. The limits of clearing within the drip line will still require protection.

   c. Cord Fence - Posts with a minimum size of 2 inches square or 2 inches in diameter set securely in the ground and protruding at least 4 feet above the ground shall be placed at the limits of clearing with two rows of cord 1/4 inch or thicker at least 2 feet apart running between posts with strips of colored surveyor's flagging tied securely to the string at intervals of no greater than 3 feet.



R0071578

Correct Methods of Tree Fencing

Triangular Board Fence

Correct Trunk Armoring

FENCING AND ARMORING

Source: Va SWCC

Plate 1.85b

R0071579

d. Earth Berms - Temporary earth berms shall be constructed according to specifications for a TEMPORARY DIVERSION DIKE (ES BMP 1.15) with the base of the berm on the tree side located along the limits of clearing. Earth berms may not be used for this purpose if their presence will conflict with drainage patterns.

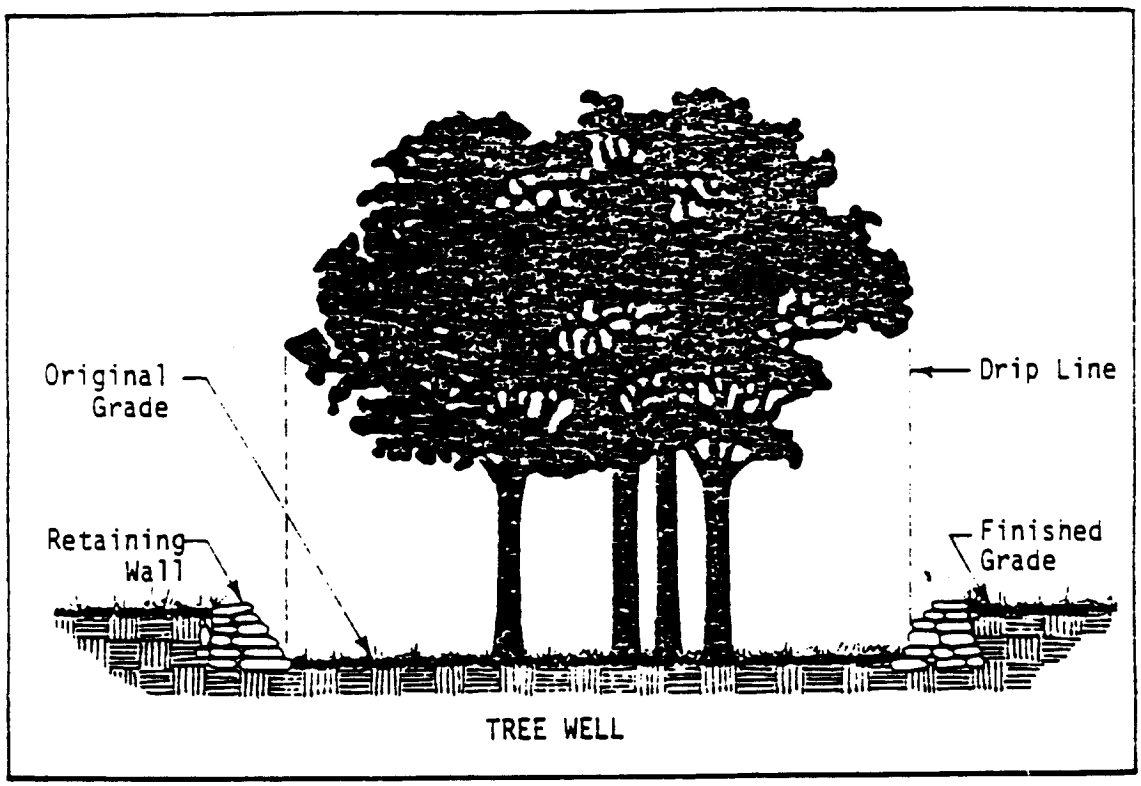
e. Additional Trees - Additional trees may be left standing as protection between the trunks of the trees to be retained and the limits of clearing. However, in order for this alternative to be used, the trunks of the trees in the buffer must be no more than 6 feet apart to prevent passage of equipment and material through the buffer. These additional trees shall be reexamined prior to the completion of construction and either given sufficient treatment to insure survival or removed.

f. Trunk Armoring - As a last resort a tree trunk can be armored with burlap wrapping and 2 inch studs wired vertically no more than 2 inches apart to a height of 5 feet encircling the trunk. If this alternative is used, the root zone within the drip line will still require protection. Nothing should ever be nailed to a tree.

Fencing and armoring devices shall be in place before any excavation or grading is begun, shall be kept in good repair for the duration of construction activities, and shall be the last items removed during the final cleanup after the completion of the project.

9. Raising the Grade: When the ground level must be raised around an existing tree or tree group, the following considerations shall be made and steps taken to adequately care for the affected tree.

a. A well may be created around the tree(s) slightly beyond the drip line to retain the natural soil in the area of the feeder roots (Plate 1.85c).



b. In the case of an individual tree, when the above alternative is not practical or desirable, the following method is recommended to insure survival of the tree (plate 1.85d).

(1) Before making the fill, remove the greeen vegetation, sod, leaf litter and other organic matter from beneath the tree or trees to a distance of 3 feet beyond the drip line, and loosen the surface soil to a depth of approximately 3 inches without damaging the roots.

(2) Apply fertilizer in the root area of the tree to be retained. Fertilizer formulations and application rates and methods shall conform to the guidelines provided in Table 1.85a.

(3) The dry well shall be constructed so as to allow for tree trunk diameter growth. A space of at least 1 foot between the tree trunk and the well wall is adequate for large, old, slow growing trees. Clearance for younger trees shall be at least 2 feet.

R0071580

TREE WELL

Source: Va SWCC

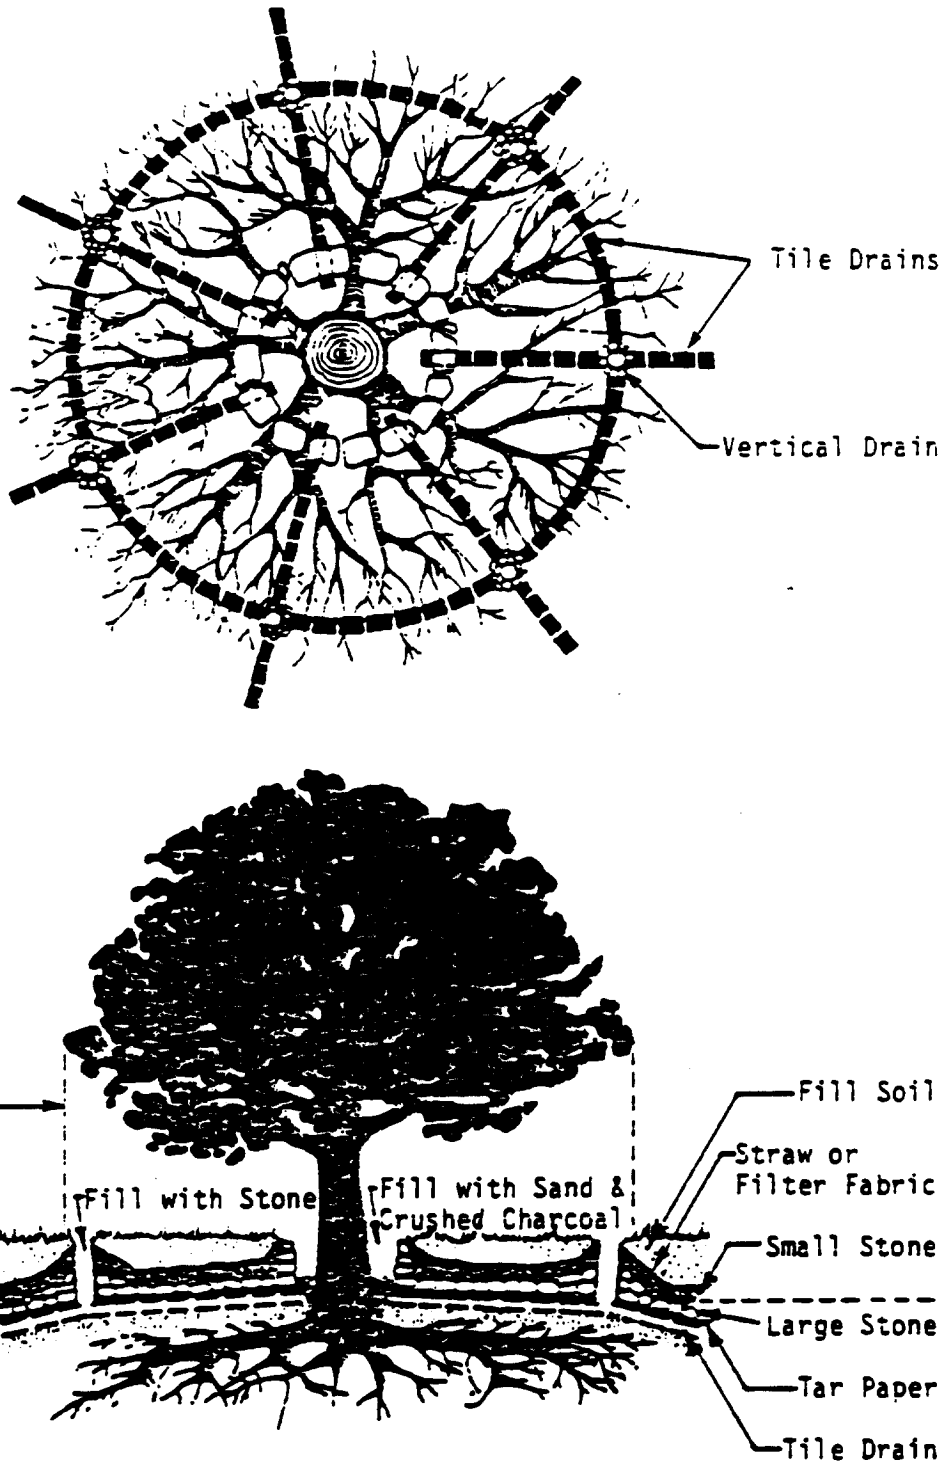


Plate 1.85c

(4) the well should be high enough to bring the top above the level of the proposed fill. The well wall shall taper slightly away from the tree trunk at a rate of 1 inch per foot of wall height.

(5) The well wall shall be constructed of large stones, brick, building tile, concrete blocks or cinder blocks with care being taken to insure that ample openings are left through the wall of the well to allow for free movement of air and water. Mortar shall only be used near the top of the well and only above the porous fill.

(6) Drain lines composed of 4-inch high quality drain tiles shall begin at the lowest point inside the well and extend outward from the tree trunk in a wheel-and-spoke pattern with the trunk as the hub. These radial drain lines shall slope away from the well at a rate of 1/8 inch per foot. The circumferential line to tiles should be located beneath the drip line of the tree. Vertical tiles or pipes shall be placed over the intersections of the two tile systems if fill of more than 2 feet is contemplated. These vertical tiles shall be held in place with stone fill. Tile joints shall be tight. A few radial tiles shall extend beyond each intersection and shall slope sharply downward to insure good drainage.

TREE TYPE	SPECIAL CONDITIONS	APPLICATION RATE & METHOD		FORMULATION
Broad-Leaf Deciduous	Greater than 6 inches dbh* except American Beeches and Crabapples	Normal	2-4 lbs. per in. dbh; Broadcast	Commercial 10-8-6 or 10-6-4
		Grade Change	4-5 lbs. per in. dbh; Broadcast	Commercial 10-6-4
	Smaller than 6 inches dbh including all American Beeches and Crabapple	Normal	1-2 lbs. per in. dbh; Broadcast	Commercial 10-8-6 or 10-6-4
		Grade Change	2-3 lbs. per in. dbh; Broadcast	Commercial 10-6-4
Narrow-Leaf Evergreen	Greater than 6 inches dbh located in groups		2-4 lbs. per 100 sq.ft. of bed area; Broadcast	Commercial 10-6-4
	Greater than 6 inches dbh, single specimens in open areas		2 lbs. per in. dbh; Broadcast	Commercial 10-6-4
	Smaller than 6 inches dbh		5 lbs. per 100 sq.ft. of bed area; Incorporated into soil	Tankage or Cotton-seed Meal
Broad-Leaf Evergreen	Where nitrogen in soil is sufficient		Liberal quantities incor-porated into soil and applied as mulch	Acid Peat Moss or Rotted Oak Leaf Mold
	Where additional nitrogen is necessary		Also add 5 lbs. per 100 sq.ft. of bed area incor-porated into soil	Tankage or Cotton-seed Meal

*dbh: Diameter at breast height (4.5 feet above ground level)

Source: Information taken from Tree Maintenance, P. P. Pirone, 1978.

R0071583

(7) Tar paper or its approved equivalent shall be placed over the tile and/or pipe joints to prevent clogging, and large stones shall be placed around and over drain tiles and/or pipes for protection.

(8) A layer of 2 to 6 inches of stone shall be placed over the entire area under the tree from the well outward at least as far as the drip line. For fills up to 2 feet deep, a layer of stone 8 to 12 inches thick should be adequate. A thicker layer of this stone, not to exceed 30 inches, will be needed for deeper fills.

(9) A layer of 3/4-inch to 1-inch stone covered by straw, fiberglass mat or a manufactured filter fabric shall be used to prevent soil from clogging the space between stones. Cinders shall not be used as fill material.

(10) Filling shall be completed with porous soil such as topsoil until the desired grade is reached. This soil shall be suitable to sustain specified vegetation.

(11) To prevent clogging of the drain lines, crushed stone shall be placed inside the dry well over the openings of the radial tiles. Vertical tiles shall also be filled with crushed rock and may also be covered with a screen.

(12) To prevent anyone from falling into the dry well, and leaves and debris from accumulating there, the area between the trunk and the well wall shall either be covered by an iron grate or filled with a 50-50 mixture of crushed charcoal and sand. (This will also prevent rodent infestation and mosquito breeding.)

c. Where water drainage through the soil is not a problem, coarse gravel in the fill may be substituted for the tile. This material has sufficient porosity to ensure air drainage. Instead of the vertical tiles or pipes in the system, stones, crushed rock and gravel may be added so that the upper level of these porous materials slants toward the surface in the vicinity below the drip line (Plate 1.85e).

d. Raising the grade on only one side of a tree or group of trees may be accomplished by constructing only half of one of these systems.

10. Lowering the Grade: Trees shall be protected from harmful cuts by the construction of a tree wall (Plate 1.85f).

a. Following excavation, all tree roots that are exposed and/or damaged shall be trimmed cleanly, painted with tree paint, and covered with moist peat moss, burlap or other suitable material to keep them from drying out.

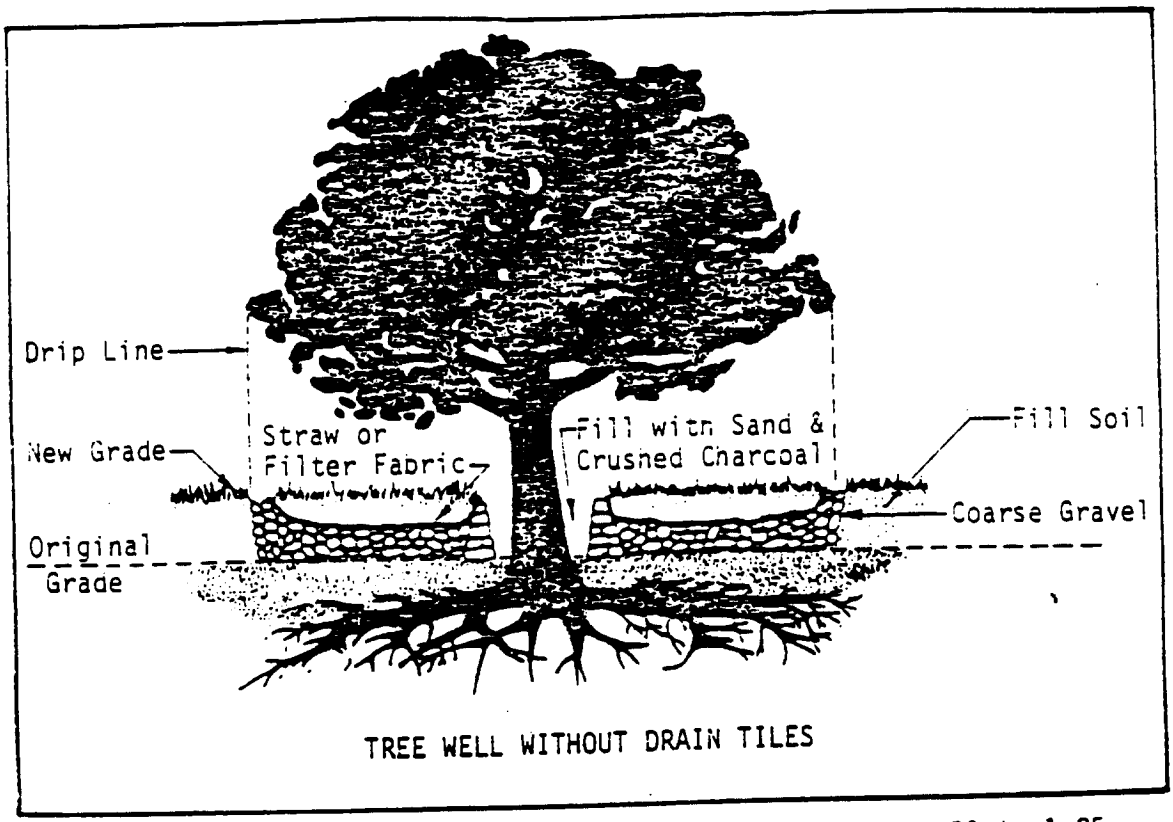

Plate 1.85e

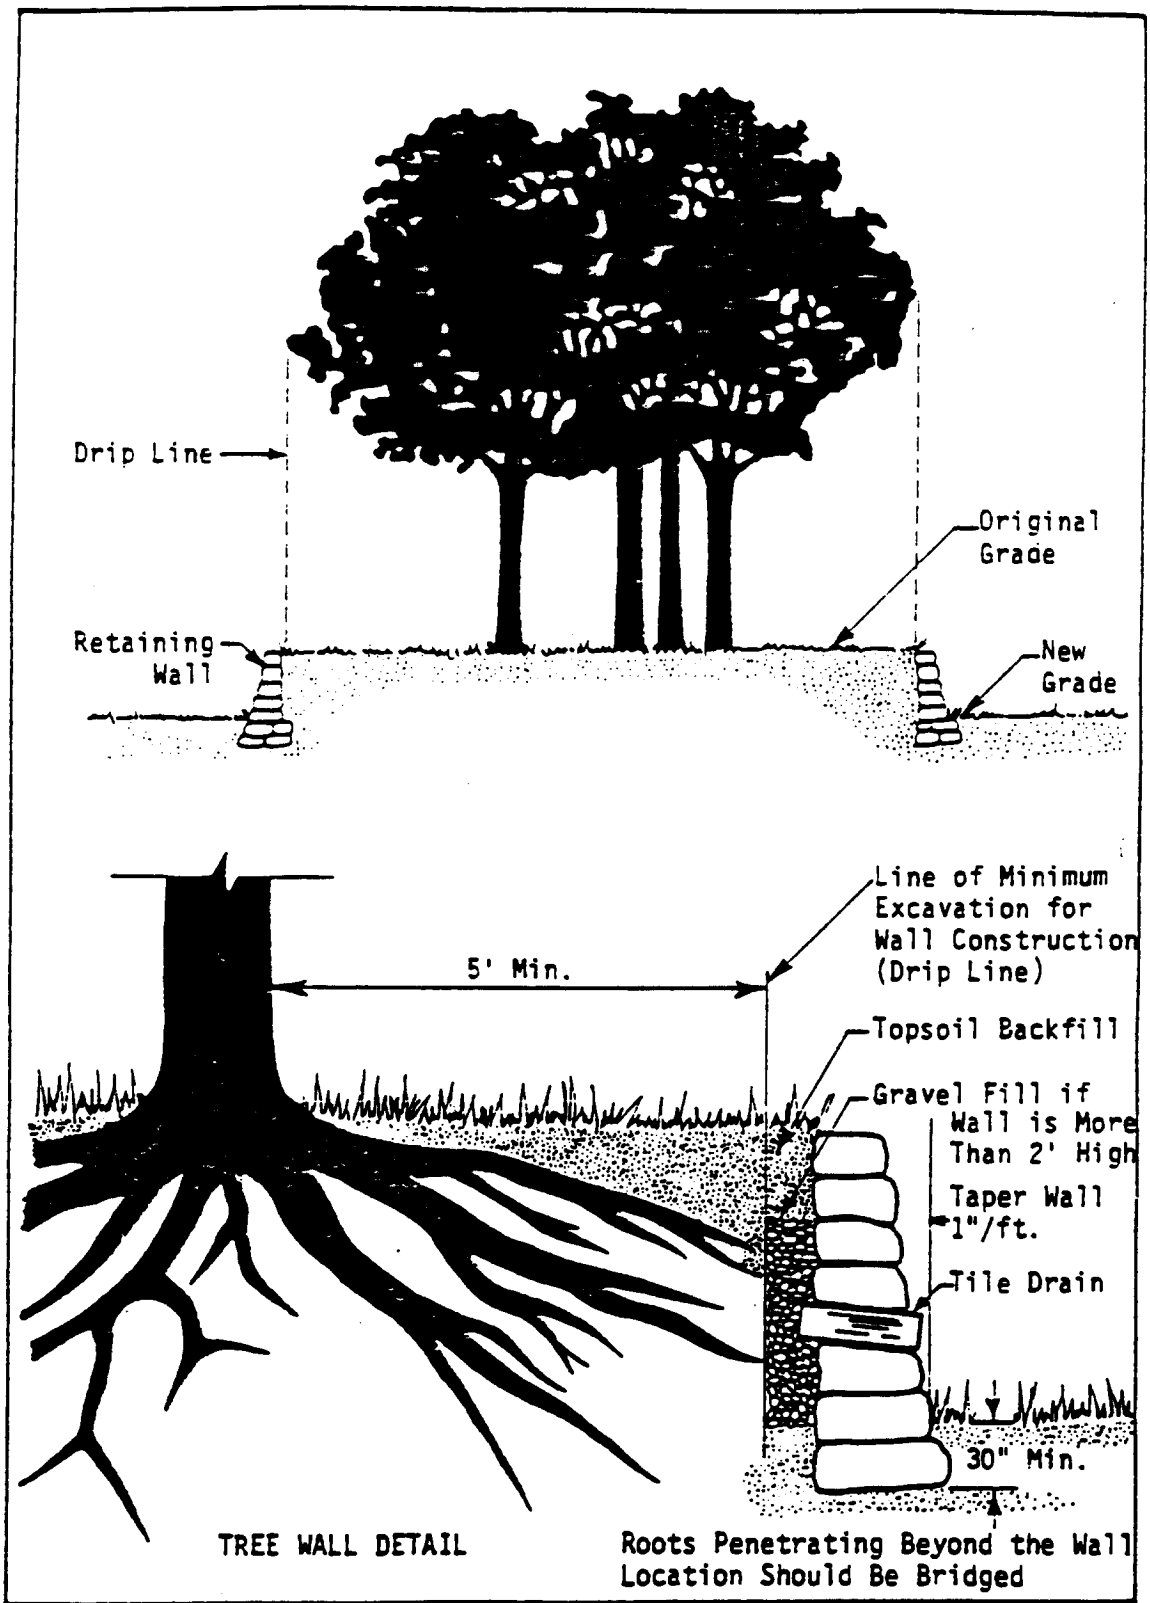
Source: Va SWCC

b. The wall shall be constructed of large stones, brick, building tile, or concrete block or cinder block in accordance with the detail in Plate 1.85f.

c. Backfill with peat moss or other organic material or with topsoil to retain moisture and aid in root development.

d. Apply fertilizer and water thoroughly. Fertilizer formulations and application rates and methods shall conform to the guidelines provided in Table 1.85a.

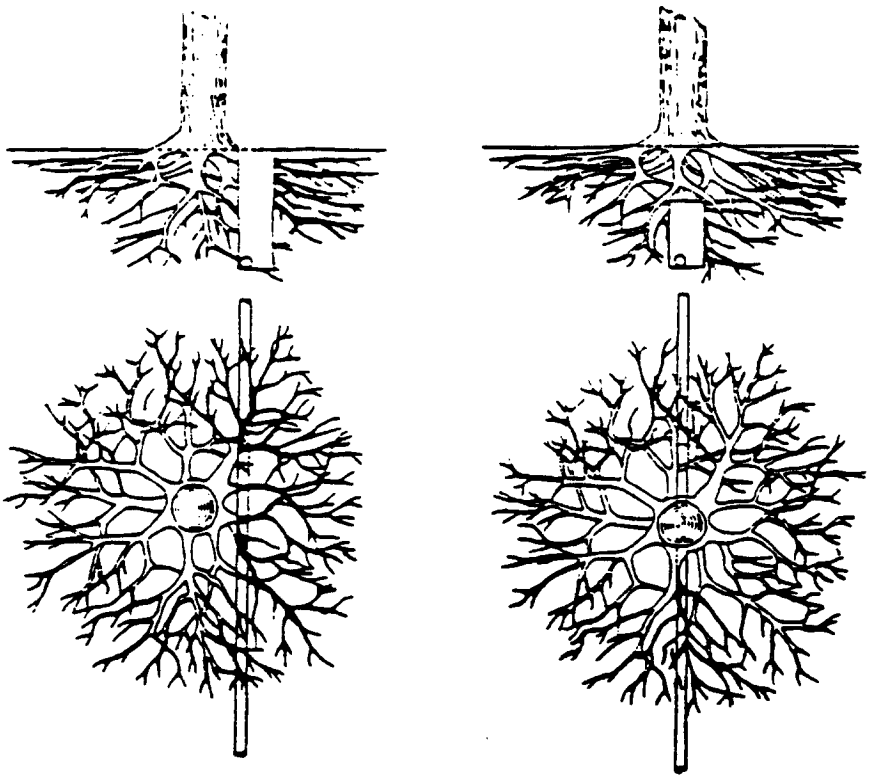
e. Prune the tree crown, reducing the leaf surface in proportion to the amount of the root loss.



f. Provide drainage through the wall so water will not accumulate behind the wall.

g. Lowering the grade on only one side of a tree or group of trees may be accomplished by constructing only half of this system.

11. <u>Trenching and Tunnelling</u>:



a. Trenching shall be done as far away from the trunks of trees as possible, preferably outside the branches or crown spreads of trees, to reduce the amount of root area damaged, or killed by trenching activities.

R0071585

Source: Adapted from Public Facilities Manual, Vol. III, Plate 1.85f Fairfax County, Va., 1976, and Trees for Architecture and the Landscape, Zion, 1968

R0071586

Destruction of Feeder Roots
Will Probably Kill the Tree

Tunneling Under the Tree Will
Preserve Important Feeder Roots

TRENCHING vs TUNNELING

Source: Tree Maintenance, Pirone, 1979 Plate 1.85g

b. Wherever possible, trenches should avoid large roots or root concentrations. This can be accomplished by curving the trench or by tunnelling under large roots and areas of heavy root concentration.

c. Tunnelling under an individual specimen that does not have a large taproot may be preferable to trenching beside it. Tunnelling is more expensive initially, but it usually causes less soil dis- turbance and physiological impact on the root system (Plate 1.85g). The extra cost may offset the potential costs of tree removal and replacement should the tree die.

d. Roots shall not be left exposed to the air. They shall be covered with soil as soon as possible or protected and kept moistened with wet burlap or peat moss until the trench or tunnel can be filled.

R0071587

e. The ends of damaged and cut roots shall be cut off smoothly and protected by painting promptly with a tree wound dressing.

f. Trenches and tunnels shall be filled as soon as possible. Air spaces in the soil shall be avoided by careful filling and tamping.

g. Peat moss or other suitable material shall be added to the fill material as an aid to inducing and developing new root growth.

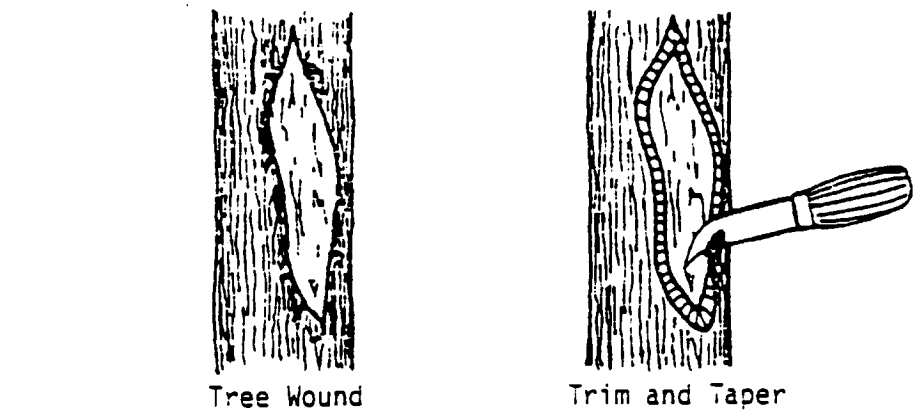
h. The tree shall be mulched and fertilized to conserve moisture, stimulate new root growth and enhance general tree vigor.

i. If a large amount of the root system has been damaged and killed, the crown leaf surface shall be proportionately reduced to balance the reduced root system. This may be accomplished by pruning 20 to 30 percent of the crown foliage. If roots are cut during the winter, pruning shall be accomplished before the next growing season. If roots are cut during the growing season, pruning shall be done immediately.

12. Removal and Replacement of Damaged Trees: Should a tree intended and marked to be retained be damaged seriously enough that survival and normal growth are not possible, the tree shall be removed. If replacement is desirable and/or required, the replacement tree shall be of the same or similar species, 2-inch to 2 1/2-inch caliper balled and burlapped nursery stock.

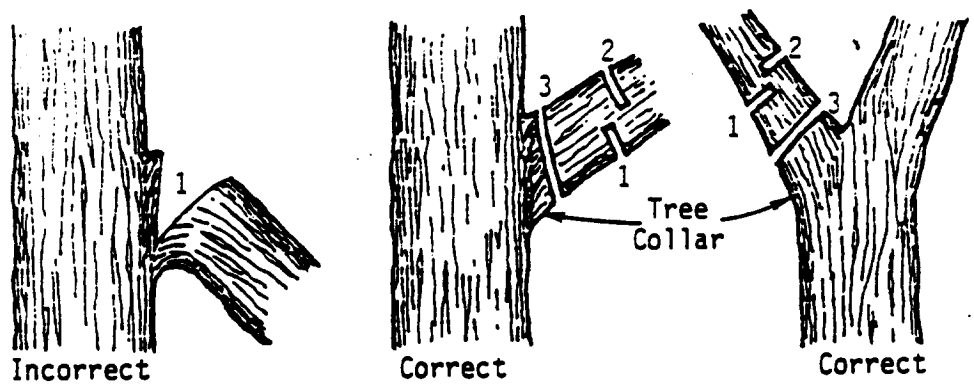
13. Cleanup: Cleanup after a construction project can be a critical time for tree damage. Trees protected throughout the development operation are often destroyed by carelessness during the final cleanup and landscaping. Fences and barriers shall be removed last, after everything else is cleaned up and carried away.

14. Maintenance: In spite of precautions, some damage to protected trees may occur. In such cases, the following maintenance guidelines should be followed.



a. Soil Aeration - If the soil has become compacted over the root zone of any tree, the ground ball shall be aerated by punching holes with an iron bar. The bar shall be driven 1-foot deep and then moved back and forth until the soil is loosened. This procedure shall be repeated every 18 inches until all of the compacted soil beneath the crown of the tree has been loosened.

b. Repair of Damage



(1) Any damage to the crown, trunk or root system of any tree retained on the site shall be repaired immediately.

(2) Whenever major root damage or bark damage occurs, remove some foliage to reduce the demand for water and nutrients.

R0071588

TREATING BARK WOUNDS

PRUNING DAMAGED BRANCHES

Source: Public Facilities Manual, Vol. III
Fairfax County, Virginia 1976

Plate 1.85h

(3) Damaged roots shall immediately be cut off cleanly inside the exposed or damaged area. Cut surfaces shall be painted with approved tree paint, and moist peat moss, burlap or topsoil shall be spread over the exposed area.

(4) To treat bark damage, carefully cut away all loosened bark back into the undamaged area, taper the cut at the top and bottom and provide drainage at the base of the wound (Plate 1.85h).

(5) All tree limbs damaged during construction or removed for any reason shall be cut off above the collar at the preceding branch junction (Plate 1.85h).

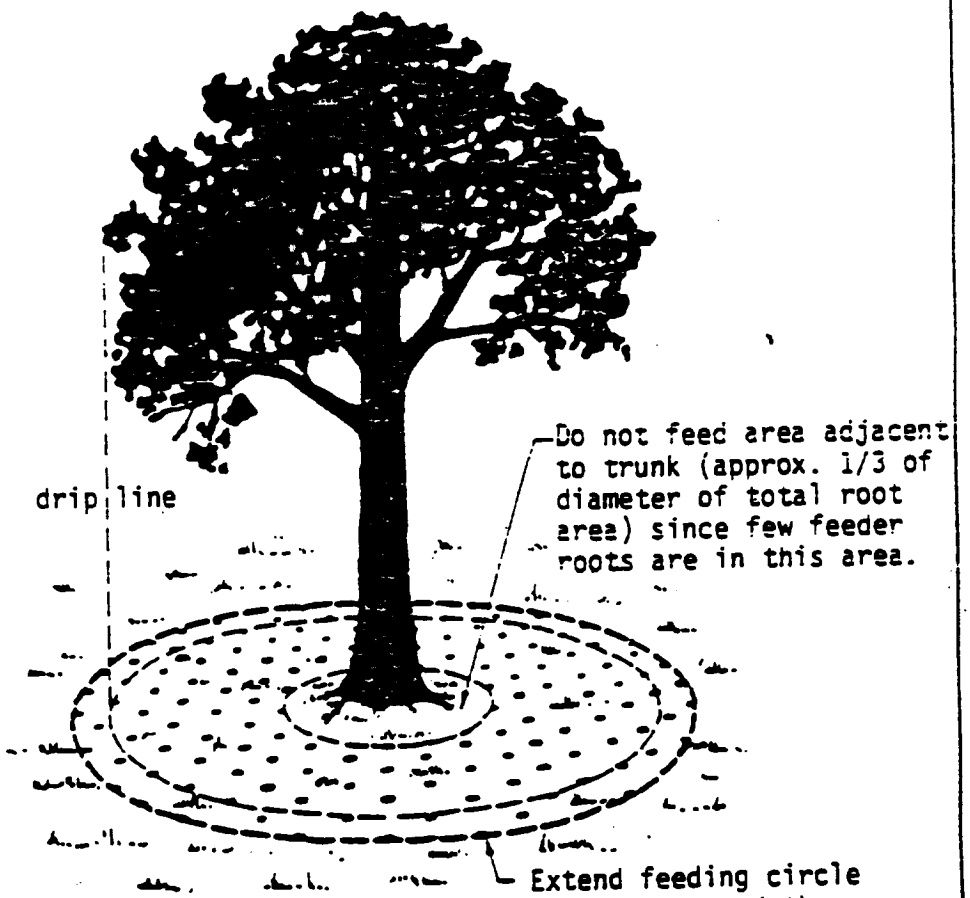
(6) Care for serious injuries shall be prescribed by a forester or a tree specialist.

c. Fertilization: Broadleaf trees that have been stressed or damaged shall receive a heavy application of fertilizer to aid their recovery.

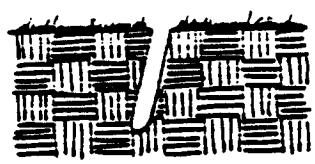
(1) Trees shall be fertilized in the late fall (after October 1) or the early spring (from the time frost is out of the ground until May 1). Fall applications are preferred, as the nutrients will be made available over a longer period of time.

(2) Fertilizer shall be applied to the soil over the feeder roots. (See Plate 1.85i). In no case should it be applied closer than 3 feet to the trunk.

The root system of conifers extends some distance beyond the drip line. Increase the area to be fertilized by 1/4 the area of the crown.



(3) Fertilizer shall be applied using approved fertilization methods and equipment.



(4) Formulations and application rates shall conform to the guidelines given in Table 1.85a.

Maintain a ground cover or organic mulch layer around trees that is adequate to prevent erosion, protect roots, and hold water.

R0071590

TREE FERTILIZATION

Holes should be approximately 18" deep and 2' apart, and they should slant toward the trunk.

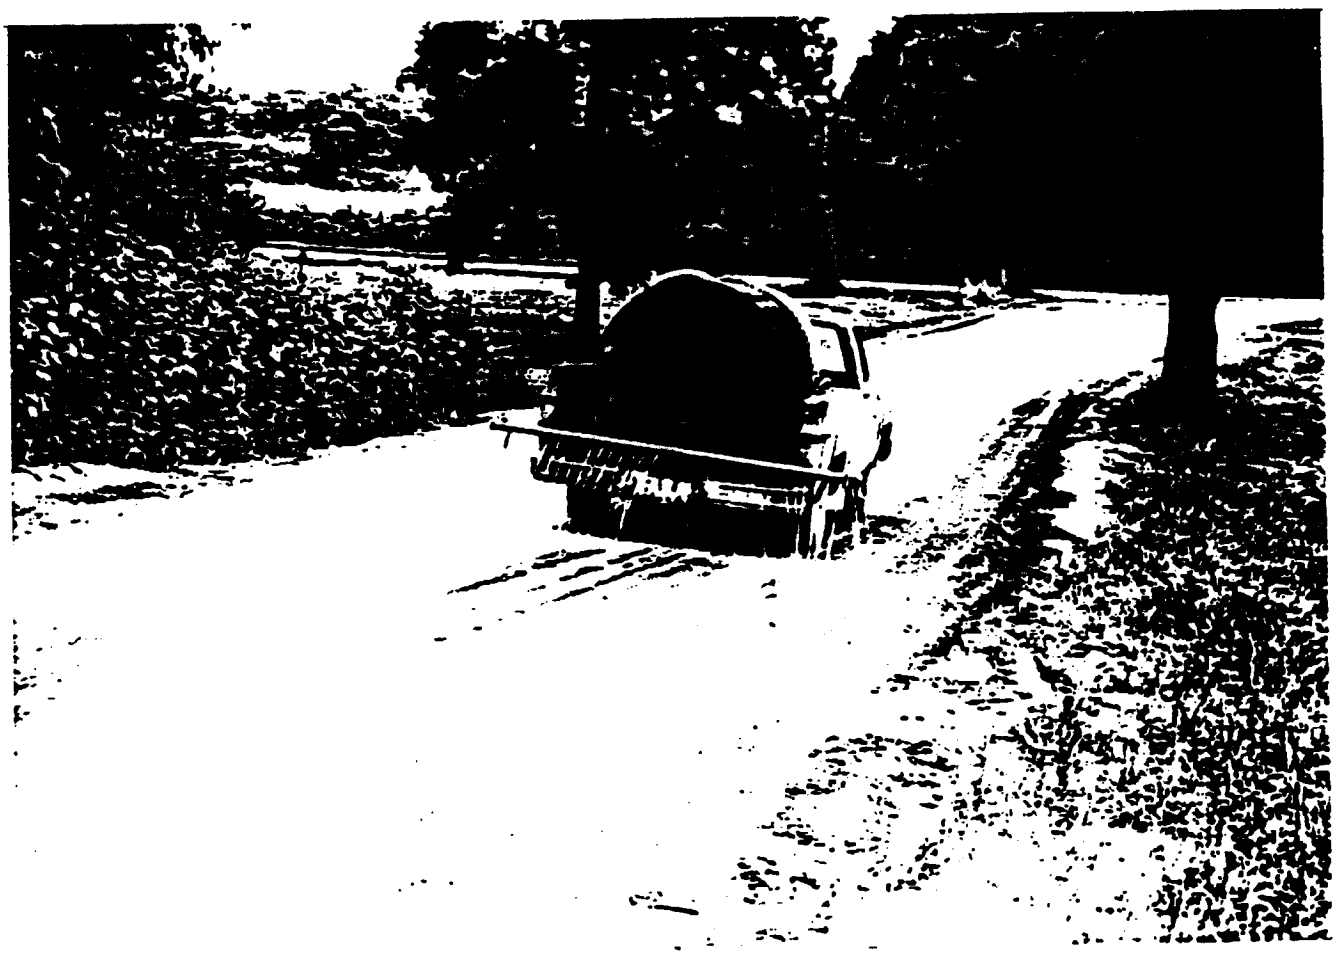
ES BMP 1.86

DUST CONTROL

Definition



Reducing surface and air movement of dust during land disturbing, demolition and construction activities.

Purpose

To prevent surface and air movement of dust from exposed soil surfaces and reduce the presence of airborne substances which may be harmful or injurious to human health, welfare, or safety, or to animal or plant life.

Conditions Where Practice Applies

In areas subject to surface and air movement of dust where on-site and off-site damage is likely to occur if preventive measures are not taken.

R0071592

Planning Considerations

Construction activities inevitably result in the exposure and disturbance of soil. Fugitive dust is emitted both during the activities (i.e., excavation, demolition, vehicle traffic, human activity) and as a result of wind erosion over the exposed earth surfaces. Large quantities of dust are typically generated in "heavy" construction activities, such as road and street construction and subdivision, commercial and industrial development, which involve disturbance of significant areas of soil surface. Research at construction sites has established an average dust emission rate of 1.2 tons/acre/month for active construction. Earth-moving activities comprise the major source of construction dust emissions, but traffic and general disturbance of the soil also generate significant dust emissions.

In planning for dust control, it should be obvious that the less soil is exposed at any one time, the less potential there will be for dust generation. Therefore, phasing a project and utilizing temporary stabilization practices upon the completion of grading can significantly reduce dust emissions.

Temporary Measures

1. Mulches - See MULCHING, ES BMP 1.75. Synthethic resins may be used instead of asphalt to bind mulch material. Resins such as Curasol or Terratack should be used according to manfacturer's recommendations.

2. Vegetative Cover - See TEMPORARY SEEDING, ES BMP 1.65.

3. Spray-on Adhesives - (Table 1.86a) - These are used on mineral soils (not effective on muck soils). Keep traffic off these areas.

Table 1.86a

SPRAY-ON ADHESIVE SPECIFICATIONS

Adhesive	Water Dilution	Type of Nozzle	Application Rate (Gallons/Ac.
Anionic Asphalt emulsion	7:1	Coarse Spray	1,200
Latex emulsion	12-1/2:1	Fine Spray	235
Resin-in-water emulsion	4:1	Fine Spray	300

4. Tillage - This practice is designed to roughen and bring clods to the surface. It is an emergency measure which should be used before wind erosion starts. Begin plowing on windward side of site. Chisel-type plows (with 12-inch spacings), spring-toothed harrows, and similar plows are examples of equipment which may produce the desired effect.

5. Irrigation - This is generally done as an emergency treatment. Site is sprinkled with water until the surface is wet. Repeat as needed.

To prevent carryout of mud onto streets, refer to TEMPORARY GRAVEL CONSTRUCTION ENTRANCE, ES BMP 1.01.

6. Barriers - Solid board fences, burlap fences, crate walls, bales of hay and similar material can be used to control air currents and soil blowing. Barriers placed at right angles to prevailing currents at intervals of about 15 times the barrier heignt are effective in controlling wind erosion.

7. Calcium Chloride - Apply at rate that will keep surface moist. May need retreatment.

Permanent Methods

8. Permanent Vegetation - See standards for permanent seeding, and permanent stabilization with sod. Existing trees and large shrubs may afford valuable protection if left in place.

9. Topsoiling - This entails covering the surface with less erosive soil material. See TOPSOILING, ES BMP 1.61.

10. Stone - Cover surface with crushed stone or coarse gravel.

APPENDIX 6-1

Example Design of a Multi-Purpose
Detention/Filtration Facility

R0071595

Multiple Purpose Detention/Filtration Facilities for Water Quantity and Water Quality Management

Introduction:

Engineers and other designers of stormwater maangement systems may often be confronted with developing installations for purposes which require different design strategies. In Florida this often involves satisfying the provisions of local or regional flood control ordinances, as well as statewide stormwater pollution control regulations. The design criteria for these purposes depends upon the level of flood protection desired by the community and the amount of pollutant removal mandated to protect water quality.

Usually, a locality will specify that stormwater runoff from a developing drainage area must be stored and released so that the post-development peak runoff rate does not exceed the predevelopment rate for a specific design storm. The detained water is discharged without any additional treatment. The release time normally varies between a few hours to no more than one day. In some localities a 10-year design storm is specified to protect downstream drainage structures. Other localities require protection from larger storms and specify that a 50-year or 100-year storm must be detained and released at a reduced rate. There are even criteria in existence which require that the peak rate of runoff from all storms must not be increased by development.

The primary design strategy for pollution control purposes is associated with the capture of the first portion of runoff (i.e., the initial 1/2 inch of runoff or the runoff from the first inch of rainfall). This water and equivalent amounts from larger storms are either percolated through the soil or filtered through suitable material and released to surface waters. In this manner pollutant removal is increased over conventional detention facilities.

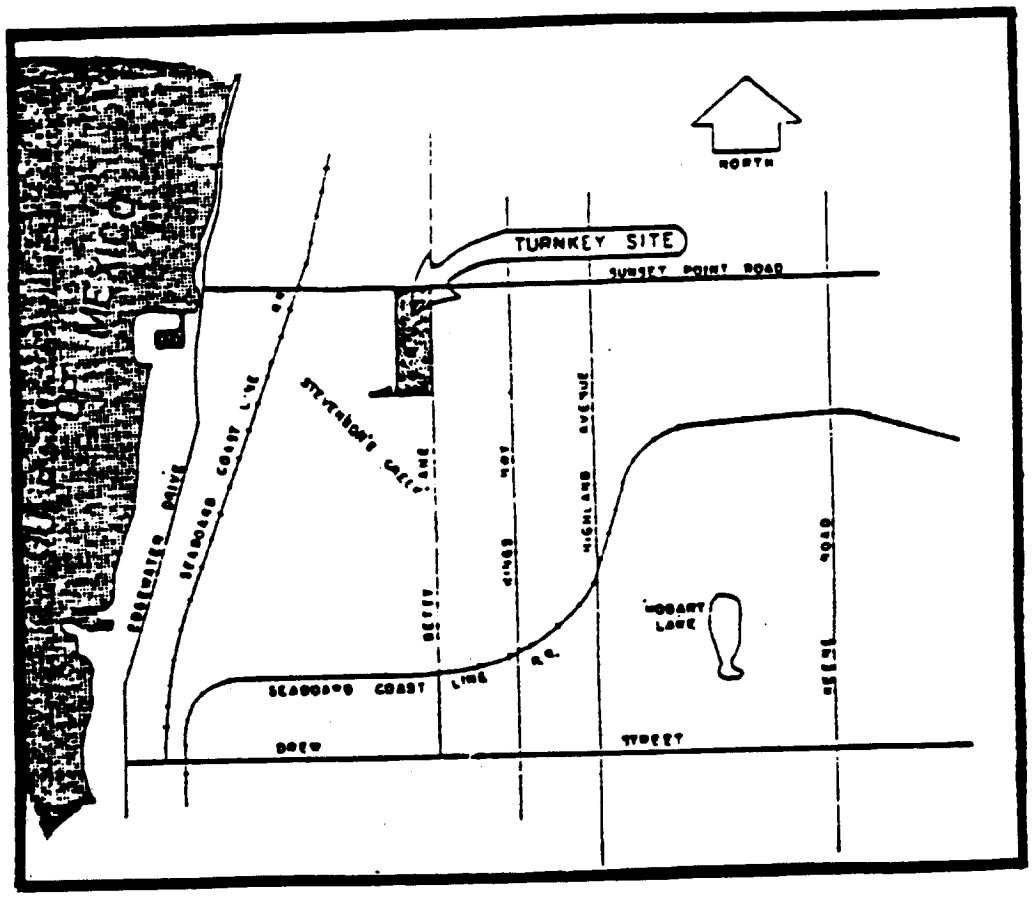
To maximize the cost benefit of an impoundment, multiple-purpose design strategies should be explored. By incorporating different treatment mechanisms at various stages (storage elevations), a number of desired purposes may be achieved within the same installation.

For example, an impoundment can be designed with an outlet structure such that the first stage will capture an initial volume of runoff (i.e., 0.5 inch). Subsequently, this water may be slowly released through a subsurface drain or filtration system. Preliminary studies conducted at the University of Central Florida indicate that 80 to 90 percent of the annual average pollutant load should be removed. The second stage begins with a weir or other type orifice which has the capacity to pass stormwater at a pre-development rate when the water elevation reaches the crest of the structure. Such facilities are usually designed to limit the discharge expected from rainfall events of up to and including the 10-year or 25-year storm thus providing for flood control downstream.

In practice, the location, size, and shape of stormwater storage areas and, consequently; the configuration (layout), depth, and length of the underdrain

or filter system is often determined by site conditions or the desires of the developer. Moreover, many engineers prefer to use what is referred to as trial and error type design procedures. In both instances, many of the physical dimensions of the facility are predetermined and the task of the designer involves doing an assessment of various factors to determine if the structure satisfies both flood control and stormwater quality regulations.

The following example illustrates a series of steps which outline how such a facility may be designed, and checked for compliance with local and statewide regulations. In this instance the project represents an actual plan submitted to the department. The site may be considered typical of many low lying, flat, relatively poorly drained areas which are very common, particularly in the coastal regions of Florida. The soil may be described as sandy, but percolation and drainage is restricted due to a fine textured subsoil layer about 6 feet below the surface. The topography is relatively flat. At the time of application the watershed area was classed as unimproved or open land, but was wooded. The developer planned to convert 4.5 acres to an apartment complex.



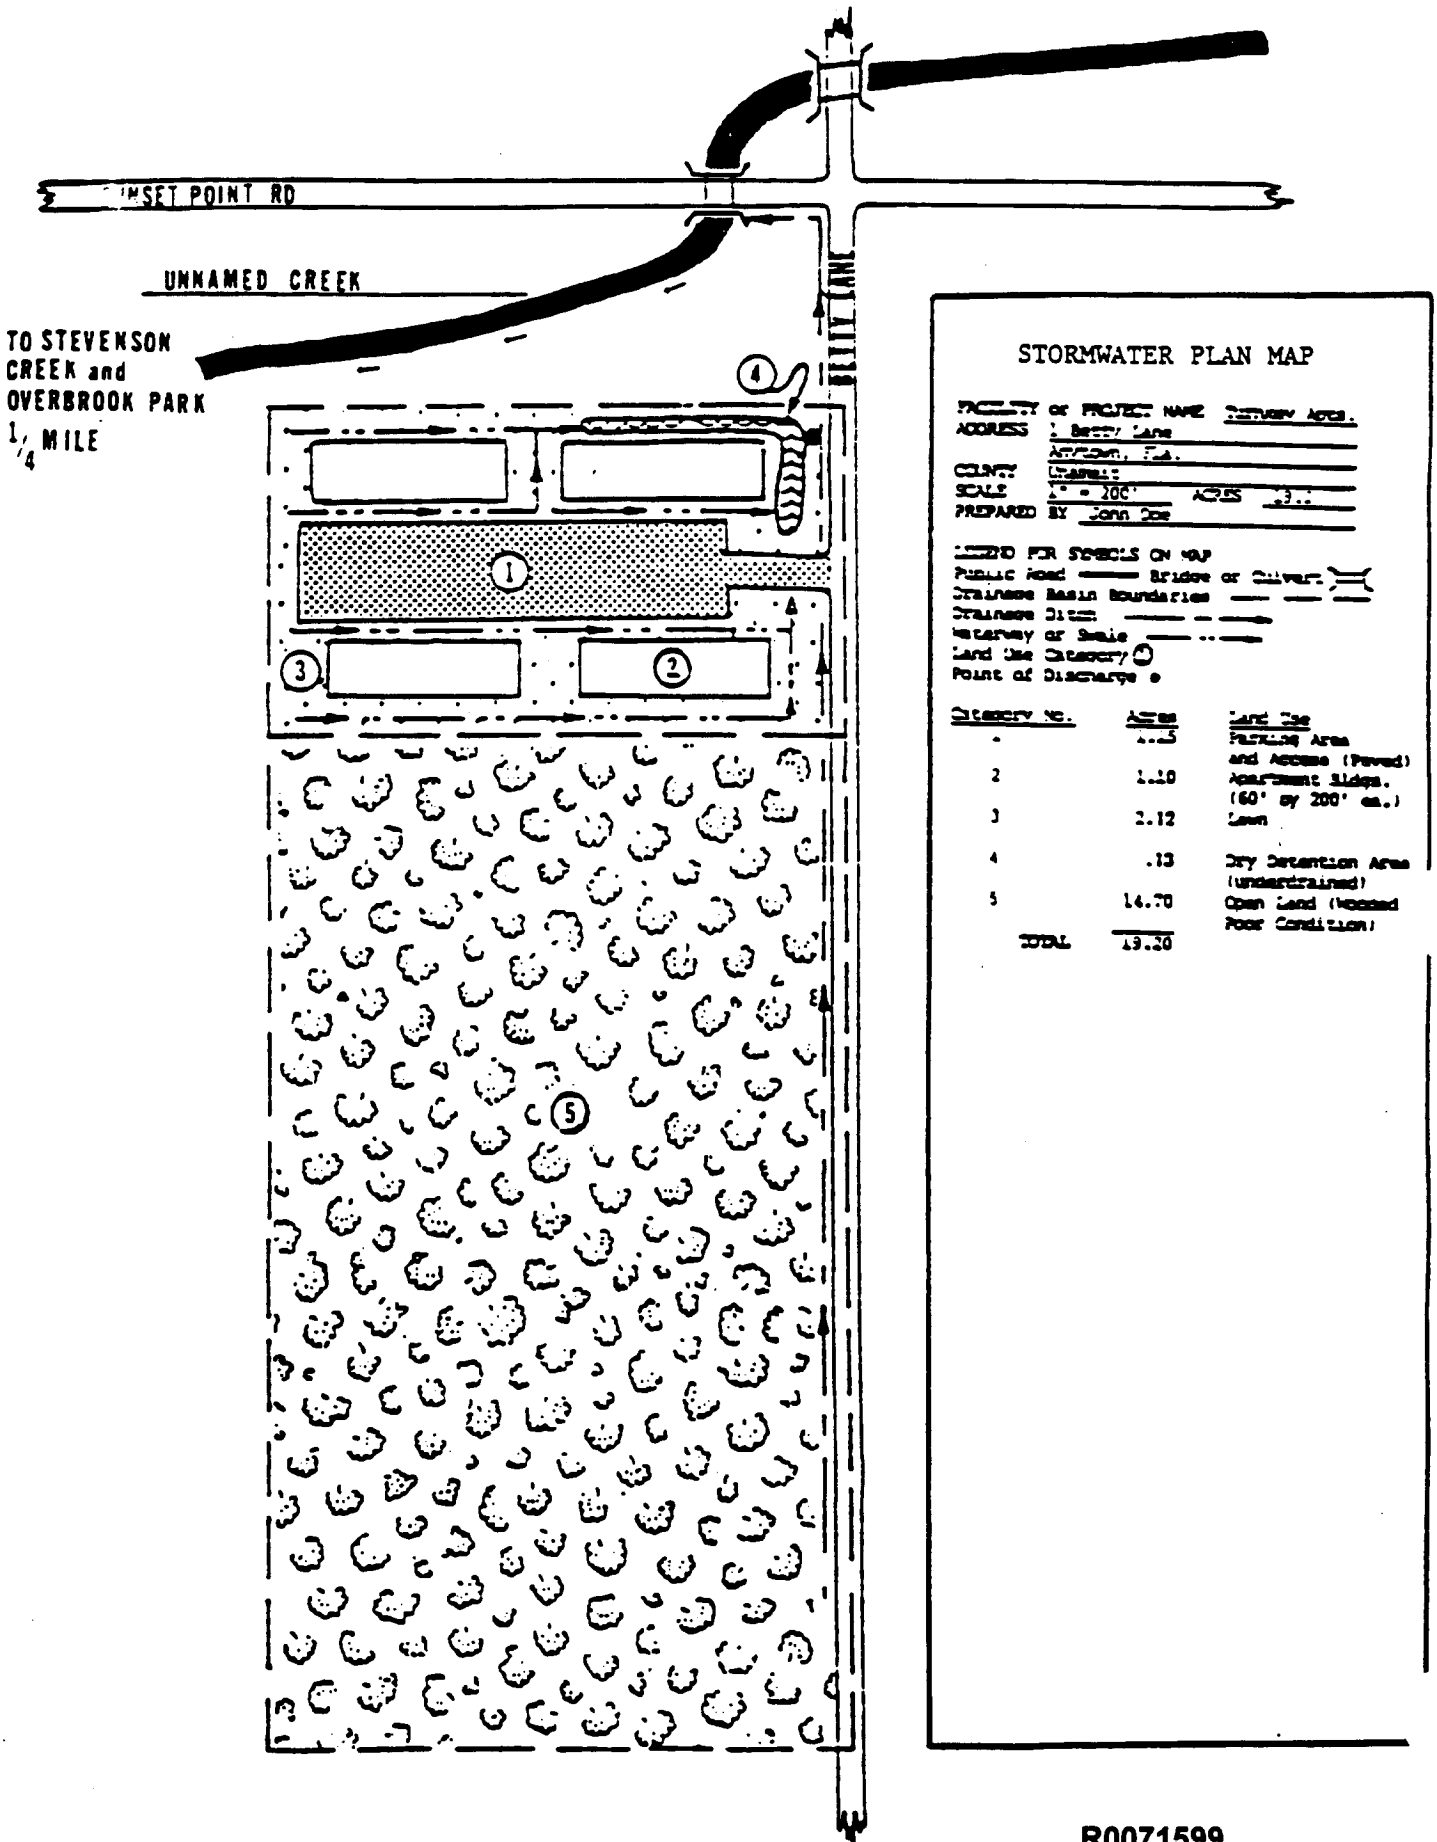
Local regulations mandated that the 25 year return frequency storm be used for design purposes to control off site flooding. A detention pond was specified to regulate the increased stormwater discharge expected. The storage area was also planned to serve other purposes including water quality improvement and as open space or a green area for enhanced aesthetics. The facility was scheduled to be fully sodded and provided with underdrain for treatment of the first one-half inch of stormwater runoff to satisfy state water quality concerns. The physical dimensions of the facilities, the drainage area size, the points of discharge into waters of the state, and the hydraulic computations are noted below and are illustrated in Figure 1 and 2. In this example the designer first calculated offsite drainage in order to determine the stage in the receiving stream. Such information is important to insure that the function of the facility will not be affected by water level elevations at the outlet of the structure.

Example Design Procedure for Multiple Purpose Underdrain/Dry Dentention Filtration Facility:

I. Estimate Water Level Elevation in Receiving Stream for the Appropriate Design Storm

Determine the flow or rate of discharge expected:

A. As noted earlier, the degree of flood protection mandated by various municipalities and/or water management districts may vary quite widely. However, it is not uncommon to find a requirement which specifies that the stormwater management system must detain the excess flow from a storm of such magnitude that it would be expected (based on statistical analysis of rainfall data) to occur on an average of once in twenty-five years. It is usually assumed that the flood stage estimated from this hypothetical storm will occur with a similar degree of frequency.



VICINITY MAP

Figure 1

R0071598

Figure 2

R0071599

In reality, the highest stage in any particular body of water which can be expected on an average of once in 25 year, is not likely to be equal to that calculated based on the flow projected from a design storm with the same reoccurance interval or return frequency. Therefore, flood flow or discharge should be determined from a frequency analysis of streamflow data if available.

Since discharge information is only collected at a limited number of locations an applicant is likely to find that flow records do not exist which can be extrapolated to a particular site. In this instance, discharges estimated using procedures developed by the Soil Conservation Service; the Rational Runoff Formula for smaller watersheds; and, other commonly accepted methods can be used to provide a reasonable estimate of peak discharge rates.

For this project it was appropriate for the engineer to choose to calculate off-site peak runoff to the receiving stream (drainage ditch) using the Rational Formula due to the small size of the watershed.

The Rational Formula is written as follows:

[Q = CIA]

where; Q = flow in cfs.

C = the rational runoff coeficient (usually selected at the discretion of the designer. Values for various land use classes are listed in Table - 1)

I = average rainfall intensity in inches/hour for the appropriate design storm (i.e., 25 yr. return frequency in this case). The maximum peak producing rainfall event is assumed to be equivalent to a storm with a duration equal to the time of concentration (TC) when using the Rational Method.

A = watershed area in acres.

Working through the various factors in the equation for this example;
Off-site area (A) = 14.7 acres (1061 ft. X 603 ft. see Figure 2)
(C) = 0.25 (Open Land "Unimproved", Table 1)

However, the (Tc) or time of concentration must be estimated prior to the selection of the appropriate value for the average rainfall intensity (I). In this example two types of flow conditions exist from the furthermost point in the watershed to the point of concern (i.e., the discharge point of the detention/underdrain facility). To compute the travel time or (Tc) for runoff water moving over this distance the designer must first calculate the time needed for overland flow across approximately 600 ft. Subsequently, the time of open channel flow through approximately 1400 ft. of drainage ditch to the point of concern must also be determined. The time required for runoff to negotiate both reaches will equal (Tc).

The travel time through each component is computed by dividing the length of flow by the average velocity. If the slope and land use of the overland flow segment are known, the average flow velocity can be read from a graph such as the one illustrated in Figure 3 provided through the Florida Department of Transportation (FDOT) Drainage Manual, Chapter 6.

R0071600

Table 1

Runoff Coefficients[a,b]

Description of Area	Runoff Coefficients	Character of Surface	Runoff Coefficients
Business		Pavement	
Downtown	0.70 to 0.95	Asphalt or concrete	0.70 to 0.95
Neighborhood	0.50 to 0.70	Brick	0.70 to 0.85
Residential		Roofs	0.70 to 0.95
Single Family	0.30 to 0.50	Lawns, Sandy Soil	
Multiunits, detached	0.40 to 0.60	Flat, 0-2%	0.05 to 0.10
Multiunits, attached	0.60 to 0.75	Average, 2-7%	0.10 to 0.15
Residential, suburban	0.25 to 0.40	Steep, 7% or more	0.15 to 0.20
Apartment	0.50 to 0.70	Lawns, Heavy Soil	
Industrial		Flat, 2%	0.13 to 0.17
Light	0.50 to 0.80	Average, 2-7%	0.18 to 0.22
Heavy	0.60 to 0.90	Steep, 7% or more	0.25 to 0.35
Parks, Cemeteries	0.10 to 0.25		
Railroad Yard	0.20 to 0.35		
Unimproved	0.10 to 0.30		

[a]The coefficients in these two tabulations are only applicable for storms to 5 to 10 year return frequencies and were originally developed when many streets were uncurbed and drainage was conveyed in roadside swales.

For recurrence intervals longer than 10 years, the indicated runoff coefficients should ' increased, assuming that nearly all of the rainfall in excess of that expected from the . year recurrence interval rainfall will become runoff and should be accommodated by an increased runoff coefficient.

The runoff coefficients indicated for different soil conditions reflect runoff behavior shortly after initial construction. With the passage of time, the runoff behavior of sandy soil areas will tend to approach that of heavy soil areas. If the designer's interest is long term, the reduced response indicated for sandy soil areas should be disregarded.

[b]From Design and Construction of Sanitary and Storm Sewers. ACSE Manual of Practice No. 37, 1970. Revised by D. Earl Jones, Jr.

Wanielista M.P. etal 1981
Reference: "Stormwater Management Manual"

R0071601

In this example, the slope was measured in the field. The average elevation changed about four (4) feet over the six hundred (600) foot flow distance.

$$\text{Average Slope (\%)} = \frac{4 \text{ ft}}{600 \text{ ft}} \times 100 = 0.67\%$$

The land use is noted in Figure 2. The area is wooded, but the stand is in poor condition. The project is surrounded by other urban areas and drainage has been improved. Therefore, the site is expected to have less capacity to store runoff than other more natural woodlands.

Using the average slope the designer may enter Figure 3 and find the correct gradient (i.e. .67%) along the bottom of the page. Moving vertically to the curve for the correct land use (i.e. wooded low storage), the average velocity may be read from the vertical scale or axis recorded along the left of the graph.

Average Velocity = 28 ft./min.

The travel time associated with the overland flow segment is equal to:

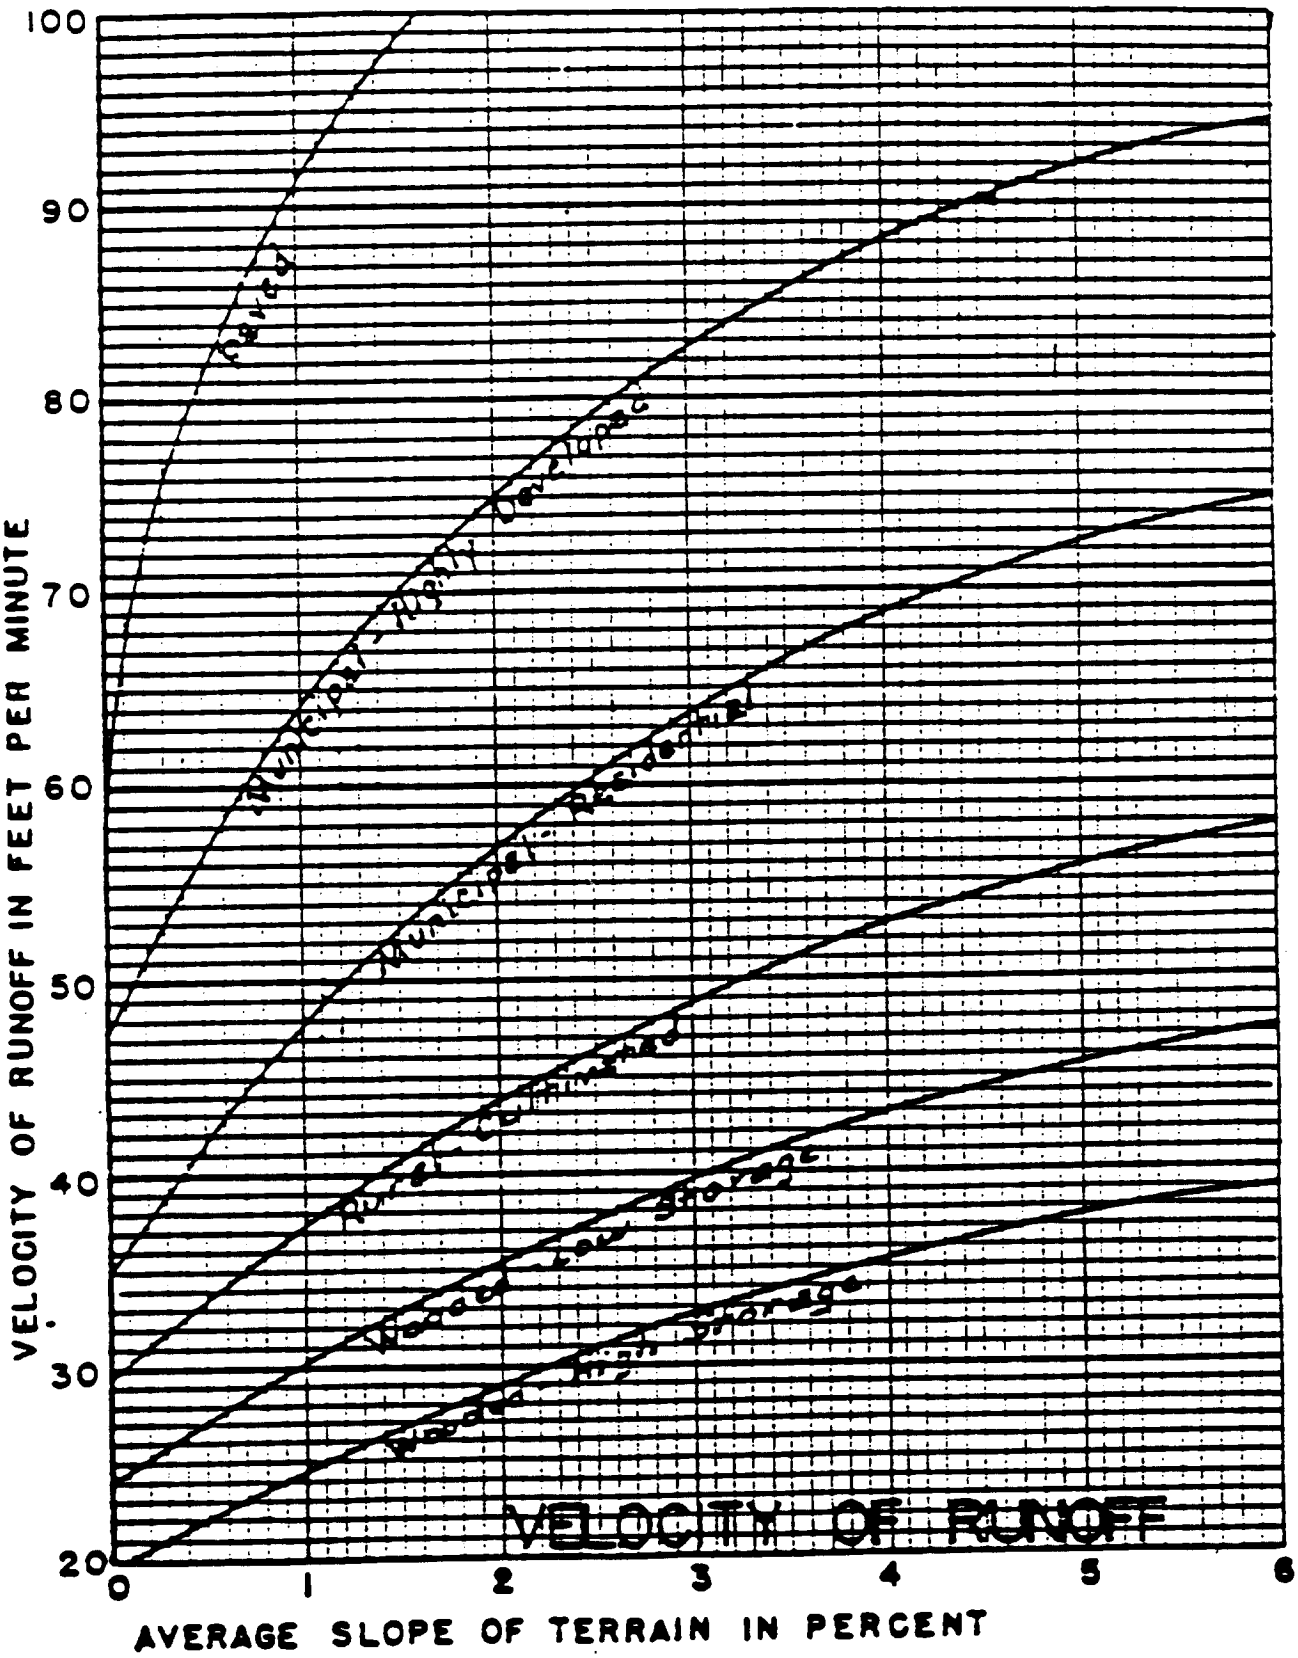
$$\frac{\text{Length of Travel (600 ft.)}}{\text{Average Velocity (28 ft/min)}}$$ therefore;

Travel Time (overland flow) = 21 min.

The next step is to estimate the time it will take for water flowing in the existing drainage ditch to reach the outlet.

The travel time for flow in the open channel can be determined by using Manning's equation.

$$V = \frac{1.49}{n} R^{2/3} S^{1/2}$$



where;

V = Velocity of flow (mean) in feet per second.
n = Coefficient of retardance used in flow formulas. In vegetation-lined channels this coefficient contains not only the effect of lining roughness but also the effect of irregularities in bed surface, channel shape, slope and alinement on the flow. The effect of blocking out a portion of the cross section by vegetation is also included.
R = Hydraulic radius in feet (i.e., the cross-sectional area divided by the wetted perimeter).
S = Slope of energy gradient in feet per foot. In vegetation-lined channels where the flow is considered to be uniform, the bed slope in feet per foot of length may be used. The use of vertical drop and slope length in computing S is satisfactory in most vegetated channels.

Table-2 as well as the "Guide for Selecting Roughness Coefficient "n" Values for Channels" compiled by Guy B. Gasken, Soil Conservation Service, USDA, Lincoln, Nebraska, 1963, and U.S. Geological Survey Water Supply Paper 1849, "Roughness Characteristics of Natural Channels" are useful guides in

R0071602

(8) Very weedy reaches	0.075	0.100	0.125	0.150

*Values commonly used in designing

R0071604

estimating "n" values of existing channels. However, as specified in the equation, information pertaining to channel dimensions and gradient is also needed. This data is normally determined from a field survey. The channel should be divided into reaches of equivalent width, depth, and slope. Constructing a cross sectional drawing illustrating the physical dimensions of each reach is useful to both the engineer and review agency personnel responsible for approving the project. In this example the channel is a constant size and shape throughout. A typical cross section is shown in Figure 4.

Typical of many roadside ditches the side slopes, at 1.1 feet horizontal to 1 foot verticle, are more steep than would normally be recommended for easy maintenance, safety, and/or erosion control (i.e. 3:1 or 4:1). The bottom elevation is 8.0 ft M.S.L. The width of the bottom is approximately 5 feet, and the main channel averages 3 feet deep. The field survey indicates the channel is trapezoidal shaped and rather poorly maintained. As would be expected, the sides and bottom are rough and heavily vegetated with weeds. The grade of the ditch is flat, averaging about .25 feet per 100 feet or .0025 ft/ft.

Based on this information and data from Table 2, a roughness coefficient or "n" value of at least .04 and possibly as high as .06 would be appropriate for the existing channel. use an average value "n" = .050. The slope (S) = .0025 ft/ft was specified earlier. The hydraulic radius (R) for a trapezoidal cross section may be determined by dividing the area of the channel by the wetted perimeter. In this instance (R) was calculated to equal 1.8.

We may now compute the open channel flow travel time. Use Mannings equation to calculate bank full velocity.

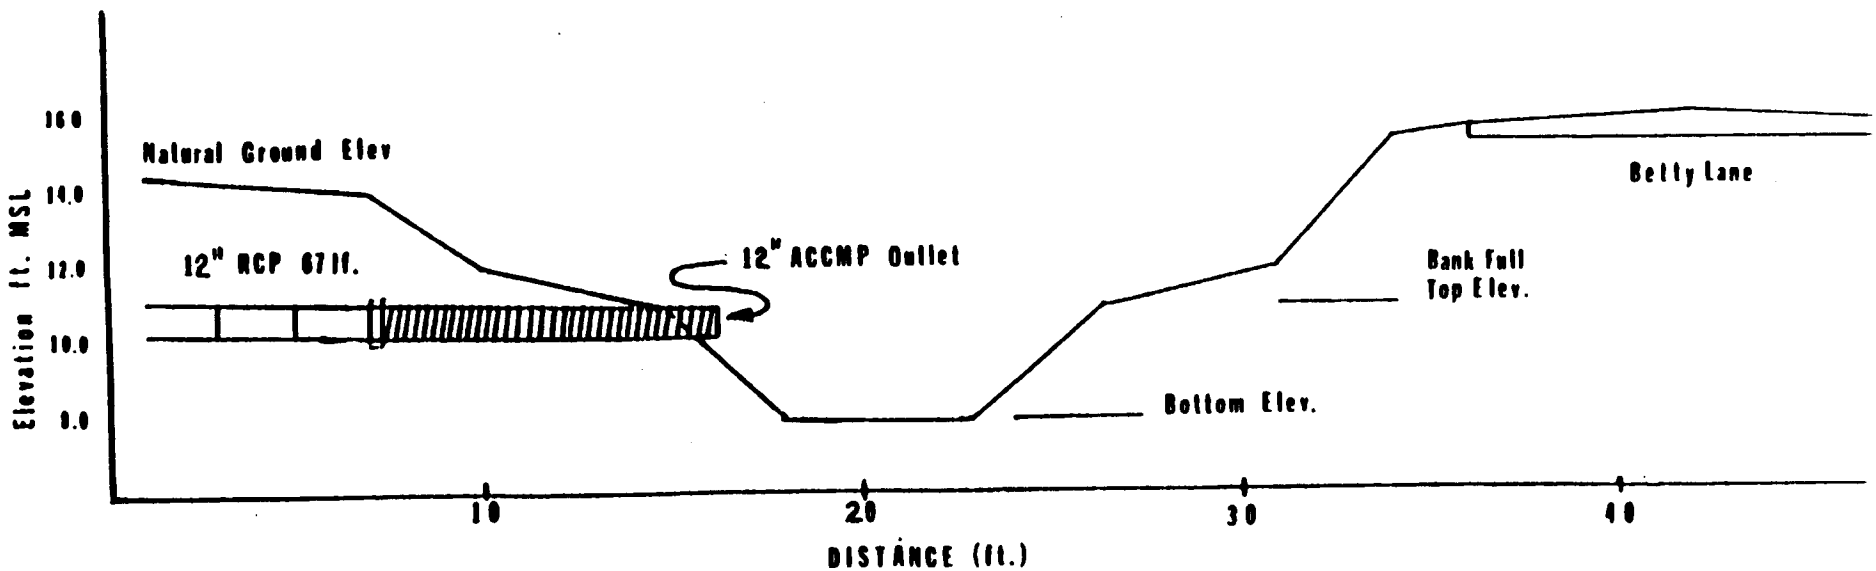
$$V = \frac{1.49}{n} \times R^{2/3} S^{1/2}$$

$$V = \frac{1.49}{.05} \times 1.8^{2/3} \times .0025^{1/2}$$

$$V = 29.8 \times 1.48 \times .05$$

$$V = 2.2 \text{ ft/sec}$$

$$\text{Travel Time (open channel)} = \frac{\text{Length}}{\text{Velocity}} = \frac{1400}{2.2} = 636 \text{ sec}$$



$$= 10.6 \text{ min.}$$

As stated earlier, the time of concentration (Tc) may be determined by adding the travel time through each reach. In this instance, (Tc) equals "overland flow" time of travel (i.e. 21 min.) plus "open channel" flow travel time (i.e. 10.6 min) or (31.6 min). In this problem use (Tc = 30 min) to estimate the rainfall intensity.

Enter Figure 5 at the point for the appropriate duration storm (i.e. 30 min). Proceed up the page to the point where the line intersects the curve associated with the appropriate return frequency storm (i.e. 25 yr). Read the value of rainfall intensity opposite this point from the vertical scale along the left hand side of the graph.

$Q = CIA$

where; the values of each factor are as discussed earlier such that ($C = 0.25$), ($I = 5.4$ in/hr) and ($A = 14.7$ Ac.)

$Q = CIA = (0.25)\ (5.4)\ (14.7) = 19.8$ cfs.

(B) Having established the 25 year peak discharge the engineer may now continue with other procedures for the determination of flood stage in the drainage ditch during the design storm.

One simple and easy to use procedure is called "Normal Depth Analysis". The method is well described by the St. Johns River Water Management District, Applicants Handbook Management and Storage of Surface Waters. The method as applicable to this example may be outlined as follows:

(1) Divide the channel section into one or more subsections or segments each having a reasonably uniform roughness coefficient, A_1, A_2, A_3 -- A_n. In this case assume the channel is uniform. Enter appropriate number of subsections as illustrated in Table 3.
(2) Determine "n" value for each individual sub-section, ("n" = .05) as noted earlier in part (A) of this example.)
(3) Select a flood stage, y_1 as a first estimate.
(4) Determine the slope of the channel (S), the cross section area (A), and hydraulic radius (R) in order to compute conveyance capacity for each sub-section based on floodstage y_1.
(5) Calculate the total discharge Q_1 that corresponds to the stage y_1. Use Manning's equation times the cross sectional area (A) to determine the discharge for each sub-section.
(6) If $Q_{25} > Q_1$, increase flood stage y_2 by a small increment. Follow steps (4) and (5) to determine Q_2.
(7) Repeat step (6) until several Q values above and below Q_{25} are established. Plot a stage vs. discharge curve from which a stage corresponding to Q_{25} can be determined.

Figure 6 illustrates the stage discharge relationship in the receiving stream at the point of discharge . Calculations are shown on Table 3. As may be seen the stage in the canal or ditch which corresponds to the peak discharge expected from the 25 year reoccurance interval storm would be approximately 9.7 feet mean sea level (MSL). In this instance, setting the outfall elevation of the discharge structure at 10.0 ft. MSL will insure that the facility is capable of operation without restrictions due to backwater effects in the receiving stream for storms up to and including the 100 year event.

The next step in the design is to:

II. <u>Determine Detention Area Storage Capacity Needed to Satisfy both State Stormwater Water Quality Regulations and Local Maximum Allowable Rate of Discharge Limitations:</u>

(A) Stormwater quality regulations in Florida are listed in Florida Administration Code Rule 17-25.
State Requirements: Hold First 1/2" of runoff to be bled down within 72 hrs. by an underdrain or filter system, natural percolation, evapotranspiration, and/or evaporation.

$$\text{Volume} = \frac{(0.5 \text{ in.})\ (4.5 \text{ acres})}{12 \frac{\text{in}}{\text{ft}}} = 0.19 \text{ Ac-ft}$$

(B) Local Flood Control Requirements: Post development rate of discharge must not exceed predevelopment rate for the 25 yr. frequency storm. Due to the small size of the project use the Rational Formula to set the maximum allowable rate of outflow. Utilize "Modified Rational Method Analysis" to determine the maximum volume of storage needed to stay within this rate of release.

(1) The allowable release rate is calculated utilizing the Rational Formula (Q = CIA) with a "C" value characteristic of the undeveloped condition and an "I" value for a storm duration equal to the time of concentration (Tc) for the basin under historic conditions. (Sometimes termed "natural conditions")

(Tc) may be determined as discussed previously. Two types of flow conditions also exist in this sub-basin of the watershed. From a point in the southwest corner of the 4.5 acre tract in question, water traveling the maximum distance must move 600ft via overland flow laterally to the drainage ditch and subsequently move by "open channel" flow to the point of interest (outlet) 300 ft downstream. The velocity associated with each flow segment was established earlier. (i.e. 28 ft/min for "overland" flow and approximately 2.2 ft/sec. in the "open channel".) Therefore;

$$Tc = \frac{600 \text{ ft}}{(28 \text{ ft/min})} + \frac{300 \text{ ft}}{(2.2 \text{ ft/sec})} \times \frac{1 \text{ min}}{(60 \text{ sec})}$$

$$Tc = 21 \text{ min} + 2.3 \text{ min} = 23.3 \text{ min}$$

Use Tc = 20 minutes for convenience; however,
Tc = 25 minutes would be preferred, given a real situation.

From Figure 5 determine rainfall intensity (I) for the 25 yr./20 minute duration storm.

I = 6.5 in/hr (FDOT Drainage Manual, Rainfall Intensity Chart, Zone 6.)

Working through the equation;
C (Predevelopment) = 0.25, as noted previously.
Area = 4.5 Acres (Figure 2)
I = 6.5 in/hr.

Maximum Release Rate or Outflow
Qp(Natural) = CIA (.25)(6.5)(4.5) = 7.3 cfs.

(2) Modified Rational Method Analysis: The term Modified Rational

R0071611

Method Analysis refers to a procedure for manipulating the basic Rational Method techniques to reflect the fact that storms with durations greater than the normal time of concentration for a basin will result in a larger volume of runoff even though the peak discharge predicted is reduced. This greater volume of runoff projected by longer duration storms must be analyzed to determine the correct sizing for detention facilities unless a specific storm duration is mandated for design purposes.

In applying this procedure the typical Rational Formula hydrograph with the peak discharge coinciding with the time of concentration for the basin (T_c), is first calculated using the normal formula Q = CIA. Following this, a family of hydrographs representing storms of greater duration are developed. The peak runoff rate for each hydrograph is equal to CIA where (I) is the rainfall intensity for the storm duration in question. The rising limb and falling limb of the hydrograph are, in each case, equal to (T_c) for the basin. The basic assumption of this method is that the area under the assumed trapazoidal hydrograph equals the volume of runoff from the theoretical rainfall. The area under the hydrograph is also equal to the peak discharge rate for that particular rainfall times the duration of the event.

In this example assume (T_c) following development will be reduced from 20 to 15 minutes. A family of hydrographs can be developed provided that the runoff coefficient (C) for the developed project is known.

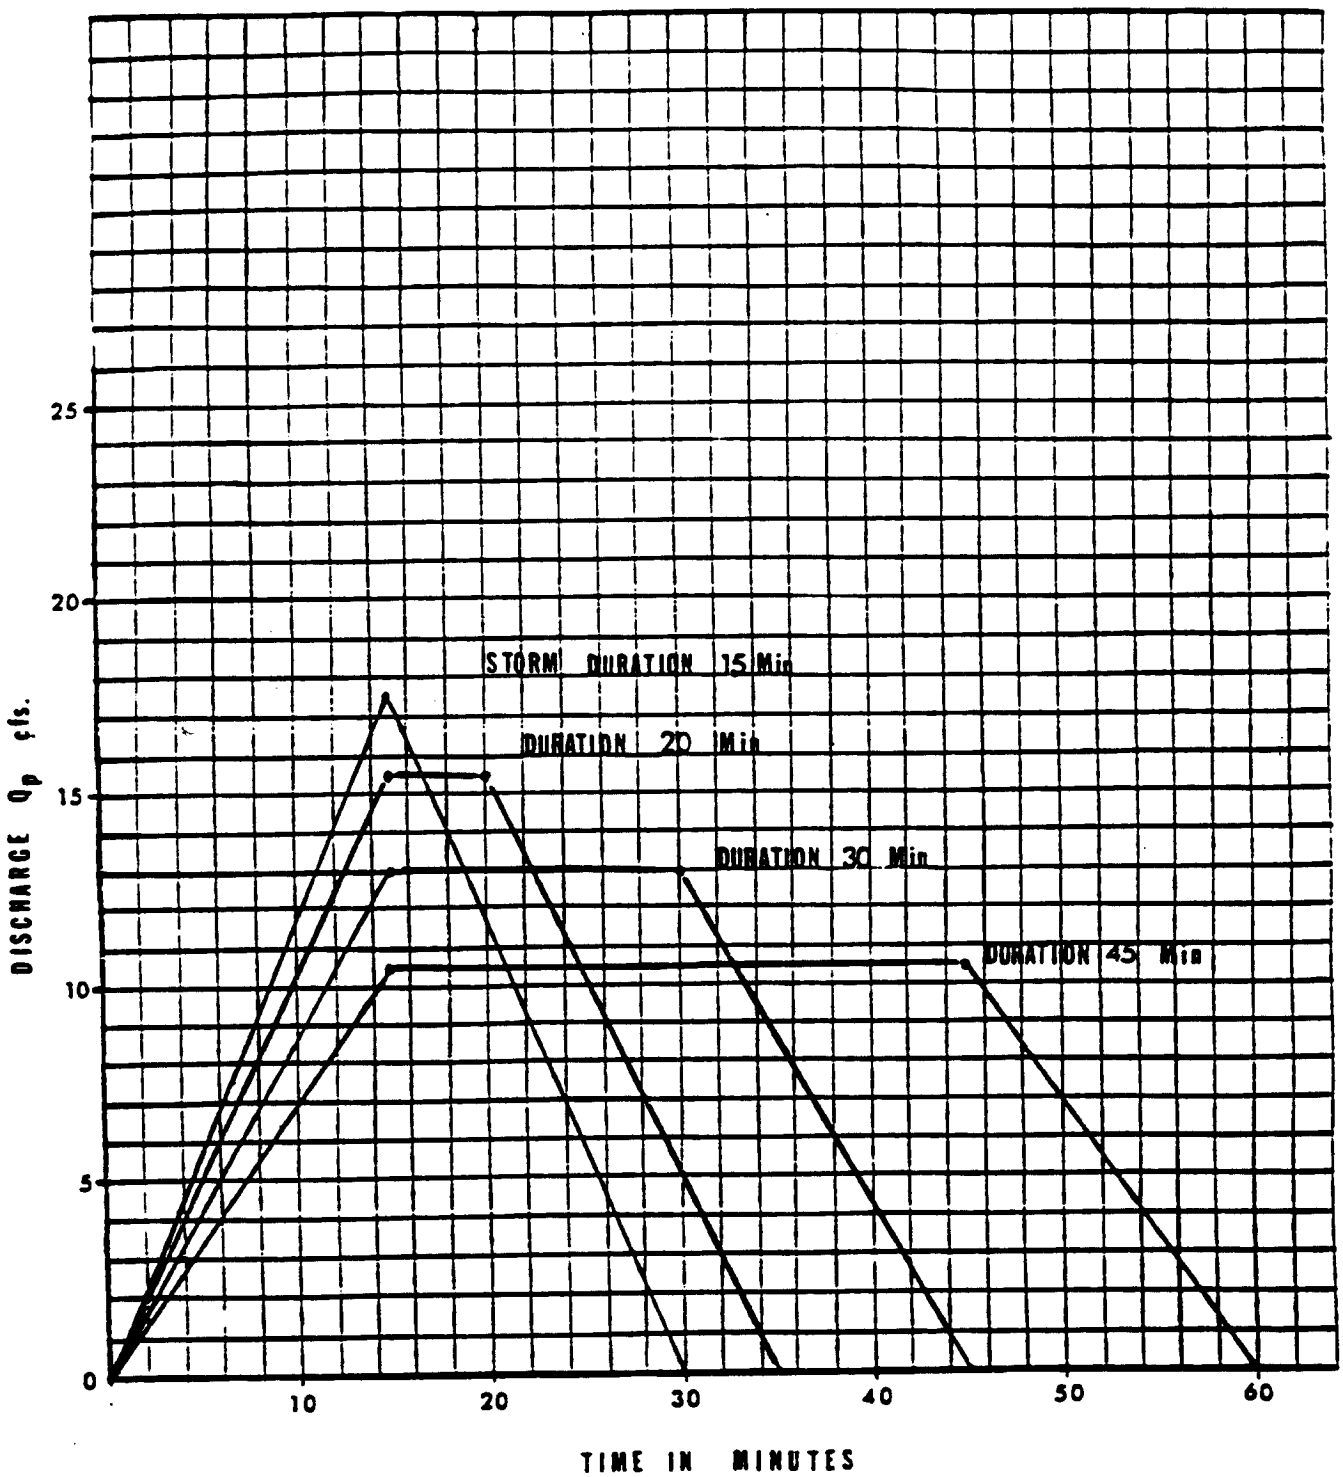
(a) The runoff coefficient following construction C (Post) may be determined based on information illustrated in Figure 2 and the values listed in Table 1.

Land Use	Acres (A)	Runoff Coefficient (C)	(A) x (C)
(Fig. 2)	(Fig. 2)	(Table 1)	
Pavement	1.15	.95	1.09
Roofs (Aptm. Building)	1.10	.95	1.05
Lawns & Other Grassed Areas (Sandy Soil, Flat Slope)	2.25	.10	.23
	4.50 Total	Total	2.37

$$C\ (Post) = \frac{A\ C\ (Total)}{A\ (Total)} = .53$$

R0071612

(b) The composit runoff coefficient as determined above is subsequently used in combination with the average rainfall intensity expected from the various duration events in inches per hour and the area of the watershed in acres to calculate the peak rate of runoff as listed in Table-4 and illustrated in Figure-7. It was mentioned previously that the area inscribed by each hydrograph and the volume of runoff in ft^3 is equal to the peak discharge rate (cfs) for that particular rainfall times the duration of the event when converted to seconds. The values for the particular watershed used in this example are listed under the column marked "Inflow" in Table-4 which also corresponds to the area under the inflow hydrographs shown on Figure-7.



"Rational Method Analysis" and other appropriate procedures normally include the simultaneous calculation of the outflow hydrograph. The maximum allowable release rate Qp (Natural) or QpN which was calculated earlier based on the historic or predeveloped conditions represents the peak of the outflow hydrograph, and the limit of the discharge which the control structure is designed to regulate. The volume of inflow which is expected to enter the facility in excess of the outflow volume leaving the system during the same time frame must be temporarily stored in the facility and released following the termination of rainfall. Most agencies concerned with water quantity control expect the engineer to size the detention facility to accomodate the storage needed for a specific return frequency storm of a duration and intensity sufficient to generate the largest difference between total inflow and outflow. Hence, the need to look at a multiple of design events of variable duration.

Concrete box inlet drop spillway control structures in combination with rectangular weirs similar to that illustrated in Figure-8 are among the most commonly used discharge facilities. The following discussion will be related to the procedures normally used in the design of this type of installation, when used in combination with an underdrain or filter system to satisfy state water quality criteria.

In conventional detention facility design the outflow hydrograph would be constructed overlapping the inflow hydrographs. As stated earlier, since the objective of the system is to duplicate historic conditions the outflow structure must be built to meet the maximum peak flow and often the time to peak (Tc usually = Tp in rational method analysis) expected assuming the watershed had remained undeveloped. In this case, it has been previously specified that the time of concentration (Tc) in the predeveloped state equals 20 minutes and the maximum

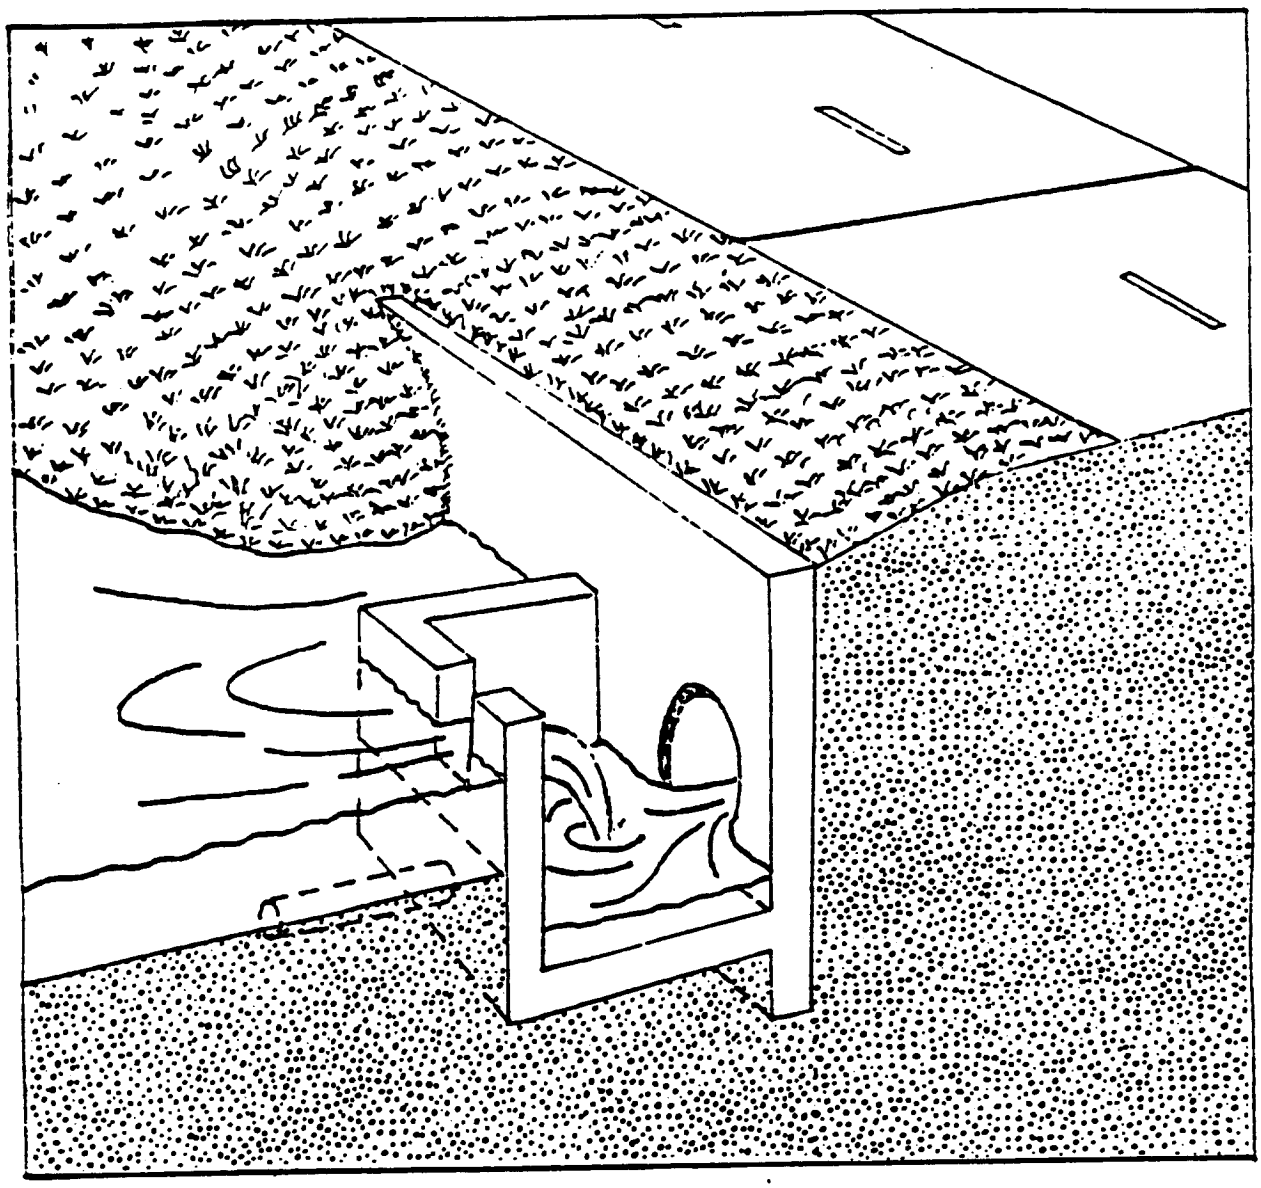

Figure 8
Detention Facility with Underdrain Pipe and Slotted
Concrete Box Drop Inlet Water Control Structure

permissible 25 year peak discharge Qp = 7.3 cfs. The outflow hydrograph superimposed on the inflow hydrograph is shown in Figure-9. The area formed by the outflow line and its intersection with the receding leg of each inflow hydrograph represents the total outflow volume. The magnitude of outflow associated with each storm may be estimated graphically from Figure-9 or it may be calculated using the following equation:

$$V(out) = 1/2Qp(N)\ [2(D + TcD) - (TcN + \frac{Qp(N)\ TcD}{Qp(D)})]$$

where:

V(out) = Volume of discharge (ft^3)
Qp(N) = Max. permissible rate of discharge or peak discharge under natural conditions (cfs)

Qp(D) = Peak discharge rate following development (cfs)
D = Storm duration (sec)
TcD = Time of concentration expected for the developed condition (sec)
TcN = Time of concentration expected for the watershed given historic or natural conditions (sec).

The results of calculations for the watershed in this example are shown in the column under the heading "Outflow" in Table-4. The maximum storage or detention volume listed in the last column of the table will not always be largest for any particular duration storm event. As noted earlier, more than one time increment should be used when evaluating the maximum storage volume required. That is, unless the regulating authority has adopted a specific duration it wishes to have the engineer design too.

From Table-4
Maximum Required Storage = 9,832 ft^3 for flood control.
Therefore;
City requirements for storage is <u>0.23 Ac-Ft.</u>

(c) It should be noted that the analysis of storage volume conducted above in part (b), is based on the presumption that runoff water is constantly being discharged up to a certain rate (maximum allowable release rate). Such analyses are appropriate for the design of conventional detention systems. However, other regulations which specify that a certain amount of this water (say 1/2" of runoff) must be stored and filtered or percolated through the soil prior to release may act to increase the storage volume that must be provided. In some cases this can be quite a substantial increase. The affect must be

Max. Allowable Release Rate Qp(N) = 7.3 cfs.

R0071618

evaluated in order to insure that the level of flood protection mandated by the local government is maintained.

For instance, Figure-10 once again depicts the array of inflow hydrographs expect from a 25 year return frequency event for four different durations of rainfall. However, the outflow hydrograph has been modified to reflect the fact that discharge will be limited to that leaving via the subsurface drain until the 1/2" storage elevation is reached. From Figure-10 it may be observed that while the general shape and peak discharge (i.e., maximum allowable rate of release) is the same for each event, the time to peak is shifted toward the right of the graph as the duration of the event increases. This is due to the shape of the inflow hydrographs derived using "rational method analysis" in which the peak rate of inflow is reduced as the rainfall duration increases and average intensity decreases. Therefore, it takes more time for the 1/2" storage elevation and the onset of weir outflow to be achieved. In this case, the basic affect of the underdrain is to move the outflow hydrograph constructed based on weir flow alone (Figure-9) to the right. As a result, less water will have been discharged over the course of the storm than would have been predicted using the procedures discussed in the preceeding section. More storage is required to insure the proper level of flood protection. The elapsed time for weir outflow to begin must be calculated for each storm duration before the outflow hydrograph may be constructed.

In order for this to be done, the designer must:

1. Select or establish the depth of the storage area required to hold the first 1/2 inch of runoff or the runoff from the first inch of rainfall as appropriate from the contributing drainage area. In most cases the design and this analysis may be simplified if the engineer simply chooses a storage depth desired. (In this example problem assume the desired depth of storage is 1.75 feet.)

2. Determine the point on the inflow hydrograph where in the 1/2" storage volume or the runoff from the first inch of rainfall occurs.

   In this particular example, for the maximum peak producing storm (i.e., that storm where duration (is equal to the time of concentration) this point may be determined based on the following equation:

$$t = 2Tc - (2Tc^2 - \frac{2Vs\ Tc}{Qp})1/2$$

   where;

Figure-10

Inflow and Outflow Hydrographs of Various
Duration Events for Turnkey Apts.
Detention/Filtration Facility

(Time of Concentration Tc = 15 min.)

(Time of Concentration Natural Conditions TcN = 20 min.)

R0071620

t = time in which the required storage volume is reached (sec)
Tc = time of concentration following development (sec)
Vs = storage volume (ft^3) needed to satisfy state water quality criteria found in section 17-25.03(2)(b), F.A.C.
Qp = peak flow expected for the storm whose duration equals Tc (cfs).

The derivation of this formula may be found at the end of this chapter (see Appendix A). However, the equation is only suitable for use when the 1/2 inch storage volume or the runoff from the first inch of rainfall occurs following the peak of the hydrograph. This may be determined by calculating the volume of discharge associated with the rising limb of each duration storm and comparing its value with that previously determined for the 1/2 inch storage volume (i.e. .19 Ac.-Ft. or 8,276 ft^3, in this instance). If the value is less than required storage, the previous equation may be used for the peak producing storm (i.e. duration = Tc). Watersheds with values of "Tc" less than 20 minutes will generally fall into this category. In these instances the appropriate storage volume will be reached during the falling leg of the maximum peak producing hydrograph.

A second equation is required to calculate the time to reach the appropriate storage or filtration volume for those circumstances when storm duration exceeds the time of concentration such that this point occurs sometime during the constant discharge phase of the hydrograph. As illustrated in Appendix B, Equation B-1, the time (t) to reach the point where the appropriate storage volume is satisfied and beyond which weir flow begins can be calculated as follows:

$$t = \frac{Tc}{2} + \frac{Vs}{QpD}$$

where:

t = Time for inflow to reach the appropriate treatment volume (sec)
Tc = Time of concentration (sec)
Vs = 1/2 inch treatment volume or runoff associated with the first inch of rainfall
QpD = Peak discharge from the design storm for the duration under consideration (cfs).

In this example the peak discharge (Qp) expected from the storm with a duration equal to (Tc) was determined to be 17.46 cfs. Since the time of

concentration was listed as 900 sec. or 15 min., the volume of inflow associated with the 15 min. duration event is equal to 1/2 (17.46)(900) = 7,857 ft^3; therefore, the time required to reach the appropriate storage volume desired (i.e., .19 Ac.-Ft.) or (8,276 Ft^3) will follow the peak discharge for every storm duration being considered. Equation A-1 may be used to claculate time (t) to reach the appropriate filtration volume for te 15 min. duration event. Values of (t) associated with other events may be determined using equation B-1. Similar equations for calculating the time to reach the appropriate volume for filtration when this point occurs sometime during the rising leg of the hydrograph may be found in Appendix C.

Table 5 lists the value (t) or time required for inflow to reach the 1/2 inch storage volume for the 15, 20, 30, 45, and 60 minute duration event in this example problem.

3. Based on site conditions, the intended use of the area, the type of facility (i.e., wet or dry), and the ingenuity and desires of the owner and designer, the configuration and layout of the detention facility and filter system is proposed. The size of the filtration bed required to accomplish drawdown within the 72 hour time frame mandated in 17-25, F.A.C. may be estimated using a number of procedures discussed in design criteria section of the Standards and Specifications for Underdrains and Filtration Systems. However, the length and width of many of these facilities are also determined based on experience of the designer. In these instances, it is the task of the designer to check for compliance with state and local regulation. For this example problem the engineer wishes to use a 265 ft long bottom filter approximately 2.5 ft. in width.

4. The discharge rate expected from the filter system at the invert elevation of the outfall structure must be determined. In filter design all outflow is usually presumed to pass through the surface of the filter.

   Given these circumstances, (Q_F) the instantaneous rate of discharge from a bottom filter or underdrain system may be estimated using Darcy's Equation assuming saturated flow conditions.

$$[Q_F = KIA = K\ (Y/D)\ A]$$

   where;
   K = Coefficient of soil permeability or filter material as appropriate (in./hr.)

R0071622

for 15 min. duration.

$t = \frac{Tc}{2} + \frac{Vs}{Qp}$ for all other duration events (see Appendix A & B).

R0071623

Y/D = Hydraulic Gradient (ft./ft.) (see Figure 11)
A = Surface area of the trench (Ac)

working through the equation; assuming,
Q_F = 12 in./hr. (based on lab permeability test of FDOT U.D. Sand)

Y = 3.75 ft. (Figure 11)
D = 2.0 ft. (Figure 11)

$$12 \text{ in/hr.} \times \frac{3.75 \text{ ft.}}{2.00 \text{ ft.}} \times \frac{(265 \text{ ft})\ (2.5 \text{ ft})}{43{,}560 \text{ ft}^2/\text{Ac}}$$

Q_F = (12 in./hr.) (1.875)(0.015 Ac)

Q_F = 0.34 cfs Use: Q_F = .35 cfs.

This represents the discharge from the detention facility when the water level is at the invert elevation of the rectangular slot in the discharge control structure illustrated in Figure 8. It also represents the value (h_1) of the outflow hydrograph illustrated in Figure 10.

5. The second stage of the outflow curve is constructed assuming that the peak rate of discharge and time to peak will be limited to the values determined previously. As illustrated in Figure 10 the maximum rate of release (h_2) is restricted to 7.3 cfs as before, and the minimum time to reach this rate of outflow will be maintained equivalent to the predevelopment condition (TcN = 20 min.).

Once these values are established, it is possible to determine the volume of outflow, by considering the outflow hydrograph to be represented by 2 trapezoidal shaped figures separated along a line (b_2) parallel to the horizontal or (X) axis of the graph at height h_1. The volume associated the lower trapezoid may be calculated by converting the time increments to seconds and multiplying 1/2 the base plus top length by the value of h_1 (ie., .35 cfs). The base (b_1) is equal to the storm duration (D) plus the value of the time of concentration (Tc). For this example, the base (b_1) associated with the 20 minute duration event where Tc is equal to 15 minutes, would be equivalent to 20 minutes plus 15 minutes = 35 minutes or 2100 seconds.

The top length (b_2) may be calculated by subtracting the time (t) to reach the 1/2 inch runoff volume (see Table-5) from the base (i.e., 2100 sec). In addition, the horizontal distance (X) associated with the point of intersection of line (b_2) and the

R0071624

receding leg of the inflow hydrograph must also be subtracted from the base. Its value may be determined since the distance along the X axis associated with a height of (h_1) above the falling leg of the hydrograph will be proportional to the horizontal distance (Tc) and peak flow (Qp)
In equation form:

$$\frac{X}{h_1} = \frac{Tc}{Qp} \quad \text{or,} \quad X = \frac{Tc\ h_1}{Qp}$$

Therefore, the length of line (b_2) separating the 2 figures at h_1 may be written:

$$b_2 = (D + Tc) - (t + \frac{Tc\ h_1}{Qp})$$

Going back to this example, the value of b_2 associated with a storm of 20 minutes duration, time of concentration Tc = 15 minutes, and the time to the 1/2" runoff volume t = 16.4 minutes, would be:

$b_2 = (1200 + 900) - (984 + 900\ (.35/15.5) = 1096$ sec.

At this point, the volume (V_1) associated with the lower trapezoid may be calculated, as follows, when the time increments are converted to seconds.

$V_1 = 1/2\ h_1$ (base b_1) + (b_2) therefore,

$$V_1 = 1/2\ h_1\ (D + Tc) + (D + Tc) - (t + \frac{Tc\ h_1}{Qp}) \text{ or;}$$

$$V_1 = 1/2\ h_1\ [\ 2\ (D + Tc) - (t + \frac{Tc\ h_1}{Qp})]$$

where:

V_1 = Volume associated with the lower trapezoidal figure (ft^3);
h_1 = Discharge expected from the filter when the 1/2" storage volume is reached (cfs);
D = Duration of the design storm (sec);
Tc = Developed time of concentration (sec);
Qp = Peak discharge expected from the design storm based on the rational formual (cfs);
t = Time to reach the 1/2" storage volume as shown in Table-5 (sec).

Estimating the volume (V_2) associated with the upper trapezoidal figure is slightly more difficult

R0071625

to determine; but, may be accomplished using the following procedures. As stated earlier, the height of the outflow hydrograph is limited to the maximum allowable rate of release, which in this case was established previously as the peak during predevelopment (QpN = 7.3 cfs). In equation form:

$h_2 = QpN$

The value of the base (b_2) was determined in the preceding section. Remember, for the 20 minute storm b_2 was found equal to 1096 seconds. However, the top length of the upper trapezoid must also be calculated in order to determine the value of V_2.

Assuming that the post development time to peak discharge must duplicate predeveloped conditions, the outflow will be limited such that the peak producing storm (i.e., 15 min. storm in this case) will reach the maximum allowable release rate (QpN = 7.3 cfs) within the same time as occurred during predeveloped conditions. Since the time to peak Tp is equal to the time of concentration in rational method analysis, the time to reach the peak rate of the outflow for the peak producing storm where D = Tc will be equal to the natural condition time of concentration (TcN) which is equal to 20 minutes. Assuming the same rate of rise for other duration storms, this value will be increased by the difference between the time (t) to reach the 1/2 runoff volume for the storm in question and (t_1) which is that associated with the peak producing event. In equation form, TcN + t - t_1) must be subtracted from the total length of the base (b_2) of the outflow hydrograph.

Likewise, the horizontal distance (X) from the terminus of the inflow hydrograph to the point where the maximum allowable release rate line (b_3) intersects the receding leg of the inflow hydrograph should also be subtracted from the length of the base in order to determine the top length of the upper portion of the outflow figure. Once again, the distance associated with the point of intersection with the falling leg and the end of inflow is proportional to the time of concentration Tc and the peak discharge Qp of the hydrograph, such that:

$$\frac{X}{h_2} = \frac{Tc}{Qp} \quad \text{or,} \quad X = \frac{Tc\ (h_2)}{Qp}$$

Therefore, the top length (b_3) of the upper trapezoid may be determined using the following equation:

R0071626

$$b_3 = (D + Tc) - (TcN + t - t_1 + \frac{Tc\ (h_2)}{Qp})$$

Consequently, the volume of runoff (V_2) associated with the upper portion of the outflow hydrograph (i.e., the area above h_1) may be determined as follows:

$V_2 = 1/2\ (h_2 - h_1)(b_2 + b_3)$ since;

$$b_2 = (D + Tc) - (t + \frac{Tc\ h_1}{Qp}) \text{ and,}$$

$$b_3 = (D + \frac{Tc}{Tc\ h_2}) - (TcN + t - t_1 + \frac{}{Qp})$$

$$V_2 = 1/2\ (h_2 - h_1)\ [\ 2(D + Tc) - (2t - t_1 + TcN + \frac{Tc\ h_1}{Qp} + \frac{Tc\ h_2}{Qp})]$$

The total volume of outflow is equal to V_1 plus V_2. Therefore, the two equations may be combined as follows:

$$Vout = 1/2\ h_1\ [2\ (D + Tc) - (t + \frac{Tc\ h_1}{Qp})] +$$

$$1/2\ (h_2 - h_1)\ [2\ (D + Tc) - (2t - t_1 + TcN + \frac{Tc\ h_1}{Qp} + \frac{Tc\ h_2}{Qp})]$$

Where:

Vout = Total volume of outflow (cfs);
h_1 = Flow expected from filter at the 1/2" runoff elevation (cfs);
h_2 = Maximum allowable release rate (cfs);
Qp = Peak flow based on rational equation (cfs);
Tc = Time of concentration following development (sec);
TcN = Time of concentraton predevelopment (sec);
t = Time for inflow volume to equal the first 1/2" runoff or runoff from the first inch of rainfall for the storm duration in question (sec) (see Table 5);
t_1 = Time for inflow volume to reach the first 1/2" runoff or the runoff from the first inch of rainfall as appropriate for the peak

R0071627

producing storm where duration = Tc (sec). (NOTE: t_1 = t for this event).

Table-6 lists the results of these calculations for this example under the column marked "outflow". Notice that the maximum storage required (14,176 ft^3) is for the 45 minute duration event. This represents 44 percent increase in the volume of storage required over that which would be needed for water quantity control alone.

Due to expected difficulties with the operation and maintenance of these systems, some municipalities currently require that water quantity and water quality criteria be considered independently. In such an instance, this project would be required to provide slightly more than 18,100 ft^3 of storage area. However, for this example assume that the local review agency will allow the designer to take credit for the outflow which may leave the system during the course of the design storm in order to reduce the storage somewhat. Storage requirements to satisfy both water quantity and water quality regulations would equal approximately .33 Ac. ft. or 14,176 ft^3.

III. Sizing the Detention Area

Having established the volume of storage needed, the designer may next determine the average area needed for the facility. Its value may be calculated by dividing the storage volume by the depth minus any freeboard required. In this case it was noted earlier that the developer did not want the holding area to exceed 3 ft. deep. Given a further local requirement mandating that .5 feet of freeboard be maintained; in this example:

$$\text{Det. Area Size} = \frac{14,176\ ft^3}{2.5\ ft.} = 5,670\ ft^2 \text{ or } .13\ Ac.$$

IV. Evaluate Weir Size Required

The type of discharge control structure shown in Figure-8 is quite common in Florida. These structures employ a slotted opening or weir in association with a larger drop inlet of concrete or metal. The former is designed to control the runoff expected for the design storm. The latter helps pass larger less frequently occurring events through the facility with a minimum of restriction, hopefully avoiding any damage. In many cases, the smaller weir or slot sometimes called a bleeder notch is rectangular. However, some areas of South Florida, particularly those within the South Florida Water Management District currently require the use of "V" notched systems to slow drawdown, encourage greater settling, and thereby increase the amount pollutant removal associated with the system. Equations are available to calculate flow through most of these types of orifices. Several are

(2) Peak Runoff (cfs) = CIA (C = 0.53, A = 4.5 Ac, I = value from second column)

(3) Inflow = Peak Runoff (cfs) x Duration (sec.)

(4) Outflow = $1/2(h_1)\ [2(D + Tc) - (t + Tc(h_1)/Qp)] + 1/2(h_2 - h_1)$
$[2(D + Tc) - (2t - t_1 + TcN + Tc(h_1)/Qp + Tc\ (h_2)/Qp)]$

(5) Storage = Inflow (Ft^3) - Outflow (Ft^3)

NOTE:

Predevelopment time of concentration (TcN) = 20 min. or 1200 sec.
Time of Concentration (Tc) = 15 min. or 900 sec.
Max. Allowable Release Rate (MARR) = h_2 = 7.3 cfs.
Outflow from filter (h_1) = .35 cfs.

illustrated, and discussed in other sections of this manual, including Chapter 5, Stormwater Engineering Calculations.

As shown in Figure-8 the weir used in this instance is rectangular. Since flow from the underdrain or filter system is expected to be quite small in comparison to the maximum allowable release rate many municipalities will often allow the designer to ignore discharge from the filtration facility when sizing the outfall for flood control purposes.

The length of the weir opening which will limit the maximum rate of flow to that determined above may be calculated by rearranging the discharge equation for rectangular shaped weirs assuming free discharge. Use the following equation;

$$Qw = 3.33\ H^{3/2}\ L$$

where;
Qw = Flow through the weir gate in cfs
Discharge Coefficient = 3.33
H = Hydraulic head above the bottom of the weir opening in feet
L = Width of the weir opening in feet

In this example it was stated earlier that weir flow will begin at elevation 1.75' above the pond bottom. Since the overall depth ignoring .5 ft. freeboard is limited to 2.5 ft. The value of H = .75 ft. The value of Qw is limited the maximum allowable release rate (7.3 cfs). Therefore:

$$L \text{ (width of weir)} = \frac{Qw}{3.33\ H^{3/2}}$$

$$L = \frac{7.3}{3.33\ (0.75)^{3/2}} = 3.375 \text{ ft.}$$

A rectangular weir or slot .75 ft. deep and 3.4 ft. wide will be sufficient to limit outflow to the rate desired.

V. Evaluate Underdrain Drawdown Time

There are 4 factors restricting the removal of detained runoff through an underdrain or filter system. These are:

1. Permeability of soil or filter material as appropriate;
2. Permeability of filter fabric;
3. Size and number of pipe perforations;
4. Maximum pipe flow;

State regulations require a 72 hour maximum drawdown time to remove the first one-half inch of runoff for a drainage basin of 100 acres or less. It is reasonable to believe that the above 4 factors control this drawdown time. It is also reasonable to believe that the most restrictive of the above 4 factors would control the drawdown time.

The following is an analysis of the concerned detention basin:

Figures 11, 12 and 13 illustrate the important dimensions of the underdrain or filter system designed to serve this facility.

A. Analysis of Factors 1 and 2

Permeability of filter media (FDOT grade underdrain sand) vs. Permeability of Mirafi Fabric. According to information published by the University of Florida and several independent testing labs, the permeability of FDOT grade underdrain sand may vary from 6 to more than 24 inches per hour. Assume an inspection was conducted to confirm the percolation at the treatment location. It was determined through field tests that:

1. Filter Permeability = 12 inches/hr.

   According to the Celanese Fibers Marketing Pamphlet the permeability of the Mirafi 140S Fabric is:

2. Mirafi 140S fabric = 0.07 cm/sec = 99.3 inches/hr. (Ref. Post, Buckley, Schuh & Jernigan Eng.)

   From the above analysis, it is reasonable to assume that Factor 1, Soil permeability, is more restrictive to drawdown time. This eliminates Factor 2, permeability of fabric from the analysis.

   To complete the evaluation of drawdown time based on soil permeability the following equations can be used:

Darcy's Law

$$Q = KiA = K \frac{Y}{D} A$$

Where;
K = Coeff. of Soil Permeability (ft./hr.)
$i = \frac{Y}{D}$ = Instantaneous Hydraulic Gradient (ft./ft.)
A = Area of trench for underdrain or filtration (ft^2).

Falling Head Equation

$$t = \int_o^t dt = - \int_{Y1}^{Y2} \frac{A_R dy}{Q}$$

t = Drawdown Time (hrs.)
A_R = Average Area of Resevoir between elevation Y_1 and Y_2 (ft^2)
Y = Head difference between water level elevation behind the structure at any point in time and either the flow line of the underdrain pipe or the top of the gravel envelope when used (ft)
D = Depth of soil column or filter material (ft.).

R0071632

Figure-13

Typical Cross-Section of Filter Trench

R0071633

Substituting Darcy's Equation into Falling Head Equation

$$t = -\int_{Y1}^{Y2} \frac{A_R dv}{K \frac{Y}{D} A} = -\frac{A_R D}{K A} (LN\ Y_2 - LN\ Y_1) \text{ or,}$$

Equation A. 1. $$t = \frac{2.3 A_R D}{K A} \log \frac{Y1}{Y2}$$

Assumptions:

1. All discharge from the pond is through the soil within the trench.
2. Groundwater is not a contributing factor.
3. Surface area of pond is constant.

Applying equation A. 1.

$A = (2.5\ ft)(265\ ft) = 662.5\ ft^2$
$K = 1^{ft/hr}$
$D = 2.0\ ft.$
$A_r = .13\ Ac. = 5670\ ft^2$
$Y_1 = 3.75\ ft.$
$Y_2 = 2.0\ ft.$

$$t = \frac{2.3\ A_R D}{K A} \log \frac{Y_1}{Y_2} = \frac{(2.3)(5670)(2.0)}{(1)(662.5)} \log \frac{3.75}{2.0}$$

or,

$t = 10.7$ hours

$t < 72$ hours

This meets the state requirement

B. Analysis of Factor 3

Pipe perforations in the underdrain also restrict the flow of water. To compute the drawdown time based on data supplied by the manufacture, the following equation can be used:

Falling Head Equation

$$t = \int_o^t dt = -\int_{Y_1}^{Y_2} \frac{A_R\ dy}{Q}$$

Where;
t = Drawdown Time (sec.)
A_R = Average Area of Resevoir between Y_1 and Y_2 (ft^2)
C = Coefficient of Discharge
A_L = Orifice area per Linear foot of pipe (ft^2)
g = Gravitational Constant ($ft./sec^2$)

Orifice Equation

$$\frac{Q}{L} = C \frac{A_L}{L} (2gy^{1/2})$$

R0071634

L = Underdrain Length (ft.)
Y_1 and Y_2 are illustrated in Figure 13 (ft.).

Substituting the Orifice Equation into the Falling Head Equation yields;

Equation B. 1.:

$$(L)(t) = -\int_{Y_1}^{Y_2} \frac{A_R\, dv}{C\, A_L\, (2gy)^{1/2}}$$

$$= \frac{-2\, A_R}{C\, A_L\, (2g)^{1/2}} [(Y_2)^{1/2} - (Y_1)^{1/2}]$$

$$(L)(t) = \frac{2\, A_R}{C\, A_L\, (2g)^{1/2}} [(Y_1)^{1/2} - (Y_2)^{1/2}]$$

Applying Equation B. 1.

A_L = 1.78 in^2/per foot of underdrain = 0.012 ft^2/per ft. of underdrain. (Information supplied by pipe manufacture).
C = 0.60
g = 32.2 ft/sec^2
Y_1 = 3.75 ft.
Y_2 = 2.0 ft.
L = 265 ft.
A_R = .13 Ac. = 5670 ft^2

$$(L)(t) = \frac{(2)(5670)}{(0.60)(0.012)\ (64.4)^{1/2}} [(3.75)^{1/2} - (2.0)^{1/2}]$$

$$(L)(t) = \frac{11,340}{0.058} (1.94 - 1.41) = 103,624 \text{ ft.-sec.}$$

(L)(t) = 28.8 lin. ft. hrs.

Since there is 265 feet of underdrain in the system,
t = 28.8/265 or,
t = 0.11 hours
t < 72 hours

This meets state requirements. The filter media is more restrictive than the pipe perforations.

C. Analysis of Factor 4.

Underdrain size and slope can also restrict the flow of water.

As shown in Figure 13, the designer has selected six inch ADS perforated corrugated polyethylene pipe for use as the underdrain in this hypothetical situation.

To compute the drawdown time the following equation can be used:

Falling Head Equation

$$t = \int_0^t dt = -\int_{Y_1}^{Y_2} \frac{A_R\, dy}{Q}$$

t = Drawdown Time (sec)
A_R = Average Area of Resevoir between Y_1 and Y_2 (ft^2)

Mannings Equation

$$Q = \frac{1.486}{n} A_p R^{2/3} S^{1/2}$$

A_p = Pipe Area (ft^2)
R = Hydraulic Radius (ft)
S = Avg. Hydraulic Gradient $\frac{Y}{(L/2)}$ (ft./ft.)
n = Roughness Coefficient
L = Length of Underdrain (ft)

Substituting Mannings into the Falling Head Equation

$$t = -\int_{Y_1}^{Y_2} \frac{A_R\, dy}{\frac{1.486}{n} A_p R2/3 (Y/L/2)1/2}$$

$$t = -\frac{A_R\, n\, (L/2)^{1/2}}{1.486\, A_p\, R^{2/3}} \int_{Y_1}^{Y_2} Y^{-1/2}\, dy$$

Equation C. 1.:

$$t = \frac{2\, A_R\, n\, (L/2)^{1/2}}{1.486\, A_p\, R^{2/3}} \left[(Y_1{}^{1/2}) - (Y_2{}^{1/2})\right]$$

Note: Half the underdrain length was used since flow is occurring through entry points along the length of the underdrain.

Applying Equation C. 1.

$A_p = 0.196\ ft^2$
R = 0.125 ft
Y_1 = 3.75 ft
Y_2 = 2.0 ft
n = 0.015 ("n" value recommended by SCS for corrugated plastic drain tube)
A_R = .13 Ac or 5670 ft^2
L = 265 ft

$$t = \frac{(2)\ (5670)\ (0.015)\ (265/2)^{1/2}}{(1.486)\ (0.196)\ (0.125)^{2/3}} \left[(3.75^{1/2}) - (2.0^{1/2})\right]$$

t = 14,054 sec.

R0071636

t = 3.9 hours

t < 72 hours

This meets state requirements

VI. Conclusion

From the preceeding analysis, the limiting factor is the soil permeability. The drawdown time for the filter system using 265 ft. of underdrain is about 11 hours. As illustrated in steps I and II, city water quantity regulations are also satisfied. The final design consists of a dry detention area approximately 2.5 ft. deep capable of providing approximately 14,200 cubic feet of storage. The facility will cover about .13 acres of land area. A 265 ft. long by 2.5 ft. wide filter trench using 2 feet of FDOT grade underdrain sand is planned for filtration of the first 1/2 inch of runoff (8276 ft^3) entering the facility. A concrete drop inlet control structure will be utilized for flood control. The installation will include a rectangular weir or slot .75 ft. deep and 3.4 wide to limit outflow from the 25 year design storm to the predevelopment rate of discharge (7.3 cfs).

Appendix A

Derivation of the Equation for Calculating Time to 1/2" Storage Volume for Storm Duration Equal to Tc Based on Rational Method Analyses.

Assume: The 1/2" storage volume or the runoff from the first inch of rainfall (Vs) occurs sometime following Tc.

Given: Hydrograph inscribed by points abc. The value of "b" represents the peak discharge "Qp" of the inflow as measured on the left or verticle axis. The duration of the storm is equal to Tc and the base of the hydrograph is equal to 2Tc. In reference to Figure A-1; ac = ad + dc, ad = dc = Tc, Therefore, ac = 2Tc.

Question: At what point in time will the volume of inflow Vi = Vs the 1/2" storage volume or the runoff from the first inch of rainfall?

Solution: This will occur at the point where the value of the volume of storage Vs = to the total volume of inflow Vi minus the volume represented by a triangle whose base is equal to the value of (Tc - x); and, whose height (h) when divided by (Tc - x) is proportional to the value of (Qp/Tc). In other words;

$Vs = V_I - 1/2(Tc - X)(h)$ and,
referring to Figure A-1
$V_I = 1/2(2Tc)(Qp)$ or, $VI = (Tc)(Qp)$

by proportional triangles

$$\frac{h}{Tc - x} = \frac{Qp}{Tc} \quad \text{or,}$$

$$h = \frac{(Tc - x)\ (Qp)}{Tc}$$

Therefore, by substituting "h" into the first equation the total relationship may be expressed as follows:

$$Vs = (Vi) - 1/2\ (Tc - x)\ (Tc - x)\ (Qp)/Tc$$

Since $Vi = (Tc)\ (Qp)$ the equation may be simplified to read:

$$Vs = (Tc)\ (Qp) - \frac{(Tc - x)^2 (Qp)}{2Tc}$$

Rearranging and solving for the amount of time (x) past Tc in which the required storage is reached leads to the following:

$$Vs + \frac{(Tc - x)^2\ (Qp)}{2Tc} = (Tc)\ (Qp)$$

$$\frac{(Tc - x)^2 \quad (Qp)}{2Tc} = (Tc)(Qp) - Vs$$

R0071638

multiplying through by 2Tc/Qp yields;

$$(Tc - X)^2 = 2Tc^2 - \frac{2\ Vs\ Tc}{Qp}$$

$$Tc - X = \sqrt{2Tc^2 - \frac{2\ Vs\ Tc}{Qp}}$$

$$X = Tc - \sqrt{2Tc^2 - \frac{2\ Vs\ Tc}{Qp}}$$

Since the point at which the appropriate filtration volume is reach is equal to (Tc + X) as shown in Figure A-1, the time to the beginning of weir flow (t) may be calculated as follows:

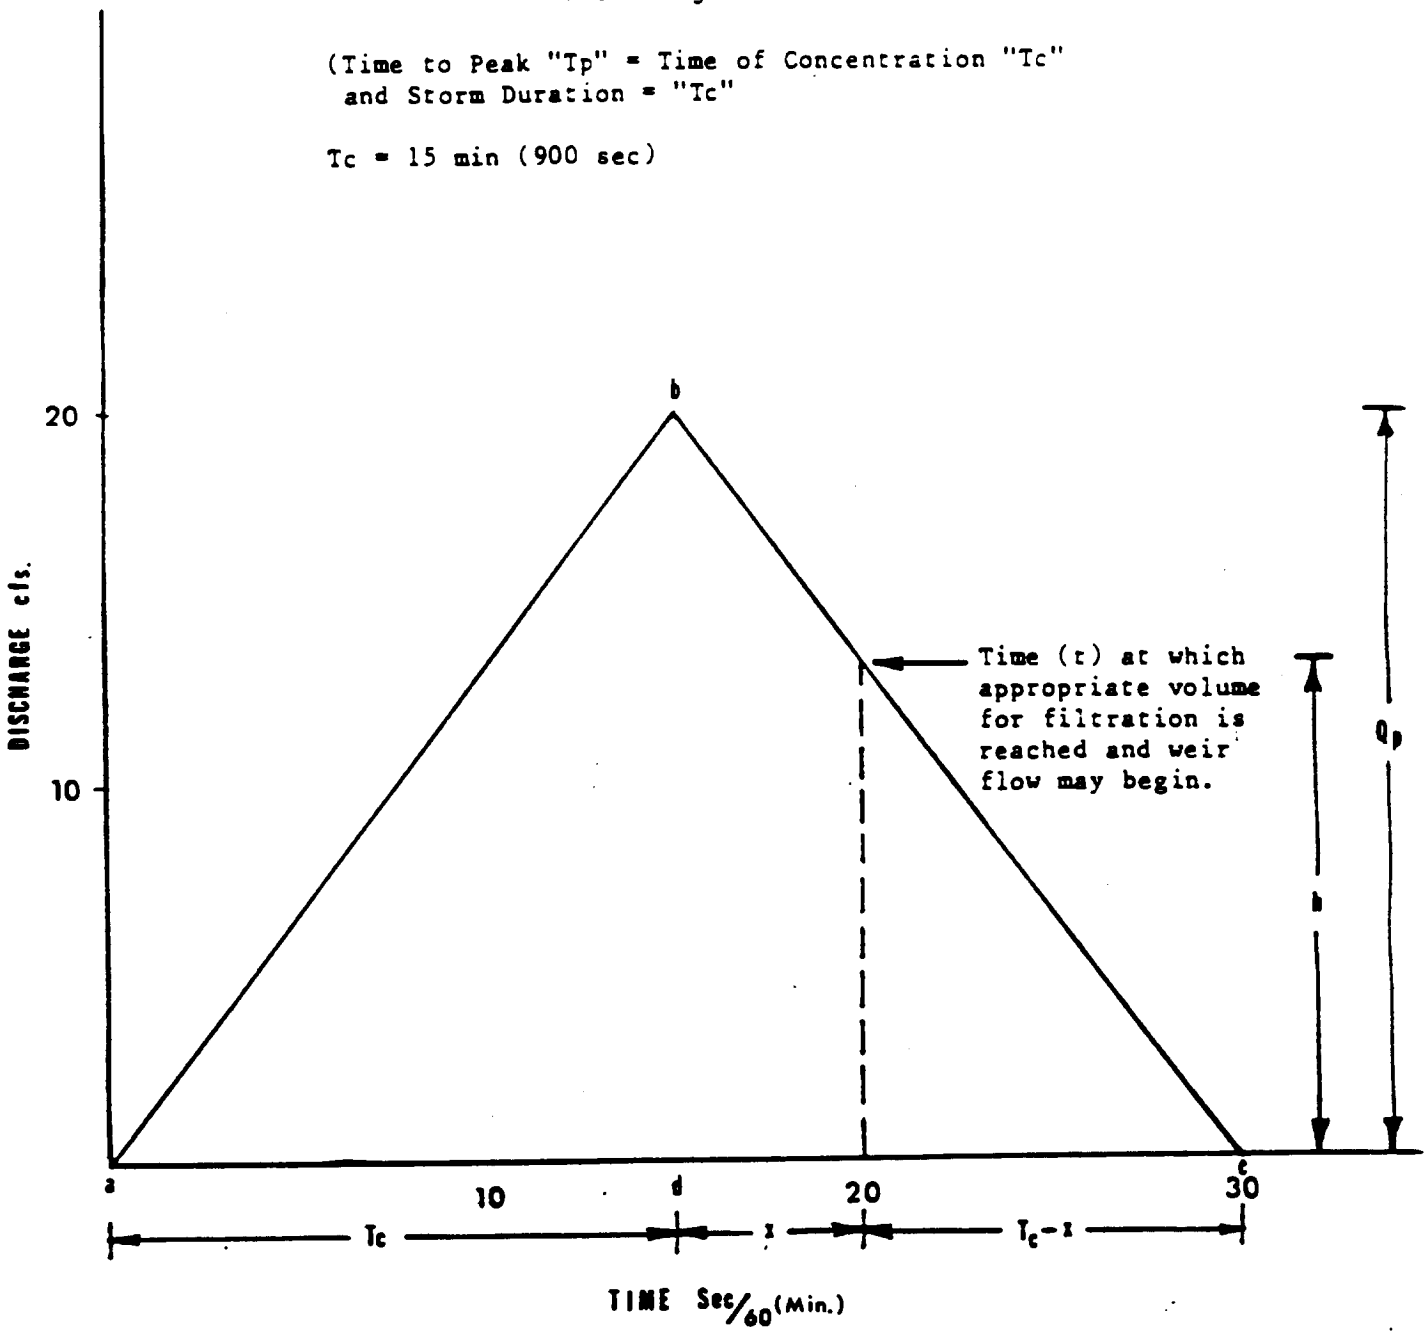
$$t = Tc + (Tc) - \sqrt{2Tc^2 - \frac{2Vs\ Tc}{Qp}} \text{ or,}$$

$$t = 2Tc - \sqrt{2Tc^2 - \frac{2Vs\ Tc}{Qp}} \quad \text{Equation A-1}$$

where;

t = Time for inflow volume to reach the appropriate storage volume such that weir flow for water quantity control may begin (sec.).

Tc = Time of concentration for the watershed following development (sec.)



Vs = Appropriate storage filtration volume for water quality treatment as specified in rule 17-25.03(2)(b), F.A.C. (ft^3).

Qp = The peak discharge expected from the design storm with a duration equal to the time of concentration (cfs).

R0071639

Figure A-1

Typical Rational Metnoc
Hydrograph for Peak
Producing Storm

R0071640

Appendix B

Derivation of the Equation for Calculating Time to 1/2" Storage Volume for Storm Duration Greater than Tc Based on Rational Method Analyses.

Assume: The 1/2" storage volume or the runoff from the first inch of rainfall occurs sometime following Tc.

Given: Rational Method hydrograph for a storm whose duration exceeds Tc represented by the trapezoidal figure inscribed by points abcd. The value of "b" and "c" representing the peak discharge of the hydrograph as measured on the left or vertical axis may be referred to as "Qp". The duration of the storm is equal to (Tc + bc) as illustrated in Figure B-1.

Question: At what point in time will the volume of inflow Vi = Vs the appropriate storage volume to satisfy the 17-25.03(2)(b) requirments?

Solution: This will occur at the point where the value of the volume of storage Vs is equal to the volume of inflow represented by a trapezoidal figure whose base is equal to the time of concentration (Tc) plus some distance (x), whose top length is equal to (x) and whose height is equivalent to the value of (Qp) the peak discharge of the hydrograph.

In equation form the relationship may be written:

$Vs = 1/2(Tc + 2x)(Qp)$ consequently;

$$Vs - \frac{Tc\ Qp}{2} = Qp(x)$$

multiplying through by $\frac{1}{Qp}$

$$x = \frac{Vs}{Qp} - \frac{Tc}{2}$$

Since the point at which the appropriate storage volume is reached is equal to distance (Tc + x) as illustrated in Figure B-1; the time to reach the point at which weir flow may begin (t) can be calculated as follows:

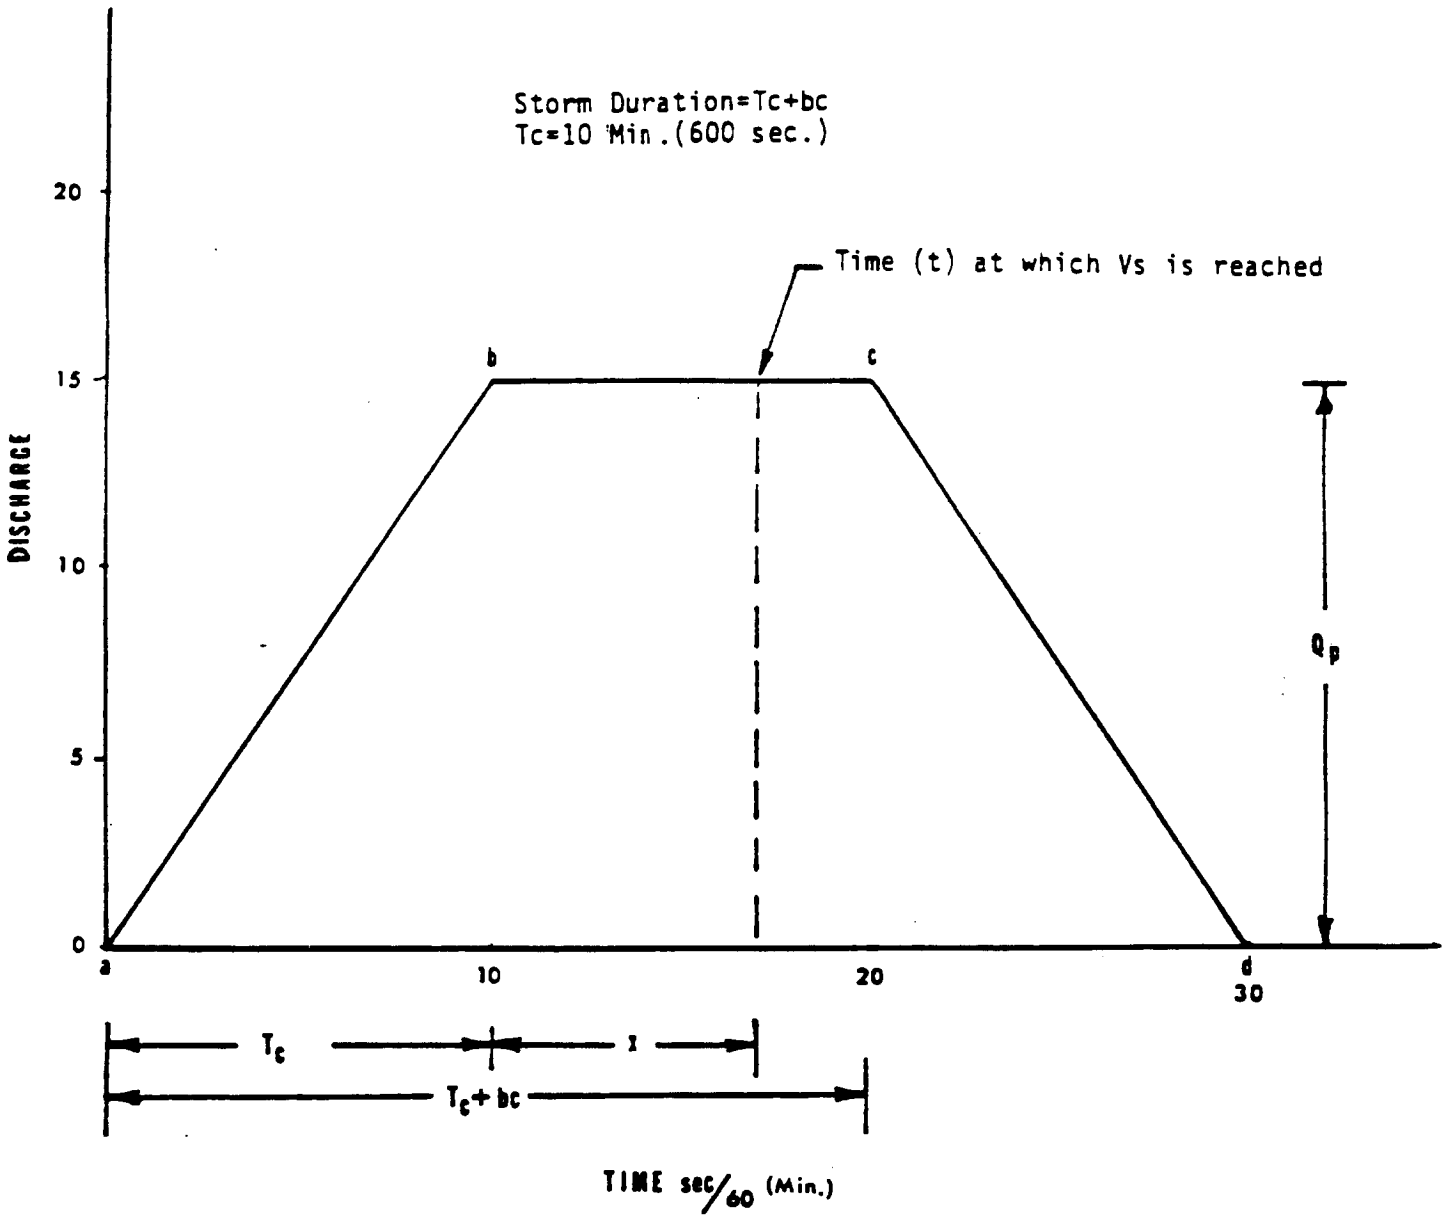
$$t = Tc + \frac{Vs}{Qp} - \frac{Tc}{2} \quad \text{or,}$$

$$t = \frac{Tc}{2} + \frac{Vs}{Qp} \qquad \text{Equation B-1}$$

Where;

R0071641

t = Time for inflow to reach the appropriate storage volume such that weir flow for water quantity control may begin (sec.).



Tc = Time of concentration for the watershed following development (sec).

Vs = 1/2 inch storage volume or runoff from the first inch of rainfall for filtration as required for water quality treatment in 17-25.03(2)(b), F.A.C. (ft^3)

Qp = The peak discharge expected from the design storm for the duration under consideration (cfs).

Figure B-1

Typical Rational Method Hydrograph
for Storm Duration Greater than the
Time of Concentration "Tc"

R0071643

Appendix C

When the appropriate storage volume is achieved prior to Tc the equations shown in Appendix A and B do not apply. However, the time required for inflow to equal the required filtration volume may be determined as follows:

Given: Triangle abc as shown in Figure C-1 in which line bc represents the peak discharge (Qp) from the design storm. Line ab represents the time of concentration "Tc" which is synonomous with the time to peak of the inflow hydrograph.

Question: Assuming the volume required for filtration or storage (Vs) is known, how long from the beginning of runoff will it take for the volume of inflow (V_I) to equal the appropriate value for (Vs)?

Solution: In reference to Figure C-1, when Vs is reached prior to the peak of the inflow hydrograph, the point in time (t) wherein V_I is equal to Vs may be represented by a right triangle whose base is equal to (Tc) minus some distance (X) and whose height (H_2) is proportional to (Qp) the peak associated with triangle abc or the rising leg of the hydrograph. In equation form these relationships may be expressed as follows:

$t = Tc - x$ and, (1)

$\frac{H_2}{Tc - x} = \frac{Qp}{Tc}$ or, (2)

$H_2 Tc = Qp (Tc - x)$ (3)

We also know based on the principles of hydrograph construction that the storage or filtration volume (Vs) is represented by the area under the hydrograph at some point "y". This area may be determined by the equation:

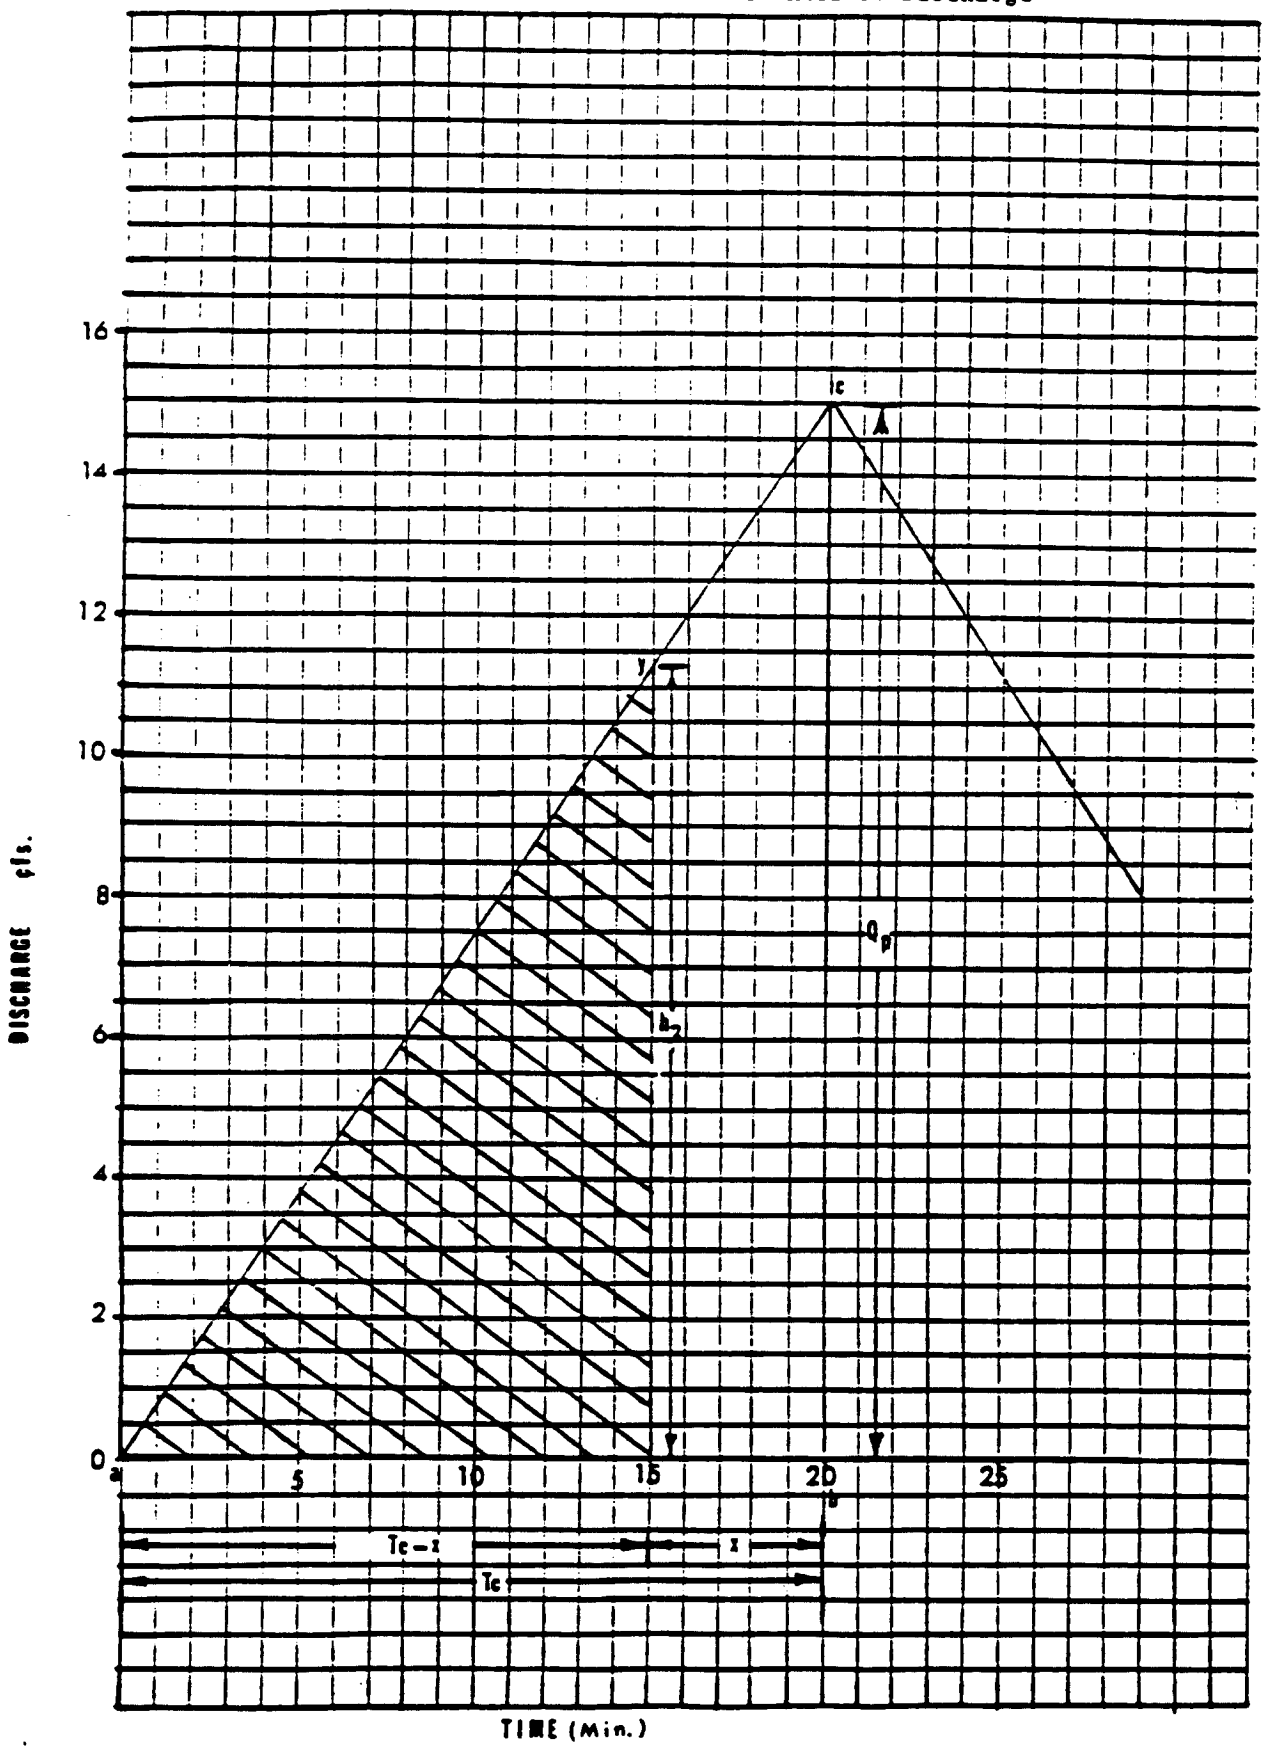
$Vs = 1/2(Tc - X)(H_2)$ or, (4)

$2Vs = (Tc - X)(H_2)$ (5)

solving for H_2

$H_2 = \frac{2Vs}{Tc - X}$ (6)

substituting into equation three



$\frac{2VS}{(Tc - X)}(Tc) = Qp(Tc - X)$ (7)

$2Vs\ (Tc) = Qp(Tc - X)^2$ (8)

$\frac{2Vs\ (Tc)}{Qp} = (Tc - X)^2$ (9)

R0071644

Figure C-1
Typical Rational Method Inflow Hydrograph Illustrating the Area Under the Curve When the 1/2 inch Storage Volume (Vs) is Reached Prior to the Peak Rate of Discharge

R0071645

Therefore;

$$(Tc - X) = \sqrt{\frac{2Vs\ (Tc)}{Qp}} \qquad (10)$$

(substituting into equation one.)

$$t = \sqrt{\frac{2Vs\ (Tc)}{Qp}} \qquad \text{Equation C-1}$$

Where:

t = Time for inflow volume to reach the appropriate storage volume and weir flow begins (sec.)

Tc = Time of concentration following development (sec.)

Vs = 1/2" storage volume or runoff from the first inch of rainfall for filtration as required in 17-25.03(2)(b) F.A.C. (ft^3)

Qp = Peak flow expected from the design storm for the duration under consideration (cfs).

APPENDIX 6-2

Discussion of Various Laboratory and Field Testing Procedures for Estimating the Hydraulic Conductivity or Coefficient of Permeability (K) of Soils and/or Filter Sands

The following exhibits are a compendium of several appendices to the design guidelines manual entitled "Underground Disposal of Stormwater Runoff", February 1980, published by the Federal Highway Administration. They have been reproduced with only minor alterations for information only with the intent of providing an aid to designers in the selection of the most appropriate testing procedure to be run. The actual test should always be conducted by professional soil scientist with experience in the proper testing procedures.

R0071647

LABORATORY PERMEABILITY METHODS

1. Constant-Head Test

In the constant-head test water flows through a test specimen under a measured hydraulic gradient (a constant amount of head is maintained) and through a known cross-sectional area (See Fig. D-3-1). Coefficient of permeability is calculated from Darcy's law arranged in the form:

$$k = \frac{q}{iA} = \frac{Q}{iAt} \qquad \text{(D-3.1)}$$

In Equation D-3.1, k is the calculated coefficient of permeability, Q is the total seepage quantity flowing in time t, $q = Q/t$ = the rate of quantity per unit of time, A is the cross-sectional area of test specimen (soil Sample) and i is the hydraulic gradient; the loss of hydraulic head per unit distance of flow, $\frac{H}{L}$.

EXAMPLE: Assume that 20 cu ft (0.56 m^3) of water flows through a test specimen with a cross-sectional area A = 1.0 sq ft (0.093 m^2), under the hydraulic gradient of 0.8, in 24 hours.

Then,

$k = q/iA$ = (20 cu ft/day)/(0.8x1.0 sq ft)

= 25 ft/day (7.63m/day)

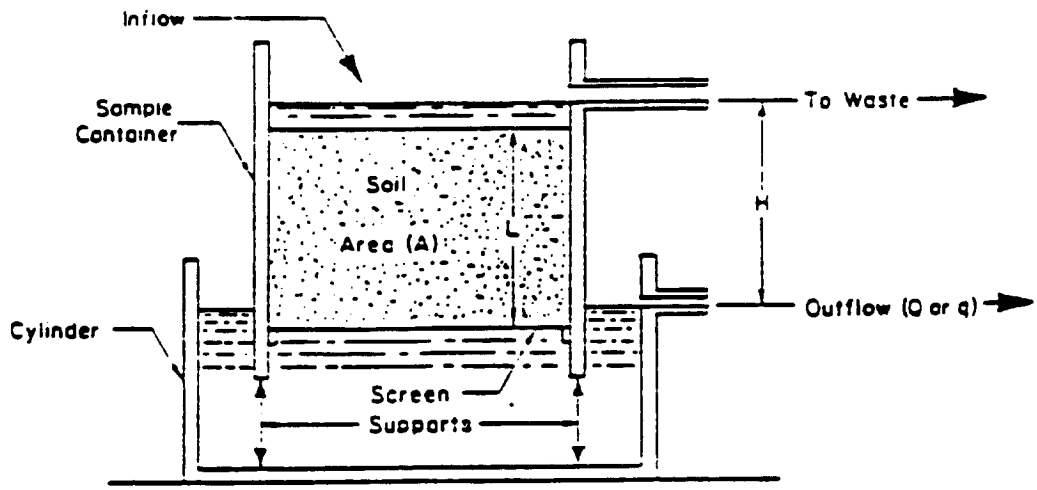


FIGURE D-3-1 CONSTANT-HEAD PERMEABILITY TEST

The constant-head test is used for determining the permeability of remolded samples of coarse-grained soils such as clean sands and gravels.

2. Falling-Head Test

In the falling-head test the amount of head inducing flow is allowed to decrease. By measuring the head at several time intervals in a small-diameter riser tube, while water is flowing through a soil specimen of greater cross-section area than the riser tube (see Fig. D-3-2), coefficient of permeability is calculated from the formula:

$$k = \frac{2.3aL}{A\,dt} \log_{10} \frac{h_o}{h_1} \qquad (D\text{-}3.2)$$

R0071649

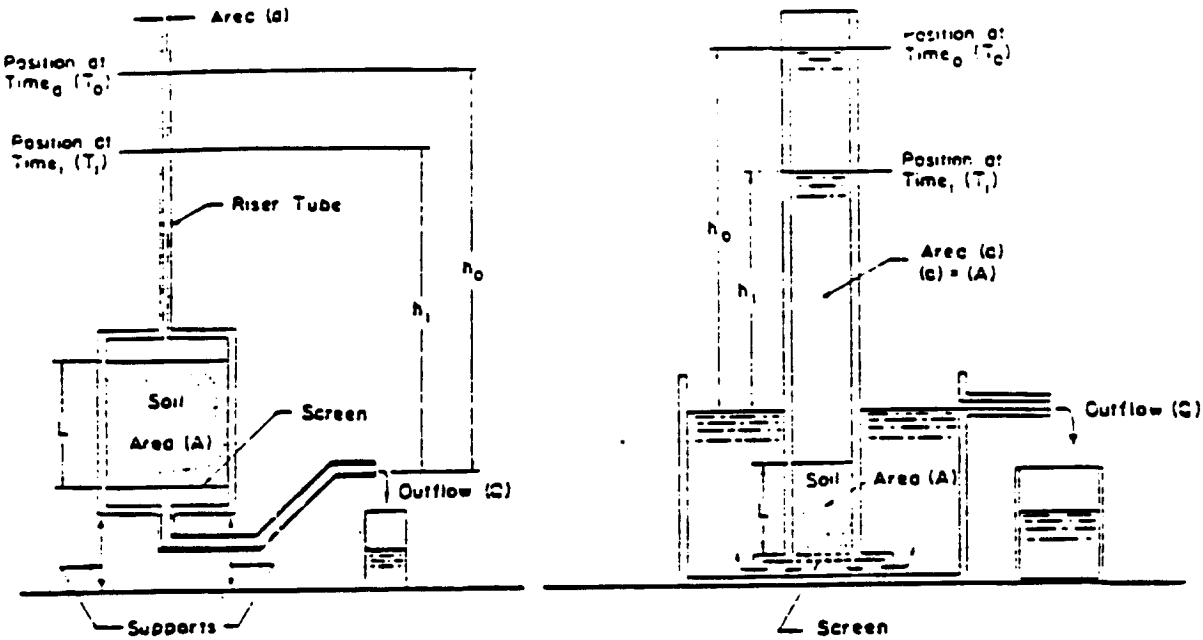

FIGURE D-3-2 FALLING HEAD PERMEABILITY TEST

In Equation D-3.2, a is the cross-sectional area of the riser tube, A is the cross-sectional area of the soil specimen, L is the length of the soil specimen, dt is the time interval during which the head drops from its initial value h_0 to some lower value, h_1.

EXAMPLE: Referring to Fig. D-3-2a, assume that h_0 = 3.0 ft (91 cm), h_1 = 2.5 ft (76 cm), dt = 6 hrs = 0.25 day, a = 0.01 sq ft (0.22 cm^2), A = 0.5 sq ft (465 cm^2), and L = 0.5 ft (15.24 cm). Using Equation D-3.2,

$$k = \frac{2.3aL}{A\,dt}\log_{10}\frac{h_0}{h_1}$$

$$= \frac{2.3(0.01)(0.5)}{0.5\ (0.25)}\log_{10}\frac{3.0}{2.5}$$

$$= (0.092)(0.079) = 0.0073 \text{ ft/day}.$$

$$(25.6\times10^{-7} \text{ cm/sec.})$$

R0071650

Figure D-3-2a and the above calculation pertain to tests on low permeability fine grained materials. If the material being tested has moderately high permeability, a falling-head test may often be made with the arrangement shown in Fig. D-3-2b, in which the cross-sectional area of the standpipe, a, is equal to the cross-sectional area of the sample, A, in Equation D-3.2. For very high permeability soils, the constant head test shown in Fig. D-3-1 is used.

In all laboratory tests, adequate precautions should be taken to minimize experimental errors. Many soil mechanics text books give the details and precautions. Generally test results are corrected to the viscosity of water at 20°C.

R0071651

FIELD PERMEABILITY METHOD FOR DESIGN
OF BASINS USING SINGLE RING TEST

Infiltration Test Specifications for Infiltration Basins with Low Water Tables (Contra Costa County Flood Control and Water Conservation District, California).

1. A 12-inch (0.304 m) diameter or larger steel pipe shall be driven into the ground a minimum distance of 12 inches (0.304 m).

2. The elevation of the ground within the pipe at the time of the test shall not vary more than one foot (0.3 m) from the final elevation of the infiltration basin.

3. A burlap sack or layer of gravel shall be placed on the soil surface within the pipe to avoid disturbance of the soil when water is poured in the pipe.

4. Water shall be put in the pipe to a depth of at least 6 inches (0.15 m) and the depth shall not exceed the depth of water in the final design of the infiltration basin. Water shall be added to the pipe when necessary to insure the ground within the pipe is always covered during the test.

5. Time measurements shall be taken for various drops in water surface within the pipe. Attached is a sample of the Infiltration Test Form (Figure D-4-1).

R0071652

6. The Infiltration Rate Curve shall be drawn using Accumulated Time from Beginning of Test in minutes as the abscissa and Infiltration Rate in inches per hour (mm/hr) as the ordinate. Refer to the typical plot on Figure D-4-2.

7. Each infiltration test shall be continuous and of sufficient duration such that the last three computed infiltration rates do not vary from each other by more than 5%.

8. A minimum of three infiltration tests shall be made for each infiltration basin and the locations of the tests shall be shown on a map.

9. The infiltration tests shall be performed under the direction of and certified by a civil engineer registered in the State of California.

10. If sufficient soil information is not available, additional soil information will be required to be furnished. This soil information shall be of the field test nature by a qualified soils technician. Depths from ground surface to beginning and end of each soil characteristic or texture shall be noted. The depth of the test hole shall not be less than six feet (1.83 m) and shall go to a depth sufficient to determine there is no layer restricting permeability.

FIELD PERMEABILITY METHOD FOR DESIGN OF BASINS USING DOUBLE RING TEST

Double Ring Method to Estimate Infiltration from Basins with Low Water Tables

At a site where an infiltration basin is planned (see Fig. D-5-1a) double-ring infiltrometer tests can be made at several locations with rings set to the planned bottom of the basin, as shown. If downward flow in the inner ring is essentially parallel, the measured infiltration rate I, can be used in estimating the drainage capability of the basin (as long as the water table is deep and the controlling flow is downward seepage, as shown in Fig. D-5-1b. For this example, the capability of the basin to discharge seepage is $Q = IA$, with Q being the capacity per day, I the vertical infiltration rate determined with the double ring infiltrometer, and A the area of the basin.

R0071655

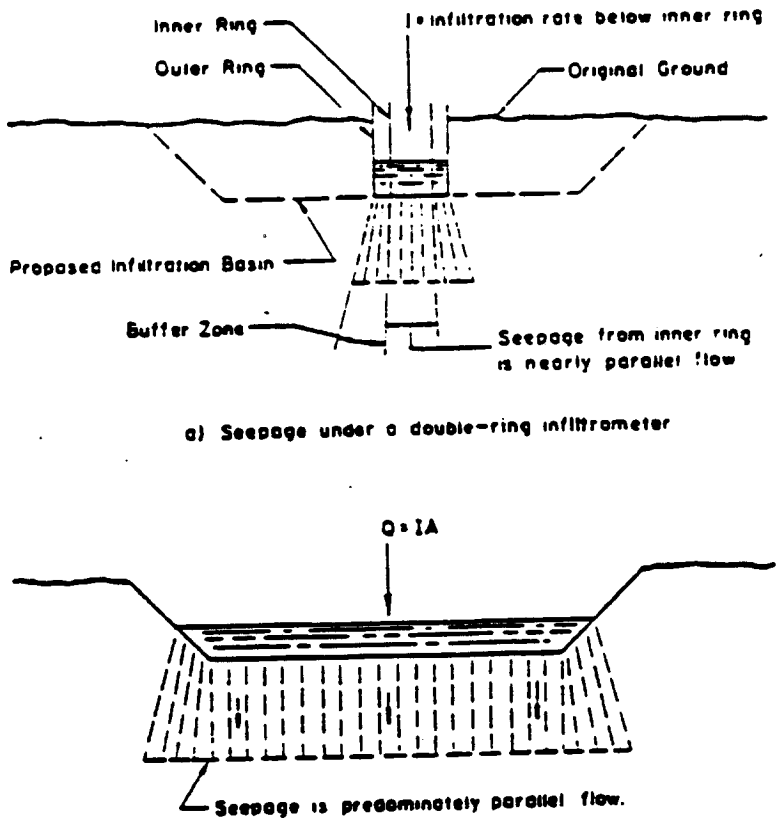

FIGURE D-5-1 DOUBLE-RING INFILTROMETER TO ESTIMATE SEEPAGE FROM INFILTRATION BASIN

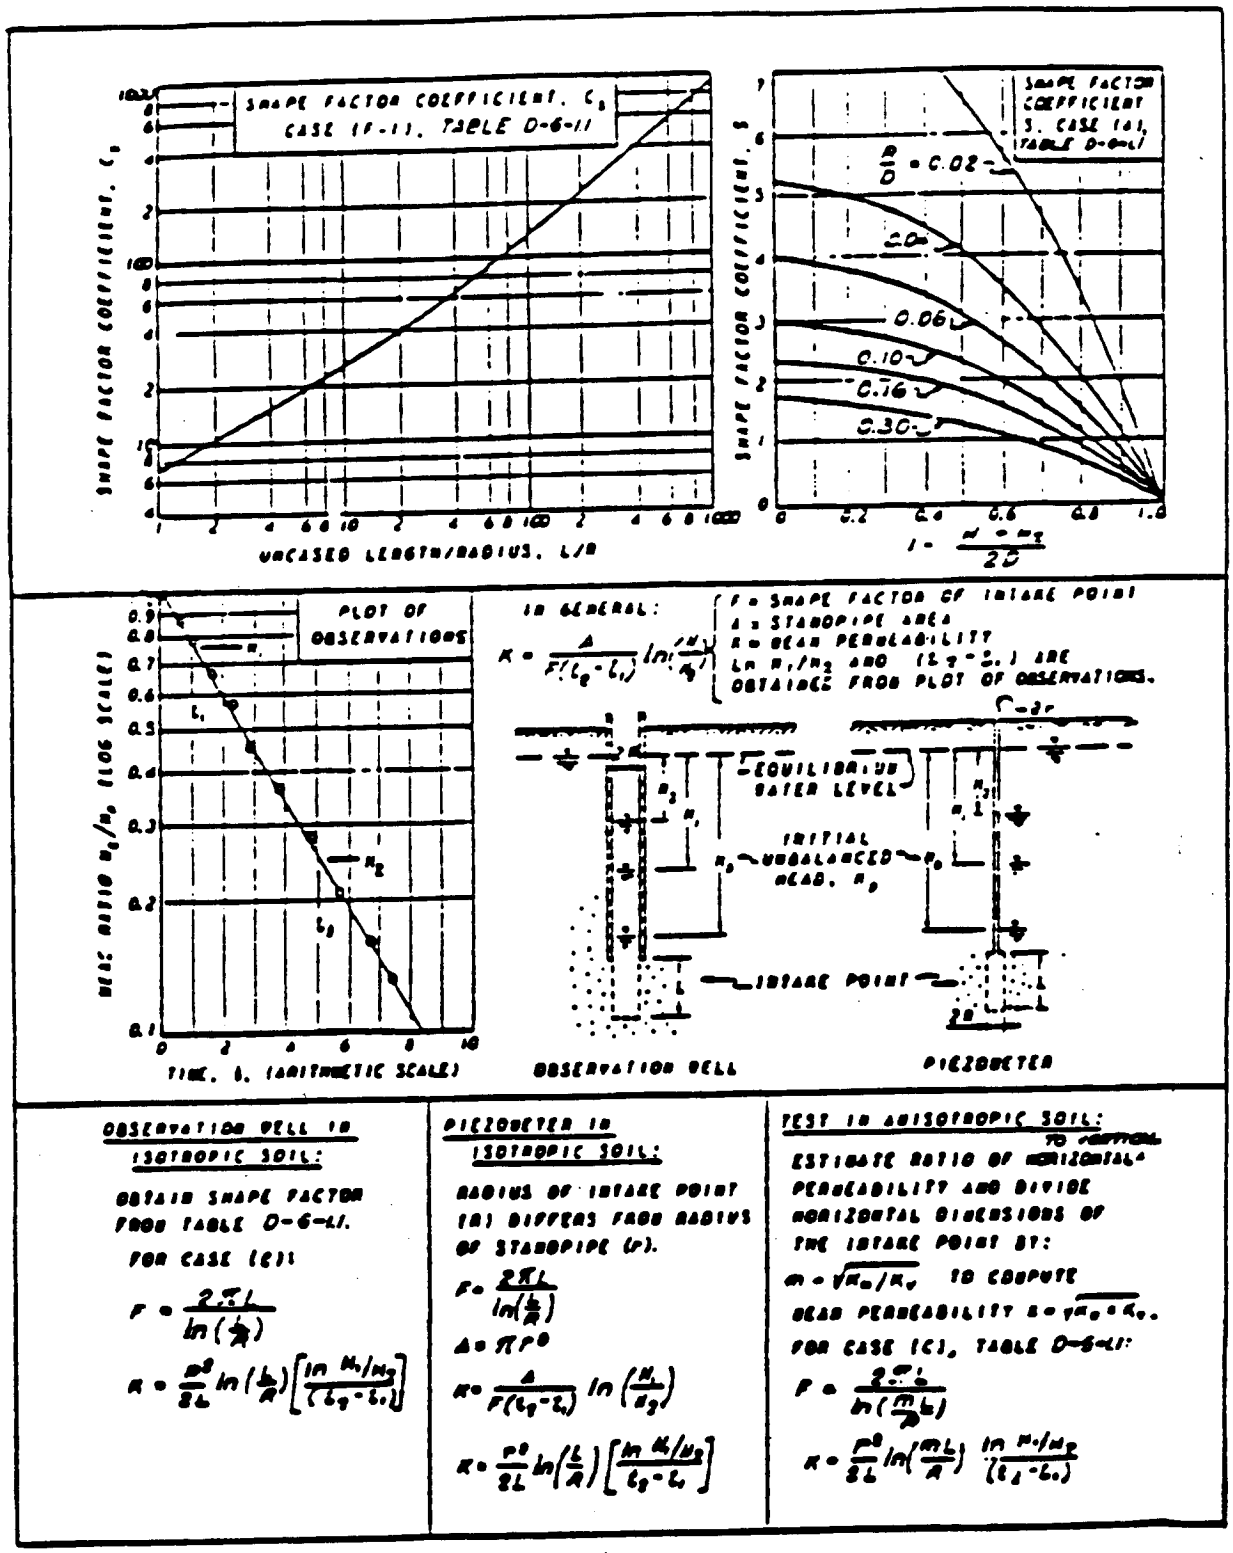
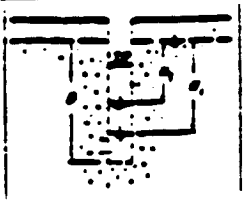
AUGER HOLE TESTS

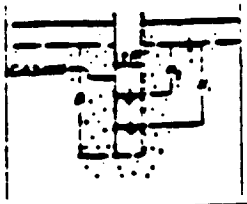
1. Variable Head Permeability Test

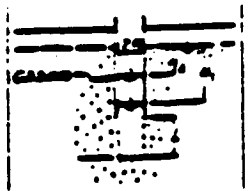
At selected points located within the limits of a proposed infiltration system, holes 9-inches (229 mm) in diameter or larger are bored to at least 2.5 feet (0.76 m) below the low-water elevation expected at the site, or at least 2.5 feet (0.76 m) below the existing water table, whichever is lower. The bottom 2.5 feet (0.76 m) of the hole must be kept open during a test, and if this cannot be accomplished with open auger holes, a 2-inch (50± mm) diameter wellpoint is put down or a cased hole is used. These tests, which may be called "variable head permeability tests" (U.S. Dept. of the Navy, Naval Facilities Engineering Command, 1974), offer a way of testing for the in situ permeabilities of soil formations. In making a test, the water level is either raised or lowered from the equilibrium level and allowed to recover while readings are made of water elevations versus elapsed time. Figure D-6-1.1 gives methods for analyzing the information. Table D-6-1.1 shows how to compute permeability using shape factors for various test configurations. If soils are anisotropic, a method for transforming the dimensions of the intake point of the piezometer or observation well is described in Fig. D-6-1.1. The Navy suggests that one "Assume various ratios of horizontal to vertical permeability until mean permeability determined from several piezometers is made equal". If tests are made in open-end or uncased boreholes, procedures and methods may be used as outlined in Table D-6-1.2.

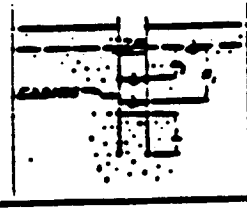
R0071657

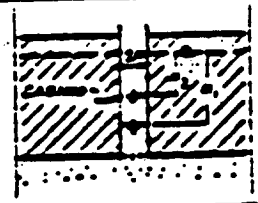












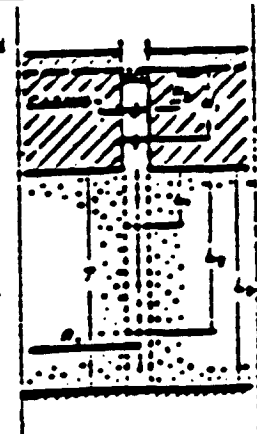


FIGURE D-6-1.1 ANALYSIS OF PERMEABILITY BY VARIABLE HEAD TESTS (NAVY, 1974)

TABLE D-6-1.1 SHAPE FACTORS FOR [illegible] PERMEABILITY FROM VARIABLE HEAD TESTS (NAVY, 1974)

	Condition	Diagram	Shape Factor, F	Permeability, K for variable head test	Applicability
OBSERVATION WELL OR PIEZOMETER IN SATURATED ISOTROPIC STRATUM OF INFINITE DEPTH	(A) Uncased hole		$F = \frac{2\pi L}{\ln(\frac{L}{r}) + A + B\frac{L}{r} - C\ln\frac{L}{r}}$	(for observation well of constant cross section) $K = \frac{r}{2L} \cdot \frac{(h_1 - h_2)}{(t_2 - t_1)}$ when $\frac{L}{r} < 50$	Summary curves for permeability determinations not applicable to stratified soils. For values of S see Fig. D-6-[illegible]
	(B) Cased hole, soil flows into casing.		$F = \frac{2\pi D}{L}$	$K = \frac{r^2 D}{2L(t_2 - t_1)} \ln(\frac{L}{r})$ when $\frac{L}{D} > 0.5$	Used for permeability determinations of small flow systems below the water table. May yield unreliable results in falling head test with silting of bottom of hole.
	(C) Cased hole, uncased or perforated extension of length "L".		$F = \frac{2\pi L}{\ln(\frac{L}{2r})}$	$K = \frac{r^2}{2L(t_2 - t_1)} \ln(\frac{L}{2r}) \ln(\frac{R}{r})$ when $\frac{L}{r} > 8$	Used for permeability determinations of greater systems below water table.
	(D) Cased hole, column of soil inside casing to height "L".		$F = \frac{\pi D^2}{2D + 4L}$	$K = \frac{D^2 \ln(2L/D)}{8L(t_2 - t_1)} \ln\frac{H_1}{H_2}$	Principal use is for permeability in vertical direction in anisotropic soils.
OBSERVATION WELL OR PIEZOMETER IN AQUIFER WITH RESERVOIRS UPPER LAYER	(E) Cased hole, casing flows with upper boundary of aquifer of infinite extent.		$F = 4R$	$K = \frac{r^2}{2R(t_2 - t_1)} \ln(\frac{H_1}{H_2})$	Used for permeability determinations where aquifer thickness is relatively thin. May yield unreliable results in falling head test with silting of bottom of hole.
	(F) Cased hole, uncased or perforated extension and aquifer of finite thickness: a) $\frac{L}{r} \geq 8.0$ b) $2.0 < \frac{L}{r} < 8.0$ c) $\frac{H}{r} < 1.00$ Note: R_e equals effective radius of aquifer at casing hole.		(1) $F = C_e R$	$K = \frac{r^2}{2C_e(t_2 - t_1)} \ln(\frac{L_e}{r})$	Used for permeability determinations of systems greater than about 5 ft. For values of C_e see Fig. D-6-[illegible]
			(2) $F = \frac{2\pi L_e}{\ln(\frac{L_e}{r})}$	$K = \frac{r^2 \ln(L_e/r)}{2L_e(t_2 - t_1)} \ln(\frac{L_e}{r})$ when $\frac{L_e}{r} > 8$	Used for permeability determinations of greater systems and for less pervious soils using pervious intake zones of considerable length.
			(3) $F = \frac{2\pi L_e}{\ln(\frac{L_e}{2r})}$	$K = \frac{r^2 \ln(\frac{L_e}{2r})}{2L_e(t_2 - t_1)} \ln(\frac{L_e}{r})$	Assume value of $\frac{R_e}{R} = 1$ for conditions where observations wells are used to determine actual value of R_e.

R0071659

TABLE D-6-1.2 MEASUREMENTS OF SOIL PERMEABILITY IN SITU (NAVY, 1974)

Property determined and name of test	Test application	Test equipment and procedure
Permeability:		
Pumping test	Applied for evaluation of problem of large scale drawdown or dewatering in materials with substantial variation in permeability.	Rate at which water is pumped from a central test well is measured while the drawdown or radial lines extending from the well is observed in a series of piezometers or observation holes. Provide 3 to 5 observation wells spaced at increasing intervals along two radial lines separated by 90 degree central angle.
Variable head test	Used to obtain individual permeability determinations in piezometers. Performed in porous tube or wellpoint piezometers which have been placed in boreholes with their intake point isolated by impervious seal.	Standpipe water level is raised or lowered from its equilibrium position and readings are taken of water levels at periodic intervals as it returns to equilibrium. Observations of differential head and time elapsed are analyzed as shown in Figure D-6-11.
Borehole test	Used to determine permeability of individual strata penetrated by borings.	May be performed in a cased, open-end borehole or an uncased borehole with double packers. Rate at which water flows out of the borehole under a constant head is measured. Use equipment and procedures of USBR Method E-18.
Auger hole test	Performed in shallow uncased auger hole. May be used in unsaturated material where the water table during testing is at a great depth below the base of hole.	Rate at which water flows out of the uncased hole is measured maintaining a constant water level in the hole. Use equipment and procedures of USBR Method E-19.

R0071660

2. Auger Hole Percolation Test of U.S. Dept of Health, Education, and Welfare

This method is described in Public Health Service Publication No. 526, "Manual of Septic-Tank Practice". It has been modified as presented below for use in determining infiltration rates for design of basins or other infiltration systems.

Percolation Tests

These percolation tests can be used to determine the acceptability of the site and establish the design size of the subsurface disposal system. The length of time required for percolation tests will vary in different types of soil. The safest method is to make tests in holes that have been kept filled with water for at least 4 hours, preferably overnight. This is particularly desirable if the tests are to be made by an inexperienced person. In some soils, such as those that swell upon wetting, it is necessary even if the individual has had considerable experience. Percolation rates should be figured on the basis of the test data obtained after the soil has had opportunity to become wetted or saturated and has had opportunity to swell for at least 24 hours. Enough tests should be made in separate holes to assure that the results are valid.

Procedure

1. Number and location of tests. - Six or more tests shall be made in separate test holes spaced uniformly over the proposed site.

2. Type of test hole. - Dig or bore a hole with horizontal dimensions of from 4 to 12 inches (0.1 to 0.3 m) and vertical sides to the depth of the proposed infiltration system. To minimize time, labor, and volume of water requirements per test, holes can be bored with a small hand auger.

3. Preparation of test hole. - Carefully scratch the bottom and sides of the hole with a knife blade or sharp-pointed instrument to disrupt any smeared soil surfaces and to provide a natural soil interface into which water may percolate. Remove all loose material from the hole. Add 2 inches (0.05 m) of coarse sand or fine gravel to protect the bottom from scouring and sediment (Fig. D-6-2.1.).

4. Saturation and swelling of the soil. - It is important to distinguish between saturation and swelling Saturation means that the void spaces between soil particles are full of water. This can be accomplished in a short period of time. Swelling is caused by intrusion of water into the individual soil particle. This is a slow process, especially in clay-type soil, and is the reason for requiring a prolonged soaking period.

In conducting the test, carefully fill the hole with clear water to a minimum depth of 12 inches (0.3 m) over the gravel.. In most soils, it is necessary to refill the hole by supplying a surplus reservoir of water, possibly by means of an automatic syphon, to keep water in the hole for at least 4 hours and preferably overnight Determine the percolation rate 24 hours after water is first added to the hole. This procedure is to insure

that the soil is given ample opportunity to swell and approach the condition it will assume during the wettest season of the year. Thus, for a particular soil, the test will give comparable results whether made in a dry or in a wet season. In sandy soils containing little or no clay, the swelling procedure is not essential, and the test may be made as described under item 5C, below, after the water from one filling of the hole has completely seeped away. Refer to Fig. D-6-2.1.

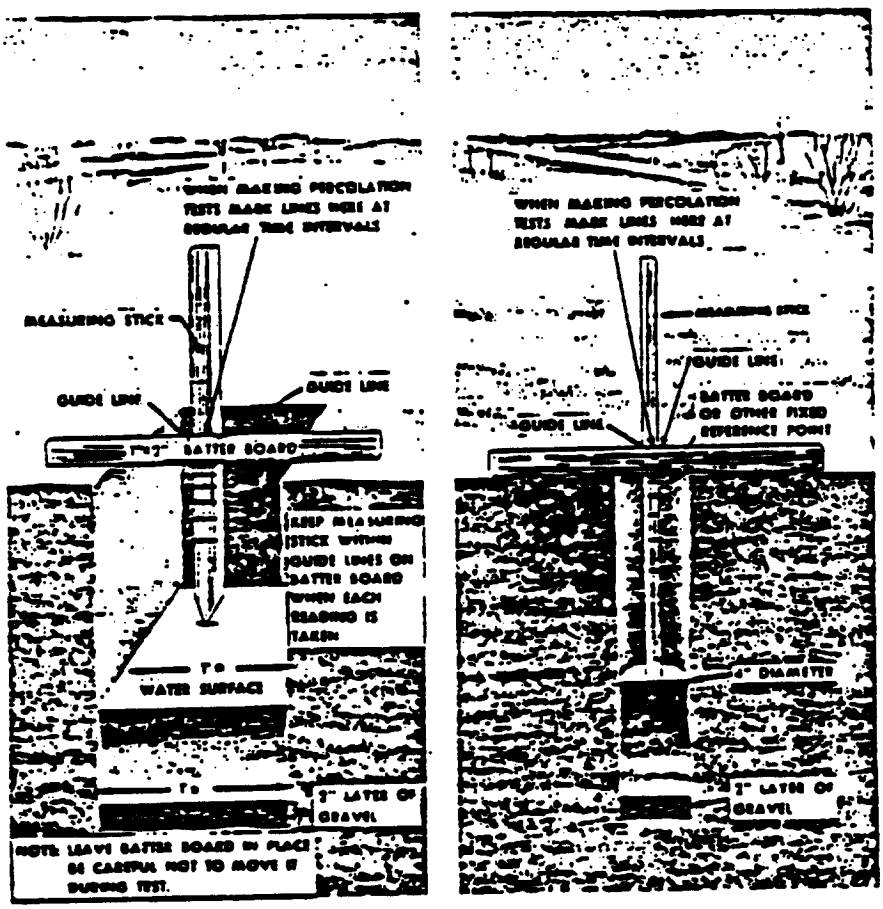

FIGURE D-6-2.1 METHODS OF MAKING PERCOLATION TESTS (FROM U.S.DEPT. OF HEW)

R0071663

5. Percolation-rate measurement. - With the exception of sandy soils, percolation-rate measurements shall be made on the day following the procedure described under item 4, above.

A. If water remains in the test hole after the overnight swelling period, adjust the depth to approximately 6 inches (0.15 m) over the gravel. From a fixed reference point, measure the drop in water level over a 30 minute period. This drop is used to calculate the percolation rate.

B. If no water remains in the hole after the overnight swelling period, add clear water to bring the depth of water in the hole to approximately 6 inches (0.15 m) over the gravel. From a fixed reference point measure the drop in water level at approximately 30 minute intervals for 4 hours, refilling 6 inches over the gravel as necessary. The drop that occurs during the final 30 minute period is used to calculate the percolation rate. The drops during prior periods provide information for possible modification of the procedure to suit local circumstances.

C. In sandy soils (or other soils in which the first 6 inches (0.15 m) of water seeps away in less than 30 minutes, after the overnight swelling period), the time interval between measurements shall be taken as 10 minutes and the test run for one hour. The drop that occurs during the final 10 minutes is used to calculate the percolation rate.

APPENDIX 6-3

Design of Exfiltration Trenches to Meet South Florida Water Management District (SFWMD) Regulatory Criteria

The following is a discussion from the SFWMD "Permit Information Manual, Volume IV," June 1986. Detailed information is provided on various field permeability testing procedures and trench design equations in order for an exfiltration system to satisfy the Districts' surface water quantity and water quality management criteria. Since SFWMD has been delegated stormwater quality permitting authority under the provisions of Chapter 17-25, F.A.C. these criteria represent the state standards pertinent to the design of these systems within the District boundaries. However, the reader should be advised that at this time, the specifications contained herein are not necessarily applicable in other areas of the State.

V. Exfiltration Trenches

A. From Paragraph 3.2.2.7 of the Basis of Review:

3.2.2.7 Underground Exfiltration Systems

a. Systems shall be designed for the retention volumes specified in Section 3.2.2.2 for retention systems, exfiltrated over one hour for retention purposes, prior to overflow, and based on test data for the site. (Note: such systems should not be proposed for projects to be operated by entities other than single owners or entities with full time maintenance staff.)

b. A safety factor of two or more shall be applied to the design to allow for geological uncertainties.

c. A dry system is one with the pipe invert at or above the average wet season water table.

Paragraph 3.2.2.2.b. is the requirement that projects with commercial or industrial zoning must provide dry pretreatment. Obviously, a project which falls into this category and is being designed to meet the criteria by using trench must have the pipe invert at or above the wet season water table. It is also a requirement that no gravity discharge from the trench system be allowed below the elevation of the top of the perforated pipe.

B. Two field test procedures for determining hydraulic conductivity will be described next. The first is the usual constant head test, the second is the falling-head test, which may be utilized in areas of excellent percolation, and when difficulty "keeping the hole filled" is encountered.

REFERENCED SECTION

3.2.2 Water quality

3.2.2.1 State standards - Projects shall be designed so that discharges will meet State water quality standards, as set forth in Chapter 17-3, Florida Administrative Code.

3.2.2.2 Retention/detention criteria

a. Retention and/or detention in the overall system, including swales, lakes, canals, greenways, etc., shall be provided for one of the three following criteria or equivalent combinations thereof (Note: Appendix 3 may be utilized where the conditions therein can be met):

1. Wet detention volume shall be provided for the first inch of runoff from the developed project, or the total runoff of 2.5 inches times the percentage of imperviousness, whichever is greater.

R0071666

2. Dry detention volume shall be provided equal to 75 percent of the above amounts computed for wet detention.

3. Retention volume shall be provided equal to 50 percent of the above amounts computed for wet detention. Retention volume included in flood protection calculations requires a demonstration of guarantees of long term operation and maintenance of system bleed-down ability. This must normally consist of proof of excellent soil percolation rates (example: coastal ridge sands) or an operations entity which specifically reserves funds for operation, maintenance and replacement (example: Orange County MSTU). (NOTE: Orange County subdivision regulation criteria for retention may be utilized for Orange County MSTU projects in lieu of District retention criteria where retention volumes exceed one half inch.)

b. Commercial or industrial zoned projects shall provide at least one half inch of dry detention or retention pretreatment as part of the required retention/detention, unless reasonable assurances can be offered that hazardous materials will not enter the project's surface water management system. Such assurances may include deed restrictions on sale property occupancy, recorded lease agreements, local government restrictive codes, ordinances, licenses, engineered containment systems, etc.

c. Systems with inlets in grassed areas will be credited with up to 0.2 inches of the required wet detention amount for the contributing areas. Full credit will be based on a ratio of 10:1 impervious area runoff to pervious area with proportional credit granted for greater ratios.

d. Projects having greater than 40% impervious area and which discharge directly to sensitive receiving water shall provide at least one half inch of dry detention or retention pretreatment as part of the required retention/detention. Sensitive receiving waters are defined as:

1. Class I or Class II waters

2. Outstanding Florida waters

3. Water bodies within a District permitted public water supply wellfield cone-of-depression which are not separated from the aquifer by strata at least ten feet thick, having an average saturated hydraulic conductivity of less than 0.1 foot per day; where the cone-of-depression is defined by one of the following: 1) in those areas of the District where no local wellfield protection ordinance has been adopted by the local governing body, the one foot drawdown line as expressed in the water table aquifer under conditions of no rainfall and 100 days of pumpage at the permitted average daily pumpage rate (where significant canal recharge is indicated, canal recharge representative of a 1 in 100 year drought will be considered). 2) Broward County Wellfield Protection Ordinance contour for Zone 3. 3) Dade County Wellfield Protection Ordinance contour showing maximum limits.

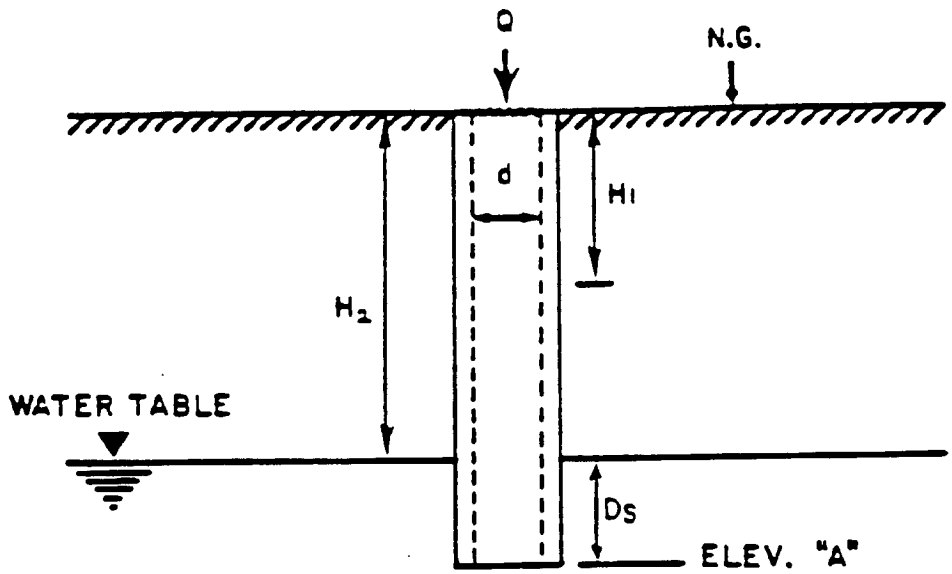
e. Water surface and roofed areas can be deducted from site areas for water quality pervious/impervious calculations.

f. Different standards may be applied to urban public highway projects.

1. Usual Condition Test

The usual test performed is an open-hole test which is either uncased or cased with fully perforated casing. The procedure is described as follows:

a. Auger a 6 to 9 inch diameter hole to a depth below the ground surface equivalent to the design depth of trench (usually 4 to 6 feet).



b. Record the distance from the ground surface to the water table prior to the addition of test water.

c. If hole walls are unstable lower screen or fully-perforated casing into the hole.

d. Fill hole with water and maintain water level at ground surface. Record rate of pumping in g.p.m. giving direct readings from water meter at fixed intervals of one minute or greater. Continue recording rate of pumping for 10 minutes following the stabilization of the recorded pumping rate.

Figure C-46 shows a cross-section of the test hole with a formula relating the hydraulic conductivity to the field information. The hydraulic conductivity obtained by this method may be either greater or less than the effective trench hydraulic conductivity depending upon the relative hydraulic conductivity of the surface layers.

USUAL OPEN - HOLE TEST

$$K = \frac{4Q}{\pi d(2H_2^2 + 4H_2 D_S + H_2 d)}$$

K = HYDRAULIC CONDUCTIVITY (CFS/FT.^{2} - FT. HEAD)

Q = "STABILIZED" FLOW RATE (CFS)

d = DIAMETER OF TEST HOLE (FEET)

H_2 = DEPTH TO WATER TABLE (FEET)

D_S = SATURATED HOLE DEPTH (FEET)

ELEV. "A" = PROPOSED TRENCH BOTTOM ELEV.

H_1 = AVERAGE HEAD ON UNSATURATED HOLE SURFACE (FT. HEAD)

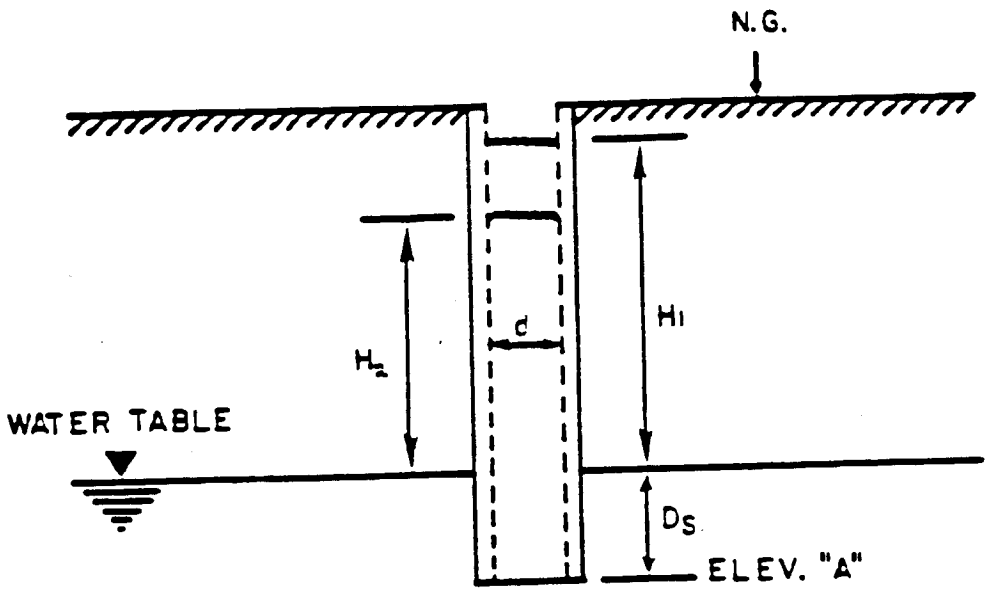
Figure C-46

R0071669

2. Falling-head Test

The falling-head test is an open-hole test which is either un-cased or cased with fully-perforated casing. The procedure is described as follows:

a. Auger a 6 to 9 inch diameter hole to a depth below the ground surface equivalent to the design depth of the trench (usually 4 to 6 feet).



b. Record the distance from the ground surface to the water table prior to the addition of test water.

c. If hole walls are unstable lower screen or fully-perforated casing into the hole.

d. Fill hole with water and maintain water level at ground surface. Cease adding water and measure the water level versus elapsed time in equal time increments, usually in 15-second increments. Continue measuring water level until it has dropped at least half the distance to the water table.

Figure C-47 shows a cross-section of the test hole with a formula relating the hydraulic conductivity to the field information.

FALLING - HEAD OPEN - HOLE TEST

$$K = \frac{d \ln (H_1/H_2)}{(2H_1+2H_2+4D_S+d)(t_2-t_1)}$$

K = HYDRAULIC CONDUCTIVITY (CFS/FT.^{2}-FT. HEAD)

d = DIAMETER OF TEST HOLE (FEET)

H_1 = HEIGHT OF WATER IN HOLE ABOVE WATER TABLE AT TIME, t_1

H_2 = HEIGHT OF WATER IN HOLE ABOVE WATER TABLE AT TIME, t_2

D_S = SATURATED HOLE DEPTH (FEET)

ELEV. "A" = PROPOSED TRENCH BOTTOM ELEV. (FT.-NGVD)

t_1, t_2 = TIME, SECONDS

Figure C-47

R0071671

3. Analysis of Test Data

In this section actual test data which was compiled during a field test of the "usual" case will be described and the soil permeability calculated. The test was performed on a piece of property in Broward County, Florida. The test hole was 9 inches in diameter augered to a depth of 6 feet. A 9 inch diameter by 72 inch long perforated casing was set in the hole. The depth to the water table prior to introduction of test water was 5.3 feet below the ground. The field data collected during the test is shown in Table C-3.

Taking the total flow into the test hole during the 75 minute test period and dividing by 75 minutes, since there was no significant variation in flow during the test, yields an average flow rate, Q, of 3.46 g.p.m., which is equivalent to 7.71×10^{-3} cfs. The diameter of the test hole, D, was 0.75 foot. The saturated hole depth, Ds, was equal to the depth of the hole, 6 feet, minus the depth to the water table, 5.3 feet, which is equal to 0.7 foot.

Utilizing the formula from Figure C-46:

$$K = \frac{4Q}{\pi d(2H_2^2 + 4H_2D_s + H_2d)}$$

$$K = \frac{4(7.71 \times 10^{-3})}{\pi(0.75)(2(5.3)^2 + 4(5.3)(0.7) + (5.3)(0.75))}$$

$$K = \underline{1.75 \times 10^{-4} \text{cfs/ft}^2\text{ft.head}}$$

R0071672

R0071673

4. Design of Trenches

Since the first publication of Volume IV, Permit Information Manual additional consideration has been given to the derivation of an acceptable exfiltration trench design formula. The latest development is shown on Figure C-48 along with the description of the appropriate parameters. The derivation of this trench sizing formula is given in the Appendix along with the derivations of the formulae used for use with the field testing procedures.

An example of the use of this formula with the data from the Broward County test site follows:

$$L = \frac{CAR}{K(H_2W + 2H_2Du - Du^2 + 2H_2D_s) + (1.39 \times 10^{-4})WDu}$$

C = 0.60

A = 10.0 Acres

R = 2.5 Inches

K = 1.75×10^{-4} CFS/FT.^{2}-FT.HEAD

H_2 = 5.0 Feet (Design Condition)

W = 4.0 Feet

D_u = 2.5 Feet

D_s = 1.5 Feet

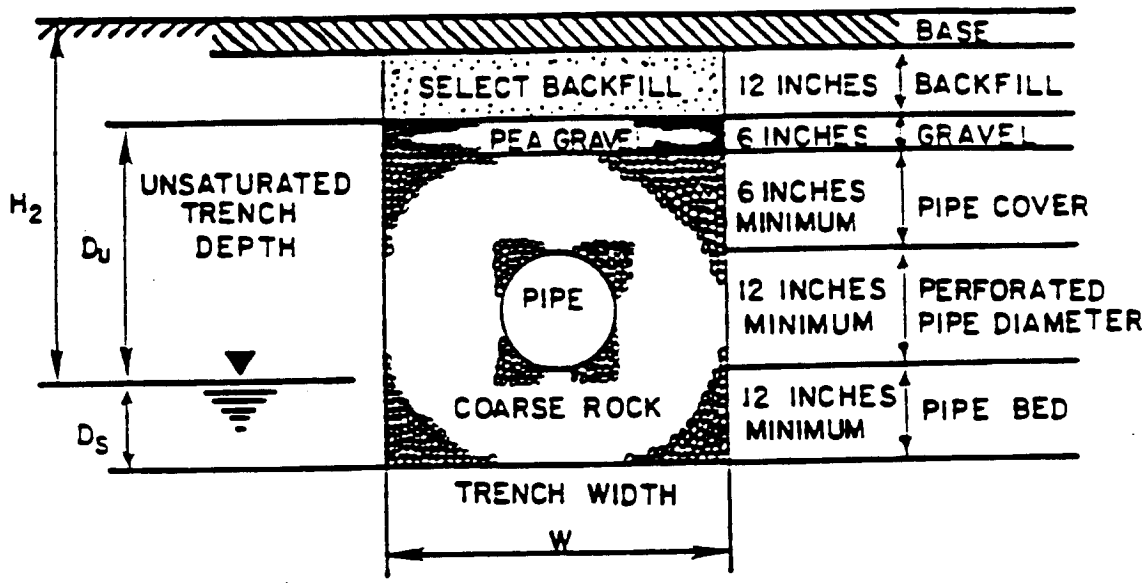
H = $D_u + D_s$ = 4.0 Feet

Solving for L gives,

L = 1389 feet of 4' x 4' exfiltration trench.

This formula can be used for sizing exfiltration trenches to meet SFWMD criteria as it is since it already takes into consideration both a Safety Factor of 2 and the 50% credit for retention systems as opposed to detention systems.

R0071674



For those situations when either: (1) the saturated depth of trench is greater than the non-saturated depth of trench; or (2) the trench width is greater than two times the total trench depth, the proportional assumptions for flow out the trench bottom are probably not valid. A conservative design formula for use in these cases would be:

$$L = \frac{CAR}{K(2H_2Du - Du^2 + 2H_2Ds) + (1.39 \times 10^{-4})WDu}$$

As with any design method a good amount of engineering judgement must be applied for use on site-specific cases.

R0071675

TYPICAL EXFILTRATION TRENCH

$$L = \frac{CAR}{K(H_2W + 2H_2Du - Du^2 + 2H_2Ds) + (1.39 \times 10^{-4})WDu}$$

L = LENGTH OF TRENCH REQUIRED (FEET)

C = RUNOFF COEFFICIENT (RATIONAL RUNOFF METHOD)

A = CONTRIBUTING AREA (ACRES)

R = ONE-HOUR DESIGN RAINFALL (INCHES)

W = TRENCH WIDTH (FEET)

K = HYDRAULIC CONDUCTIVITY (CFS/FT.^{2}-FT.HEAD)

H_2 = DEPTH TO WATER TABLE (FEET)

Du = NON-SATURATED TRENCH DEPTH (FEET)

D_S = SATURATED TRENCH DEPTH (FEET)

Figure C-48

R0071676

APPENDIX

DERIVATION OF EQUATIONS

R0071677

I. USUAL OPEN-HOLE TEST

$$K = \frac{Q}{S_1 H_1 + S_2 H_2} \qquad \text{(EQ. 1)}$$

FROM FIGURE C-46:

H_2 = DEPTH TO WATER TABLE (FT.)
D_S = SATURATED DEPTH OF HOLE (FT.)
d = DIAMETER OF HOLE (FT.)

$S_1 = H_2 \pi d$ (EQ. 2)

$S_2 = D_S \pi d + \frac{1}{4} \pi d^2$ (EQ. 3)

$H_1 = \frac{1}{2} H_2$ (EQ. 4)

SUBSTITUTING INTO EQUATION 1:

$$K = \frac{Q}{\left[(H_2 \pi d)(\frac{1}{2} H_2) + (D_S \pi d + \frac{1}{4} \pi d^2)(H_2)\right]}$$

$$K = \frac{4Q}{\pi d (2H_2^2 + 4H_2 D_S + H_2 d)} \qquad \text{(EQ. 5)}$$

R0071678

II. FALLING-HEAD OPEN-HOLE TEST

$$Q = KSH \qquad \text{(EQ. 1)}$$

WHERE, Q = AVERAGE FLOW RATE (CFS)
K = HYDRAULIC CONDUCTIVITY (CFS/FT.^{2} - FT. HEAD)
S = SURFACE AREA OF HOLE (FT.^{2})
H = HEAD ON SURFACE AREA OF HOLE (FT. HEAD)

AND

$$Q = -\frac{\pi d^2}{4}\frac{dH}{dt} \qquad \text{(EQ. 2)}$$

Q = AVERAGE FLOW RATE (CFS)
d = DIAMETER OF HOLE (FEET)
dH = CHANGE IN HEAD (FT. HEAD)
dt = CHANGE IN TIME (SECONDS)

EQUATING EQ. 1 AND EQ. 2:

$$KSH = -\frac{\pi d^2}{4}\frac{dH}{dt} \qquad \text{(EQ. 3)}$$

$$\frac{4KS}{\pi d^2}\,dt = -\frac{dH}{H}$$

$$\int_{t_1}^{t_2} \frac{4KS}{\pi d^2}\,dt = \int_{H_1}^{H_2} -\frac{dH}{H}$$

$$\frac{4KS}{\pi d^2}(t_2 - t_1) = \ln(H_1/H_2)$$

$$K = \frac{\pi d^2 \ln(H_1/H_2)}{4S(t_2 - t_1)} \qquad \text{(EQ. 4)}$$

S = SURFACE AREA OF HOLE, EFFECTIVE (FT.^{2})

$$S = \pi dL + \frac{1}{4}\pi d^2$$

$$L = \frac{(H_1+H_2)}{2} + Ds \qquad \text{(SEE FIGURE C-47)}$$

$$S = \pi d\left[\frac{H_1+H_2}{2} + Ds\right] + \frac{1}{4}\pi d^2$$

R0071679

$$K = \frac{\pi c^2 \ln(H_1/H_2)}{4\left[\pi d\left[\frac{(H_1+H_2)}{2}+D_s\right]+\frac{1}{2}\pi c^2\right](t_2-t_1)}$$

$$K = \frac{d \ln(H_1/H_2)}{(2H_1+2H_2+4D_s+d)(t_2-t_1)} \qquad \text{(EQ. 5)}$$

R0071680

III. TRENCH LENGTH EQUATION

A. VOLUME OF RUNOFF:

$$C = CAR\left(\frac{43560}{12}\right) = 3630\,CAR\ (FT.^3) \qquad (EQ.\ 1)$$

WHERE,

C = RATIONAL METHOD RUNOFF COEFFICIENT
A = DRAINAGE AREA (ACRES)
R = ONE-HOUR RAINFALL (INCHES)

B. VOLUME OF STORAGE IN TRENCH:

BASED ON 50% VOIDS:

$$V_{STOR} = 0.50\,WD_uL\ (FT.^3) \qquad (EQ.\ 2)$$

WHERE,

W = TRENCH WIDTH (FT.)
D_u = UNSATURATED TRENCH DEPTH (FT.)
L = TRENCH LENGTH (FT.)

C. VOLUME EXFILTRATED:

$$V_{BOT} = KH_2WL(3600) \qquad (EQ.\ 3)$$

WHERE,

V_{BOT} = VOLUME EXFILTRATED OUT BOTTOM IN 1 HOUR ($FT.^3$)
K = HYDRAULIC CONDUCTIVITY (CFS/$FT.^2$ - FT. HEAD)
H_2 = HEAD ON SATURATED SURFACE (FT. HEAD)

AND:

$$V_{SIDE} = L(KS_1H_1 + KS_2H_2)\,3600 \qquad (EQ.\ 4)$$

WHERE,

V_{SIDE} = VOLUME EXFILTRATED OUT A SIDE IN 1 HOUR ($FT.^3$)
S_1 = UNSATURATED TRENCH SURFACE ($FT.^2$)
S_2 = SATURATED TRENCH SURFACE ($FT.^2$)
H_1 = AVERAGE HEAD ON UNSATURATED SURFACE (FT. HEAD)
H_2 = HEAD ON SATURATED SURFACE (FT. HEAD)

FROM FIGURE C-48

$S_1 = D_u L$

$S_2 = D_s L$

$H_1 = H_2 - \frac{1}{2} D_u$

THEN:

$$V_{SIDE} = \left[K D_u L (H_2 - \tfrac{1}{2} D_u) + K D_s L H_2 \right] 3600$$

$$V_{SIDE} = 3600 K L (H_2 D_u - \tfrac{1}{2} D_u^2 + H_2 D_s) \qquad \text{(EQ. 5)}$$

SETTING THE VOLUME OF RUNOFF EQUAL TO THE VOLUME EXFILTRATED: $Q = V_{STOR} + V_{BOT} + 2V_{SIDE}$

$$3630 CAR = 0.50 W D_u L + 3600 K H_2 W L + 2\left[3600 K L (H_2 D_u - \tfrac{1}{2} D_u^2 + H_2 D_s)\right]$$

SOLVING THIS EQUATION FOR L:

$$L = \frac{1.00834 CAR}{K(H_2 W + 2 H_2 D_u - D_u^2 + 2 H_2 D_s) + 0.000139 W D_u} \qquad \text{(EQ. 6)}$$

HOWEVER, CONSIDERING THE EFFECT ON THE ANSWER AND THE NORMAL VARIATIONS IN ESTIMATION OF C WE HAVE SIMPLIFIED THE EQUATION TO READ:

$$L = \frac{CAR}{K(H_2 W + 2 H_2 D_u - D_u^2 + 2 H_2 D_s) + (1.39 \times 10^{-4}) W D_u} \qquad \text{(EQ. 7)}$$

WHERE,

- L = LENGTH OF TRENCH REQUIRED (FT.)
- C = RATIONAL METHOD RUNOFF COEFFICIENT
- A = DRAINAGE AREA (ACRES)
- R = ONE-HOUR RAINFALL (INCHES)
- H_2 = DEPTH TO WATER TABLE (FT.)
- W = TRENCH WIDTH (FT.)
- D_u = UNSATURATED TRENCH DEPTH (FT.)
- D_s = SATURATED TRENCH DEPTH (FT.)

R0071682

FOR A DISTRICT AVERAGE 3-YEAR, 1-HOUR RAINFALL OF 2.5 INCHES THIS EQUATION BECOMES, SIMPLY:

$$L = \frac{2.5CA}{K(H_2W + 2H_2Du - Du^2 + 2H_2D_s) + (1.39 \times 10^{-4})WDu} \qquad \text{(EQ. 8)}$$

R0071683

DESIGN EXAMPLE

FOR

EXFILTRATION TRENCH

R0071684

I. Given:

A. Proposed acreages

1. Lake = 1 ac
2. Roofs = 5 ac
3. Other paving = 8 ac
4. Green areas = 2 ac
5. Total = 16 ac

B. Other

1. An existing canal, along one border of the property, will be the receiving body.
2. The receiving body regulated stage is elevation 8.0' NGVD.
3. The existing average site grade is about elevation 17' NGVD.
4. The site soil drains well. Three percolation tests yield an average hydraulic conductivity of

$$1.2 \times 10^{-4} \text{ cfs/(sq ft - ft of head)}.$$

5. Average wet season water table elevation is 8.25' NGVD.
6. Current zoning is "Commercial".

II. Design Criteria

A. Quality

1. If a wet detention system, then whichever is the greater of
   a. The first inch of runoff from the entire site.
   b. The amount of 2.5 in. times the percentage of impervious.
2. If a dry detention system, then 75% of the volume required for wet detention.
3. If a retention system, then 50% of the volume required.
4. Because the site zoning is "Commercial", at least 0.5 in. of retention or dry detention pretreatment shall be provided.

R0071685

5. Any detention system shall be designed to discharge not more than 0.5 in. of the detained volume per day. A V-shaped configuration is desirable.

B. Quantity

1. The allowable discharge for the basin in which this project is located is 50 csm for a 25-year 3-day storm.

2. First floors are desired to be no lower than elevation 18.5' NGVD.

3. Parking areas.

a. Are proposed to range in elevation from 16.0' to 17.5' NGVD.

b. Shall be at least 2 ft above the control elevation.

III. Computations

A. Quality

1. Compute the first inch of runoff from the entire developed site.

= 1 in. x 16 ac x 1 ft/12 in.

= 1.3 ac-ft for the first inch of runoff.

2. Compute 2.5 in. times the percentage of imperviousness.

a. Site area, for water quality pervious/impervious calculation only

= Total project - (lake + roof)

= 16 ac - (1 ac + 5 ac)

= 10 ac site area, for water quality pervious/impervious.

b. Impervious area, for water quality pervious/impervious calculations only

= (Site area for water quality pervious/impervious) - pervious

= 10 ac - 2 ac

= 8 ac impervious area, for water quality pervious/impervious.

R0071686

c. Percentage of imperviousness for water quality.

= Impervious area for water quality / Site area for water quality x 100%

= (8 ac/10 ac) x 100%

= 80% impervious

d. For 2.5 in. times the percentage impervious

= 2.5 in. x 0.80

= 2.00 in. to be treated

e. Compute volume required for quality detention

= inches to be treated x (total site - lake)

= 2.00 in. x (16 ac - 1 ac) x 1 ft/12 in.

= 2.00 in. x 15 ac x 1 ft/12 in.

= 2.5 ac-ft required detention storage

3. Since the 2.5 ac-ft are greater than the 1.3 ac-ft computed for the first inch of runoff, the volume of 2.5 ac-ft controls. (The system proposed is wet detention, so no volume reductions are possible.)

4. Because this is a project on commercial zoned land, 0.5 in. of dry retention/detention must be provided.

= 0.5 in. x (total site - lake)

= 0.5 in. x (16 ac - 1 ac) x 1 ft/12 in.

= 0.6 ac-ft required for pretreatment

5. Compute credit for placing some system inlets in grassed swales.

a. Given:

i. Each inlet in a grassed swale drains about 0.75 acre.

ii. A typical grassed swale will consist of an area about 15 ft long and 5 ft wide. The inlet will be considered a negligible part of the area.

iii. No other pervious areas drain into the grassed swale.

b. Compute ratio of impervious to pervious area.

i. Pervious area

= 15 ft x 5 ft

= 75 sq ft pervious area.

ii. Impervious area

= 0.75 ac x 43,560 sq ft/ac

= 32,670 sq ft impervious area.

iii. Compute Impervious : Pervious ratio

= 32,670 sq ft : 75 sq ft

= 436:1

A ratio of 436:1 results in negligible credit.

6. It is proposed that the dry pretreatment be accomplished totally by exfiltration trench, and to utilize the lake for aesthetics and wet detention. Since the system should be designed to maintain the water table no more than 6 feet below natural ground, and the average site grade is at elevation 17' NGVD, the control elevation shall be 11.0' NGVD. (Note: existing water table elevation is 8.25' NGVD.)

7. Compute volume to be treated in the lake

= Total Quality Volume - Dry Pretreatment Volume

= 2.5 ac-ft - 0.6 ac-ft

= 1.9 ac-ft to be detained in the lake.

B. Trench

1. Design Criteria

a. A minimum of 2 ft of paving and backfill will be required above the trench.

b. Minimum parking area elevation is 16.0' NGVD.

c. Trench width shall be 3 ft.

d. Since control elevation is 11.0' NGVD and existing wet season water table is 8.25' NGVD, assume the water table in the vicinity of the trench to be at elevation 10.5' NGVD.

e. For trench to be considered dry, the water table must be no higher than the invert of the trench pipe. For this system, the trench bed will extend down to elevation 11' NGVD. The pipe invert will be at elevation 12' NGVD.

2. Compute trench length

a. $L = 3630\ V/(K(H_2W + 2H_2Du - Du^2 + 2H_2D_s) + (1.39 \times 10^{-4})WDu)$

L = Length of trench required (feet)

V = Volume to be exfiltrated (ac-in.)

W = Trench width (feet)

K = Hydraulic conductivity (cfs/sq ft - ft head)

H_2 = Depth to water table (feet)

Du = Non-saturated trench depth (feet)

D_s = Saturated trench depth (feet)

b. In this project, L is to be determined

$V = 0.6$ ac-ft $= 7.2$ ac-in.

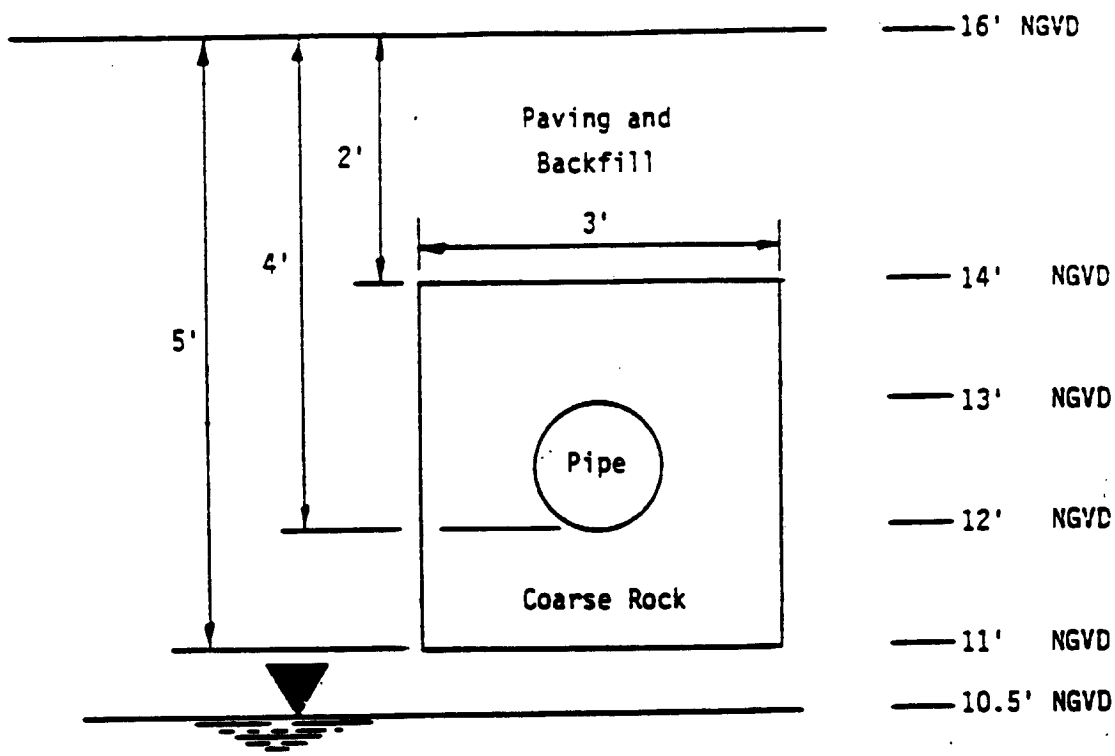
$W = 3$ ft

$K = 1.2 \times 10^{-4}$ cfs/(sq ft - ft of head)

*$H_2 = 5$ ft

**$Du = 3$ ft

$D_s = 0$



*H_2 can extend no lower than the trench bottom.

**Du is the entire trench depth, from elevations 11 to 14' NGVD, because the water table is below the trench bottom.

c. $$L = \frac{7.2}{1.2\times10^{-4}\times((5\times3)+(2\times5\times3)-(3\times3)+(2\times5\times0))+((1.39\times10^{-4})\times3\times3)}$$

= 1,290, say, <u>1,300 l.f.</u> of trench for dry retention.

R0071689

CROSS SECTION OF PROPOSED EXFILTRATION TRENCH

Figure D-E-1

R0071690

C. Other considerations

1. A weir must be installed at the downstream end of the trench system, to create true retention. The crest of the weir must be no lower than the top of the trench pipe.

2. The proposed lake-trench system should be checked to be certain it provides adequate storage for road and parking lot protection, can meet design storm discharge criteria, and can provide adequate floor protection. This would include a control structure on the lake discharge route.

R0071691

APPENDIX 6-4

Design Charts for Determining Waterway Capacity

(By the Soil Conservation Service)

Exhibits 7-4 and 7-5 have been prepared by USDA SCS to simplify the determination of waterway size for given site conditions. The tables conform to the principles outlined in SCS-TP-61, "Handbook of Channel Design for Soil and Water Conservation."

The following example demonstrates how to use the exhibits to design a parabolic channel.

Problem: Given a waterway with parabolic cross-section, determine the safe velocity and dimensions for stability and adequate capacity.

Given:		
	Runoff	Q = 55 c.f.s.
	Grade	= 5 percent
	Vegetative Cover	Bahia grass
	Soil	Erodible
	Condition of Vegetation	
	Good stand--Cut (2.5" - 3")	"D" curve retardance (from Table 6-9, pg. 6-142)
	Good stand--Uncut (6" average)	"C" curve retardance (from Table 6-9)
	Permissible Velocity V_1	5.0 f.p.s. (from Table 6-8, pg. 6-142)

Horizontally opposite 55 c.f.s. in Exhibit 7-5, Sheet 11 of 14 (5% slope) in the columns headed V_1 = 5.0 f.p.s., find T = 20.6 feet, D = 0.87 feet and V_2 = 4.54 f.p.s. Therefore, a waterway with parabolic cross section, a top width of 20.6 feet, and a depth of 0.87 feet will carry 55 c.f.s. at a maximum velocity of 5 feet per second when the vegetative lining is short (2.5" to 3" in height) and 4.54 feet per second when vegetative lining is tall (6" average). This complies with the requirements for safe velocity when vegetation is short ("D" retardance) and capacity when vegetation is tall ("C" retardance).

Technical Notes

Tech Note No. 2.109
Re: Flow Capacity - Subsurface Drains

Date: October 21, 1983
By: R.C. Reeve
Rev. - J.B. Goddard

FLOW CAPACITY--SUBSURFACE DRAINS

Although flow capacity and "n" values have been distributed in various forms in the past, this Technical Note is published to bring together in a single report the current Soil Conservation Service and ADS test information on the subject.

Regarding Manning's "n" values for design purposes, the Soil Conservation Service issued an advisory on August 31, 1978 giving "n" values for subsurface drains. A copy of this advisory (ENG-29) is included herein. Tests on larger diameters; 18" and 24" which were not available at that time, indicate that an "n" of 0.020 is reasonable for design purposes.

Attached are several tables (Nos. 1-15 and 16) from the SCS. Tables Nos. 1-15 give flow capacities in cubic feet per second (CFS) for subsurface drains flowing full at zero back pressure for sizes ranging from 3 to 48 inches (I.D.). Table 16 gives the number of acres drained for various discharge capacities for drainage ccoefficients ranging from 1/4 inch through 4 inches per day (24 hours).

Also attached are flow charts (Figure 1-7) showing flow capacities versus slope for Mannings "n" values ranging from "n"=0.012 through "n"=0.018. Flow velocities in feet per second are also shown, these charts cover the pipe sizes from 4 through 18 inches.

ADS Recommended Manning's "n" for Design

Diameter	Manning's "n" Value
3" - 6"	0.015
8"	0.016
10"	0.017
12" - 15"	0.018
18" - 24"	0.020

Advisory ENG-29

FROM: Neil F. Bogner, Director, Engineering Division, SCS

RE: Hydraulic Roughness Coefficients for Subsurface Drain and Underground Outlet Designs

A number of questions have been brought to our attention involving the selection of hydraulic roughness coefficients ("n" values) used in Manning's formula when calculating flow for corrugated plastic tubing and drain tile systems. Existing literature has been reviewed and hydraulic tests are being initiated by research groups in an effort to obtain more precise information for selection of the appropriate coefficient.

Until adequate test data becomes available, we suggest the following values for use with normal installations:

Materials	Diameter	Manning's "n" Value
Clay or Concrete Drain Tile	All Sizes	0.012 to 0.014
Corrugated Plastic Tubing	3 to 8 Inch	0.015 to 0.016
Corrugated Plastic Tubing	10 to 15 Inch	0.017 to 0.018

When more reliable information becomes available, we will revise Section 16 of the National Engineering Handbook to indicate the new suggested values.

to make everything consistent and then tell us what the inconsistent ones are between the other cases.

MR. COE: Until we have a model.

MR. KESTON: So that we create a model. And the model may change.

MR. NAHAI: With other prospective cases, I don't think it would be right to make the parties wait.

MR. COE: There's a lot of money involved.

MS. LYON: Right.

MR. NAHAI: Shall we break for lunch?

MR. LEON: Return time is 2:45, and the Board, during the lunch hour, will meet in closed session to discuss current litigation cases, including ongoing litigation: Long Beach versus Regional Board, City of Los Angeles, a petition case; City of Thousand Oaks, another petition case; and Malibu Cross Creek, a litigation case.

MR. NAHAI: Going on to No. 16, will you read the statement.

MS. GOODMAN: Sure.

This is a public meeting to consider board action of consideration of recommended best management practices for development planning and

construction for municipal storm water programs in Los Angeles County. Copies of this resolution were sent to the state Water Resources Control Board and other interested agencies, persons, and organizations.

The order of presentation of testimony at this meeting will be: board staff, public agencies, other interested agencies and groups. Anyone so desiring will be heard. If you haven't filled out one of the blue cards located on the table at the back of the room, please raise your hand and we'll get a card for you to fill out.

It would be appreciated if all persons appearing before the Board today will leave written copies of their testimony, if available. The Board will consider all testimony. However, in the interest of time, it is requested that all repetitive and redundant statements be avoided.

The setting of time limits for the presentation of evidence is at the discretion of the Board.

The hearing will now be open.

MR. NAHAI: Could each person who's going to give testimony on this item, could you please stand. Could you raise your right hand and

repeat after me.

UNIDENTIFIED SPEAKERS,

having been duly sworn, testified as follows:

MR. NAHAI: With that we'll declare the public hearing open, and could we have staff presentations.

MR. SWAMIKANNU: Mr. Chairman and respected members of the Board, I have the unenviable position of making a staff presentation after you let the public speaker, Dr. Gold, steal my thunder.

But in any case. My name is Xavier Swamikannu. I'm and engineer on Board staff. Today I present for your consideration a draft resolution for approval of best management practices for developing planning and developing construction under the Municipal Storm Water Permit for Los Angeles County.

Best management practices are methods for reducing pollution in storm water in urban runoff. You have been asked today to approve a master list of best management practices for use by municipalities in construction and planning approval programs within their departments.

Now, for some background.

The L.A. County Municipal Storm Water

Permit was adopted by this Board on July 15, 1996. The program or the permit, which is issued under federal and state law, covers 85 cities and the unincorporated areas of L.A. County. The purpose of the permit is to minimize storm water pollution that emanates from urbanized areas.

The permit itself is a program and it has nine components.

The first program management which talks about the legal authority required to enforce the permit by the municipalities. It talks about relationships between the principal permittee and the co-permittees.

The second is component of the permit is illicit connections and elicit discharges elimination. This is to basically control unauthorized discharges to the storm drain system.

The third component is public agency activities. Here we hold municipal operations to the same standard that we hold business and private industry.

The purpose of today's meeting is the next component, development -- planning and development construction.

We also have a public information

participation outreach program. We have a monitoring program in the permit to ensure that we measure the progress as well as determine if our beneficial users are being impaired or is improvement happening.

And finally, we have a compliance requirement which basically requires reporting and evaluation of implementation.

Now, for today's discussion, the Board is being asked to consider BMPs under the planning and construction components, and this is a subset of the requirements that has come to the Board.

Under the planning we have planning priority projects basically setting aside specific requirements for home subdivisions, 10 homes, 100 homes. In addition to that, we have certainly commercial facilities when they're being planned that certain BMPs be considered. These include gas stations and restaurant establishments.

The requirement here is that Urban Storm Water Mitigation Plan be prepared and submitted to the local municipality. Within the Urban Storm Water Mitigation Plans, you will have the BMPs, a broad base of BMPs.

The second component is construction, a priority construction. And under priority

construction for the municipal program, the scrutiny is only for those projects between two and five acres. Five acres and greater are handled under a separate permit program from the State directly.

Under the construction priority projects, what you have is a requirement to prepare a local storm water pollution plan or wet weather erosion control plans.

Within these plans the permittees are required to identify best management practices. As I explained earlier, these are source or structural or treatment control measures to reduce pollutions that -- to reduce pollutants that enter storm water.

What you have in the agenda package is a master list of BMPs, of best management practices, that the cities are to consider for adoption when these plans are brought before them by developers or builders. These BMPs have been taken from the state handbooks, which have been widely used since 1990.

We have received three sets of comments on the -- on the BMPs that are for consideration. The first set of comments is on a clarification on the Standard Storm Water Urban Runoff Mitigation Plan. And that is an issue which is not before you for discussion today.

The Urban Storm Water Mitigation Plans are approved by the executive officer. They will have very specific BMPs when they're presented to him for consideration. It's our intent at that time to solicit public comment.

The second set of comments was submitted by Heal the Bay. And they have requested that we consider additional BMPs that are not presently on the master list. These include source control measures, like maintenance; erosion sediment control measures, like using geotextile masks; treatment control systems, such is as catch basin inserts and other systems.

Finally, I'll go to my recommendation, or staff recommendation, that the Board adopt the draft resolution with the following changes:

Direct staff to supplement the master list with additional BMPs that have been submitted by Heal the Bay as well as the Western States Petroleum Association, and consider favorably the clarification which will be provided by the City of Los Angeles on the use of the best management practices list with discretion on the proper language to be given to the executive officer.

My presentation is concluded.

Questions?

MR. NAHAI: Any questions?

MS. DIAMOND: I have a question: Considering the memo that you got -- we all got from Heal the Bay -- and you've incorporated some of that in this recommendation -- what is your feeling about the recommendation for the brief description of each BMP? And what about the making it more useful by organizing it in a way that will be a little more user-friendly? Would you comment on that.

MR. SWAMIKANNU: Yes. The plans that I talked about, Urban Storm Water Mitigation Plans, will be prepared by the L.A. County; and therefore, they are for each of those sectors, for example, 10-homes subdivision, 100-home subdivision. And we think the details should be in that plan because that's the document that the developer or whoever is going to use.

What you are being asked to act on today is on the broader list of BMPs that ought to be considered for all these projects. The technical details will be handled in the latter -- later document. So certainly I think there is a need for better description and better identity, but that will be handled at the plan level, at the Urban Storm

Water Mitigation Plan level. And it's my understanding that's already being done.

I -- we have not looked at the storm water urban mitigation plans yet, but I've seen a draft copy from one of the permittees. I've also seen a draft from the City, and the intent of the document is to provide more detail.

Does that answer your question?

MS. DIAMOND: Yes, I think.

MR. NAHAI: Any other questions? Thank you.

MR. SWAMIKANNU: Thank you, Mr. Chairman.

MR. NAHAI: I'll move on to calling out the speakers who provided cards, and I won't take this in any particular order.

First, Mr. Charles Gale.

MR. GALE: Good afternoon, Chairman and Board members. My name is Charles Gale. I'm with the Building Industry Association of Southern California. I work in the regional office in Diamond Bar, California.

I have recently passed out some comments to your staff here about the BMPs that are taken from the California Storm Water Best Management

Practice Handbook for Construction Activity, which was published by the California Storm Water Quality Task Force. Our members have been using some of these BMPs since they've been adopted, since is 1993.

My comments today on the resolution are twofold: We're recommending that the Regional Board resolution encourage the permittees to update the BMP list periodically to reflect advances in scientific understanding and BMP developments.

Lastly, we're recommending the permittees to be encouraged to adopt flexible BMP programs that work for our industry. There has been a lot of discussion about what works on the East Coast may not work out here with our climate and soil conditions. So we would like you to, hopefully, add that to your recommendations through the Board resolution today.

Thank you.

MR. NAHAI: Do you -- I had one question.

MR. GALE: Yes.

MR. NAHAI: Do you have specific suggestions that you would like to be added to the BMPs that are going to get adopted today?

MR. GALE: Not to the BMPs but to the

resolution. I'd allow it some flexibility in updating the BMPs by the permittees.

MR. NAHAI: Thank you.

MR. GALE: Thank you.

MR. NAHAI: Mr. Steve Fleischli, please.

MR. FLEISCHLI: Good afternoon, members of the Board. Steve Fleischli, Santa Monica Bay Keeper, P.O. Box 10096, Marina Del Rey 90295.

I want to talk a little bit about why we're doing this, and I'm sure most of you know Section 402P of the Clean Water Act requires, essentially, that a reduction of pollution be achieved to the maximum extent practicable. I think it's good that we are developing a list of BMPs, but what we really need is something that moves forward towards the goals of the Clean Water Act. What we need is the linkages that are necessary.

And today we talked about there's a mitigation plan that's coming later that's going to provide all the technical detail that this Board likely will never see because the executive officer will be reviewing that, and we'll never really know where all these link together.

Our -- one of our main concerns is that

the way this is set out -- and Mark Gold talked about this issue a little bit earlier, and he certainly has been much more involved than I have on these issues.

But so you have a list of BMPs; so what? So what? In our resolution we have that these BMPs may be considered by permittees. So what? In here there's no mention whatsoever of the maximum extent practical. There's no mention whatsoever of the goal of reducing pollution utilizing these BMPs. There's no mandate whatsoever that certain land use practices incorporate treatment, for example. One example that Mark gave was with regard to parking lots and things like that.

There should be something in there that says you have to have some type of treatment at the end of your parking lot. I don't care what type it is. You know, you need the flexibility. I agree with that. But you got to do something. It all should be treated.

Those are the types of issues that we should be addressing, and my concern is that these two documents -- the BMP list and this mitigation plan with the technical information -- are considered separately and that they're not looked at in a holistic approach that we're really going to miss the

boat on why we're doing this at all.

So those are my comments. I'd be happy to provide, you know, more detail if you want me to.

MR. NAHAI: Questions for Mr. Fleischli? Maybe later on.

MR. FLEISCHLI: All right. Thanks.

THE NAHAI: Thank you.

Next Mr. Jim Langley, please.

MR. LANGLEY: Good afternoon, President Nahai and Board members. I'm Jim Langley, assistant director of the Bureau of Sanitation. And I want to thank you for the opportunity to speak very briefly here. I know you've had a lot of testimony today.

The City of L.A. is very supportive and in fact enthusiastic about the storm water program, urban runoff programs, but we also recognize that the BMPs are the heart of the development and construction planning programs. And we are committed to meeting our part of the permit requirements by July 30, 1999.

But as a point of clarification, we request that the BMP's listing be considered more as a menu of potential BMPs. Because we believe that, since the cost and pollution-control benefits were not considered originally in the evaluation for all

of these BMPs because data simply was not available, that this is a very important aspect that we need to cover before these BMPs are actually implemented.

I just distributed copies of our modifications to the resolution already, and I -- those, I think, have been distributed.

Once again, I thank you for the opportunity to speak. Are there any questions?

MR. NAHAI: Any questions of Mr. Langley? Thank you.

MR. LANGLEY: Thanks.

MR. NAHAI: Mr. Michael Kissel, please.

MR. KISSEL: Good afternoon, Mr. Chairman, members of the Board, and staff members. My name is Michael Kissel. I'm the environmental health compliance specialist with CKE Restaurants, dba Carl's Jr. Restaurants.

I'm here today to address issues of the BMP, the seven items that were listed for Restaurant Standard Urban Storm Water Mitigation Plan, for that plan just real briefly, and I've got to consolidate for the sake of time because I promised I will be brief.

Areas regarding design of equipment and accessory wash areas which also translate into

outdoor material storage areas which also -- translate also to properly designed trash storage areas, these are all, as far as quick-service restaurants are concerned, basically are trash enclosures and trash corrals. And they call for a lot of expenses that we feel can somewhat -- we see merit and we understand the necessity for drains in those areas, but for coverings berms and dikes, we feel that the incorporation of BMPs, which we already have in place in our restaurants, would be sufficient.

Areas regarding rooftop, the treatment of that, many of that -- much of that is subject to the hood-cleaning services that we have, and that's something I think we need to discuss with staff.

The control of parking lot runoff, that's a big challenge for us, and that's something we're working on. And again, we would like to work with staff and others on that.

And let's see other areas would be -- well, basically, just providing the proof of ongoing BMP maintenance too. The documentation, we feel, should be minimized because we do have a lot of documentation that we have to do anyway at the restaurants.

I'd like to close by saying that we have always made ourselves available and will continue to to the staff and working with them closely and helping develop BMPs that will work and can work in quick-service restaurants.

Thank you very much.

MR. NAHAI: Questions of Mr. Kissel?

Thank you.

MR. KISSEL: Okay. Thank you.

MR. NAHAI: Mr. Marvin Sachse.

Do we have a Marvin in here?

UNIDENTIFIED SPEAKER: Oh, he had to leave.

MR. NAHAI: Jacqueline Lambrichts, please. It's not written? You don't want to say anything?

MS. LAMBRICHTS: No.

MR. NAHAI: Well, that -- are you sure you don't want to say anything?

MS. LAMBRICHTS: Actually, my executive director should come and speak and tell you all about our adventures.

MR. NAHAI: Shall we wait for your executive director?

MS. LAMBRICHTS: No.

R0071766

MR. NAHAI: All right. Well, that ends cards. Do we have any questions of staff? Dr. Coe.

MR. COE: If I understand the staff recommendation, as in the agenda here, plus the recommendations of Heal the Bay, is that what you were saying?

MR. SWAMIKANNU: Yes. The Heal the Bay letter has a list of best management practices.

MR. COE: The letter of April 9 attached to it. You would adopt this in its entirety?

MR. SWAMIKANNU: The BMPs. But not -- the Heal the Bay letter has two components: The first component is a request for the Board to direct staff to analyze this whole BMPs in a very detailed context as they apply to situations, to set standards in fact for the BMPs themselves.

Second component is that the master list submitted to us by the permittees needs to be expanded, and those are the list of BMPs that we see at the tail end of the letter.

What staff is recommending is that we add those BMPs. We have looked at those BMPs; they're reasonable.

MR. COE: Item No. 4 of the letter.

MR. SWAMIKANNU: Yes.

And we add them to the master list. And that's the recommendation.

MR. COE: Thank you.

MR. NAHAI: I had one question: I'd like you to address Mr. Fleischli's comment, which is that -- I mean, as I understand it, it doesn't matter how many BMPs you add to this thing or who suggested them. Because if the language of your resolution reads that the permittees shall consider these BMPs, does that mean that anybody can consider and reject?

Are we really asking people to do any more than look at the BMPs that are being suggested?

MR. SWAMIKANNU: Let me address that question in two parts. The first part is: There are millions of BMPs out there. We have a California handbook that was put out by the municipalities. There has been no official recognition that those BMPs are actually sanctioned by any board or by a state agency for implementation to control storm water.

So what we have here is we have narrowed those BMPs that are applicable to the situation in the Los Angeles region. And so you have a well-defined list of BMPs that ought to be

considered.

Now, the second issue is: In a particular situation, let's say the BMPs for restaurants might be different than the BMPs for a mall with a large parking structure. And so that's a different situation, and we would like that addressed when the plans for a restaurant or the plans for a large parking lot are brought for consideration.

And so the answer to that is, yes, we have narrowed -- now, we have an officially -- we will have an officially sanctioned menu or list of BMPs for the permittees to consider and for the public to look at.

Now, whether that applies to the situation of a restaurant is the next level of resolution, and that's not before you for consideration today. And what Mr. Fleischli would like, would like that level of detail to be considered by you at this time.

MR. NAHAI: So, then, your response to that is that that level of detail will be considered at sometime, just not yet.

MR. SWAMIKANNU: Yes.

MR. NAHAI: And that when it will be considered in the future, that at that time it will

receive a force and a backing and language that will be a lot stronger than let's consider --

MR. SWAMIKANNU: Yes. I think Mr. Fleischli's issue also is the fact that that level of detail will never come up to you for consideration. It's considered only by the executive officer. That was a conscious decision we made when the permit was adopted, just for processing and saving time.

MR. NAHAI: Thank you. That's clarified.

MS. LYON: But the Board could, at its discretion, pick that up and decide it among itself?

MR. SWAMIKANNU: I'll let Jorge answer that question.

MR. LEON: You know, everybody has a law degree, but I have to take it anyway, huh?

No, you wouldn't be able to do it without amending the permit because the permit is written so that the discretion is given to the executive officer.

It's kind of an interesting question. Just -- and the only analysis I've given it is interpreting the permit. But there's got to be a discretionary call that the Board can always make on

any kind of delegation. So I suppose we could do a quick and dirty sort of a resolution that pulls that specific item back without opening up the whole permit.

MS. LYON: I imagine we could make a recommendation to the executive director.

MR. LEON: Yeah.

MR. DICKERSON: And I think I was going to probably duplicate the comment, and that is, as part of your resolution and motion to direct staff to incorporate additional detail as noted by the Heal the Bay, we would be happy to do that at a future time. If you wanted to give us a time frame even, let's say a year, to do that, that'd be great.

MR. COE: I have the same question that Mr. Nahai came up with. On this resolution -- and this is what we're asked to act on, I guess.

It said that these programs must include -- must include best management practices. But in the action or active part of the resolution, under "Therefore be it resolved," it says, "permittees shall consider the BMPs," which means they can consider them and say, well, they're no good. You know, I won't do anything.

Can we tighten that language up a

little bit to say that they "shall implement BMPs from the approved list, see Exhibit B" or something?

MR. DICKERSON: Well, on No. 3, under "Whereas," perhaps we could say the following: "Unless the BMPs have been evaluated and are considered appropriate practices for utilization by permittees in the development of their respective programs and activity." And then an additional language --

MR. COE: Just refer to that list.

MR. DICKERSON: I'm sorry?

MR. COE: "They shall." "Shall select." The action part of this is the resolve. I think that's a follow-up --

MR. NAHAI: Absolutely. If I understand you correctly, you're saying that it's okay for the permittee to be allowed to select from the various alternative BMPs, but the language, as we have it right now, would give them the option of considering and rejecting it.

MR. DICKERSON: I think it should be selecting part. Where would that go exactly? Do you have a --

MR. COE: Number 2.

MR. NAHAI: Number 2, yes.

MR. DICKERSON: Of the "Whereas"?

MR. NAHAI: No. No.

MR. DICKERSON: Right where I wrote it in.

MR. COE: "The permittee shall implement BMPs from the approved list. See Exhibit A," or something like that.

MR. FLEISCHLI: Mr. Chair, can I respond briefly? I don't believe you closed the poll and maybe you'll let me address that.

So they have to implement something from the list, something from the list. So they choose we're going to sweep. I mean, when you choose language like that, that's the type of scenario you're getting into. They'll choose one BMP on the list and say, okay. I swept my lot, and therefore I've complied with this new resolution.

If you want to amend the resolution, the language should be addressing the maximum extent practicable language and the pollution reduction language along the lines of things like, "any net increase in pollution loading above predevelopment levels is prohibited. In addition, new developments shall achieve pollution reductions to the maximum extent practical." And then maybe you say,

"Utilizing the BMPs and things like that.

And then to go even further, some language that Mark and I discussed, for example, would be, "In approving any new development project, the County in each municipality shall assure that all new developments in the county shall be required to include design practices and storm water treatment controls that will prevent any untreated discharge of storm water from paved areas and parking garages."

And maybe that's farther than you want to go today, but I think the language that's being discussed right now sets a dangerous precedent in terms of completely ignoring what the whole point of this really is. And it's not to have someone just choose one thing from a list be it sweeping or whatever, but it's the link to the water quality goals. And that's why I think it's important that, if the Board is willing to consider this other mitigation plan, that we try to link them together at some point in the future.

MR. NAHAI: When you use the phrase, "to the maximum extent practical" --

MR. FLEISCHLI: Right.

MR. NAHAI: Because I'm looking at a revised resolution that was submitted by the -- by

the City, and it suggests language like, "taking into account cost effectiveness, ease of maintenance, consistency with other environmental mandates, you know, and stuff to that effect.

When you talk about maximum extent practicable, would you count the cost effectiveness of the measure somehow in that?

MR. FLEISCHLI: Well, I think when we -- I think -- that's such a difficult question to answer, and I apologize that I'm standing up here stumbling a little. Because the Clean Water Act clearly provides economics to be considered in certain instances, and that's certainly clear.

And what we want to do is, you know -- I think we're willing to provide some flexibility in terms of what they're willing to do, but it still has to be to the maximum extent practicable. So for one particular facility, $1,000 might kill, you know, some of these guys we saw this morning. And other people, you know, $100,000 is going to be a drop in the bucket for them. And given the level of pollution that's running off the site, I think that's important.

MR. COE: Don't we have Chevrolets on the list in addition to Cadillacs? I mean, can't

they --

MR. FLEISCHLI: I think they can, and I think the appropriate -- I think -- there can be things on the list like that, and there certainly are. And the language that we're proposing in terms of, for example, the paved areas, that they implement that no discharge go untreated when it runs off the site.

We're not saying you have to do the Rolls Royce if in fact you can meet water quality goals without doing the Rolls Royce. We're not mandating that they choose the most expensive one. We're mandating that they treat it somehow, and then we look at the water quality standards, we look at the goals we're trying to achieve, and then we play with it from there.

That's the approach we've always taken, for example, with the auto wrecking facilities. There's a suite of things they can do, and that's sort of an iterative process, and if they don't get there, to the water quality goals, then they do a little bit more.

MR. NAHAI: So if one were to add language to the effect that "to the maximum extent practicable in the light of all surrounding

circumstances including economic considerations"?

MR. COE: As determined by the executive --

MR. FLEISCHLI: I would say maximum extent practical consistent with the requirements of Clean Water Act so that we don't get into debates about where the economics come into play, where they don't.

I think the dischargers try to make economics come into play at every single step of the process, and there are certainly certain steps in the process that are supposed to be purely scientific. And there are other steps in the process where economics are allowed to be considered. And so I would be more comfortable with language like that.

But I still don't -- I mean, I'm not going to sign onto a resolution to that effect without some linkage with why we're doing this for pacific -- specific activities. Excuse me. I'm going to blame it on my cold.

MR. NAHAI: You're doing very well with your cold.

Well, let's hear staff's response to Mr. Fleischli's comments, and let's see if we can move this forward to a resolution.

MR. SWAMIKANNU: I don't necessarily agree with the line of presentation that Mr. Fleischli has taken, but the permit says the best management practices has to come before the Board for consideration, and that's what we are doing today.

The issue of maximum extent practicable is a statutory standard for compliance in the municipal storm water program. That is the standard with which the permit is written and that standard stays for reducing pollution storm water, irrespective of the BMP list that you approved today.

So whether we should put in EMB here should not really be the issue because that is the statutory standard under which compliance will be measured.

Now, the way you do that is, for example, you have a document of plan for restaurants. And in that context you can go to the level of detail where you define the suite of BMPs, and the standard that you set for measuring the broader MEB standard in the act.

But to put MEB here would confuse the issue. It's not "implement to the maximum extent practicable"; it's "reduce pollution to the maximum extent practicable." And the list of BMPs here are

for an entity to select from this suite so that they can demonstrate that they have reduced or they have attempted to reduced pollutants to the maximum extent practicable, not implement a particular BMP to the maximum extent practicable because that does nothing for water quality.

MR. NAHAI: What about Mr. Fleischli's suggestion that we add basically a "whereas" that says that the reason that these BMPs are being adopted is in order to reduce pollutions in the maximum extent practical.

MR. SWAMIKANNU: That's a restatement of -- I don't necessarily disagree, but it's true whether it's in this resolution or not. So --

MR. NAHAI: I think he feels about it that it would provide some context to the resolution.

MR. SWAMIKANNU: And that's the privilege the Board has.

MR. DICKERSON: I would also note that the language that the City offered on cost effectiveness is really a replication of language on cost effectiveness that is already in the permit as well.

Perhaps one advancement on this would be on the resolution No. 2, "The permittees shall

select," perhaps the most effective of the BMPs to utilize those as opposed to others that would be less effective that might be of some language that would be helpful.

MR. COE: The definition and the decision on what's most effective to them or you or --

MR. DICKERSON: Well, ultimately, it would be their choice except for the fact that they are under an obligation to ensure they reduce pollution to the maximum extent practicable. If we find that ABMP has not been selected, which is meeting that standard, we would say, "We haven't gone far enough. We need to do more."

MR. COE: Or it can be stated as a goal under the whereases or something.

MR. DICKERSON: So we're certainly open to language that would add that.

MR. NAHAI: Well, let me make a motion to strike to get this moving then. I would move that we adopt the resolution with the two broad changes: One is to add a section to the whereases stating the purpose for which the resolution is being adopted and the BMP's being adopted.

And secondly, to change the language of

paragraph 2 of the resolution to read that the permittees shall, instead of "consider these, " it would read, "shall select and implement the most effective BMPs from the BMPs approved and attached hereto."

I mean I'm not married to that language.

MR. COE: That gets to what we're talking about, I think.

MR. DICKERSON: And we'll probably need a No. 3, which talks about directing us to incorporate additional detail, what Heal the Bay asked us to do.

MR. NAHAI: Yes.

MR. DICKERSON: And we're happy to do.

MS. DIAMOND: Would that be the selection of No. 4, or would there be more included as well?

MR. DICKERSON: I think it might be better as No. 3, but I'm not sure.

MR. NAHAI: You're saying you would attach an Attachment 3.

MR. DICKERSON: Yes.

MS. DIAMOND: I was referring to the letter from Heal the Bay, No. 4, where they would add

those additional BMPs.

MR. NAHAI: Yeah. They're going to do that but the issue is how to incorporate it. And we could have a new paragraph 1C that would read, "Attachment 3." And in it -- and Attachment 3 would then consist of the section -- the BMPs listed in Section 4, is it, of the Heal the Bay letter?

Now, if we need to add something for the flexibility of updating BMPs in the future, then --

MR. DICKERSON: I would request that we do because otherwise we have to bring it back to the Board for formal approval.

MR. NAHAI: And how would that language be?

MR. DICKERSON: That would be a No. 3, I think, under "Therefore, be it resolved," authorizing the executive officer to modify this list to incorporate additional detail as deemed necessary.

MR. NAHAI: That's fine with me.

MR. GALE: Okay. That's the language as we're looking for it. Our concern would have been that if we decided this is the list that you select and implement from, that we would be limiting technology unless there's some means of updating this

BMP list because there are many new ideas coming out every day that we deal with. So --

MR. NAHAI: Just by standing at the podium you communicated your thoughts to us.

Do we need to read through that resolution again?

MR. DICKERSON: I think I have it down unless you want you to go through it.

MR. NAHAI: Dr. Coe, would you like it read back?

MR. COE: Yes.

MR. DICKERSON: Okay. In the first whereas, we're adding a No. 4 where we would state the purpose of why this resolution's necessary and why BMPs are necessary. And the language for that is, I think, a little open right now. If you'll allow us to fill that in.

MR. COE: Is that the part about achieving maximum --

MR. DICKERSON: Yes.

And then in "Therefore be it resolved," we would have 1C that we would add with Attachment 3, and that would refer to the BMPs from Section 4 of the Heal the Bay letter. And that would be an additional attachment, that list of BMPs.

Number 2 would be modified to state, "The permittees shall select and implement the most effective BMPs from the BMPs approved and established hereto." The remainder of that would be stricken.

MR. NAHAI: "Approved and attached hereto."

MR. DICKERSON: "Approved and attached," yes.

MR. NAHAI: "Attached hereto." And then in order to deal with the next section, I think you should add a parenthesis that would say, "as may hereafter be updated," "as same may hereafter be updated" so that we're not tied into exactly these and we provide a little flexibility.

MR. DICKERSON: And then the remainder of No. 2 would be stricken; correct?

MR. NAHAI: No. Why?

MR. DICKERSON: All right. Keep that in there.

Then No. 3 under the, "Therefore be it resolved," would be to authorize the executive officer to incorporate additional detail to the BMPs as necessary.

MR. NAHAI: Okay. That's the motion. Do we have a second?

MR. COE: The detail -- Dennis, the detail includes some of the things that Heal the Bay were talking about conceptually, but reorganization --

MR. DICKERSON: Yes. The reformatting. And we will take a look at that, and if it works, we'll certainly do it.

MR. SWAMIKANNU: I would add -- you have requested that we add Section 12 from the Heal the Bay letter, BMPs. And the letter from the Western States Petroleum Association, which is the association for gas stations, they had included a list of BMPs as well which went through a state process of consensus. And I don't know if you have that before you. I would like that considered as well as part of their attachment.

MS. NAHAI: Was that in our package? I don't remember seeing it.

MR. SWAMIKANNU: Thought it was in the package. I'm sorry.

MR. COE: It's not in their letter of April 9?

MR. SWAMIKANNU: I think it was attached to the letter. The City of Los Angeles also brought that up.

MR. COE: The letter's at the end of the best management practices, just before -- near the end.

Oh, it's 16-136.

MR. DICKERSON: It's this additional material that was provided?

MR. COE: No. This was in the original --

MR. SWAMIKANNU: What was sent to you was a fax. That's what happened. It did not come with the fax. The original of that letter has that attached, and I must apologize.

MR. NAHAI: I'm sorry. I don't appear to have it in my package or in my supplemental materials so --

MR. DICKERSON: We'll have to pass on that.

If it's necessary, we can certainly bring that back for approval at a later date.

MR. NAHAI: Is that covered under the last paragraph that we've given you about adding more detail?

MR. DICKERSON: Fine. Yes. We'll look out at that one.

MS. LYON: I mean, I would hate to

ignore it since it went through the consensus process at a state organization.

MR. DICKERSON: Sounds good.

MR. NAHAI: Could we have a second?

MS. LYON: Second.

MR. NAHAI: All in favor say aye.

UNIDENTIFIED SPEAKERS: Aye.

MR. NAHAI: Motion carries.

MR. KESTON: I just want the record to note that I abstain from voting on this matter.

MR. NAHAI: Moving on to Agenda No. 17, HR Textron, Inc., Santa Clarita. This is the adoption of a resolution approving a negative debt and to adopt WDRs.

MR. NAHAI: Is this a public hearing? Do we need to administer the oath?

MR. LEON: You don't have to, but it is an action item. I don't anticipate any comments or -- but no.

MR. NAHAI: I don't have any cards on it so --

MR. DICKERSON: Mr. Chairman, I -- if there are no cards or speakers, I would certainly like to give the Board the opportunity to move by consent on this item, if there's no objection.

Sept. 16, 1999 Board Meeting Transcript
SUSMP's

VICE CHAIRMAN KESTON: Motion and second?

CHAIRMAN NAHAI: So we're deferring it to the October 28th meeting?

MR. LEON: Merely continuing.

CHAIRMAN NAHAI: Motion. Do we have a second?

BOARD MEMBER LYON: Second.

CHAIRMAN NAHAI: Any discussion? Hearing none, all in favor?

BOARD MEMBER DIAMOND: Opposed.

CHAIRMAN NAHAI: We have one opposition from Ms. Diamond.

All right. We're going to move on to Item Number 14, which is the report on the Executive Officer's intent to approve the standard urban storm water mitigation plans. And perhaps introductory remarks from Mr. Dickerson.

MR. DICKERSON: Thank you, Mr. Chairman and Members of the Board.

In 1996, this Board adopted a permit for the control of storm water pollution in the greater Los Angeles Region. That permit, the Los Angeles Municipal Storm Water Permit, implements federal law that requires municipalities to address the increasingly serious problem of storm water pollution.

The implementing features of this permit require that model programs be developed to address specific categorical sources of storm water pollution, among them construction sites, municipal facilities and new developments. Within the model program that is called "development planning" are various provisions that address the need to improve our urban environment so there is simply less storm water runoff that has not first been subject to an intervention to remove a portion of the pollutant loading carried by that storm water runoff.

These provisions are called Best Management Practices or BMPs, and they are essentially simple techniques to allow for the retention for a short time of runoff, allowing the removal of some of the pollutants carried within runoff, and ultimately rendering runoff less harmful to our water ways. In April, you approved a list of these for use in address thing problem.

Another element required by the municipal permit is what is called a Standard Urban Storm Water Mitigation Plan or, excuse the acronym, "SUSMP." SUSMPs are more specific storm water management plans for specified categories of development, as Dr. Swamikannu will explain to you shortly.

These plans have been submitted to the Regional Board, and under the terms of the municipal storm

water permit, I am charged with the responsibility of approving these SUSMPs. At our April Board meeting when the BMPs were considered, you had expressed an interest in having discussed before the Board whether the SUSMPs are ready for approval. In response, I added this item to the agenda in keeping with your direction. So, pending my approval, our set of SUSMPs that were submitted by the permittees and additional provisions relating to the American standards for BMP application that Dr. Swamikannu will explain in greater detail.

As you have seen, there is no small amount of interest in the additional provision that has been proposed. And as you will recall, this is the very same issue that was so controversial with the approval of the Long Beach Storm Water Permit.

Given the scope of interest and the nature of the comment that's we have received, it very well may be appropriate for additional time to be given to further develop the basis on which the American standards should be justified. I am open to that approach. This would mean that I am moving forward with approving the consensus submittal made by the permittees while reserving the opportunity to further modify the SUSMPs with respect to the American standard at a and later date.

As we move to Board discussion, I would

very much like your thoughts on that possibility. And I should note parenthetically that I'm hopeful that today's discussion on this matter will provide a factual basis and help illuminate this issue in greater detail at the current time.

So with that introduction I would like to ask Dr. Swamikannu to make the staff presentation.

DR. SWAMIKANNU: Mr. Chairman and Members of the Board, I will report to you on staff recommendation on the Standard Urban Storm Water Mitigation Plans. We have provided you with all comment letters that arrived until yesterday, as well as we've given you some background material. Some went with the agenda that was provided to you, "X" agenda.

Some background on the storm water permit, the Clean Water Act amendments of 1987 required that municipalities address storm water pollution. On that basis, this Regional Board issued the first storm water permit to Los Angeles County and Cities in 1990. We reissued the municipal permit in 1996, and more recently in June, we adopted a separate storm water permit for the City of Long Beach.

The compliance standard provided in the statute for the storm water program, or for the municipal storm water program, is the statutory standard of reducing

pollutants to the maximum extent practicable, commonly known as the MEP standard. In addition, the USEPA General Counsel has ruled that storm water discharges must retain water quality standards as well.

In the program requirement for the storm water permit, we have several elements. One of them is a requirement to address storm water pollution during the development planning stage, and as part of that, we had required that a development planning model be prepared for L.A. County and Cities. Within the model itself are several elements -- one, system for designating project as priority for planning purposes. There is also a master list of Best Management Practices that you have already approved. Next, the point of today's discussion, standard urban storm water mitigation plans which have to be approved by the Executive Officer. The models also include guidelines on storm water for CEQA documents and also includes an information program for developers and builders.

So what is a standard urban storm water mitigation plan? It might be defined as a model guidance document for the selection of post-construction BMPs. That's BMPs after the appropriate land use is being implemented or is being conducted. The purpose of the Standard Urban Storm Water Mitigation Plans is to ensure

that potential adverse water quality impacts are addressed during the project planning stage. That is the most efficient stage for putting in BMPs because once construction is complete, any retrofit is going to be expensive.

The manner in which we achieve this objective is to require that municipalities affirmatively review and approve a written plan that is put together by the developers or builders.

A couple of recent Board actions that impinge on the Storm Water Urban Mitigation Plan, the Executive Officer has addressed that, but I'll briefly go over it as well. You approved the Best Management Practices list for municipalities in April and you stated specifically to select from and require implementation.

In addition, when we adopted the separate storm water permit for the City of Long Beach, you prospectively applied the Standard Urban Storm Water Mitigation Plan requirements approved for L.A. County to the Long Beach permit.

These Standard Urban Storm Water Mitigation Plans were submitted to the Executive Officer for approval in July. They were revised to clarify the intent of a numerical measure. They were submitted to us as a consensus document. Basically they had gone through

public review conducted by the County, and they were also reviewed by the Cities, and the appropriate comments were addressed at that level before they were submitted to us.

The Standard Urban Storm Water Mitigation Plans have been developed for seven categories -- home subdivisions, commercial developments, gas stations, restaurant, automotive repair, single family, hillside dwellings. The positive features of the submittal to us require flow management where erosion may occur. They provide guidance on structural and source control Best Management Practices for developers and builders, and it lists treatment control Best Management Practices for home subdivisions and commercial development. By the term "treatment," I mean any (inaudible) that utilize physical or chemical processes for pollutant (inaudible), and these might be filtration settling as options.

The deficiencies, according to staff, that the requirement to consider treatment of BMPs is limited to subdivisions and commercial development. They're not required for gas stations, restaurants, single-family home dwellings and such. Similarly, a numerical mitigation measure for Best Management Practices is not included in the submittal to us.

Staff recommendation number one -- require consideration of treatment control Best Management

Practices for all seven categories; approve for Los Angeles County a numerical mitigation measure that requires application of treatment Best Management Practices to the 85th and lower percentile runoff events based on the American Society of Civil Engineers' water and (inaudible) method of calculation -- these are two national preeminent organizations for Civil Engineers as well as water (inaudible) -- or require application of BMPs to an equivalent rainfall criteria for Los Angeles County of all events up to and including the first three quarters of an inch of rainfall.

Recommendation number three -- many of the commenters had proposed alternative language for certain sections, and staff recommendation is that we review the language that has been provided to us by the commenters, and where they add clarity or otherwise improve the understanding and readability of these documents, we should make those changes.

So how is this criteria applied? How do we see it being applied? The developer will first select source control and structural control Best Management Practices from the guidance document, and these could be like trash containers. Also, select a set of treatment control Best Management Practices from the guide to effect pollutants in the total runoff from the first three

quarters of an inch. Note at this point that we have neither prescribed the Best Management Practice or Practices that should be adopted or the efficiency of the BMPs that they should be adopted.

The developer would then size these Best Management Practices to address the first three quarters of an inch. The plan would then be submitted to the municipality for approval. For example, what are the kinds of BMPs one might consider? One might consider swales to address the three quarters of an inch, for example along parkways and consider infiltration basins at the end of the swale, biofilters around the parking lot, green belt between rear yards of the homes, a detention basin serving as a lake, and some catch basin inserts to address oil, grease and perhaps trash.

Nowhere am I indicating that these are the only BMPs, and nowhere am I showing a preference for one or the other. Recall that these BMPs have been approved by the Board. You took that action in April.

Now I should try to summarize some of the comments that have been submitted to us on key issues.

The first, that we provided inadequate public notice. We provide 30-day notice where none is required, since there was no formal action being taken by the Board on this issue today. We mailed notices to all

interested parties on file. Some of them claim that they did not receive copies of the notice, which we had no way of verifying. We also noticed and conducted a technical workshop on August 10th, prior to the hearing notice, to inform and educate all interested parties on this issue.

Some of the commenters had raised the issue that the three quarters of an inch rainfall criteria is inappropriate. Staff contends that the three quarters of an inch is technically defensible. In addition, we have provided an alternative sizing criteria based on the nationally accepted model which looks at runoff, and you're really trying to control runoff and not rainfall.

The range of criteria or the criteria that we're proposing is well within the range of criteria being used by other communities around the country. The range is from half an inch to two inches -- Austin in Texas, Orlando, Florida; Washington, Maryland; Denver, Colorado.

The numerical criteria is also being used by some communities in the Los Angeles region. For example, Santa Monica has a criteria; City of Calabasas has one; Ventura County has criteria for its program; and three quarters of an inch is being used or being applied in the unincorporated area of Los Angeles County. And three quarters of an inch standard is average for local communities.

What does three quarters of an inch translate? It translates to the fact that over the long-term if you look at the rainfall and took rainfall measurements, 85 percent of the rainfall events would be treated by this BMP. And the 85 percentile can also be justified on the fact that if you increase the number or the amount of rainfall that you want to treat, you really don't get that much additional percentage of overall event. It's a cost efficient point. And as I mentioned before, the criterion is an average for local communities.

Now for the runoff model that I will briefly go over. This is the model that has been included with the manual of practice. It was done through more than five, six years of research, and the formula basically says that once you decide the amount of runoff you want to capture, there are several coefficients. For example, if you want to maximize the volume, the first coefficient to be concerned about is how much of the runoff do you want to treat, what percentage; and then the kind of area the BMPs are going to be in, whether it's a highly built-out area or it's a more developing area. And that means some storm precipitation volumes, which again are regionally specific. Based on that for the range in coastal California, the 85 percent annual runoff treatment is .12 inches to .86 inches, not determined by whether

you're well built-out or you're a new community.

This graph I would like to explain to you a little bit. On the vertical axis you have the volume of runoff. On the horizontal axis you have the rainfall depth, the number of inches. If you look at the amount of volume that has been generated by the different depths of rainfall. The graph indicates that the highest volumes are associated with the smallest amount of rainfall, and so three quarters of an inch is right in there.

What this criteria then does is promote Best Management Practices applications to smaller, more frequent. And if you look at pollutant loads, we are all concerned about the total maximum daily loads at this time. And this is actually data for Ballona Creek in a storm that happened in March 1998.

On the vertical axis, you have total copper, the loading. Horizontal axis, you have time, time of flow in the creek. If you look at the graph, three quarters of an inch or one inch would only address the rising portion. By this, what I'm trying to demonstrate is this is just a starting point. We are not trying to solve the total copper pollutant load issue. It's just a starting point, and that's what the criterion does at this point.

Some of the commenters had indicated that

perhaps this criterion would force the use of ineffective Best Management Practices. The effectiveness of any one Best Management Practice is totally distinct from the mitigation measures. The mitigation measures are broad standards for sizing. Recall also that the Regional Board resolution requires implementation of the most effective Best Management Practices. Effectiveness always is dependent on the proper application of the Best Management Practices.

And for those that are concerned there is not enough information out there on the effectiveness of Best Management Practices for development and planning, the USEPA went through considerable effort and put that in a database. This database is currently available online and on CD and it's constantly updated.

Some in the building community expressed a concern that the numerical measure mandates the capture of storm water. I wish to clarify that the intent of the measure is that a certain set of treatment Best Management Practices be applied to a definite quantity of rainfall or runoff. Storm water capture is itself only one type of application of a treatment Best Management Practice whose use may not be appropriate where space is limited. We recognize that. We will offer modifying language to clarify this intent.

Some municipalities expressed a concern that Best Management Practices maintenance would be costly, bun the maintenance of BMPs is essential, and maintenance depends on the type of BMP as well as cost depends on the type of BMP. The next is a recent journal article brought to our attention. It says, "When Best Management Practices become Worst Management Practices." The article itself was focussed on inappropriate Best Management Practices during construction, but this particular phrase holds true for BMPs when they are not properly maintained.

To summarize the numerical criteria and what does it do, it's a starting point to remove pollutants of concern in storm water. I discussed the example of copper before. A definite criterion facilitates Best Management Practice sizing and design. Pollutant load is reduced, and pollutant concentrations associated with the early peaks and early runoff events, called the first flush, is reduced as well. And ultimately the BMP effectiveness will determine actual removal.

Some commenters expressed a concern that no economic analysis had been done before we proposed this mitigation measure. I submit that none is required when implementing a federal regulation. But even so, when we

compared this numerical criterion to other storm water standards that had been in use for the last 50 years, it's reasonable.

For example, if you look at the next chart, you have vertical bars, axis, you have gradient going from 0 to 6. The highest bar is for flood control. That's a hundred-year design standard. That's the level of cost it might take for a comparable BMP. Suppose you were addressing feed lot operations. There's a requirement that you contain a 25-year storm. That bar represents that criteria.

The next threshold is for sediment removal. If you design sediment basins, you use 10-year standard. And the second bar from the left represents an equivalent criteria used in the State of Washington. And the reason it's so much higher than the criterion we're proposing is because the State of Washington is in a wetter climate regime, and given the fact we have fewer storms, we have a lower threshold.

Some commenters from the environmental community, as well as one city, expressed the concern that by limiting the Standard Urban Storm Water Mitigation Plans to seven categories, that we were being overly restrictive. I would submit that for phase one industrial facilities, these are facilities required to have separate

permits for industrial storm water. These are not listed as priority categories that we have in the permit issue. Also, commercial and state and federal facilities are not listed as priority categories in these permits as well.

On the issue of ecologically sensitive areas, the requirements in the Standard Urban Storm Water Mitigation Plan for ecologically sensitive areas, that requirement occurs or exists in the permit for the City of Long Beach. It does not exist in the permit for Los Angeles County and Cities. And so we would visit that issue when we discuss the reissuance of the permit for Los Angeles County and Cities.

One comment from the environmental community was that the antidegradation policy prohibits new development of any kind. We would say that storm water permits are a means of attaining that total maximum daily loads for impaired waters, and NPDES permits authorize conditions on new development but do not require prohibition on new development.

So I will conclude with the question, why now? Why are we proposing a mitigation measure at this point in time? And there are a few reasons.

The first, nearly a decade has gone by since we issued the Storm Water Program and we have gone far enough to look at treatment issues. There is intense

public and media awareness on the issue of storm water requirements and storm water problems as a whole. Seas of articles in local newspapers recently discussed the public perception, as well as a perception perhaps Southern California is behind the rest of the country.

The science has definitely progressed. Five years ago I could not have proposed a nationally (inaudible) number to you. Now the science is there and the basis seems reasonable. In addition, a numerical mitigation measure adds specifically and aids in Best Management Practice sizing and design. It also gives effect to the Best Management Practices list that you adopted in April, and permit frankly requires implementation now. There's an absolute deadline of July 30th, 1999 in the Los Angeles permit, and we've gone past that point.

That concludes my presentation. Jorge will address a couple of legal issues, questions that came up in the comment letters.

Thank you.

CHAIRMAN NAHAI: Thank you.

Any questions of Dr. Swamikannu?

Thank you very much.

DR. SWAMIKANNU: Thank you.

MR. LEON: Mr. Chairman and Board Members,

thank you. The comments that I have are fairly brief.

One of the comments that came up had to do with authority of the Board staff to propose the program that is before you. Basically the concern is that the Regional Board doesn't have the authority to make an interpretation that the Clean Water Act gives us the right to come up with numerical mandates in the remainder of the program. But in fact, the Clean Water Act is very broad, as we've discovered during our review of the permit that was issued to the County and as was tested to some extent.

Of course you recognize that the Long Beach mitigation was settled, but that of course wasn't one of the issues that was raised. There we argued in response to the litigation that the Board actually has the authority to require controls to reduce the discharge of pollutants and such other provisions as it determines appropriate. That's language directly out of 33 USC 342 PB iii. And in addition to that, there is an EPA interim permitting policy that authorizes more specific conditions or limitations to be incorporated into storm water permits as necessary and appropriate, and that statement can be found at 61 Federal Register 43761.

In addition to those specific regulations or -- I'm sorry -- statutes and interpretations, there's numerous court decisions that hold that administrative

agencies are entitled to discretion to a wide latitude in their interpretations of their own regulations and the laws that they implement. One such case is Chevron versus NRDC, 1984, 467 US at page 837.

It's my belief that the Board is on solid ground in considering and approving the program that is recommended by the staff.

Really quickly now, there was another comment that we also had to deal with in the Long Beach litigation, and that is by adopting the program that's before you, that the Board is creating another unfunded mandate. However, we, I think, prevail there have been cases that determine that the unfunded mandates provision that otherwise requires the states provide funding, doesn't apply to permits that are issued by the Board when it is imposing federal requirements. And it's also true that the Board is exempt from having to deal with the unfunded mandate provision where the statute implemented is a federal law and regulation and results in (inaudible).

CHAIRMAN NAHAI: Thank you. Well, with that we can move on to hearing from the audience. I have here 20 or 25 cards. We do have a three-minute limitation, and I would request that speakers strictly adhere to that time limitation. 22 cards actually.

And let's -- if I don't read your handwriting too terribly well, please forgive me. The first one I have is from a Mr. Gail or Ms. Gail from the home building industry. Going once, twice.

The second one I have is from Mr. Stan Thalenberg.

MR. WATSON: Excuse me. May we trade order in there? I had turned in my card early. Maybe it's now on the bottom of the stack, but I would like to speak first from the building industry, if I may.

CHAIRMAN NAHAI: Sure. What's your name?

MR. WATSON: My name is Richard Watson.

CHAIRMAN NAHAI: Okay.

MR. WATSON: I'm a member of the Building Industry Association of Southern California, and I've been involved in storm water quality issues since about 1990, also a member of the Executive Committee Storm Water Quality Task Force and Ventura's TMDO Water Shed Management Committee, also a member of CDIA's Water Resources Committee. I am now a consultant, but before that I spent 15 years with a major developer and builder in southern California and gained quite a bit of experience in this area.

My comments are based on a SUSMPs and the proposed changes. One of the reasons for that is I was

R0071807

one of those people who did not receive the notice, although my name is on the list to be notified. I was faxed a copy last week after BIA received a copy of the notice from the Regional Board.

There are several letters I think that have been sent into Dennis Dickerson within the last couple of days which were not in the packet that came out to you. Dennis Dickerson said they may have been added subsequently, but there are several letters that you should have from various members of the association.

I'm here today to both support and question. I support the adoption of the mitigation plans as guides to municipalities in implementing their regional or area wide permit. There are words like "every" and "all" that bother me quite a bit, and the area of source control seems to have been left out. Overall, they appear to be workable.

The major problem is the staff proposal to add numerical mitigation measures. As you know, that's why most of us are here today. I won't go through the quote of that and save a little bit of time. The environmental community basically got the County to agree to a set of numerical mitigation language terms, I guess I would say, under duress of litigation. Now what they want is for this Board, through its Executive Officer, to

impose those same or modified standards on the cities through the process of approving the SUSMPs.

As far as I know, most of the real parties of interest were not at the table during these negotiations. Other municipalities weren't there, the developers and the other business interests who were the target of this process were not there. The members of the Building Industry Association are willing to do our fair share, but we don't want to be looked upon as the low hanging fruit. We want equitable treatment based on good sites. We expect pro rata expenditures based on pro rata contribution of pollutants of concern. We don't want to waste money attacking the wrong problems with the wrong tools. Just because we got caught up in it, we have to do something.

As you know, housing addresses a major social need in the region, providing accommodation for here, and the imposition of new cost in regulations will increase the cost of housing and make it less affordable. Tradeoffs have to be concerned, and I think the unintended consequences of regulations must be evaluated. We don't really know what the cost nor the benefits of the proposed regulations will be. And we're not sure the staff does either.

I agree with what the Executive Advisory

Committee said about imposition of this without sound information being before public policy. It's not clear how the proposal is really going to help maintain or improve beneficial uses, and I have a written statement and I'll elaborate on that a little bit more.

CHAIRMAN NAHAI: Mr. Watson, I have to stop you there. Forgive me.

MR. WATSON: I would like to conclude with a request for 30 seconds. I would like to request the Board support the Executive Officer's idea of deferring the numerical mitigations, and I would further like to request that he convene a working group to thoroughly review these proposals and that be composed of people from the municipalities, the development community, the environmental community, vector control people, all sorts of interested parties, so that we could come to agreement on this.

Thank you.

CHAIRMAN NAHAI: Do we need to take a break? Five minutes.

(Brief recess taken)

CHAIRMAN NAHAI: The next speaker card that I have is Rose Collins.

Ms. Rose Collins.

MS. COLLINS: Good afternoon, Chairman and

Board Members. I'm Rose Collins with the City of Long Beach. The City of Long Beach is in agreement with cities such as Los Angeles, those represented by San Gabriel and Gateway City Cox, as well as the Executive Advisory Committee and with the County Board of Supervisors. All these agencies oppose a setting of a .75 runoff limit for a variety of reasons that differ from city to city as each of us have unique environmental charges and concerns.

As you know, we worked why partnership with the Regional Board staff and the environmental groups in developing the language for our permit issued June 30th of this year. Many positive innovative storm water programs are part of that permit. I won't enumerate all of them. I'm sure everybody's familiar with them. In fact, some cities opposed them, but I think they're pretty good. All are known to improve storm water quality.

The only issue unresolved was the SUSMP issue, as the impacts of a.75-inch mitigation standard were and still are unknown for our area. We have concerns with that issue as outlined in our letter to Dennis Dickerson. I would like to present that letter and request that it be entered as part of the public record. Tom, could you please bring that up for me?

Rather than speak on each item, as some are similar for all of the cities, I would like to highlight

the ones that are most of concern to our City. Site-specific scientific studies are needed to determine the long-range impacts of the .75 runoff mitigation on water tables, soils, and other environmental impacts. Specifically, Long Beach has sandy soil. How will mitigation through filtration affect groundwater contamination in Long Beach? Long Beach obtains 50 percent of its drinking water from groundwater wells annually. This is a big concern to us as in the summertime, our reliance on groundwater is 90 percent.

How will infiltration affect liquifaction and building codes requiring buildings to be earthquake safe? How will the .75 retention really affect the receiving waters and the beneficial uses in L.A. County?

During our permit negotiations, we asked for time to study and determine the answers to some of these, what we think to be, reasonable questions. Unfortunately, we reached an impasse and hope through this process that these studies will be conducted.

If this standard is proven without causing other environmental problems such as groundwater contamination, then we will be willing to adhere to this standard. Although we have limited data on other parts of the nation in a meeting by the Regional Board staff on August 10th of this year, we have no concrete, local L.A.

County data that supports the implementation of that standard.

We believe in and fully support scientifically based clean water programs and storm water pollutant reduction based on programs that result in real water quality improvements without significant unnecessarily expenditures. I would like to read an excerpt from the County Board of Supervisors letter which pretty much sums up our request for SUSMP implementation. In that letter, last paragraph says, "Although many cities share the same storm water quality issues, their approach to solving problems varies based on a wide range of issues within each city. Therefore, we support the City's approach to implementing the SUSMPs, thus allowing flexibility for each city to determine what is responsible, practical, within its own jurisdiction." Excuse me the words "reasonable" and "practical" within their own jurisdiction.

CHAIRMAN NAHAI: Can I stop you there, please.

MS. COLLINS: Yes.

CHAIRMAN NAHAI: Thank you.

MS. COLLINS: If I might say one last thing.

CHAIRMAN NAHAI: If everybody has one last

thing to say, we'll never get through this. Really, please.

MS. COLLINS: Thank you.

CHAIRMAN NAHAI: I hate to interrupt people. It's not in my nature. So when you force me to do that --

MS. COLLINS: Thank you.

CHAIRMAN NAHAI: Thank you so much.

The next speaker is Mr. Rufus Young from Burke, Williams. Going once, twice.

MR. YOUNG: I'm coming.

CHAIRMAN NAHAI: Okay.

MR. YOUNG: When your name is "Young," you get accustomed to sitting in the back of the room.

My name is Rufus C. Young, Junior. I'm a partner with the law firm of Burke, Williams and Sorenson. We are proud to represent a number of cities as City Attorney, among them the City of Alhambra, on whose behalf I appear here today to address and strongly support Recommendation Number 3, which is to review the comments and to consider adoption of some of those comments and rewording.

I invite your attention to the SUSMPs. In the background section of each one of them, there is a description of what they're about and how they do it. If

I may quote from the third full paragraph under "background," "Discretionary projects as defined by CEQA that fall into one of the seven categories will need to implement the appropriate SUSMP requirements." Turning to the section under "requirements" in the respective SUSMPs, you find in each case a requirement to provide storm drain systems stenciling and signage. That's all well and good, but the question is just where and by whom.

The first bullet under each of those is to provide all storm drain inlets and catch basins must be stenciled with prohibitive language and/or graphical icons to discourage illegal dumping. That's a fine requirement in concept, but is this to be done by each new gas station, each new automotive repair shop, each new restaurant. And for which storm drain inlets -- the ones on the premises of the new gas station, the ones into which storm water from the new gas station might flow, all of them in the city, all of them between the city and the ocean?

A similar issue I would raise with respect to the requirement for signs and prohibitive language and/or graphical icons discouraging illegal dumping must be posted along channels and creeks. Again, the issue is by whom, which creeks, upstream as well as down stream, down stream all the way to the ocean?

Cerritos area without paying for potentially unnecessarily structural controls that make part of the property undevelopable."

Number two, "The groundwater table in Cerritos is very high. Potential basins or swales have the potential for causing pollutants and contaminate the groundwater.

And the third, "Cerritos prides itself on the clean and attractive appearance of our city. However, we do not have the staff experience or budget to support the maintenance required with the structural controls that have been suggested for use in complying with these imposed numerical limits."

"Cerritos supports a study of the effectiveness of these controls, as well as a plan to monitor the pollutants found in our storm water in our city. Unless the effectiveness and economic viability of this proposal can be demonstrated, Cerritos will oppose the blanket requirement for all cities in Los Angeles County to retain and treat .75 inches of storm water during a 24-hour event."

And I do have a copy of this letter that I can submit for the public record.

Thank you.

CHAIRMAN NAHAI: Thank you very much. Next

Ms. Terri Grant.

MS. GRANT: Good afternoon. My name is Terri Grant. I'm speaking as Vice Chair of the Executive Advisory Committee of the Los Angeles County Municipal Storm Water Permit. I'm speaking on behalf of Desi Alvarez, the Chair, who had to leave for a meeting and on behalf of the EAC itself.

The EAC is a committee comprised of various permittees from each of the six water sheds. The committee meets monthly to discuss broad issues that impact all the permittees. The EAC contends the permittees did its job as called for and in compliance with the permit by developing the program that was submitted to the Regional Board for approval, or the Executive Officer for approval.

The program was developed through a committee of permittees and consultants. It was submitted for extensive review and comment where permittees and interested parties were allowed to provide input. The EAC contends that when a program is submitted to the Executive Officer under the permit, the Executive Officer has the option to accept or reject the program, and that unilateral changes should not be made after the program is submitted.

The EAC is opposed to the inclusion of the

numerical standard in the Standard Urban Storm Water Mitigation Plans for four primary reasons.

There's insufficient information about the levels of relevant pollutants in the receiving waters to justify and require the expensive treatment control BMPs. There's insufficient storm water monitoring data available to demonstrate that the types of activities regulated by the SUSMPs are actually causing negative impact to the receiving waters. Applying numerical standards to the approved treatment control BMPs constitutes a requirement without in-depth analysis of its costs and implications.

And fourth, a set of numerical standards which may be applicable for certain developments in one area may not be applicable for similar developments in another area.

The EAC feels the imposition of numerical limits and costs that will result from these limits without supporting information is poor public policy. The Regional Board, County, and eighty-four cities that are party to the permit exist to serve the health, safety and well being of the public. We need to work together to gather and analyze the information that is needed to implement efficient and cost effective programs to improve water quality on their behalf. The EAC submitted a letter to this effect to Dennis Dickerson.

That concludes my testimony.

CHAIRMAN NAHAI: Thank you very much.

Mr. Abasadi, please.

MR. GONZALES: Good afternoon. I'm Nasa Gonzales representing the City of Azusa.

We are opposed to the numerical limits for two main reasons. There is really no hard data behind those limits, and we've talked about cost benefits. We feel that the cost benefit study needs to be done to support such drastic requirements.

Finally, since Counties of Orange and Riverside do have not to contend with these limits, we feel that these numeric limits will (inaudible) an inherent regional inequity to Southern California.

Thank you.

CHAIRMAN NAHAI: Thank you very much. Mr. Scott Pomeron.

MR. POMERON: Good afternoon, Chairman and Members of the Board. I'm Scott Pomeron with the City of Lakewood and the Chairman of the San Gabriel Valley River Water Shed.

I would like to submit a resolution that the Council of Lakewood adopted Tuesday night for the record. I would also like to read a letter on behalf of the Water Shed. On behalf of the majority of the 29

cities that comprise the San Gabriel River Water Shed Committee, I would like to express opposition to the incorporation of numeric mitigation measures into the Standard Urban Storm Water Mitigation Plans.

Although many cities have expressed individual opposition through letters and resolutions, the members of the San Gabriel River Water Shed Committee, a recognized body under the current NPDES permit, collectively oppose the proposed numeric mitigation measures.

For the sake of brevity, I will not restate the numerous reasons for this opposition, but rather reiterate the need for more studies and research before such mandates are imposed on local governments.

In light of the fact the Executive Officer is under pressure to approve the SUSMPs, and given the concern raised by many local officials, officials entrusted with protecting the economic health of the jurisdictions they represent, the San Gabriel Valley River Water Shed Committee supports the approval of the SUSMPs as originally submitted by Los Angeles County without the problematic numeric measures.

On behalf of the Water Shed, I would like to thank the Regional Board and staff for their hard work and willingness to understand how and why local

governments are very concerned with imposing such mandates, mandates that are not based on regional specific studies and not justified by any cost benefit analysis.

Thank you.

CHAIRMAN NAHAI: Thank you very much.

The next four names would be Mr. Dean Paradise, Mr. Jay Michael -- and I cannot read the last name but representing the City of Diamond Bar, Mayor Dee Hardison from the City of Torrance, and Mr. Ron Wilkins.

Mr. Paradise.

Mr. Stan Thalenberg, I did call your name out, you know. You decided you did not want to speak at that time.

MR. THALENBERG: I got bumped. I'm with the Los Angeles County Sanitation District, and I've just been asked to say a few words about storm water discharges to the sanitary sewer.

The Sanitation District's wastewater ordinance prohibits discharging storm water into the sanitary sewer and there's a simple reason for that. The system wasn't designed to be able to handle those flows. In those specific cases where storm water needs to be discharged in the sanitary sewer, these need to be evaluated on a case-by-case basis, and I want to emphasize they also need to be approved in writing by the Sanitation

District. That's about it.

Thank you.

CHAIRMAN NAHAI: Thank you very much. Mr. Dean Paradise.

Mr. Jay Michael from the City of Diamond Bar.

MR. HOLTZ: Thank you very much. Jay Michael Holtz, and I am representing the City of Diamond Bar, and we are in opposition to the numerical standards as documented in the letter that was provided by staff.

I did want to make five additional points. First of all, economic analysis may not be required, but we would like to know where does it state in the regulations that it cannot be done in the interest of economic justice for our less affluent communities within southern California.

The research that was identified today in the staff presentation, we feel this should have been shared with the regulated communities before today. We feel that we should avoid knee jerk reactions to media publicity, but I think that was something else that was identified in the presentation, that lately have focussed on storm water as a source of viruses and other types of offensive material.

The City wholeheartedly supports the SUSMPs

as submitted, not as advised. We feel that there is definitely a need to conduct some additional research into this, and we feel as a city that your Executive Director's direction that you provide additional time to study this matter, that would be supported.

Thank you very much.

CHAIRMAN NAHAI: Thank you. Mayor Dee Hardison.

MS. HARDISON: I'm Dee Hardison. I'm the Mayor of the City of Torrance. I'm also the immediate past Chair of the South Bay Cities Councils of Governments, and I'm representing that organization today.

I had the privilege to appear before the Board some three years ago when you also adopted the storm water permit, and I have to say this is a much nicer room than the other one, and we spent many more hours there, as I remember.

You know, we came a long way. As I know, many of us cities were very -- South Bay Cities represents 15 cities in the South Bay area. We were very disappointed. We thought we got something kind of shoved upon us. But we went back and we became the cities, the part of those committees, those Water Shed Committees, and we worked over the past two, nearly three, years to make this work for you, make this work for the cities. And

we've come a long way.

I think we would be taking a definite step backwards if something that had been agreed upon without the numerical standard was then adopted. Then we're stepping backwards. We've got to continue to work together as cities here in Los Angeles County to solve water problems.

So from the South Bay Cities' perspective, we would ask you not to include at this point the numerical standards -- and the numerical standard. And again, whether it takes another group, additional time, whatever as was suggested by the Director, let's continue to work and come to consensus together so that we solve that problem.

Thank you so much.

CHAIRMAN NAHAI: Thank you.

Mr. Ron Wilkins.

MR. WILKINS: Good afternoon, Mr. Chairman and Members of the Board. My name is Ron Wilkins. I'm with the Western States Petroleum Association, with the Trade Association for the Oil Industry in the Western United States.

When I appeared before your Board in August on the City of Long Beach permit, I told that you we had participated in the development of a storm water BMP guide

for retail gasoline outlets. This was published in 1997 by the California Storm Water Quality Task Force and we incorporated those requirements into the permit.

We're now faced with another and substantially different set of proposed storm water requirements. Regretfully, in this case, industry has been effectively been precluded from participating.

It seems to be the assertion that these SUSMPs are necessary to carry out the objectives of the Clean Water Act. Background discussion of the SUSMP for RGOs -- again, Retail Gasoline Outlets -- states the two primary objectives of the Clean Water Act is to reduce discharge pollutants to the maximum extent practical. MEP means, and I quote, "To the maximum extent possible taking into account equitable considerations of synergistic added to the competing factors of but not limited to the gravity of the problem, physical feasibility, public health risks, societal concerns, and social benefits." The proposed SUSMP, particularly the numerical limit, has failed to address these criteria.

First, the gravity of the problem -- there has been no data that runoff from a well-maintained service station is resulting in the impairment of the beneficial use of any body of water.

With respect to physical feasibility, there

has, in my view, been a lack of any specificity regarding the types of improvements that would be necessary to comply with these requirements. Thus, there's been no assessment of cost, and consequently there's been no assessment at all regarding the physical feasibility.

With respect to public health risks and the like, I have heard two ideas as to what a service station might do to comply with these requirements, both of them highly, highly inadvisable. One is the use of porous pavement, grassy swales and the like. The other might be installation of an underground tank or sump.

Retail Gasoline Outlets go to great lengths to protect the subsurface environment, and even more, it might be necessary. The general philosophy is to eliminate pathways for contaminants to enter the soil. One example is the use of impervious pavement, in direct opposition to the conventional wisdom of the use of porous pavement, grassy swales and the like purposefully create direct pathways for pollutants to enter the subsurface environment.

Apparently another possibility is the use of an underground tank. Several problems associated with this, not the least of which is the public safety concern of having a large tank full of air with the possibility of a small amount of gasoline vapor.

Further, there are questions about applicability of UST requirements, double containment monitoring, and so forth, and questions about how to handle the rain water that might be collected in such a tank.

Mr. Chairman and Members of the Board, I respectfully submit that this set of proposals has major shortcomings, and I think that this needs to be brought back before your Board. I would be happy to participate in a discussion effort, and I should note for the record that I was also one of the parties that did not receive notification of this hearing.

CHAIRMAN NAHAI: Thank you very much.

MR. WILKINS: I do have a copy of my testimony, which I can leave with the clerk if you so desire.

CHAIRMAN NAHAI: Thank you.

The next four names are Mr. Rick Sausay, Mr. Gary D. Moore, Mr. Marvin Saxy and Mr. Ray Pearl.

MR. SAUSAY: Thank you, Mr. Chairman, Members of the Board. When I see myself up there, I want to -- I get this uncontrollable urge to say, "Hi, mom." My name --

(Laughter)

CHAIRMAN NAHAI: You could give yourself an

autograph or something.

(Laughter)

MR. SAUSAY: My name is Rick Sausay. I am a Staff Engineer of the Main San Gabriel Basin Water Master. Our agency is a court-appointed agency responsible for the quantity and quality of the groundwater in the Main San Gabriel Basin. Our basin provides 80 to 90 percent of the water supply for over a million people in San Gabriel Valley.

I'm here today representing Water Master because we are concerned about SUSMP and some of the concepts in there. We were not notified of this -- or were not aware of this plan being implemented until just last Monday, and so we're not real familiar with what's going on. But one of our big concerns is that the retention of storm water on an individual site, because what we fear is there will be unintended sequences.

As the low flows come down and you put in porous pavement, you put in leech fields, these various trenches, it will bring in contaminants into these trenches because of the low flows, and your subsequent large storms will come and they could possibly drive those pollutants into the groundwater. So we're very concerned about that.

Another thing is that it could be easily

like MTBE, there was a request to clear up the air quality, and then the unintended consequence was that we have contamination by MTBE, not in San Gabriel, but we know it's in Santa Monica. So we don't want this kind of thing to recur.

We're concerned also that engineers at the cities and whoever is going to implement this might just go through that recipe of Best Management Practice and say, "Okay. This one is acceptable." Well, we don't know the identification of the contaminants and the fate of those contaminants. Some contaminants are not that important to us. Some are very important to us. We would rather see the contaminants go in the streets and go down the storm drain and let the County get caught.

(Laughter)

MR. SAUSAY: What we don't want -- what we don't want is that water, that contaminant, to go into the ground, get into our water supply, and we find it in our drinking water well. That is our big concern.

So when I heard the BIA guy talking up here, he's listing all these people, and yet he did not mention the water supplier. They are the ones that are going to be impacted. And we had not been a part of the committees, we had not -- maybe we were invited, but it was not made clear to us the impacts of this thing.

And hopefully you will not tell my mother what I've said today.

(Laughter)

MR. SAUSAY: Thank you, Mr. Chairman and Members of the Board.

CHAIRMAN NAHAI: Thank you.

Mr. Gary D. Moore.

MR. MOORE: Gary Moore with the City of Los Angeles. I want to thank the Board for taking the time to hear this very important subject. As you're aware, the City is a leader in the fight against storm water pollution. This fiscal year, the City is spending over $20 million on this fight. The City has gone beyond the permit minimums and is spending over $4 million on pollution abatement capital projects.

The City supports storm water pollution reduction programs. We are mindful that such programs need to be cost efficient and result in real water quality benefits.

Simply, we cannot accept the SUSMPs as proposed nor the staff recommendations here today. I would like to point out a couple of reasons why. And Mr. Chairman, if you could give me a 30-second notice so I can stay in the three minutes, I would appreciate it.

Section 2(i)(i).a.1 of the permit specifies

that permittees develop guidance to be used when evaluating a permitting priority and exempt projects. The permit -- and I emphasize -- does not specify which projects, which BMPs are mandated for each of the projects, but states rather that the SUSMPs must incorporate the appropriate elements of the recommended BMPs. Therefore, the mandatory language that's presented in the SUSMPs goes well beyond the requirements of the permit, and as such, should not be imposed on the development project.

The establishment of a numerical limit as proposed by staff is equivalent to establishing effluent guidelines that USEPA is presently undertaking. Such a process requires the limit to be technically and economically feasible and justified based on adequate and appropriate data and subject to public review and comment. It's premature for the Los Angeles region to move forward with numerical design criteria without adequate technical and economic information to ensure informed database decision making.

What we would recommend is instead that -- instead of being labeled requirements, BMPs contained in the SUSMPs be set forth as guidance for permittees. Secondly, in determining design criteria, it should remain a local agency responsibility which is established during

the land development process based on site-specific conditions and water quality consideration and not a requirement established by the Board.

CHAIRMAN NAHAI: 30 seconds.

MR. MOORE: Okay. The City, in revising the discussion in the proof of the BMP maintenance in the current Section 8, to remove the specificity on how to prove maintenance is to be obtained and simply referred to the need of the permittee to ensure maintenance through its only legal authorities.

We've submitted two letters, August 26th and September 2nd, and we have extra copies here we'll give to the clerk. We look forward to working as part of a committee to help better write SUSMPs that I think we can all support and will help reduce storm water pollution.

Thank you very much.

CHAIRMAN NAHAI: Thank you.

VICE CHAIRMAN KESTON: Mr. Chairman, can I make a comment? Quick one. I would like to compliment the City of Los Angeles, and in particular their letter of September the 2nd from Edith Wilson. I think we received a tremendous number of letters, and this one was detailed and specific. It contained some revisions and suggestions for the Standard Urban Water Mitigation Plan for the

10-plus unit subdivision. I think they really spent a lot of time and effort putting this together, and I would like to compliment you on it because I think it's very well thought out.

MR. MOORE: Thank you very much.

CHAIRMAN NAHAI: Mr. Marvin Saxy.

MR. SAXY: Mr. Chairman, Board Members, thank you for your time. My name is Marvin Saxy. I'm a State Licensed Engineer. I have a Master's Degree in Environmental and Industrial Engineering. I am representing ADASAC, Southern California Automotive Recyclers and Baker Automotive Dismantling Recycling Associations serving over 300 Southern California recyclers in this Water Shed.

As a group we wish to place before the Board our concerns over treatment control BMPs. The SUSMPs for Retail Gasoline Outlets and auto repair shops do not mention treatment methodologies, but emphasize Best Management Practices, BMPs, for pollution prevention. From a technical perspective, we consider treatment to be an ineffective methodology for managing storm water runoff.

The Clean Water Act and General Industrial Water Permit emphasizes two elements in storm water management programs. The first is the elimination of

contamination through pollution prevention measures. The second is cost effectiveness of Best Management Practices. Neither of which is treatment. State Water Board benchmarks for water quality standards have been obtained in vast numbers of auto recycling sampling over the last few years except for zinc. Zinc is in the background and we have to address that issue separately.

Treatment control is typically associated with media filters. The Crash Industry submitted a September 9th letter to the Executive Officer describing why media filtration is technically not feasible. Sufficient time does not exist to review this document, but media filtration is not designed to remove metal ions, oil and grease, alterconductivity, change PH or remove nonsettlable solids.

Media filters with the capacity to treat .75 inches of water running off of a one-acre site will require a storage volume of over 20,000 gallons and take ten hours to treat the storm water. This is not economically feasible for most small to midsize businesses. Moreover, we have seen no evidence to indicate that storm water runoff from Retail Gasoline Outlets and auto repair facilities actually require treatment and is a concern of ADASAC and VADRA that all pollution prevention measures that have been implemented

in its present auto recycling facilities will be dispensed with in favor of treatment.

As previously stated, we feel treatment will represent an extreme expense, not improve the quality of storm water runoff, creating a permitting and regulatory nightmare for all small to midsize businesses, with little improvement to the environment and little chance of lowering risk to the human health.

Thank you for your time.

CHAIRMAN NAHAI: Thank you very much.

Mr. Ray Pearl.

MR. PEARL: Good afternoon, Chairman and Members of the Board. My name is Ray Pearl. I'm Deputy Director of Government Affairs for the Los Angeles-Ventura Building Industry Association.

I would first like to thank Richard Watson for his testimony earlier. Our chapter supports every single word that he said. Secondly, I would like to thank the numerous members of the building community who are in the audience -- builders, developers, and engineers, as well as the 20 or so that could not make it today but sent letters within the last couple of days to Mr. Dickerson.

I am here representing those companies and another 350 companies that represent our association. We, along with the other groups you've heard from today, are

opposed to the numerical mitigation measures.

I didn't realize today that we were going to do all opposed and all for this, so I'm sure that Heal The Bay and NRDC and others haven't disappeared on us. So I hope that when you consider the testimony you've heard today, that you will consider it in its entirety and not just the last word you've heard.

Mr. Dickerson started off by asking for a discussion today of sound science, and I think what you've heard so far -- and I don't think my mind will be changed in the next half hour -- we simply aren't there yet. The cost is unknown. There's no detailed analysis, and as the City of Diamond Bar stated, no, it's not a requirement, but why not. The cost is going to be significant, and we hope that that will be taken into consideration.

.75, contrary to the letter that NRDC wrote, it was a negotiated settlement with the County of Los Angeles. There was a number presented by the County, a number presented by NRDC, and they met somewhere in the middle. This was stated at the workshop in August.

Another issue was maintenance after installation, how is it going to be maintained, who is going to be maintaining it, the cost of that maintenance. These are all questions that have yet to have been answered.

It is difficult for me to assess all the ramifications of this because everything at this point is so vague. In the letter that Heal The Bay submitted to you, one of the things they mentioned was being careful about existing habitat when implementing BMPs. We would like you to not forget existing human habitat. In these type of discussions, that is so often forgotten.

We, the builders, live in Southern California. We call this home. We drink the water. We swim in the oceans as well. It's important that we be reasonable and cost effective without ignoring the water quality.

There simply is not enough information for you, Mr. Dickerson, to act. And I hope the Board will reaffirm that. I like the way you started off by saying we would approve the SUSMPs and talk about numerical mitigation at another time. I think that's eminently appropriate. Let's get answers to these questions. Let's sit down and have a discussion. Let's work together. Let's not do this backwards.

Thank you.

CHAIRMAN NAHAI: Thank you.

The next four speakers would be Mr. John Hunter, Mr. Enrique Jimenez, Mr. Ray Tahere, and Mr. Ted Morton.

Now, with respect to Mr. Tahere, he's representing more than one city here and I've agreed to provide him with a five-minute time.

So Mr. John Hunter, please.

MR. HUNTER: I'm John Hunter. I'm here representing the Los Angeles River Management Committee, a group that is comprised of about 38 cities, all draining to the Los Angeles River.

After extensive discussion and review, the committee has voted to oppose the inclusion of any numerical standards in the SUSMPs. This opposition is based on several factors -- a lack of information regarding the concentration of pollutants in the receiving waters, the monitoring data that has been collected to date does not satisfactorily demonstrate that the types of activities the numerical limits have been developed for are actually going to be of benefit to the environment, the oils and greases has not been -- I guess let me back up just one moment.

The BMPs that are -- I'm going to have do compose myself here. The numerical limits that are being imposed have not been demonstrated that they will have a positive impact on reducing the pollutants of concern. I know the words "we don't know" if a vegetative swale will reduce oil and grease to a satisfactory level. In fact,

we don't even know what that satisfactory level is going to be.

In the absence of this kind of technical data, we just don't feel that the expense of installing BMPs to meet numerical limits is going to be justified. In addition, the SUSMP, as submitted by the co-permittees, we have not been notified by the Board that they are insufficient. And as far as we know, the Board has not made a determination that the SUSMPs without the numerical limits are indeed sufficient. And we wonder, does the Board or Board staff have the authority to impose these limits.

The limits should not be imposed without expensive co-permittee involvement. We've spent probably two years, maybe more, developing the model programs with the SUSMPs, and to relatively suddenly be faced with numerical limits, we don't feel is proper. The co-permittees need a considerable amount of more time to work with this so that we can indeed see that these will work.

We do not want to impose any requirements on developers or developments unless we really know that these are going to work.

With that, I'll thank you very much.

CHAIRMAN NAHAI: Thank you.

Mr. Enrique Jimenez.

Mr. Ray Tahere.

MR. TAHERE: Mr. Chairman, Board Members, staff, good afternoon. To begin with, I would like to introduce into the public record the following cities that have written letters opposing inclusion of numerical limits into the SUSMPs. They include the cities of Whittier, San Gabriel, Montebello and Lomita. These and other cities are opposed to numerical limits for a number of reasons.

First of all, bringing in imposed numerical limits would require infiltration-type pollution controls such as porous pavement, infiltration basins, infiltration trenches and other controls that remove pollutants by discharging them into the ground. As noted in a USEPA guidance document, which I would also like to enter into the public record as part of this testimony, it says as follows: "Infiltration systems may not be appropriate where groundwater requires protection. Restrictions may also apply to infiltration systems located above sole-source drinking water aquifers. Where such designs are selected, they should be incorporated with a recognition that periodic maintenance is necessary for these areas. Long-term effectiveness in most cases will depend on proper operation and maintenance of the entire

system," end of quote.

Although the development planning model program in the SUSMPs developed by the County of L.A. reference this infiltration-type controls, neither of these documents warns of their potential for groundwater contamination. I believe this is a concern shared not only by the Main San Gabriel Water Master, but the San Gabriel Basin Water Quality Authority as well, both of which are charged with water quality protection in the San Gabriel Basin.

Although other states have numeric limits, such as the 80 percent total suspended solids removal requirement, they are not inflexible as the numeric limits now being considered by the Regional Board staff. These states give municipalities the maximum extent practicable provision discretion to consider not only controls that pose other environmental problems, but are cost ineffective as well.

In contrast, the numeric limits that are being considered would hold cities feet to the fire in meeting them no matter what. In other words, the number becomes more important than the pollutant issue. Furthermore, if the numeric limits are adopted today, cities will be pushed into a mad rush to require developers to comply.

However, neither developers nor cities have experience in the proper design or maintenance of the treatment controls required to meet the proposed numerical limits. This could produce catastrophic results as experienced by a number of municipalities throughout the country.

In consideration of the foregoing, the following is proposed. Approve the SUSMPs absent numeric limits as recommended by the Executive Advisory Committee and the seven Water Shed Management Committees. The SUSMPs, by the way, include structural controls for subject new developments. Defer the issue of numeric limits for consideration during discussion of the next permit scheduled to take place a few months from now.

Direct staff to compound a committee to discuss numeric limits and other methods for controlling pollutants from new developments. The committee should be chaired by the Regional Board staff and represented by impacted stakeholders including members of the environmental community, cities, elected officials, building industry and water producers, and water quality management agencies. The purpose of this committee would provide the Regional Board with a set of options on how to control pollutant discharges from new developments in the most cost effective and sensible way possible.

Thank you very much for your time and patience.

CHAIRMAN NAHAI: Thank you, Mr. Tahere.

I've been told that six of the environmental groups that are here today have decided to pool their time and have four speakers represent them and take about five minutes each. But I'm not sure which are the environmental groups and who the four speakers are going to be. Could somebody enlighten me on that?

MR. BECKMAN: Mr. Chairman, David Beckman, Natural Resources Defense Council. We worked out with staff to have a joint presentation on behalf of NRDC, Heal The Bay, Santa Monica Baykeeper, American Oceans Campaign, Friends of the L.A. River. And one other stakeholder and myself, Alex Halprin, and Steve Fleischli are going to do one presentation which we prepared on Power Point for you.

CHAIRMAN NAHAI: So that means that we won't hear from Mr. Ted Morrison --

MR. BECKMAN: Right.

CHAIRMAN NAHAI: -- and we won't hear from Ms. Jacqueline Ambriz?

MR. BECKMAN: Correct.

CHAIRMAN NAHAI: And I have -- Mr. Beckman, before we do that, I have a card from Mr. Charles Gail --

MR. BECKMAN: Okay.

However, neither developers nor cities have experience in the proper design or maintenance of the treatment controls required to meet the proposed numerical limits. This could produce catastrophic results as experienced by a number of municipalities throughout the country.

In consideration of the foregoing, the following is proposed. Approve the SUSMPs absent numeric limits as recommended by the Executive Advisory Committee and the seven Water Shed Management Committees. The SUSMPs, by the way, include structural controls for subject new developments. Defer the issue of numeric limits for consideration during discussion of the next permit scheduled to take place a few months from now.

Direct staff to compound a committee to discuss numeric limits and other methods for controlling pollutants from new developments. The committee should be chaired by the Regional Board staff and represented by impacted stakeholders including members of the environmental community, cities, elected officials, building industry and water producers, and water quality management agencies. The purpose of this committee would provide the Regional Board with a set of options on how to control pollutant discharges from new developments in the most cost effective and sensible way possible.

water in a 24-hour rain event. I think that's very important to talk and look at the amount of water we're looking at capturing and treating.

I'm just going to leave the comments at that at this point. Thank you.

CHAIRMAN NAHAI: Thank you.

MR. GAIL: But in closing, I want to mention that the deal you're striking with the environmental group right now is not fair. Other people in this room, cities and our industry, could have asked for the same thing. We did not know that was negotiable at this time that we could pool our resources.

(Applause)

MR. GAIL: I wish for consideration, if we're going to do this in the future, that you set the rules prior to the hearing.

Thank you.

CHAIRMAN NAHAI: I'll tell what you we'll do so you don't feel that way. Once the presentations are over, if anybody feel that's there is a point that hasn't already been made that they want to make, I would be more than happy to hear from them. I think with respect to the Building Industry Association, Mr. Gail, I think you're now the third speaker to be speaking for that industry.

MR. GAIL: Mr. Chairman, with all due

respect, you cut off our first speaker of our association this morning, a gentleman that has given his time and effort on this issue for our industry and our members. You cut him off.

Thank you.

CHAIRMAN NAHAI: I think it's been fair for everybody. Thank you.

Mr. Beckman.

MR. BECKMAN: Good afternoon, Mr. Chairman. I'll attempt first just to respond to what we've heard because it's so totally outrageous and disappointing. It seems like a lot of the cities have no understanding of the Clean Water Act, no understanding of the studies that have been done around the country for ten years, no understanding of the proven treatment technologies that have recommended, and worse yet, no understanding of the SUSMP structure which allows them the discretion to pick and choose among BMPs so that the most effective from cost perspective and environmental perspective can be selected, and problems like infiltration where water tables are high, which is a problem, can be avoided.

It's a bunch of denying, deflecting, and defending storm water programs which have yet to do the trick and which have led to a really outrageous polluted

situation in Southern California.

Let me briefly tell you what we're going to tell you so that you can track it. I'm going to cover first why we need this standard, the severe storm water pollution problem that we have, and the role of new development and redevelopment in creating the problem. Then we're going to go into the discussion of the numeric standard, why it is consistent with what's being done around the country, it's nothing new, and how it is tailored by the foremost expert in the country on storm water to local conditions.

The next slide shows two other sections. First or second -- I guess it's third on there, we want to talk to you briefly about the legal foundation for this standard because we think it's well supported, and finally which want to suggest changes to make the standard stronger, to expand the scope, and also point out to you that this is a performance standard, this is not a quality-based effluent limit, and those may also be appropriate given the fact that nearly half of the water bodies in the L.A. region are listed as polluted on the State's 303(d) list.

Go to the next slide. The one after, actually. L.A. waters, Members of the Board, are extremely polluted. 50 percent, as I indicated earlier,

are listed on your own 303(d) list. That's not the environmental community's list, it's your own. That's half of the waters in the State of California that have been determined to be impaired are in Los Angeles, which is really incredible, if you think about it. The L.A. Times, as you know, did a story recently in which they pointed out that while the respected experts consider the receiving waters here to be in very troubled states and that storm water pollution is the leading cause.

Go to the next slide. That information is comes not again from the environmental community, but from SCCWR, which has reported recently that storm water pollution is the leading source of water pollution, not only across the state, but in Southern California. And storm water pollution for pollutants of concern has increased between 200 and 700 percent during the last two decades.

We also want to point out to you that it's not just our opinion, but the EPA said and was quoted in the Los Angeles Times story, pointing out that the L.A. region lacks behind virtually every place in the nation when it comes to reducing storm water pollution. This is all relevant to whether you should move forward with a standard that will help it.

Go to the next slide. Actually, I've

already covered that. The reason that this is such an efficient way to deal with the problem has to do with the role of new development and redevelopment creating the problem, and I would like to briefly go over that.

Storm water pollution, as many of you know, has two main causal components, volume and velocity. And those are related to concentration. Development contributes directly to both factors. That's essential to understand. And in particular, by creating impervious surface often where there was none before, development has dramatic effects on increasing the quantity and quality of storm water runoffs.

Now the next set of slides show you what this is about. If you compare first of all a one-inch rain storm on a natural meadow, you get about 200 cubic feet of runoff. If you compare that to a one-acre parking lot, you can see that there's 16 times the amount of runoff or 3400 cubic feet of runoff. That's a dramatic difference, and that's why this is such an efficient and effective way of getting at the problem as part of the suite of BMPs which we think are necessary. It's not the only one, but it's an important part of the mix.

Municipalities would essentially take back a useful tool out of the quiver and say let's do other things. Well, some of the other things haven't worked.

On a larger scale, that comparison that I just showed you, in terms of a 16 times increase in runoff is even greater.

And for example, when some studies were done of an Illinois water shed, it was determined that there was approximately 200 times more runoff when you compared pre- and post-development. That's water shed-wide. And the reason the numbers are different is because the implications are magnified, and take one and magnify if over the course of a water shed and you get a much worse problem even in that one-acre comparison.

The next section Alex Halprin is going to discuss, and he's also going to discuss Section 3, which is where we are talking about the legal basis for the standard.

So with that, I'll have Alex step up and he'll be followed by Mark Owen and Steve Fleischli.

MR. HALPRIN: Chairman and Members of the Board, I just want to talk briefly first about the need for this standard and then also talk about the incredible breadth of support that this standard has in other municipalities around the country, as well as the extensive scientific basis for the standard because there seems to be a lack of understanding of those issues.

First of all, the National Center for Water Shed Protection in Washington, D.C. conducted a four-year

study on waste reduced pollutant loads. The study was not targeted for development planning, but their conclusion was that a fundamentally different approach toward development was needed to (inaudible) protect (inaudible) and aquatic sources. In addition, the Urban Runoff Quality Management, which is a book that many people have cited here today. It's a very well respected kind of leading book on this topic, has stated that structural Best Management Practices for storm water quality enhancement is the cornerstone of storm water management in newly developed and redeveloped urban areas.

This is really the key method that we're going to be able to get at the pervasive problem of storm water pollution.

Storm water BMPs have been thoroughly tested. There have been dozens and dozens of studies all over the country that are determined to be highly effective. Common storm water treatment methods, such as you can see, extended detention ponds, oil separators, vegetative swales, some of these things are simple, cost effective practices. It's a simple matter to redirect gutters toward vegetated areas, infiltration practices, other media filters, can catch as much as 75 to 90 percent of solids and lead, copper and zinc reductions of half or more. Infiltration can stop the discharge 95 percent of

solids, metals and bacteria. That gives you an idea of how effective these practices are and how much they're needed.

I want to just mention some of the other areas around the country because there's the impression, I think, being created that the Board is being asked to do some so dramatic. In fact, many other cities and municipalities around the country are doing things much more aggressive than the compromise that's been submitted by the staff today. The State of Virginia has a zero additional pollution loading standard. Montgomery County, Maryland, one-inch storm. We're talking about a three-quarter-of-an-inch storm. Here in Los Angeles County, City of Santa Monica requires that a one-inch storm be captured, a one-inch storm in 24 hours for parking lots. And as you know, the County of Los Angeles itself has adopted a .75-inch standard and has adopted it for a much broader scope of projects that are in issue here. So the County's program itself is more aggressive.

The standard that's being proposed by staff today has been developed. It's not something that came out of the blue. It's not just a negotiated position or a halfway point between two positions that were staked out there.

There are several bases for the standard.

It did come out of a consent decree and the subsequent work between NRDC and Bay Keeper and Los Angeles County. It was the standard that was supported by two of the country's foremost storm water experts, one of which is Dr. Richard Horner, a national storm water expert. We submitted his CV with our papers. He's written over a hundred technical reports, studies and books on the issue of storm water control.

Also, it's my understanding that Dr. Michael Stenstrom from UCLA, who is the Chair of the Department of Civil and Environmental Engineering, also one of the other foremost experts on storm water control, supports the standard that the staff is recommending today.

We have independent experts from Camdress and McKee (phonetic) who came and spoke at the August 10th workshop, who stated that the alternative standard recommended by Dr. Swamikannu of the 85th percentile capture ratio issue was also an appropriate, legitimate standard. And imperical data from California's own BMP handbooks that we cited in our comment letter also support the 85th percentile or .75-inch mitigation standard.

So the idea that this is a number that has come out of the blue, that there haven't been any studies or any support for it is completely hellacious.

Just so that we're clear, it is true that it's not even the standard that's recommended by the experts at NRDC has consulted with. And finally, the proposed standard is less stringent than the standard adopted by the County, again, because the County's program is much broader.

I guess I want to make one more point before I get on to this third section here, which is what this standard is, because there seems again to be some confusion about what exactly it is that we're talking about here.

Several of the cities have stated concerns about what might be an appropriate BMP for a certain situation or have expressed some concern about dangers that might be imposed by certain Best Management Practices. Those things are not at issue here today. There is nothing in staff's proposal that in any way limits the discretion of the municipalities or the developers to choose the Best Management Practices that are best suited for an individual developing a site.

As Dr. Swamikannu stated, what's at issue here is a number for already approved BMPs, BMPs that this Board has already stated are appropriate, just so that it's clear how much -- what volume of water those BMPs have to treat. And again, that number was reported by

extensive studies and experts.

One other thing that I think was stated was that this was an effluent numerical limit. I don't know where that comes from. This is not a numerical limit of any sort. Again, it's just the volume that's going to be treated by BMPs that you've already approved.

Another concern was expressed by the City of Los Angeles and others, that there might not be sufficient legal authority for the Board to adopt this standard. So I want to talk just a minute about what the legal standard is.

First of all, the Clean Water Act itself and the federal EPA regulations specifically contemplate structural controls. The (inaudible) standard places the burden on the dischargers to implement BMPs unless they can show it unnecessary. This is the language from the Federal Court with jurisdiction over this area in a suit against CalTrans which is regulated by the same municipal storm water provisions of the Clean Water Act as are the municipalities at issue here today. And the Court's interpretation of the Clean Water Act was that the maximum extent practical standard, the discharger will partly have the burden of showing the maximum extent practicable standard has been met.

The other area that people have looked at

to try to convince the Board that the Board does not have authority to adopt this standard is the permit itself, so I just want to address the permit briefly.

First of all, the permit says that SUSMPs and guidelines for their preparation must be developed. That's a mandatory duty. Secondly, it says that at the minimum, the SUSMPs and guidelines shall be prepared for the following development categories, and it lists the seven that were in the County's proposal. So this is the very minimum set of -- types of development for which these programs are to be -- the SUSMPs are going to implemented and SUSMPs are to apply. And finally, it states that all permittees must implement a program for planning measures consistent with the SUSMPs.

So there is mandatory language with respect to these SUSMPs and the Board is perfectly justified in adopting this standard under the permit.

With that, I'm going to turn it over to Steve Fleischli to address the next topic.

MR. BECKMAN: What I would like to address first of all before I hand it back to Steve is basically that the staff's proposal would apply to a narrow set of projects, the seven that were stated earlier.

And one in particular is very disturbing to the environmental community is how there could have been

an omission of SUSMP for environmentally sensitive areas is just beyond us, to think that it's going to be acceptable to put developments right on top of environmentally sensitive areas. Everyone is familiar with the problems in the Santa Monica mountains and knows how totally out control that has been over the last decade or more. It's just absolutely reprehensible.

So clearly that needs to be added. It was added within the Long Beach permit. If you want consistency across the board, it needs to be added here as well, and we were very disappointed that that was not included within there. And also within the permit itself, it calls for permittees in their project characterization system to actually consider the location of a project with respect to designated ESAs. So for that not to be here is also inconsistent with the permit.

In addition, Heal The Bay and others who supported that have stated that on the hundred-foot buffer zone for development adjacent to an ESA is needed as well because of the problems that we've been talking about for and some of the many problems the Regional Board has talked about.

The County of Los Angeles, as was stated earlier by Alex, the standards apply to a wide variety of development projects. I'm not going to go into all of

them. Suffice to say the list is more than twice as long than what's on here right now. Most notable that's on the County list that's not on here are parking lots with 24 or more parking spaces. And we've all heard about parking lots and the contributions to metals pollution as well as PAH pollution, as well as ESAs. And so it's a much, much longer list with the County that's included right here.

So clearly what we're supporting in the staff recommendations is we want it to be much stronger than what is already on there right now.

With that, let me hand it over to Steve.

MR. FLEISCHLI: I just want to touch briefly on two issues with relation to water quality standards.

We've heard a lot today from the dischargers about L.A. County being under the duress of litigation and that's why they've come to the .75 standard. Quite frankly, it's been ten years that the environmental community has been under duress of foot dragging, avoidance, and in some instances incompetence by the dischargers. It's very frustrating and that's why we move forward with these lawsuits.

We even heard Alhambra today criticizing stenciling of storm drains. To me it's just absurd that we're having debates about that sort of thing. Heal The

Bay has done 70,000 storm drains. They can do it. The cities can do it. They have 18 people on staff for every single program they do.

I want to talk about where we really should be with all of this and to show you that the .75 is really a negotiated standard. The environmental community believes we should be a lot farther than that, but we were not able to achieve that in our litigation. And we believe that the .75 standard indicates reasonable further progress towards achieving our goals.

We do believe that water quality base standards would be appropriate in this instance. As was mentioned, this is an effluent. This is not an effluent limit. This is a technology-based limit that we're talking about today, .75 treatment. It's not water quality-based at all. It doesn't talk about issues like antidegradation, which for the last couple of months, I've been talking a lot about in front of you folks.

The EPA has recognized that storm drain runoff from point and non-point sources is not exempt from antidegradation sources requirements, and that would say that actions covered by -- they say that actions covered by antidegradation include the issuance of urban permits, urban runoff permits.

Under that provision, the municipalities,

the new development projects, may not add any new pollution unless they meet certain conditions, and where it's a 303(d) listed water body, they may not add any at all, no exception at all.

Xavier made the statement this morning on his slides -- excuse me, this afternoon -- that the environmental community said no new development where 303(d) listed water bodies occur. That's not what our position is. Our position is that you might not have additional pollution loading from new development. That's where we should be heading in the long-run. We should be adding language in that says storm water runoff from new development shall not increase pollution loading above predevelopment levels. That's where we're supposed to be heading.

.75 is less than that. It's a negotiated position and the municipalities seem to think that we're here today to say that .75 is a starting point. It's not a starting point. .75 is reasonable for the progress for today. We should be moving a lot further along.

With that, I'm going to turn it back over to Mark.

MR. OWEN: The environmental community has commented on all draft versions of the EAC model SUSMP. Needless to say, nearly all of our comments were ignored

in each of the drafts, and in fact, the drafts got weaker over time, even eliminating a rain event performance standard, which is what you're hearing everyone object to today. It was in a previous draft, I think two different versions.

Perhaps the EAC's efforts to avoid controlling runoff pollution are best exemplified by the language included in the model SUSMP, which I might add is still in the model before you today. Quote, "Should any conflict be discovered with the new guidelines and any preexisting regulation, the preexisting regulation shall prevail." The poisoned pill makes the SUSMPs meaningless by ensuring antiquated regulations that degrade the environment will prevail over new guidelines designed to protect the County's aquatic resources.

Please delete this offensive language. To date, the approved model programs have been late -- including this one -- short on details, impossible to enforce, and largely ineffectual except for the public education model program. We are done with the "fox guarding the chicken coop" approach to model program writing.

Six months ago, this Board approved a BMP list to abate runoff pollution from new and redevelopment. We brought up the need for numeric performance standards

to ensure the BMP would be implemented effectively. We were told the Board would address this at a later date.

Two months ago, we brought this issue again during the Long Beach storm water permit. At that time, the Board took extraordinary measure of deferring the new and redevelopment performance standard within that permit for today's discussion on the SUSMPs. Again, nothing was done during that day.

On Long Beach, just to let you know a side, we were shocked to see them testify because as part of our negotiation, they said they would not come back and testify in opposition to this particular thing, so we think that's actually a direct breach of faith.

The Board needs to make it clear that a numeric performance standard for new and redevelopment must be adopted to ensure the protection of aquatic resources. We're not talking about policy retrofits. We're talking about the most far-reaching, cost effective way to reduce storm water pollution today and in the future.

The current situation of unsafe beaches, toxic creeks and streams, contaminated sediment hot spots and beaches that look like landfills after every single rain is absolutely unacceptable. We strongly --

CHAIRMAN NAHAI: Can we stop?

MR. OWEN: Okay.

CHAIRMAN NAHAI: Thank you. Mr. Don May and Ms. Joan Greenwood.

MR. MAY: My name is Don May. I'm a resident of Lakewood and what the very first speaker referred to, I'm a real party of interest. One of those folks that's a swimmer and a fisherman on the water, one of the people that Clean Water Act talked about when they wanted to make the waters of the country fishable and swimable in ten years. That was 30 years ago.

Surely in ten years if we can put a man on the moon, we can make our waters fishable and swimable. We're still trying.

I wanted to talk to you because I received a letter from my city, Lakewood, that I am totally in disagreement with, with the exception of the part where it talks about how Long Beach basically showed the cities how it is, through a program of coercion and litigation, that they can defeat the efforts of this Board to bring about the changes required to enforce the Clean Water Act and make our waters fishable and swimable, particularly with ESAJs.

With Long Beach with the wetlands that are down there, they require particular protection, and I would point out that under the Bolsa Chica decision, Bolsa

Chica Land Trust versus Coastal Commission, ESAJs are protected. And we urge you to look at that decision and that language.

This region indeed is the worst in the nation. And one of the things that's happened as a result of that, not only is the efforts of Long Beach used around the country as a model in how to evade doing something about storm water runoff, but that has produced ever worsening positions.

My family -- my parents, my grandparents, and seven out of eight great grandparents met the protein needs of their families through fishing through the depression through the big war. In the '60s, we saw the fish disappearing because of storm water runoff. Saw several species of black croaker, one of the China croakers that was a mainstay, disappear. And the '70s, birds having problems. In the '80s epidemics among the seals and so forth. And now we find bacteria, intercoccus viruses.

The problem from storm water runoff, it's clearly linked back to human health and this interdiction, these BMPs, is how you solve the problem.

I'd like to change a hat. I'm also a medical device manufacturer. And those of you in business who think regulation is tough should try dealing with the

FDA. The cornerstone of making medical devices safe, cornerstone of regulation by the FDA is BMPs. And the two parts of BMPs that are most important and result in safe medical devices are monitoring and numerical limits. Without numerical limits, you can't have effective BMPs. And I would point out that my medical devices, which happen to be catheters, catheters have a better medical record in terms of getting people sick, infected and dying than our beaches do. And when it comes to a point that putting one of my devices in your chest during open heart surgery poses less of a risk than going for a swim in the ocean, I think it's time to look seriously at these BMPs and the pollutant situation.

Thank you.

CHAIRMAN NAHAI: Thank you.

Ms. Greenwood.

MS. GREENWOOD: My name is Joan Greenwood. I'm a resident of the City of Long Beach, California. I am the Environmental Chair for the Wrigley Association. The Wrigley District of Long Beach is an area between Pacific Coast Highway and the 405 freeway. Our western boundary is the Los Angeles River. We are extremely concerned about the issues that have been brought to the Board today.

The City of Long Beach, in preparing it's

new strategic plan for the first time appointed an environmental task force. Four members of that 18-person task force are residents of the Wrigley District. As part of our recommendations that we'll be going to the City Council within the next month or two, we have made a strong argument for adopting the type of BMPs that are under discussion today with numerical limits and full accounting for the impact of development on the taxpayer down the road.

We already have the commitment from one member of the City Council. To bring this issue back to our new City Council, not the one that was seated when the litigation was initiated years ago, but our newly comprised City Council, there will be workshops, there will be public hearings. And again, we felt this subject was far too complex to enter into it at the time the Long Beach Municipal permit was being discussed within the city to make a change. But we intend to raise the bar, and we will raise the bar so that the City of Long Beach, when it adopts a sustainable city program within the next quarter -- and we now have the support of the other four task force on this issue -- we will be raising the bar on the storm water permits for this city.

So I did want to let you know that the people who live in Long Beach, because with all our public

testimony on this issue, the open forums, not once have we had a resident object to anything that has been put forward by your staff in terms of BMPs.

Thank you.

CHAIRMAN NAHAI: Thank you, Ms. Greenwood.

I have a final card from Chris Bertelli representing the Building Industry Association.

MR. BERTELLI: Thank you, Mr. Chairman. Thank you, Board. Building Industry Association of Southern California does represent approximately 1800 members throughout Southern California, but I will not ask for three minutes for each one of them at this point in time.

(Laughter)

MR. BERTELLI: A lot of discussion up here has been about the numerical limitation standards, and the reason we are discussing and debating about them is because they are not required under any legislation or under regulatory requirement at this point.

Our friends in the environmental community made a very nice presentation, and it included several municipalities that already have numerical mitigation standards in practice, but from what we have been able to garner from the record currently compiled by staff and

compiled by the Board, there are no results and no costs, no result or cost analysis of any of those mitigation standards.

If they're already in place in other parts of the country, we should be able to quantify those costs and those benefits and the effectiveness of those programs before proceeding on a gigantic scale here in L.A. County.

If I may just say one more comment directed toward Mr. Dickerson. You have a responsibility that none of us here, I think, envy. There are very few individuals, I would say, either in the country or in the world who can with one decision impose millions upon millions upon millions of dollars of cost upon municipalities, upon builders, and upon landowners. So I would hope the Board at this time would direct Mr. Dickerson to postpone action on this item for today so that we may all be able to sit down together and discuss this issue.

Thank you.

CHAIRMAN NAHAI: Thank you. With that, we'll ask for a response from staff.

VICE CHAIRMAN KESTON: Mr. Chairman, can we ask any of the members who spoke some questions?

CHAIRMAN NAHAI: Of course we can. We first want to hear from our staff?

VICE CHAIRMAN KESTON: Whichever you --

CHAIRMAN NAHAI: Do you have comments to add or shall we go straight into asking questions?

MR. DICKERSON: I would prefer to go with the questions at this point.

VICE CHAIRMAN KESTON: Mr. Chairman, I have some questions, one for Mr. Gold and one for Mr. Beckman. And again, everybody here sounds like a participant at the debates and discussions on water going from the north to the south. There seems to be quite a difference here.

But first as to Mark Gold, your comment about development within environmentally sensitive areas is a fairly significant one. I don't think anybody wants to destroy environmentally sensitive areas. The procedure in all municipalities for SEAs generally are very severe and stripped. If you go into L.A. County or any county, they have a CEQA document, and you have to come up with mitigations if you're going to develop at all within an SEA, but there isn't a prohibition.

I don't know if you're suggesting there should be a prohibition in its entirety or that the CEQA document be followed, and within the CEQA document, storm water requirements should be looked at.

MR. GOLD: Not even that. That's actually clearly stated within the permit. What I'm suggesting is

that as an additional category to the seven categories, is that the eighth category would be any development in an SEA. So that would also have to meet a .75-inch standard, nothing more than that. We're not trying to prohibit any development, just SEAs.

VICE CHAIRMAN KESTON: Thank you very much.

And David, my question to you is whether we go to numerical limits or not, a lot of the comments here dealt with site-specific problems. Obviously if you have a site and you have a high water table, nobody would want to put a detention basin in there.

So how do you feel about the issue of not looking at each specific site, but perhaps looking at multiple sites? If there were specific limits, numeric or otherwise, it should be across an area, five sites or whatever, so that the City retains flexibility to deal with issues where each site can be looked upon differently, but overall they're solving the issue and the problem you're dealing with.

MR. BECKMAN: Well, I think that the standard and the proposal that's in front of you accomplishes that. One of the things you might not realize in listening to the majority of the testimony is that there is not a particular BMP that's prescribed for each situation, nor is there a particular suite of BMPs

that have to be selected, nor are there untested BMPs that are being forced upon anybody. BMPs, as was stated by Mr. Halprin, are already approved, and they can be mixed and matched and implemented and designed in a way that is most effective for site-specific conditions and --

VICE CHAIRMAN KESTON: But if one site can't meet a requirement of .75 inches because it is a parking lot, that's all it is.

MR. BECKMAN: Right.

VICE CHAIRMAN KESTON: How do you feel about taking the surrounding areas and say this one exceeds it by four times, but the other ones are half, and therefore you're meeting the requirement?

MR. BECKMAN: Like a trading concept is really what you're suggesting. I think -- NRDC's position is that we're not against the concept but we've never seen one that we think makes sense specifically. I think that would introduce many of the bureaucratic issues which the cities are raising, I think inappropriately, in the context of the current proposal. Then you have to figure out well, what is the precise contribution of one place versus another place. You would have to get into monitoring issues which are not part of this proposal. There are not numeric effluent limits being proposed here.

So in a certain sense I think that might go

beyond what you're even proposing because you have to introduce some kind of numeric effluent concept in order to accomplish it. I think that's very complicated, and I would not suggest that the Board go in that direction because of the reasons I've just stated.

VICE CHAIRMAN KESTON: So you think each site needs to be dealt with --

MR. BECKMAN: That's right.

VICE CHAIRMAN KESTON: -- and have its own limit?

MR. BECKMAN: I think the evidence in the literature suggests that sites can be mitigated because it's a proportional standard. It has to do with the size of the site, obviously, and for those reasons a small site will need smaller BMPs, a bigger site may need bigger BMPs.

MR. OWEN: Just to add one thing, because there has been some real world experience here locally on this for the last seven years in the City of Santa Monica, which has instituted their one-inch standard for parking lots. In that case, obviously from the standpoint of retention and how it's actually written in this case is you can either do treatment or infiltration, which I think is a keep point. But there were some areas in Santa Monica, some areas in Malibu, when they had an

ordinance which was stronger than what we were talking about today. Where Malibu you had some geologic hazard issues of landslide, and in Santa Monica you had some requirements of a promenade they had dealt with in that circumstance with an in-lieu fee. Rather than the pollutant trading concept, if someone is building a huge baby gap on the promenade, they have to retrofit a parking lot somewhere else in the city.

VICE CHAIRMAN KESTON: I see.

CHAIRMAN NAHAI: Any other questions for any of the speakers? I had a question for Ms. Rose Collins, City of Long Beach, if she's still here. I wonder if you would help me out with something.

I remember when we were dealing with the Long Beach permit and this issue was being discussed. One of the persuasive arguments that was made by the representative of the City was don't do this to the City of Long Beach now because we have to compete with our neighboring cities for developments to come in, we need to build up our tax base, and if you do this now, it wouldn't be an equal playing field. But at such time as you're going to adopt a county-wide standard, then we'll all have an equal playing field and we won't have this issue of competition. But then what happens is you try to adopt a county-wide standard and it's good and well, but what

about Orange County and after that it could be what about Nevada or neighboring states or Canada. Or we're in a global economy, and they don't have these kinds of standards in South America.

It would appear to me at first brush, anyway, that municipalities would welcome a regulation that would set a uniform standard for everybody so that they wouldn't be put in the position of having to compete with one another. How do you respond to that?

MS. COLLINS: I agree with what you're saying. We do want a uniform standard, and we are not opposed to numeric limits per se. If people have a different impression, they've gotten the wrong impression. What we're saying is and what we said during our negotiations was if the numeric limits, if we have the scientific data that says they are going to improve our beneficial uses in our receiving waters, we will go full force ahead. We believe in these programs. As you know, Long Beach is surrounded by water. Our residents enjoy it. Tourists come in. We want clean waters.

But we want to make sure that what we're doing is correct. We want to make sure that we don't get the cart before the horse, that we have a solution before we truly identify the problem, and we want to make sure that those dollars that have been identified by some of

the building associations here today, that they are appropriate. If they're appropriate, then let's do it. And if that's the cost, that's the cost.

It's true that if you have something in L.A. County and it's not in Orange County or Ventura or whatever, that there will be a problem because those on the fringes may go to another county to do their development. But it's my understanding that the Regional Board, once they start adopting these, whether they're working on L.A. County or Ventura County or the various counties, that they're going to try to this as uniform as possible. And I'm sure statewide would work with the other counties as well, because what makes sense in one county would make sense in another.

There is a dig difference between rural and urban developments, and that's one of the reasons in some cases, in the examples that you've seen earlier, have worked because they have the land to do it. And perhaps in Santa Monica with the waiver, something along that nature, could work for us as well, but we don't know, we haven't gotten into it, and I think that's one of the reasons the cities are so apprehensive about it.

They just want to make sure that this is the right thing and we're not asking developers to spend money that's not directly contributing to the mitigation

of pollutants going into our receiving waters and affecting beneficial uses.

CHAIRMAN NAHAI: Thank you.

MS. COLLINS: Thank you.

CHAIRMAN NAHAI: Do you have any additional comments?

BOARD MEMBER COE: I have questions.

DR. SWAMIKANNU: Just a comment, Mr. Chairman and Members of the Board.

On the issue of threshold of evidence, in terms of having site-specific impacts, I think the federal regulations themselves based on long-term study nationwide are including sites in California. It's been clearly established that pollution is associated with urbanization. That's related to population as well as traffic and things like that. And the point here is that we see exceedances of metals, for example, and organics in storm water in the Los Angeles region.

We have been monitoring for at least four years now, and water quality standards are being exceeded. So the issue in new development is that we are trying to at least -- trying to obtain water quality in some of these cases or at least prevent further exceedances or higher exceedances.

So for us to require that every single

situation be justified on the basis of site-specific data is simply, to me, wasteful and probably not anticipated by the act itself. There was a broad basis for these regulations. There is a broad basis for the permits, and we have to take the next step.

Thank you.

CHAIRMAN NAHAI: Dr. Coe.

BOARD MEMBER COE: Question. This probably should be addressed to the cities, but let me ask you a question. Apparently we need these numbers -- .75-inch, 24-hour period or 85 percent tile -- so engineers can design facilities. It's a design standard. It tells you how big that you're going to build something. It tells you how much volume of runoff you're going to be able to handle. If you don't have that, then every city could be have a different design standard in handling a little runoff over here, in another city, a lot of runoff over here. In other words, one city would be improving the water quality a lot and another city not or very little.

Is that the reason we have to have a design standard and some numbers here?

DR. SWAMIKANNU: Mr. Coe, the issue previously has been certainly that we have to be consistent in the region, we have to be consistent statewide, and sometimes you might want to have different

standards for different regions. But it makes no sense to have that kind of variation within the Los Angeles area. Perhaps L.A. County and Ventura County are different in some sense and we can justify a slightly different standard for Ventura County, which is still developing as opposed to Los Angeles.

The purpose of this clearly is to level the playing field for this region, and the number is based on reasonable justification that is recommended by preeminent national associations which have gone through this process. They have these rating charts for around the country, and so the time is now.

But the second issue is given the fact that for Los Angeles County in the unincorporated area, whether we adopt a numerical mitigation measure or not, there is going to be a performance standard, and the performance standard is going to be three quarters of an inch. As part of that L.A. County Department of Public Works is going to develop design standards for the separate BMPs they're talking about -- how large they ought to be, what dimensions, and that that could then be used for all the cities. Otherwise, the whole effort is limited to just the unincorporated area. The cost efficiencies associated with that kind of a broad use of a standard as being adopted by one municipality in this region, and --

BOARD MEMBER COE: Wouldn't there be an unfair economic advantage if one city is using a less stringent standard than another?

DR. SWAMIKANNU: The question is a difficult one, what is fair and unfair. I think cities are inherently different. I think as an agency, given the fact we cannot separate the pollution problem in this region, we don't know which city it's coming from, we don't know what the relative contributes are, we would then basically be reasonable and saying everybody make the same effort to solve the problem simply because we cannot allocate the relative contribution of pollution from each of the cities.

BOARD MEMBER COE: And we're providing the necessary flexibility among the cities to take care of on-site differences through the array of Best Management Practices they can pick and choose.

DR. SWAMIKANNU: Yes, Mr. Coe. If you look at the BMP list we adopted, it's a whole selection of BMPs. Nowhere do we designate a particular BMP as being preferred over another. So we primarily have the responsibility and the opportunity to identify the BMPs that work best in the situation in which the particular site is subject to.

BOARD MEMBER COE: Thank you.

CHAIRMAN NAHAI: Let me see if I can place this in perspective for myself, if I might.

As I understand the testimony that's been presented here today, nobody quarrels with the fact that SUSMPs are appropriate and that the BMPs are appropriate and everybody is wanting to go forward on that basis.

As I understand it, the only argument is that what is being proposed is that storm water runoff from storms in 24 hours, three quarters of an inch, that BMPs need to specifically address that so that one city isn't able to say I would only regulate storm water up to, you know, a tenth of an inch, whereas another one might opt for three quarters of an inch for L.A. County being three quarters of an inch, Calabasas being an inch; is that right? Am I correct in terms of characterizing what it is that we're talking about here?

DR. SWAMIKANNU: Mr. Chairman, I think there are probably a couple of issues that you clearly state the one interpretation of the comments that I've heard today, and that is the fact that there's no flexibility from city to city. But I think the larger issue also is that once we establish mitigation measure, then there's only one standard. The BMPs have to be designed for that. So the question is the standard that's being proposed, is it reasonable? Does it actually reduce

pollution in storm water runoff?

And an additional question is, is it reasonable? Is it economic in some sense so you're not being asked to treat the hundred-year storm, which you would be more concerned about human safety at that point. And our submission to you is the fact that we have had nine years. We started with public education and started with all the other components, things that the cities are already doing to elicit connection, elicit discharge elimination, those programs have been ongoing.

Here is an area that took us time to get there. It's new development that suddenly issues associated with that. What we are saying is this is a first step. We can consider pollution prevention Best Management Practices as somebody pointed out, but also engineers will tell you in some of the situations, many of the situations, you actually have to do treatment. Three quarters of an inch, based on the historical record, is 85 percent rainfall over 24 hours. And so by implementing the BMPs, we will be able to affect a large number of events in the future. And so the standard itself is not burdensome except for the fact that some haven't had the chance to analyze it. The fact that (inaudible) applied in other parts of the country as well as (inaudible) said that it's a reasonable and optimal, and there's a point in

time when you have to make a decision. Policy makers like you always have that difficult task. Do we wait for all the (inaudible) to come in, which it never does, or do we make the best decision we can at this point in time based on the information we have? And I think that is a charge that both staff and you face in this particular aspect of the program.

CHAIRMAN NAHAI: How do you respond to the contention that as of this moment there, isn't enough science on the effectiveness of this, that we simply don't know enough? Your contention would be that we've had nine years and had a whole bunch of studies, and that this is a justifiable and reasonable and cost effective step to take at this point.

DR. SWAMIKANNU: I would modify what you just said to the fact that BMPs, the effectiveness of BMPs, are not really region specific. They might relate to the rainfall and the sizing, but they're not rating specific. So if BMP works in Maryland for parking lots, it will probably work here. That kind of information has been put together in a database by the USEPA to answer the simple question of saying we don't know right now how effective BMPs are. And the whole purpose is to make municipal planners and engineers go to that database, to look at the information there, to see how effective these

BMPs are, but for the particular circumstances that the particular development is located in. So that information is out there.

What we are probably hearing is that these BMPs have not been tested in the Los Angeles region. Even to that I would say many of these BMPs are being applied. They probably don't have, except for anecdotal evidence, any monitoring evidence to say that these are functioning within certain ranges. We might have that.

Look at the other issue. Ventura County comes within our region. They have BMPs and they have monitored the effect of them. So there's information out there which might not be apparent to many of us simply because it's not been compiled for this region.

CHAIRMAN NAHAI: And you're saying that information, that you've analyzed that information and have come to the conclusion that the three quarters of an inch numeric standard is a reasonable and justified standard.

DR. SWAMIKANNU: There's some confusion here. The two aspects to it, Mr. Coe pointed out. One is simply the sizing of BMPs, how much volume do I address, not whether BMP is effective or not. Effective means removing pollutants. Different BMPs will remove different pollutants. The standard here we're talking

about is simply how big do I need to make these things. It's like I was telling somebody, if you look at the Federal Transportation Safety Administration, they would say you have to design ways to protect public safety, but they will also tell you what that safety design is based on. They would say driving at 30 miles per hour for maybe a hundred yards, and the occupants should be able to survive that impact. So they establish a standard. Otherwise, manufacturers would have no idea how to design the vehicles, and what we are proposing here is that kind of design standard, not really saying what -- whether it's a car or it's a van or it's a truck.

VICE CHAIRMAN KESTON: Mr. Chairman, I have a couple of thoughts that I would like to express.

First of all, Xavier, I think a federal design standard for highways where a highway is a highway and it's pavement, is very different than a standard for storm water where each site is different. It drains differently, it looks differently, it's a different size.

To make one standard fit a half-acre property or a seven tenths of an acre property that we heard this morning in -- next to a Boeing plant, and have that same requirement apply to a 2,000-acre pristine property up in the mountains just doesn't -- and some are urban and some are suburban -- doesn't seem to make sense

to me.

I can understand that you look at a region or a water shed as we do today. We say that water shed has to be at a certain level, but I find it very difficult to deal with taking a two-acre property, a half-an-acre property, a 50-acre property, and say they all should have the same standard because it isn't a car, it isn't a highway. It's a very, very specific thing.

And I think that's what most of the cities are saying. They're saying the issue here is whether we're suggesting that the BMPs are guidance to a city and we let the city decide how best to deal with each specific site, we say here's your umbrella, and you've got to deal with this. This is what we want you to do. Then if we come back and say you're not doing enough, we have that responsibility. Or we go and put a straitjacket around the city and say every specific site has to be dealt with in exactly the same standard, regardless of where it is in its structure, or whatever.

So I'm really kind of bothered by that kind of a standard, and I think Mayor Hardison from Torrance really said don't shove it down our throats. Give us some time to understand each other's position and work it out. And I think that's probably the appropriate thing to do. You may wind up at the same place some months from now,

but I think everybody needs to sit down -- it's obvious that there's a misunderstanding or a tremendous difference of opinion here. I think you want to get everybody together to deal with the issues, to deal with the specifics. And before we do what we might -- what we did under the NPDES permit where perhaps we didn't give people enough time to talk, I very much suggest we give a lot of time for people to deal with this issue.

I think approval of the SUSMPs by Dennis would be appropriate, but I would defer the numerical limits until after we have stakeholders meetings, and I would identify the BMPs as guidelines and today not as a requirement because that gets back to the same question of whatever. So that would be my suggestion, Mr. Chairman.

DR. SWAMIKANNU: Can I comment on what Mr. Keston said?

Basically on the BMPs there is a choice of BMPs, and all we are saying to approving the SUSMPs is where treatment controls are appropriate and where you designed them, you designed them for a particular site. So the flexibility is there. The other issue, you talked about regional BMPs as opposed to site by site. That certainly is an alternative that could be considered in certain situations where it might not be practical to address it at the location.

BOARD MEMBER COE: What effect would a delay in a decision not made today have on the program of implementing BMPs? I probably should know this, but there must be some kind of schedule and we don't want, I don't believe, the cities all started going out and constructing something that will be in violation of the standard later on.

DR. SWAMIKANNU: The attorney, Jorge Leon, is not here, but I'll try and answer that question.

There is a deadline on the permit, in the L.A. permit where we talked about implementing all requirements by this default deadline, which is July 30th, 1999. It's gone past that. We have approved some elements of development planning, for example, we've developed for the education component, identified priority projects and such. So the issue now is suppose we do approve the Standard Urban Storm Water Mitigation Plans. They would be able to look at source control BMPs, treatment control BMPs, construction controlled BMPs. But what wouldn't be there is for anybody looking to see how do I want to design treatment control BMPs.

BOARD MEMBER COE: Let me get some clarification, if I can, on what you said just before I asked my question.

Did you say that it's an opportunity in the

R0071887

permit as stated now or it could be added that a waiver could be approved by the Executive Officer, perhaps, if additions warranted different numbers than .75 and so on?

DR. SWAMIKANNU: That's a modification that Dennis might be able to make to the Standard Urban Storm Water Mitigation plans before he approves them. That possibility is not preclude by the permit itself.

BOARD MEMBER COE: It's provided in the permit, but it's not precluded.

DR. SWAMIKANNU: It is not specifically provided in the permit.

CHAIRMAN NAHAI: How do you respond to Dr. Gold's comments about environmentally sensitive areas?

DR. SWAMIKANNU: We -- when we worked out the Los Angeles County permit, the environmental community and other representatives in municipalities worked on it together, and that was an opportunity then to work out the language, which we did, and we established it to these seven categories.

Now for us to reopen the permit and add this environmentally sensitive areas would require a reopener, which is again almost like reissuing a permit. For us to say that what was submitted to us, which is the Urban Storm Water Mitigation Plans, is limited to these seven categories and not the eight that Dr. Gold would

like, for us to call it efficient is not within the terms of the permit.

I think it's an appropriate issue to look at when we reissue the permit, which is not that far away, couple of years. We should have included it perhaps in 1996, but we just missed it. It's not right to change the scope of the program midstream.

CHAIRMAN NAHAI: So you are saying that would have to be dealt with when the permits comes up?

DR. SWAMIKANNU: That would be the appropriate time.

CHAIRMAN NAHAI: Mr. Dickerson, do you have comments for us?

MR. DICKERSON: I wanted to make sure something is understood by the Board.

AUDIENCE MEMBER: Just when are we getting a chance to respond to the environmental community?

CHAIRMAN NAHAI: We've heard all of you, and I assure you that we haven't forgotten the testimony that was presented at the beginning of the hearing. It doesn't matter if testimony is presented at the beginning or at the end. Plus we have analyzed, digested, and read through umpteen letters and this much in materials regarding both sides of the equation.

I promise you we're used to doing this and

there is no need for rebuttal.

BOARD MEMBER LYON: Mr. Chairman, I need to interject something. This was not noticed as an action item.

CHAIRMAN NAHAI: It's not. It's an informational item.

BOARD MEMBER LYON: I would like to ensure the audience that no action is going to take place today.

CHAIRMAN NAHAI: The Board is not going to take a vote today. It's not an action item. If there is a point to be made that we haven't heard before, we'll entertain it for the sake of absolute completeness.

MR. YOUNG: Mr. Chair, thank you very much again. Rufus C. Young, Junior.

A point that I had not heard before is that apparently the several representatives of NRDC and the municipalities are in agreement on something, and that point is -- and I believe this is very close to a quote, if not an exact quote, nothing in the SUSMPs limits the discretion of the municipalities to choose the method. That is not what is in the SUSMP, and I trust that there is now agreement as a result of the Board process changing the sentence in the SUSMPs that say the SUSMP outlines the necessary BMPs which must, mandatory word, be incorporated. If that is changed to discretionary, I

think we have the case of at least one municipality in agreement with the NRDC.

There is one remaining point that should be crystal clear. No one should leave this room with the view that the City of Alhambra opposes stenciling or signage.

(Laughter)

MR. YOUNG: My question was to use the book of Mica, 6-8, "What does the Lord require of thee but to do justice, have mercy and walk humbly with thy God?"

I would paraphrase that. Alhambra asks, "What does the Board -- what do you, the Regional Board, require of the cities to in turn require of the developers?" And that's our point. It's not opposition, it's how do we implement.

Thank you very much.

CHAIRMAN NAHAI: You're all going to make me regret this, aren't you. It's this lady and that's it.

AUDIENCE MEMBER: I just wanted to say that, and what we meant to say and I think what we did say, is that nothing limits the discretion of the cities within that suite of BMPs that have been provided to meet the standard. That's not to say they don't have to meet the standard or don't have to do some or one or a combination, but that there's not a prescribed BMP or a

prescribed situation, as Mr. Keston was concerned about, provided in this proposal.

VICE CHAIRMAN KESTON: Could they use others outside this list if something is better?

AUDIENCE MEMBER: I think -- I'd have to look at the text. I think the list that's provided is broad enough that virtually anything they would want to do is in there.

VICE CHAIRMAN KESTON: It's not just what's in that list, it's anything that would solve the same purpose.

AUDIENCE MEMBER: I think that the list was intended -- the reason you approved the list was to narrow from the universe of possibilities to those which you believed were appropriate, but there's a number of those that are appropriate for different situations in the list.

CHAIRMAN NAHAI: That's the list we've already approved.

AUDIENCE MEMBER: That's right.

MS. CLOSE: My name is Barbara Close. I'm with U.S. Grinder Woodward Plied, and our firm and other consulting firms have worked with the permittees in what has been submitted to the Board. I do want to make sure the Board understands that these Standard Urban Storm Water Mitigation Plans are not the only plans the

permittees have to deal with.

The Standard Urban Storm Water Mitigation Plans are not the only way development is regulated. The seven were picked because they're very broad categories of development. Mr. Gold has a concern that environmentally sensitive areas will somehow be overlooked.

Every city, in complying with the permit, has to identify priority projects in the development process. Each one of those development projects, whether it's been identified as priority, even if it's not one of these seven, have to submit an Urban Storm Water Mitigation Plan. So just because it's not one of these seven does not mean it's not going to be regulated.

I just want to make sure the Board understands that this isn't just something that's very narrowly focused on those seven categories.

Thank you.

CHAIRMAN NAHAI: Thank you.

No, no, no. I said you're going to make me regret this. We have to stop at some point. That's it. You've already spoken five minutes.

AUDIENCE MEMBER: Just ten seconds.

CHAIRMAN NAHAI: No. Thank you.

MR. DICKERSON: I want to thank the Board very much for sharing the burden that was imposed upon me

by that permit, and it's clearly something I appreciate very much. Thank you.

I do want to thank Xavier very much for his efforts in trying to explain this very complicated issue today. It's very appreciated. Thank you, Xavier.

The first comment is I just want to apologize to anyone who did not receive adequate notice regarding this. We did have a workshop on August 10th. We discussed this in detail. We did, at that time, indicate that we would be here today. So there was at least constructive notice, if not actual to some of the individuals. And there have been a number of individuals here today who we've not seen before, and I would ask that they be sure to provide their business card to our clerk so that we can be sure to ensure they are on our list to the proceeding in future notice.

Several points come out today that I think are very important. One is the clarifying language of what is specifically proposed in the SUSMPs, both what has been proposed to us and also what has been proposed by us. It seems that some additional work in that area might be very beneficial.

It's also very clear that a very solid record needs to be developed, probably beyond what we have already, with regard to this proposal in order to ensure

that it can withstand the scrutiny of subsequent legal action. I have a sense, no one has said that directly today, but I at least have a sense it could be the source of some controversy down the road if it were to be approved. I do have a concern about that.

As I noted at the beginning, at least given the controversy, the depth of the feeling and certainly I would echo Mr. Keston's comments about the desirability about having additional discussion, and it may be that through that some approaches might rise to the top that suggest that there's great unanimity on some suggested fairly quickly, while others perhaps need more in-depth discussion. So I would be very much open, as I suggested earlier, and would happily take this matter for further consideration.

With the benefit of this discussion today, I would ask the Board whether or not, given that opportunity for additional review, whether or not you would want to hear this again. I'm more than willing to take the burden from this point and finalize a proposal that I could then approve at some point in the future.

Thank you.

CHAIRMAN NAHAI: Well, do we have questions of Mr. Dickerson?

BOARD MEMBER DIAMOND: I do have one

question. How much -- you mentioned you were concerned about legal issues in the future. What about the fact that we are behind the eight ball right now already having the deadline of July 30th, I believe. Having passed, what kind of ramifications does that have?

MR. DICKERSON: We do have a permit that says that the development planning elements of -- well, actually there's a number of different model programs, five model programs, and they all have to be in place by the 30th of July. Each of those are in place at this point in time, and storm water planning, the implementation of Storm Water Management Plans, should be ongoing at this point among of the all the permittees in the county, so a lot of work is going on. I don't see our co-counsel any longer, and I would actually like to get some guidance from co-counsel with respect to that.

My initial sense is that we could probably, if there's not a legal bar to it, that the extra time might be very well spent.

BOARD MEMBER LYON: I --

CHAIRMAN NAHAI: Go ahead.

BOARD MEMBER LYON: I just wanted to say that as one Board Member, I would like to help you in your decision making process. I would have to defer to the rest of the Board as to whether they want it to come back

to this type of meeting again, but I don't think we should leave you adrift out there in your decision making process. I think the Board should aid you in direction as you meet with the stakeholders on this. So that's just my opinion.

CHAIRMAN NAHAI: I also agree with what Marilyn is saying. I don't think it's right or fair that we not share this burden with you. I think the issue is -- and if your recommendation is that more time be spent on building the record, then I would concede to -- if that is your recommendation, as it appears to be. But I would be very concerned about time and how much more time and at what stage are we going to bite this bullet and deal with the non-point source problem that so plagues us.

And I would just say to the municipalities that are here, at some point we're all going to have to bite this bullet together, and at some point we're all going to have to make sacrifices -- I will as a taxpayer, just with the rest of all of you -- to try to deal with the pollution of our waterways, and I would just plead with you that at some point where you come to realize, as a citizen of this area, that there is sufficient evidence there to adopt these standards, that we don't do it just for the sake of short. We don't reject it just for the

sake of short-side considerations, and we think about what's going to happen to the future of our region.

So with that, I will ask you how much more time?

MR. DICKERSON: I would not want to go beyond the end of the year. That would probably be an adequate time to at least vent the issue somewhat more.

BOARD MEMBER LYON: That would give the regulated community an opportunity to analyze the recommendations again, the three quarters of an inch. I think the cities, they've been here today, they've listened this and they can go back and ask their public works director what it's going to mean to our city cost-wise, can we do this, what kind of charges are going to be involved.

The cities are limited and they can't just raise taxes any longer. That ability has been taken away from them. So they need to go away from here and think about it and bring that back.

BOARD MEMBER COE: Mr. Chairman.

When does the permit come up for renewal?

MR. DICKERSON: The permit will be before the Board again in July of 2001. New applications are required to us by January 1 of 2001.

BOARD MEMBER COE: So this gives staff and

the Board and the permittees an opportunity to thoroughly reevaluate their experience with this permit and make any changes that are required.

MR. DICKERSON: Certainly within the next permit.

CHAIRMAN NAHAI: So your suggestion is that we have another delightful gathering like this --

(Laughter)

CHAIRMAN NAHAI: -- at our December meeting where we can revisit with old friends?

(Laughter)

MR. DICKERSON: Once again, thank you for sharing the burden.

Perhaps given the fact that we probably will have -- we may very well have a crowded agenda, we may want to set a special meeting time for consideration of the final proposal. Would that be acceptable to the Board?

BOARD MEMBER LYON: Yes.

CHAIRMAN NAHAI: I think it's an issue of tremendous importance.

MR. DICKERSON: And this is subject, of course, to making sure that our counsel says that that's okay to do.

CHAIRMAN NAHAI: I see our counsel nodding

his head and her head.

MR. DICKERSON: Thank you.

CHAIRMAN NAHAI: Thank you.

CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD

LOS ANGELES REGION

PUBLIC MEETING/HEARING

TRANSCRIPT OF MORNING PROCEEDINGS

January 26, 2000

9:15 A.M.

Holiday Inn
303 East Cordova Avenue
Pasadena, California

REPORTED BY:

Caroline Jetter,
CSR No. 11568
Our File No. 1-62540

APPEARANCES:

BOARD MEMBERS:

CHAIRMAN H. DAVID NAHAI
MARYLYN LYON, VICE CHAIRMAN
JACK J. COE
SUSAN CLOKE
FRANCINE DIAMOND
TIM SHAHEEN
ROBERT MILLER

ALSO PRESENT:

DENNIS DICKERSON
JORGE LEON
DR. XAVIER SWAMIKANNU
ROBYN GOODMAN

AGENDA

ITEMS	PAGE
Roll call	4
Order of agenda	5
Minutes	5
Report of nominating committee	5
2000 board meeting schedule	7
Ex parte communication disclosure	7
Uncontested items calendar	8
Public Forum	10
First 30-minute segment	78
Second 30-minute segment	119

CHAIRMAN NAHAI: Good morning, ladies and gentlemen. We have a quorum of the board present and so since it's about 9:15, let's get the proceedings underway.

We'll start with the pledge of allegiance. And I would like to ask Dr. Jack Coe to lead us in the pledge.

(Pledge of allegiance.)

CHAIRMAN NAHAI: Could we have the roll call, please.

MS. GOODMAN: Ms. Cloke?

MS. CLOKE: Present.

MS. GOODMAN: Mr. Coe?

MR. COE: Present.

MS. GOODMAN: Ms. Diamond?

MS. DIAMOND: Present.

MS. GOODMAN: Ms. Lyon?

(No response.)

MS. GOODMAN: Mr. Miller?

(No response.)

MS. GOODMAN: Mr. Nahai?

CHAIRMAN NAHAI: Present.

MS. GOODMAN: Mr. Shaheen.

R0071904

MR. SHAHEEN: Present.

CHAIRMAN NAHAI: We'd like to ask the executive officer if there are any changes to the agenda.

MR. DICKERSON: Good morning, Mr. Chairman.

Thank you. With regard to changes in the agenda, we are continuing item 3, which is the approval of the minutes from the December 9 and December 20th board meeting until the January 31 board meeting. We will have that available at that time.

Continuing items 9.4, Golden West refining company and 10.1, Carrier Corporation, until future board meeting. There are several issues that still remain on those permits that need to be addressed.

We are continuing item No. 12 Sun Coast Calamari, ACL until future board meeting. We are in discussions with that particular company to ascertain some specific facts surrounding that ACL.

We're continuing item 13 WDR in the TSO county of L.A. Trancas sewer treatment facility until a future board meeting. We have a request from the county to delay consideration of that. We will hear it, though, in the very near future, the board meeting.

Removing Ojai Valley Sanitation District ACL, that's item 14. The matter has been resolved. The sanitary district has made their penalty in full.

Continuing item 15, L.A. Turf Club ACL. This matter is going to be brought back for further consideration of -- for the board. There is a settlement offer that they wish to bring to the board, and we will have that for you at the next board meeting. Actually, it's March 2 board meeting if that's the one you got.

MS. CLOKE: That's number 15?

MR. DICKERSON: I'm sorry? Number 15, yes. And those are the changes for today.

CHAIRMAN NAHAI: We don't need to vote on it. The next item then on the agenda is item No. 4, which is the report of the nominating committee on the election of officers for the coming year. Dr. Coe?

MR. COE: Thank you, Mr. Chairman. The nominating committee this year consisted of Francine Diamond and Susan Cloke and me. The Porter-Cologne Act requires that the board elect officers the first meeting of the year. And so we're doing that.

The nominating committee after not too much deliberation and in view of the excellent leadership this past year, the unanimously nominating continuation of the present leadership with David Nahai as chairman and Marilyn Lyon as vice chairman, and we so nominate that slate of officers.

MS. CLOKE: We need a second for that. I'd like to second that.

CHAIRMAN NAHAI: All in favor?

BOARD MEMBERS: Aye.

CHAIRMAN NAHAI: So carried. I have to tell you by "excellent leadership," Dr. Coe means that they couldn't find anybody else to do it. So but thank you very much for that.

Going on the next item on the agenda is the consideration of the 2000 board meeting schedule. So we're all yours.

MS. GOODMAN: You just have to make a motion to adopt the schedule as presented.

CHAIRMAN NAHAI: Do I have a motion to adopt?

MS. DIAMOND: So moved.

CHAIRMAN NAHAI: We have a second. All in favor?

BOARD MEMBERS: Aye.

CHAIRMAN NAHAI: Any opposed? Carried.

Next item on the agenda is the board member ex parte communication disclosure item. Does any board member have any ex parte communication to report?

MR. COE: Mr. Chairman, I received a call yesterday from Paul Schoenberger of the West Coast Central Basin Municipal Water District discussing item 9.2 on our agenda, the Wheelabrator Norwalk Energy Company permit.

The problem that they have is apparently the energy company, which provides energy to the Metropolitan Hospital, will not buy recycled water from the water districts if the board approves the effluent limits as suggested by the staff.

The alternative as presented in our agenda is the use of potable water from the city supply for the cooling water, and its two sets of effluent limits. One for each supply water for cooling.

Now, we're talking about 200 acre feet that's involved, and I know the board's very much

interested in conservation and recycling of water in this Southern California.

And as I understand it, the representative of the water districts will be here today to comment on that.

CHAIRMAN NAHAI: All right. I have one item to report. I have received a call from the principal of a company called Charles Company. The gentleman had some questions to ask me about enforcement procedures with respect to a matter that is being handled at the staff level.

I answered his questions as to general procedural issues but told him that I couldn't comment at all with respect to the substance of any issue, and I just want the record to reflect that I did receive that call.

With no other items, let's move on to item No. 7, which is the uncontested items calendar. Are there any changes here, Mr. Dickerson?

MR. DICKERSON: Mr. Chairman, I would ask that the consent calendar be approved items 9.1 through 9.3, 9.5 and 9.6, 10.2 through 10.10 and item 16.

CHAIRMAN NAHAI: Do we have motion for approval?

BOARD MEMBERS: So moved.

MR. COE: Does that mean 9.2 is still on the consent calendar, Dennis?

MR. DICKERSON: Yes.

R0071908

MR. COE: If it's no problem with the discharging then.

MS. CLOKE: I'd like to second that, and I'd also like to just point out for the record and for people in the public that item No. 16, which is on our consent calendar, is a resolution in support of the safe neighborhoods parks, clean water, clean air and coastal protection.

COURT REPORTER: Can you move it just a little closer?

MS. CLOKE: I am seconding the consent calendar and pointing out for both the record and the members of the audience present today that item No. 16 on the consent calendar is a resolution in support of the Safe Neighborhood Parks, Clean Water, Clean Air and Coastal Protection Bond Act of 2000 and the Safe Drinking Water, Clean Water, Watershed Protection and Flood Protection Act.

And I wanted our support for that measure to be very publicly noted.

MR. COE: Mr. Chairman, next on the consent calendar I will abstain from 9.3.

CHAIRMAN NAHAI: Okay. Any other comments with respect to any consent calendar item?

All right. I'd just like to add to Ms. Cloke's comments the support of the board for item No. 16. And please vote for it when you get the chance.

MS. DIAMOND: Would you please note what

those proposition numbers are since we're asking people to vote for them.

CHAIRMAN NAHAI: I don't have the proposition numbers here unfortunately.

MS. DIAMOND: I think it's 13 and 12. Propositions 13 and 12.

CHAIRMAN NAHAI: Going on the next agenda item is the public forum. I have two cards. The first is from Mr. Richard Lambros.

MR. LAMBROS: Good morning, Mr. Chairman, members of the board. My name is Rich Lambros. I'm with the Building Industry Association of Southern California. I rise during this part of your agenda today to reenforce a letter that we had sent over the board staff yesterday afternoon.

It arrived late. So in the event that you have not received it, I've additional copies that I would be happy to hand over to whoever would be appropriate at this time.

Robyn, if you don't mind. **R0071910**

The letter comments on a number of concerns we have regarding another item on your agenda today and that being 11, the SUSMP proposal.

Our concerns are in regard to the public access in the way in which the public comment in the particular section of today's agenda has been arranged. And our letter makes a request that the board consider modifying your plan to have two, 30-minute presentations

to include a third 30-minute presentation.

The two presentations you're allowing for today were set up to allow for the pro and con side of this argument.

But I think if you've been reading the numerous letters that have arrived on this subject, it's pretty clear that the arguments do not neatly fall into pro and con.

They fall into, we argue, three distinct categories: The position of the permittees, the position of the environmental community and the position of the regulated community.

You've allowed time for the permittees to address you today. The other half-hour you've allowed time for the environmental community to address you today. They have a half hour, do not allow the half hour of time for the regulated community, and we would very much appreciate that opportunity on your agenda today.

We have the speakers here today. If the time were allotted, we think we could put together an effective presentation.

R0071911

CHAIRMAN NAHAI: Thank you.

MS. CLOKE: How much time did you have in mind?

MR. LAMBROS: Excuse me?

MS. CLOKE: How much time did you have in mind?

MR. LAMBROS: We were hopeful for an

equivalent amount of time as the other two components of this complicated issue. So we're requesting a half hour of time as well.

CHAIRMAN NAHAI: Do you have ten speakers here today?

MR. LAMBROS: Yes, we do.

CHAIRMAN NAHAI: Well, then, after the two half-hour segments are over, every -- I hope that everybody in this room who wants to speak will get a chance to speak. If you have ten speakers, they'll get their three minutes each.

MR. LAMBROS: Mr. Chairman, we appreciate that. Our concern is that in fairness to the complexity of the issue, you're hearing from two of the key components, but you're not allowing an equal presentation for the third components.

Under your rules, our presenters will be interrupted by someone from the other side, not allowing for a cohesive presentation of what we think is a comprehensive report.

CHAIRMAN NAHAI: Let me just respond to you. I think your comments should have really been part of item No. 11, and we should have heard them at that point.

But what we've attempted to do is to come up with a procedure that -- that hears both sides of the issue to the extent that there are two sides and enables every person who wants to make a comment to do that.

This is the procedure we came up with. This is what's been disseminated. We think it's as impartial and fair as we could get it.

It should also be understood that this is not by any means the first hearing on this issue. We had an all day hearing September 16 where many members of the organizations appeared and spoke, made their points clear.

There was an all day workshop, I think, in August. There have been many other meetings and discussions regarding this. Just for this meeting, the members of this board have reviewed something like four folders of documents with the members of your industry being very well-represented and points being very succinctly and clearly made in repetitive and great detail.

I think we -- we reviewed something like two or three inches of documents before the September meeting, again, with those points very widely made. So I think we've decided on our procedure, and it's as fair as we could do it. It's as impartial as we could do it.

And at this point in time, while I appreciate your comments, that procedure is not going to get changed.

MR. LAMBROS: May I respond at all, Mr. Chairman?

CHAIRMAN NAHAI: It's the decision. So -- go ahead. Of course.

MR. LAMBROS: Well, Mr. Chairman, as you know, the memo that came out for this procedure said that the board in fairness was going to allow some time on the pro side and some time on the con side.

The fact of the matter is, though, that you designated one individual from the EAC and one individual from NRDC, that being the permittees and the environmental community to coordinate that time.

We called both sides in this equation and requested inclusion in their 30 minutes. We feel as if time was allotted to those two components of this equation, the time was not allowed to the regulated community.

We're the ones who are going to live with this regulation. We think it's important that you allow an equal amount of time for us to present a competent presentation today.

CHAIRMAN NAHAI: I understand. And I'll tell you what. Once all of your members have spoken during the segment that they'll speak at, if at the very end of the day there is time left, after everybody has had a chance to speak on the issue and members of your organization feel that there is a point that hasn't been made, then I'd be more than happy to hear from you so that you can make sure that any point that you think that this board should take account of which hasn't already been included in the speeches during the day in the four folders of documents and the two inches of materials

before the September 16 meeting and the arguments that are going to be presented today, if at the end of the day there really is a point that hasn't been made, then I'll hear from you at that time.

MR. LAMBROS: Well, Mr. Chairman, I appreciate that. Our hope was that we could cover those points on the front end and not have to wait at the end of the day. Thank you.

MR. LEON: Mr. Chairman, it escaped my knowledge that we didn't take a vote on the consent decree. I wonder if we can have a -- I'm sorry. Not the consent decree but the consent calendar.

CHAIRMAN NAHAI: I think we have --

MR. LEON: Did they have an actual vote?

MS. CLOKE: I think -- want to vote again?

CHAIRMAN NAHAI: We'll vote again. Can I have a motion for approval of the consent calendar.

MS. LYON: I'll move.

MS. CLOKE: It was seconded by me about my comments about the --

CHAIRMAN NAHAI: About items --

MS. CLOKE: About 12 and 13 of the --

CHAIRMAN NAHAI: Thank you.

MS. CLOKE: -- proposition.

CHAIRMAN NAHAI: Just so Jorge is happy, all in favor?

BOARD MEMBERS: Aye.

CHAIRMAN NAHAI: Any opposed?

The next card I have is from a Mr. Paul Schoenberger, and I would ask that, if these comments are about item No. 11, let's leave it until we get to item No. 11.

MR. SCHOENBERGER: Thank you. Good morning, Board members. My name is Paul Schoenberger. I'm the chief of engineering and operations for the Central Basin and Municipal Water District.

And Central Basin Municipal Water District, we have the task of wholesaling imported water to an area of Los Angeles county that covers more than 1 million people.

And one of the cornerstones of the water resources management that we've been doing for the last ten years, is our recycled water system where we've been developing sources of recycled water, constructing distribution systems and finding users for this resource to stretch the water resources in our area.

And so with that, we are a very large supporter of recycled water. I know the board is a supporter of trying to increase the use of recycled water as most of the community in California, the water community in California is.

I just would like to point out that an item on the consent calendar which we support, which is item 9.2., the Wheelabrator Permit. That item has -- is in regard to a discharge. And in that what the -- the point I want to come out and discuss today is that recycled

water is treated very differently than potable water in this permit and to an extent that would exclude its use.

And in that permit, there are two different limits placed upon the discharger depending upon whether they use potable water or recycled water.

And in our view, the recycled water limits are extremely strict to the level that no source water, whether it was state water, Colorado River water, groundwater or recycled water, could meet those limits. So effectively excluding recycled water as a use.

I don't want anything that I say today to dissuade the board here from passing that permit. I just want to point that out and that I think it's really contrary to the board and our districts and the state's goal of trying to increase the usage of recycled water in the area.

This particular use is a very large user, and they represent a potential 5 to 7 percent increase in our total reclaimed water system. We've already spent to date about $50 million in this system, and it's just unfortunate that the recycled water is being inhibited from being used in this case.

And the recycled water that we would be able to serve this user really is not very different than potable water. It meets all the drinking water MCLs. It's -- you know, you can distinguish it from potable water but just marginally.

So we look forward to working with your

staff in the near future to hopefully come up with a revision on the water recycled side of that permit so -- and come back to the board with a modification to the permit. That would allow recycled water to be used in this instance. Thank you very much.

MR. COE: I have a question.

CHAIRMAN NAHAI: Sure.

MR. COE: As I understand this Wheelabrator needs water for cooling, and if they use reclaimed water, then according to the effluence limits here in our proposed permit, they have to monitor and analyze for, looks like, maybe 15 or 20 additional constituents phenols and heavy metals and --

MR. SCHOENBERGER: Yes. Metals --

MR. COE: -- so on. And they're not willing to go to the extra cost of doing that and they would, therefore, not use reclaimed water but use city water; is that correct?

MR. SCHOENBERGER: The cooling tower process concentrates up whatever source water there is and before it's discharged. So with the limits, the additional limits on the recycled water side, there's no source water available to them -- potable, groundwater, you know, state project water, Colorado water or recycled water -- that would be able to meet those limits.

So it precludes them from using the recycled water.

R0071918

MR. COE: As I understand it, you met with

staff more than once to discuss this.

MR. SCHOENBERGER: Correct.

MR. COE: Thank you.

CHAIRMAN NAHAI: Thank you, Mr. Schoenberger.

With that, we'll move to number 11, which is the SUSMP public hearing, and I've asked the executive assistant to read the opening statement.

MS. GOODMAN: This is a public meeting to consider board action regarding Standard Urban Storm Water Mitigation Plan which have been submitted to the executive officer pursuant to the requirements of the Los Angeles County Municipal Storm Water Permit order number 96-054.

During this public hearing, staff will provide a report to the board detailing the executive officer's intention to approve the Standard Urban Storm Water Mitigation Plan with changes and ask the board to adopt a resolution expressing the Regional Board's expectations regarding the SUSMP approval.

Copies of the Standard Urban Storm Water Mitigation Plan were sent to the U.S. EPA State Water Resources Control Board and other interested agencies, persons and organizations.

The order of presentation of testimony at this meeting will be announced by the chairman. Anyone so desiring will be heard. If you have not filled out one of the blue speaker cards located on the table at the

back of the room, please raise your hand, and we will get a card for you to fill it out.

It will be appreciated if all persons appearing before the board will leave written copies of their testimony, if available. The board will consider all testimony.

However, in the interest of time, it is requested that all repetitive and redundant statements be avoided. The setting of time limits for the presentation of the evidence is at the discretion of the board.

Mr. Chairman, would you now open the hearing and administer the oath.

CHAIRMAN NAHAI: I shall. Could I ask all of you who are going to give testimony in this matter please stand and take the oath.

(People sworn in.)

CHAIRMAN NAHAI: Let's talk a little bit about the procedures that we're going to follow, which I know Mr. Lambros doesn't like, but it was the fairest way we could divide to hear all of you.

What we're going to do is this: First of all, we'll have the staff presentation. After the staff presentation, there will be two half-hour segments which will be devoted to ten speakers each so that those speakers cannot exceed three minutes per person.

Those two segments will attempt as much as possible to advocate one position or another with respect to the staff proposal that's before us today.

The board members will hold their questions until the end of each of those presentations. In other words, we'll allow the staff to make their presentation. At the end of that presentation, the board members will ask questions, if they wish to.

Then one side for 30 minutes and at the end of that, the board members will pose questions to those speakers, if they wish to. Then the second 30 minutes out with questions, if there are any.

Then once those two 30-minute segments are over -- in other words, once we've heard from those 20 speakers, then it will be opened up to anybody who hasn't spoken and wishes to. And each person will be limited to three minutes each.

I heard that one person had turned in -- I don't know -- a number of cards because he thought that he represented a number of different interests. That's not the way it's going to work. Okay? Three minutes per person.

That's the only way that we can think of doing this so that we can hear from all of you during the day. Now, if at the end of the day we have time left over, I'll open up the podium, again, to anybody who feels that there's, you know, a burning point that hasn't been made during the presentation.

But you may also wish to think as we go along that, you know, we've reviewed a great deal of materials. We've heard many arguments. So if you see

that another speaker has already pointedly and emphatically made the argument that you wish to make, you know, you may wish to decide that it's not necessary to speak. So I'll just leave that up to your discretion.

Now, the three-minute rule is absolutely strict. In order to help you and to help me, we have that flashing thing there. We put it on a box so you can really see it. And when it gets to three minutes, it's going to flash; is that correct? And at that time, please stop.

I don't enjoy, you know, interrupting speakers. I really don't. So I'd really appreciate it if you won't make me do that. So once you see the flashing red lights, we promise you it's been synchronized for the proper three minutes, and please stop speaking. Thank you very much.

With that, I'd like to invite the staff presentations. And it would also be nice, if you have cell phone conversations, please step outside. Thank you. Just as this gentleman is doing.

MR. DICKERSON: Mr. Chairman, members of the board, good morning. It's perhaps fitting that agenda in item 11, Standard Urban Storm Water Mitigation Plans is on the agenda for today, our 50th anniversary as a Regional Board.

At the very least, what the board does today will serve the key point of reference in our quest to meet the mission of the Regional Board, to protect and

restore the water quality of this region.

Before I begin my formal presentation, I would like to take a moment to thank Dr. Xavier Swamikannu for his tireless efforts to manage this permit.

This is one of the most significant storm water permits in the nation and one of the greatest water quality challenges we face as a board. And yet we have only a fraction of one person funded to manage this permit.

I would also like to thank the members of my staff who over the past few weeks and days have been drawn into maelstrom of activity, especially Robyn Goodman and Ronji Harris, who responded to my urgent cry for help with good nature and dedication. Thank you.

And Jorge Leon, who has also been instrumental in developing a legal basis for this action which you have in the staff report. My sincere appreciation to each of you. Thank you.

The notion of a Standard Urban Storm Water Mitigation Plan for SUSMPs, and it's usually in the plural SUSMPs is rooted in the Municipal Storm Water and Urban Runoff Permit issued to the county of Los Angeles and its 85 municipalities in 1996.

The permit requires that SUSMPs be developed for at a minimum several development categories. These include home subdivisions, commercial developments of at least 100,000 square feet in size,

automotive repair shops, retail gasoline outlets, restaurants and single-family homes on hillsides.

Once adopted, the SUSMP would be a set of standards or criteria that developers and architects could use to design their projects in ways that will result to those properties contributing inherently less pollution when it rains.

Cities would use the SUSMPs to adopt their own enforceable ordinances and then apply them in their review and approval of project plans. SUSMP standards only apply to new development or substantial redevelopment projects in the applicable SUSMP categories.

As a consequence, the applicability of SUSMPs is limited, and their consequent effect on storm water quality in our streams will, at first, be relatively small.

As years pass and more and more property is redeveloped, a greater percentage of urban land will be retrofitted with SUSMPs. Eventually much of the L.A. Basin will gain the benefit of some enhanced level of storm water management.

It must be remembered, however, that SUSMPs are only a small part of the 1996 storm water permit requirements. Many other aspects of that permit address other issues and current problems.

R0071924

SUSMPs are simply one long-term approach to address the ubiquitous problem of pollution from storm

water runoff and to address that problem for new development to prevent the problem from getting worse. That problem is pervasive and growing.

Storm Water is the vehicle by which pollution that is deposited on our highways and roads, our curbs and gutters, our yards and alleys, is conveyed to our streams and to the ocean. And we did have some slides which are identifying some of the actual water quality impacts, the very early on, Jack, if they haven't been up yet.

When it rains, the runoff carries amazingly large amounts of pollutants that reach the ocean. It adds to toxic levels of sediments in estuaries which contribute to the deterioration of our aesthetic environment and the degradation of the aquatic environment.

The amounts of these pollutants that reach our streams every year are not measured in ounces but in thousands of pounds. And in the case of water-borne litter, hundreds of tons each year.

The problem is real. And the contribution of these pollutants contributes to many of our streams being listed on the federal 303(d) listing of impaired waters. These are impairments for which total maximum daily loads or TMDLs are required and their requisite load allocations and implementation plans to remove those impairments.

R0071925

Briefly, we are here today to consider what

are the appropriate SUSMPs to apply to categories of the developments in the staff's SUSMP proposal. We began this process with the formal submittal of SUSMPs to the Regional Board by the principal permittee of the 1996 permit. That's the county of Los Angeles.

In reviewing that submittal, staff determined that additional requirements were needed to enhance the SUSMPs submittal. After a public workshop last August, staff proposed the addition of numerical design standard to establish the size of Best Management Practices which are simple and common-sense techniques to reduce the amount of pollution in storm water runoff.

Under the terms of the 1996 permit, the executive officer is vested with the authority to approve the SUSMPs. However, by proposing a significant modification of the SUSMP by including a numerical design standard, I sought Regional Board concurrence with that recommendation.

A hearing was held on September 16 before the Regional Board. The outcome of that hearing was your agreement with my recommendation that a better record was needed and possibly some modifications to the SUSMP proposal were necessary.

The result was a series of discussions with interested parties that led to our publishing a December 7 proposal which is now before you in your binder as pages 11-1 through 11-19.

R0071926

A formal staff report has been developed,

which is dated January 18, and was submitted to you separately. Additionally, a change sheet has been issued and is being augmented today.

The SUSMP before you, the proposal before you, while an extensive document, is really quite simple and much of the language of the proposal is also noncontroversial and carries over from the text of the SUSMP submitted to the Regional Board last August.

Since the September 16 board hearing, some changes have been made to the proposal in an effort to create flexibility and to recognize the problems associated with the implementation of any substantive permit requirements.

Some of these have become the focus of additional controversy adding to the numerical design standard that was a principal point of controversy last September.

The proposal itself is partitioned into several main segments. These are definitions and then requirements applicable to all SUSMP categories. These include a number of specific areas: Peak storm water runoff rates, conservation of national areas, minimization of storm water pollution through use of BMPs, protection of slopes and channels, providing storm drain identification, proper design of outside storage areas, proper design of trash storage areas, establishing proof of long-term BMP maintenance and design standards for treatment controls.

That last item which is applicable to all categories, design standard for treatment controls, is the numerical standard which is the focus of so much controversy.

There are also specific requirements applicable to certain categories. Most of these provisions provide additional BMPs for certain types of development where those are believed necessary to provide additional controls to reduce storm water pollution.

Two additional categories of SUSMPs have been added, parking lots and environmentally sensitive areas which result in additional requirements. To build in some flexibility to the provision, a waiver provision has been included which is carefully defined and limited to certain circumstances.

Some of those are infiltration BMPs may pose a risk to groundwater quality under certain circumstances. So a waiver can be applied at that point.

There also may not be adequate space available to use BMPs. So a waiver option is allowed. And finally, soil conditions may not be suitable for infiltration BMPs. Therefore, allowing a waiver seems appropriate in that circumstance.

Remember the waiver provision is something designed to allow flexibility. The final element is provision for the county and cities to use a professional certification to represent the adequacy of the project plan as meeting the SUSMP requirements rather than having

to review and approve those documents themselves resulting in additional work by city plan review staff

I'm very sensitive having a staff that's already overworked as having to impose more work at other staffs in the cities.

Those are the fundamental elements of the SUSMP proposal. As you move to consider this matter, I would request that you think of it as two distinct proposals. First, the basic SUSMP, which is everything but the numerical standard. And then of course the numerical standard itself as the second major element.

The former is a lot less controversial than the latter. Also keeping them separate will allow you at the end of the day to perhaps provide greater clarity in your direction to staff.

So as you know, we have developed a change sheet. And so the question is what was wrong with the proposal as it was written that requires changes? First, let me talk about the basic SUSMP. To begin, we needed to better state some of the definitions.

We received various comments on a number of points of the proposal. Hillsides were one area where change was felt needed. The definition was not adequate. So in response to comments, we have now added additional clarity to state the hillsides are property located in an area with known erosive soil conditions where the development contemplates grading on any natural slope that is 25 percent or greater.

While we added the definition for parking lots, at the outset we did not make it clear that we were talking about commercial standalone parking lots between 25 and 200 spaces in size. Not all parking areas for commercial facilities and -- rather not all parking for commercial facilities under 100,000 square feet in size.

We also were unclear on setting the threshold for when a redevelopment project would have SUSMPs applied. We now have added a threshold of 50 percent of impervious surface addition or the making of improvements to 50 percent or more of the existing structure as the threshold for SUSMP conditions to apply.

The term environmentally sensitive area means different things to different people and agencies. We've limited our definition to the one adopted by the board for the city of Long Beach storm water permit.

This definition limits the areas to those identified by the county of Los Angeles, the State Water Resources Control Board and the California Resources Agency. Referenced documents have been included.

We have made a number of less significant changes in the document that are identified in the change sheet, and I will address them only if you wish clarification. I probably will have to ask the neighbors surrounding the community to help the matter here as well.

R0071930

As noted above, we have a waiver provision that has sparked opposition. The intention was to add

flexibility and creative mechanism for funding regional projects with the funds that would be saved by not installing BMPs at a given site.

However, the waiver is controversial because it does provide an out from the SUSMP requirements. Ultimately you will need to provide guidance on the propriety and appropriateness of that waiver.

Now, let's turn to the numerical design standards which has been and remains the principal focus of comments. The fundamental notion is that, if you install a BMP as part of a new development, it ought to be of an adequate size that it can be effective. That's the basic concept.

Last April you approved a resolution adopting a set of BMPs that should be used in development activities. You also said that they should be the most effective BMPs. Effectiveness is largely determined by size and degree of maintenance.

If a BMP is large enough, it could manage all the runoff generated from the largest measured storm event, and we certainly are not proposing that today. However, if it is too small, it will be less effective and perhaps ineffective for all but the smallest rain events.

We do not specify the degree to which a BMP should remove pollutants. Rather, we have proposed an amount of rainfall that a BMP should be able to manage

thereby resulting in the removal of a reasonable amount of pollutants.

The 0.75 inch standard is proposed and since will provide coverage by a BMP for 100 percent of the volume of 85 percent of the storm events.

It will rain more than .75 inches. And our proposal will not address the volume of rain that's over that amount. But we do not believe it necessary to do so to effect a considerable reduction in polluted runoff.

Most pollution is picked up in the earliest phase of a rain event. By addressing the first part of runoff, and most of the runoff, most of the time, through BMP sized to that standard, we will make a significant difference in runoff water quality.

As I noted earlier, we are talking about a relatively small amount of land for the early years. While the overall impact will be difficult to notice early on, the payoff is really for the next generation who will have a much more intrinsically cleaner environment.

Think of it as a milestone that the Regional Board in 50 years will mark as the highlight of millennial foresight. The proposal has included two exemptions that we believe are reasonable.

First is the rooftop runoff exemption. The concept here is simple. Runoff from rooftops is less polluting than runoff that traverses streets picking up oil or passing through lawns picking up what people

didn't.

If you don't need to run this cleaner water through a BMP, the BMP that you have can be smaller and cheaper to build and maintain. This rooftop exemption may not work in all cases. Where the roof itself is shown to be inherently polluting, it is excluded.

Where the rooftops has vents or air pollution control systems that may result in a residue on the roof that can then be washed off during a rain, it's excluded. If the runoff from the roof is not channeled away from the ground surface so it can pick up pollutants, there is no exemption.

Finally, if the rooftop runoff is diverted to a stream that is natural, there's no exemption. These criterias seem to make sense. NRDC in their comment letter challenges the rooftop exemption but then cannot cite a study to show that the rooftop runoff would pose a water quality problem. And indeed they acknowledge the studies are indeed underway.

It would be inappropriate to require BMPs for rooftop runoff without a clear showing that the runoff from rooftops is a substantial portion of the storm water pollution problem.

Right now we don't know. And the proposal is flexible enough to allow the numerical standard to apply once a showing is made that there is indeed a problem to be addressed.

R0071933

The other exemption from the 0.75 inch

standard is for restaurants that are less than 5,000 square feet in size. The intent is to preclude applicability of the numerical design criteria to many restaurants that are small businesses in urbanized areas while still applying the basic SUSMP package to them.

Larger standalone restaurants or those located in a commercial complex will generally be covered by exceeding the 5,000 square foot criteria or by their placement in a commercial complex that is larger than 100,000 square feet in size.

While we have proposed a 0.75 inch standard applicable to all the SUSMP development categories, the board may wish to consider some alternative to what staff has proposed. Between the 0.75 standard and no standard, there are many options.

First, the board could impose a more stringent number than 0.75 inches. One inch or more could be imposed. Alternatively, a lesser number could be chosen, for example, 0.5 inches or even a third of an inch.

No numerical standard could be adopted leaving the standard being the most effective BMP, a judgment call rather than a measurable, quantifiable and ultimately verifiable standard. **R0071934**

A standard could be required immediately or phased in over time. The standard could be applied to only a few categories now and applied to more on the basis of more information at a later time. Perhaps tied

in with consideration of the next Municipal Storm Water Permit review which is scheduled for July 2001.

The county of Los Angeles has adopted a 0.75 inch standard as a result of litigation with NRDC. In their letter, the county's letter, of January 11 at page 11-90 in the comment binder, the county argues caution in moving too fast with a SUSMP proposal given their own difficulty in implementation.

The county's cautionary comments suggest that the board should carefully consider their problems, the county's problems, with implementation.

Another issue that we have not yet addressed is that of a cost trigger. By that I mean there is an upper limit as to how much of a project's total cost that should be spent on BMPs. These costs vary substantially based on the BMP selection.

It may be worthwhile for the board to consider some value beyond which additional SUSMP expenditures or BMP expenditures would not be required based on some cost factor expressed perhaps a percentage of the project's total cost.

With this proposal, we have tried to advance the cause of storm water pollution control. I'm confident that, whatever the board's action today, we have already sent a strong message that the time for a concerted effort to address storm water pollution is now.

We have already seen substantial progress by cities to informally apply the 0.75 inch numerical

standard and in other instances to establish storm water management programs that go beyond the basics.

We are on the right track with this proposal although I believe there is ample room to fine tune the proposal to make it either more comprehensive or to instill greater flexibility. Either way, the goal of improving storm water quality will be achieved.

Now, finally I would like to just comment very quickly on the fact that I participated in a hearing yesterday before the city council for the city of Los Angeles.

And I testified on behalf of a resolution that was offered by city councilwoman Ruth Galanter and cosponsored by Mike Fuehr. And that proposal was to support the concept of the numerical standard that the board is considering today.

And in your materials that we provided to you today in the brown envelopes, I believe, at page 11-51 A-6 and 7, you have the resolution, at least a draft of it, that was offered and subsequently approved by the city council for the city of Los Angeles on a unanimous vote.

In addition, the city of West Hollywood recently sent us a letter which identifies -- that's located at 11153, A-8 also supporting the resolution that's before you.

So with that, I would like to turn the podium over to Dr. Xavier Swamikannu, who will comment

briefly on several issues including BMP costs and a bit more detail on how the 0.75 inch numerical was designed and standard is applied.

And he will be followed, I hope, by Jorge Leon, who will comment on a few legal issues. And after that, we'll respond to all comments that you have regarding to staff.

MR. SWAMIKANNU: Thank you, Dennis. Mr. Chairman and members of the board, I'm going to cover the most controversial aspect of the SUSMPs which is the numerical mitigation standard.

Basically, we have provided four approaches for reasons of flexibility. The one that's most known to everyone is a three quarters of an inch over 24 RP. But the primary method is what's called a maximized volume capture which is a recommended method by the American Society of Civil Engineers and the Water Environment Federation.

And what that does is that relates rainfall to runoff. So you're actually addressing runoff, not regular rainfall. The three quarters of an inch standard is focused on rainfall.

If you look at all these four approaches, the variation is 10 percent, which is within the norm. Some commenters have addressed the fact that some of these BMPs might be more sensitive to flow than volume.

Given the fact that we have traditionally looked at water quantity from a flood control

perspective, there is not geographical information or data to really evaluate flow sensitive BMPs at this time. So there's no specific recommendation to address flow sensitive benchmarks and (inaudible).

As I indicated, the primary method is based on the water and volume and federation recommendation. And it relates rainfall to runoff, and the formula I have before you is -- basically includes those variables. For coastal California what does that mean? It means depending on the surface area, that is impervious.

That the range could be anywhere between point one two inch and point eight six inches. So if there's less impervious space, you get the benefit of having to create less runoff. In Los Angeles it might not make that much of a difference because much of the urban area stay there.

The principal of the three quarters of an inch approach is basically the extreme events. That means heavy rainfall events are rare. And if you look over a long-term, that it's the smaller events that really matter.

And on a cumulative basis if you look at the graph, on the left side, as where the peaks are, what that's telling you is that most of the volume of rainfall over a long period is from the smaller rain events.

What does that mean? What does a three quarters of an inch mean? It basically means that we have an average for Los Angeles that, if you raise that

number, the benefit and the costs associated with building larger BMPs is minimal. That 85 percent of rainfall events equal to a less than a three quarters of an inch are addressed.

First flash which EPA indicates generally is half an inch is also addressed. And then if you do a relationship between pollutants loads and this volume that's treated by three quarters of an inch, you tend to address between, I would say, 50 and 85 percent of a pollutant load over a long-term period.

The three quarters of an inch is technically defensible. We did not have the Water Environment Federation recommendation five years ago. We have it now.

The three quarters of an inch is based on local data, and it uses a nationally accepted method to do the translation. Similar criteria are in use by other communities, and the range is anywhere between half an inch and two inches.

And we have similar criteria in this region itself. Santa Monica, Calabasas, Ventura county and unincorporated L.A. County use a similar number.

The issue of cost always comes up. How much would the design standard impose on communities? If the graph before you looks at the relative costs of different BMPs size to address storm water, the highest graph is for flood control and then you have for combined and sewer operations. You have for sediment control

You have a standard from Seattle and then you have one locally.

And if you look at the different ranges, the proposed three quarters of an inch is much less than many of the other criteria that have been used to address storm water.

I work with the city of Los Angeles staff to run through some calculations on an actual project. It's a five acre commercial development project. The project costs 6.5 million. We used a detention basin best management practices and looked at the different costs.

The excavation and hall away from the sediment from the detention basin 12,817. The land cost was during 9,000. Maintenance at one year. Maintaining it once a year $33.00. Total cost at about 42,000. If you relate that to the project cost, that's .6 percent.

Another BMP for the same project. You look at an infiltration trench and a vegetated swale combination. The land cost is minimal because it goes into part of the landscaping. Maintenance, five-year replacement of the vegetated swale as well as the trench.

If you work out the cost, again, this is less than .5 percent. We also looked at cash basin inserts, and that works out to much less. So preliminary analysis on the actual project indicates that the cost is not going to be that much.

R0071940

The numerical center that we have provides

flexibility in the choice of BMPs. You can choose a detention basin or you can choose vegetation swale. The mitigation cost is not likely to exceed environmental mitigation reasonable cost threshold which is usually about 5 percent of the project cost.

And for the BMP choice is to be made on how effective these BMPs are for the particular situation, and definitely the BMP charge maintenance or the ease of maintenance as one of those calculations.

That's the end of my presentation, and Jorge might address some legal questions.

MR. LEON: Mr. Chairman, good morning. Board members, good morning. Jorge Leon, Regional Board counsel with the office of chief counsel. I was just jotting down a couple of notes as Xavier was speaking about some of the issues that you might want to hear about.

What I'm going to propose is to just give you a quick overview of some of the legal issues, and I think it's -- going too fast?

COURT REPORTER: Slow down a little bit.

MR. LEON: For now and then I would propose to follow up on some of the specific legal issues that might arise during the parties' presentations a little bit later.

In other words, I think it would be helpful for you to understand the issues if, as the issues are raised, if I could have a response opportunity during

this staff response. It's up to you. Okay.

For now, I wanted to point out that several of the legal issues that had been raised including the appropriateness of the process that is being followed here today, whether CEQA has been complied with, what limits exist on the Regional Board's authorities and such questions as those in general have been responded to in the staff report and record of decision which is in the agenda of material at section 8 on page 14.

And a couple of other issues that are sort of noteworthy at this point involve the implication of the SUSMP provisions to discretionary versus nondiscretionary projects, and I wanted to talk a little bit about that.

The question is whether the board has or -- rather I guess it should be stated this way. Whether the executive officers' discretion which is at issue in the SUSMP proposal today ought to include discretionary or nondiscretionary projects.

The permit that is the basis of the action today of course is the storm water permit, the municipal permit 96 054. That permit speaks only of nondiscretionary projects. But it also does include some specified enumerated areas where storm controls need to be placed.

So first let me say that it's my belief that, since the permit speaks of the application of the SUSMP proposal to discretionary projects, that we're

stuck. That that's what we ought to interpret today's proposal to apply to, the discretionary projects, not the nondiscretionary projects.

However, where a nondiscretionary project is also a enumerated project, it's my belief that, because the entire philosophy of the permit was to address identified areas and those would be the enumerated areas were actual storm water issues, pollution have been found to be reliably present need to be addressed.

It's my recommendation that you apply the SUSMP proposal to those enumerated activities whether or not they are discretionary or nondiscretionary.

That would apply a more liberalized approach to the interpretation of the SUSMP application. If there are any other specific issues that you would like for me to address, I would like to try to do that now. Otherwise I'll be seated and await your call as the issues arise.

CHAIRMAN NAHAI: I'm sure there will be some legal language changes or questions on the body of the permit and then we'll give that to you.

MR. DICKERSON: Mr. Chairman, that concludes the staff presentation.

CHAIRMAN NAHAI: Do we have any questions from staff?

MS. LYON: Yes, I have. I had some questions about the hearing you went to yesterday at

Los Angeles City Council. How many council members were present?

MR. DICKERSON: I think it was 13.

MS. LYON: Was there a Public Works corrector there?

MR. DICKERSON: There was no one who spoke at the hearing, but there was a Public Works -- well, it's actually the Bureau of Sanitation. Their deputy director was present but did not testify.

MS. LYON: I find it a little hard to believe that those council members were fully informed of everything that was going on before they took their vote. So I'm not putting a whole lot of thought into the resolution.

MS. DIAMOND: I have a question. Some of the definitions are still not entirely clear to me. For example, on -- you describe the parking lot definition and the changes that were made.

Given -- would you give me an example of a parking lot that would be covered and a parking lot that would not be covered?

MR. DICKERSON: Yes. A parking lot -- the concept that we were trying to do by this specific parking lot designation was -- let's take for example a parking lot that was going to be opened up at Burbank Airport, and it's a paid for parking. It's specifically just for parking. That's what the parcel is all about. And it's not associated with a mini-mall, for example.

It's the distinction between parking which is solely for a -- solely on its own versus as part of a development. Because the distinction is that, if you have a 100,000 square foot commercial development, all the parking associated with that is going to be covered.

What we want to do is bring down that level to address strictly parking lot activities for those commercial -- excuse me. For those venues where it's strictly parking only.

MS. DIAMOND: So then it wouldn't cover a parking lot, for example, of a market that had 25 spaces or more people --

MR. DICKERSON: That's correct.

MS. DIAMOND: -- coming in and out all day or that's sort of --

MR. DICKERSON: That's correct. However, I'm certainly -- the whole point of today is really to get direction from the board as to what you think is appropriate to include if you all collectively think that it should be applied more broadly or not at all. I fully intend to follow that direction.

MS. DIAMOND: I have a couple of other questions related to the definitions. For example, retail gasoline outlets. If they're one or two pumps, but perhaps they do something beyond automotive work, they are not covered unless 50 percent or more is related to automotive gasoline repair, et cetera; is that correct? Or is that only the numeric standard?

MR. SWAMIKANNU: The retail gasoline outlet definition is basically defined to include the term what does primary mean? And here we basically use the standard industrial classification which is a federal designation of what the activity is.

And so for gas stations basically are correct. It's the numerical threshold that would not apply where there are less.

MS. DIAMOND: So the BMPs would apply, but the merit would not apply.

MR. SWAMIKANNU: Yes. Correct.

MS. DIAMOND: One other question I have would be about the restaurants. Those restaurants that are under 5,000 square feet, the smaller restaurants, I wonder if there's any way you can tell us how many restaurants in Los Angeles, for example, or in the region would that include?

We have Mc Donald's and Burger King. Lots of small restaurants all over. Is this a majority of the restaurants? Is this a small number of restaurants? It's important for me to know what percentage of restaurants are we not including in this proposal?

MR. SWAMIKANNU: It will be difficult for me to give you that number right now. But I think the 5,000 square feet basically comes from the practice around the country where do they cut out the threshold.

The concept here is that, when it's 5,000 or less, it's a smaller restaurant. And many of the BMPs

that are associated would be sufficient, and the numerical mitigation standard would not be appropriate for the smaller ones. But in terms of what number, I do not know.

MR. DICKERSON: We are --

MS. CLOKE: But they are required to have the BMPs even if they don't have the numerical standards --

MR. DICKERSON: Yes.

MS. CLOKE: -- no matter what size they are.

MR. DICKERSON: Remember the basic SUSMPs apply to all the categories all the time. With regard to the restaurant issue, the -- most restaurants now that are part of new developments are part of major complexes. And so in most cases those are going to be covered through the 100,000 square foot commercial development category.

What we're really trying to avoid here was to impose a requirement on a -- just because it's a restaurant, if they're going through a major redevelopment in an already substantially urbanized area where they would perhaps really have some problems putting in BMPs, that's the typical example that we were trying to avoid and perhaps a standalone kind of restaurant.

But I think we're finding that those are going to be -- most of the development is going to

capture the larger restaurants, I think. The numerical standard is probably going to apply to many is my feeling except for those which we've identified.

MS. DIAMOND: I have one last question, and that was on the rooftops. I know there are exemptions to the rooftop exclusion. But how -- the problem that I have with it is that we're talking about storm water being a problem because of all the paving that we have and the impervious surfaces in the region.

It seems to me that rooftops is another example of paving or impervious surfaces. Doesn't that include -- shouldn't that be considered, and what was the rationale for eliminating that or excluding it?

MR. DICKERSON: If you're talking about pavement, you're talking generally about places where cars are driving, which are dripping oil, which are subject to litter, which are subject to just people generating all different kinds of pollution.

When it rains and flows over that area, you can pick up additional pollutants. If there were no cars, if there were no people and you have paving, you probably have clean water running off even though it was developed or at least to a large degree.

The notion with the runoff from the rooftops is that, if it's running off a roof and there's no added pollutants from that roof, then why mix relatively cleaner water with relatively more polluted water which is just going to require your BMP to be

larger, more costly, more costly to maintain in the long-term, when you have don't have a very substantive solid base of information to include that runoff at this time?

The proposal does allow for a determination at some point in the future when studies come in, and I already see reference studies are underway. If those studies show that aerial deposition, for example, is causing a substantial contribution to the storm water runoff problems, it can be included at that time.

It's really a question of do we have enough evidence about the water quality if you differentiate it from the roof and from what's flowing over, let's say, a parking lot.

Do we have enough information to bifurcate that and to say that one is relatively more polluting than the other. We don't have a lot of good information right now. But we do have common sense that tells you that the rooftop runoff ought to be a lot less polluting if you don't have some of the same activities occurring obviously on the roof as you do on a parking lot. That's in essence the justification.

MR. SWAMIKANNU: Ms. Diamond, I want to correct a statement that I made. You asked me the question on retail gasoline outlets where if the receipts are less than 50 percent, do the other requirements apply.

R0071949

I think the answer is not. Basically what

we are saying the requirements are specific for retail gasoline outlets, and retail gasoline outlets are defined by the primary activity.

So if you have a big mall and there's a small pump on the side, the requirements don't apply. But what we have is in the model program, there's a priority category.

It's not -- we haven't specifically designated a business that -- where gas pumps are a subset of the activities. So the answer to your question is the requirements would not apply in that situation.

MS. DIAMOND: Thank you.

MR. COE: Yes. I have a series of questions, if I could. I'm looking at the plan, page 8, protects slopes and channels. As corrected, it says, "Project plans must include BMPs consistent with local codes and ordinances to decrease the potential of slope channels from eroding" and so on.

It's page 8 on -- well, January 21 edition. Number 4, protects slopes and channels. What if it's not consistent with what the codes and ordinances -- what happens? Does that eliminate the BMPs or --

UNIDENTIFIED: We can't hear you in the back.

MR. COE: My question, was if it's not consistent with local codes and ordinances, one could say that the cities that change the codes and ordinances so they are consistent with BMPs. We're trying to get the

BMPs installed to correct the pollution problem.

MR. SWAMIKANNU: Mr. Coe, our understanding is that once the board approves this SUSMP and Dennis approves it as well, then the cities municipalities here would be required to adopt these through changes to their codes, ordinances. Whatever.

And once that happens, I would think then -- the BMPs that are required to address somewhat would be consistent with the local codes.

MR. COE: Well, I think that needs clarification, the language. I agree with what you just said was the right thing to do.

MR. SWAMIKANNU: And we have that statement somewhere as I can look at it for you.

MR. COE: Okay. Now, on the bottom of that page where we're talking about storm drain system, stenciling and signage, the second barrel, it says that we should have signs that discourage illegal dumping. This is a minor editing.

MS. CLOKE: Prohibiting.

MR. COE: Prohibiting illegal dumping, not discouraging it. We can't discourage murder. On page 10 on the section on maintenance, it's the maintenance actually starts on the bottom of page 9, item A, proper proof of ongoing BMP maintenance. There is -- several letters came in from primarily cities.

They were a little concerned about how this is all going to take place. And we have a very large

paragraph of a concept, but they're afraid that, after the original developer disappears from the scene and sells off the property and the houses, despite the written agreements and so on, that maybe those BMPs won't be maintained properly.

And I think it is a question perhaps for Jorge Leon. Is this the best we can do on maintenance?

MR. LEON: I don't think I have a good answer for that. I'm going to have to ask for Xavier's help. Your question specifically is one of practicability --

MR. COE: Exactly.

MR. LEON: -- of what we're requiring?

MR. COE: Exactly.

MR. LEON: Whether it's practical?

MR. COE: Right. Because if we don't maintain, then pollution will reoccur, and everybody will be looking at each other. It's better to have it very clear at the beginning. And I don't know what the answer is. But from a legal viewpoint, I was asking for your thoughts.

MR. LEON: At some point it does become an issue of enforcement by the municipalities, and maybe that's the answer. We can go so far as --

MR. COE: Take a look at it.

R0071952

MR. LEON: Oh, sure.

MR. COE: Okay. There's a couple weakies in there. I think we've -- in negotiating this we've

stepped back from time to time and weakened our position, and I marked it pink, and I got a lot of pink marks through here.

But I understand that sometimes that's necessary. But for instance, on page 10, Mrs. Cloke was asking it did I bring these out?

MR. LEON: Mr. Coe, these are for the audience's and for my clarification. When you are saying the page number, are you referring to the agenda page number versus the document page number? You see that there's one handwritten and then there's another page that's typed --

MR. COE: I'm looking at the typed page number.

MR. LEON: Thank you.

MR. COE: The 6th line there. This is why I'm a little concerned about this maintenance situation. That part that was added. The condition of transfer may include a provision.

Then on the last line of that paragraph it will also encourage the transfer of this information. I think we should go through and look at things that maybe have been too weakened. I'm on page 11.

CHAIRMAN NAHAI: If I may, Dr. Coe, let me just clarify for the record that what Dr. Coe is referring to is -- is a black line version of the Standard Urban Storm Water Mitigation Plan. At the bottom of it, it's designated final tentative and dated

R0071953

January 21, 2000.

MR. COE: Correct.

CHAIRMAN NAHAI: That is the version that we're looking at.

MS. CLOKE: Actually, it has the wrong date on it.

MR. DICKERSON: We should be using the December 7 version. That's in your binder.

MR. COE: Well, I'm looking at the latest, which is in the lower left hand corner, is dated January 21.

MS. CLOKE: And it says 1909 when it should say 2000 --

MR. DICKERSON: Let me just clarify. We sent a memo to you with that final markup just for your reference only and just so you know the audience does not have that version.

MS. CLOKE: We have no handouts of that in the back?

MR. DICKERSON: We have the December 7 version.

MS. CLOKE: This is what all of us --

MR. DICKERSON: It continues to change -- there's no difference between that -- what you have is everyone has a change sheet and the December 7 version, and it's basically the same.

R0071954

MR. COE: Well, maybe I can make my reference and then you can indicate the other reference

for the audience, if they're following.

MR. DICKERSON: Okay.

MR. COE: This is page 11 under 9-B, D.

MR. LEON: Mr. Coe, I'm sorry. I'm sorry to interrupt. Mr. Chairman, it occurs to me that there's an issue that I want to make sure is real clear in the record before we take it too much further concerning the versions that are out there.

Mr. Dickerson, I'd like to ask for your clarification. Because as I understand it, what we're dealing with here is two versions. The audience has a version that has typewritten pages and handwritten pages.

And it should say in the lower left corner December 7, 1999; is that correct?

MR. DICKERSON: Yes.

MR. LEON: That's the copy that was distributed?

MR. DICKERSON: That's --

MR. LEON: The board members have the version that's dated January 21 in that same location on the lower left, but it contains the identical information --

MR. DICKERSON: It contains the changes.

MR. LEON: -- except for the fact that the changes have been inserted.

MR. DICKERSON: That's correct.

MR. LEON: Those are the only changes.

MR. DICKERSON: That's correct.

R0071955

MR. LEON: Okay. So when you make a page reference, I wonder, Mr. Dickerson, then if you would then, please, refer to the page that the audience has.

MS. CLOKE: Mr. Leon, just to further clarify that ours is a strike-out version so that we can see what was taken out and what was added and --

MR. LEON: Yes. In other words --

MS. CLOKE: -- and ours does have the wrong date on it.

MR. LEON: In other words, yours --

MS. CLOKE: It should be noted that the correct year needs to --

MR. LEON: Oh, it's in '99?

MS. CLOKE: Yes. So that if somebody's looking at this in the record, they should have that information showing what document --

MR. LEON: In other words, the version that the board members have is the compilation of the same version that staff has with the change sheet marked into it.

MR. DICKERSON: Yes.

MR. LEON: And the staff -- I'm sorry. The public has the other version. They should have a change sheet separate from the December 7.

R0071956

MR. DICKERSON: Right.

MR. COE: Third time. You know where I am here on -- on small "D," the storm water conveyance system was not directly discharged to a natural stream or

a channel segment scheduled for restoration.

MR. DICKERSON: Yes. That's on page 9 of 17 of the December 7 version.

MR. COE: Thank you. Why do we have small --

MR. DICKERSON: The notion there is --

MR. COE: (Inaudible.)

MR. DICKERSON: This goes back to -- this goes back to the notion that most of our waterways in Los Angeles county have been channelized. And this is protection for those which are not yet channelized. Because the flow of the erosive quality of a higher velocity of the flow is the issue that we're trying to address there.

MR. COE: Thank you. Page 12, item 3, properly designed vehicle equipment wash areas.

MR. DICKERSON: Yes. That's page 10 and 17 of the December 7 version.

MR. COE: The second sentence says, "To alleviative" -- it's crossed out, I guess. No. I guess that's not -- maybe I crossed out. "To alleviate this problem consider including in the project plans an area" so and so and so and so.

That's one of those areas where I think it's very weak and subject to debate. If they don't do it, they'll say we don't have to do it. I'm on page 14.

MR. DICKERSON: Page 12 of 17 of the December 7 version.

MR. COE: Item E, parking lots.

MR. DICKERSON: Yes.

MR. COE: This has been discussed, but I'm still not clear on -- this has no mention of the 5,000 square foot limit there. It has to be 5,000 square feet or greater before this applies. There's no 5,000 in there, and there is a 5,000 in the resolution which the board will be considering later on.

MR. SWAMIKANNU: Mr. Coe, page 3 of your document basically talks about --

MR. COE: Page 3?

MR. SWAMIKANNU: Of the document that you have. 3 of -- whatever. Page 3 of the version you have.

MR. COE: I'm looking at it.

MR. SWAMIKANNU: If you look at the second paragraph, it says, "Regional Board executive officer has designated two additional categories." And it says, "one is location within environmentally sensitive area." And then the next one parking lots, commercial standalone parking lots 5,000 square feet or more.

MR. COE: Okay.

MR. SWAMIKANNU: So that's where we call out the application of the requirements.

MR. COE: Now, a follow-up question and really an important part of this is -- that seems very small to be -- do I understand that numerical limits don't apply but the best management practices do for parking lots 5,000 square feet?

MR. SWAMIKANNU: The parking lot --

MR. COE: Or somewhere did I see that it's only 5,000 square feet or larger if it's heavily traveled from an industrial activity? I read a lot of documents. But this doesn't have any of that in there, and this is the plan.

MR. SWAMIKANNU: Yes. Basically says 5,000 or more standalone which is where we are right now. Standalone parking lots 5,000 or greater.

MR. COE: I see -- from comments coming in, written comments from the outside, some of the cities believe that's much too small. It would put people out of business and hard to implement BMPs. What's the source of the 5,000?

MR. SWAMIKANNU: In the 1996 L.A. County fund permit issue, we have requirements already for parking lots with 25 spaces or greater. 25 spaces or greater translates to 5,000 square feet.

MR. COE: So you're using what the county has already adopted?

MR. SWAMIKANNU: Not -- the permit that we adopted, the Regional Board adopted for L.A. County in 1996 has requirements for parking lots with 25 spaces or greater. And so we have used the same threshold. 25 spaces translates to 5,000 square feet.

MR. COE: What is our response to the cities that say that's too small?

MR. SWAMIKANNU: We are trying to address

the water pollution issue, and some of the studies that have been conducted by some of our municipalities indicates that the level of pollution from parking lots of that size is a concern.

MR. COE: Okay. My last comment at this point is page 15, limitation on use of the infiltration BMPs.

MR. DICKERSON: Yes. Page 13 of 17 of December 7.

MR. COE: We say in the second paragraph there "A water table distance separation of ten feet depth in California presumptively poses negligible risk for storm water not associated with industrial activity or high vehicular traffic."

I believe Ventura county's comment, written comments, indicated that they were a little uncomfortable with that ten feet and recommended we say that infiltration BMP shouldn't be installed over unconfined groundwater basins or aquifers.

They're worried about, of course, contaminating the groundwater supply by having these pollutants infiltrate. I realize ten feet will -- of percolation will -- there is a natural filter and will remove certain things. But can you respond to their concern and perhaps mine?

R0071960

MR. SWAMIKANNU: The ten-feet depth separation comes from studies in Fresno where groundwater is a concern. I realize that, when it's unconfined, that

the language you proposed where infiltration BMP is not being encouraged is a further clarification that we can provide.

MR. COE: I missed the last words.

MR. SWAMIKANNU: For where it is an unconfined aquifer, the infiltration BMPs can be discouraged in that situation. But where it's a confined aquifer, ten feet separation is sufficient for the studies that we've seen.

MR. COE: We don't say that.

MR. SWAMIKANNU: We can add that language, if you want.

MR. COE: Thank you very much. That's the end of my comments. I'll adjourn at this time. Thank you.

CHAIRMAN NAHAI: Mr. Shaheen.

MR. SHAHEEN: Just a follow up to some of the economic examples that you had up on the board. I just wasn't sure of the two examples that you showed for cost to implement were hypothetical or if you have a wide range of data of the actual costs to implement?

MR. SWAMIKANNU: Mr. Shaheen, we basically took a project that was in the pipeline in the city of L.A. and used the three quarters of an inch to look at the different options of BMPs. The first detention basin is a capture option. The second, vegetative swales infiltrations options and then the use catch basin insert, which is a flow over, its option -- treatment

R0071961

option.

And we use basically accepted cost estimates which are normally used to make those judgments.

So it's not a hypothetical case. It's an actual case. The city initially had concerns with the standard and so they worked with me to go over the calculations.

And so those examples indicate that, based on the flexibility we have provided, the range is very reasonable in terms of cost. Less than .1 percent to about .6 percent.

MR. SHAHEEN: Thanks. One other question possibly for Dennis, I guess. Again, I heard the comment earlier about staff recourses and even with registered or licensed people that are implementing this, how do you see staff's role, I guess, from an educational standpoint and from the standpoint if these can be consistently applied to BMPs?

MR. DICKERSON: Well, the issue of implementation is always a critical one. And with regard to our staff being able to provide oversight of what's going on at the municipality level or the county level, it's certainly very limited.

We're able to do an -- an occasional -- and certainly maybe this year not even that -- annual review of what is being done in the cities for the storm water programs. And should this be adopted, we would be

reviewing the implementation of this at that time in the future.

At the city level, the whole notion of that proposal, to have it approved by a certified professional, was to allow the city to have a mechanism by which they would be able to avoid having their own staff or hire new staff to review independently that work but rather to rely upon a professional who is adequately familiar with the information to be able to certify that it does meet that standard.

CHAIRMAN NAHAI: Mr. Miller?

MR. MILLER: Dennis, I have a question.

MR. DICKERSON: Yes.

MR. MILLER: On a single-family tract home project, if you have a detention or retention basin, what do you do after all the houses are sold? Who maintains the basin?

MR. DICKERSON: That would be the -- if you're in a large housing complex, the notion is that you would have some sort of a covenant, set of agreements, homeowners association --

MR. MILLER: What if you don't have one?

MR. DICKERSON: If you don't have one.

MR. MILLER: Most single-family projects don't have one.

MR. DICKERSON: Oh, are -- the single families that would be applied are the hillside, and what other ones, Xavier?

MR. SWAMIKANNU: I think he's talking about developments in the single-family homes.

MR. DICKERSON: Okay. I'm thinking of a distinction between, let's say, once you get up into over, let's say, 25, 50 homes, you're probably beginning to look at some kind of an association.

MR. MILLER: Not necessarily what happens.

MR. SWAMIKANNU: I think the example to look at, Mr. Miller, is Ventura county. Basically given the BMP options that we have provided, you can sort of build it into the landscape like a lake, a detention basin built like a lake, and so it adds value to the whole property.

Ventura county basically has created a fund where the developer puts in a certain amount of money up front for perpetual maintenance. That's possible. We aren't dictating options here. But several communities have done it in different --

MR. MILLER: No. I'm just curious about what happens in a for sale project where there is no association and there never will be which is -- a majority of tract housing is done that way.

R0071964

MR. SWAMIKANNU: I think that -- given the options that we have provided, the municipalities have to find -- find the mechanics. We're trying to address water quality here. So there is a community benefit.

MR. MILLER: Can the municipality then be forced to take over the maintenance of these basins if

necessary if they are community property?

MR. SWAMIKANNU: I don't know if force is the right word. But just like roads that we put in in tract homes ultimately get transferred to the municipality, and so similar mechanisms have been tried because the municipality has a responsibility to the community. We are not dictating options here, but they have --

MR. MILLER: I was just thinking of a way to make it work.

MR. SWAMIKANNU: Right.

MS. LYON: Quick question. When you had your economic examples up there, you might want to refresh my memory again. Did you have any grading costs in there? Those are quite extensive.

MR. SWAMIKANNU: Ms. Lyon, I don't think I included grading costs. The costs were associated with the BMP that structured two to three quarters of an inch. So excavation of the detention basin all the way of the sediment but not the grading of the property which I would consider as part of the project costs.

MS. LYON: Well, only if they have to comply with some of these new rules would that even be necessary. So that is part of the cost of this too. And I would like you to look a little bit further into that.

MR. SWAMIKANNU: Okay. I will.

MS. LYON: Thank you.

R0071965

CHAIRMAN NAHAI: I had a series of

questions to ask. And I'll try not to bore anybody with them, but I do need to ask them. So -- and I'll refer also to the -- the black line, the strike-out version that the board has since that was the most recent one.

I also marked up the other one. This was the most recent one that I had.

So my first question concerns -- appears on page 3, and it has to do with the definition of the 100,000 square foot commercial development. I wanted to make sure that I understand what we mean by a commercial development.

I guess this would exclude hospitals, schools, governmental buildings. It would basically -- this is a reference basically to shopping centers and office buildings?

MR. SWAMIKANNU: Mr. Chairman, my understanding is that commercial is much broader than that. It's not specific to just office buildings or malls.

CHAIRMAN NAHAI: Would it include a hospital?

R0071966

MR. SWAMIKANNU: It should. In my interpretation I wasn't trying to be restrictive in that definition.

MR. DICKERSON: I recognize your point. It's clear that the definition, if it were to apply to those, would certainly need to have greater clarity.

CHAIRMAN NAHAI: Now, hospitals and schools

and other developments, were they listed -- are they listed in the county list of SUSMPs to which the numeric limit applies?

MR. DICKERSON: I believe that's the case although NRDC might be asked that question or the county representative might be asked that. We're getting to an interesting point, though, and that is whether or not the 96 permit has a definition of commercial because that seems to me the key determinate of whether or not we have an issue here.

It does not? Xavier says it does not. So at some point today the board will have to give us some direction as to what's included in a commercial development

CHAIRMAN NAHAI: Or perhaps there may have been some kind of interpretation of the term between 1996 and now in the context of the countywide permit anyway.

MR. DICKERSON: I think it's something that we're going to have to look at. It's a very good point.

CHAIRMAN NAHAI: My next question has to do with the definition of redevelopment on page 4 and does the 50 percent test that's -- that's being applied -- and I was trying to figure out exactly how that's going to work in practice.

Because it could mean, as I read it -- and correct me, please, if I'm wrong as I read it, it could mean that you could have a 300,000 square foot development that could add 140,000 square feet and not

fall subject to the regulations.

On the other hand, you could have, you know, a much smaller development which could fall prey to -- prey is not the right word. Which could -- that's for those of you who oppose it obviously and to show you how balanced we are in the way we look at things.

You know, which could fall subject to it. And yet when you take a look at what we're trying to do, which is to control urban runoff in the pollutant mode, that wouldn't be -- you know, from a policy point of view, it wouldn't work.

So I'm wondering whether it would be appropriate to take a look at this issue and perhaps, rather than have this 50 percent test, perhaps we could talk about the addition of square footage. And that way, if you have a much smaller project that's expanding but which isn't going to have, you know, a deleterious impact, we don't impose the regulations.

If you have a much larger project, that's going to expand substantially and should be part of it. It would, wouldn't that?

MR. DICKERSON: I think that makes a lot of sense. And in fact, my expectation coming into the meeting today is by the end of the day you would provide substantial improvement to this document, and you already are. Thank you.

CHAIRMAN NAHAI: Next question regarded the definition of a restaurant which is defined as a facility

that sells prepared foods and drinks for consumption. Would that include a market?

MR. SWAMIKANNU: By "facility," I would mean a separate entity that's geographically isolated. So to a market with many other functions would not fall under this category.

CHAIRMAN NAHAI: How do you fix that?

MR. SWAMIKANNU: Prepared foods, so not raw vegetables.

CHAIRMAN NAHAI: If I go to my market and I buy a Wolfgang Puck pizza, that's a prepared food. And it's ready to consume. So we say a separate facility? A standalone?

MR. SWAMIKANNU: I agree with that comment.

CHAIRMAN NAHAI: My next question regards -- we've got source BMPs, structural BMPs and treatment BMPs. And in a number of instances, there's a bit of a blurring of the lines between structural BMPs and treatment BMPs, as I understand it; am I right, Xavier?

R0071969

MR. SWAMIKANNU: Yes.

CHAIRMAN NAHAI: When we get into some of the meat of the document -- and I'm looking, for instance, at paragraph 8 and then this is on page 9 and 10. We keep talking about -- in some places we talk about structural or treatment control BMPs and yet in other places we only talk about treatment BMPs.

For instance, at the bottom of my page 9,

it talks about verification would include the developer signed statements accepting responsibility for all structural and treatment control BMPs. That's fine.

Yet when you get to the -- to the next page in the second paragraph, for instance, it talks about -- it says if treatment control BMPs are located within a public area proposed for transfer. And then in the next sentence, again, a reference to treatment control BMPs.

And in paragraph 9, again, a reference only to treatment control BMPs. And in 9-A post construction treatment control BMPs. And should we also view referring to construction BMPs as an alternative or not?

MR. SWAMIKANNU: Yeah. I think we should include both terms at the same time. The issue, as you pointed out, we have source control BMPs which are very clear.

Structural control BMPs, for example, a shed. It's a structure, but that's not a treatment control BMP. A detention basin is also a structural control BMP but also treatment control BMP. And so in order just to be clear, I think, wherever we have treatment, we should also say structural.

R0071970

CHAIRMAN NAHAI: Structural or --

MR. SWAMIKANNU: Or treatment.

CHAIRMAN NAHAI: Jorge, perhaps you would want to take a look at the definition of treatment control BMPs and see whether you can refer -- include a

reference to source control BMPs as somehow part of that definition. Whatever shorthand -- whatever is easier.

The next thing is I couldn't understand the change in 9 A-3, which is on page 10. The way it reads right now, it says, "The volume of runoff produced by a .75 inch storm event."

Now whereas previously it talked about the volume of runoff produced from any storm event up to and including .75. And why was the change made?

MR. SWAMIKANNU: The change was made for clarity, Mr. Chairman. When we're talking about design standards, so when you design something, you design it for a particular size, and it treats everything up to that.

There was no reason to use language even up to and including. But perhaps if you think I'm wrong, then I have to be willing to consider your explanation.

CHAIRMAN NAHAI: No. I'm -- the possibility -- the probability is I'm wrong. But as I read it, this, you know, just strictly it says that post construction treatment control BMP shall be designed to -- and then it says -- mitigate storm water runoff from -- then the volume of runoff produced by a 0.5 inch storm event. Now, storm event is a defined term.

R0071971

MR. SWAMIKANNU: Right.

CHAIRMAN NAHAI: And there has to be a 72 hour --

MR. SWAMIKANNU: 24 hours is how --

CHAIRMAN NAHAI: So but would this mean that, if there was a .5 storm event, for instance, that in that event the BMP -- it says it -- it's there to mitigate storm water runoff from the volume of runoff produced by a .75 inch storm event. What if it's a .65 storm event?

MR. SWAMIKANNU: I understand that comment. My explanation of that would be -- when you design standards, you design for a particular size, and that means everything up to that is treated.

Now, for legal reasons you might want to clarify it because someone might want to circumvent the lowest that -- it's possible that that might happen. So then we would go back to the original definition that is there right now which includes everything.

CHAIRMAN NAHAI: Okay. I understand. And you're saying that the design of the BMP will be designed in such a way as to take care of anything that --

MR. SWAMIKANNU: For example, you design a car for four people. That means three people can fit, two people can fit, one can fit. But in a situation you might -- somebody might design a car for -- I don't know how you design one for four people and not for two.

R0071972

CHAIRMAN NAHAI: Possibilities come to mind. Regarding the difficult issue of implementation and how one passes on, you know, responsibilities and so forth this is how I envision it or how I see it in my

mind's eye.

If there is a large subdivision in which there is a consolidation of the BMPs so there is a set number of BMPs that is setting -- that is serving a number of homes around it, just like there's a tennis court or there's some other kind of common area within the subdivision, then I think legally anything from four lots upwards has to have a homeowners association.

So I think that will -- and if it's not a part of a common subdivision in which there's a common interest subdivision, then in that case there would be individual BMPs on individual lots, and the issue becomes how does that pass on from generation to generation?

And you know, we have municipalities, have devices in terms of recorded covenants. For instance, covenants to hold the property as one parcel or covenants to maintain tandem parking or covenants to maintain clarifiers on properties or various other things.

And those are devices by which, you know, generations of the obligations have passed from owner to owner by virtue of recorded documentation. Of course there is an enforcement aspect that's involved in that. But there's an enforcement aspect in everything that is seen and done including, you know, enforcing the conditions of tentative maps and enforcing the conditions of globing permits and what else have you. **R0071973**

So have you given thought to this device, or has there been discussion with the municipalities

about the device of recorded covenants in order to pass on from buyer to buyer the maintenance aspects of whatever BMP is selected?

MR. DICKERSON: There hasn't been that much discussion. Most of the discussion with the city has really been focused on .75 inch issue, and this particular item, if I recall, is actually language for the most part submitted by the cities to us. And so there hasn't been an awful lot of detailed looking at it.

CHAIRMAN NAHAI: Basically then this would leave it up to the cities to decide what mechanism they want to use for that?

MR. DICKERSON: Yes.

CHAIRMAN NAHAI: I think -- hopefully my final issue, regarding the waiver, I mean I can well understand that there has to be a waiver mechanism because you can't bind everything that's going to happen here in the future.

But with respect to the second waiver, I'm on page 16 in paragraph 11 and in subparagraph "ii's," it talks about unfavorable or unstable soil conditions that --

MR. DICKERSON: You're on page 13 of 17 of December 7.

CHAIRMAN NAHAI: I'm on page 15.

MR. COE: 16.

CHAIRMAN NAHAI: I'm sorry. I'm just concerned about the language because read on its face, it

R0071974

would mean that, if the soil conditions are unsuitable for infiltration, for this -- for this one kind of BMP, that a waiver may be possible for the entire SUSMP requirement.

MR. SWAMIKANNU: The purpose of the waiver, as you indicated, is to provide a parallel option in that situation, but the situation you're describing is just because one BMP is not applicable does not mean you pick up the waiver as the first opportunity.

And so we can provide that clarification to exhaust the various BMP options before you take advantage of the waiver.

CHAIRMAN NAHAI: And then finally regarding this paragraph, this is a question for you then, Dennis. How do you -- do you believe you're going to be inundated with requests for waivers, and is this something that should be brought back before the board or dealt with in another way?

MR. DICKERSON: Everyone tells me that the executive officer position must be a glutton for punishment. So that may indeed be a concern. I think we have some language as well here that has modified that somewhat.

R0071975

MR. SWAMIKANNU: The modification we have suggested is that the petition be submitted by the permittee as opposed to the project proponent. So that sort of limits the burden on the executive officer.

And these petitions can come in during with

the annual report. It doesn't have to be contemporaneous. So I think we can sort of regulate in terms of how they submit it to us.

MR. DICKERSON: The whole notion behind it is really in order to provide additional flexibility so that you wouldn't have to come back and modify the permit to allow that to occur. If it needs work, we can certainly change it.

CHAIRMAN NAHAI: Final question I had was with respect to projects that are already in the pipeline so to speak, that are going through their CEQA process right now. Those are not going to be caught by what we're doing here; is that correct?

MR. DICKERSON: Right. We need some direction from the board as to a specific date at which these are going to come into play. And I had been thinking along the lines of a -- what has to happen to make these really effective is the cities need to go back and adopt ordinances.

And so you need to give a period of time for the cities to adopt that and complete that process and then to have a point in time when plans that are coming in need to meet the standard, and it seems fair that that would be at some point after the ordinances are adopted.

CHAIRMAN NAHAI: How much time do you contemplate for the ordinances to pick up?

R0071976

MR. DICKERSON: No more than six months.

CHAIRMAN NAHAI: And then how long after that for the SUSMP requirements to become effective?

MR. DICKERSON: I wouldn't say that very much time would be needed.

CHAIRMAN NAHAI: Would any time be needed or some time?

MR. DICKERSON: I'm open to testimony on that.

MS. CLOKE: I think I'd like to hear the testimony first, and I have a lot of comments. But I'd like -- maybe some of my questions will be answered as we go through -- I'd like to reserve my questions until I've heard the public testimony.

CHAIRMAN NAHAI: So what we will do now is we'll move onto the two 30-minute segments, and the board will hold its questions until the end of each 30-minute segment. Now, I'm told that we must break at 12:30?

MR. DICKERSON: Yes.

MR. SWAMIKANNU: Mr. Chairman, before you proceed, I seek a clarification from you, Mr. Chairman.

CHAIRMAN NAHAI: Yes.

MR. SWAMIKANNU: And the clarification is on the numerical mitigation standard. You express some concern with the modifications that we have suggested. For example, the volume of runoff produced from three quarters of an inch, that discussion. I didn't get direction from you. Was my explanation sufficient to satisfy your query?

CHAIRMAN NAHAI: You want me to reaffirm my bowing to your superior interpretation?

MR. SWAMIKANNU: No. Not at all. I just want clarification.

CHAIRMAN NAHAI: What you told me is that, if I knew a little bit more about engineering, I would have known that and -- you seem to forget your example of, you know, procedure cards and so forth. I thought I maintained a very dignified silence in response to that.

MR. COE: A love of knowledge is a dangerous thing.

(Paper change.)

CHAIRMAN NAHAI: We're going to move to our 30-minute section. And what I'm going to do is I will call out, you know, four names so that -- or three names so that at all times we'll have three people waiting to speak for ease of movement. And again, are you ready with your magical device there?

MS. CLOKE: Mr. Chair, can I just suggest that perhaps people knowing that in these two, 30-minute segments they may have an order in which they prefer to be called?

R0071978

CHAIRMAN NAHAI: Okay. So the first three would be David Beckman, Alex Helperin and Mark Gold.

MR. BECKMAN: Good morning, Mr. Chairman, members of the board. Thank you very much for allowing us to address you this morning on what we believe to be one of the single most important actions this board has

taken in its 50-year history, and we don't mean that as hyperbole. We mean it quite literally.

I'm going to introduce the presentation from environmental groups. There's a number of groups in addition to NRDC that will address you this morning, and collectively they represent over half a million people and at least 75,000 people in the Los Angeles area.

What I'd like to do, by way of introduction, is to ask and answer five simple questions which address the general points we'd like to begin our presentation with and give you some sense of a context of this proposal.

If we can go to the first slide, the first question is what's at issue, and in our estimation what is at issue, as I indicated, is one of the most critical actions you can take to control storm water pollutions.

Quite literally to cut to the chase storm water pollution in Los Angeles has the region by the tail. You do not as a Regional Water Board have control of the situation, and I hope you don't for a minute think you do.

Storm water pollution is the single largest source of water pollution in this region. That's true nationally, but it's especially bad in Southern California. What can you do? You can take the step of approving the SUSMP proposal but not as proposed by the executive officer today but like it was proposed in the fall before the executive officer inserted almost a dozen

exemptions, exceptions and loopholes that have turned this proposal from a terrific one into Swiss cheese.

There's so many holes in this thing that we don't believe, as it is proposed to you, that it would have much effect at all, much good effect at all.

Go to the next slide, please.

Why is it so important? What is the issue of storm water? As I indicated, it's a huge problem. But let's just look at some facts briefly. EPA has said that the L.A. region has one of the worst storm water problems in the country, not NRDC, not the BayKeeper, not Heal the Bay, but EPA.

Storm Water has increased depending on the pollutant of concern that you focus on between 200 and 700 percent in 20 years. That's out of control, I think, by anybody's estimation.

In L.A., although it's a small portion of the land area of California, has over 50 percent of the officially listed impaired water bodies in the state which is an embarrassing statistic. We hope you agree with that.

The next slide.

What's the role of development? Why are we focused on development? Well, simply put, development is one of the most essential accelerators of storm water pollutions and its denigration of environmental resources.

R0071980

As the next slide shows, the amount of

impervious surface is directly related to runoff and as a consequence to runoff pollution.

If you could just put the next slide up. Thank you.

This is a statistic from NRDC report that was published last year. Some of you saw it a few months ago. But it is very telling. A one-inch rain storm on a one-acre natural setting, produces about 200 cubic feet of runoff. If you just pave that same acre, it's 16 times as much.

That example over all of the acres in Southern California is the answer to the question why do we have such a particularly bad problem? If that amplification of runoff and the pollution that's associated with it in a hardscape. And that's why we're focused on development and redevelopment.

Next slide.

What's the answer? What are we to do about it? Well, what you should do about it, we would suggest, is put in place an effective development planning program that has three components, a description of scope, a list of BMPs to select and a numerical standard.

What's at issue here is one in three. What's the scope and what's the size. Mr. Chairman?

CHAIRMAN NAHAI: You're the first speaker, and you've gone over three minutes. If you can, can you --

R0071981

MR. BECKMAN: Okay. I will conclude.

CHAIRMAN NAHAI: Please.

MR. BECKMAN: The rest of the speakers will get into some of the details and amplify some of the remarks I've made and answer many of the questions that were posed to staff. And again, thank you very much for the opportunity to address you.

CHAIRMAN NAHAI: Thank you.

Mr. Helperin?

MR. HELPERIN: Good morning, Mr. Chairman. Alex Helperin, from the Natural Resources Defense Council as well. I want to just talk about the -- all of the various forms of support that there are for the numerical design standard that's been proposed today.

These sources of support range from experiences in other parts of the country to local experiences and local support, the scientific and technical data as well as the expert support for this standard.

Both EPA and also the California Coastal Commission, I would note, have also stated their support for the standard.

R0071982

Next slide, please.

Just to give you a sense for some of the municipalities around the country and how widespread similar or even more stringent standards are, this is from one study of 32 municipalities around the country. And every one of these municipalities has a standard much more stringent than the one that's being proposed here

today.

Many of these are entire states including hundreds of municipalities in and of themselves. You can see in the bold along the right-hand side all of these are in excess of an inch. And again, this is just from one study.

Next slide, please.

In addition, EPA noted that Phoenix, which has similar hydrology to Los Angeles, which was not in that study -- I would just like to point out -- also has a much more stringent standard than this one.

Some of the standards in different parts of the country are hard to compare because there are different ways to measure these. This just shows you a few also from that same limited study, a few additional municipalities but also have standards that are the vast majority of the time, more stringent than ours or than the one that's being proposed.

Next slide, please.

Here in Los Angeles, as you know, the Los Angeles county has already adopted a program which is more stringent than the one that you're proposing today.

It's broader in scope. There are over 20 different types of projects that are covered. It's not limited to discretionary projects, and the permit does not restrict you to covering discretionary projects. There is discussion of discretionary projects, but there's no such limitation --

COURT REPORTER: Slow down just a little bit.

MR. HELPERIN: -- as NRDC has mentioned in our letter. And furthermore, the county program does not include a host of exceptions that we feel plague this current program.

Next slide.

Just to show you some of the 20 or more than 20 programs that are covered by the county program, you'll see about two thirds of the way down hospitals which you ask about are covered by this program much more extensive than the current proposal.

R0071984

Next slide.

Additionally, there are many local municipalities that support this program. As you can see, I've listed some of them here. Some, for instance, Calabasas are again much stronger. There are many others that supported, as the Regional Board staff has noted, such as Arcadia and Baldwin Park that aren't on this list.

MS. LYON: There's an error on there.

MR. HELPERIN: And since consistency has been brought up as major concern as far back as when the Long Beach permit came up, Long Beach stated that they wanted to wait so that there was consistency in their requirements that applied across the board.

So this is a significant factor in addition to California Coastal Commission that has applied this

standard now throughout the coastal area.

CHAIRMAN NAHAI: Thank you.

MR. HELPERIN: There's just one other slide that you might want to look at.

CHAIRMAN NAHAI: If we need to look at it at the end of the program, show it to us then.

MR. GOLD: Good morning. My name is Mark Gold. I'm executive director of Heal the Bay. One point of clarification, the Coastal Commission actually adopted a very similar standard to apply to all development -- that gets coastal development permits and local coastal plan, local coastal plan amendments and the entire coastal zone of California. So I do want to make a clarification.

I'm going to speak specifically to the exemption and waivers. I'm not going to provide the background that David did already. As he said before, there's a wide open waiver provision. The self-certification program and the insidious addition of the conflicts with local priorities provisions basically creates Swiss cheese, as he said, of the entire provision.

R0071985

One major loophole after another for developers and cities to avoid complying with the numeric design standards requirement is what we have right now.

And remember that -- that the August draft contained no exceptions whatsoever. The focus I'm going to talk about is the rooftop exemption. As a member of

the EPA Urban Storm Water Federal Advisory Committee, I've witnessed nearly every controversial position recommendation on urban runoff.

No one even proposed a rooftop exemption for new and redevelopment. No city, county or state in the entire country has a rooftop exemption. I've seen no journal article mentioning or proposing a rooftop exemption.

EPA is opposed to the rooftop exemption. Why? Because it provides an incentive to bill from lot line to lot line. This is the exact opposite direction that we should be going in and also because dozens of studies contrary to what we've heard before have demonstrated that the percentage of impermeable area is directly related to water quality flow, pollutant loading and the health of the watershed.

The staff report provides no justification whatsoever for a rooftop exemption. Where the heck did this technically and environmentally undefensible standard come from?

Neither the opposing cities the building industry had made this recommendation prior to the December 7 draft SUSMP. Well, this arbitrary standard was created from whole cloth with no substantiation whatsoever by the executive officer.

R0071986

Whether it's the Center for Watershed Protection, academia, storm water engineers or the county's own monitoring program, increases and

impermeability are directly related to increases and flow and poor water quality and ecological health. This has been substantiated time and time again.

The rooftop exemption ignores the impermeability issue altogether. Look at Malibu Creek and lagoon where flow -- which is important as water quality.

Remember, storm water flows transport pollutants to receiving waters. EPA strongly opposes the rooftop exemption. So should you. This is the most important amendment that you can make to protect water quality today. Thank you.

CHAIRMAN NAHAI: Thank you so much for keeping to three minutes. I appreciate it. The next three cards are from Heather Hoecherl, Lisa Boyle and Steve Fleischli.

MS. HOECHERL: My name is Heather Hoecherl. I'm staff attorney with Heal the Bay. In addition to the exceptions noted by Dr. Gold just a second ago, the program scope is also fatally hindered by a host of exemptions and limiting definitions which render the current proposal virtually meaningless.

These exemptions and limiting definitions are arbitrary and overly restrictive. I'd like to highlight a few of these. And just a more reasonable approach, first, we agree with staff counsel's recommendation that the SUSMP requirement should be applied to all enumerated areas in the county permit

whether the program is discretionary or not.

The second, the staff has proposed a list of categories subject to the requirements, and this list is uninclusive of the list used by L.A. county in its storm water management program. For consistency, the board should adopt the same category list used by L.A. county.

Third, several restricted definitions profoundly limit the meaningfulness of coverage for the program. For example, the definition of retail gasoline outlet currently includes only facilities engaged in filling gasoline that drive more than 50 percent of annual gross receipts from the sale of gasoline. This is way too narrow.

The staff has not put forth a good rationale for this limit, and under this definition, if a successful mini-mart or Mc Donald's is attached to a gas station, not only will the design standard or the numerical design standard not apply, but none of the SUSMP requirements would apply.

The definition should be changed to include any commercial facility which includes a pumping station regardless of whether the station has an associated convenience store or fast-food restaurant connected.

Second, the current definition of hillside is unduly restricted.

R0071988

Show us the next slide.

The way it's written in the proposal, all

three of those requirements must exist or those characteristics in order for it to be defined as a hillside.

This is inconsistent with L.A. county program where any one of these three characteristics, if one of them is met, then it would qualify as a hillside. We suggest changing the "and" to an "or" as indicated on the slide.

And again, this definition limitation is troubling because these areas would be exempted from all SUSMP requirements, not just the numerical design requirements.

Third, the proposal currently excludes small restaurants under 5,000 square feet from the BMP sizing standard. However, there is no automatic correlation between the size of the restaurant and the amount of pollution generated. In fact, the small restaurant can produce much greater storm water pollution than a larger one.

We would get rid of that limitation. We would also suggest on the parking lots to get rid of the commercial standalone limitation. The county permit has requirements for all parking lots greater than 5,000 square feet or 25 spaces, and we think that this will be consistent with that and that way nothing will fall through the cracks.

R0071989

Finally, we disagree with the staff's changes to the definition of redevelopment. We urge the

board to drop the threshold triggers which were just added and go with the definition found in the December 7 proposal. Thank you.

CHAIRMAN NAHAI: Thank you very much.

MS. BOYLE: Hello. I'm Lisa Boyle with Heal the Bay. The proposed design standard is cost-effective. BMPs can be very inexpensive. No one can argue that a development would be unduly burdened by the addition of a $500 catch basin filter or a dry well or the direction of rain gutters to permeable surface.

EPA has extensively analyzed the cost of storm water BMPs in the 1999 study, which is part of the record. In this study, using EPA's cost analysis and even assuming 100 percent imperviousness, a one-half acre development would be required to spend between approximately $675 and $8,000 to construct and install a sufficiently sized structural storm water BMP or BMPs.

A ten-acre complex would be required to spend as little as $13,500 or, using the most expensive BMPs, as much as $161,000.

These amounts are very small. They are a very small percentage of the overall costs to develop lots of this size. And I also direct you to the Regional Board's staff report at page 3 which cites that studies on the economic impacts of watershed protection indicate that storm water quality management has a positive or at least neutral economic effect while greatly improving the quality of surface waters.

Implementation of the proposed design standard right here in Los Angeles county or in -- or even more protective standards in municipalities all across the country has proven that development is not impeded by these types of standards.

In fact, some of the fastest growing regions in this country, including the state of Florida and Phoenix, Arizona have found that development can and will flourish in place with these progressive storm water design standards.

BMPs have been proven to be highly effective if they're sized appropriately. There's an incredible wealth of data in professional literature and government studies substantiating the efficiency of BMPs in removing pollutants from storm water.

In fact, the Center for Watershed Protection has concluded that there's enough data to select specific BMP groups on the basis of their comparative ability to remove specific pollutants. But BMPs must be sized correctly to be effective.

For example, oil, water separators can become overwhelmed if they're undersized. Finally, this standard is one of the most cost-effective ways that you can reduce urban runoff.

Incorporating the standard into the design and development stage is so much cheaper than retrofitting or cleaning up away from the source, as we've seen, from costly contaminated sediment cleanups at

the mouths of storm drains.

In fact, contaminated sediment dredging and disposal can cost $100 per cubic yard. So we urge you to remember the cost of not taking this proposal.

CHAIRMAN NAHAI: Mr. Fleischli.

MR. FLEISCHLI: Good morning, Mr. Chairman and members of the board. My name is Steven Fleischli. I'm the executive director at the Santa Monica BayKeeper. I think you all have a general sense of why we're here today.

We're here today because of sufficient -- significant water quality impairments in Los Angeles. But why is this issue before the Regional Board. Why are you the ones who have to deal with this? And the reason is, because under the Federal Clean Water Act, you are required to reduce pollution -- or cities are required under direction from you to reduce pollution to the maximum extent practicable.

And that's what this is all about today. Is this the maximum extent practicable? We would certainly argue that it is. We can actually come up with -- and we have come up with numerous examples that show that there's much, much more that can be done on this.

.75 versus other cities that have done one inch, one, 1.2 inches certainly in terms of maximum extent, this is reasonable in terms of that interpretation. In terms of whether it's practical, I

think the economic information you've heard that's been corroborated by staff, that's been corroborated by experts around country clearly indicates that this is practical.

The record in this case is massive. There is so much support for what you can do today in addition to the MEP standard under the Clean Water Act. You have the authority, and your mission statement in fact is to protect and enhance the water quality in the Los Angeles region.

Protecting this at the source where it starts and enhancing the rivers by preventing this pollution in the first instance is a meaningful step.

In terms of the record, you can do the next -- next slide. Actually, I'm sorry. In terms of the record, again, massive here. We have experts that support this standard from Tom Schueler from the Center for Watershed Protection, Dr. Richard Horner, Dr. Michael Strenstrom.

These people have written more materials on this than I can guarantee you the city is ever going to come up here and oppose this have even bothered to read.

And instead of looking at the evidence that's out there, all they're doing is looking for excuses today.

In terms of what's happening, some people will say that this is an effluent limit. It's not an effluent limit. It's a design standard, and what it does

is allows people and engineers to size these things properly. That's all it does.

An effluent limit would say you can only have .1 milligrams of lead run off your site. That's not what this proposes. But you clearly would have the authority to take that additional step.

The 9th Circuit has upheld that under Friends of the Earth versus Browner. It just came down last fall.

Next slide, please.

I guess the fundamental issue today is -- and for those of you who may have seen the article in the L.A. Times, based on what David Beckman has said this morning, is this is your opportunity to leave the legacy today. You can do that if you take out some of these exemptions.

Rooftop exemptions, it's absurd. You need to think about water quality and water quantity, and the Supreme Court has said in Jefferson County Public Utility District that the Clean Water Act allows you to look at water quantity and the impacts that that had on our waterways.

R0071994

And when you think about the L.A. River, when you think about Ballona Creek and those waterways, it's not just water quality. It's water quantity that has resulted in the paving over those rivers in the first place and the inability of us to meet our flood control requirements. So I will leave it at that. Thank you

very much.

CHAIRMAN NAHAI: Next cards I have are for Andy Lipkis, Beverly Winter and Terry Tamminen.

MR. LIPKIS: Do you have a clock that I'm watching up there?

MS. GOODMAN: The yellow, one minute left and --

MR. LIPKIS: Great. Thanks. My name is Andy Lipkis. I'm president of Tree People, a 15,000, member, 26-year-old local environmental organization.

I'm here to support the proposed and also push to remove the exemptions. What I'm really here to do today is to tell you this is feasible, and it's easy. It's understandable that people are scared because it seems new to Southern California.

But as you've heard, these ideas have been implemented all around the country. Specifically, though, there's an opportunity, as you've heard, to solve water quality issues but other significant issues facing Southern California including water supply, water conservation.

Because of that, Tree People launched a five-year effort, million dollar study, to prove economic feasibility and technical feasibility of doing just this. Actually, we set out not for three quarters of an inch but to trap 130-year storm on each land use in Los Angeles and show that you could retrofit sites, not just do it with new construction and still have it be

economically feasible.

130-year storm is ten inches in 24 hours. Sites can do that. We're not talking about something that's very difficult here. The partnerhsip that we brought together to make this happen included the United States Forest Service, the EPA, the L.A. Department of Water and Power, the city of Los Angeles, county of Los Angeles Public Works, city of Santa Monica, SCAG, Environment Now and numerous other agencies.

What we did was bring together leading engineers, architects, landscape architects, foresters, hydrologists from around the country. They spent four days designing retrofits and BMPs for L.A. sites. We have a book full.

What we did was take one of them, a set of them, and we retrofit a home in South Central Los Angeles. It functioned beautifully. We created a flash flood just recessing the lawns, putting in water capture devices. What it did was enhance the home, made it water safe, flood safe and especially protected the bay.

We also conducted a two-year cost benefit analysis with 200 local agency scientists and economists that backs up our data. We can provide that for you.

In addition to single-family home, we've retrofit schools. We're right now in the construction of two schools. One we're taking and making unpermeable surfaces permeable and handling flood water and storm

water from a parking lot.

Another school near L.A.X. we're putting in a 800,000 gallon cistern collecting, treating the polluted storm water from the whole campus and parking lot and using it to water the campus, replacing portered water.

Volume is a really critical issue, and we urge you to keep rooftop water in the mix because you need those volumes to help justify some of the costs of the BMPs.

You can easily handle entrenching and infiltration BMPs without the rooftop. If you add the rooftop, you add a lot of value that winds up helping the developer, helping the local homeowner because you're adding the water supply.

The results of this project are properties that are more attractive, making this more viable. Go for it.

CHAIRMAN NAHAI: Thank you very much.

MR. LIPKIS: I've got materials you can read.

R0071997

MR. LEON: Real quick housekeeping matter. A lot of the folks have provided slide presentations, just a couple slides they've put up. For the record of this proceeding, I would like for you to instruct the people who have presented slides and those who may present slides, they need to provide a copy for us whether it's a slide that they have now or whether they

can provide a copy in the hard version by the end of the week or something.

We need those things in the record of this matter and --

CHAIRMAN NAHAI: If they want it to be part of the record or they should do it in any event?

MR. LEON: Well, they should do it in any event because by putting it in front of you, you're necessarily going to consider it.

CHAIRMAN NAHAI: Does anybody need me to repeat that? Thank you. Ms. Winter.

MS. WINTER: Chairman, members of the board, my name in Melanie Winter. I'm the executive director of Friends of the Los Angeles River. And we're here to support the proposed plan without amendments and to talk a little bit about taking further from Mr. Lipkis' proposal a specific instance again of a brand new development that we had some experience in working with.

In 1998, Friends of the Los Angeles River entered into a mitigation agreement on a particular site development along the Los Angeles River at Taylor Yard.

This is a large 50-acre parcel that had never been developed. It had been dirt since God. And they were about to put on a large business park on this site. We were concerned not only with the quality from the runoff but water quantity because we're concerned about the river.

Fortunately for us the development company's president is an avid surfer and quickly understood our concerns. We began to work together on how to solve this.

Our consultants work jointly with their engineering staff to develop a drainage plan which ultimately would retain and detain surface water runoff and would remediate the water runoff.

And this plan was designed so as not to increase peak flows of surface water runoff also in a hundred year storm event.

These facilities were designed over a course of several months in working with these engineers. It was a challenging experience because it's a lot of new methods for the engineers, but it was very rewarding.

In the end, the systems were designed to -- we designed a system in the parking lot area largely. We considered a number of BMPs, including rooftop storage.

We chose from a menu of several implementing pieces of each and designed a system that incorporated bioswales, permeable surfaces and 18-inch perforated pipe subdrainage system. And sort of -- we called it BMP and weir system in the parking lot that allowed for greater percolation.

R0071999

Additionally, the storm drain's improvements designed to capture storm water runoff -- a half inch storm every 24 hours and to maintain 100-year

storm on-site. The latter was accomplished through a detention which over time it allowed percolation.

This was a large stop. These measures did not increase their costs. These costs were not increased. They were reallocated, and we all firmly believe that we could have gone for a full-inch event had we not agreed initially to not increase their projected costs at all because of the costs associated with the initial legal discussions and the six-month redesign at the site.

I think much of the resistance of the building industry seems to stem -- the fear seems to stem from the cost increase or that these are changes and that permits will be too hard to gain. We did have some initial hesitation in the permitting process, but these were quickly overcome.

And I think that with each new development, it will be easier and easier. And it's become a new standard. I think that developers need to follow legacy's lead. Change is impossible. It's critical. We need to not only keep the water clean but reduce the volume as well. We can accomplish both here.

MR. TAMMINEN: Good morning, members of the board. My name is Terry Tamminen. I'm the executive director of Environment Now and a board member of the Santa Monica BayKeeper.

R0072000

I had some remarks prepared here that would summarize the presentation you've just heard by the

environmental advocates, and I'm not going to use these because I think you have heard in great detail and much more articulately everything that I could have said to you in summary.

So instead, I'm going to provide you with a little historical context and ask you a question. And the question is this: Is this Regional Water Board prepared to have the heart and the wisdom and the intelligence and the foresight to do what all of its predecessors have failed to do?

That's the basic question. And I put it in this historical context for you because most of you are new, even those of you that have been here a little longer, other than Ms. Lyon and Mr. Coe, have not been here for more than a couple of years and certainly not even our executive officer were here ten years ago when many of us started trying to reduce storm water pollution using Municipal Storm Water Permits and State Industrial Storm Water Permits and construction permits.

And we came in front of the Regional Water Board, and we asked for help, and we got a deaf ear. So instead some of us had to sue some of the cities to establish these standards. Not a happy prospect for any of the participants.

Again, we came back, and we asked for help. When it came to Caltrans, for example, under the Municipal Storm Water Permit and their responsibilities, to the county, especially with regard to the monitoring

components of the Storm Water Municipal Plan, which obviously the monitoring is what tells you whether or not these efforts are working. And again, the Regional Water Board turned a deaf ear.

So again, the advocates had to sue and had to get these standards implemented in other ways. We've done it time and again for everything from auto wrecking junkyards to ports and municipalities. Time and time again come in front of the Regional Board and said, "This is your opportunity to do something to avoid future conflict. Help us." And instead we got a deaf ear.

So we're back today. Now, the previous boards, maybe they had a bit of an excuse because what was their answer time and again? "Well, we haven't tried the cooperative process long enough. We haven't sat around the table long enough. We haven't held hands long enough. We haven't sung Kumbaya loud enough."

But now ten years later, we have done all of that. So I repeat my question to you. Will this water board, the administration of Chairman Nahai, will this water board have the courage and have the wisdom and the foresight to take the actions required to adopt this resolution the way it was proposed in the fall without all the exemptions and the loopholes? R0072002

Make it clear. I got to tell you in every one of the cases, when I've been across the table from a defendant, they all say, "But look. If I do the things you're asking me to do, how do I know that gives me final

peace without numerical standards, without definitive standards, how do I know?"

And my answer is "You know what? You don't know." So this is your opportunity to do something not only for the environment and the environmental advocates standing in front of you here today but for the regulated community. Have the wisdom. Have the courage, and have the heart.

CHAIRMAN NAHAI: We'll go now to posing questions by board members to any of the speakers that just spoke. There are actually nine of them. But Ms. Cloke.

MS. CLOKE: How's that? I'd like -- I'm going to let you decide who answers, but among the three of you. But I'm really interested in the question of what projects -- the supplies that I'm interested in the discretionary question which it doesn't make a lot of sense to me because the new -- the -- the impact of this, as Mr. Dickerson said, is going to take time.

It's going to be cumulative, and we're not going to really see it. So I don't understand what binds us in terms of what we can include and what we can't include. I know, for example, that government buildings often go by their own level of government as to what rule they have to follow.

But it seems to me that, if we're going to impose these rules on developers and cities, that we need to impose them on ourselves as well. So I'd like

somebody to speak to those questions of what are our powers in terms of what could we include? That's question No. 1.

MR. BECKMAN: David Beckman. Let me respond broadly. And if you have specific questions, Alex Helperin may be able to respond to them. But the simple answer to your question is your powers are as broad as any land use in the jurisdiction under which the board has power, which is L.A. county and Ventura county.

You can regulate everything. And one of our fundamental points, and it's amplified by your question, that, what is before you, is a very small segment to begin with.

That was before you in September. What's happened now is the executive officer has pulled more pieces out so that of the landscape that contributes to the problem, all the different types of development projects, including those that were on the slide that Alex showed that we and the county have agreed to work with you are already only using -- only focusing on a small percentage.

The issue about discretionary versus nondiscretionary, that's also a good question. That's one of the most -- that's a purely legal loophole because in CEQA law and in planning law, discretionary projects are usually very few.

They are the really big ones that go before the board. But most of the changes to the urban

landscape are made little bits at a time by projects which do not require the approval of officials like yourself.

And so by constricting this world that you're regulating to discretionary projects, you once again, you know, focus even more minutely on only part of the issue.

So you have all the power today, if you like, to remove the discretionary exemption, which we suggest you do, and to broaden the scope up to and including what the county agreed to or even beyond it.

But certainly if you went to what the county agreed to -- and we can put it up on the slide if you'd like to see specifically what it is -- then you would have within the region, a level playing field within the county, outside the county, unincorporated and incorporated areas.

MR. HELPERIN: I would like to clarify one thing. The limitation to discretionary projects is a misinterpretation of some language in the permit. The only limitation -- this isn't even a limitation. But the only possible limitation you have is the permit that you yourself imposed in 1996.

That permit has a discussion of discretionary projects. But it's a minimum. It's not a limitation. So there's absolutely no reason why you couldn't go beyond discretionary projects and impose a requirement to have certain minimum standard just like

R0072005

any other building code that applies to all projects. That's the appropriate way to a consistent code system.

MS. CLOKE: My next question has to do with these thresholds which are being suggested, the 50 percent thresholds and the 5,000 square foot threshold.

And I'm not sure that -- I'm not sure what the appropriate threshold is. So I would like to ask you for your thoughts on the question of what constitutes, not just the number or the size for the appropriate threshold, but the reason why that's the appropriate threshold.

MR. HELPERIN: Alex Helperin again. When you say the 50 percent threshold, I assume you're referring to the gas -- retail gasoline outlets which --

MS. CLOKE: Remodeling. And I mean --

MR. HELPERIN: And redevelopment. Right. Well, first, let me just address the gas stations. If you have a pumping station and you're pumping gas, you should have these requirements applied.

There's no reason that, if you haven't attached a mini-market that happens to do a little less business, then the requirements apply. And if they do a little more, the requirements don't. Where is the logic in that?

R0072006

If you have a facility like a pumping station which keeps creating these problems, then the requirements should apply. And it shouldn't matter how much income you're getting from some alternative adjunct

facility.

With respect to redevelopment, there is a standard that we applied in the county that the county has applied which is, I believe, 50 percent of the cost -- 50 percent of the price of the total improvements on the land would require if -- let me start again.

Any redevelopment must incorporate the SUSMP requirements with respect to the area of redevelopment.

However, the redevelopment require -- the SUSMP requirements only apply to the entire facility if the improvements constitute -- if the costs of the improvements constitutes 50 percent of the cost of the existing improvements on the site. That was the standard county adopted, and I think it's an appropriate standard here as well.

MR. GOLD: Again, with the 5,000 square feet on the parking lots, on the same example -- I'm sorry. I'm Mark Gold of Heal the Bay.

In the same example that was given before in regards to the restaurants and the gas stations is that, you know, it shouldn't really matter whether it's a standalone parking lot or not on whether or not it's contributing to pollution.

R0072007

It's known that parking lots contribute to pollution. So that's the same sort of thing. As for restaurant sizes, I think we stated quite clearly that was arbitrary as well, and the irony is that basically

the size constraint that might be offered might have the exact opposite effect because it allows probably some of the smaller fast-food restaurants with drive-throughs, et cetera, might be able to squeeze through.

So I mean it's hard to say because the 5,000 is totally arbitrary. Thanks.

MS. CLOKE: I have two more, if I may. On the question of the waivers. If I said to you that I am -- that I think that you have to have some flexibility, I mean I don't think there's any board that can anticipate all circumstance, and people have to be able to make arguments.

But there's always a place where you draw that line. And so -- so if I say to you I think that we have to have some flexibility, but again, I don't know where you would recommend that line to be drawn.

I'm not -- I'm not sure even where -- where -- and I'm not sure what the effect of staff drawing the line, where there would be a line drawn, it has been.

R0072008

I want to be in the place of being as sympathetic to people's projects as I can possibly be and yet at the same time still protecting the water quality.

MR. BECKMAN: Well -- David Beckman, NRDC. Let me begin to answer this, and Alex or Mark may add to it. I think one critical component -- and we understand with the new program and really don't oppose an appropriate mechanism to bring to your attention as board

issues that come up that may not be anticipated today.

And for that reason, we think that one fundamental change that you should make is to have waiver requests come before the board.

Now, if that proves to be an unworkable situation because you have too many or they're too difficult, then you can at your -- whenever you want, you can change that mechanism.

But at least to begin with we think that it's critical that the board maintain control of the program, make sure the policy is being set in the way you want it to be set and work through these issues.

So that's one critical thing. It's not to have it at a staff level and have the executive officer be burdened with having to make the decisions. That's one issue, and I think Alex might have a couple other things to add to that.

MS. CLOKE: You might speak to permittees also being allowed two waivers.

MR. GOLD: Well, I was just going to say, if you recall the August draft, one of the things was it was strictly an 85th percentile capture standard. And one of the things the environmental community even said back there was it should be a capture infiltrator treat standard.

R0072009

And I bring that up because that really provides as much flexibility as is needed in the program because I don't know who's going to state that you can't

put a catch basin filter. And there are some BMPs that are pretty easy to do, redirecting rain gutters, those sorts of things that really doesn't really make much sense.

And where it is right now obviously is completely broad in the way it's laid out.

UNIDENTIFIED: I just wanted to say one quick thing about permittees. We are strongly against permittees granting exemptions, strongly against it. And to be blunt, it's because we don't have faith in a majority of the permittees having any interest in this program working and believe they would be overly liberal in granting exemptions.

And as Mr. Tamminen indicated that that would lead actually to more conflict. I think initially at least the board should control the program. And as it becomes clear when exemptions are appropriate or waivers, I should say, you might be able in the next permit to delegate some of that responsibility but not initially.

UNIDENTIFIED: I'll just add a comment with respect to the current standard that it has been proposed, has substantial problems. Right now it has three articulated situations in which a waiver would be appropriate plus any impracticability.

R0072010

So there's really no limits on the discretion of the executive officer at all to determine what would constitute a situation of impracticability.

Furthermore, two of the three articulated

situations of impracticability have to do with the permeability of the soil which, as you heard before, makes no sense because there are many other options, many other sources of BMPs that can be implemented.

So unless it's a substantial reworking of that language to explain that impermeability is only relevant to a waiver if every other sort of BMP has been ruled out and, as Mark said, that's very unlikely. Two of the three articulated standards that would substantiate a waiver make no sense whatsoever.

MS. CLOKE: Thank you.

CHAIRMAN NAHAI: Any other questions?

MS. DIAMOND: I have two questions. I just want to follow up on the last answer. Are you saying that, if waivers are granted, that it's probably not the case if someone applies to develop something that there are no BMPs that would work, that they may be able to say the soil is impermeable or for whatever reason something is unpracticable? But some of the BMPs should be applicable and practicable for almost any development?

MR. BECKMAN: Yes. Absolutely right. The board have already dealt with this issue last summer. You have selected cafeteria, like, a slate of things you can choose from for different situations.

R0072011

One of the flexible aspects of this proposal, it does not mandate "Thou shalt use a detention basin if" -- you know, instead of conditions. And so we have situations where infiltration may not be

appropriate. Everybody recognizes that. Don't use infiltration. We think you can cover everything.

MS. DIAMOND: One last question on the issue of conflicts with local practices. Do you think there are some situations where using the local practice might work or in all situations they should just use the BMPs that we have in the permit?

UNIDENTIFIED: We think the analog here is the one that applies in the Clean Water Act generally which is more stringent local standards can remain in place of course. But the point of what you're doing today is to set minimum standards that apply everywhere so it's a level playing field and to get away from the situation of judgment calls.

Frankly, you're also trying to change local standards. Local standards haven't worked. And so I think to open up and let anybody come in here and argue that their approach is more or less the same is going to swamp this program immediately with those kinds of comments.

And you know, the Regional Water Board is regional. And so your program should apply regionally.

CHAIRMAN NAHAI: Any other questions? I had a couple of things. I think on two of the things that you've said it's just the matter of clarifying language.

R0072012

For instance, with respect to the local practice issue, we have the language that talks about

defeat or circumvent, and I guess what you're really arguing is saying that the local practice can continue so long as it doesn't incorporate standards that are less stringent than those set forth in this document.

MR. BECKMAN: That's right.

CHAIRMAN NAHAI: The wording defeating or circumvent was supposed to get there, and it may require some clarification. And then on the other issue of the infiltration BMP as opposed to others in the waiver language, that again, is just -- I think the intent of board staff isn't as -- as Xavier testified earlier to say that just because infiltration is inappropriate or impractical, that that will -- therefore, that means that there would be a waiver of all the standards.

MR. BECKMAN: That's right. It needs clarifying. I agree with you that it wasn't the intent, but I think it's the way it reads.

CHAIRMAN NAHAI: Two other issues. First, I would like to see the L.A. county list up again. It went up and down so quickly that -- and you'll say --

MR. BECKMAN: You're telling us to speak quickly, and the court reporter is telling us to speak slow.

COURT REPORTER: Yeah. I do have to get this.

R0072013

CHAIRMAN NAHAI: I knew someone would hear that. That would have to be you, Mr. Beckman.

MS. CLOKE: I think we have to -- did we

also -- didn't I see a copy of that in what you submitted?

MR. BECKMAN: Yes. There is a copy. We made copies of our submittal for each of you but --

MS. CLOKE: I just don't want to look at it in the book. Tell me where it is. Oh, I have it. Nevermind. I found it.

UNIDENTIFIED: It's an exhibit to our letter. So you can see here that the county list begins with the seven types of projects with which you began. But recognizing that that was not a limitation, we and our experts and the county and their experts try to figure out, since we weren't doing this on a strict size basis, but rather we're doing it by project types what other sorts of project types would be problematic?

And you can see that we came up with a substantial list that we thought, if you cover all these, you're probably okay. Many of these the current proposal completely ignores. You mentioned hospitals, car washes.

There are several different -- dry cleaning -- several different categories in here. Nurseries that are simply not addressed.

R0072014

CHAIRMAN NAHAI: But now the part B categories were never included in the SUSMPs proposed by the staff; is that correct?

UNIDENTIFIED: I believe that's correct. I believe that's correct.

MR. GOLD: Except for the parking lots and

what you said.

CHAIRMAN NAHAI: One other question I had was with respect to rooftops. You know, we're getting arguments for both sides that there is not enough data to support, you know, having the rooftop exemption.

And their executive officer says there's no evidence to support, you know, not having a rooftop exemption. Could this be something that could be made subject to a reopener so that once further studies as to the impact of runoff from rooftops are available that one could visit this issue?

MR. GOLD: Well, I think you're saying -- me here answering this question because this is really an area that I've worked on for my entire career, and it's not just myself as a scientist specializing in storm water.

It's basically the top academic scientists throughout the country. It's the EPA. Everything is basically pointing to the fact that all of the problems -- a lot of the problems that we're having is that, when you increase impermeability, which of course rooftop is impermeability, it leads to all these detrimental impacts.

R0072015

I don't think there needs to be any additional studies in regards to this. I mean if we're going to sit down and wait for the aerial deposition study and then fold in the A.Q.M.D., I mean we're never going to get done.

The reality is that we need to face this right now because you're never going to -- I mean literally the body of evidence in this regard is feet tall, and it's clearly what we've seen is over time as impermeability has increased in one monitoring station or another throughout this region you've had increased pollutant loads. You've had increased flows literally by 10 or 20 fold.

Remember the Malibu Creek situation where they throw up flows from the 50's versus the 90's. And so this is basically the issue that we're trying to address, and flows are, of course, going to pick up pollutants and transport them to receiving waters, and we already know about the impaired receiving water problems.

CHAIRMAN NAHAI: So your point there is that, even if it can be established that rooftop runoff doesn't contribute a great deal to pollutant loading, that, nevertheless, in a situation where we have 50 percent of our rainfall get, you know, wasted basically, even if it was absolutely clean, the impermeability it just takes to the ocean, that having the rooftop exemption negatively impacts the ability to capture the rainfall.

R0072016

MR. GOLD: Absolutely. And that's basically it in a crux. And all the things that are associated with it, with all the various different contaminants, erosions, scour, and those sorts of things are going to occur when you fold that out and basically

you're going to have BMPs that don't work and aren't adequately maintained in that situation.

MS. DIAMOND: Can I -- just a question just to clarify. With some of the water from the rooftop in some storms, even if it's clean and pure as can be, eventually get onto the pavement and pick up the other oil and debris that's already there and then continue on its way.

MR. GOLD: Well, absolutely that's the case. And I know there's a small clause within there trying to avoid that, and I'm not going to pretend there isn't. But let's not pretend that once it gets into the M.S. 4 that everything is like all pristine and clean.

I mean this is obviously going to scour out all the pollutants that have accumulated within the catch basins, within the storm drain system and the like that are causing the problems.

I mean there's a reason why in the Caltrans case with the NRDC when they did their catch basin study and found out what was in the catch basin. Low and behold what a shock. You know, you end up finding a lot of contaminants.

That's what's in the storm drain system, and basically increased flow is going to cause that to go into their city waters.

MR. FLEISCHLI: Can I just add something real quickly to that --

COURT REPORTER: What's your name?

MR. FLEISCHLI: Steven Fleishli with BayKeeper. With regard to the proposal that the executive officer has put forth, he's tried to make a distinction to say that "Okay. If you're, like, on a Malibu Creek, then we're not going to allow this exemption to occur."

But if you look at -- and we had a meeting with environmental community with the Army Corps of Engineers very recently with regard to the Los Angeles River, and one of the biggest struggles there is all right.

There are a lot of great projects, Taylor Yard, all these other sorts of things on how we can move forward and try to restore some of the beneficial uses on these rivers. The number 1 problem that every single person there is having is the flow levels and the flooding capacity and capabilities.

How do we deal with that? And if you allow this volume to increase, essentially you're precluding us from restoring that river, the Los Angeles River, Ballona Creek, San Gabriel, and your authority clearly allows you to restore those.

In the Supreme Court, again, you don't need to base this on quality for the rooftop. You can base it solely on quantity and the impacts that quantity has had on places like the Los Angeles River that are already channelized and we would like to see restored.

CHAIRMAN NAHAI: Thank you very much.

R0072018

We need to -- it's now -- what is it? About five past 12:00. And we must break at 12:30, or we don't necessarily have to?

UNIDENTIFIED: We may not. I can check.

CHAIRMAN NAHAI: Well, in that case, I'm going to go ahead and hear from the other --

COURT REPORTER: If we can get a break soon. If you're going to go right through the lunch, then I need my break.

CHAIRMAN NAHAI: Ladies and gentlemen, we'll take a ten-minute break to allow our court reporter to get her fingers back together. And we'll see you in ten minutes.

COURT REPORTER: Thank you.

(A break was taken.)

CHAIRMAN NAHAI: We're going to go now to the second half-hour segment, and the first three speakers are Ms. Margaret Clank.

MS. CLARK: Clark.

CHAIRMAN NAHAI: Clark. I'm sorry. Mr. Bart Doyle and Mr. Desi Alvarez. Three minutes each, please.

MS. CLARK: Mr. Chairman and Regional Board members, my name is Margaret Clark. I'm the mayor protem in the city of Rosemead. I'm also a member of the San Gabriel Basin Water Quality Authority, which is charged with cleaning up the groundwater contamination in the San Gabriel basin. And I'm also on the board of the L.A.

and San Gabriel River Watershed Council.

And many of my friends here in the environmental community know that I've spent countless hours voluntarily on issues dealing with the environment, and I want you to know that that is where I'm coming from. But we do -- from a city standpoint, we do have some concerns, and I'm going to lead into those.

The executive advisory committee or EAC is the steering committee of the countywide storm water management plan. The EAC includes a mix of municipal representatives, two from the county of L.A., two from each of the six watersheds.

During our presentation, we will refer to specific provisions of the permit. We have provided each member of the board with a copy of the permit that highlights these provisions.

The permittees request the materials and evidence provided to the board be included as part of the record of this hearing. The permittees are the cities and counties of L.A. We represent municipal governments and their local elected officials which in turn represents the tax paying citizens in this region.

With respect to water quality, our objectives and those of our governing bodies are to prosecute water quality, comply with the permit and assure the compliance plans are effective in protecting water quality and ensure that compliance costs are commensurate with environmental benefits.

It is incumbent on public officials to ensure that public resources are achieving real water quality benefits and not just buying window dressing. Although the topic of record for this hearing is the SUSMPs, the EAC believes that this hearing is really about the appropriate process for developing and implementation of storm water treatment design standards for new development.

The permittees do not oppose storm water treatment design standards for new development. As a matter of the public policies, the permittees expect a thorough and fair process that provide for a stakeholder participation in the development of such technical requirements. It also expects a process that will be honored by the Regional Board and its staff.

There needs to be a clear understanding of what is required and what will be accomplished in terms of improving receiving water quality. Further, there must be a clear understanding of the public and private costs associated with implementing such a program.

The desire and need for such an orderly process for sending storm water treatment design standards is shared by the California Storm Water Quality task force which includes representatives from every major municipal storm water program in California.

Each member of your board has received a copy of this position statement. The L.A. Municipal Storm Water Permit provides a clear process for the

orderly establishment of meaningful and effective storm water treatment design standards where needed.

Therefore, the permittees oppose the staff proposal that attempts to unilaterally impose a one-size-fits-all storm water treatment design standard for new development. The permittees also oppose mandatory retention treatment controls for the subject new developments.

In considering this issue, it is important to recognize that there was wide stakeholder involvement in the development and the adoption in the L.A. permit. This is documented in finding 44 located on page 10 of the findings section of the permit where all of the groups got together.

Although the permittees had significant reservations regarding the permit, we have complied with the specified requirements. All required reports and programs have been made on schedule or in the case of the SUSMP five months before they were required.

Although the Regional Board staff proposal is presumably well-intended, it overlooks the fact that the permittees are now implementing a process leading to the development of design standards.

We believe that the proposed staff action and report need to be revised to reflect objective judgment and good faith in its interpretation of the L.A. County Municipal Storm Water Permit. Do I have one second left?

CHAIRMAN NAHAI: Well, beyond three minutes. If you do that, everybody else will want to.

MS. CLARK: I hear you.

CHAIRMAN NAHAI: I apologize.

MS. CLARK: Thank you very much.

CHAIRMAN NAHAI: Thank you.

MR. DOYLE: I will try to be brief. I am Bart Doyle, mayor of the city of Sierra Madre, and I'm also a member of the governing board of the San Gabriel Valley Council of Governments and treasurer. And I'm speaking on behalf of both organizations today.

Very briefly, I believe you have contained in your packet a resolution which was adopted by the San Gabriel Valley Council and governments of December 16 opposing the adoption and the numeric guidelines at this point in time.

And that was adopted by a vote of 27 to 0, 27 of our 30 cities were at, at that meeting, and participated. So it was a unanimous decision.

I would like to point out the details of our resolution that we are opposing the adoption of the numeric standards at this time until there can be an identification of the type of and quantity of pollutants generated by each of the types of developments that are called for in the scope of the regulation.

That the type and quantity of pollutants identified must pose a threat to and identify beneficial use consistent with the quirk, our water planning

requirements and that an evaluation of those structural controls required to meet numeric standards demonstrate the appropriateness of controlling each one of the target pollutants.

And finally, we'd like to see an out clause where there's an event that there's no feasible mitigation available that there would be available to basically do partial mitigation and otherwise opt out of any permanent requirements.

The council and governments was far more supportive of the original August 11 staff proposal for this permit, and we would suggest that you return back to that as probably the best balanced approach.

Finally, our board was sufficiently concerned that they feel that, unless there is a removal within numeric standards, that the council and governments intends to appeals the decision to the State Water Resources Board at the Water Control Board at the appropriate time.

Time is brief. I would like to go on record as saying that, as an elected official who's doing a very -- working very hard with his council and staff, I was very insulted with some of the remarks that were made earlier about the cities not taking the responsibility seriously.

We have evolved a system over a number of years. Based upon the fact that we are in the foothill area with very steep slopers that we look at hydrology.

We look at soil conditions. We do geotechnical reviews. We're in a seismically active area. We go all the way down to parcel maps and lot splits.

We conditioned a lot split on Monday night on the hydrology report. I think there are a number of cities in Los Angeles county, particularly those who are foothill communities, who are doing a very good job with this and have been doing a very good job with this.

And I think the assertion that we need to ratchet down with numeric standards is not well-founded. One other point. Because we are a foothill community, we have had catch basins and debris basins in our community since the 1930's.

I do not believe the low cost figures that were asserted by the advocates of this regulation. It is a major ongoing cost to clean these things out. Every time we have a fire or a major -- a major fire event or a major rain event, the basins have to be cleaned.

Los Angeles county maintains some of ours. We also maintain a couple of them as municipal catch basins. Our situation is that almost all of this water percolates into the east San Gabriel groundwater basin so we don't have a runoff problem. But it is an enormous ongoing expense.

It has reached the point where several years ago the county of Los Angeles has refused to accept operation and maintenance responsibilities for any more of these basins.

The other issue I would suggest you take a look at, which was not addressed previously, is the application of proposition 218 requiring a vote of the property owners under the assessments.

It's great to say, "Okay. The county won't be responsible. The city won't be responsible. We'll set up this other kind of assessment district." But what happens if the property owners don't agree to future assessments down the road for maintenance and repair? Thank you.

CHAIRMAN NAHAI: Okay. The three speakers after Mr. Alvarez will be Mr. Kennedy, Mr. Montevideo and Mr. Collacott.

MR. ALVAREZ: Good afternoon, Mr. Chairman, members of the board, my name is Desi Alvarez. And I chair the Los Angeles County Municipal Storm Water and Urban Runoff MPDES, executive advisory -- department of executive advisory committee.

And on behalf of the L.A. county permittees, I would like to point out the permittees did submit a SUSMP in accordance with the requirements of the permits to the executive officer for approval last year.

And we believe that the Regional Board needs to work with the permittees in developing an ultimate SUSMP. Since there are appreciable differences between the SUSMP model that was submitted by the permittees and the Regional Board, we have undertaken considerable discussions with Regional Board staff over

the last several months and the last few weeks almost speaking daily.

And we believe that a lot of the recommendations that were made today by your executive officer are very much in concert with some of the issues that we have raised regarding the December 8 version of the permit. However, we still believe that there are some other issues that we do have some differences.

I'd like to point out a couple of those. One of those is in the definition of environmentally sensitive areas. We believe, as the definition stands today, it is overly broad and that the definition needs to be consistent with the intent of the permit to provide special protection for areas of special biological significance.

And to meet this, we would suggest that you adopt language that basically states that the environmentally sensitive areas be defined as those that are joined, bisect or directly discharged to the significant ecological areas that's identified by Los Angeles county and any other areas of environmental significance as determined by municipalities.

The other portion of the permit where we have some significant difference is in the recommendation to implement design standards for treatment control BMPs.

And this specifically addresses itself to the requirement for a three quarter inch standard. We believe that this standard, as currently proposed, is

premature.

That there is a lot of issues that need to be worked out specifically when we talk about design of treatment facilities or flow-based, nonvolume-based. And the hydrology today is not there for the small scale events that represent the 85 percentile that we're trying to capture.

I do believe that we would be prepared to accept a alternative proposal. If you wish to consider this, that you implement a three-quarter inch volume standard for commercial development of 100,000 square feet and commercial development of 100,000 square feet only excluding all residential development in order to provide us for an opportunity to see how this works over the next 18 to 24 months.

If that is done, it should also be done in conjunction with a proposal that you will be hearing from SCAG later on. Thank you very much.

MR. KENNEDY: My name is Tom Kennedy. For a period of about six years between 1993 and 1999, a representative of the city of Vernon currently an operation's manager with the Olevenheim (phonetic) Municipal Water District of San Diego.

COURT REPORTER: Excuse me?

MR. KENNEDY: Olevenheim Municipal Water District. I was asked by the EAC to come here to speak about the chronology and the development of the SUSMPs. I was involved in that subcommittee and pretty much all

the other ones during the period of time.

However, before I proceed with that, I wanted to clarify there's been a number of references to the L.A. county program as being an example of a program that we should be following, and I just want to remind the board, as Dennis did, that a lot of the provisions in that were a result of the settlement agreement with the NRDC and not the result of a collaborative process or any sorts of scientific investigation.

Proceeding here, the staff reports suggests that the process outlined the permit be abandoned because of the implementation date of July 13, 1999 has passed. However, the lack of responsiveness by the Regional Board staff, because they're primarily understaffed, is the primary factor and delays that have gotten to this hearing at this late date.

The permittees have submitted every report and plan required by the permit on schedule. Specifically the model development planning program was submitted as required on January 29, 1998 in developing this model program. The permittees implemented a deliberate and open process to promote wide state over involvement.

R0072029

Multiple drafts were developed and circulated for comment --

COURT REPORTER: You have to slow down.

MR. KENNEDY: I'm sorry. I only have three

minutes. I'll slow down. Multiple drafts were developed and circulated --

COURT REPORTER: Sorry about that.

MR. KENNEDY: -- were developed and circulated for comment from permittees and interested parties. The permittees considered these comments in developing a program that they believe applies with all applicable state and federal regulations, the permit and which will be effective and implementable.

As has been the history of this program, Regional Board staff was sometimes less than timely in reviewing and commenting on and finally acting on the documents.

The permittees submitted a model development planning program to the Regional Board on January 29, 1998 by a letter dated April 10, 1998. The executive officer advised the permittees the program was deemed deficient.

The permittees submitted a revised program in August, 1998. Not until December 23, 1998, which is almost five months later, did the executive officer distribute the Regional Board's revision of the program to the permittees and other interested parties.

Finally, on February 11, 1999, the executive officer notified the permittees that the Regional Board staff's version of the model development planning program was approved.

And just in case I'm not able to finish, I

have a chronology (inaudible) that I can hand out for the record. While we're developing the SUSMPs, we were advised through comments received during the early planning that we should wait until after the BMP approval was done by the board.

And a comment received from -- I believe it was Heal the Bay, on April 15, 1999, it indicated that they were surprised to see the SUSMPs before the recommendation BMP list is approved by the board since the permit requires SUSMPs to incorporate the pertinent elements of BMP lists.

Heal the Bay recommends the county wait until the BMP list is approved by the board at the April meeting and then use finalized BMP lists to revise the SUSMPs accordingly, and that was one of the reasons we did wait.

And then as we finished the SUSMPs within a few week after that, I believe six weeks after that, even though we had six months to complete those. So the allegations of the staff report that we were not timely in submitting reports is unfounded. Thank you.

MR. MONTEVIDEO: Good afternoon, I guess it is now, ladies and gentlemen of the board. I appreciate your time today. My name is Richard Montevideo. I'm with the lawfirm of Rutan and Tucker.

R0072031

I'm here today on behalf of the executive advisory committee and the permittees under the permit. I want to start with a chant that I heard from the

videotape some three and a half years ago. The chant was "Pass the permit. Pass the permit. Pass the permit."

And in fact on July 15, 1996, this board passed the permit. It wasn't only a chant. It was the cause of that particular meeting. There's T-shirts that were passed out to this board, that were passed out to everyone, and they were passed out by the members of the environmental groups. You can see here pass the permit. Okay, what happened?

What happened was you passed the permit, and as you passed the permit, you imposed obligations on these permittees and more importantly, or just as importantly, you imposed obligations on yourself.

Those obligations do a number of things. But they -- with respect to the permittees, they require the permittees to submit certain programs, model program, the proposed plan right now, they have gone ahead and submitted that program that that particular plan is before you now.

Unfortunately, your focus today is not on the program that was submitted by the permittees as it is required to be by law. There is a specific administrative review process that is set forth in the permit that you passed.

Second slide, please. R0072032

This process requires that you focus on the program that was submitted by the permittees. This process is an administrative review process in effect due

process both to yourself and to members -- the permittees under this permit.

If you review the purpose, I took this directly out of the permit itself, and I've passed out copies to you. The administrative review process formalizes the procedure for review and acceptance of reports and documents submitted to the Regional Board under this order.

In addition, it provides a method to resolve any difference in compliance expectations between the Regional Board and permittees prior to initiating enforcement action. It provides a method to resolve and difference in compliance expectations.

These permittees have proceeded to propose a SUSMP program of their own. You have adopted a permit that gives them the mechanism to do that. You have adopted a permit that provides a process. What we're asking is that you follow the process.

R0072033

Next slide, please.

Very succinctly, the process is detailed in the permit, and you have the pages of the program that -- of the permit itself that lay out this program.

The executive officer has 120 days. If he doesn't like what he sees, he sends out a notice of intent to meet and confer. There are other portions of this process that is supposed to be followed.

We ask that you follow this process in your own permit. That's the whole purpose of setting forth

the process. If you do not -- next slide, please.

According to your own permit, again, this is on the second page of what I passed out. "The executive officer shall not take enforcement action against a permittee until the executive officer has notified the permittee in writing that the administrative review process has been exhausted, is that the executive officer has determined that a violation exists warranting enforcement."

We have not seen anything in terms of following this process. There has been no notice intent to meet and confer. There's been no determination within the first 120 days. All we ask is that you follow the process. All we ask is that you follow the permit that you passed.

CHAIRMAN NAHAI: Thank you very much. Following Mr. Collacott, we have Mr. Neil Miller and Mr. Tony Nisitch, I believe.

MR. COLLACOTT: Good afternoon. My name is Bob Collacott. I'm with the consulting firm of URSC Woodward-Clyde. I'm speaking here today on behalf of EAC. I'm speaking regarding the issue of the numerical design standards or numerical litigation standards.

The permittees, as was noted in the opening remarks, do not oppose the development of storm water treatment design standards for new development. In fact your permit number 96-054 prescribes a deliberate process for development of the storm water design standards.

So let's review what that process is. The first step is the development of a model program for storm water management development and planning, and that's noted on the provisions in the first part of your handout.

The SUSMP, which is intended to provide guidance in the implementation of the model program was submitted to your board in July of 1999 and amended later to address the Regional Board comments in August of 1999.

The second step in the process is the development of the integrated receiving water impacts report. And again, on -- if you look back to what is page -- a copy of page 65 of the permit, it states that the principal permittee shall, not later than July 21 of 2000, prepare and submit an integrated receiving waters impacts report.

The report shall include but not be limited to a comprehensive analysis of the results of the different monitoring data and feasible environmental indicators. It should also include recommendations on future monitoring requirements such as integration and storm water receiving water monitoring and regional receiving water monitoring if applicable. The report will be an integral part of the report waste discharge.

In other words, this report will identify in terms to receiving waters and pollutants of concern.

The staff report is premature in attempting to preempt this report which will be submitted to the

Regional Board by the permittees on July 31. The third step in this process is a component of the program evaluation report. And again, that's on page 65 of the permit. And it's highlighted on your handout.

And it states that the principal permittee shall not later than February 1st of 2001 submit a report on the identification of SUSMP components for which the performance standards will be developed and implemented during the next term of the permit.

The report shall include a schedule of development of performance standards. The performance standards will indicate the level of implementation necessary to demonstrate that efforts are being made to reduce the discharge of pollutants in storm water to the maximum extent practicable. This report will be an amicable part of the report of waste discharge."

The identification of needed performance standards will be based in part on the integrated receiving waters impacts report. Hereto, the staff report attempts to preempt the permit and report waste discharges.

The fourth step in the process is the development and implementation of the design standards criteria that will be necessary to achieve performance standards.

R0072036

It is expected that the Municipal Storm Water Permit to be issued in 2001 will describe more thoroughly the process by which the identified

performance standards and the supporting design standards or criteria will be developed.

It is clear that the permit provided a process for the development of performance standards and design criteria. It is also very clear that the permit contemplated that effort would occur "during the next permit period."

The staff recommendation attempts to circumvent the process provided by the permit and denies the opportunity for stakeholder involvement, the staff report any environmental community cites several areas nationwide that have developed storm water design standards for new development.

Where design standards have been implemented, public agencies have implemented a careful process similar to that described in the permit. In addition, they have facilitated wide stakeholder involvement in developing those standards.

On the last page of your handout, I've put a summary of my survey, and in every instance you will find that there has been wide stakeholder involvement, and it's taken some time. But anyway, in no case and each case the development of design standards --

CHAIRMAN NAHAI: Can you wrap up?

MR. COLLACOTT: Pardon?

CHAIRMAN NAHAI: Can you wrap up?

MR. COLLACOTT: In conclusion, I'd like to present another option to the board in terms of handling

R0072037

this option and that is basically to follow the process that's identified in the permit for the development and design standards. Thank you.

CHAIRMAN NAHAI: Thank you very much.

MR. MILLER: Mr. Chairman, members of the board, my name is Neil Miller. I'm the Public Works director with the city of Manhattan Beach, also a member of the EAC for the permittees here just to speak about a couple of other issues.

Those of us that are on the firing line of regulation at the local level do need very clear guidelines and information for the development community.

What seems to be missing to many of us is that clear relationship between the cost which is then -- have been examples of cost up on the board and the benefit.

In the past, the negotiations with the environmental community and with board staff, there's been a lot of discussion about the distinction of watersheds and how one's unique from another. And there are now lots of opportunities to test some of those presumptions.

R0072038

The county has their program, and Santa Monica and others have been stated as following up on what our chairman, Desi Alvarez said. We would propose to use those examples to get clear data that our building community will understand it that we can go in with a clear message and say, "Here's what these improvements

will do. This is how it will help the receiving waters." And we'll have clear examples.

There were no examples put up there. There was no examples in the permit of what the construction of these improvements will do in terms of benefit, in terms of the quality. We'd like to have that.

That will help us then go forward with the programs that we basically all want to do, but it's a matter of doing them at the right time or the program will fail.

Another issue is in maintenance, the cost of maintenance and inspections that will be required from the permit. It was mentioned earlier about proposition 218. Manhattan Beach is lucky enough to have a storm water utility.

We created it. It's a funding utility where there's an assessment on the parcels to pay for storm drain maintenance and storm drain programs. However, that was done before prop 218.

If there is a considerable amount of inspection, if this gets down to the single-family level, we will not have a methodology from that funding source to do the inspections necessary.

Of course you could say, "Well, you could look at other" -- you know, "reprioritizing your budget," and that will be a difficult thing for our council to struggle with.

R0072039

And I just want you to know that's a

constraint, and we would definitely support the high priority categories that have been presented with the exception of the numerical standards until we have the data from the programs that are in place now and following the process of the permit. Thank you very much.

CHAIRMAN NAHAI: Thank you, Mr. Neil.

MR. NISITCH: Good morning. I guess it's good afternoon. My name is Tony Nisitch. I'm the director of Transportation Engineering Services for the city of Santa Clarita, a town about 35 miles north of here. I say that because a lot of people don't know where it is. But we are a very rapidly growing area of the county.

I'd like to wrap up, I think, our part of the presentation as distinctly as I can. If you know me, that's very difficult for me to do. But what I've heard today and I've heard throughout this process is that these regulations are complex and difficult to understand.

I'll submit to you now that what I heard and what I think you heard is I don't believe that all of us in this room, number 1, understand what the proposal is that's on the table. We don't understand what it says. Further, we don't understand what it means because we don't understand the application, whether it's commercial. Is this water? Commercial? Is this water?

I think we also don't know, therefore, what

it does. In other words, will be effective in doing whatever we want to do. I think those things are before you. I don't think we have the answers to those questions. I don't think you've heard any testimony today that would counteract that.

I think there was so much confusion what we're saying, I think it's necessary to take time to develop those proposals, and I think there's time to do that. What we said is we think we need to follow the process spelled out in the permit all along.

We think, if you do that, you're more likely to hit the goal we're aiming at, and we believe that's to clean up the storm water. Something that we all share.

Another issue that I think that hasn't been talked about but I think needs to be talked about is storm water quality is but one component of the overall development process in the design, construction and maintenance of development projects that are literally millions of conditions that are considered, issued and things talked about.

I don't know of anybody -- I don't know of any reports done by anybody that would support the fact that the development process is already too simple and should in fact be lengthened and made more complex.

That goes to the point that I'm talking about whether or not we should impose these standards or we talk about waiver or we talk about flexibility,

administratively at the local level of the enforcement is taking place.

That's entirely -- it's very critical and so critical that I propose that the failure to adequately address that issue will be the downfall of these standards.

Finally, I'd just like to say we believe that there are alternative proposals that will be both more effective and more appropriate to meet the goals of the executive director on this board, and we believe you ought to take the time necessary to implement those. Thank you.

CHAIRMAN NAHAI: Thank you very much. That concludes that half-hour segment as far as speakers are concerned. We can go to board questions of the speakers that just made presentations.

MS. LYON: Yes. I think I'd like to have Mr. Desi Alvarez come back up. I believe you got cut off before you could entirely explain your alternate plan --

CHAIRMAN NAHAI: He wasn't cut off. His time was up.

MR. ALVAREZ: I was just being polite and respectful to the time limit.

MS. LYON: I was just a little bit curious if you could explain that a little bit more, please.

MR. ALVAREZ: At the last meeting of the EAC, we talked very much in depth, as we have, over and over every time we've met regarding the imposition of a

numerical design standard and the permit.

And one of the ideas that was kicked around was that there are agencies out there that are doing this already, and a lot of people are working their way through a lot of issues.

But if we had to look at a design standard now, could we live with any option. And one of the options that we did consider was that the design standard be applied to commercial development of 100,000 square feet or more and only commercial development of 100,000 square feet or more.

That would exclude all residential development whether it be subdivisions or condominium and apartment complexes and develops 100,000 square foot parcels or larger. The reason for that is because there's more control, we believe, in terms of maintenance of BMPs with commercial development.

The commercial developers tend to be a higher value type of development where the impact of the cost of implementing this requirement would be a smaller percentage of the overall costs and since we believe that a lot of this would be experimental in nature because there are a lot of issues to be worked out.

And it is not as easy as just say, "Just do it." Everytime somebody does it, they jump through all kinds of machinations to make something work short of retaining that three quarter inches on-site.

Because any treatment facilities require

many assumptions, and they're not going to be consistent and are not consistently being applied today, and that results with BMPs that may or may not work properly.

And I will give you one example. One of the issues -- or one of the treatment processes that was brought up earlier was the implementation of oil, water separators. I think somebody mentioned that.

Now, a water separator would be a very good type of treatment facility particularly targeting oil, grease and the type of stuff that's coming off of surface vehicular access type of areas.

Those are sized. As currently designed, you would end up jumping through several hoops to get from a three quarter inch to some kind of flow-base standard. If that's put in place and you get a large storm event and the flow is significantly larger, what will happen, it will just create a siphon condition in some of these oil, water separators and flush out all the sludge and everything else that the oil water separator is retaining.

And that's a very real issue. So there are a lot of design standards that do need to be developed. We would think that we just work with commercial developers in the next 18 to 24 months. It would afford an opportunity to flush out some of these issues.

We also put that in with the caveat that it go in conjunction with the proposal from SCAG. Basically there would be significant monitoring of how this is

working, and that monitoring goes to all of the design issues and implementation issues as well as cost issues that SCAG would also be available to make resources from the 208 program to provide for additional studies that would be required.

And that's a source of funding. Funding for a lot of this stuff has been very difficult to come by. We just haven't had the funds. A lot of people here will say, "We've been doing this for ten years." And it's true that ten years ago, actually probably 11 plus years ago now that we're in the year 2000, there was this regional discussion to talk about a storm water permit, and a lot of things that probably should have happened have not occurred because of lack of funding.

MS. LYON: I guess I should ask the chairman. When will we be hearing from SCAG?

CHAIRMAN NAHAI: Whenever they want to speak to us.

MS. LYON: So that would be during the general comments later?

MR. ALVAREZ: I'm not quite sure. We had submitted a list of names, and maybe our card didn't get in. But they could speak later. I believe they have a card in. Mr. Pisano is here from SCAG, and he was going to talk about their proposal.

CHAIRMAN NAHAI: I anticipate that that will take place when we come back from lunch?

MR. MONTEVIDEO: If there aren't any other

questions, I would like to follow up on what Mr. Alvarez had to say in response to this line of questioning --

COURT REPORTER: What is your name again?

MR. MONTEVIDEO: Richard Montevideo. I'm sorry. The importance of the permittees submitting a program under the existing permit is critical for this board because, if I submit you a program for purposes of the L.A. county, you can't approve that.

If the NRDC or Heal the Bay or somebody else submits a program for all of Los Angeles county, you can't approve that. Even if your own Regional Board submits a program for Los Angeles county, you can't approve that.

The permit identifies a very specific process. The process is that these permittees have to submit the program. The action that you're taking today is not on these permittees proposed program.

It's supposed to be on whether their program reduces pollutants to the maximum extent practicable. That's the charge of your executive officer.

If that charge is not followed, that means he hasn't complied with the review process. These permittees then just move forward under the program that they submitted, if there is no response that process.

I guess my point is that taking the actions being proposed, legally that you're proposing to take today or may take today, legally has absolutely no

effect. Because at the end of the day, the process that was outlined in the permit that you adopted in 1996 is a process that has to be followed.

It was proposed after much discussion, 18 months of negotiations, and it's very important that that process be followed. Otherwise whatever you do today is irrelevant. And at the end of the day, these permittees are still going to have to go through their program with Mr. Dickerson and staff and get that program resolved.

CHAIRMAN NAHAI: Thank you. We will seek our counsel's response to your contentions. Ms. Cloke?

MS. CLOKE: Mr. Doyle. Is Mr. Doyle still here? Do I have the right name? From Sierra Madre. Has he left?

MR. ALVAREZ: You have the right name. He may have had to leave.

MS. CLOKE: I see. Okay. Anybody representing a hillside community who's spoken to us in the last segment of the program.

MR. ALVAREZ: Mr. Nisitch from Santa Clarita, I think, would qualify as hillside community.

MS. CLOKE: I wanted to ask you if you would look at the definition of hillside that is in the proposed plan.

MR. NISITCH: The one -- December 7 proposal?

R0072047

MS. CLOKE: The one that has the --

CHAIRMAN NAHAI: You would have to look at

the December 7 together with the change sheet.

MR. NISITCH: It's --

MS. CLOKE: It's erosive soil conditions, grading of any natural slope that is 25 percent or greater, and there was also a condition in a previous iteration about cut and fill over 30 feet.

And I wanted to ask you is this -- does this capture -- if this were enacted, how much of your community would be involved in a standard like that?

MR. NISITCH: Let me first state that from a slope point of view quite a bit. We have -- our city is very hilly. And it's kind of a group of hills. And one of the things that the developers do is level those hills and -- to get away from that requirement. Large -- I would say perhaps maybe 50 percent of our community have looked at it in total because it would meet this definition.

R0072048

MS. CLOKE: And is that residential community or other kinds of construction?

MR. NISITCH: It's both residential and probably industrial. We have those kinds of facilities that want to locate in those areas.

MS. CLOKE: Okay. And my second question to you is when -- when these -- if this plan is approved and the commensurate city ordinances are enacted, then would it be reasonable to assume that your own building and safety department, when they go out anyway to a construction site to go through their checklist, would be

also going through this -- this would also be part of their checklist, or do you envision that this would be a separate implementation and permitting process?

MR. NISITCH: I think the answer to that question, we prefer that it be just that, another item on their existing checklist as opposed to a different item with a different person.

Those of us that looked at combination inspectors as opposed to one inspector or, you know, have a inspector as opposed to four or five that, you know, just on resource basis to go out and try to develop a standard that is so difficult you need a specialist to go do it.

Not only is it more expensive for us to administer if we find the simply -- if we need four or five people to explain it to a builder, the builder needs four or five hundred other people to figure out what it means too.

MS. CLOKE: I prefer for the building and safety implementation myself. I think that's the easiest for everybody. Thank you, sir.

CHAIRMAN NAHAI: Any other questions? I had a question for Mr. Miller, if he's still here and then -- Mr. Miller, this was my question to you. Since you represent Manhattan Beach, and in your presentation, you spoke about, you know, possible costs to builders within the city and so forth.

R0072049

And I wondered, though, in that equation,

have we stopped to think what the cost would be to the coastal economy which is so important to your city if we don't at some time, you know, move forward to deal with urban runoff pollutions --

MR. MILLER: Yes, I have --

CHAIRMAN NAHAI: -- or do you think that it doesn't affect your city at all?

MR. MILLER: No. That's not what I'm saying. It does affect our city obviously. We are a coastal community. And I think what we're saying is, though, at this point we don't have a clear picture to take to the developers, especially the smaller developers as to your $10,000 or $15,000 or $20,000 investment is going to help to what degree as far as the pollution of the ocean or the beaches right in front of you.

We haven't implemented many of the BMPs. We have gone farther than the permit requires in our local community in areas that we know where it's effective.

But just to have a broad numerical standard without that connection I think will be very difficult to implement and sell to that community -- to the development community.

R0072050

If I could just follow up, that is the reason we would like to see the results of that work that's in place now so that we'll have that.

CHAIRMAN NAHAI: Thank you. I appreciate it. Would you address Mr. Montevideo's concerns about

legal -- is this an administrative review process that we're undergoing at this time?

MR. LEON: I think it does qualify under the provisions of the permit that Mr. Montevideo has cited. And I had an opportunity to review the comments that Mr. Montevideo made, he has made previously along with some of the comments from the EAC.

And there is a response to the argument in the material that's designated the staff report reportive decision. In summary, Mr. Nahai, it's very important to recall that, despite the fact that the provisions as Mr. Montevideo has stated them to be, it's certainly -- it's an accurate portrayal of what's in the permit.

That those provisions are no longer meaningful given the fact that we've moved a long way from where we were in 1996 when the provisions were first promulgated. It's very important that the deadline for the implementation of the SUSMPs has expired. That was July 30 of 1999.

R0072051

The board can, in my view, view the provisions of the permit as now being expired and no longer meaningful in light of several practical consideration, and considerations that have to do with the impacts on the parties.

I think that the reason for the provisions having to do with the administrative review process was to protect the parties, the permittees, from having to be

unilaterally told to do at that stage of the process.

However, we've gotten to a point now where there has been lots of exchange of information between the staff. There's been lots of exchange of proposals. As I think even you, during the opening of the hearing, noted that the parties have had ample opportunity to review the previous proposals to comment on those proposals, and the staff has been responsive.

We're charged by the other side, not the EAC but the environmentalist with giving them too much because the changes to the drafts have been so extensive.

And so we're at a point where we have to decide is there any real prejudice to the parties? I think there isn't because of the fact that there's been so much exchange of information and opportunity to comment.

R0072052

Well, Mr. Montevideo said there wasn't any real meet and confer. Effectively there was. There has been, as you know, many meetings held between staff and EAC representatives and permittees.

In fact, I don't think that Mr. Montevideo or the EAC can actually cite -- certainly they haven't yet -- any real prejudice to the parties as a result of the process.

It's true, if I had my druthers, I'd rather stick to the process because it's so clean. It fits neatly into the permit requirements. But I think it's also within your discretion, given the actual facts, the

actual history, the actual process, the actual communications and the exchange of information that the board has some discretion here.

I don't think it needs to be blindly told we're going to ask you to delay for delay's sake. And that's what's happening.

CHAIRMAN NAHAI: If I understood you correctly, you're saying that to the extent the permit contemplated a process of communication back and forth of submittals of review of those submittals and comments on them, that that has taken place already over a long time with many, many communications.

MR. LEON: I think it has.

CHAIRMAN NAHAI: So that really the intent and perhaps the actual letter of that requirement has already been satisfied even though there may not be a document that says this is a meet and confer letter. But that that's not necessary because those discussions and exchanges have already taken place.

If I also hear you correctly, you're saying that in any event, now with the situation that the deadline for the finalization of the SUSMP has already passed and that that process was never intended to be one in which one side could interminably delay the process by saying or reaching the conclusion by saying here's one draft. Here's another draft and going on in that way. Is that --

MR. LEON: Absolutely.

UNIDENTIFIED: May I respond to that, Mr. Chair, just very briefly.

CHAIRMAN NAHAI: Do you absolutely have to?

UNIDENTIFIED: Well, one point because it is a very important point. What we're talking about here is a due process requirement that was specifically negotiated and included in this permit.

Now, it's one thing to say we can dispense with due process if it in effect has been complied with. But here it hasn't been complied with. There have been delays. Yes. There have been delays, but those delays, as you heard from this presentation today, were the delays primarily on the Regional Board staff, not on the part of the permittees.

So the delays you can't -- you rely upon a delay on your own part to say let's dispense with due process as provided in the permit itself. Secondly and more importantly, no prejudice, no prejudice. The permit is a specific process that has to be followed.

The process says look at what these folks have submitted to you. You have completely ignored that process. The slide that I had showed you that goes through 120 days, the meet and confer process, is a process that's designed to look at what the permittees had submitted to you and to resolve those problems beforehand, not to look at what the board is trying to mandate on these permittees. **R0072054**

Even now today we're still getting changes.

We don't even -- it's a moving target. It's your moving target. It's supposed to be -- if it's going to be a moving target, it's supposed to be our moving target.

The prejudice is that you've completely ignored the fact that it's our program that you're supposed to be focusing on, not the Regional Board's program, and you're supposed to be giving us time, not on the last day here, looking at changes. But give us time in advance to review the changes to work out the problems with our program.

CHAIRMAN NAHAI: Thank you. Any other questions?

MR. ALVAREZ: If there are no other questions, first I would like to thank the board for this opportunity. And secondly, I'd like to ask for the indulgence. There are two individuals who have been here all morning. They have to leave this afternoon. And one is Mr. Pisano, and the other one is Mr. Bruce Barrows, who's the vice chair of the Gateway Cities COG.

They would like to speak. If you could allow them to maybe come up and use their three minutes at this point, I think they would appreciate that.

UNIDENTIFIED: Mr. Chairman, there are others who have been sitting here all morning --

CHAIRMAN NAHAI: Well --

R0072055

COURT REPORTER: Wait --

UNIDENTIFIED: -- and I was told we would speak in the order in which we presented our cards. And

I think that's fair enough.

CHAIRMAN NAHAI: That's what we've arranged. Does it really matter if we allow a speaker to go beforehand?

MR. ALVAREZ: The last issue, if it makes a difference, we only had nine speakers --

CHAIRMAN NAHAI: I know. But I'm going to -- with due respect, I'm going to decline. We've decided to not grant any favorable treatment to anybody.

MR. ALVAREZ: Thank you, by the way, for your time.

CHAIRMAN NAHAI: Thank you so much. All right. Well, in that case then we will break for lunch, and we'll see you here -- what time will we see everyone?

We'll see everybody back here at 2:00.

(Lunch break.)

Staff response to comments	276
Board discussion/motion/vote	293

CHAIRMAN NAHAI: Ladies and gentlemen, please, take your seats and we'll resume. I'd like to start again, please. Please sit down.

Okay. We're going to just go forward now and allocate three minutes to each speaker. You can see the number of cards I have here. So in order to get through this, it's just so important that you limit yourselves to three minutes, please.

To start off, I'd like to call on Miss Alexis Strauss, EPA, please.

MS. STRAUSS: Good afternoon, Chairman Nahai and board members. My name is Alexis Straus. I'm the director of EPA's Water Division. Thank you for your patience in working through this issue with so many comments.

I would like to urge, as we did in our correspondence, the board's adoption of this modest proposal. I think it's very timely that this action take place now, given the overall lack of progress, I'm afraid, in implementing the permit since its adoption. Perhaps it was unavoidable that a great deal of planning discussions needed to occur, but I am willfully concerned that we lack the necessary impetus in moving from the planning stage to the implementation stage.

As I look ahead -- instead of focusing on this dilemma before you today, as I look ahead over the next ten years, we will be going through both storm

water and discharge permits two more cycles of, let's say, five-year permit terms a piece, and in each of those two cycles ahead, we need to make substantial progress.

I feel that we have not made much progress in this permit term, and we were very intricately involved in how this permit came to be established and what its terms are. And I am very concerned that here we are more than halfway through this particular permit with very little in terms of water quality protection to show for it.

But I don't mean to indicate any disrespect for the cities involved because it is a very large task, but what is before you today I think is, in fact, a very modest proposal. I think it is critical to act now to enact this particular proposal.

Although, I would favor removing some of the exemptions, for two larger reasons I think the board needs to act. One, we significantly lack adequate staffing for the Storm Water Program throughout the State of California and, in particular, in this Regional Board. This board cannot afford to have its staff spending six-plus months on this particular topic and nothing happening on all of the other aspects of the Storm Water Program, let alone the backlog in NPDES permits and all of the other aspects of the water protection programs.

I am worried that we are going to get

bogged down procedurally in this permit and that everything is not happening. There is not a sufficient field presence. There are many other requirements in the Storm Water Program that are not being met.

I think the proposal needs to be simple, and it needs to be understandable. Any of us at any level of government, a public person should be able to pick this proposal up and be able to understand the obligations they're under. And for that reason, I favor removing some of the exemptions that have been proposed, such as the rooftop exemption.

My second concern, other than are we adequately carrying out the Storm Water Program together, is that over the next ten years the Regional Board, many different parties in this room and we at EPA, will be engaged in studying the polluted waterways in this basin, looking at their sources of pollution and trying to analyze where we should allocate that pollution load, and as you understand, I'm talking about TMDLs.

The requisite steps before us are to begin to address the problems that we're having in meeting the beneficial uses, and I see today's proposal as beginning to address storm water as critical in snatching the low hanging fruit, as it were, in doing the simpler, readily available design standards for new development as a start toward what will undoubtedly be far more painful at future board meetings five and ten

years down the line as we start talking about far more stringent limits in storm water permits and far more unpalatable than the kind of proposal that is before you today.

So I think it is vital that we begin now to take these very modest steps by adopting a design standard. We're not adopting effluent limits. Then I would expect the whole room would be up in arms, but we're just looking at a design standard and the associated BMPs.

We spent six months in this dialogue. There's very little else happening on the ground at this point. I'd like to seize this opportunity to meaningfully move forward. This is but a prelude to far more difficult measures that we will be considering later. We are needing to reverse the rapid deterioration that we've witnessed in the basin's waterways in our lifetime. Thank you.

CHAIRMAN NAHAI: Does anybody have any questions?

The next card I have -- let me call out -- I'm going to call out three people as we go. Next card will be for Mr. Craig Perkins, followed by Miss Sandy Brown and followed by Miss Eileen Ansari.

MR. PERKINS: Good afternoon, members of the board. And for you new members, I'm sure that this is a good time to be added to the board and make what are going to be challenging decisions for the future of

the basin.

The first thing I'd like to do is indicate that last night at their council meeting, our city council adopted a resolution in support of the strongest possible standard. And just to relay a couple of the findings from that resolution, our council believes that a numerical standard which includes all portion of new development, including roof areas and surface parking lots, is necessary in the plans to ensure their effectiveness.

Our council also believes that up-front amounts spent on BMPs is a small percentage of total construction cost with region-wide benefits. And, thirdly, each new development project must become a part of the urban runoff solution as opposed to continuing to be a part of a growing problem.

In simple terms, the city council opposes the proposed amendments which would weaken the original draft of the standards and supports numerical -- the numerical standard as presented in the August draft, the pre-December 7th draft.

Really what it comes down to is us choosing whether we are going to continue to stay behind the curve or pledge at this point to move forward and be ahead of the curve. The bottom line where the rubber meets the road, literally speaking, is reversing over a century of standard engineering practice, which is focused on moving storm water off a

parcel as quickly as possible, essentially out of sight, out of mind. That is the concept.

And instead adopting a standard which results in stewardship of the watershed at the individual parcel level and protection and restoration of that watershed for the future. It's the only approach which makes sense. We really do truly care about water quality within this basin for the receiving waters.

My city council and I urge you to be leaders and to be visionaries to resist the temptation and to drift towards the lowest common denominator and the path of least resistance. If you do the right thing, I believe truly that a marvelous thing will occur. And what that is, is that my colleagues and peers in the design development of public works communities will use their intelligence and imagination, which is immense, to turn the past on its head and create a watershed responsible model for new development that the region so desperately needs. You're the people who can blaze that trail, and I thank you for this opportunity to speak today.

CHAIRMAN NAHAI: Thank you. Any questions?

Mr. Perkins, I had a question to ask you before you go. Any questions? I wanted to ask you, the city of Santa Monica has had a numerical limit as part of its regime now for how long?

R0072066

MR. PERKINS: For about six years, five to six years it's been in place.

CHAIRMAN NAHAI: And what numeric limit is it?

MR. PERKINS: The requirement of our municipal ordinance is that the runoff for each parcel must be reduced by 20 percent over what the average runoff factor would be for that type and size of parcel. It also has a specific requirement for parking lots, which require the retention of 1 inch within a 24-hour period. Surface parking lots.

CHAIRMAN NAHAI: And how is -- over the last six years, how has this ordinance affected the rate of development within the city?

MR. PERKINS: It has not affected the rate of development at all. And, in fact, I think that all of us recognize that Santa Monica is one of the most intensely attractive communities in terms of new development that's been occurring in the region, particularly commercial development, and, in fact, over the last five or six years, that has exploded as opposed to being reduced in any fashion.

CHAIRMAN NAHAI: What has been the rate of development companies that have failed within the city financially as a result of the ordinance?

MR. PERKINS: That would be zero to none.

CHAIRMAN NAHAI: Miss Cloke.

MS. CLOKE: Mr. Perkins, one of the

issues before this board is the question of discretionary permits, you know, commercial developments, everything that is going to be included in the scope of this permit. Can you describe for us what's included in the scope of the Santa Monica ordinance, and, if I remember correctly, it starts with single-family homes and goes up, but I don't think there are any exclusions. So if you could speak to those issues and how in your six-year experience which makes you a leader in this, how that's worked?

MR. PERKINS: Okay. Our ordinance has no exclusions whatsoever. All new development must comply with the ordinance, whether it be single family or a large commercial office building and everything in between, including all public projects, including school district and federal and state projects.

However, the problem we have had with those categories is that since they come under the Office of the State Architect for their approvals, they don't technically come through our building permit process. And so since we don't have that permitting rule, what we've done with the school district is tried to form a collaborative, cooperative relationship to encourage them to abide by the ordinance even though, technically, they could probably use that loophole to not comply, and we've been effective in doing that in some of their new construction.

R0072068

It's interesting to hear some of the

previous speakers talk about single family as an area where perhaps there should be an exclusion. It shouldn't be covered. Well, in our experience, single family is the easiest in terms of the compliance with the runoff reduction requirements. There are more opportunities. By definition, there's more open space on that type of project, and that's the most cost effective place to start if you really need to start somewhere.

So our ordinance currently is all comprehensive. There are no exclusions. The main difficulty has been in those commercial areas of the city where the development is lot line to lot line with subterranean parking. We have in those cases attempted to creatively identify BMPs which can be implemented off-site but adjacent to those projects through things like catch basin inserts, diverting water to tree wells on city sidewalks.

We're currently looking at a project where we may open up a portion of the alley behind the project for the -- increase the permeability and direct some of their rain gutters to those portions of the public right of way. So there are situations where it's very difficult, and so there needs to be a creative and imaginative look of what opportunities there may be and how to implement them.

R0072069

MS. CLOKE: Do you have a waiver system?

MR. PERKINS: There is a waiver system as

a part of the ordinance. The way it's stated is if it could be shown to be technically or financially infeasible to do the -- to comply with the ordinance, then a waiver can be requested for a full or partial waiver.

In the five or six years since I have been there that whole time and have been personally responsible for any of those waiver requests, there have been less than ten which have been granted and probably one in the last two years because as we have moved forward and gained experience and as the design community has increased their awareness and the level of technology has become enhanced, there are more and more ways available to comply. And so we feel that the waiver process, if there's some flexibility, is not really something that we have to exercise at this point.

MS. CLOKE: One final question. This is all new construction. What do you do on your end with supplies to all new construction? What do you do with remodeling and, you know, small additions and so on?

MR. PERKINS: In Santa Monica, we define "new construction" as any project which involves a 50 percent or more change to the building structure, and so that would be -- a substantial remodel would be covered by this ordinance. Anything less than a 50 percent change would not be covered at this point in time.

MS. CLOKE: And an addition?

MR. PERKINS: Yes. Yes. On a single-family home, it would have to be an addition which increased the square footage by more than 50 percent of what had been there before.

MS. DIAMOND: And just to follow up on that, on any redevelopment that has 50 percent or more, they have to then go back and they have to basically put in BMPs that affect the entire project; is that correct?

MR. PERKINS: That's correct. The entire parcel that's being developed, yes.

MS. DIAMOND: Thanks.

MS. LYON: One quick question, and do you -- do you charge in-lieu fees for any of that?

MR. PERKINS: We do not currently have an in-lieu fee provision. As a matter of fact, in the fall of last year, we identified to our city council what we believed was a need to implement an in-lieu fee for some of the very difficult parcels. That has been on hold essentially waiting for this board to make its final decision because that will in essence tell us how we need to move forward in terms of the revisions to our municipal ordinance. **R0072071**

The in-lieu fee we would only collect as a last resort if our council does, in fact, adopt that. We believe that it would be a better approach to have the developers do off-site improvements with BMPs and

catch basins or other sorts of off-site locations where a specific structural improvement can be made as opposed to -- we wouldn't want to collect money which we then have to administer and track and cause a lot of administrative problems. But we would like to have the structural BMP implemented as adjacent to the new project as possible.

CHAIRMAN NAHAI: Thank you very much.

Sandy Brown.

MS. BROWN: Good afternoon, Chairman Nahai, board members, Mr. Dickerson. I am Sandy Brown, Deputy Chief of Staff for Senator Tom Hayden, and I have a letter to read from the senator.

"Dear members of the board, if not for my commitments in Sacramento, I would appear before the Regional Water Quality Control Board today to voice my strong support for a standard that ensures meaningful reduction of urban runoff. It is time for this board to commit to solving the No. 1 source of pollution to our coastal and inland waters.

"If left untreated, runoff will continue to adversely affect millions of people and aquatic life throughout the Los Angeles region. Any minimal effort which does not ensure 100 percent mitigation of the runoff generated by no greater than a three-quarter inch storm will be nothing more than a weak step in the right direction. It is not a solution. All specified new and redevelopments must ensure such mitigation

through treatment or infiltration with no exception.

"Unfortunately, the cementation of Los Angeles enjoys wide support among the downtown power brokers, so it should be no surprise that structures including new and redevelopment parking lots, industrial sites, automotive repair garages and gas stations have become L.A.'s collection pits for pollutants.

"The storms carrying contaminated sediments to the streams, rivers and coastal waters will continue. The resultant pollution must be reduced and eventually disappear.

"Your adoption of reasonable design standards and best management practices as specified new and redevelopment is cost effective and ensures mitigation. Developers will appreciate that there are no surprises, no hidden costs when it comes to pollution prevention.

"Research indicates that 85 percent of the storms that hit the Los Angeles region dump no more than three-quarter inches of rain in a 24-hour period. The L.A. Regional Water Quality Control Board has the ability to dramatically reduce untreated storm water runoff. I hope the board will act responsibly and support a strong plan without amendments.

"Sincerely, Senator Tom Hayden."

And he is Chairman of the Senate Natural Resources Committee. Thank you.

CHAIRMAN NAHAI: Thank you.

Eileen Ansari.

MS. ANSARI: Chairman Nahai, board members, Regional Director Dennis Dickerson and staff, my name is Eileen Ansari, Mayor Pro Tem of the City of Diamond Bar and Regional Council Member for SCAG.

I stand before you from a city of 58,350 people that's an inland city, a hillside city that started being developed in 1962 and became a city ten years ago. We have a staff of 32 people. We're a contract city. We're cost effective.

One of the issues that we have -- that we continue to have is the cost of permitting. We want clean water. But I have -- as an elected official, I have to be responsible for my city, and I have to talk about for other cities also.

I wear two hats. I come to you for Diamond Bar city as an "environmentalist," quote, that started a group called "Save Tonner Canyon," concerned about runoff into canyons, and we were able to work with the builders so that we would have -- we would have collecting basins, catch basins and tried to work with builders, and we have been able to have a working relationship with builders in our city. Not always happy about things but trying to reach a compromise.

I wish to speak to you about trust. I and other members of the city council and city staff feel that the Regional Board staff is not honoring its

own permit, and here's why: Staff had revised this SUSMP issued by this Regional Board staff on December 7th of 1999 to include two requirements that the principal permittee and other permittees did not propose in its initial SUSMP submittal on July 22, 1999.

The first requires permittees to impose on new developments mandatory retention treatment controls. Nothing in the municipal permit that you adopted in June of 1999 or in the Model Development Planning Program that you adopted last year even remotely suggests that cities are supposed to impose mandatory retention treatment controls on the seven categories of new development that are now specified in the permit.

The second would require to increase the number of developmental projects requiring SUSMPs from seven to nine types. This is totally unjustified. On page 34, the permit says that, "At the minimum, SUSMPs and guidelines shall be prepared for, one, a hundred-plus home subdivisions; two, ten-plus home subdivisions; three, 100,000 square feet developments; four, auto repair shops; five, retail gasoline outlets; six, restaurants; and, seven, hillside-family dwellings."

R0072075

The two unauthorized categories that staff has added are developments located in an environmentally sensitive area and any parking lot with

24 or more parking spaces. We believe that neither staff nor the board may add these requirements without reopening the permit.

This is not to say that we are not concerned about preventing pollutant runoff from entering environmentally sensitive areas or reducing chemicals and runoff from parking lots, but they're already covered. The environmentally sensitive areas are covered in the Model Development Planning Program, and parking lots are covered in the permit. They must be swept regularly to remove debris from industrial, commercial motor vehicle parking lots. And according to studies referenced in the municipal permit, sweeping is an effective, best management practice in removing pollutants from outdoor services.

We also note in the Regional Board's staff report that the city of Long Beach permit which was adopted in 1999 limits SUSMPs preparation for four types of new development projects. Five fewer than the staff is proposing now for cities under the L.A. permit. How can this be seen as fair?

R0072076

If Regional Board staff cannot be trusted to abide by the permit that you adopted, how can we believe it is right in other matters? How can we believe that the data staff is using from the L.A. County monitoring port to justify additional requirements as being interpreted objectively, and how could we believe that the executive officer has the

authority to add new requirements without following that administrative resolution procedure that is now your permit --

CHAIRMAN NAHAI: Mrs. Ansari.

MS. ANSARI: -- or what to do to reopen the permit?

CHAIRMAN NAHAI: I've got to stop you.

MS. ANSARI: I am sorry. I didn't pay attention. I apologize.

CHAIRMAN NAHAI: You have to set an example here as an elected official.

MS. ANSARI: I know. I totally didn't look. Listen, I have to leave, but I wanted to present you this plaque from the City of Diamond Bar for your 50 years of dedicated service. And one statement, Dennis has tried to work with cities.

CHAIRMAN NAHAI: Thank you. It's beginning to feel like 50 years just today.

The next three cards that I have are from Mr. Mark Pisano, Mr. Mike Bonin and Mr. John Claussen.

MR. PISANO: My name is Mark Pisano. I'm the Executive Director of the Southern California Association of Governments. We're the Metropolitan Planning Organization for Southern California. We do growth, transportation, planning. We're also responsible or co-designated to prepare the air quality plan, and finally we are designated as the 208 area-wide management program.

I want to note that prior to my assuming my current position, I was the director of water quality standards planning, nonpoint source programs, waste load analysis for EPA in Washington.

The issue you have before you today is a difficult one. You have been challenged to leave a legacy, a legacy of cleaning up our bays and waterways for nonpoint source solution. My board supports you accomplishing that legacy, but it supports you doing it in a way in which we can be successful and we can be successful in our lifetimes. The program extends 50 to 100 years. To accomplish its objective, it does not accomplish that particular end.

My board also puts before you a proposal to work with you as your 208 area-wide management organization to accomplish your goals. That was intended by the statute, and we would like to work with you. We've made various offers over the past ten years to work with you. Those have not been taken up either through resources or through agreements.

Very specifically we proposed three very definite actions. The first is that we enter into a memorandum of understanding with you to incorporate best management practices into our livable communities guidebook, handbook that is helping us to implement the transportation air quality provisions. We have resources to accomplish that.

R0072078

We work with the Tree People in preparing

the best management. The BMP handbook, we would like to see that incorporated and, secondly, for us to move forward on a scheduled implementation of those BMPs that are not high cost, that we can clearly justify because they achieve multiple objectives.

Secondly, to enter into a multi-agency process for undertaking watershed planning activities that would enable us to determine multiple goals and the solution to multiple goals within basins. We have a model of such a watershed plan occurring in one of our subregions, namely, the Calabasas subregion, working on the Malibu Creek storm water problem. We urge that as a model.

And in so doing, we would suggest we put together an interagency collaboration of the Corps of Engineers, the Department of Interior, CalTrans, and we've had discussions with these agencies, and they are interested.

Thirdly, with respect to numerical standards, we support technically based, environmentally based, setting of standards. Very specifically, we're supportive of a TMDL supported numerical standard where we need to go further in order to achieve air quality.

R0072079

The implementation of those three steps would allow us to develop the information base so that we can have three things, and I'll close with this: We can have a partnership so you can bring together the

resources necessary to solve this problem. We'll have an educational program so people can see what they're getting for their investment.

And, finally, we would get the needed resources. Without resources, we're not going to solve this problem. If you pit the units in our region against one another, you'll put us further behind and not achieve your legacy. If we cooperate, if we collaborate, and if we integrate our various resources, we'll achieve our goals. Thank you.

CHAIRMAN NAHAI: Thank you.

Mr. Bonin.

As I call out your names, if you'd come up and maybe occupy one or two of these seats up here so that you'll be in the position to step up to the podium right away, that would be helpful as far as time is concerned.

MR. BONIN: Good afternoon. Thank you for your time. My name is Mike Bonin. I'm the Director of Community Affairs for Los Angeles City Councilmember Ruth Galanter, who represents the Sixth District in Los Angeles, including a good portion of the city's coastline.

R0072080

I want to clarify who I'm speaking for today. I'm speaking on behalf of the councilmember and a bit later I guess you're going to hear from Gary Moore, who's from the City Storm Water Program who will explain in more detail the city's official position as

taken by council action tomorrow.

I'm briefly going to do two things. That is, one, give a context to the council's position taken yesterday and a little bit of an overview of the process and then say a few words directly on behalf of the councilmember.

The council action yesterday -- I missed this morning a comment that I was a bit shocked to hear that council may not have understood exactly what they were doing yesterday. On the contrary, the council knew exactly what they were doing. The reason the council took an action yesterday is that back in October, city representatives gave some testimony to the board that the council was concerned with, so the council spent the intervening months weighing their options and figuring out exactly which position to take.

Yesterday the council debated for 40 minutes. In comparison to what you're doing here today, it doesn't seem very long. But that's longer than about 90 percent of the issues that council hears, and it was the longest issue the council debated yesterday.

R0072081

They heard from varying different sides of the issue. They heard some very strenuous testimony from the city's chief legislative analyst who urged the council not to take as strong an action as they did, and the council decided to take an entirely different

action. The council decided to make a very emphatic statement on behalf of the proposal before the board on behalf of the 85 percent, three-quarters inch rule.

The council did have some concerns, which they did express and some questions they would like answered by the board. The council, however, made it very clear that their support for the proposal was not contingent upon having those questions fully answered or fully resolved. That would be nice, but the council is more concerned with seeing some action taken and let's work out some of the details later.

So please do not misunderstand yesterday's council action as some sort of whispered sweet nothings to the environmental movement. It was a bold and declarative statement to take action and on behalf of environmental leadership and an expression of willingness on the council's behalf to assume the mantle of that leader.

Another indication of the seriousness of the council's action is that it was a consensus statement. Had the council just acted willy nilly on my boss's recommendations, it would have been an even stronger statement. **R0072082**

Councilmember Galanter, in a letter sent to you yesterday, endorses some of the -- endorses fully what NRDC and Heal the Bay and the BayKeeper are saying. Most emphatically, the issue we would urge you to look at is the issue of the roofing exclusion. We

think that guts the proposal, and the councilmember would urge you to seriously consider removing that exclusion and restoring some of the meat and the muscle of the proposal before you.

So, again, if you want some more specifics on it, Gary can testify a bit later, and I'm available for questions at whichever opportunity. Thank you.

CHAIRMAN NAHAI: Thank you very much.

There's a question for you, Mr. Bonin.

MR. BONIN: Yes.

MS. CLOKE: I'm confused. I have here a letter from Ron Deaton.

MR. BONIN: Yes.

MS. CLOKE: Who's speaking for the city asking something that is very different from what is in the motion that your boss signed, so can you clear up this confusion for me?

MR. BONIN: Yeah. What's the -- what needs clarification precisely?

MS. CLOKE: Well, he's saying that the City of Los Angeles is asking for an extension. R0072083

MR. BONIN: There was some testimony to council yesterday primarily by Councilmember Mark Ridley-Thomas, who said that it would have been nice if we could have another 30 days because the latest proposal came out on January 18th or something like that, and there were some councilmembers that shared

that sentiment.

But as I said that the council concern to have some issues resolved or to have some questions answered was very clearly stated and affirmed yesterday as not something that was conditional for the city's support. Oftentimes, the council will make -- take a position on behalf of something before the legislature and say, "We will support this only if amended." That is not the action that council took yesterday.

Does that answer it or not?

MS. CLOKE: I -- have you read Mr. Deaton's letter?

MR. BONIN: Yes, I've read Mr. Deaton's letter and the council action on which his letter is based, which is the ultimate authority that is before you. So if there's a difference, I'd refer you directly to the council action on which his letter is based.

MS. CLOKE: So this is the substitute motion 44A which is signed by Galanter?

MR. BONIN: Signed by Councilmember Galanter, seconded by Councilmember Feuer, was approved unanimously by the council yesterday 12 to nothing.

MS. CLOKE: This motion, shouldn't we have the city clerk's stamp on it or something to identify that this is the official --

R0072084

MR. BONIN: Yes, that is the official statement.

MS. CLOKE: It's not that it was introduced and then it wasn't passed?

MR. BONIN: No. That was introduced and that was passed unanimously.

MS. CLOKE: Thank you.

MR. BONIN: Anything else?

CHAIRMAN NAHAI: Thank you.

The next speaker is Mr. Claussen, and after Mr. Claussen I'd like to hear from Mr. Fred Phillips, Mr. Rufus Young and Mr. Ron Wilkiness, please.

MR. CLAUSSEN: Good afternoon, Mr. Chairman, members of the board and Mr. Dickerson. My name is John Claussen, and I'm here today on behalf of the California Restaurant Association and its members in Los Angeles County.

Before I begin, let me just point out that our letter to the board dated January 14th, our detailed comments are inadvertently omitted from your board packet, so Robyn was good enough to distribute that this morning. If you don't have it, I have extra copies.

The CRA is aware of the numerous water quality issues facing California and is interested in working with the board, the Corps Committee and the stakeholders to develop and establish fair and effective regulations to address these issues.

R0072085

The CRA has worked with its members and

the board staff to address concerns specific to the restaurant industry found in the proposed rule, and we've outlined a number of these concerns in our January 14th letter. Through the work of the board staff, some of these concerns have already been addressed, but today I'd like to highlight three of our outstanding concerns.

First, the CRA supports SCAG's proposed Clean Water Initiative and requests that the board defer action on the proposed rule if it includes the numeric standard. As stated in our written comments, we believe that there's a lack of data demonstrating that the required numeric standards are cost effective for our industry or provide additional benefit to the beneficial uses of receiving waters.

Furthermore, the CRA has always believed that the Los Angeles County Department of Public Works' Program of BMPs and inspections, which are similar to those source and structural BMPs contained in the SUSMP rule when applied to our industry are adequate and can provide an effective means of preventing the discharged pollutants to the storm drain system without the need for numeric standards.

Second, we are concerned that the real language regarding redevelopment is still too vague. In our written comments, we proposed that the definition of redevelopment only apply when there was a 50 percent increase to the size of an existing

R0072086

restaurant.

The January 18th staff report recognized this concern stating that the creation or addition -- the definition of redevelopment would be changed as to apply only to the creation or addition of 50 percent or more of impervious surfaces or the making of improvements to 50 percent or more of the existing structure.

The report also states that this change ensures that minor modifications to existing structures for properties do not unintentionally trigger SUSMP requirements. Since the rule does not define improvements, one can now interpret this definition as requiring the rule to apply to existing structures if a restaurant owner performed any number of improvements, which would have no impact on the generation of pollutants discharged to the storm water system, such as replacing flooring material or redesigning or revising the motif of the restaurant, et cetera.

And, finally, our written comments express concern about the applicability of the SUSMP rule to the small -- to small parking lots. The January 18th staff reports states that it is staff's intent that the SUSMP revisions not apply to parking lots associated with small commercial developments but only the commercial stand alone developments for parking lots.

R0072087

However, the language as stated in the

change sheet does not achieve this objective, and the rule remains vague as to the applicability to small commercial lots, and we hope that the staff will clarify this in their final rule, and that's it.

Thank you for our opportunity to comment on the staff's proposed SUSMP rule. We trust that these comments will help the board to develop a fair, effective and consistent rule while considering the needs of the restaurant industry.

CHAIRMAN NAHAI: Thank you very much.

Why are the lights not working?

MS. GOODMAN: It was working.

CHAIRMAN NAHAI: It's off now?

MS. GOODMAN: Yeah.

MR. CLAUSSEN: Do I have more time?

MS. DIAMOND: I have one question for you. Would you know, as a member of the restaurant association, what percentage of restaurants in this area are small as defined by our definition of small restaurants?

MR. CLAUSSEN: Yeah. Actually, I heard your question this morning, Miss Diamond, and I actually don't know the exact answer to that question. The CRA represents primarily the larger commercial chain type of restaurants. We represent over 700 operators in Los Angeles County. Most of those, as our guess, based on the property lines will exceed the 5,000.

Our understanding is that the 5,000 square footage exemption is for the smaller mom-and-pop-type stores, which don't generate the potential for the pollutant sources to storm water. But I don't have the exact number or percentage of restaurants that will be affected by that.

MS. DIAMOND: Thank you.

CHAIRMAN NAHAI: Thank you very much.

Mr. Phillips.

MR. PHILLIPS: Good afternoon, Mr. Chairman and staff. Thank you very much for taking time to listen to many different points of view on this matter. My name is Fred Phillips. I'm the Development Manager for the Western Region for Burger King Corporation, and I'm representing not just my own company, which has about 300 restaurants in Los Angeles County run by a hundred individual franchisees, but really for, as you had mentioned, Miss Diamond, the smaller restaurant operators within Los Angeles County because there are several thousand that would come under this particular rule.

I want to just kind of put more of a face on how this is all going to affect us as stakeholders on this. We have studied this very carefully. We have worked with Mr. Claussen at the CRA, and we do have some things we'd like to bring up about this.

R0072089

Again, most all the new restaurants that are built in Los Angeles County and in the nation, in

fact, meet these BMP standards. The issue that we have is with the numeric standards because it is something that we have never had to deal with before as an industry.

And the cost of implementation to us are still so vague from the information that we've received, the issues of filtering devices is the one that we're the most concerned about because we're basically taking a new type of a product and we're implementing into a situation that our restaurant operators and restaurant operators in general are not familiar with.

You're talking about a product or an item that has to be installed, and we have heard some of the prices quoted that it's about $500 for this and so forth. You start multiplying that times the number of catch basins you need inside of a regular parking lot, and you add to that the cost of maintenance, and since there is no proven track record for something like this in a small operation, this is not something that restaurant operators are going to want to deal with.

You can have potential toxic issues involved, and we are governed by the AQMD and health departments and so forth, so this is going to require outside vendors to come in, and we can take care of this forever, basically, with no idea of what this cost is going to be in the long run for us.

R0072090

To top that off, the other issue about

remodels is a very interesting one. It was very vague the way it was written. It said as long as the cost is 50 percent -- it didn't exceed 50 percent. Fifty percent of what?

If you remodel a restaurant -- and many of our restaurants are 10 or 15 years old. The cost of developing a restaurant 15 years ago versus now, when you implement issues such as ADA rules, you're automatically spending an inordinate amount of money into remodeling a restaurant, so we could easily exceed that 50 percent rule just by doing a simple remodeling to a restaurant.

So, again, how does that figure? Is it current cost? Is it old cost? What is it? These are issues that there really isn't anything covering it in this piece.

And, finally, in a restaurant that did not have drainage issues, you know, a 2500 foot restaurant with maybe a 15,000 or 20,000 foot lot, when they were built, there were no standards for this. It would drain directly into the street.

Would they then be required by exceeding this cost just by doing a remodel and adding 88 restrooms to their building have to dig up their parking lot and spend what we've figured between 15- and $20,000 to go in, dig it out, regrade it, redrain it and close the restaurant, losing sales and so forth during that time period?

So it's not a very simple issue we're looking at. We're looking at something that is a long-term cost to our organization on our people.

CHAIRMAN NAHAI: Thank you, Mr. Phillips. I had a question to ask you.

But, first, does anybody else have any questions?

MR. PHILLIPS: I can answer any questions you have about restaurants throughout the afternoon if you need them.

CHAIRMAN NAHAI: The Burger King restaurants that you represent are average what size of the 300 here in California?

MR. PHILLIPS: They average between 2200 to 34-, 3500 square feet, and that's about average for a McDonald's, Jack-in-the-Box, a Taco Bell or any small, independent restaurants due to the lot sizes we have in Los Angeles County.

A PERSON: Is that lot size, or is that restaurant size?

MR. PHILLIPS: That's restaurant size.

CHAIRMAN NAHAI: Wait. Wait. The questions get asked from up here, not from the members of the audience. If we allow that, we're going to have a zoo in this room; okay? Please don't do that again.

A PERSON: I'm sorry.

R0072092

CHAIRMAN NAHAI: The other thing that I wanted to just discuss with you is the 50 percent rule

as its proposed. My reading of this is that it doesn't have anything to do with 50 percent of cost. It has to do with the 50 percent addition of impervious surfaces or 50 percent addition of building area.

MR. PHILLIPS: But there was -- the way it was interpreted by us in reading it that it could be interpreted as cost of improvements to the building, and improvements to the property is very vague in that does it mean you're adding on 50 percent additional square footage, or is it talking about that? And it was interpreted by some reader that it could be interpreted that way by local government.

CHAIRMAN NAHAI: I'm having difficulty with that. Let me just read it to you. "Redevelopment means on an already redeveloped site the creation or addition of 50 percent or more of impervious surfaces or the making of improvements to 50 percent or more of the existing structure."

MR. PHILLIPS: "Making improvements of 50 percent or more of the existing structure," 50 percent of what? So in other words --

CHAIRMAN NAHAI: My question is: How could anybody possibly interpret that to mean a cost calculation?

R0072093

MR. PHILLIPS: Okay. If it says "50 percent or more of the structure," you mean 50 percent or more improvement or changes or remodeling to the structure; is that the way you understand it?

CHAIRMAN NAHAI: I mean, I just -- I didn't understand how cost was built into this formula, and so I just wanted to point that out to you.

MR. PHILLIPS: I guess the understanding would be is that's the question. 50 percent. If we go in and tear off the roof and put a new roof on the structure and we put in new plumbing and new bathrooms and so forth, we will have expended -- we will have spent more than 50 percent of work to a building that we almost have torn it down, where we might not have touched the parking lot. We might not have touched the landscaping. But we've easily exceeded 50 percent improvements to the property, and that's the question. How does it get interpreted? It was very vague.

CHAIRMAN NAHAI: Okay. Any other questions? Thank you very much.

MS. CLOKE: You will be around to answer anymore restaurant questions?

MR. PHILLIPS: I'll stick around. I've been a consultant in the restaurant business for 14 years, and I've had to deal with these situations in the past.

CHAIRMAN NAHAI: Excuse me. Mr. Bob Miller had a question for you.

MR. MILLER: The question was in that same language, are you talking about 50 percent of the area of the restaurant being increased or the percent of -- I'm not sure.

CHAIRMAN NAHAI: My only point was that it doesn't talk about 50 percent of cost. It talks about either 50 percent --

MR. MILLER: Of impervious areas.

CHAIRMAN NAHAI: -- or an addition.

MR. MILLER: 50 percent of what?

CHAIRMAN NAHAI: Of the 50 percent addition to the area.

MR. MILLER: Of the area. Okay.

CHAIRMAN NAHAI: It's not -- what I'm saying is that there is nowhere in that paragraph -- Mr. Phillips's interpretation of it was -- or those people who have spoken to him about it, their interpretation was that if you -- if something costs you a hundred thousand bucks to do it and now you're going to do a $60,000 addition, that that is the criteria for whether you'll have to comply.

MR. MILLER: All right.

CHAIRMAN NAHAI: And all I was saying is that it's not based on that.

MR. PHILLIPS: And just to reclarify my position here, I think the point I'm making isn't simply with regard to cost. I'm saying as a result of that work, you'll be expending a cost that would be a higher number than even what you're involved with building the restaurant. So you certainly would have spent more than 50 percent of work to the building that would have been done just by doing a simple remodel to

meet current codes.

CHAIRMAN NAHAI: Mr. Young.

MR. YOUNG: Mr. Chair, members of the board, my name is Rufus C. Young, Jr. I'm with Burke, Williams & Sorenson, a law firm which proudly represents the cities of Alhambra, Compton, El Segundo, Hawthorne, Lomita, Industry, Torrance and Santa Clarita in this matter, and each one of those cities objects to the limitation of three minutes per person, rather than three minutes per entity.

While we represent eight cities, those cities have interests in common, but they have some issues that are different from one another. We submit that denying the cities the opportunity to have three minutes per city, limits the cities to 22 seconds per city. That denies them procedural due process and the right to be represented by counsel.

Moving right along to the second item, lack of adequate notice. The cities in each of them objected to the lack of notice because this SUSMP has evolved significantly, recently. As recently as the 18th and as recently as the release of the change sheet. That left no adequate time to analyze or to address those changes.

R0072096

Third, the redevelopment threshold, and this is on behalf of the cities of Alhambra and Hawthorne. The 50 percent existing structure that was just discussed by the previous speaker, we suggest that

it lacks a nexus to storm water and that the requirement would be significantly strengthened if the 50 percent or more threshold were added to include 50 percent or more that would adversely impact storm water.

Take the situation where the improvements are all interior redecorating improvements over the entire -- on the entire interior of the structure. No adverse storm water impacts at all.

Fourth, the implementation date. This is on behalf of the City of industry. We suggest that there be a grandfather provision that Mr. Dickerson alert -- mentioned this morning. We applaud that and suggest that those projects for which the application has been filed and accepted by the permitting city but not -- no final action has been taken yet, that those be grandfathered if the application was filed and accepted within 180 days of the adoption of the SUSMP implementing ordinance by the permitting city.

Next, and this is on behalf of the city of Santa Clarita, the issue of clustering redevelopment or development in conservation habitat areas. We suggest that there be a modification to the first bullet, and I believe this is Item 2 on page Roman numeral II-7 of the December whatever it is version. That when feasible there be a requirement to cluster the development in or near conservation areas.

R0072097

Next point, the parking lot size, and

this is on behalf of the city of Alhambra, we suggest that the parking lot threshold be given a credit for those parking lots which incorporate a parking lot island which is vegetated, which is the best management practice. If you vegetate your parking lot islands, that shouldn't count against your 5,000 square foot limitation.

Next, on behalf of the cities of Industry and El Segundo --

CHAIRMAN NAHAI: I have to stop you, Mr. Young. I apologize. I've got to stop you. It's well over three minutes.

MS. CLOKE: We have your letter.

CHAIRMAN NAHAI: If there is time at the end, I'll ask you to come back to the podium. We have several letters from you and you've made your points very eloquently in those letters as well.

MR. YOUNG: Well, I continue with my procedural objection of 22 seconds per city is simply not adequate. Thank you very much.

CHAIRMAN NAHAI: Duly noted.

MR. YOUNG: I'll be back.

CHAIRMAN NAHAI: Mr. Wilkiness.

MR. WILKINESS: Good afternoon, Mr. Chairman -- pardon me -- and members of the board. Excuse me. My name is Ron Wilkiness. I'm with the Western States Petroleum Association, the trade association for the oil industry in the west.

Many of my member companies, as you might imagine, will be building or remodeling service stations that will be impacted by these SUSMPs. My comments are specific to the requirements for retail gasoline outlets, unique, I think, among the nine categories of planning projects that have been identified. I appeared before your board twice last year to comment on the city of Long Beach permit and again on the proposed SUSMPs.

On both occasions, I told you that as an industry we have participated in the development of an RGO Storm Water BMP Guide published in 1997 by the California Storm Water Quality Task Force. The requirements of that guide have already been adopted by various agencies in San Bernardino County, in the Bay Area and here.

Your board incorporated the requirements of the task force BMP Guide into the Long Beach permit. This is my understanding from reading the staff report that the staff is proposing to require that new or redeveloped RGOs shall meet the provisions of the Task Force BMP Guide but not the numerical standard. That's on page 12 of the staff report. Where a service station operates its service bays, additional BMPs would apply.

R0072099

I believe that a number of companies can support these requirements; however, first, there are two issues for which I would seek clarification. One,

as I read other language in the December 7th document and also in the staff report, there are at least six sets of statements that conflict and might lead the permittees to a different conclusion about their requirements. I believe that the intended requirements are those as stated in the paragraph on RGOs on page 12 of the staff report.

Secondly, the proposed SUSMP on page 11 lists the requirements for the proper design of WSPA maintenance bays. I assume too that these are the, quote, "additional requirements" referenced in the staff report on page 12. I would appreciate it very much if staff could please clarify these two questions for me, but I hope, Mr. Chairman, not at the expense of my three minutes.

CHAIRMAN NAHAI: Yeah. I think if we may, let us note your questions and we will ask them of staff at the end. I don't want to interrupt the flow of speakers by having speakers pose questions to staff.

MR. WILKINESS: I'm at somewhat of a limitation, Mr. Chairman, because I'm not sure really what my comments should be since I'm unclear on the requirement because of the conflicts in the staff report and the December 7th document.

R0072100

I would like to ask that the staff, please, revise the final version of the SUSMPs to ensure the applicable requirements for RGOs are crystal clear and consistent with page 12 of the staff report.

I also suggest that it would be appropriate for the staff to list the Task Force BMP Guide as one of the references in Table 1 of the SUSMP.

In conclusion, I have a small amount of legal fine print that I would like to add. Because of the earlier proposal that numerical design standards also be applied to new or redeveloped RGOs, WSPA requested that its attorneys determine whether there would be any associated legal issues.

Although staff's apparent abandonment of that proposal may make the legal analysis no longer relevant, it still might be of interest to your counsel, and, accordingly, I would like to hand it in for inclusion into the record of these proceedings. Thank you. I would be happy to answer any questions that board members might have.

CHAIRMAN NAHAI: Thank you very much for coming.

MR. WILKINESS: Thank you.

R0072101

CHAIRMAN NAHAI: The next three cards that I have are -- I have one from Mr. Montevideo, but he's already spoken for three minutes.

MR. LEON: Mr. Nahai, I'm sorry. Quick housekeeping issue with respect to the request that he just made. He requested an opportunity to submit what I take to be, basically, a legal argument by counsel before the close of the record, but as I understand it we're going to be closing the record of this matter

today.

Do we need to make an arrangement for him to submit something after the close of the record, or is the permission that is granted based on --

CHAIRMAN NAHAI: Isn't it being submitted at this time?

MR. LEON: I don't know.

CHAIRMAN NAHAI: Are you submitting your legal fine print to us now?

MR. WILKINESS: I would submit them with the request that it simply be made part of the record. I think that the legal analysis is superfluous based on my understanding of the requirements, but, again, because of the conflict between the statement of requirements on page 12 of the staff report versus language elsewhere in the staff report and in the December 7th document, there is some uncertainty regarding precisely what requirements are being proposed.

R0072102

If the requirements are the task force -- the California Storm Water Quality Task Force BMP Guide, that is something that we would strongly support.

CHAIRMAN NAHAI: Okay. So you think the legal argument that you're submitting is probably moot, but just in case it isn't, you want to make sure you would have put it into the record.

MR. WILKINESS: Precisely correct.

MR. LEON: Is he prepared to submit it now?

CHAIRMAN NAHAI: He already has.

MR. WILKINESS: Yes. I already have.

MR. LEON: That's what I needed to know.

MR. WILKINESS: I apologize for any confusion. Thank you.

CHAIRMAN NAHAI: The other cards that I have are from Mr. David Freeman, Mr. Tim Piasky and Mr. Ray Tahir.

MR. FREEMAN: Thank you, Mr. Chairman, for the opportunity to speak. I'm Dave Freeman, the General Manager of the Los Angeles Department of Water and Power. I'm on leave from that job for the time being, return on May 8th.

And I'm speaking for myself today as a person that's been a part of this water pollution crusade, if I can put it that way, ever since the early seventies. I was present at the creation of the Environmental Protection Act and the passage of the Clean Water Act.

I ran the Tennessee Valley Authority as a polluter and learned what it was for the EPA to crack down on me and require us to put technology that we thought was yet unproven in to clean up the air and we did it.

R0072103

And I have worked here -- in Texas, I implemented a nonpoint pollution ordinance in 1988.

And if you think this is tough, I wish you had been with me there. That's a state where the freedom to use your land the way you wish is a fairly righteous thing, and it was not a pretty sight. But we got it approved, and it's been implemented, and it's been quite successful in keeping Lake Travis and those waterways a whole lot cleaner than they would otherwise be.

Let me just try to make two points here. One, I know this seems like a tough thing for you all to do, and I know that there's a lot of opposition because this is kind of new to Southern California. But with all due respect, you're taking a very small step very late. This is not a pioneering effort.

People all over the country -- if you required other folks to have open space all around their place, put a catch basin in, a filter bed, to do a few simple things that retain 75, 80, 85 percent of the pollution that would otherwise go in, that is just no big deal.

Now, the polluters will always make it seem like a big deal, and municipalities and federal agencies like I used to run are more prickly about obeying environmental laws than private companies because they're used to giving orders and they're used to passing ordinances, and they really don't like it when some other agency hands down something that they've got to do, but it's the law, and it's happening, and it's not that big a deal.

R0072104

The plain truth of the matter is we know this pollution infects our water. That's not questionable. And we know where it's coming from. We passed a lot of environmental laws with a lot less knowledge than that, and all you're doing is attacking the growth, which may be 3 or 4 percent a year. Ten years from now, you will have done maybe a third, at the most, of the nonpoint pollution if you were able to get a hundred percent.

So you're landing in Normandy, and if you leave enough loopholes in the forces so that pollution can come driving through your forces, you'll be back in the sea again. You have got to at least make this landing in Normandy a strong one and a strong base.

All these exceptions they're talking about, all those things need to be disallowed. The issue is who's got the burden of proof? That side loses. And you need to have these people come in with factual demonstrations to you to justify any waiver or any exclusion. Thank you very much.

CHAIRMAN NAHAI: Thank you very much.

Mr. Piasky.

MR. PIASKY: Thank you. Good afternoon, Mr. Chairman, members of the board. My name is Tim Piasky representing Los Angeles County Department of Public Works. The County of Los Angeles is not opposed to the idea of the SUSMP. However, we feel the current version has several technical deficiencies as we have

brought forward in our submittal letter today as well as our letters to Dennis Dickerson dated December 28th, 1999 and January 11th, 2000.

We have concerns with all these deficiencies. However, the proposed definition of "environmentally sensitive area" has us gravely concerned. This definition is very difficult to interpret and could be interpreted to cover almost all development. This definition would also be very arduous to implement and enforce.

According to the staff report and record of decision dated January 18th, 2000, a sensitive coastal resource area would include highly scenic areas and areas possessing significant recreational value. These are very subjective categories without clear definition.

Instead, we would recommend defining an environmentally sensitive area by those adjoining, bisecting or directly discharging to a significant ecological area identified by Los Angeles County or other environmentally sensitive areas identified by a legislative body.

If this definition is not used, then we would recommend that the Regional Board staff provide a readable meets and bounds support and map instead. Thank you.

R0072106

CHAIRMAN NAHAI: I have a question to ask you, if I may. The definition of "environmentally

sensitive area" that I'm looking at says it means, "An area that's designated as an area of special biological significance by the State Water Resources Control Board, Water Quality Control Panel, Los Angeles Region Basin Plan or an area designated as a significant natural area by the California Resources Agency or an area designated as an area of ecological significance by the County of Los Angeles."

So it's talking about any area that is really designated as such either by the State Water Resources Control Board, by the California Resources Agency or by the County of Los Angeles. What am I missing? What's wrong with that?

MR. PIASKY: Well, again, the definition is very broad, and I think there's a lot of confusion as to what area that really covers. It could mean to cover almost all development. You know, nobody's seen a map that overlays all those areas to see what it is exactly we're talking about.

CHAIRMAN NAHAI: I know. But help me out here. There would have been a reason, would there not, why the County of Los Angeles would designate an area as an area of ecological significance.

MR. PIASKY: That's right. But that's only one area that's defined in there as your SCA. There are other areas that are also included. So you have to take all of those areas into effect when you're determining the definition.

CHAIRMAN NAHAI: Yeah. But each of those areas would have been designated as such either by the CRA, by the County or by the State Board.

MR. PIASKY: That's right. But we still don't know what the overlay is for all those areas. It could impact almost all development in L.A. County.

CHAIRMAN NAHAI: Okay. Any other questions of Mr. Piasky? Thank you very much.

Mr. Tahir.

MR. TAHIR: Chairman Nahai, would it be possible to allow me to trade with Councilmember Bruce Barrows who's also representing the Gateway Cities Club this afternoon. He's been waiting here for the last four or five hours, and I'd like to give him a chance to speak so that he can attend a meeting.

CHAIRMAN NAHAI: You're just trading places --

MR. TAHIR: Just trading.

CHAIRMAN NAHAI: But three minutes each.

MR. TAHIR: Yes, sir.

CHAIRMAN NAHAI: All right. No problem.

MR. BARROWS: Thank you for allowing him to switch for me. I do represent the city of Cerritos. We have taken a position on this as has the Gateway Cities Council of Governments. I do have a resolution that was passed on January the 5th I believe it is.

CHAIRMAN NAHAI: Could we have your name for the record?

MR. BARROWS: Yes. It's Bruce Barrows, Councilman, city of Cerritos.

Our main concern deals with the numerical issues, and I don't really want to go back in and revisit what everybody has said before me. But we do have concerns over that.

And I do recognize that earlier one of our members of our congress mentioned in supporting numerical standards and things like that. That was Southgate. Southgate has not taken any such position. That was -- according to the city manager, an individual had wrote a letter on city stationery, and that's a phone call that was confirmed earlier this morning. So I just wanted to clarify we don't have support on that.

The third thing to come up is as I sit here listening -- this is the first time I have been to one of your meetings, and I appreciate all the work that you're doing. I know it's a lot of work, a lot of prep and a lot of difficulties to find the resolutions.

The Gateway Cities Council of Government stands for very, very difficult economic issues that we're working on, we're doing some studies on, and were described in some very unflattering terms in parts of the area in terms of the job losses. The jobs that are missing are still below the 1989 levels. **R0072109**

We have some of the most dense cities in the nation in any county in the state. Our concerns

deal with it. These controls that are going to go in are probably going to cause some economic hardships. You know, we're not Santa Monica that has a beautiful view of the ocean. There are some cities there that have some very, very grave difficulties to overcome. We want to be sure that we have standards that we can live with.

All the cities -- our position as a council is that we're very concerned about the environment. We worked very hard on the San Gabriel and the L.A. Rivers Conservancy that was just signed into state law.

So we're not saying we're against what you're working on. We just want to make sure that we have a resolution that you come to that we can live with. And we thank you very much for the three minutes.

CHAIRMAN NAHAI: Thank you very much.

Any questions?

MR. BARROWS: Who do I submit this to?

CHAIRMAN NAHAI: To the executive assistant.

Did you have a question, any other questions?

R0072110

Thank you so very much.

The next three cards are from Mr. Arturo Cervantes, Mr. Bruce Fane and Mr. Marvin Sachse.

MR. CERVANTES: Good afternoon. My name

is Arturo Cervantes. I'm an engineer with the city of Vernon, and I just want to read a very brief statement to state our city's position on the SUSMPs.

The city of Vernon does not agree with the proposal to incorporate a numerical design standard into the SUSMPs without following the procedures as outlined by the permit. Based on the information given by the EAC presentation team, the city is asking that the Regional Board do what is correct and not approve the SUSMPs.

The city supports protecting the beneficial uses of the receiving waters. However, before costly numerical design standards are incorporated, the city agrees that a study must be conducted to identify which groups of the SUSMPs are for beneficial uses and which BMPs can effectively mitigate the potential impacts. This will ensure that we are directing our resources to meet the intended goal of the permit in protecting the beneficial uses of the receiving waters. Thank you.

CHAIRMAN NAHAI: Thank you very much.

MS. TEAFORD: I'm Bonnie Teaford with the city of Burbank. Bruce Fane had to leave and I was his alternate speaker.

CHAIRMAN NAHAI: You don't look like a Bruce Fane.

MS. TEAFORD: I don't, do I? **R0072111**

I'm Bonnie Teaford. I'm the city

engineer with the city of Burbank, and we are here representing the Arroyo Verdugo Council of Governments whose members include the cities of Burbank, Glendale and La Canada Flintridge.

And my purpose today was just to submit to the board formally the resolution that was adopted by that Council of Governments on January 21st, 2000, and that has been entered into the record. The resolution was entitled "Resolution of the Arroyo Verdugo Cities Council of Governments Advising the California Regional Water Quality Control Board, Los Angeles Region, of Its Intention to Petition the State Water Resources Control Board for Relief from Unreasonable Runoff Pollution Controls for New Developments."

We really appreciate the opportunity for dialogue today, and we look forward to working with the board on a mutually acceptable resolution of the issues. Thank you.

CHAIRMAN NAHAI: Thank you.

Mr. Sachse.

MR. SACHSE: Okay. Good afternoon, Chairman Nahai and board. Thank you for your time. Happy anniversary. I have copies of my prepared spontaneous remarks, which I'll give out after my presentation.

R0072112

My name is Marvin Sachse. I'm a state licensed professional engineer with a master's degree

in environmental engineering and industrial engineering. I'm the program manager for State Approved Storm Water Groups serving 300 Southern California auto recyclers and their trade associations.

As a group, we wish to place before the board our concerns that the well-intentioned SUSMP program will be compromised by the use of numeric limits. Recommended SUSMP program BMPs were derived from East Coast studies with very few actual installations and less hard data.

One concern with numeric limits is the litigious nature of the Clean Water Act will expose every SUSMP installation to lawsuits over the term "maximum extent practicable." Clearly defined effluent limits will eliminate the potential for unending litigations from this vague and inexact term. TMDLs will establish clearly defined effluent limits.

The Sacramento Storm Water Management Program published a November 1999 final report. This report data showed that under some conditions, total suspended solids and zinc are discharged from grassy swales and sand filters increasing pollutant loading in storm water treated by these BMPs.

Moreover, there were 14 BMPs evaluated, which were similar to the ones in the SUSMP program. Thirteen were rated not acceptable. Only one was conditionally acceptable. The Sacramento report estimated that the installed unit cost would range

R0072113

between $20,000 and one-half million dollars, depending upon treatment technologies. Operation and maintenance costs range between $400 and $4,500 per year.

Los Angeles is a desert. BMP effectiveness data has not been obtained from cities with similar weather patterns, soil conditions, rainfall and topography. Heavy metals, pesticides, fertilizers, fecal coliform are pollutants of concern and would not be significantly reduced by the SUSMP numeric limits because these particular pollutants are not generated at the targeted operation sites.

Porter-Cologne requires the water board to evaluate beneficial uses of waterways and determine what pollutant loading will not impact the beneficial uses of the waterway. This issue is not addressed in the SUSMPs or its numeric limits, but it is required as part of the TMDL process.

The SUSMP program numeric limits were developed without a scientific basis as to receiving water capacities, pollution from nonpoint sources and determination of BMP effectiveness. It is our recommendation that the L.A. Water Board consider expedited development of the TMDL program instead of implementing a parallel, albeit less well developed, SUSMP program. **R0072114**

The TMDL program provides the necessary scientific tools for the implementation of thea Storm Water NPDES program and affords the best protection for

the environment, watershed residents and businesses than the numeric limits of the SUSMP program. Thank you for your time.

CHAIRMAN NAHAI: Thank you, Mr. Sachse.

Any questions?

Okay. The next three cards I have are Mr. Lambros, Mr. Sucilo from PSOMAS and Mr. Watson, Mr. Richard Watson.

MR. LAMBROS: Mr. Chairman, members of the board, good afternoon. I'm Richard Lambros, the Executive Vice President of the Building Industry Association of Southern California.

Our association represents over 1850 member companies from throughout the six Southern California county area who are actively engaged in various aspects of the building industry. Our membership is primarily comprised of home builders who collectively build over 70 percent of the new homes in our region and who employ over 200,000 individuals in the construction trades.

Our interest in the SUSMP proposal is twofold. First, we recognize that ours is probably the leading industry that will be regulated under this plan and the one called upon to design, construct and maintain the BMPs necessary to achieve storm water mitigation.

R0072115

Second -- could you put up the second slide, please. Second, our industry strongly supports

the goals of enhanced water quality and improved storm water management. After all, when we sell homes, we recognize that we're not just selling four walls and a roof. We truly are selling a quality of life, and that quality of life is enhanced by a clean and safe environment. Clean water is certainly a part of that equation.

Our industry's commitment to water quality is already evidenced by activities such as our ongoing implementation of the statewide construction activity permit, our member education programs designed to educate our work force on the importance of storm water management and our new home buyer education program, which is designed to educate consumers as to how they can protect and preserve clean water, voluntary program by our industry.

As for the SUSMP proposal that is before the board today, we view it in two parts, much as Mr. Dickerson outlined earlier: A SUSMP, BMP component, and a numerical standard. In general, our industry supports the SUSMP BMPs in the proposal. There are a few minor changes that will be outlined later for you by Mr. Watson.

R0072116

As for the numerical standards, our industry strongly opposes the inclusion of the SUSMP at this time. Our major concern is that the numerical standard has been offered as the solution before the board has clearly identified the program. This to us

is backwards.

All successful pollution reduction programs, whether you are attempting to clean the air or the water, follow a very logical process. First, you must identify what is the pollution -- what it is that is polluting the environment. Next, identify the source or sources of that pollution, and, finally, bring all of the stakeholders together to develop a strategy to reduce the discharges of those pollutants. This proposal fails on all three counts.

That's why our industry, along with numerous other industries as was just on the board, have come together to support what we have called the Clean Water Initiative. Unlike the SUSMP proposal that is before you today, the Clean Water Initiative is based on qualitative results, not quantitative results, puts its emphasis on pollution reduction, not volumetric measures, makes a strong commitment to clean water, asks for good science from the board staff, articulates a process for producing measurable results based on sound science, invites all of the stakeholders to participate in the process. **R0072117**

Today you will hear from several other members of the building industry. As they speak, please keep in mind that as the industry principally impacted by this proposal, we would very much like to be a part of the fair process that has a chance of actual, measured and scientifically proven success.

Thank you very much.

CHAIRMAN NAHAI: Thank you. Any questions for Mr. Lambros?

Mr. Lambros, there's a question for you.

MS. CLOKE: Your association represents primarily or exclusively home building companies?

MR. LAMBROS: Primarily home building. We do have some light commercial and other builders within our membership.

MS CLOKE: And can you quantify for me the number of new homes that are constructed in this area on an annual basis or however you have that material?

MR. LAMBROS: Over 11,000 in the L.A. area in 1998. That would be L.A. County.

MS. CLOKE: Thank you.

MR. LAMBROS: Thank you.

CHAIRMAN NAHAI: Mr. Sucilo.

Please forgive me. Just carry on. I'm listening to you.

MR. SUCILO: Thank you. Good afternoon, Mr. Chairman, members of the board. My name is Ken Sucilo. I'm a project manager and registered professional engineer in the State of California with PSOMAS. For those of you who don't know PSOMAS, we're a civil surveying information systems engineering firm that serves land development and public agencies.

R0072118

One of the questions that -- at the

request of BIA, PSOMAS was asked to come up with an estimate of project-specific example costs for -- site-specific costs for implementing these water quality measures. These costs are from the perspective of the design engineer, and that's what I'm going to present this afternoon. Basically the purpose, again, is to quantify the total potential costs.

The scope of what we did -- and what I'll do is I'll present the brief results of our analysis -- is to develop preliminary designs based on the criteria and develop cost estimates based on those -- on the draft SUSMP.

One of the things that I'd like to point out is -- in presenting this is that in developing the designs, many of the interpretations or many of the criteria weren't clear, and we had to make some interpretations as to what exactly those criteria were. I was asked by the staff engineers who do the work under me, "How do I interpret certain things?" And in some cases it came down to, "Where is the comma placed in this sentence?" So that's just a comment on the SUSMP as it's written.

R0072119

The information that we'd like to present, again, it was done at the request of BIA, but we believe that it's -- we present it to you for your use and to the environmental community for everybody to use at their discretion.

We looked at three sites. A hundred

thousand foot commercial industrial site -- and for purposes of analyses we assume three acres. The design criteria was taking the first three-quarters of an inch, assuming a capital flood. So that basically captures the first flush of first three-quarters of an inch during the capital flood.

We did not do a roof exemption, and the resulting design was a one foot -- or a 600 foot long swale that's five feet wide. The capital costs, excluding land, for this project was about $10,000, which broke down to a unit cost of $3300.

CHAIRMAN NAHAI: You need to move more quickly.

MR. SUCILO: Okay.

CHAIRMAN NAHAI: You've only got a minute left.

MR. SUCILO: I've only got three examples. I'll be real --

Long-term maintenance is something that was identified, and we had estimated $800 a year, and the land area required was 3,000 square feet.

Next example, please. Thank you. A 7-acre multi-family residential site. Again, the same design criteria applied to this. Our design instead of swale this time was a detention basin. The capital cost for this project was $60,000 at a unit cost per acre of $8,600. Again, long-term maintenance is required, and this does not include land. Although,

R0072120

the land used was 18,500 square feet.

And I'll really quickly go over the last one, which is 500 acre residential site. The same criteria, 8.3 acre detention, filtration basin that passes 47 acre feet of water. The capital cost 1.1 million dollars at a unit cost of $2,500. Land use that would be used would be three acres. Thank you.

CHAIRMAN NAHAI: Thank you very much.

Any questions of Mr. Sucilo?

MS. LYON: Has that information been included in the letter you sent today?

MS. SUCILO: Some of it has been. Some of it we just finished last night.

MS. LYON: I'd like to make sure that we all get a copy of that breakdown.

MS. CLOKE: In some of the other examples that we've seen, the cost of -- the estimated cost of the improvements were shown as a percentage of the total project cost. So if you're looking -- I don't have the examples in front of me, but if you're looking at, you know, 100 units on so many acres of land and you're saying it's going to cost X dollars, whatever that was, what percentage of that is that for the total development cost?

R0072121

MS. SUCILO: We didn't calculate that. We just calculated them on a project-specific basis.

MS. CLOKE: You know, right. Because it's just -- I mean, you know if you're looking at your

personal budget, it's a lot of money. If you're looking at a multi-million dollar development project and it's 3 or 4 percent, it's a different way of understanding it. I just need to have that last piece so that I can understand what your numbers mean. Otherwise, I don't have a meaning, a context to it.

MR. SUCILO: The intent was basically to give data so that you could make that interpretation.

MS. CLOKE: I can't. I need that last piece before I can understand it.

CHAIRMAN NAHAI: Let me ask you this: For instance, with respect to the 500-acre project which was the third of your examples, and I think that you projected a 1.1 million dollar cost.

MR. SUCILO: Correct.

CHAIRMAN NAHAI: Do you -- in the figures that were presented to you, did you have any idea of the value of the project as completed, what the value as completed would be?

MR. SUCILO: Again, we took things from the design engineer, and that might be a question better answered by another member of BIA.

MS. LYON: But before you leave, I want to make sure that what you presented is part of our record.

MR. SUCILO: Well, I can leave it with you.

R0072122

MS. LYON: Could you present that at such

time?

MR. SUCILO: I could leave it.

MS. LYON: Thank you.

CHAIRMAN NAHAI: Thank you very much.

Mr. Watson.

And following Mr. Watson, I'd like to hear from Mr. Charles Gale, Ms. Lynn Jacobs and Dee Zinke I think. Forgive me. The name Nahai has been butchered in so many ways over the years that I don't feel too guilty about that.

MR. WATSON: Thank you Mr. Chairman, members of the board. My name is Richard Watson. I've been involved in the building industry since 1978 and dealing with storm water issues since 1990. My clients include both the builders and the public sector.

We in the building industry can support part of what is on the table today and we oppose part of it. We support the general objectives of the SUSMPs and the use of appropriate risk management practices. We could have even supported the SUSMPs on the table at the September 16 meeting if the numerical standards were removed. We might even be able to support those on the table today with a few changes in policy and elimination of those standards.

R0072123

We have a few specific concerns that I'd like to deal with. The latest change sheet seems to have dealt with two of those. Those are the hillsides development and definition of parking lots. The way

the staff proposed it today does work. Some of the other discussions today I'd like to see not gone back to.

So the one area that we have a real concern with the definition is the third one, the environmentally sensitive areas. Overly broad, unworkable. The proposed definition, as someone else has already said, is very vague, and it's really an example of policy that's not really been well thought out. We support the recommendations of Mr. Desi Alvarez on how to make changes.

Another area of concern of ours is implementation. We need some details on that. When will the proposed requirements be effective? More importantly, how do they relate to the development process? When do they -- when are we not vulnerable to continual change?

Ideally, these SUSMP issues should probably be dealt with at the tentative tract level. That's where we deal with spacial relationships and you can assess the amount of land and the coverage and plan something into it.

R0072124

Another concern that we have is the numerical mitigation measures. The imposition of these without more study, without more -- not delaying study but trying to make the things work in some way is not really good public policy. It's not clear how these proposed standards relate to maintenance or improvement

of water quality, what it does to the beneficial uses. So we object to that.

One that hasn't been mentioned today is the relationship to the general construction permit. Your staff has proposed that that same language be used as a -- excuse me -- as a standard for post-construction under the general construction permit. That really I think is an intrusion on the prerogatives of the state board, and I think that should be rejected.

In conclusion, I'd like to say that we're willing to do our share. We want to have equitable treatment with good science. We don't really want to waste money attacking the wrong thing with the wrong tools, and we don't like being targeted as "low hanging fruit" as Alexis Straus indicated.

I request that you direct the executive director to make changes in the document itself to clean it up, defer any discussion of this numerical mitigation measure and instead move ahead with the Clean Water Initiative, which I think has been passed out to you. That initiative will set up a process in which we can all participate. Thank you.

R0072125

CHAIRMAN NAHAI: Thank you very much.

Mr. Gale.

MR. GALE: Mr. Chairman, if I could, to accommodate our general counsel, switch our spots in our presentation with Tom Morrison. He's our general

counsel. I will take his card when he comes up.

CHAIRMAN NAHAI: Okay.

MR. MORRISON: Good afternoon, Mr. Chairman and members. My name is Tom Morrison. I'm general counsel for the Building Industry Legal Defense Foundation and also the Building Industry Association of Southern California.

I'm here today to remind the board that the fundamental issue here today is process. And by that I mean the process by which the SUSMP is adopted. I want to first echo the legal process concerns raised earlier by Richard Montevideo. Although, I will not repeat the legal arguments put forth by Mr. Montevideo, let me reiterate that the Building Foundation, the Building Industry Association of Southern California believe that neither this board nor Mr. Dickerson have the authority to implement the SUSMP program that is the subject of this hearing today.

Permit 96-054 clearly sets forth the process by which the SUSMP must be adopted. This process must be followed as long as the permit is in effect. The process set forth in that permit has not been followed and staff has failed to come up with a single, valid, legal argument supporting their contention that the process within the permit is no longer applicable.

R0072126

Mr. Leon has not cited a single provision of the permit dealing with why that process is not

applicable after July 30th of 1999, nor has he come up with a single piece of legislative history in the development of the permit itself indicating what process is to be used after July 30th of 1999 if a permit is not effective. He's simply relying on his own opinion. And may I say that by his own druthers he would rather follow the processes involved in the permit, and we would ask that you do the same.

Further, even if the board could do away with the process set forth in the permit, the Building Foundation and the BIA of Southern California believe that the provisions of the Porter-Cologne Water Act preclude the board from adopting the SUSMP proposal put forth by staff today.

Specifically, California Water Code Section 13360 prohibits this board from implementing an order that specifies the design, the location, type of construction or manner of compliance with an existing waste discharge requirement.

The basic thrust of the existing permit is that it lays out on the cities the responsibility to come up with the measures by which they will mitigate their waste discharge. The permit provides a list of BMPs which may be used, but it does not mandate any of those BMPs specifically be used.

R0072127

We believe that by taking the process away from the cities and implementing a board-sanctioned proposal, the board would be creating a

SUSMP proposal that constitutes an order specifying a particular manner of compliance with a waste discharge -- with an existing waste discharge requirement. That you cannot do under Section 13360.

Simply put, this board lacks the legal authority to adopt the SUSMP proposal put forth by staff today, and we strongly recommend and urge that you honor the process set forth in the existing permit. Thank you very much.

CHAIRMAN NAHAI: Thank you very much.

Okay. The next three people I'd like to come up would be Mr. Ross Pistone, Mr. Ray Pearl and Mr. Charles Gale.

MS. GUTIERREZ: Mr. Chairman, Miss Jacobs had to leave the meeting unexpectedly this afternoon, but she has asked that I read her statement for her today, and it is being distributed to the board. She has also hand delivered this letter to yourself and to Mr. Dickerson this morning.

My name is Gretchen Gutierrez. I'm the Executive Officer for the Building Industry Association, Antelope Valley Region. The letter reads:

"Dear Mr. Dickerson, as president of the Building Industry Association of greater Los Angeles, Ventura and president of Ventura Affordable Homes, Inc., a provider of entry-level housing to our local families, I applaud your efforts to improve our quality of life by reducing water pollution.

"However, another important component of quality of life safe, affordable, decent housing may suffer as a result of some of the components of the revised SUSMP. I urge you and the board to support the Clean Water Initiative, which I have provided you a copy of with my letter of January 20th. This initiative provides a process which will achieve the board's goals by reducing pollution. At the same time, it allows for collaboration of all affected parties in a cost-effective and scientific approach.

"Using up our land, another precious resource, to reduce pollution without exploring other proven techniques merely pits one limited resource against another. We must use our limited resources efficiently to accommodate our diverse community interests.

"Our quality of life includes decent housing, job opportunities, access to education, recreation, clean air and clean water. Comprehensive and collaborative planning with everyone at the table as contained in the Clean Water Initiative is key to maintaining and improving the quality of life that California residents deserve.

"People as well as buildings are part of our environment along with our state's natural resources. All of us must work together to protect our entire environment.

R0072129

"Thank you for considering the Clean

Water Initiative which provides the opportunity to improve California's environment."

It's signed "Sincerely, Lynn L. Jacobs, President, Ventura Affordable Homes, Inc." Thank you.

CHAIRMAN NAHAI: Thank you very much.

MS. ZINKE: Chairman Nahai, I'll try not to abuse your name. I am Dee Zinke, and I'm the Executive Officer of the Building Industry Association for greater Los Angeles and Ventura Counties.

I've been asked to come here before all of you today to talk about the issue of affordability in housing. Less than one-half of Los Angeles families earning the median income can afford the median priced home today. This is 20 percent below national levels. For every $1,000 added to the price of a home, 25,000 families are priced out of home ownership in California.

At any given night here in the southland, more than 100,000 people do not have a place to sleep at night that they call "home." Fifty percent of those are children, and fifty percent of those are children under the age of five.

The regulations proposed today do not take into account any variation in housing type. Ten units of state single-family detached housing are treated the same as ten units of multi-family condominiums. It is a one-size-fits-all edict, which shows no sensitivity to the affordable end of the

R0072130

spectrum housing.

Worse, the proposed regulation hits in fill products hardest where land is scarce and expensive. The inventory of in fill land contains many contaminated sites, and there is no recognition of the environmental benefit of cleaning up these sites for the health of the watershed.

For all the interest in encouraging housing in job centers, i.e., smart growth, this ruling makes it easier for land rich, rural areas to comply but extremely difficult for urbanized areas.

There isn't a builder in this room that advocates we should be exempt from water quality measures. We are amenable and are, in fact, currently implementing long term, best management practices to improve the quality of water runoff in addition to our construction management practices.

You have several options before you today. We would urge you to move forward with the program that encourages most effective BMPs that actually serve to clean the water. If you wish to pursue a numerical standard in your new permit, use the next 18 months to develop the evidence and accepted engineering standards that demonstrate improved water quality. **R0072131**

We are your partners in achieving water quality. We are engaged and support watershed management efforts and as a result have an affinity for

regional pollutant based solutions to protect the health of the watershed, including habitats, estuaries and bays.

California is now in its eighth year of providing less than half of the homes needed to shelter California's existing population. That's 125,000 units a year we're short or up to a million at this point for existing population.

Your job is to improve and protect the water quality. My job is ensure that you fully understand the impacts of housing in that process. Shelter is considered one of the most important basic needs. Clean water is no less precious. If more children are priced out of a home because we are guaranteeing them clean water to drink, I will sleep better at night. Right now, I don't believe the proposed numerical standard will achieve that goal.

The Clean Water Initiative goes much further to addressing our water quality needs. Thank you.

Oh, and I would like to -- if I can address the question about the housing cost or the costs that were raised earlier.

R0072132

CHAIRMAN NAHAI: Well, your three minutes are up. Let's see if there's a question to that effect from anybody on the board, then we'll do that.

MS. LYON: Wasn't that Susan's question?

MS. CLOKE: Is this the percentage? Are

you prepared to answer that question?

MS. ZINKE: I wasn't prepared to answer percentage, but I was prepared to identify that they listed a per-unit cost. You can raise the cost of development, but the costs are passed on to the home buyer. And if you've got $85,000 more, then it's $85,000 more to the cost of the product.

CHAIRMAN NAHAI: It's an $85,000 unit that's --

MS. ZINKE: I'm sorry. I meant $8,500 was what was identified per unit, so it does give you an idea of what the impact would be on affordability. Thank you.

CHAIRMAN NAHAI: Thank you very much.

Mr. Pistone.

MR. PISTONE: Mr. Chairman, members of the board, my name is Ross Pistone, and I represent the Newhall Land and Farming Company. We are a large land developer headquartered in the Santa Clarita Valley.

We recognize that we have a growing population in California, and our primary objective is to provide a desirable quality of life for the citizens of the Santa Clarita Valley. We developed master plan communities that provide a balance of homes, schools, parks, retail and industrial business opportunities.

Our company is strongly supportive of the Clean Water Act. We make continuous efforts to manage our operations to assure compliance with the multitude

of existing environmental regulations.

New development projects are currently required to go through a comprehensive environmental impact report and review process prior to their approval, and there are many restrictions currently in place for those projects adjacent to environmentally sensitive areas.

Developers are also required to comply with several other complex environmental regulations governed by various agencies, including the Department of Fish and Game, Army Corps of Engineers, Air Quality Management District, the State Water Resource Control Board and local municipalities. Often these regulations conflict with one another.

As a pro-active, responsible developer, we have established an extensive erosion control program which cost, approximately, $800,000 in 1999 for the installation and maintenance of erosion control devices.

In addition, we have developed a Storm Water Management Program, which includes an ongoing SUCWRP training program for our field personnel and subcontractors. We explained the critical importance of the Storm Water Management Program, erosion control and best management practices which must be followed.

We also have an in-house SUCWRP site inspection program. A trained inspector visits each of our active projects to assure that we are complying

with our storm water pollution prevention plan and that best management practices are being applied. Citations are issued for noncompliance and immediate corrections are required.

This SUCWRP inspection program concentrates on minimizing the potential for petroleum products and other contaminants to contact the soil, and establishes a check and balance system so that contractors' activities can be monitored and additional BMPs can be employed where necessary to prevent potential pollution.

These voluntary programs are costly but have proven to be extremely effective in addressing any impact that our operations may have on clean water. We believe that new development is not a significant contributor to water pollution if erosion control devices are installed and maintained at the project site perimeter.

We believe that it is wrong for the Regional Board to target the residential, industrial and commercial development industrial by requiring numerical mitigation measures which have no proven scientific or engineering basis. We believe that these measures will directly affect our ability to provide affordable housing and employment opportunities. R0072135

We have worked side by side with the County of Los Angeles and the City of Santa Clarita during the development of the original Standard Urban

Storm Water Mitigation Plans to assure that new regulations being proposed would be reasonable, cost effective and would result in an improvement to the overall water quality.

We believe that water quality will improve through the implementation of the original SUSMPs without numerical standards that were later added by the Regional Board. We believe that being forced to implement the numerical standards being recommended by the board for residential, commercial or industrial development through the use of detention basins and other structural BMPs will create a serious long-term maintenance problem.

We are committed to supporting the Clean Water Initiative as proposed by the Building Industry Association as we strongly believe that through these efforts we will effectively reduce pollution. Thank you for your consideration.

CHAIRMAN NAHAI: Thank you, Mr. Pistone.

Mr. Pearl.

MR. PEARL: Hi. My name is Ray Pearl. I'm Deputy Director of Government Affairs for the greater Los Angeles, Ventura Building Industry Association.

R0072136

This entire process so far has been an illustration of how a public agency can attempt to implement policy based on bad science. No matter what you have been told today, the numerical standard of .75

was a negotiated number resulting from a lawsuit settlement. In fact, the L.A. County standard exists today only because NRDC sued them and forced them to implement it.

There are absolutely no studies that have been done to justify its introduction to Los Angeles County. The proposed numerical standard is not a number based on sound science. The proposal before you simply seeks to deal with an amount of water. The building industry supports a pollutant-based approach that will actually have some effect on clean water. That proposal you've heard about is the Clean Water Initiative.

We have been left frustrated and dumbfounded by your staff who have willingly taken us down this numerical mitigation path. They have put the cart before the horse by saying, "Let's solve some unnamed problem with some kind of solution, and we'll figure the rest out later." That does not make sense. It is not only bad science, it's bad policy.

How about defining the problem? What pollutants do you seek to reduce? What are the nonpoint sources that generate these pollutants? Why not develop policies that will actually reduce pollutions from these identified sources?

R0072137

No one, including your staff, has yet to cite a single study that shows this proposal will be effective in Los Angeles County. I've been calling it

"bad science." It's really no science.

We have a basic question. How will we measure if we abide by these new requirements that we have successfully achieved water quality? We asked Mr. Dickerson that very question in a meeting. His answer was, "There is no way to know." He said, in his words, quote, "We just have to do something." That statement from a public official is unbelievable and rather sad. It is no way to conduct public policy.

It does, however, illustrate one of our main concerns. This policy is a shot in the dark with no chance of achieving water quality. This policy attacks the home building industry, and if you were to believe Heal the Bay, NRDC and others, that alone will solve our water quality program.

You are addressing one minuscule, microscopic portion of the storm water runoff issue. What good is it to clean water only for new development if you have done absolutely nothing to address the millions of people already living here?

You are also under a serious misconception if you believe the environmentalist rhetoric that this proposal will keep beaches open and drinking water safe. To use NRDC's language, it is a "sellout" this time to the environmental community that will have absolutely no impact on the problem they purportedly seek to address.

R0072138

It will not clean the bay. It will not

keep beaches open, and it will not make water safe for aquatic life. As long as I've lived in Southern California I've only heard of beaches being closed because of oil spills, sewage and medical waste. Beaches are not closed because new homes are built.

There is no proof anywhere. Ask Mr. Dickerson, ask Xavier Swamikannu that this proposal will solve any of these problems. Remember, we are just supposed to do something so that we all feel good about ourselves. How about actually doing something that solves a problem?

My final question is this: Based on sound science what specific contaminants do you and your staff attribute to new housing? The answer is still unknown and unaddressed by this proposal. We support a proposal, the Clean Water Initiative, that could prove scientifically if we abide by these new requirements water quality will improve. We do not, however, support a do nothing numerical standard. Thank you.

CHAIRMAN NAHAI: Thank you very much.

Following Mr. Gale, Mr. Ramy Awad, Ms. Elaine Freeman and Mr. Tak Fujii.

R0072139

MR. GALE: Good afternoon, Mr. Chairman and board members. My name is Charles Gale. I'm the Director of Government Affairs for the Building Industry Association. I'm in charge at the regional level of regional agencies.

I stand here before you today with almost 11 years of experience in assisting contractors and home builders comply with environmental rules and regulations. I've entitled my speech here today "Other Good Public Policies." In doing so, let me begin.

I have worked with several regulatory agencies that are faced with complying with federal laws and regulations. Such agencies include the US Fish and Wildlife Service as they implement the Endangered Species Act and the South Coast Air District as they implement the Clean Air Act.

In my experiences with the US Fish and Wildlife Service, the service always begins their process by identifying an endangered species with a biological opinion, which is subject to peer review, a process. Then the service moves forward with listing the species, assessing the critical habitat, and then develops a recovery plan to ensure the endangered species will be protected and saved. Today we can credit this program with the return of the bald eagle as well as many other species.

More familiar with this agency is the South Coast Air District. The AQMD was created because the South Coast Air Basin had the worst air pollution in the nation. I think we all know that. We've heard that. For decades, the South Coast Air District has exceeded federal air quality standards. Therefore, the AQMD established an aggressive plan to clean the air in

Southern California.

The adopted rules, which I participated in with contractors and home builders, were not easy to develop, and they were not simple. But they were developed by identifying a pollutant of concern, establishing a baseline from which to work from and then locating the industry that was responsible for the pollutants. Because of the process that AQMD has gone through, L.A. no longer hosts the worst air quality in the nation.

I bring these two agencies to your attention because they are under similar -- federal mandates similar to this agency because of what they have to achieve in their environmental goals. But they always begin the process by identifying the problem, establishing a baseline and developing a process to achieve the targeted reduction of the environmental goals they're in charge of.

This fundamental process is not present in the proposal before you today. The SUSMP proposal puts the cart before the horse by offering a numeric standard as a solution before the work has been done to identify the problem.

In conclusion, I suggest the board consider the Clean Water Initiative, which is this you have in front of you signed on by 33 companies, agencies -- not agencies but trade associations that are concerned about this issue.

It calls for identifying pollutants once again, targeting the source of pollutants and then, and only then, developing a plan that will mitigate those pollutants and achieve clean water. Because it offers the simple process, the Clean Water Initiative is the best choice in front of the board.

Further, it closely follows a process called for by SCAG and the municipalities that will even bring stronger clean water sooner to our industry -- to our region. Thank you for your time.

CHAIRMAN NAHAI: Thank you, Mr. Gale.

Are we okay to continue? Does anybody need a break?

MS. CLOKE: How many more?

CHAIRMAN NAHAI: We have a lot.

MS. LYON: I think a short break is in order.

CHAIRMAN NAHAI: Okay. A short break. No more than ten minutes. We'll see you in ten minutes.

(Recess.)

CHAIRMAN NAHAI: Let's come to order, please. Take your seats, please.

Okay. The next speaker is Mr. Ramy Awad.

MR. AWAD: Good afternoon, Mr. Chair, members of the board. My name is Ramy Awad. I'm a registered civil engineer in the State of California. I do land development projects.

I am here to voice my concern regarding the lack of data about effectiveness and cost of implementing the numerical standard. I had an opportunity to review the sample calculation for using the numerical mitigation. That sample was talking about six-and-a-half million dollar project in the city of Los Angeles.

And while I agree with the method of calculating and determining the size of the required detention basin or retention basin, I don't really agree with the cost for that basin and cost for maintenance. That calculation indicates that the size of that basin would be 40 feet wide, 40 feet in length by 40 feet and width and it varies in depths between 9 and 10 feet. And when doing the cost of the land itself, accounting for a 40 foot by 40 foot, which is 1600 square feet, and came up with a dollar amount of $28,800.

While in reality, that basin is going to be 10 feet deep, and you cannot come and construct a 40 by 40 basin, which is 9 or 10 feet deep without some sort of retaining walls all around it or laying the slopes flat. And if you do so, you have to account for cost of the retaining wall or you have to account for cost of the land when you lay slopes flatter.

In my calculation, if you lay the slopes flat at the 2 to 1 ratio, which would be the minimum acceptable for safety reasons, that would increase the

cost from $28,800 to $115,200. And maybe the dollar amount is not what we're discussing here now, but all of a sudden now it's a cost that we think it's $28,000, it's $115,000. That's four times as much. And that's something we ought to look into it and consider how -- what's the effect and what's the benefit for that?

The same example also for maintenance. I locate $33 per year for maintaining that basin, and I find it very hard to imagine that a cost to clean up a basin will be $33. If you have a swimming pool, and you bring someone to maintain it for you, it's going to cost you much, much more than that. Also, if you want to hire a handyman or a laborer to come and do any kind of work on your home would cost you much more than the $33.

And my point here is we really don't have enough data to determine the effectiveness and the real cost on the home building industry or any development utilizing the numerical standard. There are other alternatives and other proposals that I urge you to look at. Listen to the engineers. Listen to the city engineers and listen to the developers. Thank you.

CHAIRMAN NAHAI: Thank you very much.

I'd like to urge as we go through this, given the fact that the hour is getting late and we have something, like, 30 cards left, if the point that you want to make has already been made by somebody else, it doesn't do any good to hammer the board

constantly with exactly the same arguments. It really doesn't. All that does is just desensitize us to what you're trying to say.

Okay. With that, the next card is from Mr. Roger Werbell, then Miss Kathy -- or Miss Katherine Butcher and Miss Dorothy Green. Any of those three people here?

MS. CLARK: Dorothy Green had to leave and she asked me to present this to you. I'm Mayor Pro Tem of the City of Rosemead, but I'm also a board member of the Los Angeles and San Gabriel River Watershed Council. And we -- so this is to be distributed to you, and I just want to say one thing --

CHAIRMAN NAHAI: Three minutes per person. Please, Miss Clark.

MS. CLARK: That wasn't three minutes.

CHAIRMAN NAHAI: No. You had your three minutes already. Remember? Those are the rules.

MS. CLARK: Okay.

CHAIRMAN NAHAI: Thank you so much.

With that, I'd like to move to Miss Jacqueline Lambrichts. Not here? Followed by Miss Heather Kuiper and Mr. Karl Brusketter it looks like. I apologize if I'm mistaken.

MS. LAMBRICHTS: Jacqueline Lambrichts with Friends of the San Gabriel River, a new nonprofit water quality focused organization supports the numeric design standard without exception as stated in the

letter in your packet.

In the process of starting a new organization in eastern Los Angeles county, it is very encouraging to find cities in the San Gabriel Valley, such as Baldwin Park, El Monte and Pasadena that are pro-active in supporting the need for a .75 inch designed numeric standard, and their letters are included in your packet.

And just a few reoccurring statements in their letters, cities continuously updating, reviewing its policies to ensure the community quality of life as well as the protection of its natural resources. They believe the overall goal of SUSMP requirements for new development and redevelopment must be to effectively reduce pollution in storm water and urban runoff and work in partnership with the Regional Board. And again those letters are in your packet. Thank you.

CHAIRMAN NAHAI: Thank you.

MS. KUIPER: Good afternoon. I'm Heather Kuiper. I'm trained as an epidemiologist, and I'm used to talking about the data on an issue, but I think that many people have done a good job of that. So instead, I'm here to speak as a community member.

I'd like to tell you about a few of the ways that I've felt the impact of the Los Angeles area's runoff problem. First, when I worked for the county health department, some coworkers and I founded an ocean swimming club. We'd meet at my home on the

coast before work, get out our wet suits, run down the beach, jump into the ocean and swim the mile back to my house where we'd get ready for work and carpool. It felt great, and at the time I felt that I loved Los Angeles, and I loved the beach.

But then I started to feel chronically sick, and, finally, I realized that I'd have to basically stop swimming in the ocean if I wanted to feel healthy. I felt angry and scared that I was so vulnerable to a public policy issue, especially when it led to the end of a wonderful activity that should be part of the fabric of a healthy community.

Another way that I've personally experienced these types of issues is in experiencing the amount of trash that's on the beach, especially after storms. On several occasions, I've gone out to pick up trash and been completely overwhelmed by the task. I also take all of my guests out to the beach, and I take them to the Ballona Lagoons to look at the wildlife there. And when I go, I want these activities to be a source of pride to prove that L.A. is not as bad as everyone thinks it is. But each outing confronts me with an overflow of trash, and I don't feel pride, and my guests leave with an unchanged opinion of Los Angeles. **R0072147**

Finally, my intention here today is to bring home to you that these standards in protecting the beaches and the broader environment also protect

people and build the foundation of an integrated society.

I am here to be -- in an attempt to represent to you the people of Los Angeles. I cannot do an adequate job because my face is only one color, my heritage is from only one continent and I only speak one language in my home. But if you go to the beaches, you will see that they are a magnet for all of the different races and cultures of Los Angeles. There's a peaceful point of convergence for the people, and we need this place to be healthy and safe and a place people can feel proud of. A safe beach and ocean is a vivid reminder that our public officials are looking out for us.

In your deliberations, please keep in mind these broader implications of your decision. I urge you to support rigorous mitigation of urban storm water without loopholes and exceptions. The community awaits your decision and thank you very much.

CHAIRMAN NAHAI: Thank you.

Next three cards I have are from Julie Barr, looks like Miss Angu Bera and Dayna Harary.

A PERSON: They're all gone.

CHAIRMAN NAHAI: They're all gone?

A PERSON: They are members of the community who've had to leave.

R0072148

CHAIRMAN NAHAI: Okay. I will note for the record that all of them wanted to speak in favor of

the staff proposal.

Were you next?

MR. BRUSKETTER: Yeah, I was next.

CHAIRMAN NAHAI: You were?

MR. BRUSKETTER: Yeah. I was the name you couldn't pronounced.

CHAIRMAN NAHAI: Oh. You're Karl?

MR. BRUSKETTER: Right.

CHAIRMAN NAHAI: My apologies.

MR. BRUSKETTER: No problem. My name is Karl Brusketter.

CHAIRMAN NAHAI: I wouldn't want you to get the impression that I'm trying to hurry anything along.

MR. BRUSKETTER: No. I'm not in a hurry anymore.

CHAIRMAN NAHAI: I'm all ears.

MR. BRUSKETTER: All right. Thank you for the opportunity to speak. I'm here speaking as a community member, and I'm also a member of Heal the Bay and NRDC, and I wanted to tell you a little about my reality.

R0072149

About early last year I had some relatives come out from Ohio, and we went down to the beach, and we're walking along the beach, and there's trash everywhere. Everywhere. About the only good thing about the trash is that we could play hopscotch and see if we could land on patches of sand, and it

wasn't very fun.

And the other thing we looked and there's signs all over saying that you're not allowed to swim in the water because it's not safe to swim in. That was the other thing that was going on.

So I looked at my relatives, and it was embarrassing to live in L.A. and see that, that we couldn't go in the water, there was trash all over the beach. It was ridiculous.

So they went home back to Ohio with their impression of L.A. and our beautiful coastline and water. And I thought, well, I know this is not an easy issue to resolve. I know it's going to take a lot of effort on the part of the community, governmental agencies, like yourself, industry, commercial, everyone; right? But I know it can be done.

And I see this piece of regulation is a huge step in the right direction. And so for you, I don't want you to get in my shoes or in the shoes of anybody else here. I want -- you can stay in your own shoes, and I want you to frame the picture. Your relatives are going to come out and you're going to go down to the beach to enjoy it, and you're either going to see trash all over the beach, and the kids won't be able to go in the water, and you're wondering what you're going to do next. R0072150

Or you can have the second picture where you go down there, the beach is beautiful, you're

enjoying the day. There's no trash on the beach. Everybody's playing in the water. There's maybe dolphins swimming by.

I hope that you look at those two pictures, and I hope that you'll make the move so that we can get the picture too. Thank you.

CHAIRMAN NAHAI: Thank you very much.

The next three cards are from Miss Shelly Magier, Mr. Bob Warnock, and I note there was Mr. Conner Everts had a card but I know he's gone. Is Miss Magier here?

A PERSON: She's gone.

CHAIRMAN NAHAI: Mr. Warnock.

A PERSON: He's gone.

CHAIRMAN NAHAI: Mr. Moore.

MR. MOORE: Somebody's here.

CHAIRMAN NAHAI: There you are.

MR. MOORE: Hello, Mr. Chairman and board members. My name is Gary Moore. I'm with the City of Los Angeles. I'm the Storm Water Program Manager.

I think you heard yesterday that our city council does indeed endorse the plan that's in front of you today. I'd like to highlight a couple specific areas of our comment letter. One has to do with the waiver.

R0072151

As the board and the executive officer has entrusted the cities to deal with many or almost all the issues in the permit, we respectfully request

that jurisdiction to determine when a waiver is necessary would be granted to the cities. We believe that this would expedite the process and not add burden to contact the Regional Board on this issue. So -- and we also propose that we would annually with our reports submit any waivers that we had granted during that year so that everybody would know what we're doing.

The next area has to do with -- we talked a lot about the vehicles and that they seem to be causing a lot of the pollution here, and most of everything we're doing here is treatment or retention. The USEPA and the State of California has successfully worked with engine and car manufacturers to reduce vehicle air emissions. There may be opportunities to minimize vehicle equipment leaks through vehicle modifications.

We're proposing, since vehicles are called in on a regular basis for emission test, if it would not be possible to educate the vehicle operators as to the impacts of such leaks that would result in the minimal cost to the state program while potentially resulting in potential benefits to the water quality.

Another area that we addressed in our letter to you is in data gathering. We recommend that the Regional Board establish a regional ambient water quality monitoring program. What we're saying here is that similar to the air quality network, we would start sampling a base -- to establish a baseline, and during

the next year and a half while we're preparing to negotiate the new permit, we would begin to gather data. We believe that this would really help the public to gain support if indeed we go further with this program than is proposed here today.

That concludes my comments and the City of Los Angeles appreciates all your efforts. Thank you very much.

CHAIRMAN NAHAI: Thank you very much, Mr. Moore.

MS. CLOKE: Mr. Nahai, I have a question but can I have a copy of his comments?

CHAIRMAN NAHAI: Do you have an additional copy of your comments?

MR. MOORE: Those comments that I just expressed are in the letter that we distributed. Yes.

MS. CLOKE: Oh. Okay. I have that. Thank you.

CHAIRMAN NAHAI: Thank you.

The next three cards I have are from Mr. Michael Huls, Mr. Dan Grissete, and Miss Marsha Hanscom. Are any of those people here?

A PERSON: Mr. Huls has left, Mr. Chairman.

R0072153

MS. HANSCOM: Good afternoon, honorable board and staff. My name is Marsha Hanscom. I'm Executive Director of the Wetlands Action Network and Vice Chair of the Conservation Committer for the Sierra

Club, Los Angeles Chapter, which has more than 50,000 members here in this region.

We strongly agree with the staff's proposal to include the .75 inch numerical standard and, in fact, think that is absolutely a baseline. I don't think any of the environmental groups that were here today suggested that this would totally clean up our beaches and totally improve everything. We're just saying that we need to stop of the hemorrhaging, and this is the minimum acceptable.

We also strongly oppose the exceptions and exemptions that have been added since the fall, and I'd like to just suggest that -- you know, I understand your charter to be that you're not to balance the environmental municipality and business interests but rather to ensure optimum water quality in our region, in our creeks, our rivers, our wetlands, our aquifers and the bay.

And so in light of that, I hope you'll agree with me that we cannot continue to practice business as usual and expect better results in terms of our water quality.

Federal policy under the Clean Water Act, not the Clean Water Initiative, the Clean Water Act, which you have the authority to carry out as our state water regulatory body includes new guidance under the Clean Water Action Plan which says this nation has a goal to recover 100,000 acres of wetlands each year.

Now, this storm water mitigation plan can help us reach this goal. 98 percent of our we lands are gone in this area, and that's part of the problem, part of why we have so much pollution.

Let's remember what's underneath all this pavement. La Cienega, the swamp, La Ballona Estuary created by the confluence of L.A. River, Ballona Creek, Walnut Creek and Centinela Creek. If we reconnect the water with the land, this will help us minimize flood damage and remove pollutants in our waterways.

Board Member Diamond, you asked a very good question earlier about the rooftop exemption related to increasing impervious surface. This ill-founded exemption will only encourage the trend of decreasing water that is soaking into our soil. The idea is not to eliminate rainfall by catching it off the roof and sending it quickly to the bay but to allow rain water to be part of the ecological cycle that nature intended.

The gas station and parking lot exemptions are also just ridiculous. All of these new and redeveloped facilities need to be in compliance.

And I'd like to ask you to think about another vision for our parking lots and consider that in between the rows of parked cars there might be prairie needle grass and California poppies. Two species that are native and actually thrive on human trampling, but they've been decimated by years of

cattle grazing, paving, and those kinds of things are easy and inexpensive to implement.

We could have color, and we could have song back in our areas. This would attract songbirds. This would attract a lot of the species that we need to have a healthy ecosystem.

So in sum, we need your leadership to help restore our natural beauty and the quality of life in Los Angeles. And so I ask you to please approve the numerical standards, remove the exemptions that would effectively gut that, and as to the proposal submitted that all residential development be excluded, I'll just leave you with the words of Henry David Thoreau who said "What is the use of a house," even an affordable house perhaps, "if you haven't got a tolerable planet to put it on." Thank you.

CHAIRMAN NAHAI: The next card I have is great. It has no name on it. But under "representing," it says "myself and my son." So if there's a person here representing yourself and your son, there you go. Good for you. I like to represent my son wherever I go too.

MR. POPE: Thank you very much. My name is Bill Pope. And, actually, it'll be more accurate to say that I'm here -- Bill Pope, P-o-p-e -- to represent my grandchildren because it's actually too late for myself and my son.

CHAIRMAN NAHAI: I'll add that to the

card.

MR. POPE: Please.

I say it's too late for me because I started skin diving when I was in my middle teens, and I've had the displeasure of seeing the demise of our coastal area over the last 40 years from areas that had giant kelp forests and spectacular sea ferns to areas that for all practical purposes today are biologically dead.

You know, as a kid maybe you had too, some of you that are my age had the privilege of standing on the Santa Monica Pier watching the whales go by rather than having to charter a boat to go out 20 miles to sea. They don't come in too close today. I'd like for my grand kids to have that opportunity again.

But that's kind of a platitude. Let me tell you about a specific problem. My son, 26 years old, very talented musician, sound engineer, plays six instruments, composes, produces his own music, just released his first CDs as the Spinning Top and Orange. I promised I'd say those words. He -- his second CD is very inspirational music based on his experiences of life growing up around and in Santa Monica Bay. That's the good news. He's about to become financially independent.

The bad news is that he's losing his hearing from repeated ear infections that at least two

of the seven doctors, after two operations that he's been through, say that feel strongly enough that it's linked to his experiences in Santa Monica Bay because they can trace back to when it happened and what he was doing, that they told him to stay out of the bay. He's no longer -- not only has he lost his ability to enjoy the ocean, he may be losing his ability to produce income.

I came here to thank you for doing something, as some people say. My God. We haven't done something for 50 years. It's nice that we do something. Maybe we can turn the tide, but I am dismayed about all the different exemptions that I'm hearing about today that seem to be filtering in.

If we exempt rooftops and say you don't have to consider that in calculating the size of whatever you do to filter out the pollutants, you've exempted, you know, 50 to 80 percent of the land area. The result is going to end up being that the water is going to wash across the lawn and into the ocean -- again into the street and carry the pollutants to the ocean.

It's common practice to channel water away from your homes. In my neighborhood, everybody that I know of has built underground pipes to take the roof water out of the gutters and take it straight to the stream. I'm guilty of that myself. After hearing about this stuff, I'm going to go home and drill holes

in those pipes so it'll filter out.

But if we -- if you also exempt compacted soil, you end up doing the same thing. The water is going to -- even though it drops on area that's not polluted, it's going to run off, go in the street and wash more pollutants out there.

If we exempt areas -- restaurants, that are 5,000 square feet or less, according to the statistics presented by their representatives today, that's going to exempt all of them, all the new fast-food restaurants because they're all smaller than that.

So I want to urge you to implement this proposal as planned without exemptions and start doing that something that we should have done 50 years ago. Thank you very much.

CHAIRMAN NAHAI: Thank you, Mr. Pope.

The next three cards I have are from Mr. Ray Tahir, Mr. Ross Clark and Mr. Steven Braband.

MR. TAHIR: Mr. Chairman, board members, staff, good afternoon. Once again it's a pleasure being before you. My city fully supports the need for numeric design standard but only as a sizing formula for treatment BMPs. It would be silly not to have one, but it would also be silly to have a design standard act as a determinant for numeric -- for treatment retention controls for all the seven categories of SUSMPs revision that staff is recommending.

Also we're very much in support of SUSMPs, but they're opposed to the addition of two new SUSMP categories. This is because they're not included in the L.A. County permit.

My cities favor the prescription of retention treatment BMPs as long as they are allowed the discretion to determine when they should be prescribed. That is what the permit intended, and that is what other NPDES permits in California require including neighboring Ventura County, including neighboring Orange County.

What my cities are opposed to are mandatory retention treatment BMPs such as catch basin inserts and detention basins. Why? Well, for one the revised SUSMP allows developers to select any retention treatment control on that BMP list that includes structural treatment controls, as long as the developer meets the numeric design standard requirement. It matters not if the control is ineffective.

For example, the developer could comply with the retention treatment requirement by selecting catch basin inserts which are very cheap, about $800 a unit. The problem, as indicated in a recent study conducted by Woodward Klein for cities of Northern California, Alameda County in particular, is that these devices don't work well. The mesh filters that they use clog up easily. Some of them fail or lose significant chemical removal efficiency after each

storm event. As a result, Northern California cities disfavor their use. This was also why Ventura County discourages them.

In consideration of the foregoing, it is recommended that the board direct staff to approve the revised SUSMP excluding the mandatory retention treatment controls. Further, I'd like to point out to you that it appears that the Regional Board staff has not fully evaluated SEQWA in the light of these SUSMPs. I don't think the significant impacts of those requirements that are contained in staff's report has been fully evaluated and they need to be quite obviously.

On a more cheerful note, I'd like to congratulate you on your 50th anniversary, and I look forward to seeing you this evening under more festive circumstances.

MS. LYON: Ray, before you leave.

MR. TAHIR: Yes, ma'am.

MS. LYON: First part of your testimony, I was a little unclear about the cities you represent and their stance on the numeric standards.

MR. TAHIR: Okay. There are all kinds of interpretations of what numeric standards mean. Okay. Initially the numeric standards were used as determinant for requiring all subject new developments to install mandatory retention controls. Okay. That's been changed now. Now they're not talking about

numeric standard in that light but rather as a design standard. Okay. And we have no problem with that.

We need to know what size to design these structural controls in order for them to work properly. Okay. But we do not want them to act as a determinant for each of those new developments to mandatorily impose retention treatment controls because they're so extreme and very costly.

MS. LYON: What cities do you represent?

MR. TAHIR: Well, some of them are out here: Cerritos, Lakewood, Whittier, Lomita, Azusa, Duarte and a cast of others. I can't remember them all. Thank you

CHAIRMAN NAHAI: Mr. Clark.

MR. CLARK: Good morning. Or I'll change that now. My name is Ross Clark, and I'm with the California Coastal Commission Water Quality Unit.

On January 20th, our Deputy Director Jamie Kooser wrote the Regional Board a letter in support of the Standard Urban Storm Water Mitigation Plan. Today I wish to voice the commission staff's support of both the proposed Standard Urban Storm Water Mitigation Plan and the region-wide numeric design standards for post construction BMPs.

The proposed plan is a progressive step towards protecting and restoring the region's water quality and protecting coastal resources, including the use of natural habitat, public access and recreation.

Integration of BMPs into new development is a critical next step in limiting urban nonpoint source pollution. Developing standard guidance for the entire region will also help to promote watershed-wide protection for nonpoint source degradation.

Integration of post-development BMPs as proposed by this plan is consistent with the statewide NPDES pollution control plan recently adopted by the State Water Resources Control Board and the Coastal Commission. The further protection of environmentally sensitive areas corresponds with Coastal Commission's goal of protecting critical areas -- critical coastal areas of all types, including quality of water associated with wetlands, estuaries, public beaches and offshore coastal habitats.

We hope that today's action will facilitate the use of effective and appropriated BMPs that improve water quality while allowing for future development. The Coastal Commission is committed to working with the Coastal, Regional Boards and the State Water Resources Control Board within this 15-year strategy to improve the tracking of a new BMP implementation and the assessment of their success.

We feel that only through the continued assessment of BMP effectiveness and providing up-to-date technical assistance can the public be confident that BMPs are worthwhile. As of today, it looks like the public and the NRDC have provided, I think, the

most up to date and BMP effectiveness assessment that we've heard. Thank you very much.

CHAIRMAN NAHAI: Thank you, Mr. Clark.

Are you Mr. Braband?

MR. CLARK: I was Mr. Clark.

CHAIRMAN NAHAI: Oh. You were Mr. Clark. Of course you were. You still are. I hope you will continue to be for a long time.

After Mr. Braband, we have Mr. Royall Brown, Mr. Maurey Frohman and Mr. Scott Stone.

Go ahead, please.

MR. BRABAND: Good afternoon, board members. My name is Steven Braband, Biosolutions, Incorporated. I was on the Malibu Creek Watershed Facilitation Group representing the City of Malibu Waste Water Study Group for four years. I am board -- on the board of directors at the California Onsite Waste Water Association.

A division of our company handles operation and maintenance of decentralized waste water systems of commercial properties. The majority of them are in Malibu, but they range from San Louis Obispo down to San Diego County.

R0072164

The reason I come here today is that in many cases I've -- just recently I've been approached by my clients and my -- some of the vendors about operation and maintenance of some of these storm water systems. I'm here today not to see if but how our

maintenance operations are going to proceed.

First of all, I'd like to say that I support the direction that your board is going and the direction that your executive director has made recommendations for, and I fully support that. I do have some -- a few comments and clarifications of things that came up today that I'd like to address.

One of those is the accountability of maintenance. If you're going to actually enact this, I think one of your board members was going to say how are you going to ensure that once they're installed they are going to be maintained and how that's going to work. So that's a very important aspect that you have to take into account.

Another thing is consistent ordinances by city. You're going to mandate the cities to process orders, but what tends to happen at that time is they start getting different and an engineer has to figure out what city he's doing it for, what problems are going to be encountered. So if we could have consistency there, I think that -- I think we would go a long way also.

Because I deal with maintenance of about 70 percent of the restaurants in Malibu, I'd like to say that as far as restaurants are concerned, some of those small fast-food restaurants actually produce more waste than larger restaurants, and if you think of the concentration with the drive-thrus of exhaust on the

runoff, that's an issue that we should really address too.

Grocery stores with delis, I think that was brought up earlier. That we have had problems with because you don't really think that that's a problem, but the grease created and the maintenance of that for storm water becomes an issue.

Okay. Fecal contamination by pigeons and seagulls on rooftops is something that wasn't addressed, but I have had to do it, and I see I'm out of time, so thank you very much.

MS. LYON: Could you tell me the business you're in again, please.

MR. BRABAND: We have an operations in maintenance of onsite wastewater systems or decentralized wastewater control systems. Many -- well, it's not many but more and more in the rural areas wastewater systems are being treated onsite. We have --

MS. LYON: Okay. That's fine. Thank you.

MR. BRABAND: Yeah. Okay. All right.

CHAIRMAN NAHAI: Thank you.

R0072166

Mr. Brown.

MR. BROWN: Royall Brown, a resident of San Gabriel Valley. I'm a retired registered engineer in the State of California. Started my career in water quality in the State of California Department of Water

Resources. The last position I held was as an elected board member for the San Gabriel Valley on the Municipal Water District. So I've had over 40 years of experience in water quality and water quality problems in the State of California.

Yesterday we had a small urban runoff storm. The neighborhood I live in in San Gabriel Valley, I'll tell you, not one drop of that water ever reached the ocean. Why? Because we already have installed in the San Gabriel Valley multiple catch basins known as spreading grounds and diversion dams, rubber dams that already catch the water and divert it. So our receiving waters for our urban storms, some 90 percent by calculation, according to the county, of our storm water already goes to our receiving body, which is the groundwater basin in San Gabriel Valley and Central Basin in the southern portion of the county.

To make a developer -- like, I live in a canyon, a branch of Walnut Creek. I've lived there for 26 years. There's a big vacant lot that a developer has said that can have about 55 town homes on it. It would be redundant to have him put a catch basin in on a property when the public, through taxes, have already put in a catch basin downstream.

I think your regulation needs to recognize where there is already public facilities to catch this water and keep it from going to the ocean.

R0072167

You heard a lot today about beach pollution, pollution along the coast. That's a problem in itself. But if you already catch 90 percent of the urban runoff in San Gabriel Valley, San Gabriel Valley isn't really contributing to that.

And your rule about three-quarters of an inch wouldn't stop the big storms anyway. It's the big storms, once or twice a year. We have a big storm in San Gabriel Valley where any water is allowed to go to the ocean. That's not the regular storm that causes the beach pollution because on that big storm there is a horrendous amount of water going down everywhere.

We also in the processing, mother nature has provided us conveniently processing in our spreading grounds that clean up oil spills, the bacteria and the viruses that are naturally there because this area I live in, there is underlaying by oil. The oil is seeping up all the time. Otherwise, we'd have standing oil in the community if we didn't have the viruses and bacteria that clean up our spreading grounds.

So I ask you to change this permit. Make it a bifurcation by watersheds, and I understand that SCAG has suggested that to you, and I would support this type of provision only if it's amended to make it realistic to those who have already spent millions upon millions of dollars to correct this urban runoff problem. Thank you.

CHAIRMAN NAHAI: Thank you, Mr. Brown.

The next three cards are for Mr. Maurey Frohman, Mr. Scott Stone and Miss Leslie Mintz.

Mr. Frohman.

A PERSON: He's no longer here.

CHAIRMAN NAHAI: Mr. Stone.

A PERSON: I think he's in the foyer.

CHAIRMAN NAHAI: Well, Mr. Stone?

MR. STONE: Did I hear my name?

CHAIRMAN NAHAI: Are you Scott Stone?

A PERSON: No.

CHAIRMAN NAHAI: Is there a Scott Stone anywhere?

A PERSON: He's left.

CHAIRMAN NAHAI: Okay. All right. Ms. Mintz, Leslie Mintz.

MS. MINTZ: Leslie Mintz here for the public. I see and I am awakened. I hear and I am moved. I do and I understand. It's a Chinese proverb about how to learn. The permittees, the cities, can do what this standard proposes.

For months, the Regional Board has been through a detailed due process, been trying to do something. Three-and-a-half years of process, multiple opportunities for comments, versions, workshops, hearings. The provisions of the permit have been satisfied. Moreover, once the deadline six months ago, occurred the permit requirement kicked over into

adoption. The due process requirements are over.

On behalf of my environmental brethren who were here by the bus load earlier, I would ask you to please approve these standards without arbitrary exceptions that cause confusion and I think create more work for Regional Board staff and, as the EPA requested, without delay. Thank you.

CHAIRMAN NAHAI: Thank you very much.

The next card is from Mr. Charles Redden, Mr. Robert Wright and Ms. Heather Leamarinda.

MR. REDDEN: Good afternoon. My name is Charlie Redden. I'm a senior management analyst for the City of Covina. I will be responsible for implementing this plan in my city, and I don't feel that -- and I feel as it stands now that it can't be done.

What is the plan? I'm not sure. And by the board's confusion earlier this morning, I think you understand my questions. I have two different plans dated on December 7th and haven't even seen the plan dated January 21st. I received change pages two days ago to a plan that didn't match any plan that I have. What kind of review is possible under these conditions?

I have some questions and some answers have already come forth. But somebody who just gets the plan and has to implement it doesn't know because he wasn't at this meeting. Does a 5,000 square foot restaurant mean floor space, include the parking lot or

lot lines? What is the commercial stand alone parking lot? What does that mean?

By the SUSMP, an automotive repair shop includes SIC 5013. This is wholesale distribution, motor vehicles supplies and new parts. And as SIC 5014 that's wholesale distribution of tires and tubes. What is the storm water problem with these facilities?

And do I have to ask the AM PM who wants to come into my city to provide their profit and loss statement so I can determine if they are going to be a gas station or a restaurant or something else?

There's not been enough time and thought on this SUSMP. I urge you to follow the agreed-upon procedures and process that we had in the permit and do it right so the plan can be implemented. Thank you.

CHAIRMAN NAHAI: Thank you very much.

Mr. Wright.

And finally Miss Leamarinda.

MS. LEAMARINDA: Is it evening yet?

CHAIRMAN NAHAI: It's getting there.

MS. LEAMARINDA: Good afternoon. Thank you for letting me be last. I'm in a unique position. I work for the City of Calabasas. I'm the Storm Water Program Manager there. I think we have one of the most comprehensive storm water programs in the county.

But I also have the benefit of working with a lot of other cities, and I think what's evident here is that we're living and we're trying to implement

these programs in a culture of distrust. Nobody trusts each other here. It's sad and it's frustrating because what really needs to happen is that we all need to work together to find the water quality solutions. That's the only way that our beneficial uses are going to be restored. Ever. Period.

Storm water -- the problem with storm water is really well understood at the beach. We all know there's a problem. But it's not well understood at the source. Everyone's looking for a cannon, and it's a really a thousand BB guns with really the same equivalent impact as a cannon. And that's why if it was easy, it'd already be done. It's not easy. It takes a lot of time, a lot of effort and a big commitment from a lot of people.

That's why I'm proposing that we look at this as something where we're going to look at an accelerated TMDL process to implement this. Rather than just a volumetric approach.

I think it'll be more effective when we do the TMDLs we can implement best management practices that are associated with that TMDL for pollutant removal capability with the understanding of beneficial use. And then it's not a blank check. There is a final piece.

R0072172

We know that there's a problem in the water. These are -- these reaches of whatever river, you know, if it's Malibu Creek, if it's L.A. River, if

it's San Gabriel River, we know that there's a beneficial use impairment. We know pretty much what the chemical -- the big chemicals are at least for the next few years, so why not embrace that process, which is already a stakeholder process, that will deal with the pollutants of concern and will allow cities to priorities. Without it the water will not get clean.

We're assuming that all the pollutants -- for example, a lot of these -- the BMPs that are listed in the SUSMP right now have nothing to did with bacteria. Nothing. There's no disinfection. There's no -- that's what I'm listening for. I can guarantee you the bacteria isn't going to get solved with the SUSMP.

Without inclusion of the TMDL, we're going to have a schizophrenic program where we have the TMDL process over here that we have to do with this three-quarter inch limit over here and trying to figure out how we're going to get these things to merge later on is not going to work. We want to restore the beneficial uses. That's the goal. That's what's in the basin plan. That's where we should be heading. Not just figuring out what in piecemeal the way of kind of maybe we'll get there some day. **R0072173**

In my lifetime, in 25 years from now, I want the beneficial uses restored in this water. It's not going to happen with just a three-quarter inch limit and to assume that we're going to be affecting

development policies for the next, you know, 50 years and it's going to end up with water quality is a farce. It's not going to happen.

We all need to work together to find an answer to clean water solutions in our lifetime and stop worrying about being the side that's right. Thank you.

CHAIRMAN NAHAI: Thank you very much.

All right. That concludes the public cards that we have.

Did I hear a plaintive voice from the back of the room? What's your name?

MR. WRIGHT: Robert Wright.

CHAIRMAN NAHAI: Oh. I called you.

MR. WRIGHT: Well, you said my name was Stone or something. I haven't been stoned in such a long time I don't remember what it was like.

CHAIRMAN NAHAI: I called Robert Wright and you have a nickname which is Rusty.

MR. WRIGHT: I don't know why.

CHAIRMAN NAHAI: Because the card I have for you said "Robert Rusty Wright."

MR. WRIGHT: Yeah. Do you want me to give what I got here? The roof area.

CHAIRMAN NAHAI: Go ahead. Three minutes. R0072174

MR. WRIGHT: There you go. Some attorney wanted me to get this in the record. It applies only

to roof runoff with essentially no pollutants. It has the dust and fall out that would have fallen on the natural flora and fauna anyways.

But then when we did some numbers with -- I did some numbers Mr. Bill Pope. Yet on an average 3,000 square foot house, if you get an inch of rain, you get 1440 gallons off the roof, and we were trying to figure out whether you should have a leach line up on that, but then you have to do a diverter thing.

They just -- in front of my folks' house, they just put in one of the bay -- one of the 62 in the Santa Monica Bay. There are 62 outfall pipes, and they just put in one of the low flow diverters, so I get to look through that, and they're waiting for the electronics to come in on when the valve pops in and stuff. So I know a little bit about it.

And the other thing I wrote was: Why don't you just get job done and hire some people who know what they're doing, who know the construction business, who know economics and bring them together and get something that will actually do the job? Did I make my point?

R0072175

CHAIRMAN NAHAI: Thank you.

MR. WRIGHT: Thank you very much.

CHAIRMAN NAHAI: If there is anybody in the audience who feels that they have a new point that hasn't yet been expressed, I'll allow you a minute at the podium. A new point that hasn't yet been

expressed. If you said that you feel there isn't enough data -- okay.

MS. CLOKE: You have 22 seconds.

MR. YOUNG: Oh. I believe this is a new point, and it's the question of the definition of commercial, which was banded around -- by the way, for the court reporter I'm Rufus C. Young, Jr.

Might I suggest that the definition of "commercial" as applied to land use comes from the zoning ordinances of each of the respective permittees. Thank you.

CHAIRMAN NAHAI: Thank you very much.

Any other new points? Great. Thank you.

Well, that concludes, then, the testimony from the public.

Do we have a staff response? How much time, Dennis?

MR. DICKERSON: Very quick.

MS. CLOKE: Three minutes.

MR. DICKERSON: Very quick. I'll try to do this in three. TMDLs --

CHAIRMAN NAHAI: Time him, Ronji. And I don't want you to worry about the fact that you work for him.

R0072176

MR. DICKERSON: All right. TMDLs implementation plans, it's a key part, and this is an extremely important part of implementation plans. TMDLs will never work if you don't take a strong stance

on SUSMPs.

The .75 inch issue has been on the table since last August. Many, many discussions, many changes, true. But in almost every case those changes have been favorable to the people who have been complaining about the SUSMPs with respect to most of the cities. We've been trying to respond to their concerns over and over, and yet it's still not enough.

I do believe that we need a factual basis to include rooftop water within the exemption -- within the SUSMP. There simply is not, in my opinion, enough hard data to include that.

More studies, everyone wants more studies. Sure. Give us more money. Give us more time, and in all honesty, give us a lot of money and a lots of time. Otherwise, it's never going to happen.

One argument is that we cannot adopt any SUSMP requirement given the prohibition in the statute. If that were true, we could never adopt any SUSMP under any provision. That would simply be totally impossible. And Jorge I think has comments on that as well.

R0072177

The staff issue, I do hope you'll recognize that everything that we've done is on the basis of one individual working full-time, already overburdened, already spending -- diverting resources away from things that we should be doing just to focus on this issue. We truly need more staff. I'm looking

for -- yes. More staff, more money in order to get this job done. Thank you.

And finally the quotation that we need to do something. Well, yes, of course, we do need to do something. That's our job. And the idea is to do something about cleaning the water, and that's what we've been trying to do. Oh, I still have green. I think I'll let it go there and save time.

CHAIRMAN NAHAI: That doesn't mean that you've got to keep talking. I had some questions to ask you though. Do any of the board members have any questions for Mr. Dickerson?

MS. CLOKE: You go first, David. You'll probably ask all of our questions.

CHAIRMAN NAHAI: Not necessarily. I'm sure not.

I wanted to just get your reaction to a few points that were made which caught my attention. The first is that I think it was Dee Zinke who made the point that when you're talking about a subdivision of ten homes and over that that catches ten condominiums, and whereas if development of ten condominiums in terms of the amount of impervious surface that it creates, may be really no more than two-single family residences put together. How do you react to that?

MR. DICKERSON: The original -- everything that we're doing is on the basis of the original permit in 1996. I was not part of that

R0072178

discussion. And there's no split definition for condos.

Xavier, do you have any help on that?

MR. SWAMIKANNU: In 1996, we identified these seven categories, and they were generally large projects with certain specific commercial facilities, but we didn't go beyond that. We didn't contemplate apartment buildings at that time or condos at that time. So --

CHAIRMAN NAHAI: Xavier, is the only reason why condos become important is because they're subdivisions whereas apartments are not? So while apartments may be caught under the general definition of a commercial development, a ten-unit condominium subdivision may not be. Do we have any history of how that's been dealt with in the past?

MS. CLOKE: I think I could answer that question very quickly. Condominiums need subdivision maps and discretionary action.

CHAIRMAN NAHAI: That's not my point.

MS. CLOKE: I'm sorry.

MR. SWAMIKANNU: No, there's no history of that discussion.

CHAIRMAN NAHAI: The next question that I wanted to put to you is I think that Mr. Piasky who maintained that the definition of "environmentally sensitive areas" as we -- in the proposal is way too wide and that by the three categories that are put in

R0072179

there that one would not be able to identify what environmentally sensitive areas are. Can you give me your response to that?

MR. SWAMIKANNU: Mr. Chair and members of the board, my response to that is I think what Mr. Piasky is saying that he's familiar with the categorization from the county's point of view, but he's not familiar with the other two categories, the one by the State Water Resources Control Board. It is a special biological significance. And the other one from the California Resource Agencies. We have provided some reference document in the definition to go back to. And this --

CHAIRMAN NAHAI: My question is this: Those areas are readily ascertainable by reference to those reference --

MR. SWAMIKANNU: Yes.

CHAIRMAN NAHAI: -- materials?

MR. SWAMIKANNU: Yes.

CHAIRMAN NAHAI: The next thing that I wanted your reaction to was I think Mr. Braband who pointed out that we have many fast-food operations which are under 5,000 square feet and which may yet generate pollution that is out of proportion to their size. Do you have any reaction on that viewpoint?

MR. DICKERSON: We're very open to taking board direction on what would be an appropriate number in that respect.

CHAIRMAN NAHAI: And finally in connection with --

MR. SWAMIKANNU: Mr. Chair, may I add to Dennis's comment?

CHAIRMAN NAHAI: Of course.

MR. SWAMIKANNU: The 5,000 square feet threshold comes from looking at other programs around the country, and there's general policy towards prohibiting some kind of small business exemption. That's certainly under consideration.

CHAIRMAN NAHAI: And Mr. Brown pointed out that there are some areas which have on a community-wide basis, you know, what should I call them? Communal catch basins or -- is that a commonplace thing or --

MR. DICKERSON: I'm calling for some help from our engineer of residence.

MR. DASKER: Dennis Dasker of the Regional Board staff. Along the foothills, the Los Angeles County Flood Control District has placed a lot of catch basins, and they are, you know, covering certain areas. There are areas also which the local cities and other districts have put up catch basins. So there are catch basins, yes, which cover areas that are protecting areas which may be developed in the future.

R0072181

So -- but in cases like that, you have the quantity question. Wherever you put a footprint on

the ground, on some natural ground, you're going to develop a little higher flow. So every development is inching up a little higher, and you may overwhelm the community catch basin that's been put in already.

So it's something that would have to be considered when you look at the developments.

CHAIRMAN NAHAI: So it would be your position that these SUSMPs would nevertheless be necessary even in those communities?

MR. DASKER: It's something that would have to be looked at depending if it's a heavily developed area where there's very little new development coming in, it may not be critical. Other areas, it may be critical, yes.

MR. DICKERSON: It actually is a very interesting point that bears some looking into because it could be looked at as a regional SUSMP, if you will.

CHAIRMAN NAHAI: Okay. All right. Those are my questions to you. I have a number of suggestions with respect to the language of the permit as we have it later on.

But are there any other questions for Mr. Dickerson?

R0072182

MS. LYON: Only that I'm concerned with regard to cities that do have hillsides, what we're going to do in that respect. I know in particular -- I sit in the municipal category, and I'm in the city of Rancho Palos Verdes. We cannot let water percolate

down into our ground because of the geologic conditions there that will cause landslides, and I believe Diamond Bar has some similar issues. What are we going to do about that type of issue?

MR. DICKERSON: Well, with respect to hillsides -- correct me if I'm wrong -- we did adopt the language that was for a definition of hillsides that was recommended by the county and by the EAC, the Executive Advisory Committee, so hopefully we've been responsive to those, and we also have a waiver provision.

MS. LYON: Well, I'm afraid in a city like ours, it'd probably be a waiver of everything. There are so many hillsides. So I'm just curious how we're going to handle that.

MR. SWAMIKANNU: I -- I'm -- the purpose of the waiver provision is basically when you're in a situation that all BMPs don't work, infiltration is just one kind of BMP. Others might be considered. And if others are infeasible as well, then we have the end provision whereby you can contribute to a project that addresses storm water within the city.

MS. LYON: So we would be asking anybody who wanted to remodel or build in our city to contribute to some other project?

R0072183

MR. SWAMIKANNU: If you belong to these categories, home subdivision, businesses, basically these specific categories, not all development.

MS. LYON: Okay. I have another question to ask with regard to the Porter-Cologne Act. Is there anything in that Porter-Cologne Act that says that we must take a look at anything economic? I believe there is.

MR. LEON: Yes, there are provisions, Miss Lyon, in all of the proceedings, including planning. This is not a basin planning, but the staff did look at some of the economic issues, and they've been identified for the record.

MS. LYON: In the staff report, you did bring up one thing. You suggested that cities might be able to pass the cost on by a utility fee. Cities can't just arbitrarily do that any longer. That has to be by a vote of the people now, so I wasn't aware if our staff was aware of that. This is going to be a horrendous cost to cities, and I don't know how they're going to handle that.

MR. DICKERSON: I think that was put in the staff report just as a point of information.

CHAIRMAN NAHAI: As a board, are we able to encourage adoption and yet give direction to you to come back to the board with additional, you know, responses to specific questions which could then amend the plan in the future?

R0072184

MR. DICKERSON: You could certainly adopt -- as I laid out the -- you have a whole choice of options today, and really you can -- you can select

any of those in any degree. You can adopt something which then we can work on additional refinement and bring that back in the future. Certainly. So you really have just a whole range of choices that we outlined earlier.

CHAIRMAN NAHAI: Do you have a more -- a clearer definition of what constitutes a commercial development for us to consider?

MR. DICKERSON: I believe they were working on that earlier. Yes. It's right here.

MR. SWAMIKANNU: I hope -- I want to discuss commercial in the context of the storm water program -- the Federal Storm Water Program, and clearly the division there is between industrial, commercial and residential. The industrial component is covered by the statewide storm water funding under federal law, and the rest of it is covered through the municipal program, that is, commercial and residential.

So the definition I worked on is -- and can be modified but uses that concept and also takes on -- reviewed the category that L.A. County requires conditions for and identified many of those as being commercial.

So the definition means -- commercial means any development on private land that is not residential or industrial. The category includes but is not limited to hospitals, laboratories, other medical facilities, educational institutions,

R0072185

recreation facilities, multi-apartment buildings, nurseries, mini-marts, shopping malls and other business complexes. I tried to be inclusive.

CHAIRMAN NAHAI: Office buildings?

MR. SWAMIKANNU: It's not -- we could add that. I could add that.

CHAIRMAN NAHAI: Hotels? I'm asking you.

MR. SWAMIKANNU: Yeah. They are commercial. They are commercial.

MS. DIAMOND: Is there anything that is not included that's not residential? Schools?

MR. SWAMIKANNU: Agriculture, for example.

MS. DIAMOND: What about schools? Is that?

MR. SWAMIKANNU: Schools are educational institutions. I tried to put that down.

CHAIRMAN NAHAI: Oh.

MS. CLOKE: So where do buildings like public storage and warehouses, buildings that have really large roofing areas, but I don't know how -- are they also included in this category?

MR. SWAMIKANNU: The difficulty there is that public warehouses are associated with transportation and identified as industrial under the federal scheme of things.

R0072186

MS. CLOKE: But they site them in C zones in cities. Public storage facilities are in C zones as

well as in M zones. I mean --

MR. SWAMIKANNU: I'll include that.

MS. LYON: And these type of commercial businesses are already practicing best management practices; is that correct, under the basic permit?

MR. SWAMIKANNU: The industrial ones are, not the commercial ones. The whole purpose of --

MS. LYON: Well, those that lie within the cities that are permittees, we require them to do their sweeping and all that menu that you mentioned earlier.

MR. SWAMIKANNU: Yeah. We require municipalities make sure that these things happen, different soils controls.

CHAIRMAN NAHAI: And --

MS. LYON: And that's being done now?

MR. SWAMIKANNU: Yeah.

MS. LYON: Do we have feedback on how that is helping?

MR. SWAMIKANNU: I think source control, anything that's not exposed is not swept away doesn't get into the storm water. And many of the early programs we tried to integrate the existing municipal functions, and so clearly trash removal has a benefit, and there's been some effort to quantify that.

R0072187

And recently the county put together an annual report and some of that is summarized there, but we didn't really structure it towards exhaustively

quantifying the benefit, but clearly there are case examples.

MS. CLOKE: I would like to know your response to the question of discretionary projects. First of all, how they're defined in this particular document and then our ability to modify that. In planning and zoning terminology, discretionary projects, which I believe is how you apply it here, are those projects which actually go to public hearing, variances, conditional use permits, subdivision tracts and so on. And if that's so, then we're really only looking at a sliver of the projects that are in the list.

So if you look on page 3 in the January 21 document it says, "Discretionary projects that fall into one of the seven categories" and now, of course, we've added two more, but it's not really discretionary projects. It's really all the projects that you have just finished describing as commercial and so on and all the ones in this list.

MR. SWAMIKANNU: I think counsel had an opinion on that distinction and a recommendation.

MR. LEON: If you'd like me to repeat it, earlier I mentioned that by virtue of the distinction between discretionary or non-discretionary, we're not excluding those activities that are non-discretionary if those activities are listed as enumerated projects. In other words, those that are listed as enumerated

projects are inclusive both -- in other words, they should be including whether they are or not.

MS. CLOKE: So the top of page 3 it should say all --

MR. SWAMIKANNU: It should be changed.

MS. CLOKE: "All projects that fall into one of these --

MR. SWAMIKANNU: These seven categories.

MS. CLOKE: Well, the nine categories.

MR. SWAMIKANNU: Yeah.

MS. DIAMOND: So "discretionary" would be removed.

MS. CLOKE: It really should say "all projects."

Then I have one more sort of housekeeping question I just wanted to get on the record here. We have a letter in our packet from the City of Long Beach, an e-mail. And in that e-mail it says that Long Beach's understanding is that the only project categories to which the SUSMPs will apply are for home subdivisions, 10 to 99, a hundred-plus, the commercial development and ESAs.

And I believe that there's an answer to that that puts Long Beach on an equal footing with everybody else, but I'd like that answer to be in the record. I'd like that to be explained so that we're clear. One of my problems here is that it's sometimes hard to, you know, to read this and to know what it

really means.

MR. SWAMIKANNU: I can sort of start with some background so that I explain this well. Long Beach was a co-permittee to the 1996 permit, the L.A. County permit. Last year they were issued a separate permit. As part of that process, they prepared a Storm Water Management Plan. So the categories -- beyond these four categories that are listed are addressed in the Management Plan very specifically.

For these four categories, there's a specific requirement in their permit which says Storm Water Mitigation Plans need to be developed. For the other categories, the equivalent best management practices already prescribed in their management plan and the Regional Board adopted that as sufficient at that point in time.

Long Beach has also sought a clarification on the fact that the process which the executive officer recommended to you was to endorse the SUSMP for L.A. -- Los Angeles County and cities before you, as well as adopt applicable SUSMP requirements for the City of Long Beach at the same time. Long Beach wanted clarification that implementation dates for both -- effective dates for both would be the same.

MS. CLOKE: So in writing your staff report and your future reports, can you -- when you bring up the issue of Long Beach, can you make that clear that, in fact, Long Beach and Los Angeles will be

meeting the same standard, though, might be getting to it in two different ways?

MR. SWAMIKANNU: Yes. The staff report indicates that, but I will emphasize that point.

MS. CLOKE: I need to understand that when I read it.

CHAIRMAN NAHAI: Okay.

MR. LEON: Mr. Chairman, I do have a couple of housekeeping issues and two very brief substantive issues.

No. 1, with respect to the record of the proceeding, I think it would be beneficial to designate what the record of the proceeding is in the event that this matter goes up on appeal, and for that purpose, I would recommend that the record contain all staff files for today's proceeding and the transcript, of course, all staff files in the transcript for the August 10, '99 workshop held by staff. The board wasn't present. All staff files and transcript for the September 16th proceeding before the board, all circulated SUSMP proposals, those that were circulated by the staff, all SUSMP proposals from interested parties, all comments received and responses, of course, and, finally, all exhibits that were presented before the board today.

And on that topic, in the event that there's anybody in the audience who hasn't had an opportunity to provide a copy because they may not have anticipated providing a copy, I would -- I would

suggest setting a deadline of, say, this Friday to send it in to the executive officer for inclusion into the record.

CHAIRMAN NAHAI: Okay.

MR. LEON: Another housekeeping item, Miss Lyon, I'm going to advise you not to vote on this item because in your capacity as council person for the City of Rancho Palos Verdes, you're representing a permittee, and the permittees, of course, are subject to the control of this permit. And so that's my advice to you, to abstain from voting on this matter.

Really quickly on two substantive points, while I did step out, I understand that there were comments raised about the applicability of 13360 provision that generally says that the Regional Board cannot by order direct how compliance is to be had with permit provisions and any order of the board.

I just wanted to give you an opinion that I don't think 13360 prohibits the proposal that's before you today for several reasons. First order 96054, which is the Storm Water Permit, requires that the Standard Urban Storm Water Mitigation Plan be developed. Also this is all part of compliance with the Clean Water Act provisions that require the creation of the best management practices.

R0072192

Moreover, the proposal provides that the BMPs are minimum requirements, that the cities are free to require more or additional BMPs through code or by

ordinance, and that's stated specifically on page 2 of 17 of the December 7th, 1999, proposal.

Finally, I wanted to say that with respect to the argument that was had earlier with respect to the permit procedures and whether this process is in compliance with the permit procedures that I believe that we are, in fact, in substantial compliance with those permit procedures, that there have been three or four recitations of the history of this matter, and it quite clearly indicates that the history, the back and forth, the discussions, the meet and confer, even though maybe they weren't specifically described as such, were, in fact, constructive and therefore, in fact, we are in compliance with those procedures.

CHAIRMAN NAHAI: Thank you.

Let's move on to some board discussion, you know, and we can start with, you know, some exchange of viewpoints, maybe if anybody wants to discuss the matter, otherwise we can move on too. Let's start with Dr. Coe.

MS. CLOKE: I was just going to ask if we maybe just wanted to go through the --

R0072193

CHAIRMAN NAHAI: Let's have the discussion between the board members first and then we'll have, you know, the crafting of a resolution and then we'll -- it may be that nobody has anything to say right now and then we'll move straight to that other

step.

MS. CLOKE: Okay.

CHAIRMAN NAHAI: Dr. Coe, do you have any comments to offer?

MR. COE: These are comments not leading to a motion? General comments.

CHAIRMAN NAHAI: Just general comments.

MR. COE: Well, I think it's evident that the staff has done a great job in a short time, but I think it also shows I would like a more orderly process and give the staff more time to get their plan and the resolution that we're to consider all on the same time frame consistent between documents, and, at the same time as they do that, I think they could incorporate some of the things we've heard today from those who have testified.

However, I'm also reluctant to think about postponing action by this board, so I'm sort of groping with an approach that would take care of everything I've said. That's where I stand right now.

CHAIRMAN NAHAI: Well, the approach that could be implemented is that we can make -- since we will -- really what we would be doing here today is giving our executive director direction because this is not formally a board action, what we're doing is encouraging our executive director to take certain action. So that leaves -- that leaves the way open for us to say, you know, "We would like you to adopt this

but with these changes at this time and to further consider, you know, these various aspects."

MR. COE: Yeah.

CHAIRMAN NAHAI: So maybe that's the approach that will address your concerns.

Miss Cloke.

MS. CLOKE: I would like to follow the direction that you've just suggested.

CHAIRMAN NAHAI: Any other comments?

MS. CLOKE: Well, at the appropriate time I would like the opportunity to make those specific comments and the directions for consideration of the board to be -- whether or not they would like to direct Mr. Dickerson and make those suggestions, but I think we should do it as we go through the process.

CHAIRMAN NAHAI: Okay. Miss Diamond, do you have any general comments to offer?

MS. DIAMOND: Well, I think that today is the day that we need to make some decision, and I agree with the process and maybe some things that we want to ask the board -- the executive director to look into. In a conversation that I had with Mr. Dickerson, I think that it was pretty clear that you want direction from us. So the word "encourage" is probably a very strong word, at least I take it that that's how you're taking it.

R0072195

And I would like to reserve comments on specific changes to the plan as it's before us, the

staff report with some amendments that I would like to make too.

CHAIRMAN NAHAI: Mr. Miller, do you have any general comments that you'd like to express?

MR. MILLER: Well, I agree with Dr. Coe in that -- I mean so much has been done, but there's been so many questions raised today that I think we need to take a look before we deal with these things, not stopping the process but taking a look at it.

Settling things like whether they're exemptions or not exemptions. I mean, there have to be some exemptions. For example, where you live, you can't dump water into the ground. You'll slide into the ocean. We have to address those issues. You can't say "No exemptions ever." There have to be some.

Secondly, what concerns me is in cases where we require people to put these things in, how are we guaranteed they're going to be maintained? There has to be some way, some format, for somebody to take care of these things. If it's on private property, fine. You can put a cover, run it through the land and so forth. What happens if it doesn't run with the land? It's for sale or something's done off-site? Are the municipalities or the county responsible? **R0072196**

These are the issues that I'm not clear on and to cast something in concrete at this point, I'm a little reluctant to do until I have a better feeling for it. I would vote to go forward, but I need a lot

of clarification. I'd like to clean up all these questions or a majority of them. You'll never answer all of them.

CHAIRMAN NAHAI: Mr. Shaheen.

MR. SHAHEEN: Yeah. I would say as well -- I mean I -- you know, I guess you could debate a number of these things for I long time, and they've been debated, and, I mean, in my mind, you know, I really would like to move forward with something and make some progress, but definitionally there are a number of things I think need to be addressed.

From my perspective, again, I'd like staff to be able to address those things, and I'd like to be able to move forward, you know, within the framework of this but with better definitions.

MS. LYON: Well, I can't vote, but I can certainly say that speaking from a city's perspective I know that the cities all want clean water, and they want to help in that respect. It's just how we go about it. Everybody in this room wants clean water, so I think we're all going to work toward that end, and I'm sorry that I'm in a position where I can't vote.

CHAIRMAN NAHAI: I was going to say it's a good thing you spoke because we haven't heard the opinions of the cities at all.

R0072197

Let me just say this: I think we must act. You know, albeit with caveats and directions for, perhaps, further investigations as to various things,

but I'd like to say this: One of the speakers earlier on, you know, when he was talking about the building industry and said, "Well, you know, we need to stop the polluters," and, you know, I know that I speak for the rest of the board when I say that there's nobody on this board that regards the building industry in that way at all. I don't know where we would be without our builders, and affordable housing is tremendously important.

But at the same time, I think all you need to do is to fly into LAX during the day, and you'll see that what we've, in effect, done is that we've constructed this massive impermeable slide straight to the ocean, and we must at some point reverse that trend. Otherwise, we're going to really severely damage our coastal economies and otherwise we're going to severely damage exactly what it is that Los Angeles is most famous for, which are its coasts.

So with that, I can -- if everybody wants me to I can -- I think I have a pretty good handle on what kinds of changes and what kinds of directions from a consensus, and I could attempt to provide those on a page-by-page basis, and at any time I step wrong, which I no doubt will, just stop me.

R0072198

All right. With that, I am looking at the January 21st draft, which is the black-lined draft. The first change on this would be at the top of page 3.

MS. CLOKE: Can we start with page 2?

CHAIRMAN NAHAI: Yeah, but it's --

MR. COE: Mr. Chairman, I'm not sure that -- I think each of us might have different individual comments, and I'd be surprised if they were all the same. And I would concur what I think you're about to do is to go page by page through here and then everyone contribute.

CHAIRMAN NAHAI: Okay.

MS. DIAMOND: Well, I think if you look at page 2, you'll find that "discretionary projects" is mentioned, and we may want to deal with that because we were talking about --

CHAIRMAN NAHAI: Yeah. But the way we're dealing with it is at the top of page 3 of this draft, we're going to instead of using "discretionary projects," we're going to use "all projects," and I think that takes care of the problem.

MS. CLOKE: But I think that it should be clear on both pages. I think we should say what we mean in every place. Like, when you wanted to say "both structural and treatment" it should always say -- it should be consistent all the way through the document.

CHAIRMAN NAHAI: Okay.

MS. CLOKE: And the other thing that we need on that first page 2 is some discussion, or at least a direction to staff, to consider and include a start date.

CHAIRMAN NAHAI: Right. We'll deal with that.

MS. CLOKE: But it starts in here "Adopt the requirements set herein," should be -- there should be a within a -- there should be a time frame.

CHAIRMAN NAHAI: Okay. All right. Fair enough.

MR. LEON: Mr. Chairman, excuse me once again. Since the members of the audience have a version different from the one that the board members have, we will need to have clarification. If you're looking at page 2, and I think that matches up with page 2.

CHAIRMAN NAHAI: Well, just follow us through and whatever we refer to just repeat for the audience where we are.

MR. LEON: Very good. We will state the substantive headings that'll be assisting.

CHAIRMAN NAHAI: All right. So the first two changes that we would be suggesting would be in the section entitled "Background." With respect to the issue of effectiveness, what we had discussed earlier, which I think is a reasonable approach, would be six months for the cities to adopt assistant ordinances and with the requirements to take effect 30 days thereafter. So that's what I would suggest there.

MS. CLOKE: And the discretionary one as well?

CHAIRMAN NAHAI: Yeah.

MS. CLOKE: Okay.

CHAIRMAN NAHAI: You're impatient at the end of the day.

MS. CLOKE: I've been here a long time.

CHAIRMAN NAHAI: So has everybody else.

And then in the third full paragraph of the "background" section in the one, two, three, four, five, sixth and seventh line, there is a parenthetical, which is "discretionary projects," and we would suggest that that parenthetical be deleted.

Okay. Over the page, at the very top of the page, again, the word "discretionary" appears, and we would suggest that the word "discretionary" be deleted and replaced with the word "all."

Going down on that page, when it comes to the definition of -- what we would be suggesting is that a definition of commercial development be added along the lines discussed with Xavier when he was at the podium.

MS. CLOKE: One more comment on that page when you're ready.

R0072201

CHAIRMAN NAHAI: Sure.

MS. CLOKE: If you go right where it says the "Regional Board Executive Officer has designated two additional categories," one of the categories are these commercial stand alone parking lots. I think that we want to look at all parking lots. It's going

to have to be rewritten because some of them will be included in commercial developments. Some of them will -- you know, they'll appear in different forms as we go through.

But somehow I would suggest that we ask the executive director to rewrite this so that in one manner or another all parking lots of 25 or more parking spaces are addressed.

CHAIRMAN NAHAI: Oh. So you're not -- you're not talking about the thresholds of 5,000 square feet and 25 spaces?

MS. CLOKE: I'm talking about the words "commercial stand alone."

CHAIRMAN NAHAI: Okay. What you would suggest is that the words "commercial stand alone" be deleted.

MS. CLOKE: Right. And I'm saying -- exactly. And I'm saying that I understand that there will be a variety of mechanisms for addressing this, but I don't want to limit it just to commercial stand alone parking places -- parking lots.

R0072202

CHAIRMAN NAHAI: Okay.

All right. Next I would have a comment on page 4, and this isn't so much of a comment as I guess a direction to staff to review this matter, which is the redevelopment definition. I'm not at the stage where I would want to propose that this language be changed immediately, but I am concerned as to whether

the particular redevelopment, you know -- just the proportionality of it is the comment that I said earlier.

And, Dennis, how can we do this? Can we have your staff review this issue and come back to us, you know, within 30 days or something to provide another recommendation as to this paragraph or -- without delaying, you know, the process of adoption of the SUSMPs.

MR. DICKERSON: If you wish, we could -- we could go back and make the changes that you're requesting, and within a very short period of time I think if we bring back that package to you with the changes that you're recommending tonight and then you could -- the only problem with that is that when you do make those changes and if we bring it back, there's another opportunity for a public hearing, and it could be an extensive opportunity again.

On the other hand, this is something that is fully delegated to me by permit.

Jorge, I need some help here. I mean, how far can we make changes at this point without getting into process problems? **R0072203**

MR. LEON: Well, yeah. It all depends on when we want to have the board take any kind of action. We have, as I've indicated before, provided the public with extensive notice, and as long as the changes that we end up coming back with are extensive, the ten-day

notification is going to be adequate.

CHAIRMAN NAHAI: In any event, all we're doing at this point is basically expressing the opinions to the executive officer to whom the function of adopting these have been delegated.

MR. LEON: And if you don't need to have it back, then you're fine.

CHAIRMAN NAHAI: Well, you know, the humble opinion that I'm suggesting is that this provision may catch a -- you know, a relatively minor expansion and completely miss, you know, 150,000 square foot, you know, addition to a major shopping mall. Now, that doesn't seem logical to me.

So, but -- so I mean, I'm expressing the opinion that I think a different approach should be adopted for redevelopments. Perhaps what we can say is to adopt a minimum amount and say, you know, if you're going to have a 50,000 square foot addition, then regardless of this provision, you know, some kind of Storm Water Mitigation Plan would have to be -- or, you know, put it at a minimum of 100,000 square feet, which is the initial criterion for catching commercial developments anyway.

R0072204

So I'm just expressing that to you for your consideration.

MR. DICKERSON: I think it's a point very well made, and we'll certainly endeavor to incorporate that.

CHAIRMAN NAHAI: Okay. Next --

MR. COE: Mr. Chairman.

CHAIRMAN NAHAI: Yes, sir.

MR. COE: There was a lot of discussion on the definition of "environmentally sensitive area" at the top of that page.

CHAIRMAN NAHAI: Yes.

MR. COE: They refer to three different references where I guess the definition occurs. I think that needs some attention, and there have been some requests that we've heard today that the L.A. County approach should be adopted. I would prefer to just direct them to reexamine it to come up with a single definition instead of three.

CHAIRMAN NAHAI: Okay.

MS. CLOKE: Maybe it's just a map because they're already designated, so maybe it's just the inclusion of a map in this document so that people can understand what the designated areas are, because if you go, for example, to the -- if you're looking at a building permit in a particular area and you can go and see whether you're in that map in that area, so maybe that's what people need just to have that information.

I mean, you know, it's not a definition. It's just information.

R0072205

CHAIRMAN NAHAI: That's fine. We could have a -- I mean our staff's testimony was that those areas are readably ascertainable for anybody who wants

the materials, but you could provide an overlay, could you not?

MR. SWAMIKANNU: What they're asking for is a compilation of those areas and that could be done.

CHAIRMAN NAHAI: If staff can readily determine what these areas are, Dr. Coe, would you then find this definition acceptable?

MR. COE: Yeah. That definition becomes a Regional Board reference?

CHAIRMAN NAHAI: Yes.

MR. COE: Okay.

MS. DIAMOND: On that same page on the issue of parking lots, I am -- I would like to see that changed to "any parking lot, 25,000" -- I think we did talk about that, but on this page, page 4 I believe, we want to make sure that it includes "all parking lots" whether they -- not only stand alone. Any parking lot that's either 5,000 square feet or has 25 spaces should be included.

CHAIRMAN NAHAI: In other words, what you're suggesting is that the definition of parking lot here be made consistent with the reference to it as we've amended it on page 3 of --

MS. DIAMOND: That's right. That's right.

R0072206

CHAIRMAN NAHAI: The next comment I had on this page was that in connection with the definition of a restaurant, we -- I think the suggestion was made

that we add the word "stand alone" before the word "facility" so that we were not under this category catching, you know, supermarkets that have delis, for instance. They would be caught in the commercial development thing. Okay. Thank you.

I have nothing on page 5.

MS. CLOKE: I'm on page 4 still.

CHAIRMAN NAHAI: Okay.

MS. CLOKE: Just a term of art here, this "greater than nine-unit home subdivision," I think if we strike "subdivision" and put in "development" because "subdivision" has a very technical meaning that doesn't always -- that could exclude some nine-home developments and not others or some ten-home developments and not others. So if they just put "any greater than," you know, "ten" -- "greater than nine-unit home development" in terms of projects.

CHAIRMAN NAHAI: But that would then catch apartment buildings. I mean a nine-unit apartment building, you know, in terms of its footprint is hardly bigger than a house, so what we would be doing then if we do that we would be excluding single-family residences that are not on hillside, but we would be catching apartment buildings even though they have a minor impact.

R0072207

MS. CLOKE: But --

MR. LEON: I'm sorry. Quick point of clarification. Xavier points out that the definition

is within the permit and any definitions that are in the permit, such as the permit, constitute a limitation where we do not have any authority to change them.

CHAIRMAN NAHAI: Okay.

MS. CLOKE: Also on that page "retail gasoline outlet," did you have a --

CHAIRMAN NAHAI: Oh. You're talking about the 50 percent of annual gross receipts?

MS. CLOKE: Right. As opposed to if the gas is pumped there that part of the facility -- that pumped gas should be covered proportionally.

CHAIRMAN NAHAI: Is it workable proportionally, or are we in a situation that we say if you're pumping gas, you've got to do the SUSMP?

MR. DICKERSON: I think the latter.

MS. CLOKE: Okay. So that's fine with me.

MS. DIAMOND: All pumping stations should have to meet the SUSMP requirements.

MR. DICKERSON: If they're pumping gas. I think proportionality becomes very difficult to connect.

MS. CLOKE: I was trying to be flexible, but if there's gas there, I think we had need to deal with that.

R0072208

CHAIRMAN NAHAI: Okay. Anything on page 5? On page 6?

MS. DIAMOND: On the conflicts of local

practices, I think the wording of the last sentence, it says "where those practices would defeat or circumvent the intent of the SUSMP requirements." That seems to me very broad and very vague. I don't know how we can reword that, but it just seems to me that we should have standards that everybody standards so that nobody will -- you know, I just think consistency is very important.

CHAIRMAN NAHAI: Well, I think -- I know what it would need to say is that after the word "except" through the end one could delete that and say instead of that, one could say, you know, "provided that," you know, "to the extent that the standards in these SUSMPs are more stringent than those under local codes, such more stringent standards shall apply."

MS. CLOKE: And the reverse. If the local standard is more stringent than the standard --

CHAIRMAN NAHAI: Yeah. That would be understood because it's saying you continue in accordance with local codes, but then the caveat would be "provided that if the SUSMP standards are more stringent" --

MS. CLOKE: Yes.

CHAIRMAN NAHAI: -- "those would apply." So if the local codes are equivalent or more stringent, then those could be continued to be applied.

R0072209

MS. CLOKE: I understand.

CHAIRMAN NAHAI: Jorge, did you want to

do anything with the definition of treatment control BMPs to take care of the situations where -- you know, where it's -- where treatment control BMPs and structural control BMPs can be used interchangeably?

MR. LEON: The idea that we had in mind was to basically include them both in the same place because they basically --

CHAIRMAN NAHAI: Just wherever they appear you go "treatment" or "structural."

Okay. Do I need to go through and point out --

MR. LEON: No. Please, we'll do it.

CHAIRMAN NAHAI: Okay. Anything more on page 6?

Anything on page 7? Wonderful.

MR. COE: Well, Mr. Chairman.

CHAIRMAN NAHAI: I rejoiced too soon.

MR. COE: On page 7 under Item No. 1 -- actually, a general comment. There's two places here that I think the language has been weakened unnecessarily. Under No. 1, the second line, second sentence "development rate for developments where it is reasonably foreseeable," I don't know what that means.

MS. CLOKE: Take it out?

MR. COE: Yeah. And then on No. 2, the third barrel.

R0072210

MS. DIAMOND: What line is that, Jack?

MR. COE: The third barrel under line 2,

"Conserve natural areas," the third barrel, the last sentence there, "wherever practical," I think that ought to come out. I don't think that can be administered if everyone came up with their own idea.

MR. LEON: For the sake -- may I clarify for the audience, Mr. Chairman? The comments that Mr. Coe just made reference to No. 1, "Peak water runoff discharge rates" on page 5 of 17 of the December version, and No. 2, "Conserve natural areas," the small print.

A PERSON: What was the change?

MR. LEON: The recommendation was to delete the words "wherever practical."

CHAIRMAN NAHAI: Okay. Do we have anything else on page 7?

Going on to page 8, I had a comment on the first line of paragraph 4. It says, "Project plans must include BMPs consistent with local codes, codes and ordinances." Should that not really be a reference to consistent with local codes and ordinances or these SUSMPs, I mean, depending on which one of them has the higher requirement?

R0072211

MS. CLOKE: Yes. More stringent.

MR. COE: Staff said they could take care of that earlier.

MS. CLOKE: It should be consistent with what they --

MR. SWAMIKANNU: The idea was that local

codes and ordinances would be modified to adopt the SUSMP.

CHAIRMAN NAHAI: Yes. But since we've already put in the ability of local codes and ordinances to continue, we need to make that change.

At the bottom of the page, third line from the bottom, Dr. Coe had a suggestion that the word "discouraging" be deleted and replaced with the word "prohibited."

A PERSON: Could you tell us where this stuff is?

MR. DICKERSON: We're looking at page 7 of 17 at the very top where it says "Signs and prohibitive language," et cetera.

CHAIRMAN NAHAI: Any comments with respect to page 9?

MS. CLOKE: Page 9.
