S.0 SUMMARY

S.1 INTRODUCTION

This program final environmental impact report (FEIR) has been prepared to evaluate the potential environmental effects of the adoption and implementation of the proposed statewide General Exception to the Ocean Plan waste discharge prohibition and Special Protections pursuant to Public Resources Code (PRC) 36602(d)(6) and PRC 36700(f) and the related California Water Code (CWC) sections, included in Appendix 10 of this FEIR. The Regional Water Boards would implement special protections when issuing required permits for discharges into Areas of Special Biological Significance (ASBS).

This FEIR has been prepared in accordance with the requirements of the California Environmental Quality Act (CEQA) (Public Resources Code Section 21000 *et seq*.) and the State CEQA Guidelines (Title 14, Section 15000 *et seq*. of the California Code of Regulations). As specified in Section 15367 of the State CEQA Guidelines, the public agency that has principal responsibility for carrying out or approving a project is the lead agency for CEQA compliance. For purposes of the proposed project, the California State Water Board is lead agency under CEQA. As stated in Section 15123(a) of the State CEQA Guidelines "[a]n EIR shall contain a brief summary of the proposed action and its consequences. The language of the summary should be as clear and simple as reasonably practical." As required by the State CEQA Guidelines, this summary must include:

(1) a summary description of the proposed project;
(2) a synopsis of environmental impacts and recommended mitigation measures (see the table at the end of this chapter);
(3) identification of the alternatives evaluated; and
(4) a discussion of the areas of controversy associated with the proposed project.

The Public Resources Code defines six categories of Marine Managed Areas, one of which are State Water Quality Protection Areas. A State Water Quality Protection Area is a "marine or estuarine area designated to protect marine species or biological communities from an undesirable alteration in natural water quality…." The Public Resources Code further states that in State Water Quality Protection Areas "waste discharges shall be prohibited or limited by the imposition of special conditions" in accordance with the California Water Code and implementing regulations, including, but not limited to, the California Ocean Plan (Ocean Plan). Areas of special biological significance (ASBS) "are a subset of state water quality protection areas, and require **special protection** as determined by the State Water Board pursuant to the California Ocean Plan...." (emphasis added).

The Ocean Plan states that: "Waste shall not be discharged to areas designated as being of special biological significance. Discharges shall be located a sufficient distance from such designated areas to assure maintenance of natural water quality conditions in these areas." This absolute discharge prohibition in the Ocean Plan applies unless an "exception" is granted.

A survey of ASBS in 2003 recorded 1,658 outfalls, primarily storm water and nonpoint sources, into ASBS. On October 18, 2004, the State Water Board notified applicants that they must cease storm water and nonpoint source waste discharges into ASBS or request an exception under the Ocean Plan. The State Water Board has received 27 applications from nonpoint source dischargers and National Pollutant Discharge Elimination System (NPDES) permitted storm water dischargers for an exception to the Ocean Plan prohibition against waste discharges into ASBS.

Stringent terms, prohibitions, and special conditions have been proposed by State Water Board staff that, if adopted, will comprise the limitations on point source storm water and nonpoint source discharges, providing Special Protections for marine aquatic life and natural water quality in ASBS. These Special Protections are proposed for adoption by the State Water Board as conditions for an Ocean Plan Exception. The requirements in the proposed Special Protections may be summarized generally to eliminate dry weather runoff, ensure that wet weather runoff does not alter natural water quality in the ASBS, and require that adequate monitoring be conducted to determine if natural water quality and the marine life beneficial use is protected.

Baseline biological information indicates that functioning marine communities persist in ASBS, but there is some inconclusive evidence that shows biota near discharges has a different species composition than areas away from discharges. Baseline water quality data indicates that wastes are present in storm water runoff into ASBS, but that waste concentrations vary considerably. Many, but not all, storm water runoff samples met various Ocean Plan Table B instantaneous maximum objectives. Receiving water samples showed lower in concentrations of Table B metals than discharges. Additional monitoring is required to fully evaluate compliance with the prohibitions and conditions in the Special Protections.

S.2 TYPE OF EIR

This FEIR is a program EIR intended to provide information at a more general level of detail on the potential impacts of implementing the proposed project. As described in detail in Chapter 2, "Project Description," the project involves the adoption and implementation of special protections and a series of specific exceptions to the waste discharge prohibition that may be characterized as one large project and are related as individual activities carried out under the same authority and having similar environmental effects which can be mitigated in similar ways. Subsequent project-level CEQA compliance and environmental analysis at a regional or local level may be required.

S.3 PROJECT OBJECTIVES

Based on the requirements of PRC § 36602(d)(6) and PRC § 36700(f), the California Ocean Plan, CWC § 13170.2, and in the context of other state laws relating to the ASBS waste discharge prohibition and water quality, the State Water Board has identified the following objectives for the proposed project:

► In accordance with the requirements of the California Ocean Plan, adopt a statewide general exception, with conditions for a specified group of dischargers who have applied for an exception, that is consistent with other provisions of the Porter-Cologne Water Quality Control Act (Porter-Cologne) and related state water quality control plans and policies adopted by the State Water Board.

► Adopt statewide conditional Special Protections to comply with Section 13160 of the California Water Code[1].

► Help to ensure that marine life and beneficial uses of the state's Areas of Special Biological Significance waters are protected from waste discharges.

► Ensure that General Exception project and conditional Special Protections consider economic costs, practical considerations for implementation, and technological capabilities existing at the time of implementation.

The conditions in the Special Protections will assure protection of beneficial uses while allowing the continuation of essential public services, including flood control, slope stability, erosion prevention, maintenance of the natural hydrologic cycle between terrestrial and marine ecosystems, public health and safety, public recreation and coastal access, commercial and recreational fishing, navigation, and essential military operations (national security).

The costs associated with compliance with the Special Protections are less than compliance with the Ocean Plan's standing ASBS absolute waste discharge prohibition. The environmental impacts associated with compliance with the Special Protections are less than significant and the Special Protections will have a long term positive impact on protecting water quality and marine life.

S.4 PROJECT CHARACTERISTICS

The State Water Board proposes to adopt a General Exception and special protections that establish minimum requirements for the permitting, monitoring, and continued operation of selected point and non-point discharges, as required by the California Ocean Plan. The Special Protections allow responsible for these discharges to avoid

[1] State Water Board's duty under 13160 to implement the Federal Clean Water Act

having to cease discharge flows and to comply with the applicable requirements of the Ocean Plan. Both the proposed General Exception and Special Protections are elements of the proposed project analyzed in this EIR. The proposed conditional exception would impose new requirements on existing discharges. See Chapter 3.0, “Regulatory Setting,” for more information on the existing regulatory setting at the regional and local levels.

The proposed Special Protections have been drafted to address the requirements identified in the Ocean Plan and are proposed to be adopted by the State Water Board in accordance with regulations for implementation of the Environmental Quality Act of 1970[2]. The text that follows describes the major elements of the proposed general exception as they relate to the potential for the project to have an impact on the ocean environment. Section references are references to specific sections in the proposed project and special protections, which are included in Appendix 10 of this EIR.

S.4.1 Proposed Project New Statewide Exception to the Ocean Plan for ASBS Waste Discharges, with Special Protections

The State Water Board proposes to adopt a General Exception to the California Ocean Plan for ASBS Waste Discharge Prohibition for Storm Water and Nonpoint Source Discharges for the Responsible Parties identified herein and a statewide conditional Special Protections that establish minimum requirements for the permitting, monitoring, and operation of these select discharges. The Special Protections allow responsible parties to discharge waste into ASBS without having to cease discharging natural flows. The Responsible Parties must comply with the applicable minimum requirements set forth in the terms and conditions of the Special Protections. Both elements are proposed for adoption as the project analyzed in this EIR.

In some cases, such as monitoring and inspections, the proposed project would impose new requirements on existing discharges. In other cases, elements of the special protections may already be in use but may vary around the state (i.e. regional monitoring programs). See Chapter 3.0, “Regulatory Setting,” for more information on the existing regulatory setting at the regional and local levels, including examples of regulations from representative municipalities in the state, presented for comparative purposes.

The proposed Special Protections have been drafted to comply with state law and address the requirements identified in the Ocean Plan related to the waste discharge prohibition.

[2] Cal Public Resources Code §§ 21000 et.seq.; Cal. Code Regs. tit. 14, §§ 15000 et. Seq; Cal, Code Req. tit. 23, §§ 3720 et. Seq.

S. 4.2 IMPLEMENTATION OF PROPOSED STATEWIDE EXCEPTION AND SPECIAL PROTECTIONS

As required by the Ocean Plan, the implementation of new statewide Special Protections would commence 6 months after the General Exception is adopted by the State Water Board. The State Water Board would implement these requirements as conditions for applicability of the General Exception. The special protections would require actions to be completed by the Responsible Party. Compliance would be overseen by the State Water Board and the Regional Water Boards as part of the permitting process for discharges of waste into waters of the state. Local agencies (e.g., county and city departments and independent districts) would continue to be required to comply with local basin plans and local ordinances, consistent with existing law. It is also important to note that the proposed General Exception and Special Conditions would not prevent Regional Water Boards or local agencies from maintaining and adopting additional monitoring requirements that are more protective of the environment and public health than those set forth in the proposed Special Protections would constitute the minimum requirements for existing discharges identified in the General Exception located throughout the state. Failure to comply with the minimum statewide requirements could result in enforcement pursuant to Chapters 4 or 5 of Division 7 of the California Water Code. As a result, the responsible party could be required to cease the discharge, submit additional monitoring results, or could be subject to mandatory minimal penalties for each violation per day as determined by the Regional Water Board[3].

S.5 ALTERNATIVES

The State CEQA Guidelines (Section 15126.6) require that an EIR describe a range of reasonable alternatives to the project that could feasibly attain the basic objectives of the project and avoid and/or lessen the significant environmental effects of the project. The State Water Board has identified four alternatives for analysis in this EIR:

► No Action (No-Project Alternative i.e., No Exception)
► Amend Ocean Plan (Prescriptive Alternative)
►Implement Individual Exceptions for each of the 27 Applicants
► Implement a General Exception for the 27 Applicants (preferred alternative)

Section 4.0 of this FEIR provides a comparative analysis of the proposed project and the four identified alternatives. Other alternatives were considered but, for various reasons, have been rejected from further consideration in this EIR. These alternatives are described in Section 4.0, "Alternatives."

[3] Cal. Water Code § 13385

S.5.1 NO-PROJECT ALTERNATIVE: NO ACTION (i.e., No Exception)

The Ocean Plan discharge prohibition is intended to prevent undesireable alterations of natural water quality. Water Code section 13301 authorizes issuance of a Cease and Desist Order (CDO) for violation or threatened violation of a discharge prohibition in a water quality control plan. The Regional Boards enforce the water quality standards and prohibitionsand may issue a CDO. There is no requirement that a permit must also be violated. An NPDES permit does not authorize violation of any federal, state, or local law or regulation, water quality standard, or prohibition.

A State Water Board funded study completed in 2003, (SCCWRP 2003) found 1658 discharges into ASBS. Only four of these were subject to Ocean Plan exceptions issued by the State Water Board. A large number of these prohibited discharges were permitted storm water outfalls. Some of the other point source discharges identified included marine laboratories and aquariums. Other sources were not regulated under any permit, including marina and boating activities, pipes draining private property, and bluff seepage most likely contaminated with anthropogenic waste from septic systems.

In January 2006, the California Ocean Protection Council identified addressing ASBS waste discharges as a state priority. The State Water Board has included this as a priority in the 2006 Consolidated Grants Program, specifically in the Ocean Protection portion of the coastal nonpoint source grants.

CEQA requires that the Water Boards consider the “No-Project” alternative. Under this No-Project alternative, the Ocean Plan prohibition against waste discharges into ASBS would continue to apply to all discharges into ASBS. The discharger could comply by terminating the discharge or by relocating the discharge so that the receiving water quality is unaffected. These actions could potentially have far greater impacts on the biological integrity of the ASBS than the discharge itself through demolition, excavation, and construction required to remove the existing discharge and redirect it away from the ASBS. In addition, the impacts on air quality and increased green house gas emissions would also be significant. For those dischargers faced with few practical options, enforcement actions could lead to protracted litigation.

Currently, the 27 applicants applying for this exception provide essential public services, including flood control, slope stability, erosion prevention, and maintenance of the natural hydrologic cycle between terrestrial and marine ecosystems, public health and safety, public recreation and coastal access, commercial and recreational fishing, navigation, and essential military operations (national security).

This alternative would not result in better water quality protection, nor does it benefit the environment, public health and welfare, or the Water Boards’ ability to protect and restore beneficial uses. As a result, staff does not recommend adopting the "No-Project" alternative.

S.5.2 NON-PREFERRED ALTERNATIVE: AMEND OCEAN PLAN

This prescriptive alternative would amend the Ocean Plan, so that discharges authorized by an NPDES storm water permit would be allowed. This would modify the discharge prohibition for point source storm water discharges into ASBS, and would allow discharges authorized by an NPDES storm water permit. Permitted storm water discharges, regardless of the effective date of inclusion under or issuance of the permit, would be allowed as long as their outlets were constructed prior to the effective date of these amendments.

No discharges from new outlets would be allowed. However, this should not be interpreted as a ban on new development adjacent to ASBS. Permitted discharges from new development would be allowed if such development connected to existing outlets (*i.e.*, those installed prior to the effective date); even if those outlets were modified. In other words, storm water conveyances with existing points of discharge could be modified, within the limits of good engineering practices and environmental considerations, and using appropriate control measures (*e.g.,* standard urban storm water mitigation plans) to accommodate the additional flow from new development. Alternatively, if permitted discharges from new outlets are deemed to meet the criteria in Chapter III (I) of the California Ocean Plan (*i.e.*that the discharge will not compromise the protection of ocean waters for beneficial uses, and that the public interest will be served), then the discharger may petition the State Water Board for an individual exception. Therefore, while the prohibition on permitted storm water discharges from new outlets may in some cases result in some limits on growth, such limits would not constitute an absolute ban.

Non-storm water discharges (dry weather flows) through storm water conveyances can contribute significant flows and pollutants and may include landscape irrigation overflow, groundwater pumping, illicit dumping, illicit connections, individual car wash water and other discharges. Non-storm water discharges, except those associated with emergency fire fighting, would be prohibited into ASBS under this alternative. Implementation of this prohibition would be within three years of the effective date of the California Ocean Plan amendment. Dischargers would be required to specifically address the prohibition of non-storm water discharges into ASBS in their Storm Water Management Plan/Program (SWMP) for MS4 dischargers or Storm Water Pollution Prevention Plan (SWPPP) for industrial storm water dischargers. The SWMP or SWPPP would describe the measures by which non-storm water discharges would be ultimately prevented from entering an ASBS, and interim measures that would be employed to reduce non-storm water flows until the ultimate measures are implemented.

Storm water (wet weather) runoff would not be permitted to cause or contribute to an exceedance of the California Ocean Plan's water quality objectives. To accomplish this State Water Board staff would propose an iterative process with an accelerated schedule (as compared to non-ASBS permit areas). All dischargers would be required to submit their revised SWMP or SWPPP to the Regional Water Board within six months of the effective date of the approved amendments. The SWMP or SWPPP would be required to address discharges into ASBS, and how pollutants would be reduced in runoff entering these ASBS through the implementation of BMPs. The BMPs will be described in the SWMP or SWPPP with a schedule for implementation. The SWMP or SWPPP would be subject to the approval of the Regional Water Board. The schedule must be developed to ensure BMPs are implemented as soon as practicably possible.

If the results of water quality monitoring indicate discharges are causing or contributing to exceedance(s) of applicable water quality objectives, this alternative would require the discharger to submit a report to the Regional Water Board within 30 days. That report must describe BMPs that are currently being implemented, BMPs that are planned for in the SWMP or SWPPP, and additional BMPs that may be added to the SWMP or SWPPP. The report shall include an implementation schedule. The Regional Water Board may require modifications to the report. Within 30 days following approval of the report by the Regional Water Board, a discharger would then revise its SWMP or SWPPP to incorporate any new or modified BMPs that have been and will be implemented, the implementation schedule, and any additional monitoring required. So long as the dischargers were complying with the procedures described above and were implementing the revised SWMP or SWPPP, the dischargers would not have to repeat the same procedure for continuing or recurring exceedances of the same water quality objective unless directed by the Regional Water Board to develop additional BMPs.

Effluent and receiving water monitoring results are valuable in evaluating source reduction of toxic pollutants. Monitoring results can also be used to develop and adjust management plans where necessary, implement additional source controls and other best management practices to reduce the discharge of the pollutants, and determine compliance with water quality objectives. Effluent and receiving water monitoring would be recommended as part of amendments to the California Ocean Plan. Minimum monitoring would include effluent flow measurements, visual observations for trash, and receiving water monitoring of chronic toxicity, indicator bacteria analysis, measurements of bioaccumulative impacts through chemical analysis of mussel (*e.g.*, mussel watch) or sand crab tissue analysis, and an intertidal and/or subtidal benthic community analysis. These minimum monitoring requirements would not preclude the State Water Board or

Regional Water Boards from imposing additional monitoring requirements as well. For example, for those dischargers operating under the general industrial storm water NPDES permit, they would also be required to conduct the effluent monitoring required under that permit in addition to the monitoring requirements being proposed herein.

Chronic toxicity tests on critical life stages of three kinds of marine organisms (fish, invertebrate, and plant species) on receiving water samples would be required during a minimum of two storm events. Except for the minimum sampling from two storms for chronic toxicity testing, the Regional Water Board would determine all other sample number, frequency, locations, and monitoring details. In making determinations regarding sample number, sampling frequency, sample locations, and other monitoring details the Regional Water Board would consider the size and characteristics of the watershed contributing to the discharges. The Regional Water Board would also have the option to relieve the permittee of receiving water self-monitoring requirements (with the exception of chronic toxicity) if the permittee provides support to a regional monitoring program that includes the applicable receiving waters and indicator bacteria, tissue chemistry, and benthic community components.

Staff previously attempted to pursue this approach in 2003, and the State Water Board~~,~~ at that time directed otherwise. Environmental groups and the discharger community were not in favor of this approach. In addition, USEPA did not support this approach. An attempt to amend the Ocean Plan may, again, engender major resistance from stakeholders.

S.5.3 NON-PREFERRED ALTERNATIVE: Implement Individual Exceptions for Each Storm Water and Nonpoint Source Discharger

The State Water Board has adopted seven individual exceptions to date for sewage treatment, desalination brine, public aquarium, and marine lab discharges. State Water Board staff intends to continue the approach of implementing and reviewing individual exceptions for these types of point source discharges, because each facility is sufficiently different to warrant individual exceptions with individual special conditions. Only three marine laboratories/public aquariums remain to be issued exceptions.

There are 27 applicants for an Ocean Plan exception being addressed by this proposed exception. These applicants have a variety of activities but all primarily have in common permitted storm water or nonpoint source discharges. As such, the same special conditions and prohibitions are generally applicable to all of these entities. Granting individual exceptions for each entity would entail developing, noticing, and adopting an individual CEQA document and exception for each entity. With current staff resources, it is estimated that such an approach would take at least an additional three years (from the date of this document) to complete. That approach would delay protecting natural water quality in the ASBS during the time it would take to adopt individual exceptions for each of the 27 applicants. Furthermore, adopting individual exceptions for storm water and nonpoint source dischargers would be inefficient, taking up significant staff and Board Member time and resources.

Because this alternative would delay the protection of water quality in ASBS, would be inefficient, and would not provide any advantages, staff does not support this alternative.

S.5.4 PREFERRED ALTERNATIVE: IMPLEMENT A GENERAL EXCEPTION FOR SELECTED DISCHARGERS (PREFERRED ALTERNATIVE)

Under this alternative, the State Water Board would adopt a general exception to the Ocean Plan discharge prohibition that would impose special conditions on the group of 27 storm water and nonpoint source dischargers who have applied for an exception. The proposed conditions could include: cessation of non-essential, non-storm water runoff; maintenance of natural water quality within ASBS, including during precipitation (design storm) events, by limiting wastes in storm water runoff and other activities that would otherwise cause a degradation of ocean water quality in the ASBS; and monitoring water quality and marine aquatic life within ASBS to ensure the protection of beneficial uses over time. Under this alternative, discharges must comply with all other applicable provisions of the Ocean Plan, including those provisions that maintain and protect natural ocean water quality and marine communities from pollution.

For dischargers subject to NPDES permits, prohibitions and special conditions collectively referred to as “Special Protections” for the ASBS, would be implemented through storm water management plans. For nonpoint source dischargers, the Special Protections would be implemented through a WDR, waiver, or conditional prohibition and a pollution prevention plan. All ASBS dischargers would continue to have three major requirements: (1) a continued prohibition of non-storm water discharges and runoff, with only certain exclusions; (2) wet weather runoff controlled so as not to violate “natural ocean water quality” in the ASBS receiving water; and (3) monitoring to ensure protection of beneficial uses. These three requirements of the Special Protections would be incorporated into each applicant’s permit or WDR.

The Special Protections are intended to maintain the natural hydrologic cycle and coastal ecology by allowing the flow of clean precipitation runoff into the ocean, while preserving coastal slope stability and preventing anthropogenic erosion. The 27 applicants for this exception provide essential public services, including flood control, slope stability, erosion prevention, maintenance of the natural hydrologic cycle between terrestrial and marine ecosystems, public health and safety, public recreation and coastal access, commercial and recreational fishing, navigation, and essential military operations (national security). Therefore, the exception and the terms, prohibitions, and special conditions embodied in the Special Protections for ASBS are not only protective of beneficial uses, but are in the public interest as well.

The State Water Board's effort to address storm water and nonpoint source waste discharges into ASBS using the Ocean Plan exception process is nearly complete. Applicants have now applied for exceptions, providing the necessary information for staff to proceed. In addition, the State Water Board has held three public scoping meetings, and several stakeholder meetings, for the exception and has initiated a stakeholder effort to collaborate on ASBS regional monitoring. Continuing with the general exception process for storm water and nonpoint sources would meet statutory and Ocean Plan regulatory requirements; because the process is ongoing, it would be practical and efficient to continue. Discharges authorized by an NPDES permit (and WDRs or waivers for nonpoint sources) would be allowed, but under strict limiting conditions aimed at ensuring protection of receiving water quality and marine life.

This alternative, that proposes to adopt a general exception with the Special Protections for the group of 27 storm water and nonpoint source dischargers who have applied for an exception is the alternative recommended by Staff. The remaining issues and alternatives address conditions associated with this general exception.

Continuing with the General Exception process would meet statutory and regulatory requirements for maintaining compliance with the Ocean Plan. This approach is practical and efficient, and will address all storm water and nonpoint source issues simultaneously. Terms and conditions, or "Special Protections", would be implemented through permits/storm water management plans. The General Exception approach would afford protection to the dischargers from protection from citizen suits, if the dischargers are in compliance with their permits. These permits/SWMPs/SWPPPs must conform to the Special Protections in the exception.

S.6 ENVIRONMENTAL IMPACTS AND MITIGATION

Chapter 6.0 of this FEIR evaluates in detail the environmental impacts that would result from implementation of the proposed project and sets forth mitigation measures required to avoid or reduce environmental impacts. Section 8.0 describes the potential for the proposed project to have growth-inducing impacts and potential cumulative impacts.

S.7 AREAS OF CONTROVERSY AND ISSUES TO BE RESOLVED

Section 15123 of the State CEQA Guidelines requires that a summary of an EIR identify areas of controversy known to the lead agency, including issues raised by agencies and the public. During the public comment period for the notice of preparation/initial study (NOP/IS), and in previous stakeholder meetings, various comments were received regarding the proposed project and Special Protections. In general, areas of potential controversy known to the State Water Board include:

- ASBS comprise 1/3 of the State's coastline. The concept of "special biological significance" recognized that certain biological communities, because of their value or fragility, deserve very special protection that consists of preservation and maintenance of natural water quality conditions. Preliminary findings from the recent submittal of ocean plan exception applications show ocean water quality conditions in many of the 34 ASBS not meeting the Ocean Plan levels necessary for the protection of marine life.

- State law (the Public Resources Code and the California Water Code) recognizes ASBS and the prohibition of waste discharges, and the need to provide special protections for water quality. Many of the ASBS are co-located with Marine Protected Areas (MPAs). The MPA Initiative is a major program of the current administration, being spearheaded by a Blue Ribbon Task Force and the Department of Fish and Game. Protecting water quality in ASBS and MPAs fits as an integral part of that process.

- Preliminary findings from the recent submittal of ocean plan exception applications show runoff to contain toxic levels of constituents, and receiving ocean water in some ASBS at times does not meet water quality objectives for the protection of marine life. Most of the significant discharges into ASBS are permitted storm water runoff (approximately 350). Hence certain developed ASBS are a more manageable microcosm of our greater ocean storm water issues. By focusing on ASBS storm water and certain nonpoint discharges, with comprehensive monitoring and control efforts, we will make measurable progress in solving the last great pollution problem in the coastal ocean.

- The costs associated with compliance with the Special Protections. There will be costs for controls, but there is a set-aside in Prop 84 ($35 million) to address ASBS discharges.

- Regulatory effects – additional workload for Regional Water Board and/or local agency staff that cannot be accommodated within existing budgets, concerns about impairing the ability of local agencies to protect water quality and implement Special Protections.

- ► Property development – concerns about whether siting requirements and Special Protections absolute restrictions on “no new outfalls” and discharge points to ASBS will limit property development.

  These issues were considered in the preparation of this FEIR and, where appropriate, are addressed in the environmental impact analysis presented in Chapter 6.

Granting the general exception will not violate federal antidegradation requirements because water quality will not be lowered, but rather, will be improved within the ASBS affected. Further, adoption of the General Exception will not violate the State Water Board’s antidegradation policy (SWRCB 1968) since water quality conditions are anticipated to improve; the discharges will not unreasonably affect present and anticipated beneficial uses; the discharge will not result in water quality lower than that prescribed in the Ocean Plan; and beneficial uses will be protected and potential impacts will be less than significant with mitigation incorporated.

It is anticipated that the applicants identified in this General Exception project will implement various individual or collaborative projects to comply with the terms and conditions or “Special Protections.” As part of the scoping and environmental analysis conducted for the General Exception project, project types identified include: Low Impact Development (LID); dry-weather flow diversions; and Best Management Practices (BMPs), such as Pollution Prevention BMPs and Treatment BMPs, such as infiltration basins and Gross Solids Removal Devices (GSRDs).

S.8 PUBLIC PARTICIPATION AND ADDITIONAL STEPS IN THE CEQA REVIEW PROCESS

This FEIR is being circulated to local, state, and federal agencies involved with the project and is being made available to interested organizations and individuals who may wish to review and comment on the report. The public review period for the DEIR began on January 18, 2011, and ended on May 20, 2011. During that period, written comments on the environmental document were sent to the State Water Board at the following address:

Ms. Jeanine Townsend, Clerk to the Board
State Water Resources Control Board
Division of Water
1001 I Street, 24th Floor
Sacramento, CA 95814

Copies of the FEIR can be reviewed at the following locations:

State Water Resources Control Board
1001 I Street
Sacramento, CA 95814
(916) 341-5280

The FEIR is available on the State Water Board's Web site at:
http://www.waterboards.ca.gov/water_issues/programs/ocean/asbs.shtml.

Following the close of the public comment period, the State Water Board prepared this final EIR (FEIR) that provides responses to comments on environmental issues addressed in the FEIR. Proposed responses to comments will be circulated to public agencies for review. A public hearing on the FEIR will be held by the State Water Board in the hearing room at the California Environmental Protection Agency building, 1001 I Street, Sacramento, California. Public comments on the FEIR will be accepted at this hearing before the State Water Board decides whether to certify the EIR and approve the proposed project.

1.0 INTRODUCTION

The State Water Resources Control Board (State Water Board), under its Resolutions No. 74-28, No. 74-32, and No.75-61, designated certain Areas of Special Biological Significance (ASBS) in the adoption of water quality control plans for the control of wastes discharged to ocean waters. To date, thirty-four coastal and offshore island sites have been designated ASBS. The names of these ASBS were changed by the State Water Board in April 2005 (Resolution No. 2005-0035).

Since 1983, the California Ocean Plan (Ocean Plan) has prohibited the discharge of both point and nonpoint source waste to ASBS, unless the State Water Board grants an exception. The Ocean Plan allows the State Water Board to grant exceptions to plan requirements where the State Water Board determines that the exception "will not compromise protection of ocean waters for beneficial uses, and, [t]he public interest will be served." Prior to granting an exception, the State Water Board must hold a public hearing and comply with the California Environmental Quality Act, Public Resources Code §21000 et seq. (CEQA). In addition, the United States Environmental Protection Agency must concur.

ASBS are also accorded special protection under the Marine Managed Areas Improvement Act (Act), Public Resources Code §36600 et seq. Under the Act, ASBS are a subset of state water quality protection areas and, as such, "require special protection as determined by the [State Water Board]" pursuant to the Ocean Plan (Pub. Resources Code §36700(f)). In all state water quality protection areas, waste discharges must be prohibited or limited by special conditions, in accordance with state water quality law, including the Ocean Plan (*Id.* §36710(f)).

The Public Resources Code (PRC) defines six categories of Marine Managed Areas (MMAs). These six categories are Marine Reserves, Marine Parks, Marine Conservation Areas, Marine Recreation Management Areas, Marine Cultural Preservation Areas, and State Water Quality Protection Areas (SWQPAs). Under state law the Reserves, Parks and Conservation Areas are further categorized as Marine Protected Areas (MPAs).

The PRC states that ASBS are a subset of SWQPAs and require special protection as determined by the State Water Board pursuant to the Ocean Plan and the California Thermal Plan. Specifically, PRC section 36700 (f): "Areas of special biological significance are a subset of state water quality protection areas, and require special protection as determined by the State Water Resources Control Board pursuant to the Ocean Plan adopted and reviewed pursuant to Article 4 (commencing with Section 13160) of Chapter 3 of Division 7 of the Water Code and pursuant to the Water Quality Control Plan for Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California (California Thermal Plan) adopted by the state board."

Section 36710(f) of the PRC states as follows: "In a state water quality protection area, waste discharges shall be prohibited or limited by the imposition of special conditions in accordance with the Porter-Cologne Water Quality Control Act (Division 7 (commencing with Section 13000) of the Water Code) and implementing regulations, including, but not limited to, the Ocean Plan adopted and reviewed pursuant to Article 4 (commencing with Section 13160) of Chapter 3 of Division 7 of the Water Code and the Water Quality Control Plan for Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California (California Thermal Plan) adopted by the state board. No other use is restricted." This language replaced the prior language that required point sources into ASBS to be prohibited or limited by special conditions, but allowed nonpoint sources to be controlled to the extent practicable. In other words, the absolute discharge prohibition in the Ocean Plan is maintained, unless an exception is granted.

It is important to note that many ASBS/SWQPAs occupy the same geographic areas as other State MMAs, including many MPAs. Furthermore, there are many ASBS that overlap Federal MPAs (e.g., National Marine Sanctuaries) and as of March 6, 2009, are now part of the National System of Marine Protected Areas.

The discovery of ASBS discharge prohibition violations began with the Irvine Coast ASBS, co-located with Crystal Cove State Park. On November 16, 2000, the Santa Ana Regional Water Quality Control Board (Regional Water Board) issued a cease and desist order (CDO) to the Irvine Company, the California Department of Transportation (Caltrans), and the California Department of Parks and Recreation. The CDO contains findings that the dischargers were violating or threatening to violate the discharge prohibition contained in the California Ocean Plan against discharges to the Irvine Coast ASBS. Caltrans petitioned the State Water Board to review the CDO. On April 26, 2001, the State Water Board decided Caltrans was in violation of the Ocean Plan ASBS discharge prohibition in that:

- there are waste discharges from Pacific Coast Highway,
- discharges on the beach above the high tide line do constitute discharges to the ASBS,
- the Ocean Plan does in fact regulate the discharge of wastes through storm water conveyances, and
- coverage under Caltrans' statewide NPDES permit for storm water discharges does not relieve the discharger from complying with the Ocean Plan prohibitions on discharges into the ASBS.

This finding prompted the Board to fund the Southern California Coastal Water Research Project (SCCWRP) to perform a statewide survey to assess the extent of these storm water and nonpoint source discharges. In SCCWRP, working with the

State Water Board's Ocean Unit, found 1,654 discharges to potentially be in violation (SCCWRP 2003).

To address these issues, on October 18, 2004, the State Water Board notified responsible parties to cease storm water and nonpoint source waste discharges into ASBS or to request an exception under the Ocean Plan. Several responsible parties submitted requests, or conditional requests, for exceptions. Subsequently, the State Water Board provided general instructions for exception application packages via its website. The State Water Board sent letters (in a few cases later in 2005) to responsible parties, providing specific instructions and a deadline for submission of the application package by May 31, 2006.

The State Water Board has received 27 applications for the general exception to the Ocean Plan prohibition against waste discharges to ASBS. The applications were filed by permitted storm water dischargers and nonpoint source dischargers, who are identified in Table 1.

The Ocean Plan also states that "The State Board may, in compliance with the California Environmental Quality Act, subsequent to a public hearings, and with the concurrence of the U. S. Environmental Protection Agency, grant exceptions where the Board determines: a) the exception will not compromise protection of ocean waters from beneficial uses, and b) the public interest will be served." In order not to compromise beneficial uses, natural water quality must be maintained in an ASBS. Examples of public interests are marine research, education, and flood control. The exception process, in compliance with the Ocean Plan, is the mechanism by which the Special Protections for the ASBS may be instituted.

The Project title is "Exception to the California Ocean Plan (Ocean Plan) for the City of Carmel-by-the-Sea, Connolly-Pacific Company, Department of Parks and Recreation, California Department of Transportation (Caltrans), U.S. Department of Defense (Air Force), Humboldt County, Humboldt Bay Harbor District, Irvine Company, City of Laguna Beach, Los Angeles County, City of Malibu, Marin County, City of Monterey, Monterey County, City of Pacific Grove, Pebble Beach Company, City of Newport Beach (and on behalf of the Pelican Point Homeowners), U.S. Department of Interior (Point Reyes National Seashore), City of San Diego, San Mateo County, Santa Catalina Island Company (and on behalf of the Santa Catalina Island Conservancy), The Sea Ranch Association, City of Trinidad, Trinidad Rancheria, U.S. Department of Interior (Redwoods National and State Park), and U.S. Department of Defense (Navy) storm water and nonpoint source discharges into ASBS. The following ASBS are included in this exception: Redwoods National Park, Trinidad Head, King Range, Saunders Reef, Del Mar Landing, Jughandle Cove, Gerstle Cove, Point Reyes Headlands, Duxbury Reef, James V. Fitzgerald, Año Nuevo, Pacific Grove, Carmel Bay, Point Lobos, Julia Pfeiffer Burns, Salmon Creek Coast, Laguna Point to Latigo Point, San Nicolas Island

and Begg Rock, Northwest Santa Catalina Island, Western Santa Catalina Island, Southeast Santa Catalina Island, Heisler Park, Robert E. Badham, Irvine Coast, La Jolla, and San Clemente Island. See Table 1. below.

1.1 DEFINITION OF THE PROJECT UNDER CEQA

The proposed project under CEQA is the adoption and implementation of the proposed General Exception and a statewide Special Protections that establish minimum requirements for the permitting, monitoring, and continued operation of selected point and non-point discharges, as required by the California Ocean Plan (the related California Water Code section, included in Appendix 10).

The proposed General Exception would be adopted into the Ocean Plan (Water Quality Control Plan for Ocean Waters of California), in furtherance of legislative policy set forth in Section 1300 of Division 7 of the California Water Code (CWC)(Stats. 1969, Chap. 482). The Regional Water Boards would implement the Special Protections along with those authorized local agencies that would be given authority by the Regional Water Boards to implement and enforce the policy. See Section 2.0 "Project Description," for a more detailed description of the proposed special conditions and the project objectives. The proposed special protection is presented in Appendix 1.

1.2 LEAD AGENGY

Under CEQA, the lead agency is the public agency with primary responsibility over the proposed project. The State Water Board is the lead agency under CEQA for this project because of its regulatory authority over water quality in California and, as specified in the legislation, its lead role in adopting the new General Exception and Special Protections.

1.3 PURPOSE AND FOCUS OF THIS EIR

The purpose of an EIR is to disclose and mitigate impacts of a proposed project and determine feasible alternatives that could reduce those impacts. An EIR does not recommend either approval or denial of a project. An EIR is an informational document used in the planning and decision-making process by the lead agency and responsible and trustee agencies. It assists decision makers in fulfilling CEQA's requirement that they balance the benefits of a proposed project against its environmental effects in deciding whether to carry out a project.

If the lead agency decides to carry out a project addressed in an EIR, it prepares findings of facts that discuss the disposition of each of the significant environmental effects addressed in the EIR. If adverse environmental effects are identified as significant and unavoidable, the proposed project still may be approved by the lead agency if it finds that the social, economic, or other benefits of the project outweigh its unavoidable risks. The lead agency would then prepare a statement of overriding considerations, in addition to the findings, that discuss the specific reasons for approving the project, based on information in the EIR and other information in the record.

The overall purpose of this EIR is to fulfill the following CEQA objectives:

► identify the project's significant environmental effects on the environment,
► indicate the manner in which these significant effects can be mitigated or avoided,
► identify alternatives to the project,
► facilitate public involvement, and
► foster coordination among various governmental agencies.

This EIR is a program EIR intended to provide information at a general (or programmatic) level of detail on the potential impacts of implementing the proposed project. As described by Section 15168(a) of the State CEQA Guidelines, a program EIR is one that may be prepared on a series of actions that can be characterized as one large project and that are related (1) geographically; (2) as logical parts in a chain of contemplated actions; (3) in connection with the issuance of rules, regulations, plans, or other general criteria to govern the conduct of a continuing program; or (4) as individual activities carried out under the same authorizing statutory or regulatory authority and having generally similar effects that can be mitigated in similar ways.

Because the proposed project involves the adoption and implementation of special protections and a series of specific exceptions to the waste discharge prohibition that may be characterized as one large project and are related as individual activities carried out under the same authority and having similar environmental effects which can be mitigated in similar ways, a General Exception with special conditions associated with a statewide (coastal and waters surround islands) program, a program-level EIR is the appropriate framework in which to address the project's environmental impacts. Subsequent, project-level CEQA compliance and environmental analysis at a regional or local level may be required if subsequent actions implementing the Special Protections are proposed that do not fall within the scope of this EIR.

The focus of this FEIR is determining, on a broad scale, the potential environmental impacts of the proposed project and identifying mitigation measures for those impacts that may be significant. Additionally, although not required by CEQA, an analysis of fiscal and economic impacts is included in this EIR to assist in the process that is followed in the adoption of new exceptions to the Ocean Plan regulations.

1.4 EIR SCOPING PROCESS

The State Water Board held numerous meetings and discussions regarding the development of the Special Protections. Participating agencies and stakeholders and Responsible Parties included Natural Resources Defense Council (NRDC) California Coastkeeper, The California Stormwater Quality Association (CASQA), the California Coastal Commission (CCC) and the National Oceanic and Atmospheric Administration (NOAA). During 2005 through 2009, the stakeholders and Responsible Parties reviewed and provided input on the Draft Staff Proposal, Draft Special Protections and, Draft Data Report.

A Notice of Preparation of a Statewide Program Environmental Impact Report and Initial Study were prepared for the project and posted to solicit public input and comment on February 9, 2010. A 30-day public review period on the NOP began February 9, 2010, and ended on March 15, 2010. During that period, the public could submit written comments to the State Water Board on the NOP and issues to be evaluated in the EIR. Comments were received and are posted on the State Water Boards ASBS webpage - http://www.waterboards.ca.gov/water_issues/programs/ocean/asbs_comments031510.shtml.

1.5 ORGANIZATION OF THIE DOCUMENT

This FEIR is organized into the following chapters:

► The Executive Summary summarizes the public review process, provides a brief overview of the project description, and describes the project alternatives.

► Chapter 1.0, “Introduction,” provides an overview of the proposed project and the intent of the Project, identifies the lead agency, describes the purpose and focus of this FEIR, describes the EIR scoping process, outlines the chapters of this FEIR.

► Chapter 2.0, “Project Description,” identifies existing Responsible Parties in violation of the ASBS waste discharge prohibition.

► Chapter 3.0, “Regulatory Setting,” presents an overview of existing government requirements affecting ASBS, representative requirements of Regional Water Boards that are already in effect and environmental protection requirements.

► Chapter 4.0, “Alternatives Analysis,” describes alternatives to the proposed project, including a no-project alternative; identifies the environmentally superior preferred alternative. Alternatives that have been proposed and rejected from further consideration are also identified in the chapter, along with the reasons for their rejection.

- Chapter 5.0, “Environmental Baseline,” includes sections on each of the ASBS environmental issue areas that may be significantly affected as a result of the General Exception Project and Special Protections are analyzed in detail in this EIR. For each issue area (e.g., water quality and marine life), the section describes the existing environmental setting, describes a range of representative conditions, presents thresholds for determining the significance of impacts, evaluates the environmental impacts associated with implementing the project~~,~~.

- Chapter 6.0, “Environmental Analysis,” includes sections on each of the environmental issue areas that may be significantly affected as a result of the Project and Special Protections and are analyzed in detail in this EIR. For each issue area (e.g., water quality and biological resources), the section describes the existing environmental setting and regulatory framework, describes a range of representative conditions, presents thresholds for determining the significance of impacts, and evaluates the environmental impacts associated with implementing the project.

- Chapter 7.0, “Economic Analysis,” discusses potential costs related to the implementation of the Special Protections and potential waste discharge prohibition management practices.

- Chapter 8.0, “Other Statutory Requirements,” presents a discussion of cumulative impacts that could result from implementation of the proposed project in combination with other past, present, and reasonably foreseeable future projects in the area; discusses the potential for growth-inducing impacts; discloses the significant and unavoidable impacts identified in the environmental impact analysis; and describes the significant and irreversible environmental changes associated with implementing the project.

1.7 AGENICIES THAT MAY USE THIS DOCUMENT

Regional Water Boards and local agencies, including counties and cities, may use the information provided in this EIR to assist them in assessing the environmental impacts of their point and non-point source discharges into ASBS, or in modifying local ordinances and land use plans to conform to the proposed special protections.

2.0 PROJECT DESCRIPTION

This chapter describes the proposed statewide general exception and Special Protections for storm water and nonpoint source discharges to ASBS. Prior to that, it provides an overview of information about the existing discharges into ASBS, provides background on the number and locations of these discharges throughout the State, information about the environmental concerns related to ASBS, and an overview of the existing Ocean Plan regulations in the State.

2.1 OVERVIEW OF THE DISCHARGES

PROJECT DESCRIPTION

(General Exception for ASBS Storm Water and Nonpoint Source Discharges, with Special Protections for ASBS)

The parties identified herein seek an exception from the Ocean Plan's prohibition of waste discharges into ASBS. The exception with conditions, if approved, would allow their continued storm water and nonpoint source discharge into the Redwoods National Park, Trinidad Head, King Range, Saunders Reef, Del Mar Landing, Jughandle Cove, Gerstle Cove, Point Reyes Headlands, Duxbury Reef, James V. Fitzgerald, Año Nuevo, Pacific Grove, Carmel Bay, Point Lobos, Julia Pfeiffer Burns, Salmon Creek Coast, Laguna Point to Latigo Point, San Nicolas Island and Begg Rock, Northwest Santa Catalina Island, Western Santa Catalina Island, Southeast Santa Catalina Island, Heisler Park, Robert E. Badham, Irvine Coast, La Jolla, and San Clemente Island ASBS. This would provide additional protections for beneficial uses that are not currently provided.

On October 18, 2004, the State Water Board notified applicants to cease storm water and nonpoint source waste discharges into ASBS or to request an exception under the Ocean Plan. Several applicants submitted requests, or conditional requests, for exceptions. Subsequently, the State Water Board provided general instructions for exception application packages via its web site.[4] The State Water Board sent letters to applicants, providing specific instructions and deadlines for submission of the application packages.

The State Water Board has received 27 applications for the general exception to the Ocean Plan prohibition against waste discharges to ASBS. The applications were filed by permitted and non-permitted storm water dischargers and nonpoint source dischargers, who are identified in Table 2. A map showing locations of the ASBS that are subject to the general exception is provided in Figure 2.1.

U.S. Dept. of Interior, Redwoods National and State Park	Redwoods National Park
U.S. Dept. of Defense, Air Force	James V. Fitzgerald

Applicant	ASBS
U.S. Dept. of Defense, Navy	San Nicolas Island & Begg Rock
U.S. Dept. of Defense, Navy	San Clemente Island

Figure 2.1 Map of ASBS Sites and General Exception Applicants

The mitigating terms and conditions for the general exception are the Special Protections (Appendix 1) that will limit the storm water and nonpoint source waste discharges by the applicants to the affected ASBS. The intent is to ensure that such discharges will be controlled to protect beneficial uses within ASBS and to protect and maintain the natural hydrologic cycle and coastal ecology (e.g., the flow of clean precipitation runoff into the ocean, while preserving coastal slope stability, and preventing anthropogenic erosion). The fundamental requirements include: (1) Cessation of non-storm water runoff, (2) Maintenance of natural water quality within ASBS, including during precipitation (design storm) events, by limiting wastes in storm water runoff and other activities that would otherwise cause a degradation of ocean water quality in the ASBS, and (3) Adequate Monitoring to assure that beneficial uses are protected.

3.0 REGULATORY SETTING

3.1 OVERVIEW OF EXISTING FEDERAL AND STATE REGULATIONS AFFECTING ASBS

This section describes current federal and state laws, the regulations and practices that govern California's coastal water quality in consideration of the Special Protections. These laws, programs, and practices represent the regulatory setting for measuring incremental impacts of the Special Protections.

3.1.1 Porter-Cologne Water Quality Control Act and Federal Clean Water Act

3.1.1.1 <u>Porter-Cologne Water Quality Control Act</u>

The Porter-Cologne Water Quality Control Act (Porter-Cologne) is the State of California's primary water quality control law and addresses two key functions – planning and waste discharge regulation. Porter-Cologne provides the State Water Board and the nine Regional Water Boards the responsibility and authority necessary to protect and enhance water quality in California. Of these nine Regional Water Boards, six have jurisdictions that include the coastal waters of the State.

A. Water Quality Objectives and Water Quality Control Plans

Porter-Cologne requires the State Water Board to adopt state policies for water quality control and statewide water quality control plans, including a plan for ocean waters (Water Code §§13170, 13170.2, 13391). Water quality control plans designate beneficial uses of water, establish water quality objectives to protect those uses, and contain a program to implement the objectives. Statewide water quality control plans and policies are binding on the Regional Water Boards. The plan adopted by the State Water Board to protect ocean waters is designated the Water Quality Control Plan for Ocean Waters of California, referred to as the California Ocean Plan (Ocean Plan). Each Regional Water Board is also required under Porter-Cologne to adopt and implement water quality control plans (basin plans) which recognize the unique characteristics of each region with regard to natural water quality, actual and potential beneficial uses, and water quality problems.

B. Authority to Regulate Point and Nonpoint Sources

Porter-Cologne establishes a program to regulate waste that could affect water quality through waste discharge requirements (WDRs), conditional waivers of WDRs, or prohibitions (see Water Code §§13243, 13263, 13269). The term "Waste" is broadly defined in Porter-Cologne and includes toxic pollutants, as well as other waste substances [Id. §13050(d)]. "Waters of the state" is similarly broadly defined to include all surface waters, including bays and estuaries, and California's coastal ocean waters up to the State's three nautical-mile boundary.

Porter-Cologne also authorizes the Water Boards to investigate water quality and to require waste dischargers to submit monitoring and technical reports (Id. §§ 13267, 13383). In addition, Porter-Cologne gives the Water Boards extensive enforcement authority to respond to unauthorized discharges, discharges in violation of applicable requirements, discharges that cause pollution or nuisance, and other matters. The enforcement options include, among others, cleanup and abatement orders, cease and desist orders (CDOs), and administrative civil liability orders (Id. §§13301, 13304, 13323).

Under Porter-Cologne, all waste discharges, that could affect water quality, including nonpoint source discharges of waste, must be regulated. Nonpoint source (NPS) pollution, unlike point source pollution from industrial and sewage treatment plants, comes from many diffuse sources. Some types of NPS pollution are caused by rainfall or snowmelt moving over and through the ground. As the runoff moves, it picks up and carries away natural and human-made pollutants, depositing them into lakes, rivers, wetlands, coastal waters, and groundwater. NPS pollution may originate from several sources, including agricultural runoff, forestry operations, urban runoff, boating and marinas, active and historical mining operations, atmospheric deposition, and wetlands.

Nonpoint sources in California must be regulated under WDRs, conditional waivers of WDRs, or basin plan prohibitions. However, WDRs need not necessarily contain numeric effluent limits. The state's Policy for Implementation and Enforcement of the Nonpoint Source Pollution Control Program (NPS Policy) provides guidance regarding the prevention and control of nonpoint source pollutant discharges and enforcement of nonpoint source regulations (e.g., WDRs). In practice, the Regional Water Boards do not usually impose numeric effluent limits on nonpoint pollution sources; rather, they primarily rely on implementation of Best Management Practices (BMPs) to reduce pollution.

3.1.1.2 Federal Clean Water Act

The Water Boards are also required to implement the federal Clean Water Act (CWA). Under section 303(c) of the CWA, the Water Boards adopt water quality standards for waters of the United States. The beneficial use designations and water quality objectives (together with an antidegradation policy) constitute water quality standards for purposes of the CWA (See Clean Water Act § 303(c) (2) (A); 40 C.F.R. §§131.3(i), 131.6). All water quality control plans, which include the water quality standards, must be approved by the U.S. Environmental Protection Agency (U.S. EPA).

Pursuant to Section 402 of the CWA, the Water Boards issue National Pollutant Discharge Elimination System (NPDES) permits. Section 402 of the CWA requires that all point source discharges of pollutants to waters of the United States be regulated under a NPDES permit. Typical discharges that are regulated under NPDES permits include discharges from publicly owned treatment works (POTWs) and industrial facilities. In addition, certain storm water discharges are regulated under the NPDES permit program.

In accordance with Section 401 of the CWA, the Water Boards also assess the potential effects of federally permitted or licensed projects that could harm beneficial uses. Under section 401, the State can issue water quality certifications to ensure that water quality is not degraded due to the action. The Water Boards also implement the total maximum daily load (TMDL) program, which is required under section 303(d) of the CWA.

3.2 CALIFORNIA OCEAN PLAN AND ASBS

The Ocean Plan establishes water quality objectives for California's ocean waters and provides the basis for regulation of wastes discharged into the State's coastal waters through control of point and nonpoint source discharges. The State Water Board adopts the Ocean Plan, and both the State and the six coastal Regional Water Boards implement and interpret the Ocean Plan. The Ocean Plan consists of an Introduction, Sections I thru III, and supporting tables and appendices.

The introduction describes the purpose of the plan, the State Water Board's authority to develop, adopt, and implement the plan, applicable waters, wastes, and discharges, and the principles guiding the development and interpretation of the plan.

Section I identifies the applicable beneficial uses of marine waters including: protection and enhancement of marine life, ASBS, fish migration, fish spawning, shellfish harvesting, rare and endangered species, recreation, industrial water supply, commercial and sport fishing, mariculture, aesthetic enjoyment, and navigation.

Section II presents narrative and numerical water quality objectives adopted by the State Water Board to protect these beneficial uses. Chapter III describes the controls and prohibitions applicable to ocean discharges and the process for preparing waste discharge requirements for permittees discharging into ocean waters.

Section III includes:

- The criteria that each discharger must meet before a new discharge can be permitted,
- Technology based effluent limitations as well as a method for translating water quality objectives into discharge specific water quality based effluent limits,
- The process for nominating and designating ASBS for consideration and approval,
- Discharge prohibitions (e.g., municipal or industrial sludges, bypassing, discharge into ASBS, and others) and general provisions,
- A mandate that requires dischargers to monitor their discharges, and
- Provisions for allowing exceptions to the Ocean Plan under special circumstances, as discussed below.

3.2.1 <u>Areas of Special Biological Significance</u>

Appendix I of the Ocean Plan defines ASBS as those *areas requiring protection of species or biological communities to the extent that alteration of natural water quality is undesirable*. Section II of the Ocean Plan designates the preservation and enhancement of ASBS as a beneficial use of ocean waters.

The State Water Board first established the concept of "areas of special biological significance" in the 1972 Ocean Plan and the Water Quality Control Plan for Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California (Thermal Plan). The coastal Regional Water Boards identified candidate areas and recommended the areas to be designated as ASBS to the State Water Board. Following those recommendations, on March 21, 1974, the State Water Board, in Resolution No. 74-28, Designation of Areas of Special Biological Significance, decided that: *"The list of Areas of Special Biological Significance will be used to identify for planning purposes, those areas where the regional water quality control boards will prohibit waste discharges...."* Thirty-one ASBS were designated at that time. Two more ASBS were designated later in 1974, in Resolution No. 74-32, and in 1975 another ASBS was designated in Resolution No.75-61. As of 2010, there are 34 ASBS.

The most recent amendment to the Ocean Plan that addresses ASBS occurred in 2005 when the State Water Board adopted Resolution No. 2005-0035 to conform to the nomenclature adopted by the Legislature within the Marine Managed Areas Improvement Act, as described in Section 1.3.

3.2.2 <u>Discharge Prohibition into ASBS</u>

Since 1983, the Ocean Plan has prohibited waste discharges to ASBS (SWRCB 1983); however, earlier versions of the Ocean Plan did not. The 1972 Ocean Plan required that waste be discharged *"a sufficient distance from areas designated as being of* *special biological significance to assure maintenance of natural water quality conditions in these areas."* State Water Board guidance issued in the early 1970's advised the Regional Water Boards that sewage or industrial point source discharges that would alter water quality in an ASBS should be prohibited. Nonpoint source waste discharges, including storm water runoff, would be controlled to the extent practicable. At that time, the Water Boards focused primarily on discharges from traditional point sources, such as sewage treatment plants, into ASBS.

The 2005 Ocean Plan, in Section III. E., Implementation Provisions for Areas of Special Biological Significance, states that "*Waste* shall not be discharged to areas designated as being of special biological significance. Discharges shall be located a sufficient distance from such designated areas to assure maintenance of natural water quality conditions in these areas".*

The 2005 Ocean Plan does allow the Regional Water Boards to approve *"limited term"* (i.e., weeks or months) activities as described in Section III. E. Limited-term activities include, but are not limited to, activities such as maintenance/repair of existing boat facilities, restoration of sea walls, repair of existing storm water pipes, and replacement/repair of existing bridges. Limited-term activities may result in temporary and short-term changes in existing water quality. Water quality degradation shall be limited to the shortest possible time. The activities must not permanently degrade water quality or result in water quality lower than that necessary to protect existing uses, and all practical means of minimizing such degradation shall be implemented.

Despite the prohibition against waste discharges into ASBS, a survey identified approximately 1,658 outfalls (SCCWRP 2003). Storm water and nonpoint source discharges make up the majority of the discharges identified. In response, the State Water Board initiated a concerted effort to address the discharges and to bring them into compliance with the Ocean Plan. This effort includes addressing storm water and nonpoint source discharges and developing an exception for these discharges that achieves and maintains the natural water quality of the receiving water in the ASBS. A General Exception for 27 applicants is the subject of this document which focuses on permitted storm water and nonpoint source discharges into ASBS.

Historically, the State Water Board has applied the prohibition to "direct discharges" regardless of whether the discharge represents point or nonpoint source. The prohibition does not apply to upstream discharges to rivers that flow into ASBS. These indirect discharges into naturally occurring streams are regulated under the Basin Plans by the Regional Water Boards to protect downstream beneficial uses.

3.2.3 <u>ASBS and Exceptions to the California Ocean Plan</u>

Section III (I) (1) of the 2005 Ocean Plan states:

> *"The State Board may, in compliance with the California Environmental Quality Act, subsequent to a public hearing, and with the concurrence of the U.S. Environmental Protection Agency, grant exceptions where the Board determines:*
>
> *a. The exception will not compromise protection of ocean waters for beneficial uses, and,*
>
> *b. The public interest will be served."*

In order to initiate the exception process, an applicant must prepare and submit an application requesting an exception to the appropriate Regional Water Board and the State Water Board. The application should include information and data to enable the State Water Board to make the appropriate determination in regard to the request for the exemption and compliance with CEQA.

In order to be granted an exception, the application and supporting documentation must support a finding that the discharge has not resulted in the alteration of natural water quality in the receiving waters. The application must also support a finding that the public interest will be better served by granting the exception. An example of relevant factors might include the degree of environmental damage that would occur if the discharge were moved (e.g., if the discharge were in a particularly fragile area and moving it would cause greater damage than leaving it). When considering an exception, the State Water Board must comply with CEQA in the consideration of environmental impacts, preparation of environmental documents, and comply with Porter-Cologne, the Federal Clean Water Act, and the State Water Board's policies and procedures relating to Water Quality Planning.

If the State Water Board acts to approve an exception, the submittal package and State Water Board documents are submitted to U.S. EPA for concurrence. Although an exception grants permission to discharge into an ASBS, the exceptions are generally subject to review every 3 years during Ocean Plan Triennial Reviews. Exceptions do not function as permits (WDRs or waivers). In order to legally discharge into an ASBS, the discharger must obtain both a permit and an approved exception.

Four ASBS exceptions were issued between 1975 and 1990. These were for the following single point source discharges: (1) the Navy's waste water treatment plant outfall at San Clemente Island, (2) the Humboldt County Resort Improvement District waste water treatment plant outfall at Shelter Cove, (3) the Carmel Sanitary District (currently Carmel Area Wastewater Treatment District) outfall, and (4) the Navy desalination plant discharge at San Nicolas Island. Since 2004, three additional exceptions were issued by the State Water Board (see section 3.4.1 below) for a current total of seven exceptions to allow discharge into an ASBS.

3.3 MARINE MANAGED AREAS IMPROVEMENT ACT

Assembly Bill 2800 (Chapter 385, Statutes of 2000), the Marine Managed Areas Improvement Act, was approved by the Governor on September 8, 2000. This law added sections to the Public Resources Code (PRC) that are relevant to ASBS (36602(d)(6). The act defines six categories of marine managed areas (MMAs). These six categories are marine reserves, marine parks, marine conservation areas, marine recreation management areas, marine cultural preservation areas, and state water quality protected areas (SWQPAs). Section 36700(f) of the PRC defines a SWQPA as "a non-terrestrial marine or estuarine area designated to protect marine species or biological communities from an undesirable alteration in natural water quality, including, but not limited to, areas of special biological significance that have been designated by the State Water Resources Control Board through its water quality control planning process." Section 36710(f) of the PRC stated: "In a state water quality protection area, point source waste and thermal discharges shall be prohibited or limited by special conditions. Nonpoint source pollution shall be controlled to the extent practicable. No other use is restricted." The classification of ASBS as SWQPAs went into effect on January 1, 2003 (without State Water Board action) pursuant to section 36750 of the PRC (SWRCB 1979).

Senate Bill (SB) 512 (Chapter 854, Statutes of 2004) amended the MMAs portion of the PRC, effective January 1, 2005, to clarify that ASBS are a subset of SWQPAs and require special protection as determined by the State Water Board pursuant to the Ocean Plan and the California Thermal Plan. Specifically, SB 512 amended the PRC section 36700 (f) definition of SWQPA to add the following: "Areas of special biological significance are a subset of state water quality protection areas, and require special protection as determined by the State Water Resources Control Board pursuant to the California Ocean Plan adopted and reviewed pursuant to Article 4 (commencing with Section 13160) of Chapter 3 of Division 7 of the Water Code and pursuant to the Water Quality Control Plan for Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California (California Thermal Plan) adopted by the state board."

Section 36710(f) of the PRC was also amended as follows: "In a state water quality protection area, waste discharges shall be prohibited or limited by the imposition of special conditions in accordance with the Porter-Cologne Water Quality Control Act [Division 7 (commencing with Section 13000) of the Water Code] and implementing regulations, including, but not limited to, the California Ocean Plan adopted and reviewed pursuant to Article 4 (commencing with Section 13160) of Chapter 3 of

Division 7 of the Water Code and the Water Quality Control Plan for Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California (California Thermal Plan) adopted by the state board. No other use is restricted."

This language replaced the prior wording stating that point sources into ASBS must be prohibited or limited by special conditions, and that nonpoint sources must be controlled to the extent practicable. In other words, the absolute discharge prohibition in the Ocean Plan stands, unless an exception is granted.

3.4 REGULATORY ACTIONS AND RELATED TECHNICAL EFFORTS

3.4.1 <u>State Water Board Evaluation of Discharges into ASBS</u>

In 2000, the State Water Board received a petition from California Department of Transportation (Caltrans) that questioned the applicability of the ASBS discharge prohibition to storm water discharges. The petition sought review of a CDO issued by the Santa Ana Regional Water Board to the Irvine Company, Caltrans, and the California Department of Parks and Recreation. The CDO found that the dischargers were violating or threatening to violate the prohibition against discharges to the Irvine Coast ASBS. In 2001, the State Water Board adopted Order WQ 2001-08 in which the State Water Board held that the ASBS discharge prohibition in the Ocean Plan applies to storm water discharges. The State Water Board also held that Caltrans coverage under a storm water permit did not relieve the discharger from complying with the Ocean Plan prohibition. These findings prompted the State Water Board to fund a statewide survey by the Southern California Coastal Water Research Project (SCCWRP) to assess the extent of storm water and nonpoint source discharges into ASBS as described in Section 3.2. In 2003, SCCWRP, working with the State Water Board's Ocean Unit, found 1,654 discharges without Ocean Plan exceptions. Waste discharges identified as draining (or having drained) into ASBS include point sources of waste water (fish cleaning stations, marine labs and aquaria, wastewater treatment plants), sanitary sewer system overflows, permitted storm water discharges and associated dry weather flows, and nonpoint sources including marina and boating operations, military operations, septic seepage, and runoff from golf courses and other sources. A majority of the discharges into ASBS were identified as nonpoint source and permitted storm water discharges.

Staff then began the effort to address ASBS waste discharges, where appropriate, under the Ocean Plan exception process. The proposed exceptions generally fell into two categories. The first category consists of individual exceptions for marine laboratory discharges. The second category constitutes a group exception for storm water and nonpoint source runoff discharges into ASBS by identified responsible parties. For the first category, the State Water Board has adopted three individual exceptions for marine lab waste seawater and storm water runoff. The exceptions were for the Scripps Institute of Oceanography (SIO) in La Jolla, USC's Wrigley Institute on Santa Catalina Island, and the UC Davis Bodega Marine Laboratory.

The second category covers entities with storm water and nonpoint source runoff discharges into ASBS. To address these discharges, State Water Board staff sent letters in late 2004 notifying ASBS dischargers that they must cease discharging or apply for an Ocean Plan exception. Another round of letters was sent in August 2005 to those respondents who requested exceptions, further describing the data that must be submitted to proceed with the exception process. For storm water and nonpoint source applicants, the original deadline for submitting that data was May 31, 2006, but the State Water Board staff has allowed late applications to be accepted.

All of these discharges are currently in violation of the Ocean Plan ASBS waste discharge prohibition because they lack an exception. Twenty-seven parties with either nonpoint source or permitted storm water discharges have applied for an exception from the Ocean Plan ASBS waste discharge prohibition. Due to the large number of discharges and responsible parties, staff developed several alternative approaches for addressing these discharges as described in Section 4.0. Alternatives under consideration include no action, relocation of all discharges, and proposing a General Exception which serves as the basis of this document. As described in Section 4.0, staff believes that a general exception is the most effective means to regulate discharges into ASBS.

3.4.2 Natural Water Quality

SIO operates and maintains the outfalls into the La Jolla ASBS. The State Water Board issued the first Ocean Plan exception (after the SCCWRP survey) to SIO (Resolution No. 2004-52). The San Diego Regional Water Board subsequently issued an NPDES Permit to SIO. As part of the SIO exception, State Water Board directed staff to create an ASBS Natural Water Quality Committee (NWQC) to define natural water quality in the San Diego-Scripps ASBS in La Jolla. The NWQC had a three-year mission to advise State Water Board staff regarding impacts of SIO's discharges into an adjoining ASBS. While the committee focused on SIO and other relevant data in the vicinity of SIO, they also recognized the importance of their work in the greater context of the ASBS, Ocean Plan, and storm water issues.

In September 2010 a final report from the NWQC was presented to the State Water Board, which included a definition of Natural Water Quality. The definition states that natural water quality is "That water quality (based on selected physical chemical and biological characteristics) that is required to sustain marine ecosystems, and which is without apparent human influence, *i.e.*, an absence of significant amounts of:

a) man-made constituents (*e.g.,* DDT);

b) other chemical (*e.g.,* trace metals), physical (temperature/thermal pollution, sediment burial) and biological (*e.g.*, bacteria) constituents at levels that have been elevated due to man's activities above those resulting from the naturally occurring processes that affect the area in question; and

c) non-indigenous biota (*e.g.,* invasive algal bloom species) that have been introduced either deliberately or accidentally by man."

The definition also states that: "it is not practical to identify a unique seawater composition as exhibiting *natural water quality*. Nevertheless, the committee believes that it is practical to define an *operational natural water quality for an ASBS*, and that such a definition must satisfy the following criteria:

- it should be possible to define a *reference* area or areas for each ASBS that currently approximate *natural water quality* and that are expected to exhibit the likely natural variability that would be found in that ASBS,

- any detectable human influence on the water quality must not hinder the ability of marine life to respond to natural cycles and processes."

The NWQC's complete definition of Natural Water Quality and their other findings may be found in the Summation of Findings, Natural Water Quality Committee 2006-2009, in Appendix 8.

3.4.3 Storm Water and NPS Discharges

Most of the discharges currently discharging into ASBS are either storm water or nonpoint source discharges. The means by which these discharges are regulated is described below.

A. Storm Water

The NPDES Storm Water Program implemented by the Water Boards has three distinct components – municipal, industrial, and construction.

1) Municipal Discharges

The State Water Board regulates storm water discharges from municipal separate storm sewer systems (MS4s). The MS4 program issued permits in two phases, Phase I and Phase II. Under Phase I, which started in 1990, the Regional Water Boards have adopted NPDES permits for medium (serving between 100,000 and 250,000 people) and large (serving more than 250,000 people) municipalities. Most of these permits are issued to a group of co-permittees encompassing an entire metropolitan area. These permits are reissued as the permits expire. As part of Phase II, the State Water Board adopted a General Permit for the Discharge of Storm Water from Small MS4s (WQ Order No. 2003-0005-DWQ) to provide permit coverage for smaller municipalities, including non-traditional Small MS4s, which are governmental facilities such as military bases, public school campuses, and prison and hospital complexes. The State Water

Board has also adopted a statewide permit which addresses the storm water discharges from the California Department of Transportation (Caltrans) right-of-way.

The MS4 permits require the discharger to develop and implement a Storm Water Management Plan/Program (SWMP) with the goal of reducing the discharge of pollutants to the maximum extent practicable (MEP). MEP is the performance standard specified in Section 402(p) of the CWA. The management programs specify what BMPs will be used to address certain program areas. The program areas include public education and outreach; illicit discharge detection and elimination, construction and post-construction and good housekeeping for municipal operations. MS4 permits also require permittees to reduce the discharge of pollutants so that water quality standards are met. In general, medium and large municipalities are required to conduct chemical monitoring, though small municipalities are not. Also, the Small MS4 General Permit provides that the SWMP must be available for public review and comment, and must be approved by the appropriate Regional Water Board, or its Executive Officer, prior to permit coverage commencing.

2) Industrial Discharges

Under the industrial program, the State Water Board issues a General NPDES Permit that regulates discharges associated with ten broad categories of industrial activities. This Industrial General Permit requires the implementation of management measures that will achieve the performance standard of best available technology economically achievable (BAT) and best conventional pollutant control technology (BCT), and achieve compliance with water quality standards. The permit also requires that dischargers develop a Storm Water Pollution Prevention Plan (SWPPP) and a monitoring plan. Through the SWPPP, dischargers are required to identify sources of pollutants, and describe the means to manage the sources to reduce storm water pollution. For the monitoring plan, facility operators may participate in group monitoring programs to reduce costs and resources.

3) Construction Discharges

The construction program requires dischargers whose projects disturb one or more acres of soil (or whose projects disturb less than one acre but are part of a larger common plan of development that in total disturbs one or more acres) to obtain coverage under the General Permit for Discharges of Storm Water Associated with Construction Activity (Construction General Permit). The Construction General Permit requires the development and implementation of a SWPPP that lists the BMPs the discharger will use to control storm water runoff and the placement of those BMPs. Additionally, the SWPPP must contain a visual monitoring program, a chemical monitoring program for non-visible pollutants to be implemented if there is a failure of BMPs, and a sediment monitoring plan if the site discharges directly to a water body impaired for sediment.

Consistent with federal law (See, 33 U.S.C. §§ 1311(b) (1) (C), 1342(p) (3) (A); *Defenders of Wildlife v. Browner* (9th Cir. 1999) 191 F. 3d 1159, 1165-1166), the Construction General Permit and Industrial General Permit contain provisions requiring compliance with applicable water quality standards.

4) Caltrans

In 1996, Caltrans requested that the State Water Board consider adopting a single NPDES permit for storm water discharges from all Caltrans properties, facilities, and activities, which would encompass both the MS4 requirements and the statewide construction general permit requirements. The State Water Board issued the Caltrans general permit in 1999, requiring Caltrans to control pollutant discharges to the MEP for the MS4s and to the standard of BAT/BCT for construction activities through BMPs. The State Water Board also required Caltrans to implement more stringent controls, if necessary, to meet water quality standards.

B. Nonpoint Sources

Under Porter-Cologne, all waste discharges that could affect water quality must be regulated, including nonpoint source discharges of pollution. Nonpoint source (NPS) pollution, unlike point source pollution from industrial and sewage treatment plants, comes from many diffuse sources. Some types of NPS pollution are caused by rainfall or snowmelt moving over and through the ground. As the runoff moves, it picks up and carries away natural and man-made pollutants, depositing them into lakes, rivers, wetlands, coastal waters, and groundwater. NPS pollution may originate from several sources, including agricultural runoff, forestry operations, urban runoff, boating and marinas, active and historical mining operations, atmospheric deposition, and wetlands.

Nonpoint sources in California must be regulated under WDRs, conditional waivers of WDRs, or basin plan prohibitions. However, WDRs need not necessarily contain numeric effluent limits. The state's NPS Policy provides guidance regarding the prevention and control of NPS pollutant discharges and enforcement of nonpoint source regulations (e.g., WDRs). In practice, the Regional Water Boards do not usually impose numeric effluent limits on nonpoint pollution sources; rather they primarily rely on implementation of management practices to reduce pollution.

In 1998, California began implementing its Fifteen-Year Program Strategy for the Nonpoint Source Pollution Control Program, as delineated in the Plan for California's Nonpoint Source Pollution Control Program (NPS Program Plan). The legal foundation for the NPS Program Plan is the CWA and the Coastal Zone Act Reauthorization Amendments of 1990 (CZARA), and state law. The agencies primarily responsible for the development and implementation of the NPS Program Plan are the State Water Board, the nine Regional Water Boards, and the California Coastal Commission (CCC). Various other federal, state, and local agencies have significant roles in the implementation of the NPS Program Plan.

The NPS Program Plan addresses six categories of nonpoint sources including agriculture, forestry, urban areas, marinas and recreational boating, hydromodification, and wetlands/riparian areas/vegetated treatment systems. For each category, the NPS Program Plan specifies management measures (MMs) and the corresponding management practices. The NPS Program Plan provides five general goals:

- Track, monitor, assess, and report NPS Program activities.
- Target NPS Program activities.
- Coordinate with public and private partners in all aspects of the NPS Program.
- Provide financial and technical assistance and education.
- Implement MMs and associated management practices.

3.5 REGULATORY SETTING BIOLOGICAL RESOURCES

This section addresses biological resources that could be affected with implementation of the proposed project. The information presented is based on literature reviews and a review of existing documentation and research prepared expressly for the project. As explained in the IS, impacts on marine biological resources range from “no impact” to “potentially significant. These issues are addressed in the impact analysis.

Biological resources in California are protected and/or regulated by a variety of federal and state laws and policies. In addition, in many parts of California, planning efforts are underway to conserve local or regional habitat and species. Many regulations applicable to biological resources do not include water quality issues; however, a number do, particularly those relating to fisheries and other aquatic resources. Key regulatory and conservation planning issues applicable to the proposed project are discussed below.

3.5.1 Federal Regulatory Setting

3.5.1.1_Federal Endangered Species Act

Pursuant to the federal Endangered Species Act (ESA, 16 U.S.C. §§ 1531 et. seq.) the U. S. Fish and Wildlife Service (USFWS) and National Oceanic and Atmospheric Administration Fisheries Service (NOAA Fisheries Service), formerly National Marine Fisheries Service (NMFS), have regulatory authority over federally listed species. Under ESA, a permit is required for any federal action that may result in “take” of a listed species. Section 1532 (19) of ESA defines take as “to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct.” Under federal regulations, take is further defined to include the modification or degradation of habitat where such activity results in death or injury to wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering.

3.5.1.2 Clean Water Act Section 404

Section 404 of the Clean Water Act (CWA) requires project proponents to obtain a permit from the U.S. Army Corps of Engineers (USACE) before performing any activity that involves the discharge of dredged or fill material into "waters of the United States," including wetlands. Dredge and fill activities range, but involve any activity, such as construction, that results in direct modification (e.g., alteration of the banks, deposition of soils) of an eligible waterway. Waters of the United States include navigable waters, interstate waters, and other waters where the use or degradation or destruction of the waters could affect interstate or foreign commerce, tributaries to any of these waters, and wetlands that meet any of these criteria or that are adjacent to any of these waters or their tributaries. Many surface waters and wetlands in California meet the criteria for waters of the United States. In accordance with Section 401 of the CWA, projects that apply for a USACE permit for discharge of dredged or fill material must obtain water quality certification from the State Water Board or the appropriate Regional Water Board indicating that the project will uphold state water quality standards.

3.5.1.3 National Marine Sanctuaries Act

The National Marine Sanctuaries Act (NMSA) authorizes the Secretary of Commerce to designate and protect areas of the marine environment with special national significance due to their conservation, recreational, ecological, historical, scientific, cultural, archeological, educational, or esthetic qualities as national marine sanctuaries. Day to-day management of national marine sanctuaries has been delegated by the Secretary of Commerce to NOAA's Office of National Marine Sanctuaries. The Channel Islands, Monterey Bay, and Gulf of the Farallones National Marine Sancturaries regulate the discharge of material or matter, including the discharging or depositing from beyond the boundary of the sanctuary any material or other matter that subsequently enters the sanctuary and injures a sanctuary resource or quality (See 15 CFR § 922.72, 922.82, 922.132 for specific regulatory language including exceptions).

3.5.2 State Regulatory Setting

3.5.2.1 California Endangered Species Act

Pursuant to the California Endangered Species Act (CESA), a permit from the California Department of Fish and Game (DFG) is required for projects that could result in take of a plant or animal species that is state listed as threatened or endangered. Under CESA, "take" is defined as an activity that would directly or indirectly kill an individual of a species. Authorization for take of state-listed species can be obtained through a California Fish and Game Code Section 2080.1 consistency determination or a Section 2081 incidental take permit.

3.5.2.2 Section 1600 of the California Fish and Game Code

All diversions, obstructions, or changes to the natural flow or bed, channel, or bank of any river, stream or lake in California that supports wildlife resources is subject to regulation by DFG, under Sections 1600–1603 of the California Fish and Game Code. Section 1602 states that it is unlawful for any agency to substantially divert or obstruct the natural flow or substantially change the bed, channel or bank of any river, stream or lake designated by DFG, or use any material from the streambeds, without first notifying DFG of such activity. The regulatory definition of a stream is a body of water that flows at least periodically or intermittently through a bed or channel having banks and supports fish or other aquatic life. This includes watercourses having a surface or subsurface flow that supports or has supported riparian vegetation. DFG's jurisdiction within altered or artificial waterways is based on the value of those waterways to fish and wildlife. Accordingly, a DFG Streambed Alteration Agreement must be obtained for any project that would result in diversions of surface flow or other alterations to the bed or bank of a river, stream, or lake.

3.5.2.3 California Ocean Plan for Areas of Special Biological Significance

Section 13170.2 of the California Water Code directs the State Water Board to formulate and adopt a water quality control plan for ocean waters of California. The State Water Board first adopted this plan, known as the California Ocean Plan, in 1972. Over the years, the plan and Public Resources Code have been amended to bolster the protection of important coastal and marine areas. The California Ocean Plan establishes water quality objectives for California's ocean waters and provides the basis for regulation of wastes discharged into the state's coastal waters. The plan applies to point and nonpoint source discharges and the plan provides numeric and narrative water quality objectives for discharges to marine environments, including bacterial, physical, chemical, biological, and radioactivity standards for offshore water quality. For the most part, these standards, which are intended to protect aquatic resources, are more stringent than those for contact recreation, but are less stringent than those applied to drinking water to protect public health.

Other water quality objectives that provide some protection of biological resources include thresholds established from baseline conditions, such as that dissolved oxygen content shall not be less than 10% of what occurs naturally, as well as the pH shall not be more than 0.2 units from what occurs naturally. Nutrients shall not cause objectionable aquatic growths or degrade indigenous biota. Numeric standards are set for a wide variety of constituents. For biological characteristics, the plan states that marine communities shall not be degraded and that shellfish and fish must be fit for human consumption. Both the State Water Board and the six coastal Regional Water Boards implement and interpret the Ocean Plan. The California Ocean Plan identifies the applicable beneficial uses of marine waters. These beneficial uses include preservation and enhancement of designated ASBS, rare and endangered species, marine habitat, fish migration, fish spawning, shellfish harvesting, recreation, commercial and sport fishing, mariculture, industrial water supply, aesthetic enjoyment, and navigation. To date, 34 ASBS are classified within the state. Thirteen occur north of the San Francisco Bay, seven along the Central Coast, and the remaining 14 occur in southern California, 10 of which are islands.

3.5.2.4 Porter-Cologne Water Quality Control Act

Under the Porter-Cologne Water Quality Control Act, “waters of the state” fall under the jurisdiction of the appropriate Regional Water Board. The Regional Water Board must prepare and periodically update water quality control plans (basin plans). Each basin plan establishes numerical or narrative water quality objectives to protect established beneficial uses, which include wildlife, fisheries and their habitats. Projects that affect wetlands or waters of the state must meet discharge requirements of the Regional Water Board, which may be issued in addition to a water quality certification or waiver under Section 401 of the CWA.

4.0 ISSUES AND ALTERNATIVES TO THE PROPOSED PROJECT

4.1 INTRODUCTION

This section describes the major policy related issues identified and alternatives that have been considered by staff during the development of the Special Protections for Selected Storm Water and Nonpoint Source Discharges into Areas of Special Biological Significance. Each issue analysis contains the following sections:

Issue: The section describes the major policy related issues identified and alternatives that have been considered by staff during the development of the Special Protections.

Issue Description: A description of the issue or topic and (if appropriate) any additional background information, list of limitations and assumptions, description of related programs, or other information.

Alternatives: For each issue of topic, at least two alternatives are provided for consideration. Each alternative is evaluated with respect to the program needs under state law including the California Water Code and the Public Resources Code.

Staff Recommendation: In this section, a recommended alternative (or combination of alternatives) is identified and proposed for adoption by the State Water Board.

4.2 PROJECT ALTERNATIVES TO ADDRESS EXISTING DISCHARGES INTO ASBS

How should the State Water Board address existing discharges into ASBS in light of the Ocean Plan's prohibition on discharges into ASBS?

Issue Description: The Ocean Plan establishes water quality objectives for California's ocean waters and provides the basis for controlling point and nonpoint source discharges into ocean waters of the State. As described in detail in Section 3.0, the Ocean Plan has contained a prohibition of waste discharged to ASBS. In response to a 2000 petition submitted by Caltrans questioning the intent of the prohibition to include storm water, the State Water Board adopted Order WQ 2001-08 in which the State Water Board held that the ASBS discharge prohibition in the Ocean Plan applies to storm water discharges. The State Water Board also held that Caltrans coverage under a storm water permit did not relieve the discharger from complying with the Ocean Plan prohibition. These findings prompted the State Water Board to fund a statewide survey to assess the extent of storm water and nonpoint source discharges into ASBS. The survey identified 1,658 discharges (SCCWRP 2003). A majority of the discharges into ASBS were categorized as nonpoint source and permitted storm water discharges. None of the identified nonpoint source and permitted storm water discharges had been granted exceptions to the Ocean Plan.

Since the initial survey, the State Water Board adopted three individual exceptions for marine lab waste seawater and storm water runoff. These exceptions were granted to Scripps Institute of Oceanography in La Jolla, the University of Southern California's Wrigley Institute on Santa Catalina Island, and the University of California at Davis Bodega Marine Laboratory.

The remaining dischargers were notified by a letter in 2004 that stated they must cease discharging or apply for an Ocean Plan exception. Follow-up letters were sent in August 2005 to those respondents who requested exceptions, describing the exception process in greater detail. Currently, 27 parties have applied for an exception from the Ocean Plan ASBS waste discharge prohibition. While the State Water Board has the authority to grant exceptions that meet the criteria described in Section 3.2.1, there are alternative approaches that could be considered to address these discharges. Several alternatives, including the staff recommended alternative to pursue a general exception for select storm water and nonpoint source discharges into ASBS, are presented below.

Alternative A: No-Project Alternative (i.e., No Exception)

CEQA requires that the Water Boards consider the "No-Project" alternative. Under this No-Project alternative, the Ocean Plan prohibition against waste discharges into ASBS would continue to apply to all discharges into ASBS. The discharger could comply by terminating the discharge or by relocating the discharge so that the receiving water quality is unaffected. These actions could potentially have far greater impacts on the biological integrity of the ASBS then the discharge itself through demolition, excavation, and construction required to remove the existing discharge and redirect it away from the ASBS. In addition, the impacts on air quality and increased green house gas emissions would also be significant. For those dischargers faced with few practical options, enforcement actions could lead to protracted litigation.

Currently, the 27 applicants applying for this exception provide essential public services, including flood control, slope stability, erosion prevention, and maintenance of the natural hydrologic cycle between terrestrial and marine ecosystems, public health and safety, public recreation and coastal access, commercial and recreational fishing, navigation, and essential military operations (national security).

This alternative would not result in better water quality protection, nor does it benefit the environment, public health and welfare, or the Water Boards' ability to protect and restore beneficial uses. As a result, staff does not recommend adopting the "No-Project" alternative.

Alternative B: Amend the Ocean Plan's Prohibition to Allow Existing Discharges into ASBS under Special Conditions

The State Water Board could consider amending the Ocean Plan prohibition to allow existing storm water and nonpoint source discharges that meet specific criteria to discharge into ASBS. Under this alternative, special conditions would be proposed as new provisions in the Ocean Plan. These provisions could include:

- A prohibition on new discharge points
- A prohibition on non-storm water discharges inclusive of those discharged into storm water conveyance systems that are not otherwise authorized
- Wet weather runoff controlled to be as similar to naturally occurring streams as possible, and not to alter natural water quality in the ASBS
- An accelerated iterative process specifically implementing management practices that fully address discharges into ASBS
- Specific monitoring requirements to ensure protection of beneficial uses

In 2003 and early 2004, staff proposed similar amendments to the Ocean Plan; however, the proposed amendments were met with severe criticism from the regulated community, environmental advocacy groups, and U.S. EPA. The concept of amending the discharge prohibition to allow select discharges to continue under specific conditions challenged the concept of designating ASBS as areas deserving of special protection. Others felt the regulatory requirements would be overly burdensome and too difficult to meet. State Water Board staff believes that this alternative would continue to face stiff opposition and, if proposed, would require a significant commitment of resources to prepare planning documents based upon the issues raised and the written comments previously received. As a result, staff does not support this alternative at this time. However, this approach may be considered in the future after the special conditions in the exception are fully implemented and evaluated.

Alternative C: Implement Individual Exceptions for Each Storm Water and Nonpoint Source Discharger

As mentioned above, the State Water Board has adopted seven individual exceptions to date for sewage treatment, desalination brine, public aquarium, and marine lab discharges. State Water Board staff intends to continue the approach of implementing and reviewing individual exceptions for these types of point source discharges, because each facility is sufficiently different to warrant individual exceptions with individual special conditions. Only three marine laboratories/public aquariums remain to be issued exceptions.

There are 27 applicants for an Ocean Plan exception being addressed by this proposed exception. These applicants have a variety of activities but all primarily have in common permitted storm water or nonpoint source discharges. As such, the same special conditions and prohibitions are generally applicable to all of these entities. Granting individual exceptions for each entity would entail developing, noticing, and adopting an individual CEQA document and exception for each entity. With current staff resources, it is estimated that such an approach would take at least an additional three years (from the date of this document) to complete. That approach would delay protecting natural water quality in the ASBS during the time it would take to adopt individual exceptions for each of the 27 applicants. Furthermore, adopting individual exceptions for storm water and nonpoint source dischargers would be inefficient, taking up significant staff and Board Member time and resources.

Because this alternative would delay the protection of water quality in ASBS, would be inefficient, and would not provide any advantages, staff does not support this alternative.

Alternative D: Implement a General Exception for Selected Dischargers (Preferred Alternative)

Under this alternative, the State Water Board would adopt a general exception to the Ocean Plan discharge prohibition that would impose special conditions on the group of 27 storm water and nonpoint source dischargers who have applied for an exception. The proposed conditions could include: cessation of non-essential, non-storm water runoff; maintenance of natural water quality within ASBS, including during precipitation (design storm) events, by limiting wastes in storm water runoff and other activities that would otherwise cause a degradation of ocean water quality in the ASBS; and monitoring water quality and marine aquatic life within ASBS to ensure the protection of beneficial uses over time. Under this alternative, discharges must comply with all other applicable provisions of the Ocean Plan, including those provisions that maintain and protect natural ocean water quality and marine communities from pollution.

For dischargers subject to NPDES permits, prohibitions and special conditions collectively referred to as “Special Protections” for the ASBS, would be implemented through storm water management plans. For nonpoint source dischargers, the Special Protections would be implemented through a WDR, waiver, or conditional prohibition and a pollution prevention plan. All ASBS dischargers would continue to have three major requirements: (1) a continued prohibition of non-storm water discharges and runoff, with only certain exclusions; (2) wet weather runoff controlled so as not to violate “natural ocean water quality” in the ASBS receiving water; and (3) monitoring to ensure protection of beneficial uses. These three requirements of the Special Protections would be incorporated into each applicant's permit or WDR.

The Special Protections are intended to maintain the natural hydrologic cycle and coastal ecology by allowing the flow of clean precipitation runoff into the ocean, while preserving coastal slope stability and preventing anthropogenic erosion. The 27 applicants for this exception provide essential public services, including flood control, slope stability, erosion prevention, maintenance of the natural hydrologic cycle between terrestrial and marine ecosystems, public health and safety, public recreation and coastal access, commercial and recreational fishing, navigation, and essential military operations (national security). Therefore, the exception and the terms, prohibitions, and special conditions embodied in the Special Protections for ASBS are not only protective of beneficial uses, but are in the public interest as well.

The State Water Board's effort to address storm water and nonpoint source waste discharges into ASBS using the Ocean Plan exception process is nearly complete. Applicants have now applied for exceptions, providing the necessary information for staff to proceed. In addition, the State Water Board has held three public scoping meetings, and several stakeholder meetings, for the exception and has initiated a stakeholder effort to collaborate on ASBS regional monitoring. Continuing with the general exception process for storm water and nonpoint sources would meet statutory and Ocean Plan regulatory requirements; because the process is ongoing, it would be practical and efficient to continue. Discharges authorized by an NPDES permit (and WDRs or waivers for nonpoint sources) would be allowed, but under strict limiting conditions aimed at ensuring protection of receiving water quality and marine life.

This alternative, that proposes to adopt a general exception with the Special Protections for the group of 27 storm water and nonpoint source dischargers who have applied for an exception is the alternative recommended by Staff. The remaining issues and alternatives address conditions associated with this general exception.

Staff Recommendation: Adopt Alternative D, the general exception for 27 specific parties, with Special Protections for ASBS. Eliminate the other alternatives, (Alternatives A, B, and C) from further consideration.

4.3 ALTERNATIVES TO THE CONDITIONS IMPOSED UNDER THE GENERAL EXCEPTION

This section describes the major policy issues associated with the conditions imposed through the general exception identified in Alternative 4.2.D described above. The proposed Special Protections define the terms and conditions that will limit the storm water and nonpoint source waste discharges by the applicants to the affected ASBS.

The intent is to ensure that such discharges will be controlled to protect beneficial uses within ASBS and to protect and maintain the natural hydrologic cycle and coastal ecology. The conditions include: cessation of non-essential, non-storm water discharges and runoff; maintenance of natural water quality within ASBS, including during precipitation (design storm) events, by limiting wastes in storm water runoff and other activities that would otherwise cause a degradation of ocean water quality in the ASBS; and monitoring water quality and marine aquatic life within ASBS to ensure the protection of beneficial uses over time.

Discharges must comply with all other applicable provisions of the Ocean Plan. Natural ocean water quality must not be altered as a result of the discharge(s), and marine communities must be protected from pollution.

These terms and conditions are designed to address the applicants' waste discharges in a practical framework, acknowledging that the first priority controls are for higher threat discharges to the beneficial uses of ASBS. The compliance schedule in the Special Protections (provision of these mitigating terms and conditions) provides an action strategy for the applicants to achieve compliance with these terms and conditions.

The proposed Special Protections cover only those applicants discharging waste into an ASBS, who submitted an approved or conditionally approved exception application; the proposed Special Protections cover only the applicants' permitted storm water discharges and nonpoint source discharges.

4.3.1 Conditions imposed on Storm Water and Nonpoint Source Discharges

Issue: What conditions should be imposed upon discharges under the general exception?

Issue Description: Completely ceasing all discharges would interrupt the hydrologic cycle by removing storm water runoff and therefore fresh water flows into large sections of coastline, a situation that would be inconsistent with the natural ecology of these areas. In addition, the immediate cessation of discharges without a reasonable alternative would not be in the public interest because it may result in flooding, endangering health, safety, and property. However, allowing these waste discharges under current conditions is also not protective of natural ocean water quality, due to the potential and sometimes actual presence of pollutants in the runoff.

Alternative A: Allow Permitted Storm Water and Nonpoint Source Discharges with No Additional Conditions Beyond those in Existing Permits

As discussed in Section 3.0 and Section 4.2 above, allowing discharges into the ASBS would conflict with the Ocean Plan ASBS waste discharge prohibition and increase the risk of degradation to natural water quality and marine communities. The storm water NPDES permits require the discharger to develop and implement a SWMP or SWPPP with the goal of reducing the discharge of pollutants to the maximum extent practicable (MEP). However, reduction of pollutants to MEP is not adequately protective of natural water quality in ASBS.

NPDES storm water permits do not cover nonpoint source discharges. Except for the agricultural discharges at the Año Nuevo ASBS in the Central Coast Region (covered under the conditions of an Agricultural Waiver of Waste Discharge Requirements), no other nonpoint source discharges into ASBS are currently covered under a WDR or Waiver. Even in the case of the Año Nuevo ASBS agricultural runoff via State Park property, the conditions in the waiver are not adequately protective of natural water quality in ASBS.

Staff does not support this alternative, which would allow all discharges into ASBS under existing conditions that are not adequately protective of natural water quality in ASBS.

Alternative B: Allow discharges if limited by prohibitions and other special conditions beyond those in existing permits.

As mentioned above, it is ecologically important to maintain the hydrologic cycle, specifically the flow of fresh water from the terrestrial environment into the ocean. Therefore, some amount of storm water runoff should be allowed to continue. However, that storm water runoff should be clean, i.e., controlled to prevent pollution and alteration of natural water quality in the ASBS.

As discussed in Section 5.8.1, many of the current storm water runoff discharges tend to meet Ocean Plan objectives in the receiving water at least some of the time. However, some measured sites did not meet objectives when sampled; for example, approximately 25% of ASBS waters had measured concentrations of copper above the six-month median objective. Therefore, focused efforts will be required to control certain discharges to meet natural water quality in ASBS receiving waters within the proposed implementation schedule. These focused efforts may involve the installation of structural BMPs at the mouth of these discharges.

In order to prevent pollution from entering the ASBS, certain waste prohibitions must be maintained (e.g., prohibition on trash, which can harm marine life due to ingestion and entanglement). Any proposed or new storm water runoff discharge must be routed to existing storm water discharge outfalls and must not result in any new contribution of waste to an ASBS. “Existing storm water outfalls” are those that were constructed or under construction prior to January 1, 2005. “New contribution of waste” is defined as any addition of waste beyond what would have occurred as of January 1, 2005. Other limiting conditions should include that:

- The existing discharges are authorized by an NPDES storm water permit, or under WDR, a conditional waiver of WDR, or a conditional prohibition;
- The existing discharges comply with all of the applicable terms and conditions contained in the Special Protections;
- The existing discharges must be essential for flood control or slope stability, including roof, landscape, road, and parking lot drainage, and are designed to prevent soil erosion;
- The existing discharges of runoff occur only during wet weather; and
- The existing discharges of runoff are composed of only storm water runoff.

Because this alternative provides greater protection for ASBS, staff is recommending this alternative.

Staff Recommendation: Alternative B - Allow discharges if limited by prohibitions and other special conditions beyond those in existing permits.

4.3.2 Non-storm water runoff

Issue: Should non-storm water runoff (e.g., dry-weather flows) be allowed under the Special Protections?

Issue Description: Generally, dry weather flow surface runoff accounts for a significant portion of the total mass of contaminants that enter the coastal ocean waters. Dry weather flows, which may occur during summer or winter dry seasons, often originate from multiple anthropogenic sources that may include groundwater from pumping and dewatering, swimming pool drainage, dehumidifier or HVAC condensates, and excess runoff from landscape irrigation. Such flows have the potential to mobilize household, industrial, and construction site wastes, used crankcase oil, pesticides, and bacteria and carry them untreated to the ocean through storm drains, streams and/or other conveyance systems. Thus, the potential for environmental impact is high. In addition, dry weather flow in storm drains and nonpoint source conveyances does not usually represent a natural hydrological condition in California.

Existing permitted storm water municipalities incorporating changes to address dry-weather flows can consider updating local ordinances and codes, reviewing and adjusting the General Plan, and updating existing policies and procedures. Additional funds and resources may also be required to ensure BMPs are maintained after the projects are complete through increases in inspections and education. BMPs that could trigger or benefit from ordinance modification in one or more agency jurisdiction include dry weather flow diversions. Dry weather flow diversion devices direct flow through a pipe or channel to a local municipal sanitary sewer system for conveyance and treatment at a local wastewater treatment plan during dry weather. Implementing dry weather flow diversions should be considered where the diversion is reasonably close to a sanitary sewer system, if cost effective to implement, and the sanitary sewer authority is willing to accept the flow during the dry season.[5]

Other measures could be implemented to prevent dry weather flows from permitted storm drain systems or nonpoint sources. These may include, but are not limited to, public education, installation of swales for intercepting flows prior to reaching the ASBS, and installation of other low impact development (LID) solutions.

Staff has also identified actual or potential situations in which groundwater seepage into storm drains may result in minor dry weather flows that are beyond the ability of the applicants to control. Staff believes that most, if not all, of this seepage is shallow groundwater resulting from precipitation infiltrating and raising the groundwater table. Inflow through cracks in drain pipes results in seepage into the storm drains. These flows are very minor and do not usually persist throughout the year.

Alternative A: Allow all non-storm water runoff.

Allowing all non-storm water runoff would conflict with the intent of the Ocean Plan to prevent the alteration of natural water quality within ASBS. Dry weather flows are frequently caused by human activities that can introduce pollutants into receiving waters, and in high-density areas result in significant waste discharge flows when not properly controlled. Staff does not support this alternative.

Alternative B: Do not allow non-storm water runoff.

Prohibiting all non-storm water runoff is impractical, especially when considering the number of discharges identified and the impact that this alternative could have on essential public utilities, emergency response actions, structural stability, or slope stability. Proposing this alternative would not benefit the public interest, because certain non-storm water runoff essential for environmental protection, public services, and public health and safety would be prohibited.

Alternative C: Allow only non-storm water runoff that is essential for emergency response purposes, structural stability, or slope stability, and discharge(s) associated with incidental groundwater seepage.

This alternative would allow only non-storm water runoff that is essential for environmental protection, public services, and public health and safety. This alternative

[5] Most Publicly Owned Treatment Works (POTWs) were not designed and constructed with sufficient excess dry weather flow capacity to accept dry weather flow discharges. Further, POTWs were constructed with development fees and operated and maintained with sewer connection charges. On-going operating and maintenance costs would need to be assessed to these dry weather diversion projects.

would define the discharges and those specific types that could be discharged through a storm water system in accordance with the general exception. All other discharges of non-storm water would be in violation.

Staff is proposing the terminology "Discharges of non-storm water runoff" that would be defined as: any waste discharge from an MS4 (or other NPDES permitted storm drain system), or from nonpoint sources, to an ASBS that is not composed of storm water. The following non-storm water discharges should be allowed, provided that the discharges are essential for emergency response purposes, structural stability, slope stability, or involve incidental groundwater seepage:

- Discharges associated with emergency fire fighting operations.
- Foundation and footing drains.
- Water from crawl space or basement pumps.
- Hillside dewatering.
- Naturally occurring groundwater seepage via a storm drain.

Authorized non-storm water discharges shall not be allowed to cause or contribute to a violation of the water quality objectives in Chapter II of the Ocean Plan nor alter natural ocean water quality in an ASBS. All other non-storm water runoff should be strictly prohibited.

A concern brought up in stakeholder meetings was construction dewatering. Upon consideration, staff does not believe that construction dewatering is essential for emergency response purposes, structural stability, or slope stability. Construction dewatering is a result of a coastal development project that would need to get permits and approvals, including coverage under an NPDES permit. This in turn would require compliance with water quality standards. Therefore, construction dewatering would continue to be prohibited from discharges into ASBS. Because this alternative attempts to balance the need for essential discharges with the intent to protect natural water quality, staff recommends this alternative for consideration by the State Water Board.

Staff Recommendation: Alternative C - Allow only non-storm water runoff that is essential for emergency response purposes, structural stability, or slope stability and incidental groundwater seepage.

4.3.3 Military Training Discharges

Issue: Should military training discharges be included in the exception?

Issue Description: The U.S. Navy operates at San Nicolas (SNI) and San Clemente (SCI) Islands for national security purposes, including training activities involving live ordinance. The use of military ordinance is obviously harmful to marine life, results in accumulations of pollutants on the sea floor, and may result in accelerated erosion from coastal cliffs. At SCI, training activities can involve explosives, naval gunnery target practice, discharges from small arms fire (collectively referred to as use of military ordinance), and amphibious vehicular/vessel activity on the shore. There are many places at SCI where this activity takes place, including but not limited to the Shore Bombardment Area (SHOBA) Operations and Basic Underwater Demolition/SEALs (BUD/S) locations. Missile launching is performed at SNI, and portions of the expended missiles are known to fall into the adjacent portion of that ASBS. All other locations on SCI and SNI are considered off limits for this type of activity as unexploded ordinance or off range live fire would represent a critical safety hazard to base personal.

Military operations have been ongoing at these islands before the ASBS were designated. These islands represent highly unique locations for many military test and training operations due to the close proximity to major bases located on the mainland while isolated far from large population centers to maintain public safety and national security. Currently, these islands are the only Navy facilities in the contiguous U.S. where these types of training activities can be conducted safely and routinely. As a result, these operations are considered essential to maintain operational readiness and national security.

Alternative A: Enforce the ASBS prohibition for all discharges of military ordinance for training purposes in ASBS waters. Staff does not recommend this alternative be pursued given the unique national security role these facilities provide.

Alternative B: Include the discharge of military ordinance in the exception, subject to prohibitions and limiting conditions. The discharge of explosives in ASBS waters at military closure areas in the vicinity of Wilson Cove and Castle Rock at SCI would be prohibited. At SNI, with the exception of discharges from missile operations, no other discharges of explosives or deposition of waste ordinance is allowed within ASBS waters. Discharges must not result in a violation of the water quality objectives, including the protection of the marine aquatic life beneficial use, anywhere in the ASBS.

Staff Recommendation: Alternative B, including discharges of military ordinance in the exception subject to prohibitions and limiting conditions. Military discharges would continue to be conditioned on compliance with water quality objectives everywhere in the ASBS.

4.3.4 Miscellaneous Point Source Discharges

Issue: Should point source discharges from sinks and fish cleaning stations be allowed under the General Exception?

Issue Description: Sinks and fish cleaning stations constitute non-storm water discharges, and are point sources of wastewater. Surface discharges of graywater and fish offal constitute waste discharges that alter natural water quality, and result in accumulations of organic matter in the ASBS. A fish cleaning station with a direct point source discharge of fish offal is located at Shelter Cove (King Range ASBS). Staff is also aware of a sink with a direct point source discharge at the marine mammal training Naval Ordnance Test Station (NOTS) pier on SCI. These discharges to ASBS surface waters are considered as non-essential because other options exist, such as collecting fish offal and transporting off-site for land disposal, and the use of onsite storage or treatment systems below ground for fish offal and graywater. This has been accomplished at Gerstle Cove ASBS, Salt Point State Park, that now utilizes a below ground storage tank.

Alternative A: Include point source discharges from sinks and fish cleaning stations into ASBS surface waters in the exception.

Alternative B: Do not include waste discharges from sinks and fish cleaning stations into ASBS in the exception.

Staff Recommendation: Alternative B, do not include waste discharges from sinks and fish cleaning stations into ASBS in the exception. This alternative will maintain the prohibition of waste discharges from sinks and fish cleaning stations into ASBS.

4.3.5 Monitoring and Compliance

Issue: How should ASBS monitoring be best performed?

Issue Description: Typically, major dischargers to coastal waters, such as POTWs, have provided the bulk of monitoring data on ocean receiving waters. Point source dischargers implement self-monitoring programs under NPDES permits that are designed to assess compliance with effluent and receiving water limitations. Resource agencies and some federal programs also provide monitoring data. Generally, these monitoring efforts have been the primary mechanism by which regulatory agencies, resource managers, and permitted dischargers have evaluated the condition of the ocean receiving water and effluent. However, this type of monitoring, with primary focus on major dischargers, has resulted in acknowledged data gaps and the lack of coordinated coast wide information. Further, these efforts in general were not designed to assess compliance with the Ocean Plan prohibition against waste discharge to ASBS and the goal to maintain natural water quality in ASBS.

Regional monitoring efforts, in contrast to individual discharger monitoring programs, can provide a greater awareness of the regional nature of environmental stressors and impact, and a greater knowledge of the interactions between localized sources of anthropogenic impact and larger-scale environmental processes (e.g., El Nino, Pacific Decadal Oscillation) and the role of terrestrial runoff and storm water plumes on the nearshore coastal zone. A regional scale monitoring program can provide information that focuses on key indicators and processes, and ensures a cost-effective approach to assessing conditions in the ASBS.

There are existing regional monitoring programs in the state. The Regional Monitoring Program in San Francisco Bay assesses each major permitted discharger into the Bay; fees are based on the dischargers' loadings to the Bay of key contaminants. These fees are combined and used to support the regional monitoring, data analysis, and reporting activities carried out by the San Francisco Estuary Institute.

The Central Coast Long-term Environmental Assessment Network (CCLEAN) program in Monterey Bay is currently funded by four POTW agencies with ocean discharges. One of these POTWs discharges into the Carmel Bay ASBS.

The Southern California Bight Program is coordinated by SCCWRP and is funded with a combination of in-kind support and monetary contributions from participants, much of which is made available as the result of periodic compliance monitoring offsets.

While the Ocean Plan gives background concentrations in Table C, these concentrations are intended to be representative of ocean water quality in deeper water where the POTW discharges are often located. Table C does not represent nearshore or surf zone natural water quality, especially during storm conditions with suspended bottom sediment and nearshore natural runoff. The State Water Board's Surface Water Ambient Monitoring Program (SWAMP) has provided funding to SCCWRP to determine the range of natural water quality in the nearshore environment, and to help develop statewide and regional efforts to monitor ASBS for comparison to those levels of natural water quality. To date, the groundwork has been set for regional monitoring in three sections of the state (southern, central, and northern), and regional ASBS monitoring has been initiated as part of the Bight 08 program. Furthermore, statewide random monitoring has been initiated in ASBS to determine water quality in ASBS areas with direct discharges and without.

Staff firmly believes that the best approach for understanding the effects of discharges is a regional monitoring approach using methods and protocols consistent with other regional efforts across the State. There are significant benefits associated with regional monitoring groups some of which include:

- Access to greater resources,
- Variety of expertise and experience amongst the members,
- Increased cost effectiveness through cost sharing and in kind services, and
- Greater flexibility or ability to respond to new findings or needs.

The use of consistent methods and protocols also provides many advantages. When consistent methods and protocols are employed, the resulting data can be compared and integrated across broad spatial scales and across programs, greatly increasing the overall utility of the data.

However, there may be some instances where an individual is unable or unwilling to join a regional monitoring group. Under this scenario, the individual discharger must adhere to prescriptive monitoring conditions in the Special Protections in order to assure the adequacy of that individual program.

Alternative A: Require all applicants to participate in a regional monitoring program. Under this alternative, all monitoring would occur under the Regional Monitoring Program. Each regional monitoring group would be responsible for sampling reference areas for natural water quality and, in addition, for evaluating the impact of discharges on the receiving water.

Alternative B: Allow applicants to choose either an individual monitoring program or to participate in a regional monitoring program. Although Alternative A, requiring participation in a regional monitoring group, provides many advantages over individual efforts, there may be some instances where an individual is unable or unwilling to join a regional monitoring group. As a result, staff believes that the type of receiving water monitoring, individual or regional, should be a decision made by the applicant.

However, if an individual monitoring program is chosen, the discharger must adhere to prescriptive monitoring conditions in the Special Protections in order to assure the adequacy of that individual program. Therefore, conditions contained in the Special Protections allow for the applicant to select an individual monitoring program or join a regional monitoring program.

Staff Recommendation: Alternative B, Allow applicants to choose either an individual monitoring program or to participate in a regional monitoring program.

4.3.6 Design Criteria for Structural Best Management Practices

Issue: What design criteria should be required of structural BMPs?

Issue Description: The cost of wet weather treatment systems and consideration that these systems may be physically incapable of handling some large wet weather events are major concerns. Engineers need a target control level to design a structural BMP to meet water quality needs.

Selecting the optimal storm size represents the first step toward the construction of effective structural BMPs. It is frequently impractical and not cost effective to plan and construct a structural BMP for the largest storm possible. Does one select the 100-year storm or the 1,000-year storm? In either case, such storm events do not have a high likelihood of happening in the near term. Staff believes that it is better to select a design storm that represents more typical conditions, so that runoff from the majority of storms is controlled to reduce waste discharges to minimal levels. A storm of one inch of precipitation per day should be the minimum design criteria, which would be consistent with design criteria in MS4s throughout the state. However, a BMP should not be constructed in such a way that will result in blockage at higher flows, divert water away from the main channel, or increase the risk of flood damage or loss of life.

BMP effectiveness is another important design consideration. Target concentrations could be obtained from the Ocean Plan. Those values presented in Table B, measured as instantaneous maximum chemical concentrations for the protection of marine life, are appropriate in this role, as these values were adopted to protect aquatic life in marine waters of California. Based upon baseline chemical water quality data evaluated to date, these targets appear achievable as most discharges sampled met those concentrations. Instantaneous maximums are appropriate because storm water runoff is highly episodic and brief in duration.

BMP effectiveness can also be evaluated by reduction of discharge flow. Dischargers have suggested that BMPs be designed to reduce flows by percolating the majority of the runoff into the ground; staff has considered this approach as well. This approach addresses overall pollutant loading by reducing flows rather than reducing concentrations. As design criteria, staff is recommending a reduction in flow equal to 90%.

Alternative A: Set a design criteria of Ocean Plan Table B for all storm events.

Alternative B: Set a design criteria of Ocean Plan Table B for typical storm events.

Alternative C: Set a design criteria of volumetric reductions for all storm events.

Alternative D: Set a design criteria of volumetric reductions for typical storm events.

Alternative E: Allow flexibility for the discharger to choose either Ocean Plan Table B or volumetric reductions for typical storm events. Staff believes that the goals of meeting compliance would be best served by allowing flexibility to address discharge conditions on a case-by-case basis. Therefore, staff recommends this alternative, to allow either a concentration approach using Table B Instantaneous Maximum or a volumetric reduction of 90% from baseline flow, and a design storm of one inch of precipitation per day, or in some instances, the design storm identified in MS4 permits as applicable to the Responsible Parties identified herein.

Staff Recommendation: Alternative E - Allow flexibility for the discharger to choose either Ocean Plan Table B Instantaneous Maximum concentrations or volumetric reductions of 90%, and a design storm of one inch per day.

4.3.7 <u>Compliance Schedule</u>

Issue: When should final compliance be determined?

Issue Description: Storm water management plans and other equivalent planning documents require considerable thought on the part of the discharger, considering a multitude of factors. Typically, these planning documents must then be approved by their respective management bodies, and approved by Regional Water Boards. Implementation of certain nonstructural BMPs may be relatively quick, but structural BMPs require further planning, design, permitting, and construction, and therefore may take some time to implement.

From an environmental protection perspective, it would be preferable for all ASBS discharges to achieve the condition to maintain natural water quality in ASBS immediately, but this could be difficult due to the reasons described above. The storm water and nonpoint source programs typically use an iterative approach to achieving compliance, which may last for more than one permit cycle. However, discharges to

ASBS are not typical discharges in that they clearly violate the Ocean Plan and put sensitive and significant biological communities at risk.

Staff does not believe that compliance should be required immediately nor does staff believe that an iterative approach is appropriate. Staff originally considered requiring the storm water management plans or other equivalent pollution prevention plans to be completed in six months, but staff has reconsidered based on comments received during stakeholder meetings. Staff has modified the draft Special Protections to allow one year for completion and submittal of the storm water and other pollution prevention planning documents.

Regarding final compliance, staff continues to believe that full compliance can be accomplished by addressing and controlling the highest threat discharges within a four-year period from the effective date of the General Exception.

Alternative A: Require immediate compliance.
Alternative B: Use an iterative compliance approach without fixed compliance deadlines.
Alternative C: Require compliance within a four year period.

Staff Recommendation: Alternative C - Require compliance within a four year period.

4.3.8 <u>Compliance Monitoring</u>

Issue: Should compliance monitoring rely on effluent or receiving water data, or both?

Issue Description: The special protections proposed for specific storm water discharges would allow some minimum amount of waste to be discharged during storm events, however, the discharges are required to maintain natural water quality. In order to evaluate a discharge's potential effect on receiving waters, samples may be collected of the effluent, described as "end of pipe", within the receiving water after mixing has occurred or through a combination of both. Staff held several stakeholder meetings, attended by the regulated community, environmental advocacy groups, scientists, and Regional Water Board staff, where considerable discussion occurred on the issue of how compliance should be measured. The stakeholders agreed that compliance should ultimately be measured in the receiving water by comparison to natural ocean water quality. Under this scenario, natural water quality is defined qualitatively and the range of concentrations and conditions is determined at reference stations, taking into account natural changes to water quality that occur as a result of the storm event.

However, there may be cases when the receiving water monitoring results indicate that natural water quality is not attained, but effluent monitoring indicates that the discharger is not causing or contributing to the receiving water exceedance. In such cases, when the discharger is not contributing to pollutant loading (i.e., discharging waste) into the ASBS, then the effluent monitoring data and oceanographic observations could be considered by Regional Water Boards to ascertain compliance.

Alternative A: Require each discharger to conduct effluent monitoring to determine compliance.

Alternative B: Require each discharger to comply by achieving natural ocean water quality as measured in the receiving water. Staff believes that compliance is best measured within the receiving water. However, staff recommends that core monitoring include effluent monitoring so that the loading and water quality characteristics of the discharges are well understood.

Staff Recommendation: Alternative B - Compliance with the ASBS special protections requiring each discharge to meet "natural ocean water quality" shall be measured in the ocean receiving water.

5.0 ENVIRONMENTAL BASELINE

This subsection presents the existing environmental conditions throughout the state as appropriate for the specific topic area, in accordance with California Environmental Quality Act Guidelines (State CEQA Guidelines) Section 15125. The discussions of the environmental setting focus on information relevant to the issue under evaluation.

5.1 ASBS DESCRIPTIONS

5.1.1. Redwoods National Park

The Redwoods National Park lies along the coast of northwestern California in Humboldt and Del Norte Counties. Inland, a series of overlapping jurisdictions include Federal Park Lands and three California State Parks: Jedediah Smith Redwoods State Park, Del Norte Coast Redwoods State Park, and Prairie Creek Redwoods State Park. The coastal boundaries of Redwoods National Park are just south of Crescent City in the north (41°44.1' north latitude, 124°9.5' west longitude) and just to the north of Stone Lagoon in the south (41°15.7' north latitude, 124°5.7' west longitude) (SWRCB 1981). The Redwoods National Park ASBS encompasses 62,643 acres (97.88 mi^2; 253,510,283 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 35.9 miles (57.826 km), encompassing about 2.31% of California's coastline[6].

The ASBS is included in this designation for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) it has a variety of intertidal and subtidal habitats; (3) high turbidity of coastal waters has resulted in the development of an unusual assemblage of plants and animals unique to this area of the California coast; (4) this area has large stocks of annual flora; (5) sea stars *Solaster simpsoni* and *S. dawsoni* are common in this region, but no where else in California; (6) intertidal biota is transitional in character with both boreal and temperate marine elements.

5.1.2 Trinidad Head

The Kelp Beds at Trinidad Head ASBS is located at approximately 41°03'15" north latitude, 124°08'10" west longitude, which is 28 miles (45 km) north of Eureka, California

---

[6] The estimates of the areas, lengths, and percent of the coastline provided below are from the 1:24,000 scale coastline GIS layer "coastn27" from the State Lands Commission 1994, including the Northern and Southern Channel Islands, Ano Nuevo Island, Bird Rock, and the larger Farallon Islands. The estimates of percent of California coastline is based on a coast length of 1556 miles at a scale of 1:24,000, and does not include San Francisco Bay, other enclosed bays and inlets, or small coastal rocks/islands.

and encompasses areas both north and south of Trinidad Head. The northern area is fully exposed to winds and waves, while the southern area is semi-exposed because of the sheltering effects of Trinidad Head (SWRCB 1979). The ASBS encompasses 297 acres (0.46 mi^2; 1,201,206 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 1.8 miles (2.947 km), encompassing about 0.12% of California's coastline.

The ASBS is included in this designation for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) it has a diversity of intertidal habitat types, with close assemblage and association of seabirds, marine mammals, and intertidal plants and animals, and the dense beds of bull kelp; (3) there is an abundance of brown seaweed, *Cystoseira osmundacea*, a diverse population of intertidal algae and other major plant material producers in the nearshore zone; (4) a lack of abundant herbivore populations related to the presence of large amounts of silt in the water for a substantial period each year or lack of suitable habitat, particularly for juveniles within the ASBS; (5) the sea strawberry, *Gersemia rubriformis*, is commonly found, as well as intertidal presence of *Cnemidocarpa finmarkiensis*; (6) there are dense beds of *Nereocystis luetkeana*, which are uncommon in many areas of the State.

5.1.3 King Range

The King Range ASBS lies between the mouth of the Mattole River to the north (40°17'45" north latitude, 124°52'37" west longitude) and a point near Whale Gulch to the south (39°52' 37" north latitude, 123°58'34" west longitude). Most of the coastline is in Humboldt County, with approximately 4.5 miles (7.2 km) at the southern end of the area in Mendocino County. Two towns of small size are near the ASBS: Garberville, 18 miles (29 km) east of the coastline at Point Delgada, and Petrolia, 5.5 miles (8.8 km) from the mouth of the Mattole River (SWRCB 1979).

The coastline is impassible at several points during high tides, but can be negotiated at almost all points during low tides. Except for an all-weather road to the Shelter Cove development on Point Delgada, travel along the coastline is by foot or four-wheel drive vehicle. From the mouth of the Mattole River to the southern border, 30.2 miles (48.3 km) of coastline (exclusive of offshore rocks) lies within the King Range National Conservation Area (SWRCB 1979). The ASBS encompasses 25,055.5 acres (39.15 mi^2; 101,395,704 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 32.7 miles (52.621 km), encompassing about 2.10% of California's coastline.

A Marine Protected Area (MPA), the Punta Gorda State Marine Reserve, overlaps the King Range ASBS in about ¼ square-miles (0.64 km^2) in the northwest corner of the ASBS.

The ASBS is included in this designation for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) this is a remote area with very little human activity present; (3) most of the coastal area is fully exposed to wave impact, causing only the hardiest intertidal species to be successful in survival in the littoral zone; (4) in Shelter Cove, a highly diverse intertidal biota is encountered; (5) mussel beds and associated intertidal habitats are more extensive and better developed than at any other location in Humboldt and Del Norte counties and also experience the most severe of impacts caused by human activities; (6) bladder kelp, *Macrocystis integrifolia*, is present both at the northerly intertidal limits and afloat at Shelter Cove.

5.1.4 <u>Jughandle Cove</u>

The Jughandle Cove ASBS is located in Mendocino County, California at approximately 39°22’45” north latitude, 123°49'15” west longitude, and is 5 miles (8.04 km) south of Fort Bragg on California State Highway 1 (Highway 1) (SWRCB 1981). The ASBS encompasses 203 acres (0.32 mi^2; 822,094 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 1.5 miles (2.479 km), encompassing about 0.10% of California’s coastline.

The ASBS is included in this designation for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) it may include the northern extent of the ranges of the puffball sponge, *Tetilla arb*, the honeycomb worm, *Phragmatopoma californica*, and the compound ascidian, *Polyclium planum*.

5.1.5 <u>Saunders Reef</u>

The Saunders Reef ASBS is located in southern Mendocino County along the northern coast of California (38°51' north latitude, 123°40' west longitude), 4.6 miles (7.5 km) southeast of the town of Point Arena. The small town of Anchor Bay is located 5 miles (8 km) to the south. The exposed portion of the reef occurs in the south-central portion of the ASBS, approximately 0.6 mile (1 km) west of Saunders landing and is marked by a navigation buoy. Cliffs, up to 100 feet (30 m) high, border the eastern mean high tide boundary and Highway 1 parallels the ASBS near the edge of the cliffs (SWRCB 1980). The ASBS encompasses 730 acres (1.14 mi^2; 2,953,786 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 1.6 miles (2.559 km), encompassing about 0.10% of California’s coastline.

The ASBS is included in this designation for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) localized high population densities and large size of individual red abalone, offshore reef surrounded by a bull kelp, *Nereocystis luetkeana*, forest; (3) this area is relatively undisturbed by humans.

The designation was recommended by the Regional Water Board and supported by DFG. No opposition to this designation was submitted.

5.1.6 Del Mar Landing

The ASBS encompasses 53 acres (0.08 mi^2; 213,112 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 0.6 miles (0.961 km), encompassing about 0.04% of California's coastline. Del Mar Landing ASBS is entirely overlapped by Del Mar Landing State Marine Park.

The ASBS was designated for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) to preserve land, or land and water areas in a natural condition and to protect the aquatic organisms and wildlife found here for public observation and study. The designation was recommended by the Regional Water Board and supported by DFG. No opposition to this designation was submitted.

5.1.7 Gerstle Cove

The Gerstle Cove ASBS is located in Sonoma County at about 39°33'57" north latitude and 123°19'45" west longitude. The nearest towns are Gualala, located about 20 miles (32 km) north on Highway 1, and Jenner, located about 23 miles (37 km) south on Highway 1 (SWRCB 1979). The ASBS encompasses 10 acres (0.02 mi^2; 39,754 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 0.6 miles (0.961 km), encompassing about 0.04% of California's coastline.

The ASBS encompasses the Salt Point State Park and State Marine Conservation Area, a MPA designated by DFG.

The ASBS was designated for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) it is a relatively pristine cove that is representative of the natural marine environment of Sonoma County.

The designation was recommended by the Regional Water Board and DFG. This is inclusive of a reserve and underwater park for the use of divers and nature observers.

5.1.8 Point Reyes Headlands

The Point Reyes Headlands ASBS is located in Marin County, California. The area is situated entirely within the boundary of the Point Reyes National Seashore Park. The Headlands site is 11 miles (17.6 km) from the nearest town, Inverness (SWRCB 1980). The ASBS encompasses 1,047 acres (1.64 mi^2; 4,237,491 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 4.8 miles (7.720 km), encompassing about 0.31% of California's coastline.

In 1972, DFG declared the Point Reyes Headlands as a Marine Life Reserve. Since then, the Point Reyes Headlands has had the reserve status protection and all marine life has been protected from human collecting and fishing activities. The Point Reyes State Marine Conservation Area is entirely overlapped by the Point Reyes Headlands ASBS. The MPA and ASBS share the same boundary along the coastline. The oceanic boundaries are parallel to the shore and to each other, though the MPA boundary extends about ¼ mile off the coast and the ASBS boundary extends about ½ mile off the coast.

The ASBS was designated for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) the subtidal community at the ASBS is one of the most diverse in the San Francisco Bay region; (3) the intertidal zone has great species diversity including California mussel, gooseneck barnacles, acorn barnacles, and red abalone.

The designation was recommended by the Regional Water Board and supported by the Point Reyes Bird Observatory. No opposition to this designation was submitted.

5.1.9 Duxbury Reef

The Duxbury Reef ASBS is located near the town of Bolinas in Marin County, approximately 14 nautical miles (26 km) northwest of San Francisco. The ASBS is located within 37°53' to 37°56' north latitude, 122°44' west longitude. The center of the municipality of Bolinas is located approximately ¾ mile (1.2 km) from the Agate Beach entrance to Duxbury Reef. Subdivisions extend much closer, with some homes actually overlooking the reef from the surrounding mesa. The reef lies at the base of a high headland, called the Bolinas Mesa. According to contours shown in the most recent geologic map of the Point Reyes Peninsula, there are at least 8,320 acres (33,669,845 m^2) of watershed providing drainage to the ASBS (SWRCB 1979). The ASBS encompasses 876 acres (1.37 mi^2; 3,543,446 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 3.4 miles (5.0 km), encompassing about 0.22% of California's coastline.

The Duxbury ASBS is almost entirely overlapped by the Duxbury Reef State Marine Conservation Area. The MPA and ASBS share most of their boundaries along the coastline, but the northern boundary of the ASBS extends about 1/16 mile north of the MPA boundary. The south-eastern coastal boundary of the MPA extends about 1/8 mile beyond the ASBS boundary. Oceanic boundaries are parallel to the shore and to each other, though the MPA boundary extends about ¼ mile off the coast and the ASBS boundary extends about ½ mile off the coast.

The ASBS was designated for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) it contains a rich intertidal biota which has several unique components of sea slugs, rock inhabiting clams and worms, a rare burrowing anemone, and a unique acorn worm; (3) it is the largest shale reef in California.

The ASBS designation was recommended by the Regional Water Board and supported by DFG and Dr. Gordon Chang. No opposition to this designation was submitted.

5.1.10 <u>James V. Fitzgerald</u>

The James V. Fitzgerald ASBS is a strip of exposed coastline with adjacent intertidal reefs, extending from the westerly extension of the centerline of Fourth Street in Montara in the north to Pillar Point breakwater in the south (SWRCB 1979). The ASBS encompasses 518 acres (0.81 mi^2; 2,097,013 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 5.5 miles (8.784 km), encompassing about 0.35% of California's coastline.

The James V. Fitzgerald ASBS is entirely overlapped by the James V. Fitzgerald State Marine Park, though the southern ASBS boundary extends around Pillar Point, whereas the MPA boundary ends at the point.

The ASBS was designated for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) dense stands of bull kelp are found along with red algae; (3) there is a diverse array of invertebrates that inhabit the broad reefs such as sea stars, starfish, crabs, chitons, and purple urchins; (4) there are three types of subtidal habitat.

The ASBS designation was recommended by the Regional Water Board and supported by DFG, Department of Parks and Recreation (DPR), and the Sierra Club. No opposition to this designation was submitted.

5.1.11 <u>Año Nuevo</u>

The Año Nuevo ASBS is situated along the central California coast in San Mateo County (approximately 37°06' north latitude, 122°20' west longitude) near the San Mateo-Santa Cruz County Line. The nearest town, Davenport, is 9.7 miles (15.5 km) to the south of the ASBS. Pescadero is 14.4 miles (23 km) north of the ASBS. Other towns near the ASBS are Half Moon Bay, 35 miles (56 km) to the north and Santa Cruz, 25 miles (40 km) to the south. Within the ASBS boundary is the Año Nuevo State Reserve (SWRCB 1981). The ASBS encompasses 13,560 acres (21.19 mi^2;

54,875,399 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 4.9 miles (7.847 km), encompassing about 0.31% of California's coastline.

Approximately half of the Año Nuevo State Marine Conservation Area overlaps with the Año Nuevo ASBS. The ASBS, which extends about 3½ miles (5.63 km) offshore, is overlapped along ¾ of coastal boundary by the MPA, which extends about ¼ mile (0.4 km) offshore.

The ASBS was designated for the following reasons: (1) it has a diversity of habitat and biological assemblages, with large and highly diverse marine invertebrate populations that are very unique and not present at any other mainland ASBS site; (2) thousands of marine birds and mammals utilize the site as a breeding and feeding habitat.

5.1.12 <u>Pacific Grove</u>

The Pacific Grove ASBS is oriented in a northwest-southeast direction, adjacent to the town of Pacific Grove in Monterey County. For purposes of description, the ASBS is considered to lie along an east-west axis. The western seaward boundary of the ASBS is at 36°38'36" north latitude, 121°55'42" west longitude and is a seaward extension of Asilomar Avenue. The eastern seaward boundary is at 36°37'24" north latitude, 121°53'54" west longitude and is a seaward extension of Eardley Avenue. Land areas are only south of the ASBS, and offshore bay waters are north of the ASBS (SWRCB 1979). The ASBS encompasses 469 acres (0.73 mi^2; 1,898,526 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 3.2 miles (5.120 km), encompassing about 0.20% of California's coastline.

The ASBS overlaps with the Pacific Grove Marine Gardens State Marine Conservation Area.

The ASBS was designated for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) it has dense beds of giant kelp *Macrocystis pyrifera*; (3) surf grass dominates large areas; (4) endangered sea otters forage in this area.

5.1.13 <u>Carmel Bay</u>

The Carmel Bay ASBS is located in Monterey County, immediately adjacent to the town of Carmel. The ASBS is south of the Monterey Peninsula, just north of the Santa Lucia mountain range, and west of the Carmel Valley. Pescadero Point, the northern boundary of the ASBS, is located at 36°34' north latitude, 121°57' west longitude; Granite Point, the southern boundary, is located just north of Point Lobos at 36°31' north latitude, 121°56' west longitude. The seaward boundary of the ASBS is formed by a straight line drawn between Pescadero and Granite Points; the landward boundary is the mean high tide line (SWRCB 1979). The ASBS encompasses 1,584 acres (2.48

mi^2; 6,411,404 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 6.7 miles (10.756 km), encompassing about 0.43% of California's coastline.

The Carmel Bay ASBS is entirely overlapped by the Carmel Bay State Marine Conservation Area.

The ASBS is included in this designation for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) the intertidal zone is a valuable educational resource, due to the high biodiversity and excellent access.

5.1.14 Point Lobos

The Point Lobos ASBS is located at about 30°10' north latitude, 121°45' west longitude, within Monterey County, California. The closest town is Carmel, located immediately upcoast on Highway 1. The Point Lobos ASBS is adjacent to the Point Lobos State Natural Reserve (Park) and is entirely overlapped by the Point Lobos State Marine Conservation Area. The ASBS encompasses 691 acres (1.08 mi^2; 2,795,439 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 9.4 miles (15.131 km), encompassing about 0.60% of California's coastline.

The ASBS is included in this designation for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) a variety of marine mammals are present within the ASBS throughout the year, including the threatened Stellar Sea Lion (*Eumetopias jubatus)*.

5.1.15 Julia Pfeiffer Burns

The Julia Pfeiffer Burns ASBS is located at about 30°10' north latitude, 121°45' west longitude, within Monterey County, California. The closest town is Carmel, located about 35 miles (56.327 km) up the coast on Highway 1 (SWRCB 1980). The ASBS encompasses 1,743 acres (2.72 mi^2; 7,052,623 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 3.7 miles (6.020 km), encompassing about 0.24% of California's coastline.

The Julia Pfeiffer Burns ASBS is entirely coincident with the Julia Pfeiffer Burns State Park.

The ASBS was designated for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) it is a biologically rich portion of the California coast.

5.1.16 Salmon Creek Coast

The Salmon Creek ASBS is adjacent to the Los Padres National Forest at the southern end of the Big Sur area of central California's Coast Range. The ASBS encompasses 1,458 acres (5,898,623 m^2; 2.28 m^2) of coastal marine habitats. The length of coastline included in the ASBS is 3.4 miles (5.533 km), encompassing about 0.22% of California's coastline.

The ASBS was designated because it has a diversity of habitat and biological assemblages.

5.1.17 Laguna Point to Latigo Point

The eastern boundary of the Laguna Point to Latigo Point ASBS is Latigo Point (34°01'34" north latitude, 118 °45'20" west longitude) in Los Angeles County and the western boundary is Laguna Point (34°05'40" north latitude, 119°6'30" west longitude) in Ventura County. The ASBS lies in an approximate east-west orientation. Fifty-five percent (55%) of the shoreline (and area) lies in Los Angeles County and 45 percent lies in Ventura County. The eastern boundary is about 16.4 miles (26.4 km) from the City of Santa Monica and 4.1 miles (6.6 km) from Malibu Beach. The western boundary is about 6.5 miles (10.5 km) from Port Hueneme-Oxnard and 15 miles (24 km) from Ventura (SWRCB 1979). The ASBS encompasses 11,842 acres (18.50 mi^2; 47,923,090 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 24.0 miles (38.603 km), encompassing about 1.54% of California's coastline.

The Laguna Point to Latigo Point ASBS is overlapped by the Big Sycamore Canyon State Marine Reserve in about 1/8 of the ASBS area.

The ASBS is included in this designation for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) it has a healthy assemblage of giant kelp, *Macrocystis pyrifera*.

5.1.18 Santa Catalina Island

Santa Catalina Island is located at 33°22' north latitude, 118°25' west longitude and lies approximately 20 miles offshore of the Palos Verdes Peninsula. The island is 22 miles (35.4 km) long, 8 miles (12.9 km) across at its widest point, and is oriented in a general northwest to southeast direction. Santa Catalina Island is part of Los Angeles County. Avalon is the only city on the island. There is a community located between Catalina Harbor and Isthmus Cove, known as Two Harbors. Approximately, 100 permanent residents of Two Harbors maintain the local recreational facility utilized by vacationers, the area's primary industry (SWRCB 1979).

The Northwest Santa Catalina Island ASBS is located at the western end of the Island (33°27' north latitude, 118°33' west longitude). It includes most of the area west of Two Harbors (known locally as the Isthmus) (SWRCB 1979). The ASBS encompasses 13,235 acres (20.68 mi^2; 53,561,672 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 20.9 miles (33.599 km), encompassing about 1.34% of California's coastline. A small portion of the Northwest Santa Catalina Island ASBS overlaps all of the Arrow Point to Lion Head Point Invertebrate Area (MPA).

The ASBS is included in this designation for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) it is possibly a transitional zone between subtidal area containing predominantly northern and southern species; (3) due to the proximity to University of Southern California's Catalina Marine Science Center, many scientific studies have yielded valuable information about the area.

The Western Santa Catalina Island ASBS begins at the north end of Little Harbor and extends south to Ben Weston Point. Its seaward boundary follows the 300-foot (91.4 m) isobath or a line one nautical mile offshore, whichever is more distant. The ASBS encompasses 2,247 acres (3.5 mi^2, 9.09km^2) of various coastal marine habitats. The length of coastline included in the ASBS is 0.26 miles (0.42 km).

The Southeast Santa Catalina Island ASBS extends from Jewfish Point to Binnacle Rock on the east end of Santa Catalina Island. Its seaward boundary follows the 300-foot isobath or a line one nautical mile offshore, whichever is more distant. Approximate coordinates of the center of the area are 33°18'30" north latitude, 118°18' west longitude (SWRCB 1979). The ASBS encompasses 2,756 acres (4.31 mi^2; 11,151,303 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 2.9 miles (4.628 km), encompassing about 0.18% of California's coastline.

The ASBS is included in this designation for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) it represents a warm water region of the Channel Islands. The physical and biological conditions are a marked contrast to the northern Islands, and are more similar to San Clemente Island.

5.1.19 Robert E. Badham

The Robert E. Badham ASBS extends along the coast of Corona del Mar in Orange County. The area is contained within the approximate map coordinates 33°34'50" to 33°35'25" north latitude, 117°51'10" to 117°52'20" west longitude (SWRCB 1979). The ASBS encompasses 220 acres (0.34 mi^2; 888,804 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 0.7 miles (1.113 km), encompassing about 0.04% of California's coastline.

A small portion of the Robert E. Badham ASBS overlaps all of the Robert E. Badham State Marine Conservation Area MPA. The MPA and ASBS share the same coastal boundary, though the MPA extends a very short distance from shore (less than ¼ mile). The northwestern corners of both Irvine Coast MPA and Crystal Cove MPA also overlap with the ASBS.

The ASBS is included in this designation for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) offshore reefs provide abundant habitat for a variety of species.

5.1.20 Irvine Coast

The Irvine Coast Marine Life Refuge ASBS encompasses the nearshore waters between the southern border of Corona del Mar and Abalone Point in Orange County. Boundaries of the ASBS are contained within the approximate map coordinates 33°33'20" to 33°35'05" north latitude, 117°49' to 117°51'55" west longitude (SWRCB 1979). The ASBS encompasses 941 acres (1.47 mi^2; 3,806,657 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 3.4 miles (5.461 km), encompassing about 0.22% of California's coastline. The ASBS was designated because it has a diversity of habitat and biological assemblages.

The entire Irvine Coast ASBS is overlapped by MPAs. Crystal Cove State Park is adjacent to the ASBS, and the Irvine Coast State Marine Conservation Area and ASBS share coastal boundaries. The Marine Conservation Area extends about ¼ mile oceanward, into the ASBS, the oceanic boundary parallel to the coastal boundary. The Crystal Cove State Marine Conservation Area northeast boundary is shared with the oceanic boundary of the Irvine Coast State Marine Conservation Area. The Crystal Cove State Marine Conservation Area extends about ¼ mile beyond the oceanic boundary of the ASBS.

5.1.21 Heisler Park

The Heisler Park ASBS comprises the nearshore waters near the town of Laguna Beach, Orange County. The approximate map coordinates for the area's boundaries are 33°32'25" to 33°32'45" north latitude, 117°47'15" to 117°47'55" west longitude.

The Heisler Park ASBS is entirely overlapped by the Heisler Park State Marine Reserve and Laguna Beach State Marine Conservation Area, which overlap each other as well. Beyond the immediate coastal bluffs of the Reserve are located a public park and public beach access. The landward side beyond the park is fully developed with private residences and businesses. Access on foot to the Reserve is provided by paved paths and steps, and signs announcing the Reserve are posted on all of these accesses (SWRCB 1979). The ASBS encompasses 32 acres (0.05 mi^2; 129,456 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 0.5 miles (0.781 km), encompassing about 0.03% of California's coastline.

The ASBS was designated because it has a diversity of habitat and biological assemblages.

5.1.22 La Jolla

The La Jolla ASBS is located at 32°51'52" north latitude, 117°15'15" to 117°16'15" west longitude, in La Jolla Bay, adjacent to the town of La Jolla, in the City of San Diego in San Diego County. The shoreward boundary line is the mean high tide line from the south end of SIO to Goldfish Point. It is the south 1/6 of the San Diego-La Jolla Underwater Park, which was created in 1970 (City of San Diego Municipal Code). The Park itself extends from Point La Jolla westward, then northerly to the San Diego city limits, a north-south distance of approximately 7 miles (11.265 km) along a line about 1 mile out from the shoreline for a total surface area of 5,977 acres. The seaward boundaries are designated by a series of five orange-red marker buoys which are clearly identified; and the on-land accesses at Goldfish Point, the La Jolla Beach and Tennis Club, and the south end of Kellogg Park are visibly marked as entrances to the Ecological Reserve.

The northern shore is a fine sandy beach, whereas the southern shore is composed of rough boulders or ledges at the base of cliffs with one pebble beach in the Devil's Slide area. The northern three-fourths of the shoreline face westward while the southernmost one-fourth faces northward (SWRCB 1979).

The ASBS encompasses 453 acres (0.71 mi^2; 1,832,543 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 1.7 miles (2.714 km), encompassing about 0.11% of California's coastline.

The La Jolla ASBS is completely overlapped by the La Jolla State Marine Conservation Area MPA, which extends beyond the ASBS in the southwest corner.

The ASBS is included in this designation for the following reasons: (1) it has a diversity of habitat and biological assemblages; (2) it is in close proximity to SIO and is a desirable scientific study locale.

5.1.23 <u>San Nicolas Island & Begg Rock</u>

The ASBS encompasses 63,658 acres (99.47 mi^2; 257,615,348 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 26.9 miles (43.318 km), encompassing about 1.73% of California's coastline. The ASBS is included in this designation because it has a diversity of habitat and biological assemblages.

San Nicolas Island (SNI) is used by the U.S. Navy for shipboard launches of missiles and targets. The island is instrumented with metric tracking radar, electro-optical devices, and telemetry and communications equipment to support long-range and over-the-horizon weapons testing and fleet training.

5.1.24 <u>San Clemente Island</u>

San Clemente Island (SCI) is the southernmost of California's Channel Islands, located 78.3 miles (126.011 km) west of San Diego and 63.3 miles (101.871 km) south of Long Beach. It is the primary maritime training area for the U.S. Department of the Navy Pacific Fleet, and the Navy Sea, Air and Land (SEALS), and also supports the U.S. Marine Corps, the U.S. Air Force, and other users. SCI is used by the U.S. Navy to conduct readiness training, research, development, test and evaluation (RDT&E). Navy ownership of the island allows for fleet training, weapon and electronics systems testing, and research and development activities (U.S. Dept. of the Navy, 2007). It is also home to a variety of unique and rare ecological resources on land, and some of the richest marine communities in the world in adjacent waters. The island is approximately 24.1 miles (38.785 km) long and is 5.2 miles (8.368 km) across at its widest point (San Clemente Island website, www.scisland.org.) The ASBS encompasses 49,162 acres (76.82 mi^2; 198,952,668 m^2) of various coastal marine habitats. The length of coastline included in the ASBS is 58.5 miles (94.089 km), encompassing about 3.76% of California's coastline.

The ASBS was designated because it has a diversity of habitat and biological assemblages.

5.2 GEOLOGICAL SETTING

5.2.1 - Terrestrial Geological Setting

The terrestrial geological setting of the ASBS is important due to the influence of the topography, rock and soil on watersheds, runoff, and sediment deposition in the marine environment.

5.2.1.1. Redwoods National Park

The coastal geology of this ASBS is a mixture of three major components: the Franciscan Complex, Quaternary deposits, and modern beach sands. The Franciscan Complex consists mainly of chert, metavolcanics (greenstones) sandstones, shales, siltstones, and conglomerates that formed an accretionary wedge as ocean crust collided with the North American Plate. As a result, rocks of the Franciscan Complex are extensively folded, sheared, and metamorphosed, typical of a mélange. Most of the intertidal rocks and sea stacks are derived from Franciscan rock types. Differential weathering and erosion is prevalent within the Franciscan Complex as less competent beds composed of shales and siltstones are easily eroded when exposed directly to wind and wave action, resulting in unstable slopes.

The beach extending southward from Crescent City to Nickel Creek is composed entirely of geologically recent beach sands and is intermixed with boulders and rocks near White Knob at the south end of the beach (SWRCB 1981).

5.2.1.2 Trinidad Head

Similar to Redwoods National Park, surficial geology is also dominated by the Franciscan Complex, Quaternary marine deposits, and geologically recent beach sands. Highly resistant Trinidad Head consists of a metavolcanic, intrusive block of hornblende and diorite within the mélange. Greenstone and metavolcanic rocks are found around the base of Trinidad Pier and in the southern portion of the ASBS. Chert is found in the cobble field on the upper beach of the southern part of the ASBS. Most of the more resistant intertidal rocks and stacks are mineralized sandstone called "greywacke." The coastal bluff consists of a thick sequence of Quaternary deposits deposited during periods of marine inundation during the past 1 to 2 million years. The coast line has since been uplifted and eroded.

The present day geological picture is a result of differential weathering and erosion of the major components. Following winter storms, erosion of the Franciscan blue clays is particularly evident and results in increased turbidity of the nearshore zone. Coastal bluffs in the vicinity are relatively unstable and, as a result, the bluffs are currently designated as open space to lessen the possibility of increased erosion and damage to property (SWRCB 1979).

5.2.1.3 King Range

King Range consists largely of rocks in the ubiquitous Franciscan Complex formation, along with various metavolcanic intrusives or metamorphic rocks. However, greenstones and cherts typically characteristic of the Franciscan Formation are lacking for the most part. Metavolcanic intrusives, sometimes evident as pillow structures (indicating their origin underwater) are also found at Shelter Cove in the coastal bluffs.

Rocks of the King Range show evidence of persistent crustal deformation as evidenced by the numerous folds, thrust faults, reverse faults, and strike-slip faults initiated during the Tertiary period that have continued to develop into present times. The San Andreas Fault meets the Mendocino Fracture Zone just north of the ASBS; severe seismic hazard will continue to exist along this section of the coast (SWRCB 1979).

A high ridge runs parallel to the coast through the entire area. The slopes of this ridge drop precipitously into the intertidal zone along the coastline, and are cut by numerous small streams. The entire coastline is undergoing active uplifting as the Eastern Pacific Plate is moving under the Continental Plate.

Only three areas of relatively flat ground are found along the coast: (1) Shelter Cove, where the adjacent ridge line drops to gently rolling hills about 1/2 mile (0.8 km) from the coast; (2) Big Flat, an alluvial fan at the mouth of Big Flat Creek; and (3) Spanish Flat, a narrow terrace extending for 2 miles (3.2 km) from Randall Creek to Spanish Creek. Huge rock slides and talus slopes fall directly into the intertidal zone at several points.

The main fault in the area is the Point Delgada Fault, either a branch of the San Andreas Fault, or the main fault itself. At Shelter Cove, several surface breaks opened during the 1906 earthquake. Nowhere are the effects of local seismicity on intertidal substrates more evident than at the huge Kaluna Slide, just north of Shelter Cove. Fractured, broken rock extends from Kaluna Cliff directly into the intertidal zone. The main break of the Point Delgada Fault is exposed near the top of the cliff; movement along the fault apparently triggered the slide in 1906.

5.2.1.4 <u>Pygmy Forest Ecological Staircase</u>

The ASBS lies within the coastal belt of the Franciscan Formation, which reaches along the coast from Cape Mendocino to Point Arena. This section of the Franciscan Formation averages 15 miles (24 km) wide and consists primarily of greywacke. Subsequent and irregular uplifting in this portion of the Franciscan Formation resulted in the series of wave cut marine terraces that form the Pygmy Forest Ecological Staircase. Possibly, another terrace is still being formed subtidally (SWRCB 1981).

5.2.1.5 <u>Saunders Reef</u>

The Saunders Reef area is part of the Gualala Block, which comprises all the rocks west of the San Andreas Fault between Fort Ross and Point Arena. The block consists of over 3.8 miles (6 km) of Upper Cretaceous to recent marine sediments that are highly faulted and folded (Boyle, 1967). There are four major geological units in the area: (1) the German Rancho Formation; (2) the Iverson Basalt; (3) the Gallaway Formation; and (4) marine terrace deposits.

The German Rancho Formation outcrops only in the southern portion of the area near Iverson Point, where it underlies the marine terrace deposits. The sandstones of the

German Rancho Formation consist of medium to very coarse sand that is normally graded with sharp or erosional bases, deposited via turbidity currents in quite deep waters. The sands are mainly comprised of quartz and k-feldspar with muscovite and carbonaceous material. The mudstones in this formation contain muscovite, montmorillonite, kaolinite, feldspar, and quartz (SWRCB 1980).

The Iversen Basalt unit, stratigraphically, overlies the German Rancho Formation and underlies the Gallaway Formation. The Iversen Basalt comprises all of the sea stacks found in the southern part of the ASBS, and along most of the seacliffs.

The early-Miocene Gallaway Formation consists of cemented mudstones and occasional porcelanite, as well as some dolomite concretions and benitonite beds. The mudstones consist of quartz, feldspar, calcite, montmorillonite, pyrite, glauconite, and organic matter. The sandstones consist predominately of quartz and feldspar and are exposed in the intertidal only in the northern-most part of the ASBS study area. The broad, intertidal terrace in the northern portion of the ASBS study area is underlain by the Gallaway Formation.

On land, there are at least three marine terrace levels immediately adjacent to the Saunders Reef area. These Pleistocene terraces lie at elevations of up to 197 feet (60 m), providing evidence of the relatively recent tectonic uplifting which has occurred in this area.

Beaches along the Saunders Reef ASBS are cobble-boulder beaches with little sand. The sea cliffs at the northern-most part of the study area are of the Gallaway Formation. The remainder of the sea cliffs in the ASBS is composed of the massive Iversen Basalt. Consequently, the cliffs are steeper than they are to the north. Due to rock falls and fresh water runoff, the sea cliffs in the area appear to be retreating rapidly landward, undermining Highway 1 in some places (SWRCB 1980).

5.2.1.6 <u>Gerstle Cove</u>

Like the Saunders Reef ASBS described above, this ASBS is part of the Gualala Block, west of the San Andreas Fault. The geological units in the area are the German Rancho Formation; the Iverson Basalt; the Gallaway Formation; and marine terrace deposits described previously.

The adjacent land mass is emergent coast, featuring a series of wave-cut marine terraces produced by relatively higher sea levels (SWRCB 1979).

5.2.1.7 <u>Point Reyes Headlands</u>

Point Reyes Headlands lies west of the San Andreas Fault and consists largely of granodiorite, which are more closely associated with rocks from southern California that have traversed northwestward along the San Andreas Fault hundreds of miles (SWRCB 1980). Core samples have revealed that the granitic rocks extend 1,370 feet (417 m) below sea level. These rocks range in composition from quartz diorite to adamellite, containing more quartz and potash feldspar. Most of the granitic rocks of the Point Reyes Peninsula are deeply weathered. Overlying parts of the granite on the Point Reyes Headlands ASBS are large patches of conglomerate, a hard sedimentary rock composed of large and small-size pebbles and cobbles, all cemented together. From the Lighthouse area of the Headlands to the intertidal zone, there are large blocks of conglomerate. Giant sea caves have been etched into the conglomerates at the surf zone. These conglomerates are not found anywhere else on the Point Reyes Peninsula. The conglomerates are overlaid in an unconformed manner by basal glauconitic sand of the Drakes Bay Formation.

To the north of the Point Reyes granitic promontory are alignments of ridges and valleys that run approximately east to west. The ridges are harder layers of the Drakes Bay Formation and are folded into an anti-cline-syncline pattern. The valleys are remains of tributaries, which drain into the drowned-valleys of Drakes Estero and Estero de Limantour (Galloway 1977, cited in SWRCB 1980).

5.2.1.8 Duxbury Reef

This location is the southernmost point of the Monterey Shale Formation, which consists of chert, porcelanites, organic shales, and thin hard sandstones in considerable variation. The headlands are composed of sandstones that are undergoing continuous erosion by winds (SWRCB 1979).

Except for a small area of unconsolidated terrace deposits at the northern boundary of the ASBS, the whole of the area consists of Monterey shales. These shales cover most of the area from Duxbury Point to Double Point in the Point Reyes National Seashore, and extend as far north as some areas in the Tomales Quadrangle. The surfaces of outcrops are normally smooth and covered with vegetation, but where the shale is chert, a crag or pinnacle may be formed by differential erosion.

The headlands (Bolinas Mesa) overlooking the Duxbury Point area are composed of sandstones, which are undergoing continuous erosion by winds. The reef is composed of harder organic shales and some cherts. These harder rocks are continually being exposed by rapid erosion of the mesa.

The Monterey sandstones and mudstones are well bedded and dip at an angle 45° seaward. Thus when bedding planes are lubricated with rainwater or drainage, landslides are apt to occur at the sea cliff. Waves during high tides quickly move the material at beach level, with the slide gradually being eroded back to reach a stable angle of repose. Since 1859, Duxbury Point has eroded about 200 feet (60 m), Bolinas Point about 160 feet (50 m), and an unnamed point about 4,000 feet (1,200 m) north of Bolinas Point has eroded about 200 feet (60 m). Along the stretch of coast adjacent to the ASBS, the Monterey sandstones and mudstones are well bedded and dip seaward contributing to landslides at the sea cliff (SWRCB 1979).

A large slump block landslide is located north of Palomarin Beach, where beach erosion is undercutting the toe of the slide area (USGS, 2005). Between Bolinas and Duxbury points, the wave-cut platform and beach are also inundated by waves causing landslides by undercutting the base of the cliffs. Failure is facilitated by increased subsurface flow of water and saturation due to septic effluent from cliff-top homes as well as winter rainfall. Between Bolinas and Duxbury points, the average rate of recession along the cliff base ranges from 6 to 24 inches per year. Between Duxbury Point and Terrace Avenue, the mudstone is weathered and fractured, particularly near the San Andreas Fault. Numerous homes line the cliff edge and since the area was initially subdivided in 1927, many of these lots and Ocean Parkway have been damaged by cliff erosion; several homes have been removed from their foundations (Griggs et al, 2005).

Duxbury Reef is the largest exposed shale reef in California. Its prominences extend up to 1 mile (1.6 km) out to sea at Duxbury Point, and from 1/4 to 1/2 mile (0.4 to 0.8 km) from the high tide line in other areas. Wave action has carved channels and depressions in the rocks, but more resistant ridges have remained as high protrusions, resembling small islands (SWRCB 1979).

5.2.1.9 James V. Fitzgerald

The Fitzgerald Marine Reserve straddles the geologically active Seal Cove Fault, which extends northward to connect with the San Andreas Fault near Bolinas Lagoon in Marin County. The San Andreas Fault is probably responsible for the seismic activity of the Seal Cove Fault and secondary faults which diagonally transect the ASBS. Seismic activity at either the Seal Cove or Bay Area faults could result in surface rupture along the faults, high levels of ground shaking, ground failure (such as land sliding), and tsunami inundation (SWRCB 1979).

The trace of the Seal Cove Fault is exposed in the sea cliff just north of the reserve headquarters. The mouth of San Vicente Creek, which drains the San Vicente watershed, is located just south of the headquarters. South along the west side of Seal Cove Fault, bedrock and overlying marine terrace deposits are vertically lifted about 150 feet (45 m) to form the Pillar Point headland and ridge. It is the west face of this ridge which forms the sea cliffs south of the headquarters. The bedrock cliffs are composed of consolidated sandstone, siltstone, and mudstone, much of it embedded in clay, which together form the Tertiary (Pliocene) Purisima Formation. The overlying marine terrace deposits, which cap the Purisima bedrock, consist of weakly consolidated, slightly weathered sands and gravels of more recent (Pleistocene) origin. The cliffs gradually increase in height in the southerly direction and are being actively eroded over most of the length of the reserve. With little or no beach present, the most resistant subtidal and intertidal reefs offer only local resistance to wave action. As a result, land-sliding occurs along the length of this section of the ASBS (SWRCB 1979).

North of the marine reserve headquarters, the shoreline of Fitzgerald ASBS changes abruptly. This section of coastline is characterized by rugged rock outcrops and smaller reefs of granodiorite of Mesozoic origin (Geologic Map of California 1963). Elevation of these cliffs ranges from 25 to 50 feet (7.6 to 15 m) in most places. Occasional sandy or cobble beaches are present between rock outcrops (San Mateo County 1976, cited in SWRCB 1979).

5.2.1.10 Año Nuevo

The ASBS consists of a small rocky island lying about 0.5 miles (600 m) offshore from a low headland which juts about 1.5 miles (2 km) out into the Pacific Ocean from the general north-northwest trend of the coastline in San Mateo County. The surface of an emergent marine terrace forms the broad, nearly horizontal plain of Point Año Nuevo. The wave-cut platforms mantled with terrace deposits truncate folded beds of the Purisima (Pliocene) and Monterey Formations (Miocene) (Tinsley 1972, cited in SWRCB 1979). With the exception of the south shore of Point Año Nuevo where near vertical sea cliffs of 60 to 90 feet (20 to 30 m) are present, the coastline either lacks cliffs or has small cliffs, usually less than 6 to 10 feet (2 to 3 m) high. South of Point Año Nuevo, three major fault strands within the San Gregorio Fault zone intersect the coastline and the rather continuous Santa Cruz terrace sequence comes to an abrupt end. Lateral discontinuities and tilting of well-preserved marine terraces help define major structural blocks within the fault zone and document significant differential movement among these blocks from Point Año Nuevo north to San Gregorio Creek (SWRCB 1981).

Along the south shore of Point Año Nuevo, five faults exposed in the sea cliff clearly offset the 100,000 year-old marine terrace. The Frijoles Fault consists of a 300 foot wide zone of crushed and pervasively sheared sandstones and siltstones of the Pliocene Purisima Formation and is exposed in the sea cliff on the south shore of Point Año Nuevo. The competent rock of the Purisima Formation dips gently northeast and forms high vertical seacliffs, capped by the first marine terrace west of the fault zone. Lower cliff height and greater instability due to numerous landslides off the cliff face characterize the sea cliff in the fault zone.

Alluvial deposits consisting of interbedded clays, peats, silts, and poorly sorted sand and gravel, composed primarily of clasts of Santa Cruz Mudstone, are found east of the fault juxtaposed against the crushed Purisima Formation (Weber and LaJoie 1979, cited in SWRCB 1981).

There are two dune fields within this ASBS at Point Año Nuevo and Franklin Point. The 300 to 350 acre dune field at Point Año Nuevo consists of fine-to-medium grained sand derived from a windward beach. Along the north shore of Point Año Nuevo, beach sands are winnowed by the prevailing northwesterly winds and the finer grained sands are carried up onto the low terrace above the beach (SWRCB 1981).

5.2.1.11 Pacific Grove

The ASBS is located at the northern end of the Santa Lucia Mountains, where these mountains descend beneath Monterey Bay. The geology of the shoreline and nearshore waters of the ASBS is relatively simple, consisting only of Santa Lucia granodiorite. The rock is highly fractured and, therefore, weathers easily to sand size particles. The rock mass is cut by dikes, which are somewhat more resistant to weathering than the granodiorite. The rocks are extensively jointed in several directions, the most persistent being parallel to the shoreline; jointing frequently occurs perpendicular to this, thus producing a blocky pattern in the exposed outcrops best seen at Lucas Point and Otter Point.

The sandy beaches within and adjacent to the ASBS are derived entirely from the granodiorite. Arnal et al (1973) noted that Monterey Bay is a closed system with no sediment being transported into or out of the bay to the north and south. Also, the shoreline at Pacific Grove is situated such that longshore transport into the area from south bay beaches is highly unlikely (SWRCB 1979).

5.2.1.12 Carmel Bay

The ASBS coastline is characterized by alternating rocky points and extensive granitic sand beaches. The Carmel River drains into the ASBS just south of Carmel Point. San Jose Creek drains into the south end of the Carmel River State Beach, a steep sandy cove that encloses the Carmel submarine canyon.

Several distinct formations are found at different locations along the shoreline. The granite outcroppings represent the northwestern-most extension of the Santa Lucia mountain range, for which granodiorite is the basement rock. Subtidally, most of the floor and walls of the Carmel submarine canyon consist of granodiorite, which accounts for the unusually high visibility here. Intertidally, granodiorite occurs as promontories, boulders, and cobble at Pescadero Point, Carmel Point, in the vicinity of the buried sewer outfall, and at the north end of Hudson Cove. Inland of the ASBS, granite outcrops occur north of Stillwater Cove, in the Carmel Valley, and along San Jose Creek, extending south to Point Lobos (Simpson 1972, cited in SWRCB 1979).

The Carmelo series, also common in and adjacent to the ASBS, consists of sandstone, siltstone, conglomerate, and shale. The dominant rock type in the ASBS is a conglomerate, consisting of igneous pebbles embedded in a coarse-grained, well-cemented matrix. Subtidally, the Carmelo Formation consists of all four rock types and underlies Stillwater Cove; from here, it continues southward to a point 300 yards (274 m) seaward of Ocean Avenue at the north end of Carmel City Beach. In the intertidal zone, this formation is visible adjacent to Stillwater Cove, in the promontory just north of

Monastery Beach, and adjacent to Hudson Cove. Inland, the Carmelo Formation occurs north of the Carmel Mission (northeast of the Carmel River mouth).

The Tremblor Formation, consisting of a white to brownish sandstone intermixed with conglomerate occurs at several shoreline locations between the volcanics at Arrowhead Point and amongst the Carmelo Formation at Pebble Beach and Stillwater Cove. Inland, this formation occurs northeast of the Carmel Mission. Lava outcrops or extrusions occur both subtidally and intertidally at Arrowhead Point.

Quaternary rocks identified as Aromas Red Sandstone occur in cliff sides and along the beach from Arrowhead Point south to Carmel (Mission) Point. Recent unconsolidated sediments form terraces, which underlie the Pebble Beach Golf Course and are visible adjacent to the intertidal area. Submerged terraces of this composition also occur throughout Carmel Bay. Sand beaches occur frequently along the ASBS (SWRCB 1979).

5.2.1.13 Julia Pfeiffer Burns

The area is within the Coast Range Geomorphic Province and is classified as Mesozoic granitic rock. The coastline is very steep resulting in restricted watersheds that are drained by canyons. Within the ASBS, two small watersheds occur, Partington Creek draining into Partington Cove and McWay Creek Draining into Waterfall Cove (SWRCB 1980).

The geology, climate, and ecology make the Big Sur area landslide-prone. Landslides in frequently damage Coast Highway and may impact nearshore marine life. Rocks weakened by faulting and fracturing contribute to landslide conditions. During the storm season Big Sur experiences heavy rainfall and high wave energy, and during the fire season wildfires remove vegetation, making slopes vulnerable to erosion. In 1983 a landslide at Julia Pfeiffer Burns ASBS resulted in closure of the highway for more than a year and generated nearly 3 million cubic yards of debris (USGS, 2004).

5.2.1.14 Salmon Creek Coast

Salmon Creek is among the most southern of watersheds along the Big Sur coast. The eastern boundary of the watershed is the coastal ridge of the Santa Lucia Range. This area is underlain by rocks of the Franciscan Complex, which are known to erode more easily than rocks further north in the same mountain range. A major fault, the Sur-Nacimiento fault, traverses the area. There are an abundance of ultramafic rocks rich in magnesium and iron and there is more serpentine here than elsewhere in Big Sur. Soils derived from these rocks support an unusual flora, including a number of plants that grow only in serpentine (Henson et al., 1996).

5.2.1.15 San Nicolas Island

SNI topography was initially formed and subsequently shaped by changes in sea level and differential uplift of the island. The central portion of the island gently slopes upward (from north to south) to a height of 900 feet (274 m) above mean sea level. Cliffs along the northern perimeter of the island's central mesa lead to seven well-defined marine terraces visible on the north side of the island. The most notable geographic feature of SNI is the series of Eocene marine terraces. Terraces are covered by windblown sand (dune) deposits that decrease in depth from northwest to southeast. The average surface elevation is 500 feet (152 m) above mean sea level, with a maximum elevation of 908 feet (276 m) above mean sea level.

SNI is thought to be underlain by the Franciscan Formation, which consists of a variety of rocks including deep-marine sedimentary rocks as well as metamorphosed igneous rock. Underlying both dunes and marine terrace deposits are alternating layers of Tertiary marine sandstone and siltstone. All units have been folded into a broad anticline. The axis of this fold runs parallel to the length of the island, plunges slightly southeast, and is offset by several Pre-Quaternary faults. Marine terrace deposits are composed of unconsolidated clayey, silty sands, some of which are cemented together by caliche, a cement-like calcium carbonate deposit formed by the downward percolation of rainwater in dune and marine terrace deposits. Fossils occur throughout Eocene sedimentary units and marine terrace deposits on SNI, and occur extensively throughout surface and subsurface units. Fossils of marine terrace deposits consist of over 250 species of mollusks and other invertebrates. These assemblages are presumed to occur throughout marine terraces on SNI and are unique in their completeness (Vedder and Norris 1963 in US Navy San Nicolas Island Integrated Natural Management Resources Plan 2006-2010).

5.2.1.16 Laguna Point to Latigo Point

The Ventura-Oxnard plain lies at the north end of this ASBS and consist of a large alluvial deposit from the Ventura River, Santa Clara River, and Calleguas Creek drainages. Calleguas Creek drains into the ASBS through Mugu Lagoon. A barrier bar with a single tidal opening bounds the seaward side of the lagoon.

The Santa Monica Mountains rise steeply to the east of the Ventura-Oxnard plain. These mountains, part of the Transverse Ranges province, are primarily composed of sedimentary rocks. This region is characterized by steep mountain slopes and few offshore reefs. Along the coastal bluffs, the region is structurally the most complex within the ASBS. The rocks are highly folded and steeply dipping so that very different rock types lie next to one another. The western part of this bluff coast from Little Sycamore Canyon to Trancas Beach is made up of older Tertiary (Miocene) erosion resistant rocks of the Trancas Formation. The white cliffs of Paradise Cove are outcrops of the Miocene Age Modelo Formation, which forms steep inclined bids from Zuma Beach Eastward to Corral Beach (beyond the ASBS boundary). This formation is predominantly siliceous shale and was probably formed in the deep sea. The headland at Point Dume is a highly resistant igneous breccia that has protected the softer sedimentary shale behind it from erosion. In addition to the Miocene deposits, there is an irregular veneer of Pleistocene marine terrace deposits on the bluff, between the ocean and the mountains adjacent to the eastern section of the ASBS that tends to form steep-sided stream gullies and sea cliffs.

A major east-west low angle thrust fault, the relatively young Malibu Coast Fault, separates the Santa Monica Mountain escarpment from the central Malibu bluff coast. The fault generally can be traced in the central and eastern part of the land adjacent to the ASBS by the distinct change in slope between the terrace of the Malibu bluff and the rapidly rising Santa Monica Mountains behind. High angle faults tend to run north from this fault into the Santa Monica Mountains. The Malibu Coast Fault runs inland from offshore at Las Flores Canyon to the east of the ASBS, and re-enters the sea at Little Sycamore Canyon within the ASBS. Many smaller faults run roughly north-south in the Santa Monica Mountains and often provide the basis of the steep-sided canyons in the area. The largest of these faults is the Sycamore Canyon Fault. Additional faults may separate the Trancas and Modele Formations at the western end of Zuma Beach and another fault may exist offshore of Point Dume, separating the Point from the Modele Formation.

Between Point Mugu and Deer Canyon the shallow water areas off the headlands are regularly bordered by bedrock outcroppings and boulder fields that give way to sand beyond a depth of no more than 10-15 feet (3 to 4 m) (SWRCB 1979).

5.2.1.17 <u>Santa Catalina Island</u>

The major exposed rock on Santa Catalina Island is Catalina schist, a low-grade layered metamorphic rock. Landslides commonly occur where it forms steep slopes. To the northwest, the land adjacent to the ASBS is extremely rugged, with steep drop-offs to the ocean and narrow ravines.

The highest peak adjacent to the ASBS is Silver Peak, reaching an elevation of 1,804 feet (549 m). Adjacent to the Northwest Santa Catalina Island ASBS the isthmus is the land area with the lowest elevation (less than 20 feet; 6.1 m) and also has the narrowest width of any portion of the island (0.25 miles). The Isthmus area is geologically very active, as indicated by frequent landslides (SWRCB 1979).

Approximately 59% of the island's surface drainage enters Western Santa Catalina Island ASBS; streams include Big Springs and Little Springs Canyon, Fern Creek, Cottonwood Creek, Sweetwater Canyon, Cape Creek, Middle and Bullrush Canyons. Only Cottonwood and Middle Canyons have perennial flow into the ASBS. Runoff and erosion during the storm season is known to cause road damage on the road to Ben Weston Beach.

The southeast portion of the island is mountainous with steep, rocky cliffs. A large industrial quarry operation is located adjacent to the Southeast Santa Catalina Island ASBS (SWRCB 1981).

5.2.1.18 San Clemente Island

SCI is the exposed portion of an uplifted fault block composed primarily of a stratified sequence of submarine volcanic rock (andesite, dacite, and rhyolite) and volcanic rocks of Miocene age (12 to 15 million years old). The volcanic rock is over 1,969 feet (600 m) thick and is overlain and interbedded with localized sequences of Miocene and Pliocene marine sediments, many of which contain microfaunal and megafaunal fossils. The highest point on the island is about 2,000 feet (610 m) above sea level, in an area southeast of the island's center. Elevations gradually slope toward the north and south ends of the island (Olmsted 1958 in US Navy, 2008). Several steep, narrow canyons are located throughout SCI, with some over 500 feet (152 m) deep and drop sharply into the sea (SCS 1982 in US Navy, 2008).

The steep east-facing cliffs of the northeastern portion of the island are part of a continuous escarpment along the eastern side of the island, from Pyramid Head to Wilson Cove; there is also an isolated segment of the escarpment from Wilson Cove to Lighthouse Point (Dolphin Bay). Elevations of the eastern escarpment range from sea level to 1,965 feet (599 m) above mean sea level. The coastal and upland marine terraces dominate the western side of the island, as well as the northern and southern ends; the terraces are considered among the most well-defined examples of such features (Yatsko 1989 in US Navy, 2008).

5.2.1.19 Robert E. Badham

The ASBS is fronted by sandstone bluffs that slough rubble at their base. Several small drainages enter the beach zone in the northern portion of the ASBS forming marshy areas (SWRCB 1979). One of these drainages is Buck Gully.

5.2.1.20 Irvine Coast

The Abalone Point region is composed of a siltstone bench that is easily accessible from the adjacent beach only at times of low spring tides. The benchwork is part of a several hundred foot high cliff that also helps to limit access to the area. Just north of Abalone Point is a broad sand beach that stretches the entire length of the reserve. This sandy beach, over 3 miles (4.8 km) long, is interrupted by small rocky outcroppings only twice, at Reef Point and at a small rocky bight just south of Crystal Cove. Sandstone bluffs line the entire beach; erosion of these bluffs is particularly noticeable in the Scotchman's Cove region. The bluffs appear less eroded in the area around Pelican Point, where fossil-bearing rocks are found (SWRCB 1979).

5.2.1.21 La Jolla

The La Jolla ASBS is a small alluvial basin bounded on the south by the westward-trending sides of the Soledad Mountain, which reach the sea at Devil's Slide to Point La Jolla (commonly called Alligator Head). To the east and north, the basin is bordered by a high ridge that forms the cliffs north of SIO. The alluvial fill of this basin rests on a seaward sloping basement Eocene sandstone and shale with a thickness of 30 to 40 feet (10 to 12 m) (SWRCB 1979).

5.2.2 - Intertidal and Subtidal Topography and Substrate

The intertidal and subtidal geological setting provides habitat for benthic marine life. Different substrates (e.g., mud, sand, and various types of hard rock) and topographic features (e.g., slope, orientation, etc.) represent different habitats and therefore are inhabited by different biological communities.

5.2.2.1 Redwoods National Park

A variety of subtidal substrates exist within the ASBS. North of the Klamath River, substrates are composed of sands, gravels, and rocks ranging in size from boulders [5 feet (1.5 m) or greater in diameter] to giant sea stacks. South of the Klamath River, substrates appear to be composed mostly of sands and finer sediments (SWRCB 1981).

5.2.2.2 Trinidad Head

On the South Side of Trinidad Head, the substrate is rocky. Typical profiles include sheer rock faces from three to 14 meters deep. When surveyed in the late 1970s rock substrate was generally clean to about four meters deep; below that depth there was progressively more silt deposition to the bottom at about 14 meters deep. On the East Side of Trinidad Head, to about two meters deep, rocky substrates are generally either vertical or steeply inclined. Deeper than two meters, piles of boulders slope to the bottom between approximately three to six meters. On the East Side of Trinidad Rock, the bottom consists of well-worn boulders of low relief. Immediately east of Trinidad Rock, the area consists of irregular bedrock and boulders to a depth of about six meters. Obtrusive bedrock extends upward and often above datum. Patches of gravel also occur in the ASBS (SWRCB 1979).

5.2.2.3 King Range

The submarine topography off the coastline is complex and varied. Tidally emergent rocks are common within a quarter of a mile (400 m) of the shore, usually surrounded by coarse sand bottoms. The continental shelf (200 m depth) is apparently quite near the shoreline, within 4 to 5 miles (6.5 to 8.0 km), at several points. Three submarine canyons approach the shore along the coast: the Delgada Canyon just north of Point Delgada, the Spanish Canyon off Spanish Flat, and the Mattole Canyon just north of Punta Gorda.

Flat, shelf-like intertidal rock formations are absent along the coast except at two points. The first, about 1.1 miles (1.8 km) north of Punta Gorda, is a sedimentary (probably Franciscan) formation extending into the intertidal zone for approximately 40 yards (38 m) perpendicular to the sand beach. The second, at Point Delgada, is a well developed series of bench formations (clearly Franciscan) extending 80-90 yards (70-80 m) from the coastal bluffs to a drop-off into the subtidal zone. The intertidal rock formations at Point Delgada are extensive, with evidence of weathering by surge channels and wave action. Boulders 0.5-2 meters in diameter are scattered through the intertidal zone and have fine to medium grain sands around their bases. The stable substrate and modest protection from predominantly northwest waves have resulted in the establishment of a geologically amenable intertidal habitat (SWRCB 1979).

5.2.2.4 Jughandle Cove

Areas to 10 feet (3 m) deep within the small northern cove consist of boulders and interspersed sand. Beyond this depth, the bottom is bedrock, boulder, and some localized cobble and gravel patches. A series of offshore rocks extend northwesterly from the southern border of the cove. Their faces are roughly vertical and descend 10 to 35 feet (3 to 11 m) to the bottom (SWRCB 1981).

The headlands north of Jug Handle Creek Cove drop vertically, as an irregular and often overhanging wall, to about 15 feet (5 m) deep, where the bottom is dominated by large boulders and submerged pinnacles. The bottom of Jug Handle Creek Cove is filled with clean medium-grained sand, which continues offshore to beyond 60 feet (18 m) deep. Boulders emerge from the sand on the borders of the cove (SWRCB 1981).

A series of rocks extend northwestward from the southern border of Jug Handle Creek Cove. From 10 to 30 feet (3 to 9 m) emergent rocks rise from the sand to the surface. Further offshore, to 45 feet (14 m) deep, the series continues as isolated submerged rocks rising out of the sand (SWRCB 1981).

The extreme southern cove within the ASBS has a gently sloping bedrock and boulder bottom. Nearshore emergent rocks in the northerly portion of this cove are in places surrounded by sand and cobble bottoms. Bedrock dominates deeper areas within the cove and offshore the bottom is similar to that off the northern headlands (SWRCB 1981).

5.2.2.5 <u>Saunders Reef</u>

Rock samples obtained by SCUBA divers indicate Saunders Reef is part of the Gallaway Formation. The reef is actually a complex of low parallel ridges and outcrops from 1.5 to 39 feet (0.5 to 12 m) high. Some of these are exposed at low tide. The bottom between the ridges and outcrops is composed of rock, cobble, and coarse sand. Large ripple marks were found in this area indicating very high surge velocities (SWRCB 1980).

5.2.2.6 Gerstle Cove

The submarine topography within the ASBS is extremely irregular, probably owing to exposure of the coastline to wave action, and concomitant erosion of the shoreline. The hardness of the sedimentary rock is highly variable, resulting in differential erosion producing a wave-cut and indented coastline. Thus, large slump blocks and boulders are continually being supplied to the marine environment. Large to small boulders dominate most of the gently sloping subtidal terrain. Slump blocks, wash rocks, and emergent sea stacks also occur immediately offshore and constitute the only other topographic features in and adjacent to the ASBS (SWRCB 1979).

5.2.2.7 <u>Point Reyes Headlands</u>

The Point Reyes Headlands ASBS extends from the intertidal zone out to 2,000 feet (609 m). At the south face of this 2,000 foot line, the depth is about 100 feet (30 m). However, at the western boundary of the ASBS zone, the depth probably is greater than 150 feet (45 m), while at the eastern boundary, at the Chimney Rock area, the depth is less than 60 feet (18 m) (SWRCB 1980).

The submarine topography consists of large granitic boulders throughout the shallow water zones with large amounts of sand interspersed between the boulders. At the west end, almost directly below the lighthouse, is “The Wall" - a vertical granitic face which drops 60 feet (18 m) to the sloping sandy bottom at 85 feet (26 m) (SWRCB 1980).

In contrast to “The Wall" of the western side of the ASBS, the submarine topography at Chimney Rock consists of large boulders 3 to 8 feet (1 to 2.4 m) in diameter. Sand surrounds these boulders and gently slopes out to the 60-foot isobath line. Large, vertical intertidal sea caves are also located amidst the conglomerate rocks about 150 feet (45.7 m) east of the Lighthouse (SWRCB 1980).

Chimney Rock: At the east end of the ASBS is a large granitic sea stack with a single 50 foot (15 m) pinnacle that resembles an isolated chimney. This stack was a part of the main cliff during the past; erosion divided the section from the eastern promontory. Surrounding Chimney Rock are large boulders which make up the intertidal and subtidal configuration. Sand surrounds these granitic rocks and continues in a gentle slope out beyond the 60 foot (18 m) isobath. Since the refractory waves sweep around the Chimney Rock area, there is movement of sand throughout the year (SWRCB 1980).

Pelican Arch: This unique granitic rock is 30 feet (9 m) in height and is a sea arch that is a frequent habitat of the Brown Pelican, Pelecanus occidentalis. The birds often perch on the arch while resting from their feeding activities within the area (SWRCB 1980).

Saddle Cove: The cliffs between Chimney Rock and Saddle Cove are nearly vertical, rising from sea level to about 190 feet (58 m). A small beach at the base of a sloping grade illustrates much erosion (SWRCB 1980).

Split Rock: Massive granitic rocks which have split off from the south cliffs provide the name of this area as Split Rock Cove. The waters of this cove are much deeper than that of the major coves within these southern-facing cliffs. The 30 foot (9 m) isobath bends deeply into Split Rock Cove. The deep water enables large waves to come very close to the area which gives Boulder Beach a steep profile with rounded cobbles and boulders (SWRCB 1980).

Sea Lion Cove: Granitic rocks, large and small, are scattered throughout the area west of Split Rock Cove. The smooth surfaces of these rocks enable many sea lions to haul out in this area. Coarse sand surrounds these granitic stacks. Sea Lion Cove is the major area for the California Sea Lions. Two sandy beaches in Sea Lion Cove enable hundreds of these mammals to haul out (SWRCB 1980).

Sea Caves: The conglomerates of the Point Reyes Headlands ASBS extend from the highest point of the cliff at 612 feet (186 m) to the surf zone where the depth is 30 feet (9 m). The waves erode these conglomerates, etching out giant sea caves. Large conglomerate boulders and coarse sand make up the benthic substrate at the base of these cliffs, which are a favorite niche for the Common Murre, Uria aalge (SWRCB 1980).

“The Wall”: It is a 60 foot submarine cliff just below the Lighthouse at the western edge of the ASBS. The base of “The Wall" is 85 feet (26 m) below sea level with sand and rocks sloping out beyond 100 feet (30 m). This unique vertical wall is probably a result of faulting action of the Headland (SWRCB 1980).

Ideal diving conditions are almost impossible to realize as giant waves smash across this western promontory year-round. The underwater surge from the refractory wave trains is severe, preventing divers from maintaining a fixed position on the wall. Moreover, the water visibility is extremely poor, at best about 30 inches (76 cm), both from the sediments stirred up by the wave-surge and by the darkness of these depths (SWRCB 1980).

Murre Rock: Just west of the Lighthouse, outside of the ASBS boundary, are two large granitic sea-stacks, which are the main nesting sites for thousands of Common Murre, Uria aalge. These birds reside at the rock year-round (SWRCB 1980).

5.2.2.8 Duxbury Reef

Duxbury Reef is also the largest exposed shale reef in California. The bottom topography immediately offshore from the ASBS consists of eroded reef remnants interspersed with sand bottoms. Depth increases to 30 feet (9.1 m) about ½ mile (0.8 km) from shore and to 60 feet (18 m) at a distance of 1 mile (1.6 km). The bottom types in this outer area beyond the ASBS were not investigated, but probably consist of sand (SWRCB 1979).

Duxbury Reef's prominences extend up to 1 mile (1.6 km) out to sea at Duxbury Point, and from ¼ to ½ mile (0.4 to 0.8 km) from the high tide line in other areas. Wave action has carved channels and depressions in the rocks, but more resistant ridges have remained as high protrusions, resembling small islands. Most of these islands or prominences can be reached by foot at very low tides, but intervening channels are often deep and treacherous. Presumably, as the waves erode the outer reef rocks, new areas are continuously being exposed at the base of the cliffs. The reef, then, is slowly moving in a northeasterly direction as new rocks are exposed by wind erosion and old rocks are eroded down by waves. The rocks making up the reef itself contain calcium carbonate. Boring organisms, such as clams and worms, also contribute to the destruction of carbonate in the reef as do humans who chip away the rocks to extract the clams (SWRCB 1979).

5.2.2.9 James V. Fitzgerald

The overlying marine terrace deposits consist of weakly consolidated, slightly weathered sands and gravels of more recent origin. The reefs in the southern section are comprised of Pliocene shale or mudstone. These flat shale beds form a discontinuous rocky intertidal area.

The flat shale beds in the southern section of the ASBS form a discontinuous rocky intertidal area almost 3 miles (4.8 km) long. During low tides [below mean lower low water (MLLW)], much of the outer edge of the reefs, 500 to 1,000 feet (150 to 300 m) offshore, may be reached from shore. The reefs are broken up by numerous tidal channels with steep or overhanging sides, which run perpendicular to the shoreline, and by protected lagoons with rock/cobble bottoms, as at Seal Cove where a sand beach also occurs. Most of the reefs are fairly flat, but often exhibit greater relief toward the inner edge next to the cliffs. Tidepools of varying size and at varying tidal heights are abundant throughout the reefs. South of Frenchman's Reef and Whaleman Harbor, intertidal reefs are largely replaced by a wider sandy beach. Another extensive intertidal reef occurs south of Pillar Point. The southernmost edge of the Pillar Point Reef is marked by Sail Rock, which rises 32 feet (9.7 m) out of the water.

Approximately 1,000 feet (300 m) offshore to the south of Frenchman's Reef and 650 feet (200 m) southwest of the Pillar Point, there are extensive subtidal reefs adjacent to the intertidal reefs at depths of 20 to 35 feet (6 to 11 m). Due south from Sail Rock (on the Pillar Point Reef), the intertidal and subtidal reefs are continuous with one another at least for a distance of 250 feet (80 m) offshore. The subtidal reefs at Pillar Point occur as a series of urchin-pitted shelves extend into gradually deepening water. The reefs here, as at the dive site off Frenchman's Reef, exhibit great relief, rising as high as 10 to 15 feet (3 to 4.5 m) from the bottom. The reefs are frequently broken by narrow surge channels, which run roughly perpendicular to the shore.

Seaward of the exposed rock to the northwest of Frenchman's Reef, similar subtidal reefs and outcrops occur, which are of lower relief (5 to 10 feet or 1.5 to 3 m) than those south of Frenchman's Reef and the Pillar Point Reef. Large boulders protruding from the base of the reefs and outcrops are common. Away from the rock, the reef drops off to what appears to be the end of the reef system in that immediate vicinity. Approximately 300 feet (100 m) from the rocks is a broad, flat sandstone bottom at a depth of approximately 35 feet (11 m). Very little sand was present. The sandstone was devoid of macroscopic organisms.

About 300 feet (100 m) off the southern tip of Seal Cove, for at least 150 feet (50 m) to the north, the bottom consists of small reefs, large outcrops and associated boulders at an average depth of 20 feet (6 m). Large sandy areas were not encountered; increasing surge indicated the presence of shallower reefs to the north.

Further evidence of continuity between the intertidal and subtidal reef systems was indicated by the presence of broad 30 to 50 feet (10 to15 m) flat reefs about 1,000 feet. Moss Beach has similar flat reefs (350 m) offshore of Moss Beach. In this area, the subtidal reefs are at a depth of about 30 feet (9 m) and typically rise 3 to 7 feet (1 to 2 m) off the bottom.

Extensive subtidal reefs were not found in the northern end of the ASBS, though small reefs and rock outcrops appeared to be prevalent close to shore. Deeper water occurs closer to shore in the northern section of the ASBS than in the south. For the Reconnaisance Survey (SWRCB 1979), a dive was made approximately 1,300 feet (400 m) offshore of the Montara sewage outfall line, which existed at that time but has since ceased operation. At a depth reading of 70 feet (21 m), the bottom had not yet been reached, so the dive was terminated. Small reefs and outcrops were located at a depth of about 40 feet (12 m) around 500 feet (150 m) offshore. These were similar in size and relief [5 to 10 feet (2 to 3 m) high] to those found northwest of Frenchman's Reef. Similarly, large boulders were often found at the base of the outcrops. At this northern site, proportionately more of the bottom is comprised of wider sandy surge channels at the base of the rocky areas (SWRCB 1979).

5.2.2.10 Año Nuevo

The region of Año Nuevo Island to Año Nuevo Creek is characterized by very irregular bottom topography with shoals and stacks rising vertically from the ocean floor (Arnal et al., 1978 in SWRCB 1981). An average depth of approximately 29 feet (10 m) was found for the submarine plateau (SWRCB 1981).

Beach sediments are coarser in the winter than in the summer. Beach sediments found at Waddell Creek, Greyhound Rock, and Elliott Creek are coarser than those of the Año Nuevo area. Very coarse sediments are present only in the winter and are probably due to the high energy of the storm waves. Waddell Creek and Greyhound Rock receive the direct impact of wave energy, as the prevailing direction of waves is from the northwest and the Año Nuevo area has a southern shore exposure. For Point Año Nuevo, the coastal erosion due to wave energy from 1603 to 1970 was found to be 25,000 cubic yards/year (SWRCB 1981).

5.2.2.11 Pacific Grove

The ASBS is located in Monterey Bay, a wide-mouthed, deep bay which is bisected by an extensive submarine canyon. The canyon, as delineated by the 100-fathom curve, occupies 19% of the Bay's area. It drops off most steeply near shore and is 100 fathoms deep only 1½ miles (2.4 km) offshore. At the mouth of the Bay, the canyon is about 450 fathoms deep and 5 miles (8.0 km) wide (SWRCB 1979).

The canyon is aligned in a northeast-southwest direction, so at the mouth of the Bay the canyon is much closer to the southern headlands (4.1 miles, 6.5 km) than it is to Santa Cruz, at the north end of the bay. The south canyon wall is also steeper, dropping from 100 to 900 fathoms in 1½ miles (2.4 km) off Point Pinos (SWRCB 1979).

The ASBS lies within the southern "shallows" of the bay, a water area enclosed by the Monterey Peninsula on the west side. Within the ASBS, depth contours are more compressed than in the rest of the southern shallows. The 40 fathom curve is 1 mile (1.6 km) offshore at Pacific Grove, but 3 miles (4.8 km) offshore at Monterey (SWRCB 1979).

The subtidal topography of the ASBS consists of shallow water reefs, interspersed with fields of coarse-grained sand. Kelp beds generally mark the location of reefs during the summer. There are also numerous shallow submerged rocks in the ASBS near Point Pinos, Lucas Point (Aumentos Rock), Lovers Point, and Point Cabrillo (SWRCB 1979).

5.2.2.12 Carmel Bay

The submarine topography of the ASBS is dominated by the Carmel Canyon, a major tributary of the Monterey submarine canyon. The Monterey canyon, one of the largest in the world, originates just offshore from Moss Landing, and extends into the center of Monterey Bay. The Carmel Canyon originates about ¼ mile offshore from the mouth of San Jose Creek in the ASBS. It extends offshore in a westerly direction for about 3 miles (6 km), then turns abruptly and continues to the northwest for 12 miles (19 km) before joining the Monterey canyon. The Carmel Canyon drops off steeply, reaching a depth of 1,200 feet about 1 mile (200 fathoms, 1.6 km) offshore and a depth of 3,000 feet about 6 miles (500 fathoms, 9.7 km) offshore. The 120 foot (20 fathom) contour generally separates the canyon from shallower regions of the bay. In most locations, the 120 foot (20 fathom) curve is less than ½ mile offshore; the canyon widens quickly so that it includes most of southern Carmel Bay.

It is thought that fault lines determined the orientation of Carmel Canyon (Martin and Emery, 1967). The nearshore 3 mile portion of the canyon is aligned with the westward trending Carmel Valley fault; the offshore 12 mile portion is aligned with the northwesterly feeding Carmel Canyon fault (a seaward extension of the Sur and Palo Colorado faults) (Moritz, 1968 in SWRCB 1979).

5.2.2.13 Point Lobos

Vertical rocky walls are associated with coastal cliffs, promontories, offshore rocks, and submerged reefs with overhangs, crevices, and seams as additional features. Boulders ranging up to 10 feet (3 m) or more in diameter are common. Reefs occurred to at least 60 feet (18 m) deep and rose 30 feet (9 m) from the bottom. Reef tops are of low relief. Gravel and sand are found at all depths on horizontal surfaces, and play a role in scouring rock and, therefore, changing topography. No bathymetric information is available for the ASBS or surrounding areas (SWRCB 1979).

5.2.2.14 Julia Pfeiffer Burns

Vertical rocky walls are associated with coastal cliffs, promontories, overhangs, crevices, and seams offshore rocks and submerged reefs with as additional features. Boulders ranging up to 10 feet (3 m) or more in diameter are common. Reefs occurred to at least 60 feet (18 m) deep and rose 30 feet (9 m) from the bottom. Reef tops are of low relief. Gravel and sand are found at all depths on horizontal surfaces, and play a role in scouring rock and, therefore, changing topography (SWRCB 1979).

5.2.2.15 <u>Salmon Creek Coast</u>

A dive survey was recently conducted by Partnership for Interdisciplinary Studies of Coastal Oceans (PISCO) researchers at a location ½ mile (2.4 km) north of Salmon Creek. The subtidal habitat was characterized as gravel and small cobble at 60 feet (18 m) deep. There were also boulder fields and sand-filled channels (Carr et al., 2006).

5.2.2.16 Laguna Point to Latigo Point

The Laguna Point to Latigo Point ASBS extends from the intertidal zone seaward to the 100 foot contour line, except at the head of Mugu Canyon, where it includes depths of, at most, 125 feet (38.1 m). Except near the canyons, the bottom slopes off gently with a gradient of about 1.7% to 3% and consists primarily of medium to very fine, well sorted sand, especially below 60 feet (18.28 m) depths.

Nearshore areas, particularly between Bass Rock, just west of Deer Canyon, Lechuza Point, and between Point Dume and Latigo Point, have a variable relief where the sand is replaced by extensive rock reefs. These reefs show a high degree of variability, ranging from cobble fields on a sand base to towering and precipitous bedrock ridges and gigantic boulders up to 30 to 40 feet (9 to 12 m) in diameter. The soaring reefs and ridges between Bass Rock and Lechuza Point generally lie parallel to shore and consist primarily of an erosion resistant brecciated rock. The more inclined reefs between Point Dume and Latigo Point generally run perpendicular to or at an angle away from the shore and consist of a more erosive sandstone. A few small reefs of this latter type run parallel to shore off Zuma Beach. Point Dume itself is of a mixed igneous brecciated rock origin. Just off the point, a few sea stacks terminate in sand.

The generally gentle sand slope of the ASBS is interrupted at two locations by submarine canyons: Mugu Canyon to the west and Dume Canyon to the east. Both are steep walled canyons of very fine sand to mud. These canyons are primarily offshore from the ASBS. They begin at about 50 to 60 foot depths, 500 to 800 feet (154 to 244 m) offshore, and rapidly descend with a slope of 8 to 33%. In the deeper parts of both canyons (beyond the ASBS), poorly described rock outcrops apparently occur (Shepard and Dill, 1966 in SWRCB 1979).

Beyond the boundary of the ASBS, the ocean floor continues to slope off gradually as the continental shelf. Below a depth of about 300 feet (91.4 m) (ca. 2 to 3 miles offshore), the bottom drops off more steeply as the continental slope. The slope terminates in the enclosed Santa Monica Basin at a depth of about 1,500 feet (457 m).

There is a large submarine ridge about 5 miles offshore due south of La Jolla Beach, which projects out from the shelf. It rises to within 250 feet (76 m) of the surface.

There are two old artificial reefs within the ASBS. The one off Paradise Cove was installed by DFG in 1959. It is in 60 feet (18 m) of water, is composed of old autos, and covers an area of about one-tenth of an acre. This reef has largely deteriorated. The second reef, at about a 45 foot depth, is off the County Lifeguard Headquarters at Zuma Beach. It is small and composed of old toilets, bathtubs, etc. Both reefs are surrounded by sand (SWRCB 1979).

5.2.2.17 Santa Catalina Island

Northeast Santa Catalina Island: Sand and mud comprise the majority of the subtidal substrate from the outer boundary of the ASBS to within approximately 500 yards (457 m) offshore. Nearshore, the main subtidal substrates in the ASBS are boulder slopes and sandy slopes, with a few rocky reefs. Cliffs are rare.

In general, the subtidal area of the ASBS is rimmed with boulder slopes to a depth of 50 to 100 feet (30 m). Boulder size varies with depth. Shallow sloped areas often have a narrow band of medium-sized boulders (1 m diameter) interspersed with coarse sand closer to shore. Cactus Bay exemplifies this type of substrate. Larger boulders (4 - 8 m diameter), also interspersed with sand, are found from 10 to 50 foot (15 m) depths. With increased depth, the number and size of boulders decreases and the percentage of sand increases. In most areas surveyed, sand comprised nearly 100% of the substrate beyond 100 foot (30 m) depths.

Sandy substrate is rare in water shallower than 40 feet (12 m) between Catalina Head and Arrow Point, with the exception of Starlight Beach and Parson's Landing. However, from Arrow Point to Blue Cavern Point there are many coves, such as Emerald Bay, Howland's Landing, and Isthmus Cove, with sandy subtidal substrate. These coves are enclosed by rock outcroppings and boulders extending to a depth of approximately 40 feet (12 m).

There are three types of nearshore sediments: (1) Lithic sediment composed of rock particles; (2) organic sediment composed of biological fragments such as shells and sea urchin tests; and (3) calcareous sediment composed of $CaCO_3$ primarily from coralline algae.

Areas with heavy runoff, such as Parson's Landing and Cactus Bay, have lithic sediments, usually grading from coarse to fine sands as depth increases. Catalina Head and West End areas, which have large populations of mollusks and relatively heavy wave action, have organic sediments. Sediments found in some of the coves from Emerald Bay to Big Fisherman Cove contain a large percentage of calcareous debris.

The intertidal area of the ASBS is not extensive. The shoreline is extremely rugged, with the main landmass rising steeply out of the ocean. Consequently, intertidal habitats are quite restricted in vertical range. The southwest (windward) side of the island is exposed to wave action and, in certain areas, minimal intertidal areas exist (e.g., Catalina Head). However, the leeward side does not benefit from wave activity, and the combination of steep slopes and low wave action results in poor intertidal habitats. Relatively good intertidal habitat, characterized by gently sloping solid substrate, can be found only at Ship Rock, Bird Rock, and Big Fisherman Cove Point.

Approximately 40% of the ASBS intertidal area consists of solid rock walls, and about 45% consists of various-sized boulders. The majority of these habitats are extremely steep in profile. The remaining 15% of the intertidal area consists of sandy or cobble beaches. Virtually no beaches exist from Catalina Head to the West End, with the exception of Sandy Beach. Between Catalina Head and Arrow Point boulders occupy most of the intertidal habitat. Many small coves and sandy beaches occur along the northeast (leeward) coast from Arrow Point to Blue Cavern Point, although cliffs and boulder areas predominate in this region as well (SWRCB 1979).

Western Santa Catalina Island: Intertidal geomorphology ranges from fine sand beaches to bedrock outcrops often forming boulder aprons. About 20% of the beaches are sandy and 80% are rocky. Little Harbor is the most protected from wave action and therefore the sandy beach has a slightly higher organic content. The nearshore substrate ranges from sandy areas offshore sandy beaches to high relief boulder fields near rocky headlands. Approximately 55 % of the nearshore subtidal substrate is sandy bottom. Grain size in these soft bottom areas decreases with depth, with muddy bottom in some areas on the shelf. Large exposed offshore rocks structures are located off of Ben Weston Point, the rocky headlands between Shark Cove and Beach, and between Beach and Ben Weston Beach (Sentinel Rocks) (SWRCB 1981).

Southeast Santa Catalina Island: The ASBS is fully exposed to south swell and steep, rocky cliffs limit the extent of the intertidal area. Binnancle and Church Rock are the most exposed; Jewfish Point is somewhat protected. About 60% of the intertidal zone is rocky substrate.

In the western portion of the ASBS about 80% of the subtidal habitat is composed of sandy sediment, but the subtidal substrate near headlands are characterized by exposed bedrock, sometimes with pockets of sand. Boulders are also common in the nearshore subtidal. Rocky bottom becomes less common with increased depth and distance from the shore. Sediments grain size in soft bottom areas decreases with depth, with muddy bottom in some areas on the shelf.

In the eastern portion of the ASBS a shallow, flat shelf extends from the shore to a depth of about 15 feet (4.5 m). The shelf is composed entirely of gravel and cobble. Beyond the shelf, the substrate slopes sharply into deeper water.

The intertidal area of the eastern portion of the ASBS has been highly modified by the quarry operations there. Most of the intertidal zone there consists of large boulders, and smaller areas have gravel or small boulders as intertidal substrate. Subtidally within the quarry area the substrate has been modified by quarry operations as well. Occasionally, boulders are dislodged by waves and are deposited subtidally, and the quarry operators replace these boulders in the intertidal zone. In addition small amounts of rock debris is lost to the subtidal zone during barge loading operations (SWRCB 1981).

5.2.2.18 La Jolla

The general submarine topography in the La Jolla Basin area can be described as a narrow (about 2 miles; 3.2 km) continental shelf, traversed submarine canyon that approaches to within about 300 m of the shore. The canyon empties into the broad San Diego Trough, which is a part of the irregular submarine region of deep basins and intervening ridge termed the Continental Borderland.

The substrate in the northern half of the Reserve is fine sand mixed with varying amounts of silt and/or mud. Surveys on sandy substrates, both on the northern sand shelf and inshore of the head of Jolla Canyon, describe this sand as fine and white, interspersed with occasional patches of mud. Presumably, this mud is derived from storm water runoff. The mud is never so abundant that the sand appears a thing other than clean, white sand on superficial glance. The fine sand is well sorted, with median grain diameters of: 0.20 mm in samples from the beach; 0.12 mm in samples from 5 to 10 meters depth; and 0.09 mm in samples from 30 meters depth. The sand grains are fairly uniform in size, with 90% of the 5 to 10 meter samples in the 0.08 to 0.19 mm size. The sand is mainly quartz, although 5% is heavy minerals, 3% micaceous materials, and less than 3% silt (Fager, 1968). According to Fager, this silt/mud content from storm water runoff is insignificant, but this area was close to the end of the SIO pier. The silt/mud concentration or deposition is probably considerably 9 as one moves southward, approaching the offshore area of the largest storm drain located at the foot of Avenida de la Playa.

The sandy bottom in the northern third of the Reserve slopes evenly and gently seaward down to depths of 100 feet (30 m) at a distance 1200 to 1300 feet (365 to 396

m) from shore. The slope steepens somewhat so that depths of 400 to 500 feet (122 to 152 m) are reached in the next 500 meters. This broad sandy shelf is bordered on the north and south by the two branches of the La Jolla branch of the La Jolla Submarine Canyon. The shore-most 300 meters consists of a fine, white sandy substrate that is similar to the sandy shelf immediately north. At a depth of ca. 30 feet (9 m), however, the slope steepens noticeably and there is a 4 to 5 feet (1 to 2 m) clay bank that distinguishes the canyon at a depth of 50 feet (15 m). The canyon head itself is characterized as a wide bowl-like structure, rimmed by a basement of Eocene sandstone/shale. The sides are extremely steep (nearly vertical) in some areas, whereas other areas have a gradual sloping side. There are occasional small rock outcroppings, but these are rare and this branch of the canyon is much less spectacular in its steepness and undercut ledges than the head of the more northern SIO branch. The biota reflects the difference between the physical structures of these two heads.

The southern third of the ASBS is much more diverse in substrate than the others. The area immediately inshore of the southern wall of the canyon is sandy, at least to depths of 35 feet (10 m). Flat sandstone ledges are exposed in much of the Devil’s Slide corner of the Ecological Reserve, extending as far northward as the southern end of the La Jolla Beach and Tennis Club. These ledges are found from shore to depths of at least 25 to 30 feet (7.5 to 9 m). In the subtidal areas offshore from the westward-facing section of shoreline, these flat ledges are a reflection of the intertidal and cliff strata, being tipped up some 20 to 30° northward. This allows for undercutting along the northern ledges of these reefs, and it is along these northern, undercut ledges of the larger reef formations that many of the marine animals concentrate. Offshore from the northward-facing shoreline, this pronounced tipping becomes less and less distinguishable, especially with the shallow substrate along this section of the shoreline. At depths between 20 and 35 feet, there is a series of more or less parallel ridges made up of mudstone boulders. These ridges point shoreward toward the corner between Devil's Slide and La Jolla Caves and trend seaward on a northwesterly direction where they cross the Ecological Reserve boundary depths of 35-50 feet (10-15 m).

There is a small deposit of cobbles offshore from the La Jolla Beach and Tennis Club that becomes exposed during the winter months some years after a period of heavy surf; this patch extends for about 100 meters along a front parallel to the shoreline and at depths of 40 feet (3 to 12 m) (SWRCB 1979).

5.2.2.19 <u>San Nicolas Island</u>

SNI is farthest offshore and is more exposed to open ocean conditions than any of the Channel Islands. Its orientation with respect to the prevailing swell patterns create exposure to more severe sea states and wave conditions along both sides of the island. There are few coves and wave protected areas on San Nicolas Island (MLPA SAT

2009). Little else is known by staff about the subtidal and intertidal geology at San Nicolas Island, except that the presence of rocky intertidal and kelp forest communities (see biological baseline section) indicate the presence of rocky substrate.

5.2.2.20 San Clemente Island

The bathymetry surrounding SCI is irregular in shape, with Catalina Basin to the east and San Nicolas Basin to the west. A narrow island shelf extending to a depth of about 330 ft (100 m) surrounds SCI, extending from 0.3 to 3 nm (0.5 to 5.5 km) from the island's coast. Offshore relief east of SCI is extreme due to San Clemente Escarpment, leveling off at a depth of about 3,280 ft (1,000 m) below Mean Sea Level (MSL) in Catalina Basin. Offshore relief south and west of SCI is more gradual, though depths reach a maximum of about 5,900 ft (1,800 m) in San Nicolas Basin (CDMG 1986 in US Navy 2008).

The eastern shoreline of SCI is protected from most prevailing swell patterns and generally receives little wave exposure. This "lee" effect results in the structuring of species assemblages and relatively warm-water, wave-protected communities. The western or windward side of SCI includes substantial bedrock, has a more gradual slope, and receives more wave exposure compared to any other site in its bioregion (MLPA SAT 2009). Little else is known by staff about the subtidal and intertidal geology at SCI, except that the presence of rocky intertidal and kelp forest communities (see biological baseline section) indicate the presence of rocky substrate.

5.3. METEOROLOGICAL AND OCEANOGRAPHIC CONDITIONS

5.3.1 - Climate

Climactic conditions influence ASBS habitat conditions. For example, precipitation is the major factor influencing runoff quantities, and air temperature can influence intertidal life.

5.3.1.1 Northern Coast ASBS

The northern California climate is characterized by a mild maritime climate. In the summer months, a region of high pressure lies off the coast, generating the prevailing northwesterly winds and coastal fog. In winter, this high pressure zone moves southward and is replaced by a low pressure zone off the coast. Storms are common in the fall and winter. Cool, moist air masses move toward the coast during winter months and on contacting the coastal hills, are uplifted, cool, and drop their moisture as rain. The highest average monthly temperatures occur in late summer and fall, and the lowest in December and January. During the day, cool ocean air moves onshore as air heated over the land rises; at night, air tends to move from the cooler land masses toward the warmer ocean. In general, the seaward night flow is best developed in

January (winter months) and least developed in July (summer). This seaward night flow is primarily from the northeast and flows down the canyon slopes to the ocean (SWRCB 1979) (Felton 1965, cited in SWRCB 1980).

5.3.1.2 <u>ASBS at Point Reyes Peninsula and Near the Entrance to San Francisco Bay</u>

The area of the Point Reyes Peninsula and the entrance to San Francisco Bay are characterized by cool, dry, foggy summers and cool, rainy winters. This coastal climate keeps summer temperatures well below those found a few miles inland. The Pacific Ocean tends to reduce the seasonal temperature range. Wind patterns reflect seasons. During winter storms, winds originate from the south, while high pressure systems generally bring brisk northwesterly winds in the spring and summer. Offshore breezes are warmer (SWRCB 1979).

5.3.1.3 <u>Central California ASBS</u>

In general, the climate of the central California coast is characterized throughout the year as having moderate temperatures controlled by the circulation patterns of the North Pacific Ocean (SWRCB 1981). Wind direction varies seasonally with the location of the Pacific High pressure cell. When this cell is centered over the North Pacific, generally between April and September, the coast catches the eastern edge of the gyre, and prevailing winds are from the northwest. These winds are deflected down the coast by the coastal mountain ranges. Upwelling begins and the cooler water brought to the surface creates a cold zone near the coast. The interior valleys begin to heat up and the rising air creates a thermal low pressure area that draws cold air in from the ocean. Water vapor then condenses to produce the fog and low cloud-cover. In the late summer and early fall, the Pacific high-pressure system moves offshore and the interior valleys cool down (SWRCB 1979).

5.3.1.4 <u>Southern California Bight ASBS</u>

Southern California is characterized by a Mediterranean climate with mild temperatures and seasonal winter rainfall. Weather in this area is largely controlled by the Eastern Pacific high, which is located off the coast of Northern California during the spring and summer months; this high pressure cell prevents low pressure systems from moving down the coast into southern California. The summers are warm and without precipitation but moderated by prevailing westerly winds from the ocean and typical summer coastal fogs (SWRCB 1979).

5.3.2 - Oceanographic Conditions

The physical and chemical oceanography in each coastal region represents the habitat that determines the type and abundance of marine life in ASBS. The following information is intended to provide a generalized description of oceanographic conditions that influence ASBS along the California coast.

Seasonal changes in wind direction commonly create seasonal patterns for the currents off of the California Coastline. For much of the year, the California Current brings colder northern waters southward along the shore as far as southern California (MLPA 2006). The California current is the eastern leg of the North Pacific Gyre, a massive, clockwise-moving current system which encompasses the entire North Pacific Ocean (SWRCB 1979). The California Current is a wide, slow moving southeastward flow between 48°N and a southern limit of 23°N. The western limit of the California Current is the boundary region between sub arctic water and eastern north Pacific central water, which at 32°N is about 434.9 miles (700 km) from the coast. The western edge is often set at 621.4 miles (1,000 km) offshore. The majority of the water movement to the south occurs between 124.3 and 310.7 miles (200 and 500 km) offshore, maximum water speeds are shallower than 0.12 miles (200 m). The upper waters of the transition area are more influenced by sub arctic water than the waters below 0.06 miles (100 m) (Allen et al. 2006).

The flow off of the northern California coast is strongest nearshore during the spring and early summer and offshore during the late summer and early fall (Allen et al 2006). Most of the California coast north of Point Conception is dominated by the southward flowing California Current (SWRCB 1980).

The seasonal presence of the California Current corresponds with that of the Pacific high-pressure cell, which is responsible for prevailing northwest winds that blow of the north and central coast. Beginning in March, as the California Current travels south along the coast, surface waters are driven to the right, or offshore, by the combination of northwesterly winds and the Coriolis force. This triggers the upwelling of cold, nutrient-rich water from the depths along the coast, causing this oceanographic season to be termed the Upwelling Period. By September, as the northwesterly winds die down, upwelling ceases and warmer waters return to the coast making way for the Oceanic Period (SWRCB 1979).

The Oceanic Period lasts into October, when the predominant winds move to the southwesterly direction. Close to shore, the California Undercurrent carries equatorial water northward along the Baja California and California coasts beneath the California Current, at depths greater than 655 feet (200 m) (SWRCB 1979). North of Point

Conception in late fall and winter, its core gradually rises from 200-300m to the surface and becomes known as the Davidson Current (MLPA 2006). This current reverses direction intermittently even in surface waters during the winter (SWRCB 1979), and may be continuous with the California countercurrent during this period (Allen et al 2006). It carries equatorial Pacific water of higher salinity and temperature than generally exists at this latitude, and has an important moderating effect on winter ocean temperatures (SWRCB 1979).

The Southern California Bight is the 300 km of recessed coastline between Point Conception in Santa Barbara County and Cabo Colnett, south of Ensenada, Mexico. The dramatic change in the angle of the mainland coastline creates a large backwater eddy in which equatorial waters flow north near shore and subartic waters flow south offshore. This unique oceanographic circulation pattern creates a biological transition zone between warm and cold waters that contains approximately 500 marine fish species and more than 5,000 invertebrate species (SWRCB 1979).

The water transport in the Southern California Bight is influenced by the California Current and the Southern California Counter Current (SWRCB 1980). The prevailing direction of swell in the California Bight is from the west (SWRCB 1979). The California Current flows southward along the coast (Michaels 2005). The California Current is generally located at the surface over the seaward slope, well outside of San Clemente Island and several hundred kilometers offshore of the mainland; it flows toward the equator. Within the Bight a large scale eddy effect takes place and surface water is transported poleward by the Southern California Counter Current. The Southern California Countercurrent occurs in the upper half of the Southern California Bight throughout the year except during April. It occurs in the southern half of the Bight from April to December. Around Point Conception, the Southern California Countercurrent meets with the California Current, creating a rich transition zone. Counterflow north of Point Conception occurs during the fall and winter months (Allen et al 2006). Closer to shore, the current over the coastal shelf, in depths up to 60 meters, flows toward the equator (Dailey et al 1993). In very shallow water adjacent to the surf zone, the longshore current has a net southward flow and deposits sand into the heads of submarine canyons (SWRCB 1980). Upwelling also takes place in the Southern California Bight, in which nutrient rich bottom water rises to the surface.

When the California Current reaches Point Conception, it continues south well off the coast of the Southern California Bight and even beyond the outer islands. However, some of the California Current is diverted eastward at San Miguel Island. This water flows along the north coast of the northern Channel Islands and then splits into three parts and becomes the Southern California Countercurrent. One segment continues eastward along the northern Channel Islands and escapes into the Santa Monica Basin off Anacapa Island. Another segment moves northward across the channel at about the latitude of Santa Barbara. As it nears the coast, it divides into the other two parts: a westerly flowing current along the coast from Santa Barbara to Point Conception (thus forming a counterclockwise gyre in the Western Santa Barbara Basin) and an easterly flowing and weaker portion of the current moves along the coast from Santa Barbara to Port Hueneme, where it also enters the Santa Monica Basin. The eastern arm of the Southern California Countercurrent forms a counterclockwise gyre in Santa Monica Bay, which flows northerly and then westerly along the Malibu Coast from El Segundo all the way to Point Dume; here it rejoins the offshore eastward flowing current. The combined water mass moves primarily southward off the coast from Santa Monica Bay to well beyond the Mexican Border, where it finally rejoins the California Current (SWRCB 1979).

Laid over this general pattern throughout California are both short-term and long-term changes. Local winds, topography, tidal motions, and discharge from rivers create their own currents in nearshore waters. Less frequently, a massive change in atmospheric pressure floods the eastern Pacific with warm water, which suppresses the normal pattern of upwelling. These short-term climatic changes, called El Niño, reduce the productivity of coastal waters, causing some fisheries and seabird and marine mammal populations to decline and others to increase. For instance, warm waters that flow north in an El Niño carry the larva of California sheephead and lobster from the heart of their geographical range in Mexico into the waters off California (MLPA 2006).

Other oceanographic changes last for a decade or more and these natural fluctuations can have significant impacts on the health and composition of marine life. In these regime shifts, water temperatures rise or fall significantly, causing dramatic changes in the distribution and abundance of marine life. The collapse of the California sardine fishery occurred when heavy commercial fishing pressure on sardine populations coincided with population reductions in response to cooling of offshore waters in the late 1940s and early 1950s. In response to the decline in sardines, California law severely curtailed the catch. In 1977, waters off California began warming and remained relatively warm. The warmer water temperatures were favorable for sardines, whose abundance greatly increased. But the warmer waters also reduced the productivity of other fish, including many rockfishes, lingcod, sablefish, and those flatfishes that favor cold water for successful reproduction (MLPA 2007).

Currents and other bodies of water may differ dramatically in temperature and chemistry, as well as speed and direction. These factors all influence the kinds of marine life found in different bodies of water. In general terms, geography, oceanography, and biology combine to divide California marine fisheries and other marine life into two major regions north and south of Point Conception. Within each region, other differences emerge (MLPA 2007).

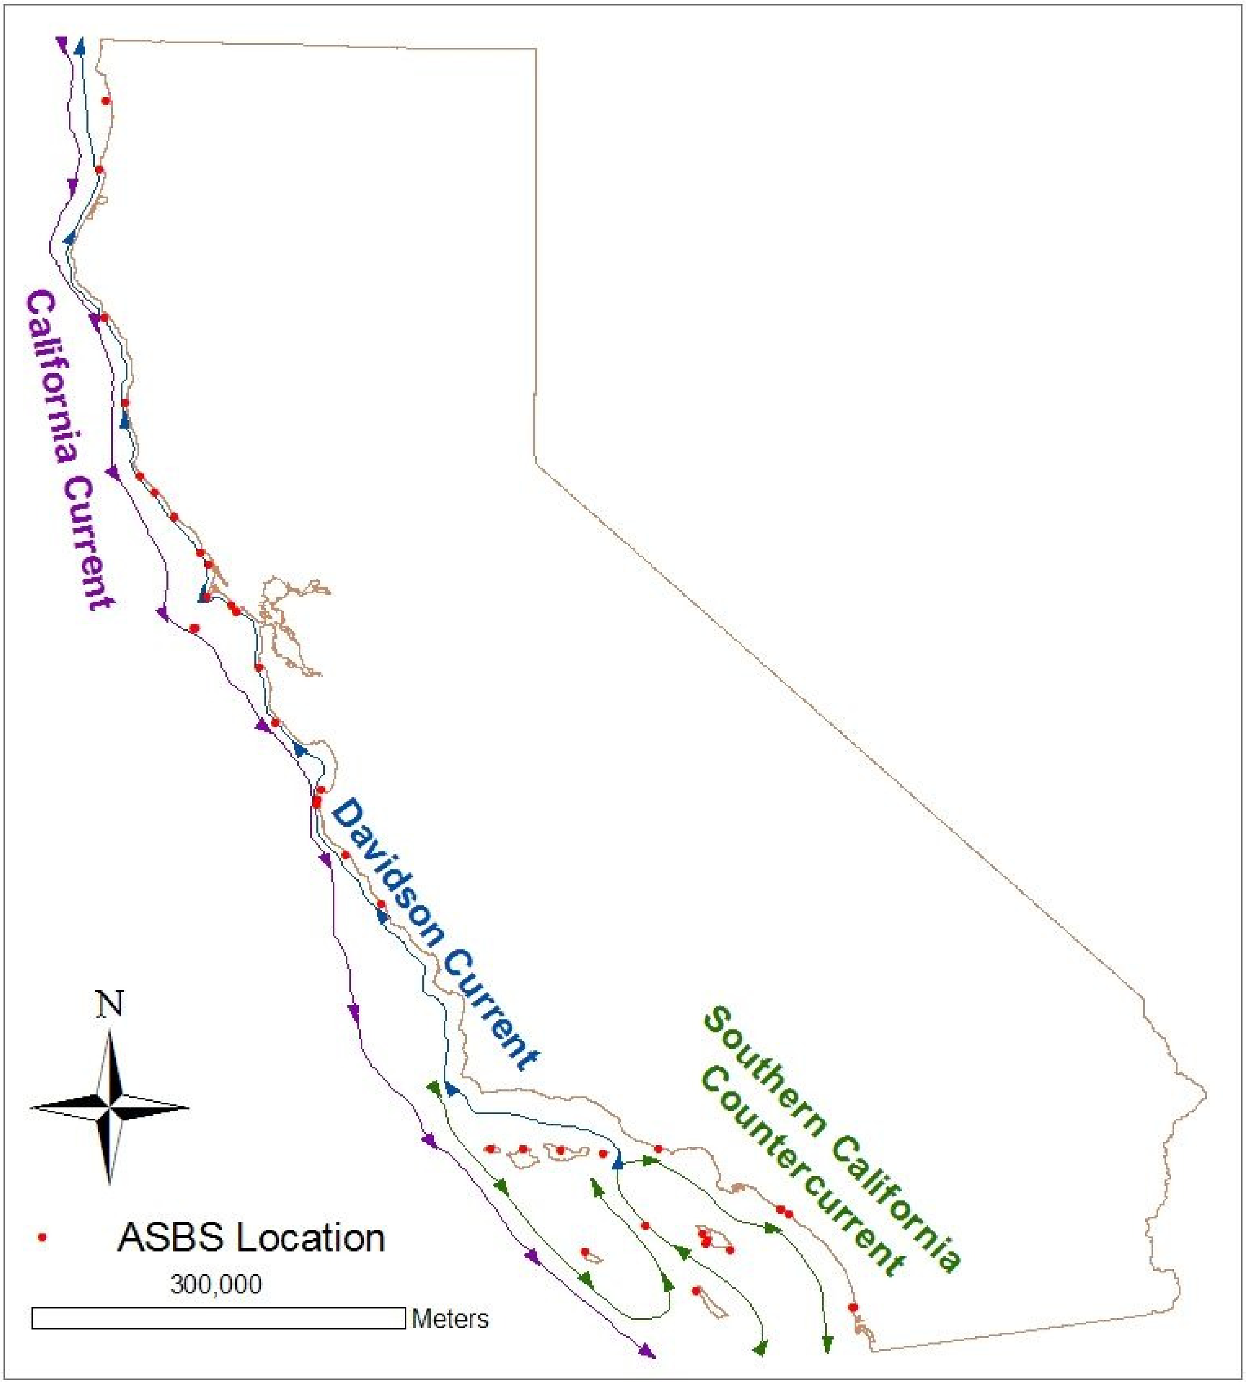

Figure 1. Generalized Major Surface Currents in California Coastal Waters.

5.4. WATERSHED AND LAND USE CHARACTERIZATIONS

State Water Board staff analyzed watersheds adjacent to ASBS for impermeability (impervious surfaces) based on land use data [Calwater 2.2]. The results are presented in Table 5.4.1. Impervious surface greater than 50% was found in watersheds draining to the Pacific Grove, La Jolla, Robert E. Badham, and Irvine Coast ASBS.

Table 5.4.1. Percent Impervious Surfaces adjacent to ASBS

ASBS Name	%
Redwoods National Park	7.61
Trinidad Head	8.55
Kings Range	2.46
Jughandle Cove	28.04
Saunders Reef	10.59
Del Mar Landing	29.69
Gerstle Cove	8.69
Point Reyes Headlands	4.03
Duxbury Reef	5.37
James V. Fitzgerald	24.73
Año Nuevo	4.86
Pacific Grove	64.52
Carmel Bay	25.57
Point Lobos	11.05
Julia Pfeiffer Burns	5.62
Salmon Creek Coast	4.77
Laguna Point to Latigo Point	18.05
North West Santa Catalina Island	4.05
Southeast Santa Catalina Island	4.05
Robert E. Badham	72.50
Irvine Coast	53.73
Heisler Park	28.19
La Jolla	91.64
San Nicholas Island and Begg Rock	6.24
San Clemente Island	5.15

Specific watershed land uses and conditions adjacent to ASBS are as follows:

5.4.1 - Redwoods National Park

Most of the land adjacent to this ASBS is occupied by Redwoods National Park and is jointly managed by the National Park Service and the California State Parks. Rugged cliffs and sparse primitive campgrounds are the primary land use, in addition to limited recreation hiking trails. There are 27 streams emptying into this ASBS mostly carrying runoff from rural and wilderness watersheds. The Klamath River and Redwood Creek are impaired by NPS pollutants attributable mainly to agricultural, timber harvesting, and urban land uses. This watershed is also impacted by hydro modification and removal of riparian vegetation.

Caltrans classified and mapped the land use and summarized population density within ASBS tributary drainage areas (TAS). Sixty-nine point nine percent (69.9%) of the TAS is open space-public land, 17.5% is agricultural land, and 7.8% is very low density-residential. The remaining land use type is less than 2% each of medium and low density-residential, water, and urban reserve. Population density in the TAS is less than 100 people per squared mile.

5.4.2 - Trinidad Head

This watershed encompasses both urban and rural watersheds. Trinidad Bay has marina facilities including mooring field, vessel haulout, maintenance facilities, and commercial crabbing/fishing pier facilities. Bleach and other detergents are known to still be in use by boat owners within the ASBS mooring field. The City of Trinidad's main storm drain discharges directly into the ASBS. Sources of other NPS pollutants arise from vehicle and boat parking directly on the beach, and runoff originating from the adjacent asphalt parking lot. Humboldt State University Marine Lab is located near the headlands. Residences and commercial structures in Trinidad are served by septic systems. Timber harvesting is also a major land use in the watershed and may contribute sediment and related silviculture chemicals.

5.4.3 - King Range

The northern part of this watershed is mostly wilderness managed by the Bureau of Land Management. The town of Shelter Cove is in the southern part of this ASBS on approximately 2 miles (3.2 km) of developed coastline, including houses, businesses, a golf course, a paved airstrip and parking lots along the shore. There is also a fish cleaning station and boat launch. Shelter Cove is primarily residential, with some commercial development to support the local tourism industry. Immediately north of the ASBS is the mouth of the Mattole River, which is impaired by sediment and temperature resulting from livestock agriculture, timber harvesting, and urban land uses.

5.4.4 - Jughandle Cove

The watershed of the Jughandle Cove ASBS is the California State Parks Jug Handle State Reserve. This largely natural watershed, located about 5 miles (8.04 km) south of Fort Bragg, is natural open space and undeveloped. The primary use is dedicated to the Ecological Staircase hiking trail, with a visitor parking area adjacent to Highway 1. The watershed includes Highway 1, which crossed over Jughandle Creek approximately 100 meters upstream of the ASBS. Jughandle Creek may be a source of sediment load in the winter, due to past logging operations. Homes in the area have septic systems, and there is also a lumber mill that may contribute pollutants to the watershed. With the exception of NPS runoff from the Reserve's parking lot and associated access trail, there are no other potential sources of pollutants known to drain directly into the ASBS.

5.4.5 - Saunders Reef

The watershed of this ASBS has about 1.6 miles (2.57 km) of coastline that runs parallel to Highway 1 along a fairly rural part of Northern California. A residential area is located inland of the southern end of the ASBS, directly adjacent to the southern boundary point. These homes are served by septic tanks, and due to the soil conditions, drainage from these septic tanks may escape into this ASBS. There are also two parking lot turnouts with the boundaries of the Saunders Reef ASBS coastline.

Caltrans classified and mapped the land use and summarized population density within ASBS TAS. Fifty-seven point seven percent (57.7%) of the TAS is open space-public land and 41.5% is low density-residential. The remaining land use is undetermined. Population density in most of the TAS is less than 100 people per squared mile.

5.4.6 - Del Mar Landing

The watershed immediately adjacent to this ASBS is a part of the Sea Ranch private community, which has residential development, storm drains, and walking trails along the coastline. The watershed includes Highway 1, which is less than ½ mile from the coast. With the exception of four nonpoint source and storm water conveyances, there are no other sources of pollutants known to drain directly into the ASBS; however, eight ephemeral streams draining into or near the ASBS potentially carry pollutants from upstream sources. Homes in the project study area are serviced by a sanitary wastewater treatment system. A golf course is located approximately ½ mile north of the ASBS.

At The Sea Ranch Association (TSRA), nearly 60% of land use is common area, of which the primary use is open space dedicated to the preservation of the natural environment. A small percentage of commons at TSRA is used for roads, recreation facilities, and community facilities. Remaining land use consists of residential and commercial areas. The County of Sonoma limits lot coverage (building footprint) to no more than 35% of the lot area. As a result, impervious surfaces are reduced by lot coverage limitations and by paving restrictions of TSRA's design review body. Of the 58 lots in the study area, most have gravel drives and only a few have paved drive surfaces.

5.4.7 - Gerstle Cove

The watershed of Gerstle Cove ASBS is primarily State Parks recreational open space, with Highway One located in the watershed as well. State Parks facilities include a public restroom, fish cleaning station, campground, roads, multiple parking lots, and a visitor's center. There are six ephemeral watercourses and seven groundwater seeps along the coast.

5.4.8 - Point Reyes Headlands and Duxbury Reef

The surrounding land mass of the Duxbury Reef ASBS has at least 8,320 acres (33,669,845 m^2) of drainage leading into several streams. During storm events, it is common to see small waterfalls in the Bolinas Point area, flowing directly into tide pools on the reef. At various points along the ASBS, groundwater is observed seeping from the cliffs into the beaches or over the rocks.

The largest Bolinas Mesa drainage network includes Alder Creek and several tributary drainages to the north and south. Storm water runoff flows overland or through groundwater seepage within a system of roadside ditches and culverts to the major drainages on the Mesa. The majority of the land use draining to the discharge point and into Alder Creek is single family residential served by septic systems; however, there are several agricultural operations (commercial gardens); a variety of commercial sole proprietorships (Dentist offices, massage offices, etc.); and certain ranching/livestock operations—most notably a small portion of Niman Ranch (cattle) and the Vanishing Point Ranch (horses). Due to the rural nature of the area, many Bolinas Mesa residents have chickens, goats, horses, and/or other livestock property.

Approximately 250 developed properties drain into the Alder Creek watershed. An estimated 79% of the roads within the Alder Creek watershed are unpaved and are not maintained by Marin County. The remaining 21% of roads are County maintained, paved roads. The area of land that drains to Alder Creek is 275 acres (1.11 km^2).

5.4.9 - James V. Fitzgerald

This watershed encompasses an array of land uses such as residential, rural residential including horse properties, and agricultural. The beaches are well visited by the public. Half Moon Bay Airport is directly east of the ASBS and Pillar Point Harbor marina is located immediately south of the ASBS. San Vicente Creek drains a developed portion of the watershed directly to the ASBS and is chronically contaminated with coliform bacteria and is 303d listed.

Caltrans classified and mapped the land use and summarized population density within ASBS TAS. Seventy-two point six percent (72.6%) of the TAS is low density-residential, 17.8% is medium density-residential, 8.7% is agricultural, and 0.8% is industrial. Population density varies from 100 to 5,000 people per squared mile.

Pillar Point Air Force Station (AFS) occupies the land at the southern end of the ASBS. There are about 10-15 site personnel employed there. The storm water runoff discharge into the ASBS originates from Pillar Point AFS tracking station on the bluff. Storm water runoff at Pillar Point AFS either infiltrates into site soils, sheet flows over the cliff side into the ocean, or is channeled off-site through engineered drainages. Storm water runoff from the developed areas, approximately 8.3 acres (33,589 m^2) of Pillar Point AFS, collects in a small concrete drainage channel adjacent to the circular facility perimeter road and is directed towards a sump near the guardhouse. Runoff is then discharged to the north through a culvert and subsequently conveyed through an engineered concrete drainage channel down the cliff face to the beach below. The watershed draining to the ASBS is composed of approximately 36% impervious surface (includes pavement and building coverage) and the remaining 64% is composed of vegetated hillsides. The land use is primarily characterized by open space, as well as administrative and industrial land uses.

County of San Mateo properties north of Pillar Point AFS within the Fitzgerald ASBS watershed are approximately 4.5 square miles (11.65 km^2) and are located in unincorporated San Mateo County. The dominant land uses are residential, park/open space, ranching and equestrian facilities, a sewage pumping facility, small-scale agriculture, and light commercial/industrial. Three residential communities are located in the watershed; Montara, Moss Beach, and Seal Cove. The community of El Granada is also located in the southern end of the ASBS and drainage from the area flows to Pillar Point Harbor, discharging at a point located just outside of the ASBS boundary.

As of 2000, the combined population of Montara and Moss Beach was less than 5,000. The Half Moon Bay Municipal Airport majority of storm water runoff from this facility flows to the Pillar Point Harbor, which is located outside of the ASBS boundary.

5.4.10 - Año Nuevo

The watershed adjacent to the Año Nuevo ASBS is the Año Nuevo State Preserve, managed by California State Parks. Access to beaches is limited and most visitors to the park are confined to marked footpaths, and trail bypasses are sources of erosion and downstream sedimentation. There are 17 natural streams or gullies that drain into the ASBS; the most significant are from the rural watersheds of Año Nuevo Creek to the south, and Cascade Creek to the north. Highway 1 is also a source of road runoff, and is located in those watersheds. Farming (primarily artichokes, brussel sprouts, and flowers) is conducted adjacent to and within the reserve boundaries. There are direct nonpoint source discharges into the ASBS from those agricultural fields, and agricultural discharges may influence the streams as well.

Caltrans classified and mapped the land use and summarized population density within ASBS TAS. Sixty point nine percent (60.9%) of the TAS is low density-residential, 24.4% is open space-public lands, and 14.5% is agricultural. Population density in the TAS is less than 100 people per squared mile.

5.4.11 - Pacific Grove

Flows originating from this Monterey County watershed arise primarily from urban runoff. The Hopkins Maine Laboratory and the adjacent Monterey Bay Aquarium have several point sources of laboratory and aquarium waste seawater that discharge into the ASBS. These two institutions will be covered under an individual exception, and not part of this General Exception.

The only somewhat natural drainage into the Pacific Grove ASBS is from Greenwood Creek, which runs through Greenwood Park. Upstream from the park, the creek again becomes part of the storm drain system. All other freshwater discharges to the ASBS are from storm drains (SWRCB 1979).

Within the jurisdiction of the City of Pacific Grove, this area of watershed adjacent to the ASBS comprise of a total of approximately 940 acres (3.80 km^2), predominately residential. The downtown retail sector comprises 30 acres (121,405 m^2). The Pacific Grove Golf Links contribution is approximately 43 acres (174,014 m^2) in size. Parks, open space, and a recreational trail system border the entire length of the ASBS.

5.4.12 - Carmel Bay

The watersheds adjacent to the Carmel Bay ASBS include the city of Carmel-by-the-Sea and Pebble Beach Golf Course. Approximately 60% of the urban runoff from Carmel-by-the-Sea flows through storm drains directly into the ASBS, and 40% drains directly into the Carmel River, which also flows into the ASBS. The Carmel Area Wastewater District sewage treatment plant has an existing exception and discharges treated wastewater at a submerged location offshore of the Carmel River. The other discharges drain runoff from the Pebble Beach golf course, streets, highways, and private homes. And there are ten springs/seeps that may drain nonpoint source pollutants into the ASBS.

Eight natural streams also drain the golf course and Carmel-by-the-Sea before flowing into the ABSS. There are several watersheds adjacent to the Carmel Bay ASBS; however, all freshwater discharges are seasonal. Pescadero Canyon drains into the ASBS at the north end of Carmel City Beach, and San Jose Creek drains into Monastery Beach. The principle drainage is the Carmel River Basin, which covers a total of about 225 square miles (585 km^2) (Army Corps of Engineers, 1974) in a northwest-southwest direction. Carmel Valley, the lower portion of the watershed, extends eastward about 15 miles (24 km) from the river mouth.

Caltrans classified and mapped the land use and summarized population density within ASBS TAS. Twenty-nine point one percent (29.1%) of the TAS is low density residential, 28.5% is agricultural, 25.2% is open space-public lands, and 14.6% is medium-residential. The remaining land use type is less than 2.0% each of urban reserve, low density commercial and high density residential. Population density of about half of the TAS is less than 100 people per squared mile. Population density in the remaining area of the TAS ranges from 100 to 10,000 people per squared mile, though, it should be noted that density exceeds 5,000 people per square mile in the city of Carmel-by-the-Sea.

5.4.13 - Point Lobos

Located just south and adjacent to the Carmel Bay ASBS, inland in the Point Lobos State Reserve, managed by State Parks. The State Reserve is regularly visited by a large number of day hikers and scuba divers, and included several small campgrounds and a small boat launch ramp at Whalers Cove. Land use outside of, but near, the State Reserve is primarily rural residential. There are 39 streams or natural gullies that drain small watersheds and walking paths along the coastline. To the south there are residences and a hotel.

Caltrans classified and mapped the land use and summarized population density within ASBS TAS. Eighty-two point nine percent (82.9%) of the TAS is open space-public land, 13.8% is low density-commercial, and 2.3% is medium density-residential. Population density of the TAS is less than 100 people per square mile.

5.4.14 - Julia Pfeiffer Burns

Cliffs along this stretch of Big Sur Coastline are rugged and steep, greatly limiting access to the shoreline. Inland is the Julia Pfeiffer Burns State Park, which has a small campground and parking area near McWay Falls. Most drainage into the ASBS is runoff from rural and wilderness watersheds, but there are 25 discharge locations from Highway 1. After a large landslide triggered by heavy rains during the winter of 1982-83, Caltrans road-clearing operations on Highway 1 resulted in the deposition of massive amounts of sediment into the ASBS, completely filling McWay Cove. The cove had been populated by diverse rocky intertidal and subtidal marine life; now McWay Falls flows onto a sandy beach. As a result, sediment erosion and downstream deposition into the ASBS is a continuing concern as deposition of sand, and scour, associated with the currents transporting that sand is known to impact marine life there.

Within the Julia Pfeiffer Burns ASBS, two small watersheds occur, Partington Creek draining into Partington Cove and McWay Creek draining into Waterfall Cove (SWRCB 1980). Caltrans classified and mapped the land use and summarized population density within ASBS TAS. Ninety-nine point two percent (99.2%) of the TAS is open space-public lands and 0.7% is low density-residential. Population density of the TAS is less than 100 people per square mile.

5.4.15 - Salmon Creek Coast

Caltrans classified and mapped the land use and summarized population density within ASBS TAS. Ninety-nine point seven percent (99.7%) of the TAS is open space-public lands and the remaining land is agriculture. Population density of the TAS is less than 100 people per square mile.

5.4.16 - Laguna Point to Latigo Point

This watershed is located in both Ventura and Los Angeles counties. It is the largest mainland ASBS in southern California. State Parks administers many beaches and campgrounds in the northern and central sections along the coast, and Los Angeles County administers the beaches in the southern portion. About 31 natural streams drain into the ASBS. Point Mugu Naval Base occupies the northern portion of the watershed and surrounds Mugu Lagoon, which is an estuary of Calleguas Creek. Calleguas Creek is impaired by a variety of pollutants. The land in the northern section of the watershed is otherwise largely undeveloped, and the majority of the direct discharges into the ASBS are from the pipes leading to the beach from Highway 1. The southern and central sections of the watershed lie in Los Angeles County and include the populated portion of Malibu developed with beachfront homes. A large number of direct discharges in this area are from roads including Highway 1, and urban landscape runoff from homes and small businesses. Most of the residential sited and commercial buildings are on septic systems or are served by small secondary treatment systems. Effluent from the septic or secondary treatment systems is discharges to land via leach fields or spray irrigation. Some of the leach fields are located on or near the beach. Several beaches along the coast are CWA Section 303d listed for beach closures and high coliform counts.

Within the City of Malibu jurisdiction the watershed environment westward of Malibu Canyon Road to the Ventura County line is in a relatively undisturbed state. The slopes and hillsides are dominated by coastal sage scrub and chaparral vegetation, and large areas of riparian habitat in the canyons. The natural environment from the Civic Center and eastward has suffered some biological degradation. Grading and development eliminated some native hillside vegetation in some areas, portions of creeks have been channelized, and kelp beds have largely diminished or disappeared, but reef and rock zones still provide habitat for many species of fish.

More than 15% of the total land in Malibu is public open space. One thousand eight hundred and sixty-nine point nine (1,869.9) acres (7.57 km^2) of open space are used for public recreation, including regional parks, local parks, beach parks, and general open space. Local and regional parks make up 743.7 acres (3.0 km^2) of the open space in Malibu. Vacant, undeveloped private land comprises 60.4% of all land in the City

(7578.3 acres; 30.66 km^2), most of which is in its natural state containing tree, brush, shrub, and grassland vegetation. With a majority of the land in Malibu still sitting as undeveloped open space, it is evident that the general character of the land has changed little since 1974, when the ASBS was first designated.

Eight small watersheds totaling 33,000 acres (133.5 km^2) drain into the ASBS along the County of Los Angeles coastline. This area consists of the unincorporated County of Los Angeles, City of Malibu, State Parks, National Parks, and Caltrans roadways. The County of Los Angeles has jurisdiction over approximately 12,300 acres (49.7 km^2) of the total drainage area. The land use is almost entirely natural open space. Small portions of the drainage area also include low density residential developments, small agriculture plots, and beach parking areas.

Within the State Department of Parks and Recreation jurisdiction, Point Dume is comprised of 31 acres (125,452 m^2) of parkland. There are 2,972 lineal feet (905.8 m) of beach associated with this unit; about half of that is isolated from the unit with a parking area that is administered by the County of Los Angeles. There are other State Parks with associated infrastructure located at this ASBS.

Caltrans classified and mapped the land use and summarized population density within ASBS TAS. Eighty-six point one percent (86.1%) of the TAS is open space-public lands, 4.9% is low density-residential, 4.8% is very low density-residential, and 2.6% is medium density-residential. The remaining land use type is less than 1.0% each of low density commercial, industrial, high density residential, planned development, high density commercial, water, urban reserve, and mixed use. Population density of the TAS varies from less than 100 to 10,000 people per square mile, and in a few relatively small areas, reaches 20,000 people per square mile.

5.4.17 - Northwest and Western Santa Catalina Island

Within the Northwest portion of the Island, there are 17 natural streams and gullies draining into the ASBS. Drainage from the community of Two Harbors consists of small gullies and pipes used mainly for storm water runoff. Two Harbors also has marina facilities consisting of mooring field and pier facilities. Youth camps with structures for camping, picnicking, and recreational use much of the coastline in this area. Adjacent to the Blue Cavern Cove are the intake line for the University of Southern California (USC) Wrigley Catalina Marine Science Laboratory and the leach field for the treated domestic wastewater from the Marine Science Center. USC has a waste seawater discharge covered under an existing exception.

Western Catalina is used primarily by boaters, the island residents and tourists, and has areas for camping, picnicking, hiking, and surfing. There are five natural streams draining this area. A road runs along part of the coastline of the ASBS, and may contribute to storm water runoff, portions of the road are annually paved with oil slurry that may be discharged into the ASBS.

Santa Catalina Island Company (SCICO) occupies the majority of the land adjacent to the ASBS, Open Space Easement and Conservancy Area. The Two Harbors area and Little Geiger Cove to Howland's Landing are the Non-Easement, Non-Conservancy areas owned by the SCICO. The land use is dominated by residential areas, view corridors/public uses, campgrounds/hostels, and lodges/inns. The SCICO has two secondary stage wastewater treatment plants with land disposal near the ASBS. Additionally, SCICO has removed the underground fuel storage tanks previously located at the vehicle fueling facility, located adjacent to the beach.

The high use visitor period runs roughly from Memorial Day in May through Labor Day in September. During that time, the City of Avalon, as well as other recreation areas and summer camps on the island, are generally filled to capacity. During the remaining months, the population drops to a fairly constant level of permanent residents while other areas retain a minimum number of more-or-less permanent, maintenance-type personnel (Los Angeles County, Department of Regional Planning. 1983. Local Coastal Plan, Santa Catalina Island).

5.4.18 - Southeast Santa Catalina Island

The City of Avalon is located on Santa Catalina Island and is relatively close to but not immediately adjacent to the ASBS.

This watershed has two direct discharges and three natural streams draining to the ASBS. The major source of anthropogenic impact is associated with a large quarry. The Connolly-Pacific Company (Connolly) facility is located in the Pebbly Beach Extractive Use Zone in the Santa Catalina Island Local Coastal Plan. Connolly leases the property from the Santa Catalina Island Company. There is a jetty constructed at the quarry. Connolly must maintain the natural shoreline contours, meaning some rocks are added periodically to areas where storms have caused slippage. Connolly is also required to reconstruct a "natural" hillside topography upon reclamation. The facility is approximately 248 acres (1 km^2) and is completely pervious (i.e., no paved roads or parking areas).

5.4.19 - Robert E. Badham

Uses of the watershed, nearshore and offshore, areas in this ASBS include industrial service supply, navigation, recreation, commercial, sport fishing, and shellfish harvesting. Three natural streams flow into the ASBS which carry urban runoff from the Corona Del Mar area of Newport Beach. Urban runoff may be contributing toxic pollutants such as pesticides and other organics, and some impacts are also resulting from hydromodification in the upstream portions of one of the streams, Buck Gully, which is CWA Section 303d listed.

The land immediately behind the coastal bluffs of the Robert E. Badham ASBS is nearly completely developed, and private homes line most of the cliff edge. Public access to the Refuge is provided by a large, partially paved walkway at Poppy Avenue and by climbing over the rocks along shore from the north (from the Corona del Mar area) (SWRCB 1979).

The City of Newport Beach urban land use includes 38,394 housing units and a population of 70,032 in 2000. Within the immediate watershed drainage area of the ASBS, there is a total population of 4,523. Of the approximately 32,000 acres (129.5 km^2) that make up the City of Newport Beach, the drainage area of the Newport Beach Marine Life Refuge consists of 1,659.32 acres (6.72 km^2). The majority of the drainage area is either residential, 733.27 acres (2.95 km^2), or vacant land, 729.06 acres (2.95 km^2). The rest of the watershed is open land and recreation (100.22 acres; 405,575.9 km^2), mixed use or under construction (82.74 acres; 0.33 km^2), commercial and public (10.44 acres; 42,249 m^2), and transportation and utilities (3.61 acres; 14,609 m^2)). There are no industrial areas within the watershed. The vacant land is located on either side of Buck Gully and Morning Canyon Creek and is bordered by residences and open parks.

5.4.20 - Irvine Coast

Most of the watershed is urbanized with the exception of the Crystal Cove State Park area, which contains some of the last undeveloped Orange County coastline. There are 16 natural gullies or streams in this watershed mostly drain urban areas, the Pacific Coast Highway, and park facilities and then into the ocean. Los Trancos Creek is impaired by fecal coliform bacteria. In addition there is groundwater spring that drains the coastal bluff forming a small surface stream into the ocean.

Caltrans classified and mapped the land use and summarized population density within ASBS TAS. Fifty-six point two percent (56.2%) of the TAS is open space-public lands and 43.8% is medium density-residential. Population density in about 65% of the TAS is less than 100 people per squared mile. Population density of a relatively small area of the TAS ranges from 5,000 to 10,000 people per square mile. The remaining area of the TAS has a population density of 100 to 500 people per square mile.

The California Department of Parks and Recreation, in the Crystal Cove State Beach area, is comprised of 2,791 acres (11.29 km^2) of land. There are 16,800 lineal feet (5.12 km) of beach associated with this park. The park has approximately 8 miles (12.87 km) of trails. The park is bisected by Highway 1. There are 174,120 square feet (16,176 square meters) of parking lot at the Pelican Point facility. Developed area in the park amounts to about 0.5% of the total area. Caltrans has developed collection infrastructure to accumulate all roadway drainage and eliminate any direct runoff from the Highway 1 section over most of the area that has the potential to impact the ASBS. About 50% of the park is bordered by urban development and golf course; with the remainder undeveloped back country to the top of the coastal drainage ridgeline.

5.4.21 - Heisler Park

Discharges into the Heisler Park ASBS arise from hardscape, street, and storm drains. There is one gully that drains runoff from an urban portion of the City of Laguna Beach. The City of Laguna Beach jurisdiction includes 1,225 property lots, 26,000 residents, and the current resident watershed population of approximately 2,500 to 3,000 people. It is estimated that about 3,000,000 tourists visit the city each year. Land use of the watershed area is predominantly residential and a small percentage of commercial use along the Pacific Coast Highway. The reserve watershed area consists primarily of residential development from the beach cliff area, extending inland to the narrow coastal plain and up on the hillsides. There are no industrial businesses or facilities within the watershed. There are five city parks and recreation areas which amount to 61 acres (246,858 m^2), and there is one city facility, the City Park Division operations yard.

5.4.22 - La Jolla

The adjacent, highly urbanized watershed here has nine naturally occurring streams or gullies also drain the developed La Jolla town area into the ASBS. Within the ASBS watershed area, there are approximately 1,640 households based on the 2000 census. It is estimated that the current resident population is 6,060 people in the watershed. During the summer months, visitors and tourists significantly increase the amount of people in the community.

Because the watershed is built out, it is anticipated that the existing percentage of impervious surface will not significantly change in the future. The watershed is fully developed and has been for several decades; land uses, and assumedly storm water quality, have remained fairly static during this time. There are approximately 1,452 acres (5.87 km^2) in the ASBS drainage area. Of this total, 80% is urbanized area and 20% is undeveloped or dedicated open space. There are no industrial businesses or facilities within the watershed.

5.4.23 - San Nicolas Island and Begg Rock

SNI is approximately 61 miles (98 km) from the mainland. The island, managed by the U.S. Navy, is not open to the public. There are 35 natural gullies and ephemeral streams on the island, which drain into the ASBS. There are residential and industrial areas, pier, barge landings, roads, structures, missile testing activities, and an airfield on this island that may contribute to pollutants into the ASBS. A desalination plant operated by the Navy discharges brine under an individual exception.

5.4.24 - San Clemente Island

SCI is located 49 miles (79 km) from the mainland. The island is managed by the U.S. Navy and is not open to the public. There are residential and industrial areas, piers, barge landings, roads, structures, military training activities (including the use of ordinance), and an airfield on this island that may contribute to pollutants into the ASBS. There are also 100 natural gullies and ephemeral streams that drain into the ASBS. A large area in the southern part of the island is used for military operations, including explosion of ordinance. This undoubtedly results in erosion and resulting sedimentation into the coastal portion of the ASBS. A sewage treatment plant operated by the Navy discharges into an excluded zone within the ASBS under an individual exception.

There are 214 watersheds on the island. The revised universal soil loss erosion occurs on most of the island at a rate of less than 4 tons per acre per year, though the northeast coast of the island erodes at 12 to 23 tons per acre per year.

5.5. BIOLOGICAL COMMUNITY BASELINE

5.5.1 - ASBS Reconnaissance Surveys (1979-81)

Biological surveys were conducted and reported in the State Water Board's California Marine Waters, Areas of Biological Significance Reconnaissance Survey Reports (1979-1981). The results have been summarized in Table 5.5.1 (below) to display the number of flora (plant and algae), invertebrate, and fish species found in each ASBS.

Table 5.5.1. Number of flora (algae and marine vascular plants), invertebrate, and fish species found in each ASBS, as summarized from biological surveys conducted for the State Water Board's Reconnaissance Survey Reports (1979-1981)

ASBS Name	Number of Flora Species	Number of Invertebrate Species	Number of Fish Species
Redwoods National Park	35	433	29
Trinidad Head	24	407	0
King Range	28	181	11
Jughandle Cove	14	72	9
Saunders Reef	31	157	13
Del Mar Landing	No Survey Conducted		
Gerstle Cove	39	310	26
Point Reyes Headlands	31	299	16

ASBS Name	Number of Flora Species	Number of Invertebrate Species	Number of Fish Species
Duxbury Reef	6	89	0
James V. Fitzgerald	33	159	12
Año Nuevo	35	634	14
Pacific Grove	87	521	17
Carmel Bay	30	125	78
Point Lobos	27	242	15
Julia Pfeiffer Burns	17	151	26
Salmon Creek Coast	No Survey Conducted		
Laguna Point to Latigo Point	43	613	86
Northwest Santa Catalina Island	38	254	38
Southeast Santa Catalina Island	44	260	27
Robert E. Badham	7	90	13
Irvine Coast	5	187	24
Heisler Park	15	160	28
La Jolla	20	151	36
San Nicolas Island & Begg Rock	No Survey Conducted		
San Clemente Island	No Survey Conducted		

5.5.2 - Marine Wildlife

5.5.2.1 <u>Marine Reptiles</u>

Marine sea turtles occur in California waters. Four species of federally protected sea turtles may be along the California coast: green (*Chelonia mydas* FE), leatherback (*Dermochelys coriacea* FE), loggerhead (*Caretta caretta* FE), and olive ridley sea turtles (*Lepidochelys olivacea* FE). These marine turtles are circum-global in distribution but breeding colonies have not been observed in California (Coastal Conservancy 2005).

5.5.2.2 <u>Marine Birds</u>

Birds comprise the most conspicuous group of animals occurring along the California coast; that many individuals are easily visible from land during all seasons and tidal conditions. Most marine bird populations are seasonal; heaviest use occurs during spring and fall migrations, and in winter. During the summer, most of the species are nesting elsewhere (SWRCB 1979).

Birds are important predators of many of the fish and invertebrates inhabiting the coast. In the rocky intertidal zone, several species of shorebirds (especially black turnstones, surfbirds, rock sandpipers, black oystercatchers, willets, and whimbrels) prey on water lice, salt water fleas, and other small crustaceans. Bristle worms, a variety of small mollusks, and occasionally representatives of other invertebrate taxa are also preyed upon. Gulls feed on crab, seastars, *Pisaster ochraceus*, and sea urchins. On the sandy beach, sanderlings and marbled godwits probe for water lice, *Excirolana*, salt water fleas, *Orchestoidea* and *Paraphoxus*, the sandcrab, *Emerita analoga*, and adult and larval insects. Seabirds that capture food near the water surface (pelicans, phlaropes, terns, and gulls) or dive beneath the surface (loons, grebes, cormorants, sea ducks, and alcids) forage on zooplankton, squid and fish, as well as mollusks and crustaceans taken from the seafloor (SWRCB 1979).

Of the 100+ other species occurring somewhat regularly along the California coast, the great majority nest outside of California, with many species migrating annually to the Arctic to breed. Small numbers of some of these species, often immature birds, remain here throughout the summer (SWRCB 1979).

Seabirds found in the Southern California Bight include Xantu's murrelet (*Synthliboramphus hypoleucus*), California gull (*Larus californicus*), Heermann's gull (*Larus heermanni*), western gull (*Larus occidentalis*), Royal tern (*Sterna maxima*), California brown pelican (*Pelecanus occidentalis*), ashy storm-petrel (*Oceanodroma homochroa*), Brandt's cormorant (*Phalacrocorax penicillatus*), and double-crested cormorant (*Phalacrocorax auritus*) (SWRCB 1979) (PRBO 2005). The California least tern (*Sterna antillarum*) and elegant tern (*Thalasseus elegans*) forage and nest along the California coast. The bald eagle (*Haliaeetus leucocephalus*) is also present along the coast and in the Channel Islands. They were listed as an endangered species in 1967 when their population drastically diminished from exposure to the chemical pesticide DDT. Recovery efforts were made to repopulate this species and, after successful attempts, they were downgraded to threatened species in 1995. As of July 6, 1999, they were recommended for delisting by the U. S. Fish and Wildlife Services due to the increase in numbers found to exist (DFG 2001).

North of the Bodega Marine Life Refuge, along the California coast in the area of the Saunders Reef ASBS, pelagic birds spotted included the Pigeon Guillemot, Brown Pelican, Pelagic Cormorant and Western Gull. On the cliffs over the inter-tidal, birds found nesting include Common Ravens, Black Oyster Catchers, Cliff Swallows, and Pelagic Cormorants (SWRCB, 1980). Gerstle Cove, Del Mar Landing, and Jughandle Cove ASBS are all in the vicinity of the Saunders Reef ASBS and would likely have similar wildlife species.

Farther north, at the Trinidad Head ASBS, Western Gulls rest on offshore rocks. Numerous sea-birds also rest or nest on Blank Rock and Flatiron Rock. Blank Rock specifically serves as a nesting are for Fork-tailed Petrels, Leach's Petrels, Brandt's Cormorants, Pelagic Cormorants, Western Gulls, Common Murres, Pigeon Guillemots, Cassin's Auklet, and the locally rare Tufted Puffin (SWRCB, 1979). Due to the close proximity of the Trinidad Head ASBS to both the Redwood National Park ASBS and the King Range ASBS, the bird life found at these locations should be similar.

Along the northern and central coast, several species nest close to the intertidal zone, and are present as year-round residents. The black oyster catcher nests on rocks just above the reach of the waves. A smaller shorebird, the snowy plover, nests on the upper areas of beaches. Among seabirds, pelagic cormorants nest in scattered colonies along sea cliffs. This species builds nests on rock shelves along the cliff faces above the surf. Brandt's cormorant, a larger species which typically selects flat areas on islands for colony sites, is also present in large numbers along the northern and central coast. Gulls and black oyster catcher also nest along the coast (SWRCB 1979).

5.5.2.3 Marine Mammals

All marine mammals are protected under federal law (Marine Mammal Protection Act). Members of this group are predominantly carnivorous and represent the upper end of the marine food chain in the coastal waters. The three orders of marine mammals found along the California coast are the seals and sea lions (*Pinnipedia*), the sea otters (*Fissipedia*) and the dolphins, porpoises, and whales (*Cetacea*); the seals and sea lions are the most easily observed and abundant (SWRCB 1979). Table 5 displays NOAA's information about the presence of marine mammals within certain ASBS from Point Reyes southward.

North of Point Reyes, marine mammals in the Saunders Reef ASBS include the Harbor Seal and the California Sea Lion (SWRCB, 1980). Other ASBS locations in the area such as Gerstle Cove, Del Mar Landing, and Jughandle cove would also support Harbor Seals and California Sea Lions. At the Trinidad Head ASBS, both California Seal Lions and Stellar Sea Lions haul out on Blank Rock and Flatiron Rock. Harbor Seals use exposed rocks in Trinidad Bay and the western sector of the ASBS as resting sites (SWRCB, 1979). Due to the close proximity of the Trinidad Head ASBS to both the Redwood National Park ASBS and the King Range ASBS, similar marine mammal activity is assumed to also be found in these localities. River otters have been observed along the east side of Trinidad Head (SWRCB, 1979).

5.6. EXCEPTION APPLICATION BIOLOGICAL SURVEYS – MARINE BENTHIC COMMUNITY

5.6.1 - Redwoods National Park ASBS

5.6.1.1 Marine Resources of Redwood National and State Parks (Cox et al. 2005)

Redwoods National and State Park submitted a report entitled Marine Resources of Redwood National and State Parks (Cox et al. 2005), which was a comprehensive assessment of coastal resources on sandy shores and rocky in Redwoods National and State Parks. This report included an inventory of the algal, invertebrate, and fish species present at three selected sites, and community dynamics surveys consisting of seasonal monitoring of abundant and/or ecologically important organisms.

Sandy intertidal sites include: Crescent Beach, Gold Bluffs Beach, and Redwood Creek Beach. Rocky intertidal sites include False Klamath Cove (FKC), Enderts Beach (END), and Damnation Creek. The study site at FKC was near discharges, previously identified in the Southern California Coastal Water Research Project (SCCWRP) 2003 Report, associated with Highway 101 roadway runoff. END and Damnation Creek happened to be near natural outlets of varying sizes. The species distribution in the rocky intertidal was examined on a presence/absence scale at each of the sites, with a standardized biodiversity protocol used to map and derive a complete species list for Damnation Creek.

It should be noted that Cox et al re-inventoried the identical sites as that described in reports by Boyd and DeMartini from 1977 (1974-76 field work for National Park Service) and 1981 (1980 field work for State Water Board). Voucher specimens were collected for all possible invertebrate and algal species. Some species were photographed in lieu of collection due to preservation difficulties. Algae were identified using Abbott and Hollenberg (1976) and Gabrielson et al (2004). Invertebrates were identified using Morris et al. (1980) Kozloff (1993), and Kozloff (1966). Measurement of the algal and invertebrate species of the July 2005 survey were recorded as five abundance categories; abundant, common, present, uncommon, or rare.

A total of 114 algal taxa were recorded in inventories of FKC and END in 2005. Thirty eight algal species were found at these sites in 2005 that were not listed by Boyd and DeMartini (1977). Three species of algae (*Haplogloia andersonnii, Pterygophora californica and Pikea robusta*) were found at END in 2005 and 1977 and at FKC in 1977, but were absent from FKC in the 2005 survey. One species, *Odonthalia washingtoniensis*, was only found at FKC in 2005 and 1977. Two species, *Calliiarthron tuberculosum* and seersucker kelp *Grateloupia setchellii,* were only found at END in 2005 and 1977. However, when comparing the algal community found during the 2005 and 1977 rocky intertidal inventories, no clear patterns emerged to assess potential impacts from storm water runoff or ocean water conditions.

Invertebrate inventories at FKC and END found a total of 176 invertebrates in 2005. Of these, 77 were not previously recorded. Invertebrate species inventoried at FKC (near to discharge sites) and END showed no clear pattern in species presence or absence. There were no conclusions pertaining to storm water runoff effects.

From June 2004 to November 2005, community dynamics surveys were conducted for algal and invertebrate communities based on the design of Multi-agency Rocky Intertidal Network (MARINe) (www.marine.gov). Methods adapted from MARINe included scoring percent cover of algal species in permanent photo-plots as well as enumerating mobile invertebrates within the plots, and monitoring seastar plots and surfgrass transects. In addition, select rocky tidepools were repeatedly sampled to provide a more quantitative assessment of specific resident species of tidepool fishes.

Permanent photo-plots were set up at FKC, Damnation Creek, and END. All plots were sampled and photographed every 2 to 3 months from June 2004 though November 2005. Sampling was done for all three sites within six days during lowest tides. The photo-plots were established to record changes in the cover of certain populations including: mussels (*Mytilus californianu*s), barnacles (*Chthamalus dalli and Balanus glandula*), and three species of algae (*Endocladia muricata*, *Pelvetiopsus limitata*, and *Fucus gardneri*). These five sessile populations were chosen for monitoring because they are conspicuous, bed-forming, abundant, and ecologically important. *Fucus gardneri* was not dense and continuous enough at END, nor was there dense enough *P. limitata* at Damnation Creek when the study was initiated, to merit plot establishment for those species at those sites. At Damnation Creek, five additional mussel plots were sampled. These plots were located in the outflow of Damnation Creek where salinity is often much lower than in the other mussel plots. Otherwise, each species type was monitored in five replicate plots at each site.

The 2004-2005 surveys do not provide adequate data to directly assess a response to the effects of storm water runoff or possible constituents in the ocean water. The targeted species are generally known for their tolerance to a variety of physical and chemical environmental conditions, and were not chosen by the researchers as selected species with known tolerances or sensitivity to anthropogenic contaminants occurring from storm water runoff or in the ocean receiving waters. However, this approach does constitute a thorough representation of seasonal data for the year and provides valuable baseline data on the conditions at three sites.

The State Water Board staff asked Dr. Peter Raimondi, of the University of California at Santa Cruz Center for Ocean Health (2008), to evaluate the Cox et al report in the context of the ASBS discharge question. According to Dr. Raimondi, the purpose of this report was to generally characterize the intertidal resources in the Park and the study design was not suitable to provide a dedicated assessment of the possible impacts of storm water to ASBS.

5.6.1.2 PISCO/MARINe (Raimondi 2006)

Dr. Peter Raimondi performed a data assessment for 8 of the 10 ASBS within the influence of Caltrans discharges. In his report (Data assessment for ASBS/Ocean Plan for Caltrans, March 12, 2006), Dr. Raimondi summarized site characteristics and provided a brief ecological community analysis of established rocky intertidal monitoring stations. These established stations are either a PISCO or MARINe site and provides a continuum of data collected using either Community Dynamics Survey or Biodiversity Protocol. PISCO/MARINe monitors three sites in the Redwood National Park ASBS at END, FKC, and Damnation Creek. All three are sites monitored using Community Dynamics Surveys, but only since 2004. Damnation Creek was also monitored using the Biodiversity Protocols.

Enderts Reef is comprised of a gently sloping (5°) bench of intermediate width and moderate relief. The surrounding coast is made up of boulder, bedrock, and pebble beaches. No biodiversity data were collected here but the species trends seem typical for this sort of site. One species of special interest was recorded here, the surfgrass, Phyllospadix spp. No invasive species were recorded at this site.

FKC reef is comprised of bedrock and boulders. The reef is a gently sloping, long reef of moderate relief. The surrounding coast is made up of bedrock, boulders, and sand. No biodiversity data have been collected here but species trends have been collected (since 2004) and seem typical to this point. Two species of special interest were found here, the surfgrass, *Phyllospadix* spp. and the sea palm, *Postelsia palmiformes*. No invasive species have been found here.

Damnation Creek reef is comprised of pebbles, boulders, and bedrock. The reef is a gently sloping, long reef of moderate relief. The surrounding coast is similar to the sample site. One species of special interest was recorded here, the surfgrass, *Phyllospadix* spp. No invasive species were recorded at this site. Dr. Raimondi compared the ecological communities in a series of "reference" sites in northern California. Species richness at Damnation Creek was 111 species, whereas species richness at reference sites ranged between 98 and 113. However, Damnation Creek differed in community composition significantly from all other sites. This was likely due to the site being remote, pristine, and of different geomorphology than the reference sites.

5.6.2 - Trinidad Head ASBS

One report was available for the Trinidad head ASBS, Sean Craig's 2006 Humboldt State University (HSU) Study intertidal survey, prepared for the City of Trinidad, and the Trinidad Rancheria Ocean Plan exception application. This survey provided a quantitative comparison of rocky intertidal species at one of the discharge sites, identified in the SCCWRP 2003 survey, and at a location distant from the discharge.

The selected waste discharge location is a site where the City of Trinidad's primary storm water outfall is located. Directly adjacent to this pipe is the outfall pipe of HSU's Telonicher Marine Lab, and the location is also influenced by the pier's parking lot runoff and certain boat cleaning operations. The selected "undisturbed" rocky intertidal sampling site was comparable in substrate and located approximately 100 meters northeasterly along the shoreline away from the first site.

Both sampling sites were similar in appearance consisting of boulders partially submerged in sand and appeared to be generally unmoved throughout time. Both sampling stations were examined for vertical and horizontal zonation of the marine life. Boulders were randomly selected along a single axis within four distinct shore regions from the high shore to the low shore. These regions were labeled: High, Mid-High, Mid, and Low. A 0.25 square meter quadrat was placed at each sampling point measuring both the vertical and horizontal arrangement of organisms on each boulder. Surveys were conducted during low tide on three consecutive days, May 25, 26, and 27, 2006. Thirty quadrat samples were collected on 10 boulders at the outfall site, and 36 quadrat samples were collected from 12 boulders at the undisturbed site. Each randomly selected boulder was measured for species abundance, composition, and general pattern of zonation of the intertidal algae and invertebrates. Measuring the vertical and horizontal arrangement of organisms allowed for the examination of changes in species composition at the outfall site as compared to the control site.

The log-normal model of abundance and diversity was used to compare the discharge site with the control site. Sessile and mobile invertebrates were measured for abundance using a count and then the log was taken. Anemones and algae were counted as percent cover. The report stated that when considered together, the diversity and abundance of biologically similar organisms within a community are more powerful in assessing the effects of disruption than when taken separately. A log-normal model of abundance and diversity is one tool in applied ecology for use to test ecosystem integrity, disruption, and health.

Craig reported the same species present at both the outfall (discharge) site and the "undisturbed" location; a total of 23 species were recorded, 10 macrophyte and 13 invertebrate species. The report stated that the outfall site and the "undisturbed" site show a similar pattern in both vertical and horizontal zonation of species. Fucoid algae, including *Fucus gardneri* and *Pelvetiopsis limitata,* were found restricted to the higher regions of boulders generally below the barnacle line across the shore. Also found in the highest zone were a group of red algae species *Mastocarpus papillatus*, *M. jardinii*, *Cryptosiphonia woodii*, *Endocladia muricata* and *Neorhodomela larix.* All four shore zones included barnacles *Chthamalus dalli* and *Balanus glandula,* abundant at the upper reaches of the boulders. The anemone *Anthopleura elegantissima* was present in all but the high zone at both locations.

Abundance between the two sites was not the same. Craig provided the explanation that the difference in organism abundances between the two sites may be due to the physical positioning and slope of the shore line, and describe the outfall site as a long gentle slope more protected from heavy wave action as compared to the “undisturbed” site and filling in more slowly during the incoming tide. The “undisturbed” site was described as being less protected with the potential to be more rapidly immersed with an incoming tide.

At the request of State Water Board staff, Dr. Raimondi performed a statistical analysis of the Trinidad intertidal data set described above. In that assessment, he used Bray-Curtis ordination (PRIMER software) to compare community structure at reference and impact locations. Using the design and data provided, there is evidence that the impact (outfall) location is different from the “undisturbed” location based on comparison of community composition. This effect was complicated by the interaction between effluent “treatment” (impact vs. undisturbed) and tide height.

For species sampled by counts and those sampled by percent cover, 1 of 3 tidal height zones differed between outfall and undisturbed areas, although the differences in the other zones were close to significant. The p value for the species sampled by counts in the low tide zone was 0.023 (2.3%) and the p value for percent cover species in the mid tide zone was 0.005 (0.5%). The p values describe the level of significance of the sample statistics, with lower p values indicating a greater certainty that there are differences between outfall and undisturbed sites.

Algal species contributing the greatest difference between the discharge and undisturbed site was the red algae *Cryptosiphonia woodii,* being more abundant at the discharge site (Table 5.6.1). The aggregating sea anemone *Anthopleura elegantissima* was clearly more abundant at the undisturbed site.

Table 5.6.1. Percent cover, intertidal algae, and the aggregating sea anemone A. elegantissima, and their contribution to differences between the outfall site (Group 1) and the undisturbed site (Group 2)

	Group 1	Group 2	
Species	Av.Abund	Av.Abund	Contrib%
Cryptosiphonia woodii (%)	40.33	0.2	21.38
Anthopleura elegantissima (%)	1.78	17.6	17.52
Endocladia muricata (%)	6.11	17.2	16.04
Fucus gardneri (%)	15.67	3.3	14.9
Pelvetiopsis limitata (%)	8.11	1.1	9.59
Mastocarpus papillatus (%)	4.44	4.3	7.46
Mastocarpus sporophyte (%)	2.56	5.2	6.69

The barnacle *Chthamalus dali*, black limpets, and the barnacle *Balanus glandula* contribute the greatest differences between the outfall and undisturbed sites (Table 5.6.2.).

Table 5.6.2. Counts, Intertidal invertebrates, and their contribution to differences between the outfall site (Group 1) and the undisturbed site (Group 2)

	Group 1	Group 2	
Species	Av.Abund	Av.Abund	Contrib%
Chthamalus dali (count)	2.47	3.82	34.97
Little Black Limpets (count)	0.64	2.34	20.81
Balanus glandula (count)	1.69	1.35	15.71
Littorines (count)	0.42	0.69	8.49
Lottia digitalis (count)	0.61	0.1	6.23
Chitons	0.41	0	4.5

For species sampled by counts and those sampled by percent cover, 1 of 3 tidal height zones differed between outfall and undisturbed sites, although the differences in the other 2 of 3 zones were close to significant.

The following figures provide a graphic representation of the Bray-Curtis multivariate results provided by Dr. Raimondi. Each symbol represents a quadrat sample result. The graphs show that some outfall and undisturbed quadrats cluster together, but some outfall quadrats cluster separately as do some undisturbed quadrats. This displays the differences between the outfall and undisturbed community data sets.

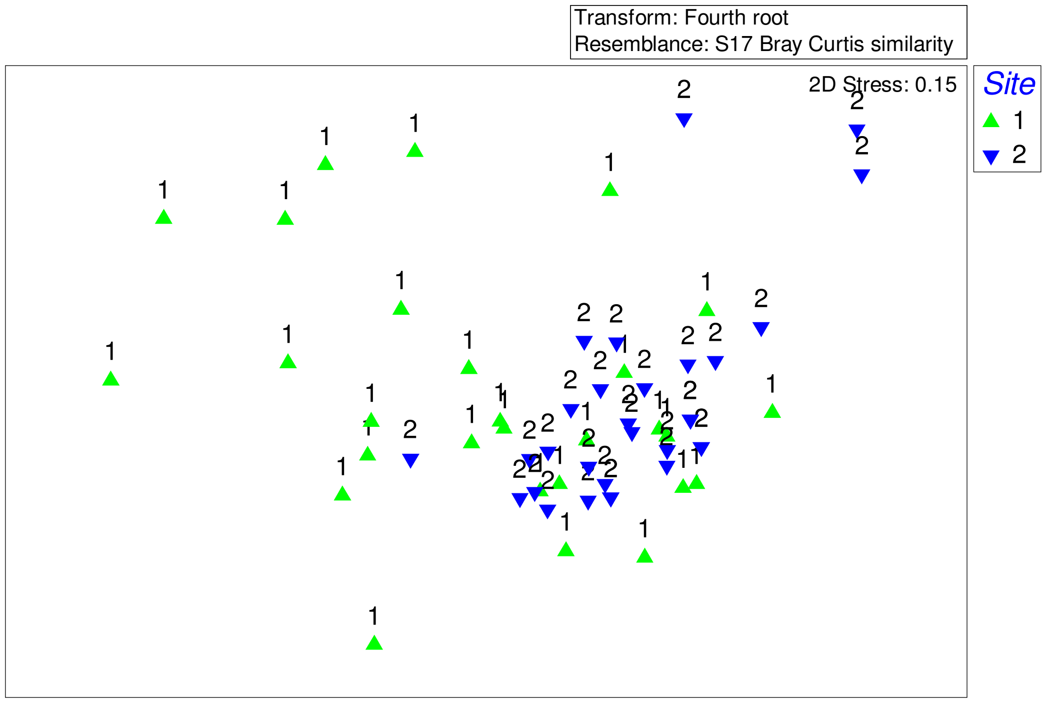

Figure 5.6.1. Trinidad Head ASBS. All tidal zones combined. Site 1 is the outfall site and Site 2 is the "undisturbed" site.

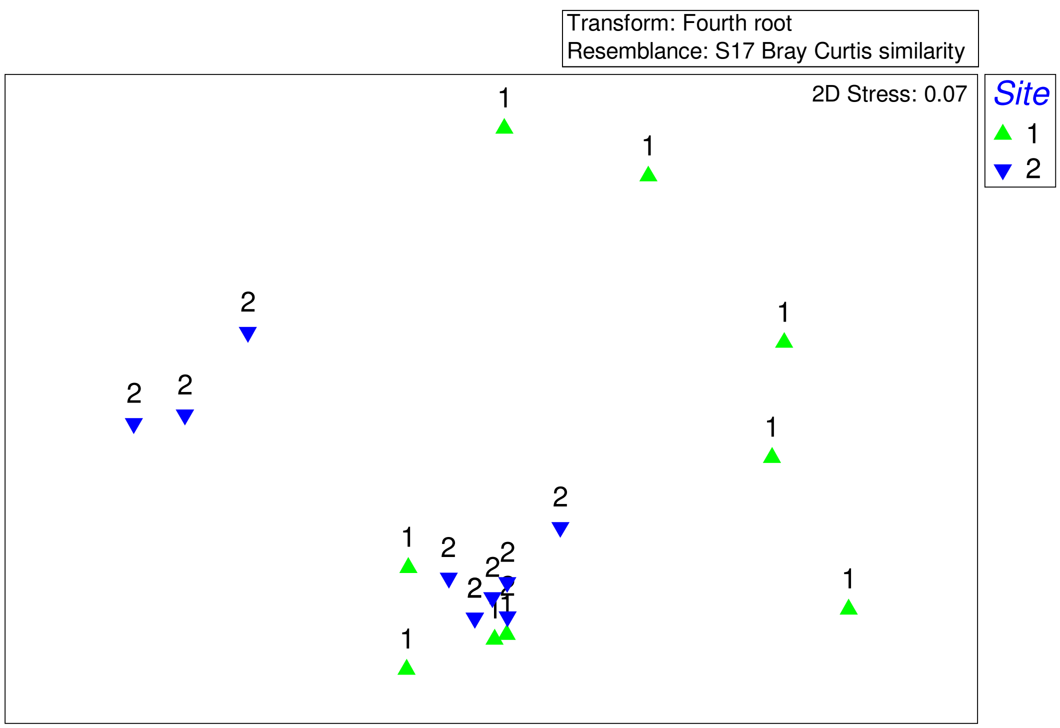

Figure 5.6.2. Trinidad Head ASBS. Low tide zone, species measured by counts. Site 1 is the outfall site and Site 2 is the "undisturbed" site.

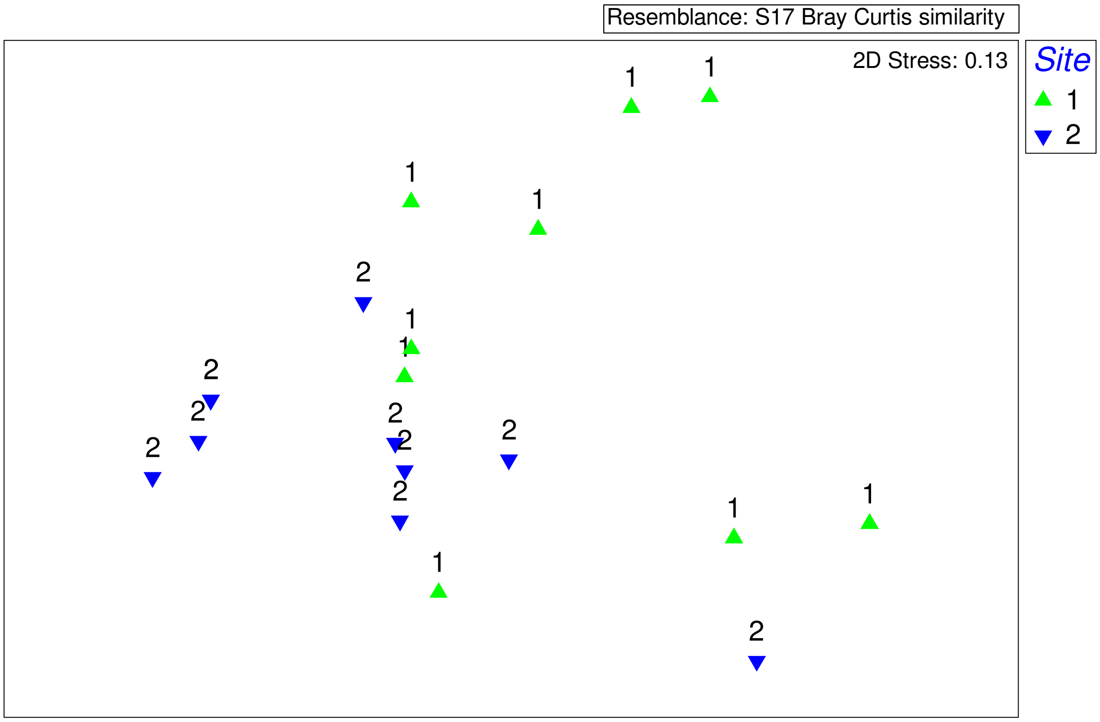

Figure 5.6.3. Trinidad Head ASBS. Mid tide zone, sessile species measured by percent cover. Site 1 is the outfall site and Site 2 is the “undisturbed” site

5.6.3 - Del Mar Landing ASBS

There was one report available, a Baseline Inventory of the Rocky Intertidal Zone at the Del Mar Landing Ecological Reserve May 2006 by Jacqueline Sones et al. This inventory was prepared for the TSRA Ocean Plan exception application and provides a quantitative comparison of marine species at two of TSRA’s discharge sites and at two control sites.

The 2006 Sones report provided relevant quantitative information at four selected points along the 1 kilometer of rocky shoreline of the ASBS. Prior to this work, very little rocky intertidal community inventory work had been done at the Del Mar Landing ASBS. Steve Obreski conducted some work at Sea Ranch in 1972, but the exact locations of his study sites are unknown and the data in his report was considered too preliminary and too narrow to use for this initial study (Sones et al. 2006). John Pearse wrote a site description for a rocky intertidal area near Walk-On Beach, a location approximately 3 kilometer south of the Del Mar Landing ASBS. This report did not represent a complete inventory effort of the rocky intertidal biotic community, but did provide an informative overview of the area (Sones et al. 2006).

Also near Walk-On Beach and part of TSRA, the University of California at Santa Cruz's Coastal Biodiversity Survey Team (Raimondi, SWAT) conducted surveys of the rocky intertidal community in 2001 and 2005. Though the topography at Walk-On Beach is slightly different than at Del Mar Landing, that inventory provides a quantitative measure of diversity and abundance of the rocky intertidal algal and invertebrate community in the vicinity.

Sones conducted her biological inventory of the rocky intertidal community at the Del Mar Landing ASBS in April 2006. The ASBS is located off Helm Road at the northern end of the Sea Ranch community. It covers approximately 1 kilometer of rocky shoreline. Four rocky intertidal sites were sampled during the inventory, two discharge sites and two control sites. Two discharges (storm water conveyances) drain into the ASBS near the "discharge" sites, one at Helm Road, and another approximately 185 meters further east. "Control" sites were selected in areas distant from discharge sites, approximately 80 meters away, and considered by the survey team to be most likely free from potential influence of the discharges. Transects were set up and surveyed near both discharge sites and at two control sites located a reasonable distance away from the direct influence of the storm water outfalls. The control sites were also chosen based on similarities in substrate, slope, aspect, and wave exposure.

Surveys were conducted on two consecutive days, April 21 and 22, 2006. At each site, single 5-meter long transects were laid out in each of four tidal zones (high, upper-middle, lower-middle, and low zones). Transects were set up parallel to the shoreline running from east to west at approximately the same tidal height for each zone. Photographs were taken of each transect, as well as selected algae and invertebrates encountered during the surveys. Five 20cm x 20cm quadrats were randomly placed along each transect. The sampling design was 5 quadrats per zone x 4 zones per site x 4 sites for a total of 80 quadrats. The entire survey comprised of 40 quadrats in discharge sites and 40 in control sites.

All species in each quadrat were identified and the percent cover of sessile invertebrates and algae, and number of individuals for mobile invertebrates, were calculated. Mussels were not destructively sampled, so the algae and invertebrate counts represent the topmost layer of the mussel bed, most notable in the lower-middle zone.

Fifty-eight species of marine algae and invertebrates were recorded in all the quadrats and pooled across discharge and control sites. Of these, there were 26 species of algae and 32 species of invertebrates. Of the 32 invertebrates, 13 were sessile species and 10 were mobile species. Twenty-two species of algae were found at the discharge sites versus 25 species of algae at the control sites. Twenty-nine species of invertebrates were found at the discharge sites versus 22 species of invertebrates at the control sites. Approximately 70% (n=40) of all species were shared between the discharge and control sites.

Raw data was pooled from all tidal zones prior to statistical analysis. Species richness, sessile invertebrate cover, sessile invertebrate diversity, mobile invertebrate abundance, mobile invertebrate diversity, algal cover, algal diversity, and total cover were analyzed using a general linear model (Analysis of Variance). Models evaluated the measures of interest as a function of location (west vs. east) and outfall (discharge vs. control). Thus, the results reflect overall impacts of the discharge after accounting for differences in the two locations. Measures of diversity were calculated using the Shannon Diversity Index (H). Dr. Matt Bracken (Bodega Marine Laboratory) performed the data analysis.

Sones et al reported no significant differences between the discharge and control sites. However, invertebrate richness was reported to be slightly higher at the discharge sites and algal richness was slightly higher at the control sites. The only measure that was close to being significantly different was the mobile invertebrate abundance driven by one species, the checkered periwinkle (*Littorina plena/scutulata).* Sones et al concluded that these trends were insignificant and probably due to sampling artifacts and the high variability of rocky intertidal communities.

At the request of State Water Board staff, Dr. Raimondi performed a statistical analysis of the Sea Ranch/Del Mar Landing intertidal data set described above. In that assessment, he used Bray-Curtis ordination (PRIMER software) to compare community structure at discharge and control locations. Using the design and data provided, there is evidence that the discharge locations are different from the control locations based on comparison of community composition. For species sampled by percent cover and those sampled by counts, 2 of 4 zones differed between discharge and control areas. For species sampled by percent cover, the upper-middle tide zone (p=0.042) and the low tide zone (p=0.002) differed between discharge and control locations. For species sampled by counts, the high tide zone (p=0.001) and the upper-middle tide zone (p=0.015) differed between discharge and control locations.

Algal species contributing the greatest difference between the discharge and control sites in the upper-middle intertidal was the red algae *Endocladia muricata,* being more abundant at the discharge site (Table 5.6.3.). Two red algal species, *Odonthalia floccosa* and *Polysiphonia* sp., both had an average abundance of zero at the discharge sites.

Table 5.6.3. Percent Cover, Upper-middle intertidal algae, and their contribution to differences between the discharge site (Group Impact) and the control site (Group Reference)

	Group Impact	Group Reference	
Species	Av.Abund	Av.Abund	Contrib%
Endocladia muricata	30.2	24.4	19.23
Mastocarpus papillatus	28.6	8.4	14.65
Gelidium coulteri	24.7	3.8	14.51
Cladophora columbiana	16	13.43	11.79
encrusting coralline algae	1.83	10.8	6.78
Odonthalia floccosa	0	8.63	5.42
Petrocelis	2.6	7.33	4.85
Halosaccion glandiforme	6.53	2.33	4.37
Fucus gardneri	1.1	5.1	3.46
Mazzaella flaccida	0.63	5.45	3.32
Polysiphonia sp.	0	4.6	2.99

Algal species contributing the greatest difference between the discharge and control sites in the low intertidal zone was encrusting coralline red algae*,* being more abundant at the discharge site. *Odonthalia floccose*, while present at the discharge sites, was more abundant at the control sites (Table 5.6.4.). The sand castle worm *Phragmatopoma californica* had an average abundance of zero at the discharge sites.

Table 5.6.4. Percent Cover, Low intertidal algae and sessile invertebrates, and their contribution to differences between the discharge site (Group Impact) and the control site (Group Reference)

	Group Impact	Group Reference	
Species	Av.Abund	Av.Abund	Contrib%
encrusting coralline algae	60.5	19.4	26.29
Hedophyllum sessile	33.8	20.8	20.47
Odonthalia floccosa	17.1	35.5	16.23
Phragmatopoma californica	0	20	10.08
erect coralline algae	9.4	12.6	6.31
Polysiphonia sp.	0.93	8.1	4.55
Petrocelis	5.2	2.7	3.58
Endocladia muricata	0.7	4.1	3.25

Limpets (*Lottia)* and littorine snails contributed all of the difference between the discharge and control sites in the high intertidal zone (Table 5.6.5.)*. Lottia digitalis* and *L. scabra* were more abundant at the control sites, while *Littorina* was more abundant at the discharge sites.

Table 5.6.5. High intertidal mobile invertebrates (measured by count), and their contribution to differences between the discharge site (Group Impact) and the control site (Group Reference)

	Group Impact	Group Reference	
Species	Av.Abund	Av.Abund	Contrib%
Lottia digitalis	0.33	1.33	33.88
Lottia scabra	0.49	1.44	31.95
Littorina plena/scutulata	3.34	2.41	31.7

From the following table, it can be seen that limpets and littorine snails again contributed to the difference between the discharge and control sites in the upper-middle intertidal zone, as did the black turban snail *Tegula funebralis* and the murex snail *Nucella ostrina* (Table 5.6.6.).

Table 5.6.6. Upper-middle intertidal mobile invertebrates (measured by count), and their contribution to differences between the discharge site (Group Impact) and the control site (Group Reference)

	Group Impact	Group Reference	
Species	Av.Abund	Av.Abund	Contrib%
small limpets	0.63	1.29	19.72
Littorina plena/scutulata	1	0.59	19.62
Tegula funebralis	0.61	0	16.37
Lottia scabra	0.46	1.01	15.61
Lottia pelta	0.33	0.32	8.42
Nucella ostrina	0.1	0.42	7.14
Lottia paradigitalis	0	0.24	3.69

The following figures provide graphic representations of the Bray-Curtis multivariate results provided by Dr. Raimondi. Each symbol represents a quadrat sample result. Red symbols represent the west discharge (WD) and east discharge (ED) sites. Blue symbols represent the west control (WC) and east control (EC) sites. The numbers represent the tidal zone (1= high, 2= upper-middle, 3= lower-middle, 4= low) of each quadrat.

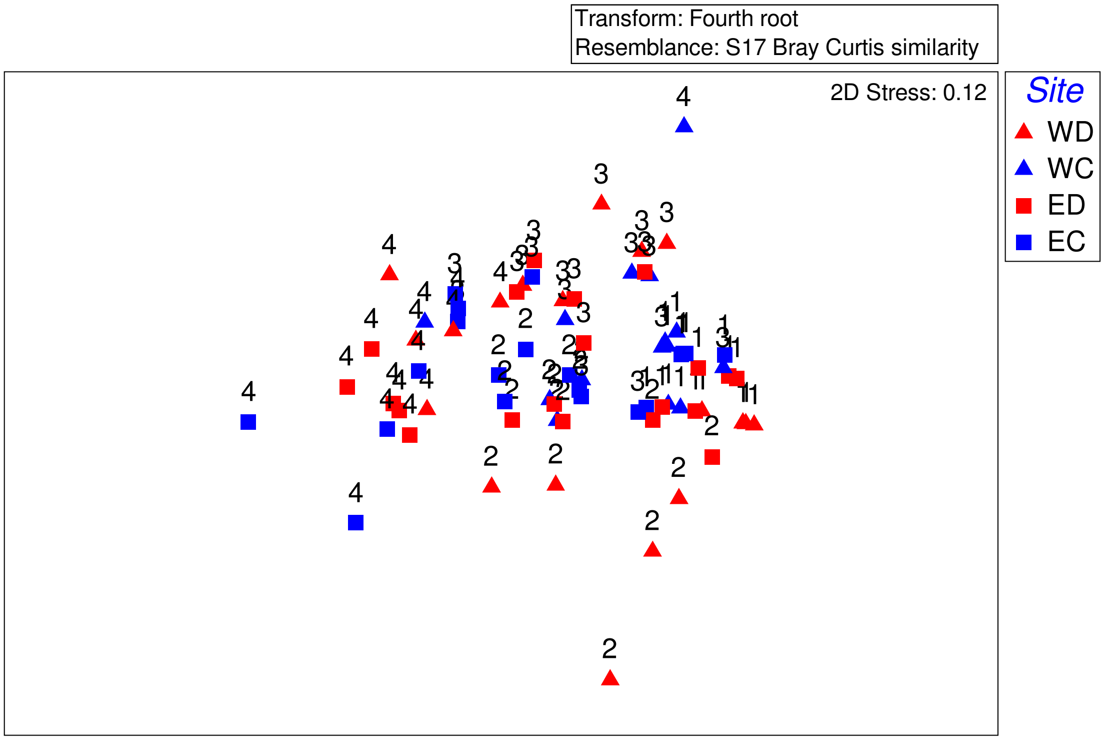

Figure 5.6.4. Del Mar Landing ASBS. Species measured by percent cover. All tidal zones (1-4) shown. WD and ED are discharge sites; WC and EC are control sites.

The above figure shows that discharge quadrats in zone 2 (upper-middle intertidal) clusters out nearer the bottom right of the graph, mostly away from the control sites from the same tidal zone.

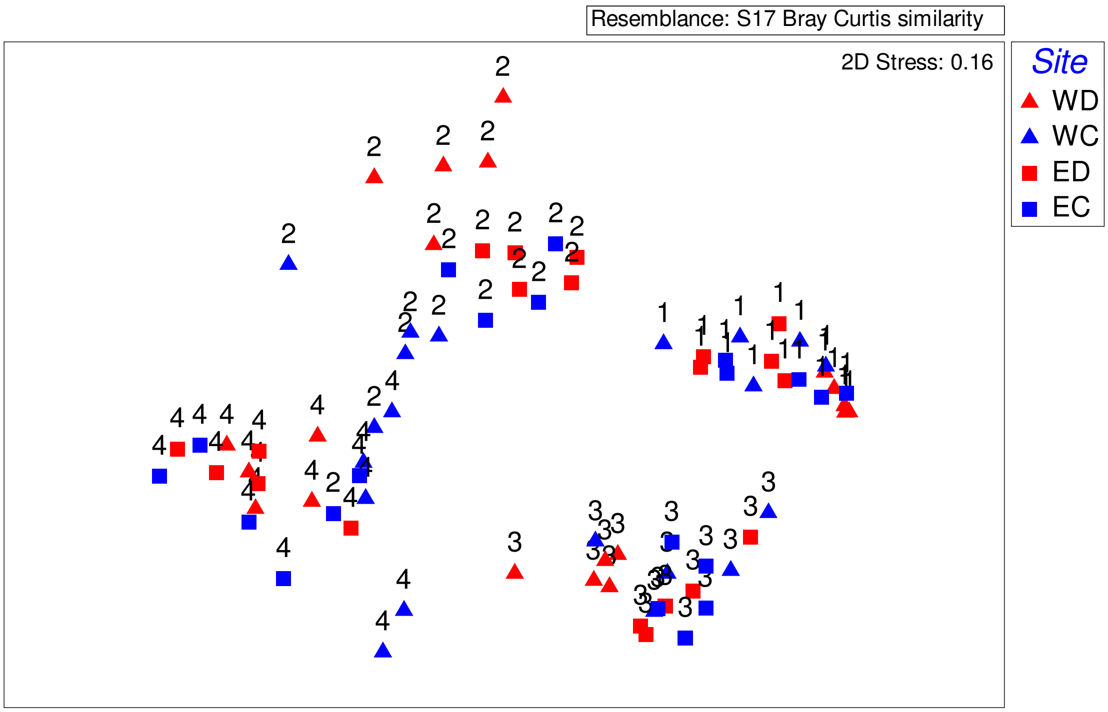

Figure 5.6.5. Del Mar Landing ASBS. Species measured by counts. All tidal zones (1-4) shown. WD and ED are discharge sites; WC and EC are control sites.

The above figure shows that tidal zones cluster together. However, note that the discharge quadrats (WD and ED) from the upper-middle tide zone tend to cluster separately at the top of the graph. While not as obvious, the discharge quadrats (WD and ED) from the low tide zone tend to clump together between two sets of control quadrats from the same tide zone.

5.6.4 - Duxbury Reef ASBS

There was one recent report available, prepared by Dr. Raimondi on July 17, 2008, for the County of Marin, Duxbury Reef (Alder Creek).

Dr. Raimondi used existing PISCO and MARINe data sets and new data in a primarily multivariate assessment of communities at a discharge site (Alder Creek) and reference areas. New data were collected using PISCO biodiversity protocols at sites arrayed in a gradient away from discharge.

Dr. Raimondi concluded that: "*There are clearly differences in the communities between Alder Creek and nearby sites. Part of this is due to differences in the geomorphology of the site, particularly the deep channel that separates the inshore from offshore reef. However, part of the difference also seems due to the presence of an input from the discharge and/or the creek that empties into the site. Based on the information collected during this survey and from the Coastal Biodiversity Surveys our assessment* *is that the differences seen at Alder creek are likely due to a combination of trampling (minor effects) and the geomorphological features (primarily fine sediments and freshwater) present at Alder Creek. Based on our surveys and reconnaissance, the effect of the input (natural or other) appears to be over a relatively small spatial scale, probably no larger than a few hundred meters along shore."*

5.6.5 - James V. Fitzgerald ASBS

5.6.5.1 <u>PISCO/MARINe (Raimondi 2006)</u>

As mentioned previously, Dr. Raimondi performed a data assessment for 8 of the 10 ASBS within the influence of Caltrans discharges. In his report (Data assessment for ASBS/Ocean Plan for Caltrans, March 12, 2006), Dr. Raimondi summarizes site characteristics and provides a brief ecological community analysis of established rocky intertidal monitoring stations. These established stations are either a PISCO or MARINe site and provides a continuum of data collected using either Community Dynamics Survey or Biodiversity Protocol. PISCO has also carried out Biodiversity surveys at Fitzgerald Marine Reserve.

James V. Fitzgerald is a gently sloping, long, bedrock reef of very low relief. The biodiversity survey (2002) found 96 species at this site, which is high for this region. Two species of special interest, owl limpets and surfgrass were found and, according to Dr. Raimondi, it is likely that abalone may also occur here. No invasive species were found in their surveys. The result of the community analysis showed that Fitzgerald Marine Reserve clustered out with a series of central coast sites, including Pigeon Point, Andrew Molera, Mill Creek, and Rancho Marino. The latter three sites are either reserves or de-facto reserves because of physical isolation. The species present gave no evidence of degradation. There are no extensive long-term data that could be used to detect change.

5.6.5.2 <u>Pillar Point Storm Water Outfall in the James V. Fitzgerald ASBS (Tenera 2007)</u>

In 2007, Tenera studied the rocky intertidal community at the US Air Force Pillar Point storm water outfall. This outfall at Pillar Point is in the southern section of the ASBS.

This report examined the Pillar Point watershed, land use, storm water discharge volumes, and the potential for water quality effect on the biota. Impacts from the main storm water outfall to the rocky intertidal habitat were quantitatively evaluated using a gradient transect method. Additionally, investigations of other relevant marine life habitats were qualitatively surveyed for potential storm water impacts. A previous study performed by Tenera in 2004 in the northern sector of the ASBS near San Vicente Creek was also evaluated in its potential relevance to storm water impacts on the intertidal life. Tenera also examined the previous State Water Board's Reconnaissance Survey performed in the 1970's (SWRCB 1979), comparing the qualitative findings of that report with the current data.

A quantitative marine survey was performed in July 2007 where the U.S. Air Force storm water outfall discharges into the James V. Fitzgerald ASBS. The primary study design was to compare the rocky bench closest to the outfall with a reference area further away from the outfall. The immediate discharge area is a 55 meters (60 yd) wide sand beach. The closest rocky habitat to the outfall is a low-lying intertidal bench rock platform that is approximately 45 degrees lateral to the initial trajectory line of outfall discharges, and is separated from the outfall by the sand beach.

Quadrats were sited along transects on the bench rock platform along a gradient distance away from the discharge. Sampling was done at increasing distances (sites) from the outfall and beach. A nearby low-lying bench rock platform, in a reference area with a sand beach backing the platform, was sampled in the same fashion for comparison. This design resulted in a cross shore approach along with the use of impact/reference areas along shore.

One limitation of the Tenera 2007 study is that the study was performed during the dry season, and it is possible that species may have recovered since the prior rain events of the previous wet season. The assessment of storm water discharge effects is limited from the study being a one-time survey of only 2 areas, and due to naturally occurring variation between sites. It is possible that a larger, more intensive sampling effort over a longer duration may detect possible storm water discharge effects. However, effects may still not be detected with additional studies without further investigation of species and their sensitivity to various constituents found in the runoff and ocean water.

Another limitation was related to the limited period covered by the survey. A one-time survey assumes that the reference area adequately represents baseline conditions and the species and patterns of abundances that would be present near the storm water outfall if the outfall were absent. While every effort was made to locate a reference area that was similar in habitat characteristics to the area sampled along the outfall transect, differences in community composition were still expected, due to the number of natural factors that can vary unpredictably over time and space and, therefore, affect the composition and spatial patterns of species abundances. Factors include wave impacts, microhabitat differences, sand scour, pre-emption of space by sand, sand burial, predation, grazing, and competition for space, to name a few.

The storm water outfall and reference transects were densely populated with a variety of species, characterized mainly by the algae and surfgrass. Invertebrates were less common. The relative scarcity of invertebrates was likely due to the abundant layer of sand covering the rocks. The influence of sand is likely year-round in the study area. The sand likely prevents many motile invertebrates from remaining firmly attached to rocks and the sand tends to smother rock boring and tube-dwelling invertebrates.

The bench rock platform nearest the Pillar Point storm water outfall and the reference platform are low-intertidal elevation platforms, and thus lack the higher elevations supporting species more characteristic of the upper-intertidal zone (e.g., rockweed communities). Species characterizing the bench rock platforms were surfgrass (*Phyllospadix torreyi*), oar kelp (*Laminaria sinclairii*), split kelp (*L. dentigera*), hollow-branch seaweed (*Gastroclonium subarticulatum,* previously *G. coulteri*), and iridescent seaweed (*Mazzaella splendens,* previously *Iridaea cordata*). All are obligate low-intertidal or low-intertidal/shallow-subtidal occurring species.

In general, Tenera found most of the species sampled to be more abundant on the storm water outfall transect than the reference transect. Analysis was primarily based on community level comparisons between impact and reference areas using multivariate techniques found in PRIMER software. This multivariate analysis of the community data did reveal that many of the differences in species abundances between transects were statistically significant. According to Tenera, the storm water outfall and reference areas were both densely populated with species indicative of a healthy marine community and characteristic of rocky habitats exposed to high wave action. There were no indications of stress to the marine community near the Pillar Point storm water outfall based on the presence of unusual species patterns.

Tenera's multivariate analysis revealed various species that were significantly different in abundance between transects. A variable abundance pattern was seen in the distribution and abundance of surfgrass (*Phyllospadix torreyi*) and oar kelp (*Laminaria sinclairii*). These two species can be common along sandy shores, and were abundant on both transects. However, where they were most abundant along the transects was different between transects. On the storm water outfall transect, surfgrass had low abundance in the sand beach-bench rock interface zone but abundant at distances further away from the outfall and sand beach. In contrast, surfgrass on the reference transect was most abundant in the sand beach-bench rock interface zone. While this may indicate that storm water can limit the abundance of surfgrass near the outfall, other factors may account for the relative lower abundance of surfgrass in the sand beach-bench rock interface zone near the outfall. Feather-boa kelp (*Egregia menziesii*) and oar kelp were relatively abundant in this zone near the outfall. Feather-boa kelp and oar kelp may have limited the potential amount of surfgrass that could have otherwise grown in that area. The differences in species abundances may have also been due to different spore and seed settlement opportunities between species and whether sand cover was a factor during the times of settlement.

While the sand beach was a large habitat type in the area, large amounts of sand also covered the bench rock platforms, entrapped at the bases of the algal branches and fronds. The algae emerging from the sand provides direct evidence that the rocks were at one time not covered by sand. The shifting sand in the area probably has a large effect in constantly altering species abundances and their distributions in the area. Any changes resulting from sand effects, such as scour and burial, could easily mask any potential effects from storm water discharges.

The State Water Board staff asked Dr. Raimondi (2008) to evaluate Tenera's report and conclusions. According to Dr. Raimondi, there is an inconsistency between the basis of the design and analysis and the conclusion. The goal of a design in the ASBS context should be to assess the possibility of impact due to discharge. This was the intent here. The conclusion of no evidence of impact, given that statistical results suggest differences between areas, suggests that the design was not adequate to test the implicit hypothesis.

Tenera also performed a qualitative survey in 2007 at the Pillar Point sector of the ASBS. The purpose of this survey was to supplement the findings of the gradient transect study performed on the bench rock platform near the main storm water outfall. This qualitative study includes the other marine life habitats in this area, including rock walls and outcroppings. Shore walk surveys were done to further characterize the marine community in the overall study region. It is important to note that, during the Tenera 2007 qualitative assessment, storm water was not discharging from the main outfall. The shore walk surveys of the Pillar Point storm water outfall area covered a shoreline distance of approximately 450 meters (492 yds) and documented a variety of species in habitats not sampled by the gradient transects. Observations were recorded and assessed for unusual patterns in species distributions in other areas that were readily apparent and could possibly be attributed to effects from storm water discharges.

All areas observed in the qualitative survey were populated by a variety of species indicative of a healthy, rocky intertidal marine community. Most of the differences between the general area of the storm water outfall transect and general area of the reference transect were in the zone where the sand beach transitions into rocky habitat. Various habitat areas, other than where the gradient transects were located, were specifically searched for sea lettuce (*Ulva* spp.) as an indication of freshwater and constituent influence. There were no areas of algal blooms that would possibly be indicative of a pollution or high nutrient influence.

Tenera stated that a discharge response can be found in the northern sector of the ASBS at the perennially flowing San Vicente Creek, where sea lettuce is found to be quite abundant, while none is found near the Pillar Point storm water outfall. The watershed of San Vicente Creek is also larger than that of the Pillar Point, with multiple land uses. The abundant sea lettuce at San Vicente Creek indicates that prolonged drainages from relatively large watersheds with multiple land uses are needed to elicit and sustain a discharge response. Discharges from the Pillar Point headland are much smaller and less frequent, and the areas drained are not used for ranching, farming, or residential living, as what occurs in the San Vicente Creek watershed. There may be a smaller likelihood that discharges from the Pillar Point storm water outfall would cause the same type of change seen at San Vicente Creek. Should such changes occur, however, they would be expected to be smaller in spatial scale and more temporary in nature.

5.6.6 - Año Nuevo ASBS

5.6.6.1 PISCO/MARINe (Raimondi 2006)

As mentioned previously, Dr. Raimondi performed a data assessment for 8 of the 10 ASBS within the influence of Caltrans discharges. In his report (Data assessment for ASBS/Ocean Plan for Caltrans, March 12, 2006), Dr. Raimondi summarizes site characteristics and provides a brief ecological community analysis of established rocky intertidal monitoring stations. These established stations are either a PISCO or MARINe site and provides a continuum of data collected using either Community Dynamics Survey or Biodiversity Protocol.

Año Nuevo is a long, gently sloping reef of moderate relief. It is comprised of sedimentary rock and sand. Año Nuevo is a UC Marine Reserve site co-administered by the State. The biodiversity surveys (2002) found 92 species at the site. In these surveys, one species of special interest was found, surfgrass, but both owl limpets and black abalone have been found in other surveys. Invasive species were not found at this site. Cluster analysis of the ASBS sites relative to a suite of reference sites in the central coast indicates some interesting patterns. Año Nuevo differs from all other sites in the region. Evaluation of the species lists and the site characteristics suggests that this is mainly due to geomorphology (mixed rock and sand). It is also possible that the site is affected directly and indirectly by the impacts of the large population of elephant seals that resides at Año Nuevo.

5.6.7 - Pacific Grove ASBS

Tenera performed "A Comparative Intertidal Study and User Survey, Point Pinos, California" (July 2003), which was submitted as part of the City of Pacific Grove's exception application. The purpose of the Point Pinos Survey was to investigate the effects of visitor use on the Point Pinos rocky shoreline located on the Monterey Peninsula, and just outside the western boundary of the Pacific Grove ASBS, and was not designed to survey the biological community at outfall locations, or the effects of discharges on the ASBS. In this report, site descriptions were compared to Point Pinos, which receives high levels of visitor use because of its scenic values and easy accessibility from roads, adjoining parking lots, and trails. One of the main attractions of Point Pinos is the rich, diverse marine life along the rocky shore. Tide pools are common in the area, and small sandy beaches also occur along the upper shore.

Five sites surveyed in the State Water Board 1979 Reconnaissance Survey Report (SWRCB 1979) were revisited in July 2002. One of the five sites was located at Point Pinos and the other four sites were situated along the shoreline between Point Pinos and Hopkins Marine Station. A species list was developed for each site by walking the area and noting all species encountered. All identifications were made in the field. In contrast, it was not clear in the original study if samples had been collected for laboratory identification. The tide level was slightly above MLLW (above the surf grass zone) during the 2002 survey. Two biologists worked separately in the search effort at each site and created a combined species list for each site. The combined search effort at each site was between 1-2 hours.

The Point Pinos report found it difficult to use the data from the State Water Board 1979 Reconnaissance Report (field survey in 1977) and current data to make direct comparisons over time, as the species list appeared to be affected by differences in the intensity of search effort, time spent at each site, tidal levels during the surveys, and detail to adequately characterize the sampling sites. It was found that the most common species were still present in all areas in both surveys, but there was uncertainty concerning the continued or past occurrences of less common species. Without the same sampling effort in both surveys, there was no assurance in whether a species was not present or simply overlooked.

The total number of algal and invertebrate species found at the Point Pinos site was similar between the 1977 and 2002 surveys. In contrast, more species were found at each of the four other sites in the 2002 survey compared to the 1977 survey, but all of the sites also had species that were unique to one or the other survey.

The appendices in the 1979 State Water Board Report contain other species lists. Tenera found that those lists could not be used for comparison with the current survey. The list of intertidal invertebrates for several areas in the State Water Board Report is based on the cumulative listings from 27 literature and museum references dating in the 1940s-1960s. The species were tabulated for large general areas (Point Pinos, Monterey Peninsula, Pacific Grove, Hopkins Marine Station). Because the collecting locations were not specified, the data were of limited use in comparing changes in faunal composition over time. Also, the number of species found in each area probably reflects the number of times each area was sampled. Tenera found, however, that Point Pinos was a popular study area between the 1940s and 1960s, as the species list for Point Pinos is the longest. Tenera concludes that, from their observations, overall diversity has not changed at the Point Pinos site since the survey in 1977.

Tenera found one conclusive difference, however, between the 1977 and 2002 surveys. This was a lack of sea palms (*Postelsia palmaeformis*) in the present survey, although they were not able to conclude whether its absence was due to visitor impacts or other causes. Although not listed as a species of special concern or of rare, endangered, or threatened status by DFG or the U.S. Fish and Wildlife Service, California Code of Regulations prohibit cutting or disturbing this species. Regardless, this species is illegally collected for consumption.

5.6.7.1 <u>Barry et al. (1995)</u>

A paper by J. P. Barry (Monterey Bay Aquarium Research Institute), C. H. Baxter (Monterey Bay Aquarium Research Institute and Hopkins Marine Station), R. D. Sagarin (Hopkins Marine Station), and S. E. Gilman (Hopkins Marine Station) was reviewed. Of 45 invertebrate species studied at the Hopkins Marine Station in the Pacific Grove ASBS, the abundances of 8 southern species increased and the abundances of 5 northern species decreased. Annual mean shoreline ocean temperatures at Pacific Grove have increased by 0.75° C over the past 60 years. This paper's conclusion was that changes in the invertebrate fauna in the rocky intertidal community between the period 1931 to 1933 and the period 1993 to 1994 indicate that species' ranges shifted northward, consistent with predictions of change associated with climate change (i.e., warming). However, State Water Board staff also reviewed other work by Schiel et al (2004), which found (for the area at Diablo Canyon) that changes in community structure were common and there was little support for the hypothesis of predictable directional changes in northern and southern species based on biogeographic models (i.e., there was no obvious connection to global warming).

The State Water Board staff asked Dr. Raimondi (2008) to evaluate Barry et al to determine if the data provided had any potential for use in the question of the effects of runoff on marine life. According to Dr. Raimondi, this paper did not provide any insight relevant to an assessment of runoff into ASBS.

5.6.8 - Carmel Bay ASBS

A report by Dr. Richard Ford, dated April 30, 2005, was reviewed. There were two parts to the report. Fieldwork was performed in southern California in the Irvine Coast ASBS, and subtidal survey data from other reports [not Dr. Ford's original data but rather field work by Dr. Michael Foster (Moss Landing Marine Lab)] in Carmel Bay were assessed. The connection between the Irvine Coast work and the assessment of dive survey data from the Carmel Bay study is that both ASBS were adjacent to golf courses. Dr. Ford's report concluded that runoff caused no discernable impact on marine life in the Carmel Bay ASBS.

The State Water Board staff asked Dr. Raimondi (2008) to evaluate this report regarding Carmel Bay ASBS. According to Raimondi, there is no direct support for Dr. Ford's conclusion. The design is inadequate for the determination of impact (or lack of impact) from golf course runoff in Carmel Bay.

5.6.8.1 PISCO/MARINe (Raimondi 2006)

In his report "Data assessment for ASBS/Ocean Plan for Caltrans, March 12, 2006", Dr. Raimondi summarizes site characteristics and provides a brief ecological community analysis of established rocky intertidal monitoring stations. Two MARINe/PISCO sites within the Carmel Bay ASBS are adjacent to Caltrans roadway drainages: Carmel Point and Stillwater Cove. Carmel Point is a long, gently sloping reef made up of bedrock and boulders. It is a high relief reef surrounded by bedrock, boulders, and sand. Dr. Raimondi has been following black abalone for the last two years at this site because it has a healthy abalone population, which is increasingly uncommon with the progression of withering disease. Dr. Raimondi does not do biodiversity or community dynamics surveys at this site.

Stillwater Cove is a gently sloping bedrock reef of intermediate length. It is a high relief reef surrounded by other bedrock reefs and sandy coves. Dr. Raimondi conducts biodiversity surveys (2001, 2005), abalone surveys (since 2001), and community dynamics surveys (since 2000) at this site. Ninety species were found at this site and species trends and abalone populations appear healthy. Three species of special interest have been found at this site: abalone, owl limpets, and surf grass. Sea palms are not found here because the site is protected from high wave energy. No invasive species have been found at this site. Based on cluster analysis, Stillwater Cove is similar to a site to the south, Point Sierra Nevada. These two sites are then most similar to Point Lobos, which makes sense given the proximity of Stillwater Cove to Point Lobos.

5.6.9 - Point Lobos ASBS

In his report "Data assessment for ASBS/Ocean Plan for Caltrans, March 12, 2006", Dr. Raimondi summarizes site characteristics and provides a brief ecological community analysis of established rocky intertidal monitoring stations. These established stations are either a PISCO or MARINe site and provides a continuum of data collected using either Community Dynamics Survey or Biodiversity Protocol.

Point Lobos is a marine reserve and one of the most protected sites along the central coast. Point Lobos is a gently sloping, long, bedrock reef that has high relief and which is topographically complex. The biodiversity surveys (2001, 2005) found 90 species at this site. In addition, community dynamic and abalone surveys have been performed at Point Lobos since 1999. Community trends and abalone populations appear healthy at this site. Three species of special interest have been found at Point Lobos: abalone, owl limpets, and surfgrass. According to Dr. Raimondi, it is very likely that sea palms may occur at this site at the more exposed locations. Based on cluster analysis, Point Lobos differs from all other sites along the central coast. Looking at the species list and site characteristics, the separation of Point Lobos seems to be due to its topographic complexity and high relief. Also, the species composition of this site is not suggestive of a degraded state.

5.6.10 - Julia Pfeiffer Burns ASBS

"Side-casting" is the movement of sediment down-gradient off of a road. Side-casting that result in sediment deposition into the ocean is considered a waste discharge regulated under the Ocean Plan and prohibited in ASBS.

A side-casting event was conducted by Caltrans after a landslide resulted from heavy rains in the winter of 1982-83; the landslide closed Highway 1 for almost 2 years. The natural portion of this slide deposited some material on the beach, but the majority of the slide was on the upper hillside and not into the ASBS. The road clearance work resulted in moving over 3 million cubic meters of soil onto the shore, burying large portions of the ASBS intertidal and subtidal habitat. The manipulation of the McWay landslide produced an extreme physical and ecological event, with severe ecological impacts. The manipulated slide material covered about 23,700 square meters of intertidal boulders, cobble, and gravel beach. The natural beach was completely buried under the side-cast slide material. The waterfall on McWay Creek once flowed into a rocky cove populated by diverse intertidal and subtidal marine life. Now that cove is buried by a sandy beach. The adjacent subtidal habitat was also buried out to about 20 meters water depth, burying natural rock pinnacles (originally in water depths of 20-25 meters) and fine sand habitat.

The subtidal slide material is more prone to movement by wave action than the previous subtidal fine sand habitat. In addition, none of the slide sediment above the high tide line had been adequately stabilized with terrestrial vegetation, and there has been further erosion of the slide material (257,000 cubic meters) below the highway and into the ASBS. Aside from the obvious effects of direct burial of the affected natural intertidal and subtidal communities, scouring by coarse sediments (sand scour), deposition of fine sediments, and increased turbidity are an ongoing result of the side-casting event.

Starting in 1985, the Benthic Lab at Moss Landing Marine Laboratory has investigated the movement of this sediment into the ocean and its resulting impacts on the near shore marine communities. Surveys were performed to assess biological and physical conditions in the slide affected areas, which include terrestrial, intertidal, and subtidal zones. Natural rocky habitats around the slide have been shown to be disturbed by sand scour, with the vertical pinnacle wall communities being radically modified. Barnacle (more tolerant of scour) cover is higher, and cover by sponges, tunicates, and anemones is lower than what would be found naturally. Barnacle recruitment has spread into the kelp forest, and impacts of fine sediment and turbidity affect under-story algae in the kelp forest (Oliver, 1998).

The Monterey Bay National Marine Sanctuary funded PISCO to assess effects of erosion and landslides along the Big Sur Coastline. It is clear, from that more recent work, that there were pronounced and long-lasting effects of the material deposition at the McWay slide (Raimondi, 2008).

In his report (Data assessment for ASBS/Ocean Plan for Caltrans, March 12, 2006), Dr. Raimondi summarizes site characteristics and provides a brief ecological community analysis of established rocky intertidal monitoring stations. These established stations are either a PISCO or MARINe site and provides a continuum of data collected using either Community Dynamics Survey or Biodiversity Protocol. Partington Point (also called Pardington Point) is a short, steep, bedrock reef of moderate relief. This reef is one of the characteristic steep reefs of the Big Sur coast that are unlike most other central California reefs (more like the reefs of the Gulf of the Farallones). Two species of special interest, abalone and owl limpets, are found at Partington Point. No invasive species have been found at this site. Species richness of the ASBS sites in the central coast region (Año Nuevo, Point Lobos, Julia Pfeiffer Burns at Partington Point, and Carmel Bay) ranges from 75-92 species. The lowest value, 75, was found at Partington Point, which is a very small reef. Still, this site is not atypical when compared to a suite of reference sites in the central coast. Based on cluster analysis, Partington Point is similar to another Big Sur site, Lucia, which has similar geomorphology.

5.6.11 - Laguna Point to Latigo Point ASBS

5.6.11.1 <u>PISCO/MARINe (Raimondi 2006)</u>

Dr. Raimondi performed a data assessment for 8 of the 10 ASBS within the influence of Caltrans discharges. In his report (Data assessment for ASBS/Ocean Plan for Caltrans, March 12, 2006), Dr. Raimondi summarizes site characteristics and provides a brief ecological community analysis of established rocky intertidal monitoring stations. These established stations are either a PISCO or MARINe site and provides a continuum of data collected using either Community Dynamics Survey or Biodiversity Protocol.

Old Stairs is a reef composed of bedrock, boulders, and sand. It is a relatively long, gently sloping reef of moderate relief. It is surrounded by sand and a few other bedrock reefs. Dr. Raimondi found 54 species at Old Stairs in their biodiversity survey (2001). Old Stairs is also a site that has been monitored using community dynamics surveys since 1994. One species of special interest, the owl limpet, is found at Old Stairs. Abalone has long been absent from this region. Surf grass is found nearby. No invasive species have been found at Old Stairs. In the community analysis with other nearby sites, Old Stairs groups out with Mussel Shoals in a group distinct from other southern California reefs. Species diversity and trends are typical for southern California and suggest anthropogenic impact (collection, trampling, and other more indirect effects). Number and size distributions of key species (like sea stars and owl limpets) are lower than would be expected in a protected area.

5.6.11.2 Summary of Biological Resources of the ASBS (Ambrose & Lee 2007)

The Ambrose & Lee 2007 report was performed for the City of Malibu and summarizes information from previous field studies conducted at the Laguna Point to Latigo Point ASBS; it also presents a summary of a collection of recent data from 1994 through 2006.

The biological community at Paradise Cove was selected by Ambrose and Lee as the place most representative of relatively undisturbed conditions within the ASBS. Paradise Cove can be compared to other southern California study sites using a statistical clustering technique. Dr. Raimondi had performed such comparisons among a set of MARINe sites sampled in southern California. In his analysis, the rocky intertidal near the community at Paradise Cove was reported to be most similar to the community at Alegria, a site in Santa Barbara County south of Point Conception that has little human disturbance. However, possible disturbance from storm water or other anthropogenic discharges effects are not part of the MARINe study site design or analysis. Other sites that clustered with Paradise Cove were Arroyo Hondo and Coal Oil Point in Santa Barbara County, and Mussel Shoals and Old Stairs in Ventura County. General observations by Ambrose and Lee suggest that Paradise Cove historically supported and continues to support a relatively rich, rocky intertidal community compared to other intertidal reefs in the ASBS.

Ambrose and Lee concluded that the lack of consistent, quantitative data for sandy beach communities makes it difficult to compare Paradise Cove (the selected “reference” site) to other areas within the ASBS. Most notably, there are considerable differences among different beaches. For example, in the 1970’s, Morin and Harrington (SWRCB 1979) reported higher diversity of macroinvertebrates on sandy beaches around Paradise Cove compared to Zuma Beach, which is up coast from (west of) Point Dume. Morin and Harrington attributed this to differences in physical factors, such as exposure and influence of beach wrack. Dugan et al (2003) also emphasized the influence of different physical factors and wrack. Since these differences still exist throughout the ASBS, Ambrose and Lee anticipated that there will still be significant differences in the sandy beach communities on the various beaches. When comparing Paradise Cove as a reference area with few discharge sites, the potential for impacts to the marine life, and the other selected research areas within the ASBS, Ambrose and Lee conclude that there is insufficient data to determine if there has been general degradation in the ASBS over the past 30 years, or whether certain sites have changed more than others. In addition, there is insufficient data to link discharges to the condition of the sandy beaches presented in this report.

Ambrose and Lee recommended that an intertidal marine life study be designed to encompass gradient transect sampling at the two representative storm water discharge sites (MUG 232 and MUG 430, SCCWRP discharge data ID points) and at the selected reference location. These discharge sites were selected to be representative of the City of Malibu's storm water flows. In addition, the reference location was selected at a site between MUG 375 and MUG 386. A transect survey would provide data which can then be analyzed for differences in species composition and abundance between sites; and further analyzed for differences in quadrats and their physical distance from the discharge source.

5.6.12 - Irvine Coast ASBS

5.6.12.1 <u>PISCO/MARINe (Raimondi 2006)</u>

Dr. Raimondi performed a data assessment for 8 of the 10 ASBS within the influence of Caltrans discharges. In his report (Data assessment for ASBS/Ocean Plan for Caltrans, March 12, 2006), Dr. Raimondi summarizes site characteristics and provides a brief ecological community analysis of established rocky intertidal monitoring stations. These established stations are either a PISCO or MARINe site and provides a continuum of data collected using either Community Dynamics Survey or Biodiversity Protocol.

This ASBS is co-located with Crystal Cove State Park. Other surveys have been done at this site including a number of projects from faculty and students at California State University, Fullerton. This ASBS, like most sites in Southern California, is heavily visited and there really is no expectation of areas not being impacted (Raimondi 2007).

The reef at Crystal Cove is composed of bedrock and boulders. It is a relatively long, gently sloping reef of low relief. It is surrounded by areas of bedrock, boulders, and sand. Dr. Raimondi found 114 species at this site in their biodiversity surveys (2001, 2003, 2004), which is a high number for this region. Community dynamics surveys have been conducted at this site since 1995. Two species of special interest are found at this site, owl limpets and surf grass. Abalone has long been absent from this region. The invasive species *Sargassum muticum* and *Caulacanthus ustulatus* are both found at Crystal Cove. In the community analysis with other nearby sites, Crystal Cove groups with Dana Point and Scripps (Dike Rock), suggesting its similarity to 2 relatively nearby sites. Species diversity suggests anthropogenic impact (extraction, trampling, and other more indirect effects). Number and particularly size distributions of key species (like sea stars and owl limpets) are lower than would be expected in a protected area.

5.6.12.2 MBC Applied Environmental Sciences (MBC 2004)

One report for the Crystal Cove Park site within the Irvine Coast ASBS, "Characterization of the Rocky Intertidal Crystal Cove State Park," was prepared for DPR by MBC Applied Environmental Sciences of Costa Mesa, CA (MBC 2004).

The study was designed to characterize two intertidal areas of Crystal Cove State Park, at Treasure Cove and Reef Point, during the spring and fall of 2003. This MBC study was not designed to address the question of the effects of runoff on ecosystem health. Still the results are valuable and are described below to explain the status of intertidal life in the Irvine Coast ASBS.

This study was designed to duplicate methods utilized previously in the area by Valencic in 1986. Like Valencic's previous survey, this 2004 study was designed to assess seasonal variation in the intertidal community of Crystal Cove during one year. This report compares the results of the spring and fall 2003 intertidal surveys at two sites in Crystal Cove State Park, and to a lesser extent compares these results to those of the 1986 survey and other work in the area. Four tidal communities were examined at each reef: low, mid, upper-intertidal, and mussel zones. Each tidal level was identified by characteristic species: the low zone was characterized by low algal turf and coralline algae, the mid zone by rockweed, the upper-intertidal zone by barnacles and littorine snails, and the last by mussel communities.

The study involved the use of rectangular quadrats sited along pre-established transect lines. The location of each quadrat was recorded as the transect line identification, the distance in meters along the transect, up coast or down coast direction, and perpendicular or parallel placement of the quadrat relative to the transect line. Quadrat locations were initially chosen in spring 2002 as representative of a tidal level/community in the area. Five replicate quadrats were selected for each tidal level at each reef site. A PVC frame with an inside diameter of 50cm x 75cm was placed on the sample site. At least two digital photographs were taken of each quadrat. In the laboratory, the photoquadrats were examined on a desktop computer monitor. Each photoquadrat picture was converted to Photoshop (PSD) file format, which allow an additional visual gridline layer to be added to each photo. The gridlines divided each photo into 10 equal sections.

Percent coverage and species identification for each quadrat were determined from a single photo, with the additional photos reviewed to assist with identification and to ensure that all species were noted. In several cases, two photos of the same quadrat were examined and analyzed independently as a quality check of methods. Identification was made to the lowest possible taxonomic level, with the exception of two similar, coexisting red algae species, *Gelidium* and *Pterocladia*, which were collectively identified as algal turf. Species were enumerated as percent cover.

Treasure Cove is located at the northern end of the park and has poor public access except during low tides. The upper rocky intertidal at Treasure Cove is characterized by relatively low-lying, flat bedrock which occasionally is covered or scoured by the coarse beach sands. The mid intertidal at Treasure Cove is characterized by bedrock, which extends seaward as exposed craggy ridges with fairly sharp relief and numerous channels and pools to the down coast side of the area; while more centrally, ridges are fewer and most of the mid-tidal-level fauna is found on bedrock and boulder outcroppings within numerous shallow pools. The low intertidal at Treasure Cove is typified by low relief, flat bedrock benches. Offshore of this area are large exposed and mussel covered bedrock outcrops that are accessible only on very low tides on calm days. The mussel sites at Treasure Cove are reoccupied plots established in 1986 on the flat top of the rocky point to the down coast side of the area.

Species richness generally increased in the Treasure Cove area between spring and fall 2003, except in the upper level plots that had one fewer species in fall. Total percent cover at Treasure Cove was also higher in the fall, even though percent cover of the lower level plots in fall was nearly 20% less than in spring. In total, 20 species covered 54% of the area in spring, and 24 species covered 56% of the available substrate in fall. While a core group of dominant species was found in the area during both seasons, the contribution of those species differed notably between seasons. Algal turf, the dominant species in the low and mid level plots and present at all levels in spring, was reduced considerably in the area by fall. Coralline alga, present in low abundance at the low and mid-levels in spring, replaced algal turf as the dominant species in the low and mid levels and was present at all levels in fall. Coralline alga and algal turf are generally found in very similar conditions at Crystal Cove, on fairly flat surfaces in the low intertidal or in areas with pooled water. The decline of algal turf throughout Treasure Cove, along with a reduction in total coverage by all species at the low-level plots, suggests that the algal turf decline was due to seasonal variations such as water and air temperature and day length, but not competition from other species. The increase in coralline alga in the Treasure Cove area in fall appears to be a result of increased availability of suitable habitat.

Reef Point is the southernmost rocky intertidal reef at Crystal Cove State Park. This area is near two pedestrian trails and is easily accessible to the public. The rocky intertidal at Reef Point is composed of three slightly separated rocky structures. The reef farthest down coast is a narrow, high relief rock ridge that runs offshore of the beach. Slightly up coast of this ridge is a relatively low relief flat, rocky bench. Continuing up coast is the main Reef Point structure, where sampling for this project was undertaken. Attempts to relocate the 1986 plots were unsuccessful, so all quadrats were located along the new transect lines. Exposed ridges support the upper level and mussel communities examined in this study. Farther offshore, the mid and low levels are characterized by a relatively flat area with exposed bedrock and boulders interspersed by shallow pools, channels, and sandy areas. Slightly offshore of the lower intertidal areas are larger, high relief rock structures, including several large offshore rocks. The intertidal area at Reef Point is exposed to waves from both the south and northwest. Sand movement in the area is greater than at Treasure Cove, and parts of the low relief areas, particularly on the up coast side of the reef, are subject to burial by sand.

Species richness was slightly higher in spring than in fall at Reef Point, although the low and mussel-level plots had slightly more species in fall. Overall percent cover was very similar between seasons, with a slight increase at all but the mid-level plots in fall. In total, 24 species covered 68% of the area in spring, and 22 species covered 69% of the available substrate in fall. The contribution by the dominant core species was found to be fairly similar during both seasons. Algal turf was somewhat reduced in the area in fall, but not as noticeably as at Treasure Cove. At the low intertidal quadrats, increase in percent cover of coralline alga in fall was about the same as the reduction in algal turf; while in the mid levels, increases in coralline alga, rockweed, and bare substrate were similar to the reduction in percent cover of algal turf. This may suggest that a local, possibly seasonal, reduction of algal turf allowed the expansion of other species.

In fall, several of the intertidal quadrats at Reef Point were partly inundated by sand. Although sand was also present in some plots in spring, it was not as prevalent as in fall. Some organisms were covered to an extent that could impair their survival. For this reason, percent cover of sand was noted for the fall Reef Point surveys. The amount of sand was highly variable and sand was noted in some quadrats at low-, mid- and upper-intertidal levels. Mussel plots on the bedrock ridges were above the level of sand inundation, even during the fall sampling. Coverage of sand ranged from relatively low at three low-intertidal plots to 100% cover at one upper intertidal photo-quadrat. Excluding the mussel level, sand cover averaged about 20% at Reef Point in fall.

Seasonal totals from both sites at Crystal Cove State Park suggest that the intertidal biota remains fairly consistent between seasons, with 27 species covering 61% of the available substrate in spring and 26 species covering 63% of the substrate in fall. However, specific tidal levels show notable differences between spring and fall. Percent cover at low level plots in the fall were reduced by about 10% from spring values, while species richness was higher. This is likely a result of the general reduction in algal turf with a resultant increase of availability of substrate as mentioned previously. At mid-level quadrats, a slight increase in percent cover in fall accompanied a slight decrease in species richness. Both cover and richness were very similar between seasons, making the mid-intertidal the most seasonally consistent level. In upper-intertidal quadrats, the level with the lowest total percent cover during both seasons, species richness decreased from 19 species in spring to 15 species in fall, while average percent cover increased by about 5% during that same period. The increase in percent cover at the upper level plots appears to be related to an increase in white acorn barnacles at Reef Point, and coralline alga at Treasure Cove. In the mussel-level plots, six more species were found in fall than in spring. On average, 10% more of the available substrate was covered in fall, with most of the additional cover accounted for by increases in California mussel. When results from both seasons are combined, Treasure Cove and Reef Point both were found to support 27 intertidal species, although cover of available substrate was about 13% higher at Reef Point. Cover at all levels was greater at Reef Point, particularly in the upper-intertidal, with about 30% more substrate covered than at Treasure Cove. This difference is likely related to scouring by coarse sand noted in the upper-intertidal at Treasure Cove. At Reef Point, the finer grained sand that inundates the site does not seem to scour the rock substrate clean as it does at Treasure Point.

Large and relatively well-protected tidal pools at Treasure Cove support populations of conspicuous, and occasionally numerous, large intertidal invertebrate species, including sea urchins (*Strongylocentrotus* spp), giant keyhole limpets (*Megathura crenulata*), California sea hares (*Aplysia californica*), and sea cucumbers (*Parastichopus* spp.), while hermit crabs and snails are common in the rocky pools. Difficult public access to the area helps protect these species from being harassed or taken by park visitors. However, the upper-intertidal level at Treasure Cove, the most depauperate of the quadrats surveyed during this study, are occasionally scoured by coarse sand, while the rocky substrate in the mid-tide level tends to be craggy with notable vertical relief. These physical characteristics differ from those found at the same tidal levels at Reef Point, and likely contribute to the differences between areas at those levels. The physical characteristics of the low-intertidal and mussel community plots at Treasure Cove are fairly similar to those at Reef Point, and, consequently, these levels are the most similar between the sites. At Reef Point, while the hard substrate is well populated, pools are generally sandy and smaller than at Treasure Cove, and with easy public access, large species are rare.

In 2003, species richness appeared to be lower than had been noted in previous studies in the Crystal Cove area; however, species composition and especially the dominant species were similar to those in previous surveys in the area (MBC 1971, Valencic 1986). In comparison to the results of the 1971 study, which included surveys at Reef

Point, species richness was notably lower. However, the earlier study conducted both in situ investigations and intertidal scrapings. Differences in sampling methods may account for the disparity in results. In the 1986 project, results were not well quantified for the intertidal survey, although Valencic's descriptions of the communities at both areas are similar to those found in the recent study. The low intertidal in the Valencic study seemed to be at a slightly lower tidal level than during the current study, judging by the presence of *Phyllospadix*, *Egregia*, and other fairly large plant species. Although occasionally found in the current 2003 field work, these species are much more common slightly lower in the intertidal than in areas surveyed in this survey, although observations outside of this study may suggest that presence of these larger plant species is seasonally variable at the low-tidal level.

Overall, Shannon-Wiener species diversity (H') for all surveys and tidal levels combined was 1.91, with the highest diversity (1.99) for results of the combined fall survey. Diversity was consistently lowest at the low-tidal level stations and tended to be highest at the upper-tidal level on most transects, although not notably higher than at mid or mussel quadrats. Overall, diversity with all tidal levels combined was generally similar to values found at mid, upper, or mussel zones.

The seven most abundant species (each of which covered 1% or more of the area during all surveys) together occupied 58% of the available intertidal substrate at Crystal Cove State Park. The remaining 25 species collectively occupied another 4% of available substrate. Algal turf (*Gelidium/Pterocladia* spp) was the most abundant taxa, covering an average of 26% of the available substrate during both seasons at the two sites. California mussel (*Mytilus californianus*) was the next most abundant species, accounting for about 11% of the total coverage in the quadrats, followed by the calcareous red coralline alga *Corallina* spp with 7% of the cover, the white acorn barnacle (*Balanus glandula*) and the tar-spot alga (*Ralfsia* spp.) with about 5% each and the aggregating anemone (*Anthopleura elegantissima*) and rockweed (*Silvetia compressa*) each covering about 2% of the total available substrate. Two taxa, algal turf and tar-spot alga, were the only species to occur in all tidal levels at both sites during spring and fall. Algal turf was more abundant at all levels during the spring surveys, while most other species were similarly abundant between seasons or were slightly more abundant in fall.

A dendrogram was constructed based on the percent cover for each species at each site. The 16 sites (two seasons, two locations, and four levels) fell into three groups based on community composition and abundance. Tidal level appeared to be the most important determining factor, with all low intertidal sites found in Group III and all mussel sites falling into Group II. Site location was the next most important factor, with all Reef Point upper quadrats and spring mid-level quadrats grouping with the mussel level in Group II, and both Treasure Cove upper quadrats and spring mid level falling into Group

III with the low- intertidal sites. Season appeared to be the least important factor. Group I, the most dissimilar from the other groups, contained only one site, the fall Treasure Cove mid level. Relative percent cover of the dominant alga species, algal turf and coralline alga, at the Group I site differed notably from that at any other site in the study area. Site clustering was strongly related to relative percent cover of California mussels at each site. At Group II sites, California mussel covered at least 3.5% of the available substrate, while at Group I and III sites California mussel was absent, or occurred only in low abundance (MBC 2004).

5.6.12.3 Ford et al. (2007)

This report was prepared for the Irvine Company in April 2007 by Richard F. Ford (San Diego State University and Hubbs-Sea World Research Institute), Barbara B. Hemmingsen (San Diego State University), Michael A. Shane (Hubbs-Sea World Research Institute), Eric Strecker (GeoSyntec Consultants, Inc.) (This report was referred to earlier in the context of Carmel Bay ASBS. However, here only the applicability of fieldwork performed in the Irvine Coast ASBS is considered.).

This was a comprehensive report that evaluated water quality, subtidal habitats, and the intertidal zone. For intertidal communities the goal was to conduct quantitative marine ecological studies of benthic invertebrates, algae, and surf grass epiphytes in the rocky intertidal zone at the best attainable reference site (Emerald Bay) and at sites influenced by runoff from Muddy and Los Trancos Canyons. In addition effort was made to compare and evaluate these together with the corresponding water quality information to assess similarities and differences among sites.

Using photoplots and on-site surveys, five species groups were sampled: (1) the *Anthopleura elegantissima* and associated species; (2) *Mytilus californianus* and associated species; (3) Anthopleura sola and associated species; (4) algal turf species; and (5) barnacles (Balanus glandula, Chthamalus dalli and C. fissus). The major conclusion was that there is no evidence of impacts related to discharge.

State Water Board staff requested Dr. Raimondi to review the Ford et al work as it relates to Irvine Coast ASBS. According to Dr. Raimondi (2008), this was a very difficult report to assess. In Dr. Raimondi’s opinion, the authors did not rigorously test the hypothesis that reference and control sites differed in their biological communities. They did test whether there were long or short-term trends in species numbers (cover, abundance, etc.) that differed between reference and impact locations. The underlying basis of the long-term hypothesis was not supported. Here the idea was that evidence of an impact would be manifest in a trend at the impact sites relative to the reference site. This could indicate increasing degradation at the site. An alternative is that the community at the impact site(s) is in steady state, yet still degraded. In such a situation, no trend would occur. In addition, there was no assessment of the community. Such assessments are often more sensitive than species-specific assessments. Finally, this design rests on the adequacy of the reference site. In southern California, the selection of a reference site is difficult and an alternative approach involving a series of possible reference sites could have provided a more robust context for the results. Despite the stated short comings, Dr. Raimondi stated that the Ford et al study was otherwise of very good quality.

5.6.13 - La Jolla ASBS

As part of their exception application, the City of San Diego included four recent reports that pertain to the La Jolla ASBS. Two of these reports were “Ghost Forest in the Sea: The Use of Marine Protected Areas to Restore Biodiversity to Kelp Forest Ecosystems in Southern California” (Parnell et al. 2005a) and “Effectiveness of a Small Marine Reserve in Southern California” (Parnell et al. 2005b).

Recent subtidal habitat surveys, such as the “Effectiveness of a Small Marine Reserve in Southern California“ (Parnell et al. 2005b), provides new data not otherwise performed since the Kobayashi ASBS Reconnaissance Surveys (Kobayashi et al. 1979) which surveyed the conspicuous species in the kelp-forest, submarine canyon, and boulder-reef habitats of the San Diego-La Jolla Ecological Reserve. The Kobayashi surveys did not provide detailed baseline data necessary for a temporal comparison, but this Parnell et al report conducted inside/outside comparisons among similar microhabitats that were discriminated quantitatively. This ensured that inside/outside comparisons were conducted between similar habitats, increasing the likelihood that differences were due to the protection within the Reserve.

This work by Parnell was not designed to address the question of the effects of runoff on subtidal ecosystem health. Still the results are valuable and are described below to explain the status of subtidal life in the La Jolla ASBS.

The kelp habitat in the reserve is characterized by reefs, sharp vertical relief, crevices and overhangs, and moderate levels of sand. The entire La Jolla kelp forest was divided into squares of 250 meters on each side; surveys were conducted using band transects placed randomly within a grid. At least two transects were conducted within each square. Habitat parameters included depth measurements and estimates of sharp vertical relief within 1 meter of the transect line at every 1 meter interval mark, substrate type (sand, bedrock, rock, cobble), and algae every 0.5 interval mark, and the presence/absence of major benthic features (ledges, crevices, overhangs) along 5 meter sections. Sixteen transects were conducted within the single grid box located in the kelp habitat within the reserve. The algal species that distinguished this habitat from other areas within the kelp bed were *Egregia menziesii, Eisenia arborea, Cystoseira osmundacea, Desmerestia spp*., and turf-forming red algae.

For kelp habitat, inside/outside density comparisons revealed significantly higher densities of male and female sheephead, rock scallops and red urchins inside the reserve. Densities of lobsters were nearly significantly greater inside the reserve. Of the fishes, only male sheephead displayed size differences between the reserve habitat and similar habitat outside. Overall, Parnell found the results to indicate that the reserves provide protection only for species that are strictly residential or sessile. Parnell found that historical comparisons of densities in the kelp habitat inside and outside the reserve indicate alarming declines in many fished species inside the reserve: lobsters, green abalone, pink abalone, octopus, kelp bass, and scorpionfish (*Scorpaena guttata*), whose mean densities have sharply declined.

In the submarine canyon habitat, vermilion rockfish and male sheephead appear to be protected well. Both species were observed in significantly higher abundances in the La Jolla branch of the La Jolla underwater canyon located inside the reserve, than the Scripps branch of the canyon located outside. No size data are available; however, they are probably the only populations of large individuals of these species remaining in the La Jolla area.

The surveys in the boulder-reef habitat were specifically targeted at green abalone for logistical reasons. However, Parnell commonly observed several very large lobsters in the northeastern shallows of the reserve. Individuals of this size outside the reserve are very rarely observed; therefore the reserve may be protecting some resident lobsters. Further evidence of this is the observation that lobster traps are still common at the western margin of the reserve late in the lobster season.

Parnell counted 33 species of invertebrates and 27 species of fish in the band transects. Of these, only the species currently or historically targeted for commercial or recreational harvest were included in the inside/outside comparison.

Inside/outside reserve comparisons were only possible for seven species of animals. These comprised of kelp bass, barred sand bass, male and female sheephead, red urchins, spiny lobster *Panulirus interruptus*, rock scallop *Crassedoma giganteum,* and pink abalone *Halliotis corrugata*. There were not enough individuals of other target species to conduct statistical comparisons. The results indicate that individual species' comparisons were significant ($\alpha = 0.05$) for red urchins, rock scallops, and male and female sheephead, whose densities were all higher in the reserve. Adult sea urchin populations were significantly larger inside the reserve. Smoothed size-frequency distributions of red and purple urchins show differences that probably reflect fishing pressure on red urchins outside the reserve.

In general, the results of the inside/outside comparisons and the comparisons with historical data yielded four general conclusions: (1) The Reserve at the La Jolla ASBS appears to protect only a few harvested species, those that are sessile or highly residential, suggesting that the reserve is too small; (2) Comparisons with historical data indicate that most harvested species in the reserve, even some species for which reserve effects were observed, have declined seriously since 1979; (3) Green abalone in the boulder-reef habitat, red urchins in the kelp habitat, and vermilion rockfish and sheephead in the canyon habitat displayed large individuals in higher densities inside the reserve than outside; and (4) Historical data are important in determining reserve effectiveness when baseline date are lacking because they provide a historical perspective with which to gauge inside/outside comparisons.

5.6.14 - San Nicolas Island & Begg Rock ASBS

One report was available, the Biological Survey Report prepared by Merkel & Associates (April 2007), for the Navy's exception application for (SNI. Quantitative intertidal and subtidal biological surveys were performed at representative discharge sites and at two reference locations. This report also includes biological survey work previously performed by other researchers and provides a comprehensive assessment of the various subtidal and intertidal "eco-regions" of SNI.

Sampling stations were determined by conducting a reconnaissance of each location and selected based on several criteria including representation of the general area, access, unexploded ordinance (UXO) avoidance, operational safety, proximity to observed or expected runoff, proximity to sensitive wildlife, and whether or not there is a habitat area of sufficient size to sample.

Two metrics were derived from these surveys: (1) number of taxa and (2) abundance or percent cover. Since there were no benchmarks available for the metrics, comparisons were made to reference conditions within an associated island eco-region. Based on historical data, these community measurements are highly variable. Merkel and Associates considered differences of 50% in the number of taxa or abundance/cover between any two sites to be in the realm of natural variation. If a metric measured at a station was lower by 50% or more than the associated reference station, then that metric was flagged. When one or both metrics at a station were flagged, the biologist considered substrate data, historical data if available, looked at results of the receiving water and sediment measurements for causal relationships, and used best professional judgment to determine if intertidal or subtidal habitats required additional evaluation. State Water Board staff disagrees with this approach using the 50% criteria. A difference of 50% is an inadequate measure of differences between impact and reference sites; not supported by peer reviewed literature.

Graphs were prepared for species or taxonomic groups that were relatively abundant, and in some instances, species were placed into taxonomic groups for graphing purposes. Summary tables were prepared for species or taxonomic groups that were not relatively abundant or common. In addition, a species list was developed from this and previous surveys.

Results indicated a high degree of biological variability in the intertidal and subtidal zones around SNI, possibly due to differences in substrate type and coverage such as cobble, boulder, bedrock, or sand. Generally, different substrate supported different assemblages of organisms and at some locations the presence of competitive dominants led to biological interactions. According to Merkel and Associates all marine habitats surveyed at SNI had diverse, healthy communities; variability amongst communities was attributed to natural variability and they believed there was no indication of direct impacts associated with Navy activities. The metrics used to determine potential impacts to beneficial uses further indicated biological variability within an island eco-region, supporting the need to have multiple reference locations. According to Merkel and Associates, the biological data, in combination with water and sediment chemistry, and toxicity, provided a weight of evidence that Navy discharges do not compromise protection of ocean waters for beneficial uses.

Long-term trends in giant kelp forest populations have been studied at SNI. For a National Park Service study, six benthic study sites (10–12 m deep) have been sampled semiannually since 1980, and they have concluded that at Dutch Harbor giant kelp populations fluctuate on a cyclical pattern and sea urchin grazing is not significant; on the west end of SNI sea urchin grazing heavily influences giant kelp populations, which may lead to a higher turn over rate with more frequent recruitment pulses.

Based on decades of sampling kelp forests within the Channel Islands, the National Park Service suggested annual sampling for Channel Island sites for a minimum of 10 years, with an initial, consistent annual sampling program necessary to provide an adequate baseline to describe perturbations.

Subtidal Survey Methods: At each subtidal sample station, a diving biologist using SCUBA determined the distribution and abundance of subtidal invertebrates and algae at the -40 feet (-12.19 m) MLLW isobath. A 25-meter long transect tape was established at each isobath. Kelp abundance was counted in 10, randomly placed 5-meter long by 2-meter wide band transects (10m2). Observations included the number of kelp plants in each band transect, the number of stipes at a height of one meter above the bottom, and the size of the individual plants. Four size categories were measured: newly recruited kelp plants (minimum size 2-10 cm), juveniles (10-40 cm in length), subadult (between 40 cm and 2 m), and adults (greater than 2 m in length).

Biologists documented the abundance of key indicator plant and invertebrate species in 10, randomly placed 1-meter by 1-meter quadrats (1 m^2). Biologists also quantified substrate type (sand, rock, cobble) and algal cover using a point contact method with 20 points sampled within the 1m^2 quadrat. Target species/assemblages were surveyed at each subtidal sampling location. These were common subtidal organisms present during previous Navy surveys performed in 1998. Other species of interest were also noted. Formal fish transects were not conducted, but all fish species observed were recorded to document presence and relative qualitative abundance (e.g., abundant, common, rare).

Intertidal Spatial Assessment Methods: At each sample station, marine biologists recorded the abundance and/or percent cover of organisms at each of three tidal elevations (+5, +3, and 0 ft MLLW) using a 0.25m^2 quadrat following methods used for previous Navy surveys at SNI in 1998. A 10-meter long transect tape was established at each tidal elevation, and four randomly placed quadrats along the transect line were sampled at each of the three tidal elevations. Two biologists were assigned to each quadrat to record abundance and/or percent cover (for invertebrates, algae, and substrate) for several target species that were determined to be key species in the previous Navy marine resources inventory in 1998. Abundance was quantified by counting total individuals within each 0.25m^2 quadrat and percent cover was measured using the point contact method at 20 points within each 0.25m^2 quadrat.

Several algal species were grouped into taxonomic categories to allow efficient field sampling and comparison with past studies. All species in the genus *Corallina* were grouped into the group coralline algae, red turf included low-lying red algae (e.g., *Gelidium* spp.), red foliose was made up of leafy erect red algae (e.g., *Pterocladia* spp.), Ralfsiaceae included all encrusting brown algae in the Ralfsiaceae family (e.g., algae that resemble “black tar”), and other browns included brown algae such as *Dictyota* spp., *Dictyopterus* spp., *Zonaria* spp., *Halydris* spp., *Colpomenia* spp., *Leathesia* spp., *Scytosiphon* spp., *Fucus gardneri, Selvetia compressa,* and *Pelvetiopsis limitata.*

A total of six sites were chosen for sampling around SNI. They include four sites that are representative of areas that receive discharges associated with distinct Navy operational activities such as airfield, water desalination, and rocket launch operations. The total also included two locations chosen to represent areas that receive storm water runoff not associated with Navy activities, and thereby are considered a reference condition. Because there are insufficient historical data to assess how reference conditions might vary around the island, two reference locations were chosen to represent potential differences that might occur on either side of the island. The sampling locations are:

Corral Beach and **Dutch Harbor** were selected reference locations. Corral Beach is located between Blue Whale Cove and Tranquility Beach and was chosen as a reference location to account for potential spatial variability. The general area consists of rocky bluffs, with relatively small pocket beaches. The intertidal area ranged from vertical rocky bluffs to cobble, with surge channels. The intertidal sampling location was located in the vicinity of an ephemeral stream/drainage, and consisted of bedrock at all tidal levels. The subtidal zone consisted mostly of boulders and bedrock with moderate relief of up to 2.5 meters. Patches of sand were common in deeper areas or in pockets between rocky outcroppings. Water and sediment samples were collected outside the surf zone directly offshore of the drainage. Intertidal sampling was conducted on the rocky platform west of drainage, and subtidal sampling was conducted directly offshore of the drainage. Dutch Harbor, located on the south-central portion of SNI, consists of a rocky headlands separated by sandy beaches, and was chosen as a reference location to account for potential spatial variability. The intertidal area consists of rocky intertidal platforms separated by sandy beach, and the subtidal area consists of bedrock with moderate to high relief of up to 3 meters, separated by sand patches. Water and sediment samples were collected outside the surf zone directly offshore of the headland. Intertidal sampling was conducted on the rocky platform east of the headland, and subtidal sampling was conducted directly offshore of the headland. One notable observation included the presence of black abalone (*Haliotis cracherodii*) within some of the intertidal ledges.

Coast Guard Beach is an area of point source brine discharge from desalination operations. Coast Guard Beach is located on the eastern portion of the island, and was requested by the State Water Board to be sampled. The area is predominantly sandy beach habitat, with the exception of a riprap jetty that extends approximately 250 feet (77 m) into the ocean. The subtidal habitat is also primarily sandy substrate, although west of the jetty at an approximate depth of 25 feet (8 m), scattered low-relief rocky substrate is present. The brine discharge area is located on the back beach, east of the jetty. Water and sediment samples were collected outside the surf zone directly offshore of the brine discharge area. Subtidal sampling was conducted west of the jetty in the area of low-relief rocky substrate. For a large portion of the year, the sandy beach serves as a nursery and breeding area for northern elephant seals and California sea lions. Strong southerly currents (i.e., running from north to south) are common in this area, and were experienced while sampling.

At Coast Guard Beach, nine species or taxonomic groups were flagged for the subtidal habitat for exceeding the 50% difference criteria, and included: *Macrocystis, Pterygophora, Laminaria, Parastichopus, Pisaster*, urchins, sponges, ectoprocts, and ascidians. The total number of species was within the 50% criteria. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability, competitive interaction (biotic), substrate variability, exposure, and species mobility.

For the intertidal analysis, species abundance or percent cover and number of taxa from Coast Guard Beach were compared to Corral Beach and Dutch Harbor. Sixteen species or taxonomic groups were flagged for the intertidal habitat at Coast Guard Beach for exceeding the 50% difference criteria, and the total number of species also exceeded the 50% criteria, which was expected considering that the intertidal habitat at Coast Guard Beach consisted of sandy substrate and that all of the indicator organisms were primarily those found on firm or rocky substrate. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by substrate variability.

Daytona Beach, located in the southeast portion of the island, is representative of a storm water runoff area associated with barge landing operations. A large pier, used to load and unload barges, is located along a sandy stretch of beach. The intertidal area is sandy beach, as well as the habitat adjacent to the pier. However, mature giant kelp forests are located offshore, both east and west of the pier. Water and sediment samples were collected outside the surf zone adjacent to the pier, while subtidal sampling was conducted in the kelp forest east of the pier. For a large portion of the year, the sandy beach serves as a nursery and breeding area for northern elephant seals and California sea lions.

At Daytona Beach, four species or taxonomic groups were flagged for the subtidal habitat for exceeding the 50% difference criteria, and included: *Pterygophora*, red turf algae, ectoprocts, and ascidians. The total number of species was within the 50% criteria. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability, competitive interaction (biotic), substrate variability, and exposure.

For the intertidal analysis, species abundance or percent cover and number of taxa from Daytona Beach were compared to Corral Beach and Dutch Harbor. Similar to Coast Guard Beach, 16 species or taxonomic groups were flagged for the intertidal habitat at Daytona Beach for exceeding the 50% difference criteria, and the total number of species also exceeded the 50% criteria, which was expected considering that the intertidal habitat at Daytona Beach consisted of sandy substrate and that all of the indicator organisms were primarily those found on firm or rocky substrate. According to Merkel and Associates there was no apparent impact to beneficial use based on these metrics as they can be explained by substrate variability.

Tranquility Beach is located on the northern portion of the island, and is representative of a storm water runoff area associated with the residential area (Nick Town). Nick

Town is located on a mesa above Tranquility Beach, with a ravine that may potentially transport storm water from Nick Town to near shore receiving waters. The majority of the intertidal area is comprised of sandy beach, with rocky intertidal platforms on the east and west ends of the beach. An expansive giant kelp forest is located offshore of Tranquility Beach, with the substrate consisting of a mixture of bedrock with high relief (4 meters in some places) and large boulders with interspersed patches of sand. Water and sediment samples were collected outside the surf zone directly offshore of the ravine. Intertidal sampling was conducted on the rocky platform west of ravine, and subtidal sampling was conducted directly offshore and to the north of the ravine.

At Tranquility Beach, five taxonomic groups were flagged for the subtidal habitat for exceeding the 50% difference criteria, and included: *Laminaria*, red turf algae, *Parastichopus, Pisaster*, and ectoprocts. The total number of species was within the 50% criteria. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability, competitive interaction (biotic), substrate variability, exposure, and species mobility.

For the intertidal analysis, species abundance or percent cover and number of taxa from Tranquility Beach were compared to Corral Beach and Dutch Harbor. Eight species or taxonomic groups were flagged for the intertidal habitat at Tranquility Beach for exceeding the 50% difference criteria, and included: encrusting coralline algae, turf and geniculate coralline algae, *Sargassum*, littorine snails, mussels, chitons, turban snails, and urchins. The total number of species was within the 50% criteria of the reference locations. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability, substrate variability, exposure, and species mobility.

Blue Whale Cove is located on the northern portion of SNI and is representative of storm water runoff associated with rocket launch operations. Rocket launch platforms are located on a mesa above Blue Whale Cove, with a ravine that may potentially transport storm water from the platforms to near shore receiving waters. Similar to Tranquility Beach, the majority of the intertidal area in Blue Whale Cove is sandy beach, with rocky intertidal platforms on the east and west ends of the beach. An expansive giant kelp forest is located offshore of Blue Whale Cove, with the substrate consisting of a mixture of bedrock with high relief (4 meters in some places) and large boulders with interspersed patches of sand. Water and sediment samples were collected outside the surf zone directly offshore of the ravine. Intertidal sampling was conducted on the rocky platform west of the ravine, and subtidal sampling was conducted directly offshore and to the north of the ravine.

At Blue Whale Cove, eight species or taxonomic groups were flagged for the subtidal habitat for exceeding the 50% difference criteria, and included: *Laminaria*, red turf algae, coralline turf, *Pisaster*, urchins, sponges, ectoprocts, and ascidians. The total number of species was within the 50% criteria. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability, competitive interaction (biotic), substrate variability, exposure, and species mobility.

For the intertidal analysis, species abundance or percent cover and number of taxa from Blue Whale Cove were compared to Corral Beach and Dutch Harbor. Ten species or taxonomic groups were flagged for the intertidal habitat at Blue Whale Cove for exceeding the 50% difference criteria, and included: geniculate and encrusting coralline algae, *Sargassum*, green algae, limpets, littorine snails, mussels, chitons, turban urchins, and anemones. The total number of species was within the 50% criteria. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability, substrate variability, exposure, and species mobility.

At the request of State Water Board staff, Dr. Raimondi performed a statistical analysis of the SNI intertidal data set described above. In that assessment, he used Bray-Curtis ordination (PRIMER software) to compare community structure at reference and impact locations. Dr. Raimondi expressed concern about the choice of reference sites (rocky reefs). Using the design and data from Merkel and Associates, there is evidence that discharge locations are different from selected reference locations based on comparison of community composition. This is based on data for both the species that were counted (p=0.001) and for those sampled by estimating percent cover (p=0.039).

Limpets, anemones, and the purple sea urchin (*Strongylocentrotus purpuratus*) contribute the greatest differences between the reference and impact sites. All three of these, as well as mussels, the black turban snail *Tegula funebralis*, bladder chain kelp *Sargassum agardhianum,* chitons, and littorine snails were more abundant at the reference sites (Table 5.6.7.). Of those taxa with contribution to the differences, only barnacles were more abundant at the discharge sites.

Table 5.6.7. Counts, intertidal invertebrates and algae (*Sargassum agardhianum*), and their contribution to differences between the reference sites and the discharge (impact) sites

	Group Reference	Group Impact	
Species	Av.Abund	Av.Abund	Contrib%
Limpets	2.64	1.49	23.09
Anemones	0.51	0.5	13.21
Strongylocentrotus purpuratus	0.72	0	11.66
Mussels	1.01	0.15	8.7
Tegula funebralis	0.47	0.18	8.48
Sargassum agardhianum	0.23	0.04	7.43
Chitons	0.54	0.15	7.37
Barnalces	0.96	1.53	6.69
Littorina spp	0.94	0.38	5.25

Erect coralline red algae (*Corallina*) and red algal turf contributed the greatest differences between the reference and impact sites (Table 5.6.8.). Both erect and encrusting coralline red algae and the surf grass *Phyllospadix* were more abundant at reference sites. *Chaetomorpha*, a filamentous green algae, had a relatively high average abundance at the discharge sites and was virtually absent at the reference sites. Green algae are often a preferred food item for intertidal grazers and, therefore, are often not abundant. It is possible that eutrophication causes filamentous green algae to be more productive and, therefore, more abundant, exceeding grazing rates.

Table 5.6.8. Percent cover, intertidal vascular plant (*Phyllospadix*) and algal taxa, and their contribution to differences between the reference sites and the impact sites (Group 2)

	Group Reference	Group Impact	
Species	**Av.Abund**	**Av.Abund**	**Contrib%**
C_Coralline Algae	25	6.46	26.72
Red Turf	3	4.67	21.61
C_Phyllospadix	11.25	10	13.10
C_Chaetomorpha sp.	0	12.08	11.07
Other Browns	0.38	0.46	7.40
C_Encrusting Coralline Algae	6.04	1.04	7.06
Ralfsiaceae	0.21	0.46	6.64

For species sampled by counts and those sampled by percent cover, 1 of 3 tidal height zones differed between outfall and undisturbed sites, although the differences in the other 2 of 3 zones were close to significant.

The following figures provide a graphic representation of the Bray-Curtis multivariate results provided by Dr. Raimondi. Each symbol represents a quadrat sample result.

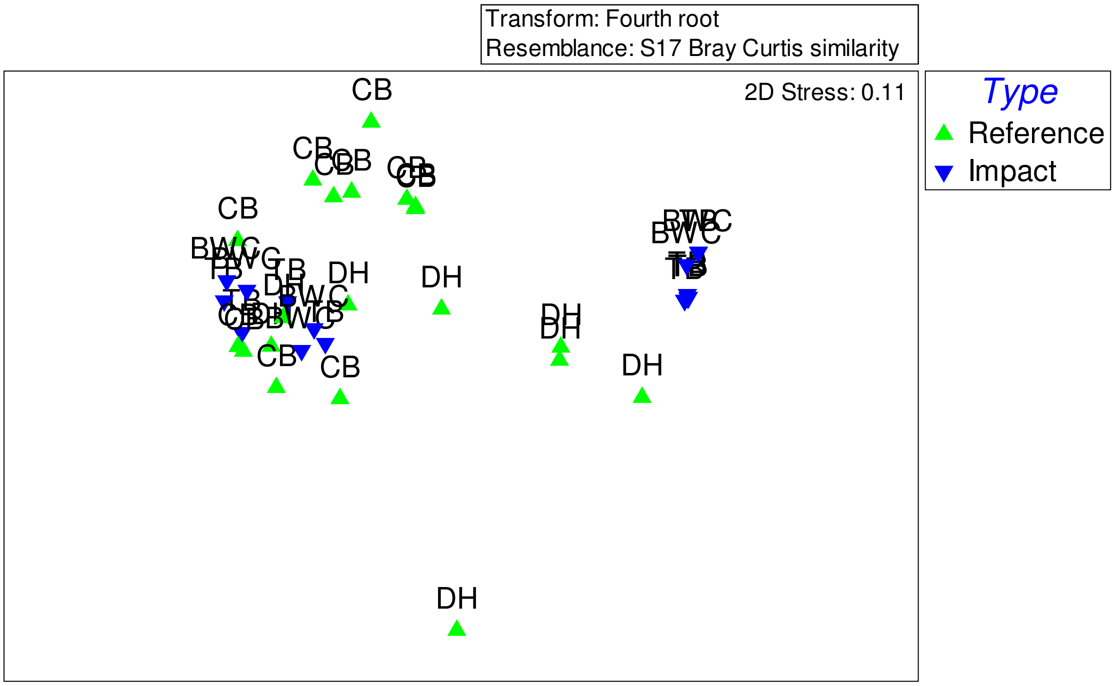

Figure 5.6.6. San Nicolas Island ASBS. All tidal zones combined, species measured by counts. The green pyramid symbols are for Dutch Harbor (DH) and Corral Beach (CB) reference sites. The blue inverted pyramid symbols are for discharge sites.

In the above graph representing a multivariate cluster assessment of data for intertidal species measured by counts, many of the reference sites cluster in the center. While there is some overlap with discharge sites on the left side of the graph, there is a cluster of only discharge sites on the right side.

In the following graph representing a multivariate cluster assessment of data for intertidal species measured by percent cover, there is a tight cluster of reference sites in the upper left and a few reference sites loosely clustered in the bottom center. The discharge sites are clustered in the center left and lower left, and also loosely clustered and scattered along an axis in the upper center and upper right.

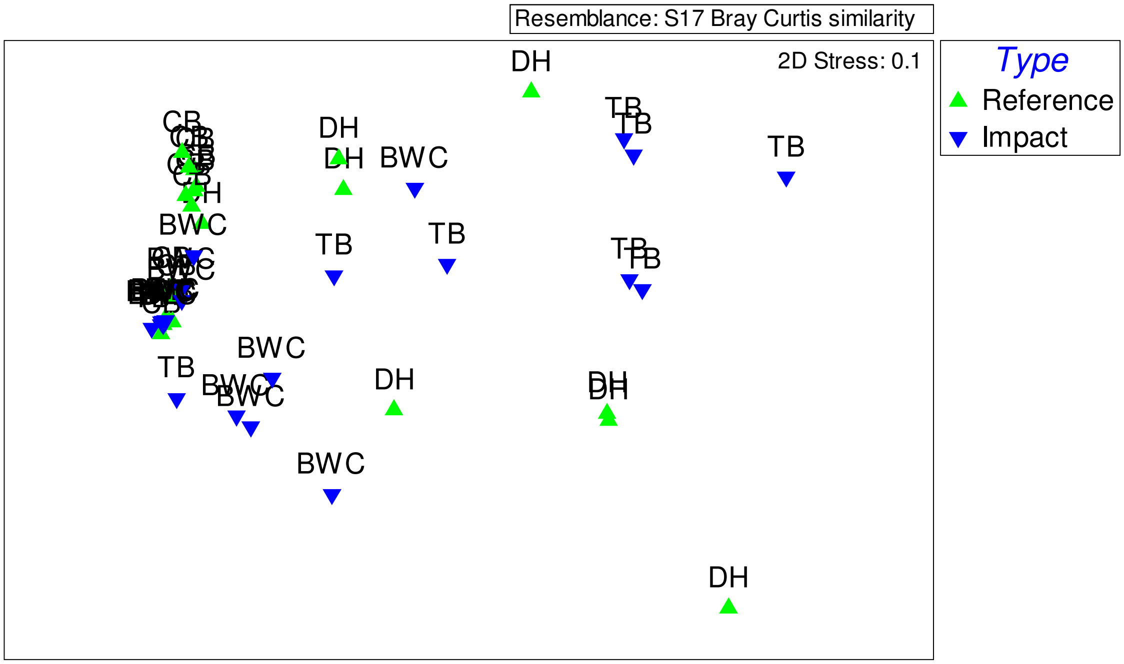

Figure 5.6.7. San Nicolas Island ASBS. All tidal zones combined, species measured by percent cover. The green pyramid symbols are for Dutch Harbor (DH) and Corral Beach (CB) reference sites. The blue inverted pyramid symbols are for discharge sites.

5.6.15 - San Clemente Island ASBS

One report was available, the Naval Auxiliary Landing Field, San Clemente Island Area of Special Biological Significance Biological Survey Report (Merkel & Associates February 2007). The report provides a comprehensive assessment of the various subtidal and intertidal “eco-regions” of SCI, including significant data of the status of surrounding kelp forests. Their report also includes previous biological surveys performed at SCI.

Several marine biological surveys have been conducted at SCI to either meet permit conditions (focused) or to assess the biological communities around the island. The focused surveys were aimed at documenting potential effects of the SCI wastewater treatment plant outfall on marine biota. These surveys included both intertidal and subtidal surveys in the vicinity of the Wilson Cove sewage point source outfall. According to Merkel and Associates, results of the focused surveys suggested that very localized impacts to marine biota occurred in the intertidal zone directly in the vicinity of the outfall, but there were no apparent effects 15 meters (50 ft) beyond the outfall or in the subtidal zone.

Previous island-wide surveys were conducted to document and compare the habitat around SCI with other Channel Islands. The island-wide surveys were all subtidal, kelp forest surveys, and results indicated that the subtidal communities at SCI were diverse and healthy in comparison to the other southern Channel Islands (e.g., Santa Catalina, Santa Barbara, Anacapa, and Santa Cruz Islands), and similar to SNI. Fish, algae, and invertebrates displayed a high degree of diversity, and most noted species were observed from juveniles to aging adults. SCI's relative remoteness, limited anchorages, and unpredictable operational closures likely play a significant role in reducing fishing pressure and subsequent impacts to the associated marine communities. According to Merkel and Associates, no visible impacts from Navy operations were observed on the underwater communities at visited sites.

The island-wide surveys delineated four island eco-regions around the island. Although the number of sites sampled within each island eco-region was too low to describe significant differences between island eco-regions, some notable trends in habitat classification were apparent. First, the only two sites classified as developing kelp forests were located on the east shore, where bottom substrate and oceanographic conditions possibly limited perennial kelp forests from forming. As expected, the north and west island eco-regions were dominated by mature kelp forests and sand bottom with sub-canopy brown algae. These mature kelp forests supported dense stands of understory algae unlike the Pyramid and east island eco-regions, which were dominated by encrusting invertebrates on the hard substrate. Dense understory algae were most typically present where high flow, nutrient rich oceanic water was consistently available, as in the north and west shore eco-regions of SCI. The Pyramid eco-region had a southeast aspect and typically experiences less wind and swell than other exposures throughout the island.

Methodologies from previous surveys were reviewed to assist in the development of methods to meet the State Water Board request. Due to logistical constraints, including access to portions of the island, potential weather concerns, diver safety and bottom time limitations, and the distance between potential sampling locations, the methods were developed to provide the best information to satisfy the request by the State Water Board and also to make comparisons with previous survey data.

Results indicated a high degree of biological variability in the intertidal and subtidal zones within an island eco-region, primarily due to differences in substrate type and coverage (e.g., cobble, boulder, bedrock, sand). Generally, different substrate supported different assemblages of organisms, and at some locations the presence of competitive dominants (e.g., mature giant kelp forest) led to biological interactions. According to Merkel and Associates, all marine habitats surveyed at SCI had diverse, healthy communities. Variability amongst communities was attributed to normal variability and there was no indication of direct impacts associated with Navy activities. The metrics used to determine potential impacts to beneficial uses further indicated biological variability within an island eco-region, supporting the need to have multiple reference locations.

Two metrics were derived from these surveys: (1) number of taxa, and (2) abundance or percent cover. There were no benchmarks available for these metrics so they can only be compared to reference conditions. In the case of SCI, the comparisons were made to reference conditions within an associated ecoregion. Based on historical data, these community measurements are highly variable. According to Merkel and Associates, differences of 50% in the number of taxa or abundance/cover between any two sites would be considered in the realm of natural variation. Therefore, if a metric measured at a station was lower by 50% or more than the associated reference station, then that metric was flagged. When one or both metrics at a station were flagged, the biologist considered substrate data, historical data if available, looked at results of the receiving water and sediment measurements for causal relationships, and used best professional judgment to determine if intertidal or subtidal habitats required additional evaluation. Again, State Water Board staff disagrees with the adequacy of a 50% criterion in determining differences between impact and reference sites.

Graphs were prepared for species or taxonomic groups that were relatively abundant and, in some instances, species were placed into taxonomic groups for graphing purposes (e.g., red turf and red foliose algae were grouped into a red turf algal taxonomic group). Summary tables were prepared for species or taxonomic groups that were not relatively abundant or common. In addition, a comprehensive species list was developed from this survey, and previous surveys.

Subtidal Survey Methods: At each sample station, a diving biologist using SCUBA determined the distribution and abundance of subtidal invertebrates and algae at two isobaths (-12 and –40 ft MLLW). A 25-meter long transect tape was established at each isobath. Kelp (i.e., large brown algae) abundance was counted in 10, randomly placed 5-meter-long by 2-meter-wide band transects ($10m^2$). Observations included the number of kelp plants in each band transect, the number of stipes at a height of one meter above the bottom, and the size of the individual plants. Four size categories were measured: newly recruited kelp plants (minimum size 2-10 cm), juveniles (10-40 cm in length), subadult (between 40 cm and 2 m), and adults (greater than 2 m in length). The characteristic color and wavy pattern of the blades allowed biologists to readily identify even relatively small *Macrocystis* plants.

Biologists documented the abundance of key indicator plant and invertebrate species in 10 randomly placed 1-meter by 1-meter quadrats ($1m^2$). Biologists also quantified substrate type (sand, rock, cobble) and algal cover using a point contact method with 20 points sampled within the $1m^2$ quadrat. A list of target species/assemblages that were surveyed at each subtidal sampling location is provided. These were common subtidal organisms present during previous Navy surveys. Other species of interest were also noted. Formal fish transects were not conducted, but all fish species observed were recorded to document presence and relative qualitative abundance (e.g., abundant, common, rare).

Intertidal Survey Methods: At each sample station, marine biologists recorded the abundance and/or percent cover of organisms at each of three tidal elevations (+5, +3, and 0 ft MLLW) using a 0.25m² quadrat following methods used for previous surveys at SCI. A 10-meter long transect tape was established at each tidal elevation, and four randomly placed quadrats along the transect line were sampled at each of the three tidal elevations. Two biologists were assigned to each quadrat to record abundance and/or percent cover (for invertebrates, algae, and substrate) for several target species that were determined to be key species in the previous marine resources inventory. Abundance was quantified by counting total individuals within each 0.25m² quadrat and percent cover was measured using the point contact method at 20 points within each 0.25m² quadrat. A list was composed of target intertidal species/assemblages that were surveyed at each intertidal sampling location. These species are common intertidal organisms and are considered to be representative organisms that were present during previous surveys. Other species of interest and substrate type (rock, cobble, sand) were also noted. Cobble was defined as small, moveable rock generally less than 12 inches in diameter.

Several algal species were grouped into taxonomic categories to allow efficient field sampling and comparison with past studies. All species in the genus *Corallina* were grouped into the group coralline algae, red turf included low-lying red algae (e.g., *Gelidium* spp.), red foliose was made up of leafy erect red algae (e.g., *Pterocladia* spp.), Ralfsiaceae included all encrusting brown algae in the Ralfsiaceae family (e.g., algae that resemble "black tar"), and other browns included brown algae such as *Dictyota* spp., *Dictyopterus* spp., *Zonaria* spp., *Halydris* spp., *Colpomenia* spp., *Leathesia* spp., and *Scytosiphon* spp.

A total of 10 locations were chosen for biological sampling around SCI. These included five locations that were representative of areas with discharges associated with distinct Navy operational activities. The total also included five locations chosen to represent areas that receive natural storm water runoff not associated with Navy activities, and thereby considered a reference condition. The five reference locations were chosen because historical data indicated that there are four eco-regions around the island that result in different reference conditions. The 10 sampling locations and survey results, grouped by island eco-region, are:

Castle Rock (CR) was chosen as a reference location for the north eco-region and is located approximately 0.5 miles (0.8 km) west of Bird Rock. A rocky bluff backed the intertidal area, with patches of cobble at higher tidal levels, leading to bed rock at lower tidal levels. An expansive kelp forest was present offshore with extensive surf grass beds present near shore. The substrate in this area consisted of a mixture of bedrock with moderate relief (2 meters in some places) and large boulders with interspersed patches of sand.

Northwest Harbor (NW) is located in the north eco-region, and was an area requested to be sampled by the State Water Board since in-water Basic Underwater Demolition/SEALS (BUD/S) training occurs in near shore waters. In-water ordinance detonation (explosives) training occurs directly offshore of BUD/S Camp on sandy subtidal habitat in water ranging from 10 to 15 feet (3 to 4.5 m) deep. The area boasts a wide variety of different marine habitats, including sandy beach, rocky intertidal habitat composed of boulders and cobble, and also formational rock along the western shoreline, sandy subtidal habitat, and a diverse rocky subtidal habitat. The cove is somewhat protected by prevailing northwesterly winds and swell, by a small island (Bird Rock) located offshore that provides a roosting area for a variety of sea birds and marine mammals. An extensive giant kelp forest was present both within the cove and further offshore. The ASBS sampling location was situated east of the sandy beach, along the boulder and cobble intertidal area, on a rocky headland between BUDS Camp and Graduation Beach. The subtidal sampling locations were situated directly offshore of the intertidal locations.

Five species or taxonomic groups were flagged for the intertidal habitat at NH for exceeding the 50% difference criteria, and included: coralline algae, *Sargassum*, green algae, barnacles, and mussels. The total number of species was within the 50% criteria, which was almost expected as the comparisons are among organisms or groups of organisms that were previously reported to be common species at SCI. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability, competitive interaction (biotic), substrate variability (the substrate at NH was predominantly boulder, while CR was bedrock), and exposure (NH is more protected than CR).

Four species or taxonomic groups were flagged for the subtidal habitat at NH for exceeding the 50% difference criteria, and included: *Cystoseira*, *Phyllospadix*, crustose coralline algae, and urchins. The total number of species was within the 50% criteria. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability, competitive interaction (biotic), substrate variability, exposure, and species mobility.

East Airfield (EA) is located in the north eco-region and east of the runway, and is representative of a storm water runoff area associated with airfield operations. The site was situated below a steep rocky bluff, with two distinct geological formations, and a small pocket beach that extended into the subtidal zone. The intertidal area was heterogeneous with rocky outcroppings separated by sand at lower tidal levels, small benches with tide pools at mid-tidal levels, and irregular and steep upper tidal level. A very narrow band of rocky substrate that supported giant kelp was present near shore, with sandy subtidal habitat present further offshore. A more extensive kelp forest was present down coast of this site.

Three species or taxonomic groups were flagged for the intertidal habitat at EA for exceeding the 50% difference criteria, and included: coralline algae, *Sargassum*, green algae, and limpets. The total number of species was within the 50% criteria. According to Merkel and Associates there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability (e.g., green algae tend to be ephemeral species), competitive interaction (biotic), and substrate variability (the substrate at EA was predominantly bedrock outcropping with sand patches, while CR was bedrock).

Twelve species or taxonomic groups were flagged for the subtidal habitat at EA for exceeding the 50% difference criteria, and included: *Laminaria*, *Cystoseira*, *Sargassum*, *Phyllospadix*, *Dictyota*, red turf algae, crustose coralline algae, and all of the invertebrates. The total number of species was within the 50% criteria. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability, competitive interaction (biotic), substrate variability (the 40-ft isobath at EA was all sand, while CR was bedrock with high relief), exposure (EA is more protected than Castle Rock), and species mobility.

Eel Point (EP) is within the west eco-region. This region tends to be characterized as having a wide shelf of mostly bedrock with expansive kelp forests. It is also exposed to large swell for the entire year. The EP site was located within the cove south of Eel Point, and was chosen as a duplicate reference location for this eco-region to account for potential spatial variability. The intertidal area within the cove ranged from vertical rocky bluffs to cobble. The sampling location was located south of the point in the vicinity of an ephemeral stream/drainage, with boulder and cobble present at higher tidal levels, and bedrock at lower tidal levels. The subtidal zone consisted mostly of bedrock with moderate relief of up to about 2.5 meters. Patches of sand were common in deeper areas or in pockets between rocky outcroppings.

Lost Point (LP) is within the west eco-region, and was also chosen as a reference location for this eco-region. The LP site was located within the cove south of Lost Point. The intertidal area within the cove ranged from vertical rocky bluffs to cobble. The sampling location was located south of the point in the vicinity of an ephemeral stream/drainage, with boulder and cobble present at higher tidal levels, and bedrock at lower tidal levels. The subtidal zone consisted mostly of bedrock with moderate and high relief of up to 4 meters. Small patches of sand were common in deeper areas or in pockets between rocky outcroppings.

West Airfield (WA) is located on the very north section of the west eco-region. This site is located in West Cove, and is representative of a storm water runoff area associated with airfield operations. West Cove is a protected cove relative to the other sites within this region, with a small sandy beach bordered by a steep rocky intertidal area to the north, and relatively flatter intertidal bench to the south, where intertidal sampling was conducted. Sand extends into the subtidal zone providing a clear path for entrance into West Cove. Mid- to high-relief rock and bedrock were present to the north and south, which supported a dense giant kelp forest.

Twelve species or taxonomic groups were flagged for the subtidal habitat at NH for exceeding the 50% difference criteria, and included: *Laminaria*, *Cystoseira*, *Sargassum*, *Phyllospadix*, *Dictyota*, red turf algae, crustose coralline algae, and all of the invertebrates. The total number of species was within the 50% criteria. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability, competitive interaction (biotic), substrate variability (the 40-ft isobath at EA was all sand, while CR was bedrock with high relief), exposure (EA is more protected than CR), and species mobility.

One taxonomic group was flagged for the subtidal habitat at WA for exceeding the 50% difference criteria, and included: crustose coralline algae. The total number of species was within the 50% criteria. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability, competitive interaction (biotic), substrate variability (the 40-ft isobath at EA was all sand, while CR was bedrock with high relief), exposure (EA is more protected than CR), and species mobility.

Stone Station or East Reference (REF) is located in the east eco-region, and was chosen as a reference location for this eco-region. Similar to other locations within this region, the island drops off very rapidly with steep depth contours in the subtidal zone. The sampling area was located in the vicinity of an ephemeral stream/drainage, with large boulders and cobble present in the intertidal and subtidal zones. A narrow, but dense stand of giant kelp was present in the subtidal zone.

Naval Ordnance Test Station (**NOTS) Pier** (NT) is located in the east eco-region, and was an area requested to be sampled by the State Water Board since the area is used to stage testing operations and is a potential source of runoff. The east side of the island drops off very rapidly and, as a result, there are not large expansive stands of giant kelp as along the west shore, but rather relatively narrow bands that parallel the coast. The intertidal zone was predominantly cobble and boulder, which also extended into the subtidal zone. The subtidal zone consisted mostly of very large (often several meters in size) boulders with small patches of sand. Adjacent to the boulder habitat were large expanses of sandy subtidal habitat that supported isolated beds of eelgrass.

Five subtidal species or taxonomic groups were flagged for the subtidal habitat at NOTS Pier for exceeding the 50% difference criteria, and included: *Pterygophora*, *Laminaria*, *Cystoseira*, *Dictyota*, and red turf algae. The total number of species was within the 50% criteria. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability (e.g., *Pterygophora* was relatively uncommon at NT), competitive interaction (biotic), and substrate variability (the 40-ft isobath at reference location had a high percentage of sand compared to the NOTS location).

Intertidal species abundance or percent cover and number of taxa were compared to a reference location (Stone Station). Three species or taxonomic groups were flagged for the intertidal habitat at NOTS Pier for exceeding the 50% difference criteria, and included encrusting coralline algae, *Eisenia*, and littorine snails. The total number of species was within the 50% criteria. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability, competitive interaction (biotic), and substrate variability (the substrate at the reference location was predominantly cobble), and species mobility.

Sun Point (SP) was chosen as a reference location for the Pyramid eco-region. Unlike many of the other locations, SP area has a large sandy beach, with large expanses of sandy subtidal habitat offshore. Relatively small, but dense stands of giant kelp were only present on patch reefs located offshore. The intertidal and shallow subtidal sampling locations were located east of an ephemeral stream/drainage. The intertidal zone consisted of a relatively low relief bedrock bench, while the shallow subtidal zone consisted of moderate to high-relief bedrock with sand. The deeper subtidal sampling location was located further offshore, and consisted of bedrock and cobble with moderate amounts of sand.

Horse Beach Cove (HB), in the Shore Bombardment Area (SHOBA), is representative of an area that has an active bombing range, and is within the Pyramid eco-region. The sampling location was along the western shore of HB, an area that was predominantly irregular bedrock in the intertidal and shallow subtidal zones. Deeper subtidal areas consisted of lower relief bedrock and boulder interspersed with sand. Sandy habitat was more common in the deeper depths, towards the center of the bay.

The location sampled in the Pyramid eco-region included Horse Beach. Species abundance or percent cover and number of taxa were compared to a reference location (Sun Point). Four species or taxonomic groups were flagged for the intertidal habitat at

HB for exceeding the 50% difference criteria, and included barnacles, the colonial snail *Serpulorbis*, littorine snails, and mussels. The total number of species was within the 50% criteria. According to Merkel and Associates, there was no apparent impact to beneficial use based on these metrics as they can be explained by competitive interaction (the intertidal zone at Horse Beach had a high cover of turf algal species which may affect the distribution of invertebrates), substrate variability (the substrate at the reference location was predominantly a bedrock bench compared to a irregular bedrock platform with tidepools), and species mobility.

Six subtidal species or taxonomic groups were flagged for the subtidal habitat at Horse Beach for exceeding the 50% difference criteria, and included *Phyllospadix*, *Dictyota*, red turf algae, sponges, ectoprocts, and ascidians page. The total number of species was within the 50% criteria. According to Merkel and Associates there was no apparent impact to beneficial use based on these metrics as they can be explained by natural variability, competitive interaction (biotic), and substrate variability (the 40-ft isobath at Horse Beach location had a high percentage of sand compared to the Sun Point [reference] location).

As mentioned previously, State Water Board staff disagree with the use of a 50% criteria as an adequate measure of differences between impact and reference sites. Also, the conclusions provided by Merkel and Associates, that there was no apparent impact to beneficial use and that all of the variability observed was due to natural variability, seemed to rely heavily on subjectivity/best professional judgment when a more objective statistical approach should have been employed. Multivariate cluster assessments (such as Bray-Curtis) would be a better way to determine differences between discharge and reference sites, as was performed by Dr. Raimondi for SNI and other ASBS data above.

At the request of State Water Board staff, Dr. Raimondi performed a statistical analysis of the SCI intertidal data set described above. In that assessment, he used Bray-Curtis ordination (PRIMER software) to compare community structure at reference and impact locations. Using the design (selected reference stations and low replication) and resulting data from Merkel and Associates he found no statistical evidence that discharge locations are different from selected reference locations based on comparison of community composition.

However, Dr. Raimondi expressed an important concern about the choice of reference sites (rocky reefs). In addition, he did not support the use of a 50% difference between sites as a criteria evaluating effects of ASBS discharges.

Natural spatial variability in such environments is high. Merkel and Associates had collected limited data for each zone at each location, characterizing the community by only 80 points for species cover and by counts in a 1 meter square quadrat area. Dr. Raimondi stated that the power of the design used by Merkel and Associates is likely to be low. He went on to state that proper estimation of the effect of discharges in the presence of such high natural variability is made much more rigorous by increasing the sample replication.

5.6.16 - Exception Application Biological Surveys - State Water Board Staff Conclusions

There was a great deal of information provided in the exception applications regarding fish, invertebrate and primary producers in ASBS. These studies provided valuable information concerning the status of marine life in ASBS. However, not all of the studies provided were designed to answer questions concerning the effects of anthropogenic runoff on intertidal or subtidal communities in ASBS. Even those studies that were designed to provide information about the effects of runoff had very different survey site designs, survey methods, and data assessment procedures.

Based on a review of the above information, functional biological communities are found in all ASBS with anthropogenic runoff influences. There is adequate evidence to allow an exception to the Ocean Plan for storm water and nonpoint source discharges, as long as they are properly controlled. The adoption of Special Protections will only reduce pollution and improve habitat, thereby allowing for improved and sustained protection for marine aquatic life.

While functioning biological communities do persist at ASBS, some of the initial data indicates that there were some differences identified between those ASBS survey sites influenced by runoff and survey "reference" sites. While impacts may not be overtly conspicuous, there may be some effects from anthropogenic runoff. For three out of four data sets tested by Dr. Raimondi using Bray-Curtis multivariate analysis, there was a difference (p value significance levels < 5%) in community composition between runoff sites vs. reference sites with no direct waste discharges. Still, these differences are not conclusive because of the inconsistencies and inadequacies of survey designs. There is probably not enough reliable data yet to say that it is definitely the runoff causing differences, or if it is due to some other coincidental perturbation. Additional biological monitoring must be performed in order to insure protection of marine aquatic life. Further staff conclusions regarding future biological monitoring are as follows:

- A rigorous regional approach, with statewide consistency, should be developed for the next round of surveys to adequately quantify the effects of discharges on marine life.

- The reference areas the applicants/consultants picked may have been chosen better than they were. This can be improved by having the reference sites selected with the advice of a team of experts.

- There would be much more power to assess community differences and impacts, or if any differences are due to natural variability, if there are adequate replication and more reference sites.

- Community composition should be compared between discharge and reference sites using statistically robust techniques such as multivariate cluster analysis.

- Ideally, the results of this rigorous and comprehensive sampling effort will yield an index of community health in relation to waste discharges, and possibly the identification of less comprehensive cost-effective biological indicators for future use.

5.6.17 Southern California Bight 08 Regional Biological Monitoring

A well-planned approach to biological investigations is required to adequately address the question of runoff impacts. Toward this end State Water Board staff supports of a regional approach to monitoring, with statewide comparability, including biological monitoring, relying on expert scientists to design and review biological monitoring efforts and to develop objective, statistically sound data assessments.

In part to overcome the limitations addressed by Raimondi in 2009, a regional ASBS biological monitoring program was implemented in southern California as part of the Bight 08 ASBS monitoring program. Twenty one rocky intertidal sites were quantitatively sampled for habitat quality, invertebrate and algal abundance and composition by Raimondi's UC Santa Cruz Coastal Biodiversity research team. The monitoring question focused on differences between reference and ASBS discharge sites. Preliminary results indicated that: 1) there were no significant differences in macro-invertebrate or algal species richness based on geographic grouping or type of site (discharge vs. reference); 2) there were large geographic differences in algal and sessile invertebrate species composition, likely reflecting natural biogeography, but no statistically significant differences between reference sites and ASBS discharge sites; and 3) there were large geographic differences in mobile invertebrate species composition, once again reflecting natural biogeography, but no statistically significant differences between reference sites and ASBS discharge sites. However, the answers differed when sessile and mobile species were jointly considered. Not only were geographic differences observed, but differences were also observed at two discharge sites relative to reference condition[7] (Figure 5.6.8.). The two discharge sites different from reference condition (i.e., outside of the confidence ellipse) are located at the La

[7] Report to the State Water Resources Control Board, Summation of Findings, Natural Water Quality Committee, 2006-2009, September 1, 2010.

Jolla ASBS and the Laguna Point to Latigo Point ASBS. While these sites are both discharge sites and also different from reference, it is still unknown as to what role the discharges and other anthropogenic influences may have causing these differences.

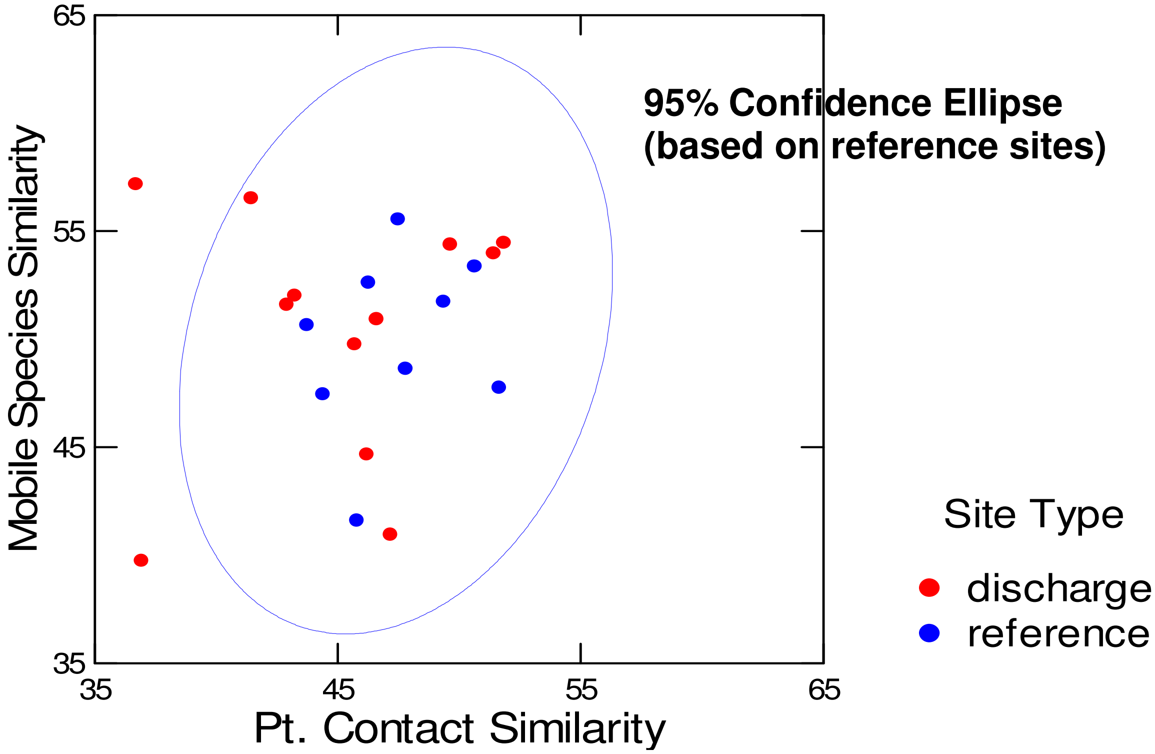

Figure 5.6.8. Similarity of Community Indices and Confidence Ellipse. Source: Pete Raimondi (UC Santa Cruz)

Because of the value of biological information, ASBS stakeholders in southern California supported monitoring of 70 subtidal rocky reef sites. Quantitative sampling for habitat quality, vertebrate, invertebrate and algal abundance and composition was coordinated by Dr. Dan Pondella at Occidental College with collaborators at UC Santa Barbara and San Diego State University. Similar to the intertidal monitoring, the monitoring question focused on differences between reference and ASBS discharge sites. Data analysis for the subtidal rocky reefs has not progressed as far as the intertidal monitoring. Initial data examination has identified clear differences in community composition based on habitat characteristics (i.e., rock relief), but large differences in biological community characteristics between ASBS and reference sites have yet to be determined.

While more work is needed to further investigate the relationship between biological condition and water quality impacts, it demonstrates the importance and value of biological data. and the ASBS Natural Water Quality Committee has suggested to the State Water Board that the above data is sufficient to warrant further investigation. [8]

5.7. BASELINE DISCHARGE INFORMATION

The SCCWRP 2003 Final Report on Discharges into State Water Quality Protection Areas found 391 municipal or industrial storm drains, 1,012 small storm drains, 224 nonpoint sources, and 66 seeps or springs that may have been influenced by nonpoint source wastes. SCCWRP also found 637 naturally occurring intermittent (gullies) or perennial streams. Since the SCCWRP survey, State Water Board staff has identified another 96 drainages, most of which are storm water or nonpoint source discharge sites. There are 473 runoff discharges into ASBS exceeding 18 inches in diameter or width; 315 of those discharges exceeded 36 inches in diameter or width. Other types of discharges occur in many of the ASBS not associated in terms of an end of pipe discharge, but include many high-threat nonpoint sources as well, e.g. marina and boating operations.

5.7.1 - Caltrans – Multiple ASBS

As part of their assessment of highway discharges to 10 of the ASBS, Caltrans evaluated 186 Caltrans maintained highway discharges to ASBS. Of those 186, 83 discharges were immediately into an ASBS and 103 were either attenuated through natural vegetation (65) or are discharged to ASBS via streams (38) along the coast just prior to draining into an ASBS. Direct discharges that are attenuated by natural vegetation and soil would likely not reach the ASBS surface waters as frequently as those direct discharges that drain immediately into an ASBS (e.g., a storm drain outfall into the intertidal zone). Discharges into streams in near proximity to an ASBS (e.g., from a highway bridge along the coast) may be diluted by watershed runoff. Storm water discharges associated with highway runoff have the potential to be considered of a higher threat depending on specific highway and watershed conditions. It should be noted that run-on occurs upstream of and into some of these highway drains, and some of these highway discharges drain across parks and beaches as well. Therefore, highway discharges are also discussed below for specific ASBS.

5.7.2 - State Parks – Multiple ASBS

California Department of Parks and Recreation discharges are primarily related to storm water runoff and non-point source discharges from roadside parking or pull-out areas in 11 ASBS. Many of the storm drain related discharges are co-located with Caltrans storm water conveyances.

---

[8] Report to the State Water Resources Control Board, Summation of Findings, Natural Water Quality Committee, 2006-2009, September 1, 2010.

5.7.3 - Redwoods National Park

Although Redwood National Park facilities are some of the most remote in the State, this ASBS is impacted by 303d listed water bodies, primarily for sediment and temperature. There are 39 storm drains in the ASBS that include storm water runoff from highway facilities (contribution from Caltrans, see above) and beach access parking lots.

5.7.4 - Trinidad Head, Trinidad Rancheria

The mooring field is occupied by commercial and recreational fishing boats from May through October. Staff is not aware of any live-in occupation of boats. State Water Board staff is concerned that release of metals by corrosion-protective “zincs” and bottom paint (copper) could damage the kelp beds. Commercial fishing and crabbing boats within the mooring field and on the pier continue to routinely use bleach and detergents to clean gear and boats (See Fish and Game Warden enforcement citation, April 2008). These marina and boating activities are considered to be high threat.

Land based sources at Trinidad include a storm drain system, the pier, boat haul out ramp, and parking lot, and seepage from the coastal bluff. The main Trinidad storm drain is adjacent to the HSU Telonicher Marine Lab waste seawater outfall (the HSU discharge is not included in this exception).

5.7.5 - King Range, Shelter Cove

The County of Humboldt and the Humboldt Bay Harbor Recreation and Conservation District higher threat discharges at Shelter Cove include point and non-point source discharges. Point source discharges include storm drains conveying residential and road runoff directly into the shoreline. Recreation boaters park their vehicles directly on the beach utilizing the concrete boat launch; these types of nonpoint source discharges likely carry fuel, oil, and grease. The recreational and commercial fishing industry is served by a fish cleaning facility immediately adjacent to the shoreline. The highly concentrated fish wastes are ground up and then discharged directly back into the ocean via a suspended pipe into the intertidal zone. This highly concentrated waste is considered to be of high threat.

5.7.6 - Del Mar Landing

TSRA properties have three main storm drains carrying residential and road runoff into the ASBS. These are considered to be of higher threat discharge due to the nature of their size, and direct discharge into the intertidal zone.

5.7.7 - Point Reyes Headlands

Point Reyes National Seashore has seven storm drain and nonpoint source discharges considered to be of lower threat. These discharges are primarily associated with the runoff and related contaminants from the lighthouse visitor center and recreational facilities. While outside the ASBS, nonpoint source discharges from historical dairies may introduce pollutants to Drake's Bay, which in turn may reach the ASBS.

5.7.8 - Duxbury Reef

The County of Marin's discharges to this ASBS are primarily sources from residences, parking lots, and road runoff, and may include nutrients, bacteria, or pathogen contamination from septic seepage (seeps are mentioned as a potential pollutant source but are not included in the exception). There are five storm drains and nonpoint sources considered to be of medium threat. One naturally occurring drainage, Agate Creek, may pose a higher threat.

5.7.9 - James V. Fitzgerald

The County of San Mateo and the Department of the Air Force convey point and nonpoint discharges including residential and road runoff. This ASBS has 19 municipal, military, or transportation related higher threat discharges. California State Parks and Caltrans have discharges impacting this resource as well.

5.7.10 - Pacific Grove

The City of Monterey and the City of Pacific Grove discharge to this ASBS and, combined, have 44 municipal storm drains greater than 0.25 meters carrying residential and road runoff into the ASBS. These are the discharges that are considered to be of a higher threat due to the nature of the impervious surface area of the watershed and amount of roads parallel to the intertidal zone and shoreline.

5.7.11 - Carmel Bay

The Carmel Bay ASBS has 33 storm drains greater than 0.5 meters in diameter discharging directly into the ASBS. Applicants are the County of Monterey, the Pebble Beach Company, the City of Carmel-by-the-Sea, Caltrans, and State Parks. In addition to the larger storm drains, there are 135 smaller storm drains, 0.2 meters to 0.3 meters in size. These discharges are considered to be a considerable threat due to the very nature of the source and size of the discharges; golf course runoff carries with it pesticides, herbicides, rodenticides, and fertilizers; and residential and road runoff carries oils, grease, and metals. Copper is used as an adjuvant in many herbicides, pesticides, and fertilizers, and is also carried in the runoff.

5.7.12 - San Nicolas Island

Although SNI may be considered small, remote, and relatively undeveloped, this Naval facility has 10 industrial storm drains that are considered to be of higher threat. Military operations include missile launches and tracking. There is also an airfield and an active waterfront.

5.7.13 - Laguna Point to Latigo Point

Residential runoff, highway runoff, recreational facilities, and septic leach fields located on the beaches are considered to be high threat in this ASBS. There are 120 municipal storm drains discharging directly to the ocean. The applicants are the City of Malibu, the County of Los Angeles, Caltrans, and State Parks.

5.7.14 - Robert E. Badham

The City of Newport Beach is the primary applicant in this ASBS. Urban runoff in the heavily developed watershed is conveyed via three storm drains greater than 1.0m and three storm drains 0.2m to 0.33m in diameter. These discharges are considered to be of higher threat due to the nature of the constituents in urban runoff.

5.7.15 - Irvine Coast

Urban, highway, golf course, and recreational facilities are the primary sources of high threat discharges to this ASBS. There are 16 storm drains greater than 0.5 meters in diameter. Applicants include the City of Newport Beach on behalf of the Pelican Point Homeowners Association, Irvine Company, Caltrans, and State Parks.

5.7.16 - Heisler Park

Urban runoff, trash, sediment, and untreated storm water runoff are considered to be of high threat to this ASBS. There are three storm drains greater than 0.5m in diameter owned and maintained by the City of Laguna Beach.

5.7.17 - La Jolla

The City of San Diego is the applicant of 14 storm drains larger that 0.5m in diameter, and 156 other storm drains considered being of higher threat to this ASBS.

5.7.18 - San Clemente Island

Military operations at this remote ASBS and the related runoff associated with these activities are considered to be of high threat. Storm water and nonpoint sources include 16 industrial storm drains with potential sources of industrial and military related activities. The island has an airfield drained by storm drains and an active waterfront. Training exercises include live fire, shore bombardment, and ordinance detonation at specific locations, specifically the SHOBA and BUD/S areas. A sink draining into the ocean is located at the NOTS pier.

5.7.19 - Southeast Santa Catalina Island

Connolly-Pacific Company owns and operates a quarry located on the Southeast Santa Catalina Island. This is an industrial facility mining aggregate material from the hillside using the shot method. Explosives are drilled into the hillside and then detonated to release the rock. Material is then transported to the separator plant for sorting. The product is then stockpiled and subsequently loaded onto barges for delivery to the mainland. Quarry operations include petroleum storage tanks, maintenance and equipment yard, and stockpiled aggregate.

5.7.20 - Northwest and Western Santa Catalina Island

SCICO owns 1,530 acres (6.19 km^2) in the Two Harbors area of this ASBS and is the main center of population of the west end of the island. In addition to providing dock facilities for the mainland cruise boats, there is an estimated 720 moorings and anchorage, where private boats can be accommodated. Services and marine related facilities include automotive, fuel facilities, sewer pump out, barge ramps, and wastewater reclamation plant.

Additional smaller anchorages and moorings are located throughout other small island coves. The largest of the group, Fourth of July Cove, contains approximately 200 anchoring and 42 moorings with supporting marina and pier facilities leased and operated by the Fourth of July Yacht Club. Nonpoint source discharges associated with marina and boating operations are considered high threat.

Recreational activities (e.g., camping) also take place at these two ASBS. The Catalina Conservancy manages camping facilities at the Western Santa Catalina Island ASBS. Roads to the recreational sites are coated with road oil and occasionally are eroded. Some of that road oil may pollute the ASBS.

Table 5.7.1. Higher Threat Waste Discharges for Storm Water and Nonpoint Source Discharges. General Exception Applicants

ASBS No.	ASBS Name	Regional Water Board	No. of Higher Threat Discharges	Sources of Threats
1	Jughandle Cove	1	1 (Caltrans bridge)	Highway runoff

ASBS No.	ASBS Name	Regional Water Board	No. of Higher Threat Discharges	Sources of Threats
2	Del Mar Landing	1	3 storm drains	Residential and road runoff
3	Gerstle Cove	1	1 storm drain, and boat ramp area	Recreational facility, parking lot and boat ramp runoff
5	Saunders Reef	1	6 storm drains	Highway and parking runoff
6*	Trinidad Head	1	5 storm drainages and nonpoint sources, 1 waste seawater outfall	Pier and mooring field; boat cleaning; urban runoff
7	King Range, specifically in the immediate vicinity of Shelter Cove	1	9 storm drainages, 1 fish cleaning station, 1 boat ramp	Fish cleaning point source; launch ramp and marine operations; residential and road runoff,
8*	Redwood National Park	1	39 storm drainages	Highway parking lot and campground runoff
9*	James V. Fitzgerald	2	19 municipal, military or transportation storm drains	Sewage collection and pumping facility - sewage spills; residential, parking and highway runoff
11	Duxbury Reef	2	5 storm drains and nonpoint sources medium threat	Residential parking lot and road runoff;
15	Año Nuevo	3	14 storm drainages and nonpoint sources	Agriculture runoff and highway runoff
16	Point Lobos	3	16 storm drainages and nonpoint sources	Parking lot and boat launch, recreational facility and road runoff
18	Julia Pfeiffer Burns	3	38 storm drainages > 0.25m	Highway runoff and legacy sedimentation
19	Pacific Grove	3	44 municipal storm drains > 0.25m	urban runoff
20	Salmon Creek Coast	3	22 storm drainages > 0.25m	Highway and rural residential runoff
21	San Nicolas Island & Begg Rock	4	10 storm drains	Military operations and industrial runoff
23	San Clemente Island	4	16 storm drains	Military operations and industrial runoff
24	Laguna Point to Latigo Point	4	120 municipal storms drains	Residential runoff; highway runoff; recreational facilities and septic leach fields on beach
25	Northwest Santa Catalina Island	4	26 storm drains and nonpoint source discharges	Residential commercial and road runoff; pier and mooring facilities
26	Western Santa Catalina Island	4	3 nonpoint sources	Boating, camping, and road runoff
28	Southeast Santa Catalina Island	4	2 storm drainages/nonpoint sources	Quarry operations and barge landing
29	La Jolla	9	14 storm drains >0.5 m, plus 156 storm drains 0.2 -0.5 m	Urban runoff
30	Heisler Park	9	3 storm drains >0.5 m, plus 2 other large storm drains of undetermined size	Urban runoff, sediment, trash, irrigation runoff and untreated storm water runoff

ASBS No.	ASBS Name	Regional Water Board	No. of Higher Threat Discharges	Sources of Threats
32	Robert E. Badham	8	3 storm drains ≥ 1.0 m, 3 storm drains 0.2 – 0.33 m	Urban runoff
33	Irvine Coast	8 and 9	16 storm drains > 0.5 m	Urban and highway runoff, golf course and recreational facilities
34	Carmel Bay	3	33 storm drains ≥ 0.5m, 135 storm drains 0.2 – 0.3m, plus golf course nonpoint source runoff	Golf course runoff, urban, and highway runoff recreational facilities

* Please note all highlighted ASBS are affected by 303 (d) listed water bodies. For additional information regarding these ASBS, see ASBS by 303 (d) Listed Waterbodies excel spreadsheet posted at http://www.waterboards.ca.gov/water_issues/programs/grants_loans/asbs/index.shtml.

5.7.21 - Waste Discharge Prevention and Treatment

As part of their exception applications, applicants submitted information regarding their pollution prevention and control efforts. Included in this section are summaries of those efforts, Best Management Practices (BMPs) or other controls, or treatment that applicants have described in their exception applications.

5.7.21.1 Department of Transportation - Caltrans

The Caltrans Statewide Storm Water Management Plan (SWMP) identifies permanent and temporary BMPs that have been approved for statewide application. The BMPs fall into four categories; Design Pollution Prevention BMPs, which include permanent soil stabilization systems; Treatment BMPs, which include permanent treatment devices and facilities; Construction Site BMPs, including temporary soil stabilization and sediment control, non-storm water management, and waste management; and Maintenance BMPs, includes litter pickup, toxic controls, street sweeping, etc.

Treatment BMPs may include biofiltration: strips/Swales, Infiltration Devices, Detention Devices, Traction Sand Traps, Dry Weather Flow Diversion, Gross Solids Removal Devices (GSRDs), Media Filters, Multi-Chamber Treatment Train, Wet Basins, and Non-structural maintenance BMPs (Caltrans Storm Water Quality Handbook, Maintenance Staff Guide (CTSW-RT-02-057[1]), May 2003).

Throughout their project planning and design process, Caltrans considers Design Pollution Prevention and Construction Site BMPs for every project. Descriptions, appropriate applications, siting criteria, and design factors for the approved Design Pollution Prevention and Treatment BMPs are listed in the Caltrans Storm Water Quality Handbooks Project Planning and Design Guide.

5.7.21.2 California Department of Parks and Recreation

At Crystal Cove (Irvine Coast ASBS), State Parks has worked under a Water Quality Action Plan for the Irvine Coast ASBS according to the requirements of a Cease and Desist Order (Santa Ana Regional Water Board CDO R8-2000-87). This order involved septic systems associated with the Historic District and Reef Point Parking Lot management in Crystal Cove State Park, as well as the operation of the Newport Coast Development and the Pacific Coast Highway Drainage tributary to the park. The Reef Point Parking Lot plan includes a vacuuming program twice per month (June-October), and once per month (November-May), a trash removal protocol, which includes litter removal from all parking areas daily, inspection, and removal of litter from culverts, drainages, and other areas. As part of their erosion control efforts, a vegetation management program is ongoing, implementing coastal sage scrub revegetation both within natural drainages and on the bluff top. Dry weather flow management efforts include routine maintenance of the public shower area to prevent unnecessary use of fresh water.

Additionally, the Crystal Cove State Park has worked to fulfill the requirements of the El Morro Cease and Desist Order (San Diego Regional Water Board CDO R9-2003-0285 and R9-2003-0228, rescinded September 12, 2007 R902007-0109). These requirements included quarterly monitoring and reporting to the Regional Water Board and final inspection (December 2006).

At Salt Point Park (Gerstle Cove ASBS), a fish cleaning facility is located at the Salt Point parking lot and visitors' area, near the restroom facilities. There is no discharge to surface waters from the Fish Cleaning Station.

In other State Park units adjacent to ASBS, current treatment processes, pollution control, and BMPs include toilet facilities, both permanent and portable, throughout the park units. Trash receptacles and scheduled trash pick-up are a part of each State Park unit's operation. Department-wide educational activities regarding BMPs are continual. Public presentations at park units continue to attempt to educate the public about damage that can occur if litter is not disposed of correctly. Other issues are discussed such as chemical impacts (e.g., oil and grease). The use of pesticides in park units is supervised by licensed applicators. Recycling programs and collection facilities are located in most park units.

5.7.21.3 Humboldt County Department of Public Works

New homes and businesses in the lower Shelter Cove area of the King Range ASBS are required to connect to the existing sewer system. This requirement is being implemented through the Coastal Development Permit process administered by the Humboldt County Planning Division. Construction BMPs for erosion and sediment control are required for construction in Shelter Cove. This is also implemented through the Coastal Development Permits issued by the Humboldt County Planning Division. Inspections during construction are performed by the Humboldt County Planning and Building Division.

Development in Shelter Cove is regulated by the Local Coastal Program land use designations and zoning ordinances, and the Coastal Development Permit process. The land use designations, zoning, and permitting processes regulate parcel size, allowable uses, housing density, commercial development, and sewer and septic development in Shelter Cove. The sanitary wastewater treatment plant is operated by the Shelter Cove Resort Improvement District (SCRID) and is covered under an existing exception (Resolution No. 83-81). SCRID treats the wastewater and a portion is recycled to irrigate the golf course on the airstrip.

Land along the ocean bluffs has been acquired by the Bureau of Land Management to be kept relatively undeveloped.

Humboldt County plans to coordinate with the Shelter Cove Resort Improvement District to develop policies and projects to protect and improve local water quality, such as drainage improvements, storm water treatment BMPs, and water quality testing.

5.7.21.4 Department of the Air Force

The Air Force has several pollution prevention plans in place at their Pillar Point facility at James V. Fitzgerald ASBS. Current BMPs include: a Spill Prevention Control and Countermeasure Plan; an Integrated Natural Resources Management Plan; an Annual Wastewater Inventory; a Wet Weather Preparedness Plan (scheduled for 2006 implementation); and parking lot, building, and drainage system repair and maintenance. Structural BMPs include double-walled above ground storage tanks and storm water runoff energy dissipaters.

5.7.21.5 The Sea Ranch Association

At present, there are no treatment processes, pollution controls, or management practices for waters entering the storm drains. Dry weather flows into the storm drain system are effectively non existent since natural drainage patterns were minimally disrupted and private lots do not drain to a comprehensive storm water collection system, as found in most modern subdivisions. The opportunity for pollutants or toxic substances to enter the drainages to the Del Mar Landing ASBS may be limited by several factors, including the above drainage practices and storm drain system. Another factor is land use in the watershed area draining to the ASBS, which is limited to residential and natural common areas.

5.7.21.6 Marin County Department of Public Works

Marin County municipalities have been actively managing storm water runoff since the early 1990s through their Storm Water Pollution Prevention Program (MCSTOPPP). This storm water management plan details the BMPs being implemented to reduce the impact of road maintenance activities on watercourses in the County, including drainages to the Duxbury Reef ASBS. The performance standards outline BMPs for the following Phase II storm water program elements: Municipal maintenance, Illicit discharge controls, New Development and Construction controls, Industrial and Commercial Discharges, and Public Information and Participation.

Street sweeping occurs on a semi-annual basis on County maintained roads. The County Parks Department is exploring an agreement with County road maintenance staff to sweep the Agate Beach Parking Lot in the fall. Ditch cleaning occurs in the summer and during the winter on an as-needed basis to maintain flow.

5.7.21.7 City of Trinidad

Although septic system discharges are not covered under the exception, it is worth noting that the City of Trinidad is in the process of implementing an On-site Wastewater Treatment System (OWTS) management program. The program is supported by grants from the U.S. EPA and State Water Board. The overall goal of this program is to eliminate the potential contamination of ground and surface waters by maintaining the proper function of all the septic systems and avoiding any septic failure in the City potentially affecting Trinidad Head ASBS.

5.7.21.8 Point Reyes National Seashore

Point Reyes National Seashore (PRNS) implements a General Management Plan (GMP), which includes the three ASBS within their jurisdiction. These are classified in this GMP as: Wilderness Subzone Bird Rock and Double Point ASBS; Marine Reserve Subzone Point Reyes Headlands Reserve; and Biotic Sensitivity Subzone Duxbury Reef Reserve and Extension.

The PRNS Water Resources Stewardship Report (WRSR) is used to support park staff in identifying strategies to meet park desired conditions, and to develop indicators that may be used to measure success. Also, their Coastal Watershed Assessment documents available information and highlight to park managers where more monitoring, or implementation to improve conditions, is necessary.

5.7.21.9 City of San Diego

Current treatment processes, pollution controls, and/or BMPs throughout the La Jolla ASBS City-wide practices, such as street sweeping, storm drain cleaning, and education/outreach efforts, are implemented in the ASBS watershed. Five of the City's 17 ASBS discharge points are currently outfitted with low-flow diversion devices, and additional diversions are planned. The City is currently planning specific ASBS water quality strategies in conjunction with Coastkeeper and SIO as part of the Prop 50 and "Consolidated Grant" grant program.

5.7.21.10 City of Newport Beach

The City is employing three tactics to reduce the discharge of pollutants to the Robert E. Badham ASBS which include: avoidance transport of pollutants (transport prevention), minimize sources of pollutants (source control), and mitigate (treatment control).

5.7.21.11 City of Laguna Beach, Heisler Park ASBS

At the Heisler Park ASBS, the City of Laguna Beach has several pollution prevention measures and water quality management plans in place. The City plans to increase infiltration of storm water through land development requirements and implementation of Municipal Storm Water Permit Standard Urban Storm Water Mitigation Plan (SUSMP) requirements. Additional efforts include a city ordinance ban on smoking at public beaches and trash and grease control measures. Source control measures include street sweeping, pet waste management, pesticide management, illicit discharges, and commercial inspections. Treatment control management measures include dry weather diversion of municipal storm drains that discharge directly to the ASBS, storm water filtering of municipal storm drains that discharge directly to the ASBS, and implementation of BMPs under the NPDES Municipal Separate Storm Sewer Systems (MS4) Permit Programs.

Dry weather flow efforts include implementation of water conservation methods and implementation of effective enforcement Management Measures. The City has made water conservation mandatory within the Heisler Park ASBS drainage area and is enforcing over irrigation issues within the watershed.

The City of Laguna Beach has completed improvements to the sewer system by cleaning and televising the lines, and repairing defects to the lines in all high priority areas.

5.7.21.12 City of Malibu

Within the Laguna to Latigo ASBS, the City of Malibu waste discharge prevention and treatment activities include, but are not limited to, city ordinances, onsite wastewater treatment systems, illicit connection/illicit discharge elimination program, planning and construction of new development and redevelopment projects, street maintenance, public information through Malibu Current Quarterly Environmental News and other sources, and the Ocean Friendly Garden Program.

5.8. PESTICIDE APPLICATIONS IN ASBS

Table 5.8.1 (below) provides information taken from exception applications related to pesticide applications.

Table 5.8.1. Pesticides Applied by Applicants

ASBS	Applicant	Pesticide/Herbicide Use
2	Sea Ranch Association	Pesticides and Herbicides not used within the drainage study area
6	Trinidad Rancheria,	None used
	Trinidad City	None used
	Dept. of Parks and Rec.	Use of pesticides in park units is supervised by licensed applicators.
7	Humboldt County- Public Works Dept.	no information provided
	Dept. of Parks and Rec.	Use of pesticides in park units is supervised by licensed applicators.
8	U.S. Dept. of the Interior-redwood National State Parks	no information provided
	Dept. of Parks and Rec.	Use of pesticides in park units is supervised by licensed applicators.
	Dept. of Transportation (Del Norte County)	Garlon 4: 32 oz/acre; Pathfinder: 32 oz/acre; Roundup Pro: 64 oz/acre
9	Dept. of the Air Force	Stopped use in 2002
	Dept. of Parks and Rec	Use of pesticides in park units is supervised by licensed applicators.
	County of San Mateo	None used on land that drains into the ASBS
11	Marin County- Dept. of Public Works	unknown, personal/private property use only
11,12	Point Reyes National Seashore	Integrated Pest Management (IPM)
19	Pacific Grove City- Public Works Dept.	Pesticides and Herbicides used: Fusalade II; 0.4 to

ASBS	Applicant	Pesticide/Herbicide Use
		0.6 ounce/1000 sq. ft
		Roundup pro; 1.6 % sol'n, spot spray 1.6 gallon/100 gal water
		Pendulum; 40 lb bag per 1/5 acre, 100 to 200 lb/ acre
		Turflon Ester; 1/2 to 1 quart/acre
		Garlon 4; 1 to 8 quarts/acre
		Surflan; 1.5 to 8 quarts/acre
		Rodeo; 3/4 to 1.5 % sol'n, spot spray
		Pro Spreader Activator; Non-ionic surfactant, 2-8 ounces/100 gal water
21	U.S. Dept. of the Navy	Herbicides and pesticides used /year at SNI (in gallons)
		Roundup: 8 gallons Garlon: 6 gallons
		Termador: 0.5 (diluted) Suspend: 0.75 (diluted)
23	U.S. Dept. of the Navy	Herbicides used in 2005 (gallons): Roundup, 45; Garlon, 15
		Previously used herbicides: Rodeo, Pathfinder
24	Los Angeles County- Dept. of Public Works	no information provided
	Malibu City-Public Works	no information provided
	Dept. of Transportation	Endurance: 32 oz/acre
		Manage: 1 oz/acre
		Oust: 2 oz/acre
		Pathfinder: 128 oz/acre
		Pro-Spreader: 4 oz/acre
		Reward: 64 oz/acre
		Roundup Pro: 96 oz/acre; 128 oz/acre
		Telar: 1 oz/acre
		Transline: 8 oz/acre
		Fusilade II T&O: 24 oz/acre
		Gallery 75DF: 16 oz/acre
		Embark 2-S: 64 oz/acre
		Dimension Ultra 40WP: 24 oz/acre
		Montar: 224 oz/acre
	Dept. of Parks and Rec.	Use of pesticides in park units is supervised by licensed applicators.
25	Santa Catalina Island Company	None used
28	Connolly Pacific Company	no information provided
29	San Diego City	Rodeo and Roundup applied on an as-needed, ad hoc basis

ASBS	Applicant	Pesticide/Herbicide Use
		Rodeo and Roundup applied prior to street resurfacing
30	Laguna Beach City	Fertilizers: Turf Supreme, Gro Power Plus, Grow More
		Pesticides/Herbicides: Roundup Pro, Fusilade II, Metaldyhyde 7.5,

5.8.1 – Exception Application Water Chemistry Data

Applicants applying for an exception to the Ocean Plan supplied sampling data from various waterbody types. This data, along with pertinent data from other sources (e.g., data from other storm water discharges already operating under an exception or samples collected by State Water Board staff) were assessed. Data for Ammonia (NH_3), Arsenic (As), Cadmium (Cd), Chromium (Cr), Copper (Cu), Lead (Pb), Mercury (Hg), Nickel (Ni), Selenium (Se), Silver (Ag), Zinc (Zn), and Polynuclear Aromatic Hydrocarbons (PAH) are provided in Appendix 2 for discharges, receiving water, ocean waters away from discharges (i.e., background) and coastal streams draining in to ASBS. These data may be compared to the objectives for metals and ammonia in the California Ocean Plan Table B, shown in Table 5.8.2 (below). The Ocean Plan Table B 30 day average objective for PAHs is 0.0088 µg/L. In addition, a separate PAH, fluoranthene, has an individual 30 day average objective of 15 µg/L. However, the PAH objectives are provided in the Ocean Plan for human health (bioaccumulation/seafood consumption) and not for marine aquatic life protection.

Table 5.8.2. California Ocean Plan Table B Objectives

Constituent	Inst. Max.	Daily Max.	6 Mo. Median
Arsenic	80 µg/L	32 ug/L	8 ug/L
Cadmium	10 µg/L	4 ug/L	1 ug/L
Chromium	20 µg/L	8 ug/L	2 ug/L
Copper	30 µg/L	12 ug/L	3 ug/L
Lead	20 µg/L	8 ug/L	2 ug/L
Mercury	0.4 µg/L	0.16 ug/L	0.04 ug/L
Nickel	50 µg/L	20 ug/L	5 ug/L
Selenium	150 µg/L	60 ug/L	15 ug/L
Silver	7 µg/L	2.8 ug/L	0.7 ug/L
Zinc	200 µg/L	80 ug/L	20 ug/L
NH_3N	6,000 µg/L	2400 ug/L	600 ug/L

Ammonia nitrogen concentrations in receiving water and discharges ranged from 0.01 to190 mg/L (10 to 190,000 µg/L), with a median of 0.2 mg/L (200 µg/L). The highest concentration was from storm runoff from a roof at the Monterey Bay Aquarium (which is not addressed as a party in this exception but has applied for an individual exception.)

This high concentration may be due to gull and other bird droppings. The next highest concentration was 81.9 mg/L (81,900 µg/L) at the Pillar Point Air Force Base, which is a facility to be covered under this exception.

Table 5.8.3 provides the number of samples for copper, lead, nickel, zinc, and PAH for each sample category. It is important to note that while most of the data represented grab samples, a few data points represent composite sampling.

Table 5.8.3. Number of Samples Collected by Category and Constituent

Constituent	Waterbody Category	Number (n)
Copper	*Stream*	16
	Ocean Background Water	9
	Discharges	154
	Ocean Receiving Water	58
Lead	*Stream*	15
	Ocean Background Water	9
	Discharges	144
	Ocean Receiving Water	61
Nickel	*Stream*	15
	Ocean Background Water	9
	Discharges	128
	Ocean Receiving Water	58
Zinc	*Stream*	15
	Ocean Background Water	9
	Discharges	143
	Ocean Receiving Water	58
PAH	*Stream*	12
	Ocean Background Water	10
	Discharges	43
	Ocean Receiving Water	23

The data was assessed using SYSTAT software. Non-detects in the data set were converted to the numeric values of the detection limits in order to perform the statistical analysis. Generally, most of the baseline data was not normally distributed and exhibited high variability for most constituents and categories.

The following figure displays the data distributions for copper, lead, nickel, and zinc.

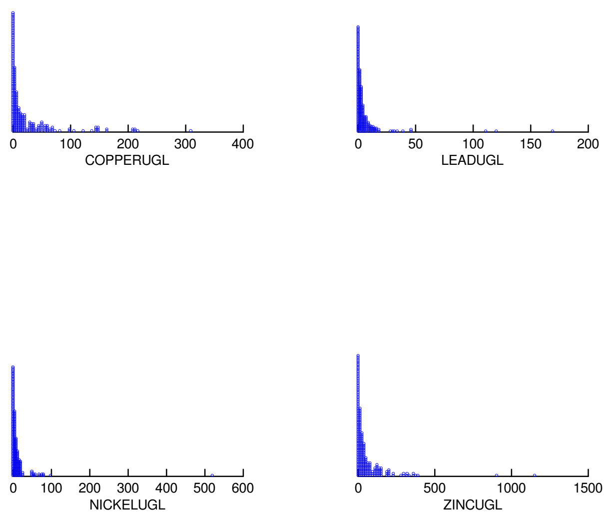

Figure 5.8.1. Data Distributions for Copper, Lead, Nickel, and Zinc.

Based on the skewed nature of the data, a log transformation was performed and "box and whiskers" graphs are provided below to present the data.

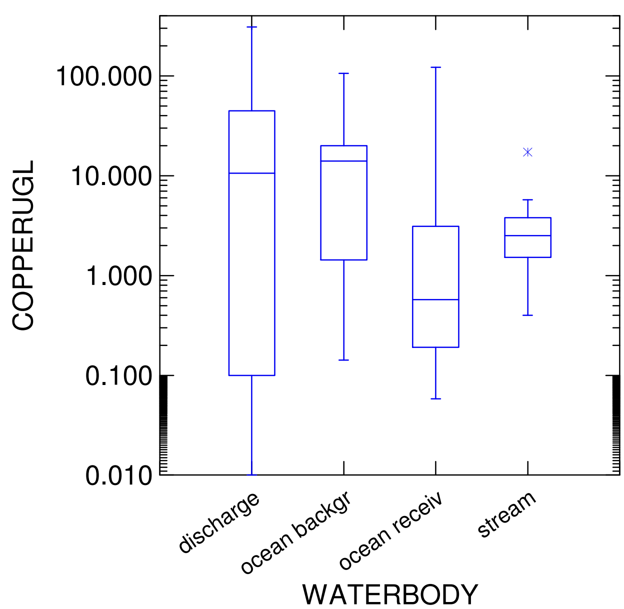

Figure 5.8.2. Copper

The median copper concentration for discharges was 10.6 μg/L and the maximum concentration was 309 μg/L. Seventy-five percent (75%) of the discharge results for copper were below 44.7 μg/L.

Ocean receiving water had a median value of 0.57 μg/L and the maximum concentration was 122 μg/L. Seventy-five percent (75%) of the copper results in the samples were below 3.1 μg/L and 90% are below 26.81 μg/L. The Ocean Plan six-month median is 3.0 μg/L for copper, and the instantaneous maximum is 30 μg/L.

Although based on only nine samples, copper data for ocean waters away from the discharge ("background") was elevated and variable. The median copper concentration in background waters was 14.0 μg/L. This indicates the possibility that ASBS waters may have elevated copper concentrations from sources other than direct discharges such as developed watersheds, even those outside of the ASBS boundaries. Streams draining to ASBS had a median copper concentration of 2.5 μg/L, which is lower than the median copper level in discharges.

Copper is a common constituent in urban runoff and is leached from anti-fouling coatings on vessel hulls. Copper at high levels (above the Ocean Plan standards) is toxic to critical life stages of marine life including the brown alga *Macrocystis pyrifera,* and echinoderms. According to a review by Saiz (1996) the mean no effects concentration (NOEC) for giant kelp gametophyte growth is 16.7 μg/L, and for sea urchin fertilization it is 9.1 μg/L (see Table 5.8.4.).

Table 5.8.4. Data derived from a Comparison of Critical Life Stage Bioassays Performed by Several Different Laboratories

Test Species	Mean NOEC μg/L	st. dev.
Giant Kelp (*Macrocystis pyrifera* gametophyte growth)	16.7	3.4
Giant Kelp (*Macrocystis pyrifera* gametophyte fertilization)	36.2	14.7
Sand Dollar (*Dendraster excentricus* fertilization	11.6	3.4
Purple Sea Urchin *Strongylocentrotus purpuratus* fertilization)	9.1	4.0

In abalone, copper accumulates in the gill, digestive gland, and foot muscle. The gill is the primary site of copper accumulation and toxicity, while the foot and adductor muscles are secondarily impacted. Mucus accumulation or cytological damage at the gill from the accumulation of copper inhibits sufficient oxygen delivery to the muscles. Since their survival is dependent on adherence to rock surfaces, a reduction of muscle function could be fatal. In addition, abalone exposed to copper may develop asphyxial hypoxia (Viant, Walton, TenBrook, Tjeerdema 2001). Giant kelp, abalone, and echinoderms are present in ASBS.

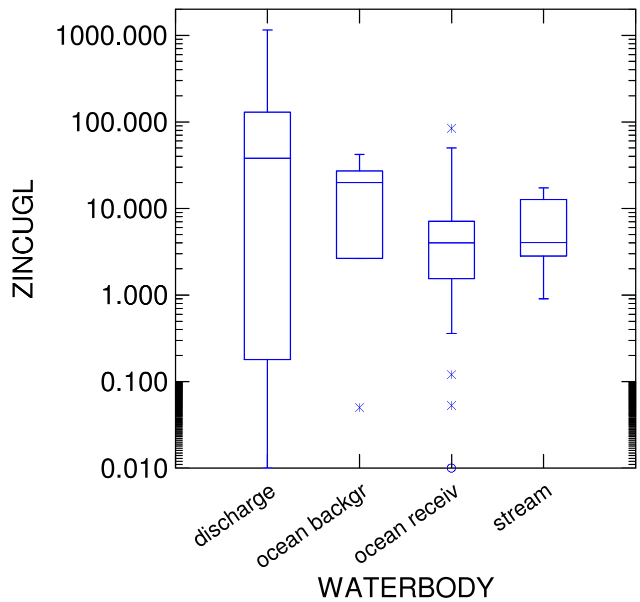

Figure 5.8.3. Zinc

Zinc is another common constituent in urban runoff and is also discharged from vessel hulls (zinc sacrificial anodes). Zinc concentrations were higher in discharges than in the other categories. The median zinc concentration for discharges was 38.0 µg/L and the maximum concentration was 1,150 µg/L. Seventy-five percent (75%) of the discharge results for zinc in the discharges category were below 129.75 µg/L.

Ocean receiving water had a median concentration value of 4.009 µg/L and the maximum concentration was 84.2 µg/L. Seventy-five percent (75%) of the zinc results in the samples were below 7.1 µg/L and 90% were below 30.62 µg/L. The Ocean Plan six-month median is 20 µg/L and the instantaneous maximum is 200 µg/L.

Although based on only nine samples, zinc data for background waters were somewhat elevated. The median zinc concentration in background waters was 20.0 µg/L and the maximum concentration was 42 µg/L. This again indicates the possibility that ASBS waters may have elevated zinc concentrations from sources other than direct discharges. Streams draining into ASBS had a median zinc concentration of 4.046 µg/L, which is lower than the median zinc level in discharges.

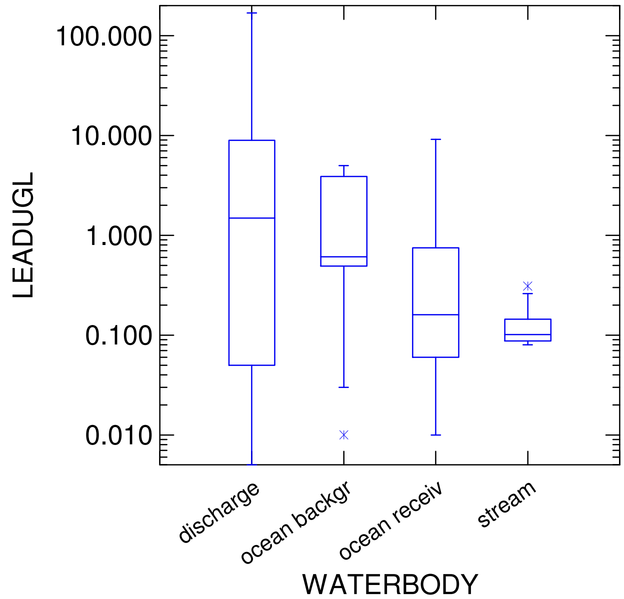

Figure 5.8.4. Lead

Lead concentrations were again higher in discharges category. The median lead concentration for discharges was 1.495 µg/L and the maximum concentration was 169 µg/L. Seventy-five percent (75%) of the discharge results for lead in discharges were below 8.95 µg/L.

Ocean receiving water had a median concentration value of 0.16 µg/L and the maximum concentration was 9.14 µg/L. Seventy-five percent (75%) of the lead results in samples were below 0.751 µg/L and 90% were below 5.0 µg/L. The Ocean Plan six-month median is 2 µg/L and the instantaneous maximum is 20 µg/L.

Although based on only nine samples, lead data for background waters were slightly elevated. The median lead concentration in background waters was 0.607 µg/L and the maximum concentration was 5.0 µg/L. This again indicates the possibility that ASBS waters may have elevated lead concentrations from sources other than direct discharges, such as developed watersheds, even those outside of the ASBS boundaries. Streams draining into ASBS had a median lead concentration of 0.101 µg/L, which is lower than the median lead level in discharges.

One source of lead toxicity found in the environment is anthropogenic activity, including old plumbing found in houses built before 1986. However, even new homes that claim to have “lead-free” plumbing may still contain up to eight percent lead (EPA, 2006). Lead may also be found naturally in the environment. Lead binds to sediment particles in aquatic environments and does not accumulate in fish, but does in some shellfish and mussels (EPA, 2006).

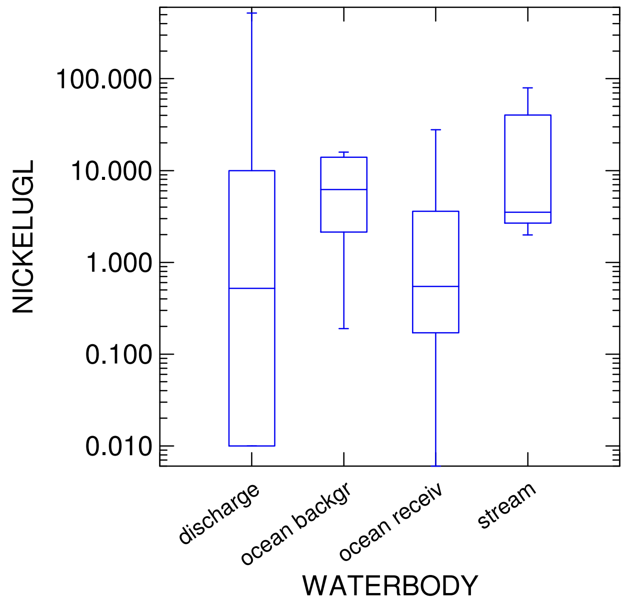

Figure 5.8.5. Nickel

Nickel concentrations were again higher in the discharges category. The median nickel concentration for discharges was 0.52 µg/L, but the maximum concentration was 520 µg/L. Still, 75% of the discharge results for nickel in discharges were below 9.94 µg/L.

Ocean receiving water had a median concentration value of 0.547 µg/L and the maximum concentration was 27.9 µg/L. Seventy-five percent (75%) of the nickel results in samples were below 3.6 µg/L and 90% were below 14.26 µg/L. The Ocean Plan six-month median is 5 µg/L and the instantaneous maximum is 50 µg/L.

Although based on only nine samples, nickel data for background waters were slightly elevated. The median nickel concentration in background waters was 6.2 µg/L and the maximum concentration was 15.9 µg/L. This again indicates the possibility that ASBS waters may have elevated nickel concentrations from sources other than direct discharges, such as developed watersheds, even those outside of the ASBS boundaries.

Streams draining into ASBS had a median nickel concentration of 3.5 µg/L, which is higher than the median nickel level in discharges. Therefore, some component of the nickel in the discharges may be from natural geologic sources.

Nickel has adverse effects on aquatic life such as bacteria, protozoans, mollusks, crustaceans, echinoderms, fishes, amphibians, etc. (Eisler, 1998). Nickel is sometimes found in anthropogenic discharges from mining, industrial, and urban areas. Natural sources of nickel primarily stem from certain minerals (e.g., chalcopyrite, pyrrhotite, pentlandite, garnierite, niccolite, zaratite, and millerite) (EPA nickel, 2006).

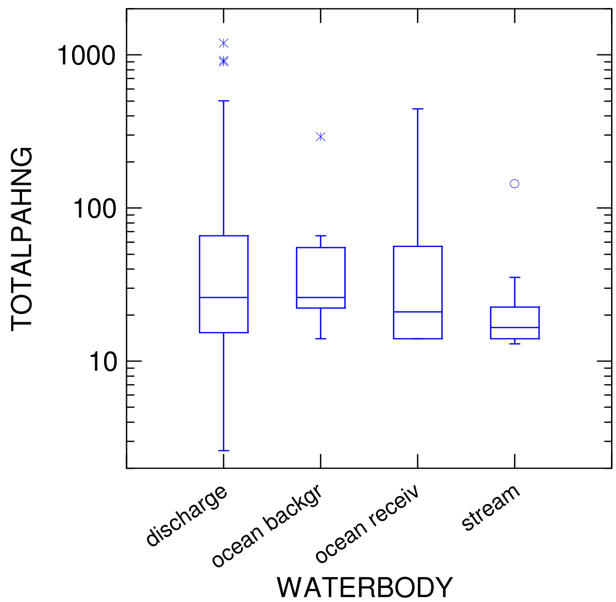

Figure 5.8.6. Ocean Plan PAH

For purposes of recording and assessing PAH data, fluoranthene was combined with the other Ocean Plan PAH compounds. Median and 75th percentile PAH values for discharges, receiving water, and background waters were all somewhat similar. Streams had a similar median level, but a lower 75th percentile value. The discharge PAH concentrations displayed the most variability, with many outliers. Maximum values were much higher for discharges. (It should be noted that the City of San Diego's PAH data was not included in the graph because their Method Detection Limit was measured in micrograms per liter rather than nanograms per liter, thus making all reported levels "Non-Detect" without actual reported levels.)

PAHs may be found in crude oil and petroleum products, and also as a result from the combustion of hydrocarbons. PAHs are known constituents in storm water discharges. The sealcoat found on the surfaces of asphalt, especially parking lots, are a huge source of PAHs found in the environment (USGS PAHs, 2007). The sealcoat can flake off from cars driving on it and then be washed away by rain or erosion into natural bodies of water. Other sources of PAHs include dyes, plastics, and pesticides (EPA PAHs, 2006). PAHs can also bind to sediments in aquatic environments; this leads to problems in these ecosystems that include: inhibited reproduction, delayed emergence, sediment avoidance, and mortality in aquatic invertebrates (USGS PAHs, 2007).

Based on the available results, 11 ASBS did not have metal concentrations in receiving water or discharges above the instantaneous maximum objectives. However, seven did have receiving water or discharge levels above the instantaneous maximum objectives. At the Heisler Park ASBS, the City of Laguna Beach reported elevated levels of copper at a storm drain flow (high reading of 36 µg/L). At the La Jolla ASBS, the City of San Diego reported five elevated levels of copper (high reading of 81.2 µg/L) in storm drain samples taken. At Laguna Point to Latigo Point, the County of Los Angeles reported elevated levels of chromium at four locations (high reading of 97 µg/L) and copper at four locations (high reading of 81.2 µg/L) in storm drain samples taken.

The City of Pacific Grove and Hopkins Marine Laboratory reported elevated levels of zinc at one location (high reading of 201µg/L), copper at two locations (high reading of 69.2 µg/L), mercury at one storm drain was 0.72 µg/L. (While mercury was elevated, the sampling procedures might not have been adequate to avoid sample contamination. Therefore, the mercury results may or may not be relevant, but are reported anyway.)

At SCI, the Department of Defense, US Navy, reported elevated levels of arsenic at two locations (high reading of 87 µg/L), chromium at seven locations (high reading of 1,010 µg/L), copper at fifteen locations (high reading of 309 µg/L), lead at six locations (high reading of 169 µg/L), nickel at five locations (high reading of 520 µg/L), zinc at six locations (high reading of 1150 µg/L), and mercury at one location (high reading of 0.6 µg/L) in storm drain samples taken. (Again, while reported here, there is some question regarding the adequacy of sampling techniques for mercury.)

At Northwest Santa Catalina Island, the Santa Catalina Island Company reported elevated levels of chromium at two locations with a high reading of 43.8 µg/L in storm water runoff. At Southeast Santa Catalina Island, the Connelly-Pacific Company reported elevated levels of copper at three locations (high reading of 40.5 µg/L), and nickel at one location (high reading of 54.00 µg/L) in storm water runoff.

Sea otters and other marine wildlife inhabit certain ASBS. Recently sea otters, which inhabit the ASBS along the Central Coast, have been affected by disease and contaminants. Disease is responsible for roughly 40 percent of the deaths; a rate that is relatively high when compared to disease-caused deaths in other wild predators (USGS 1999). The most frequent infectious disease identified has been toxoplasmosis. *Toxoplasma gondii*, a protozoan disease spread by cat feces, causes inflammation of the brain. Other disease-causing agents have also been identified. The sources of *T. gondii* are terrestrial and may be linked to wastewater treatment plant discharges and/or storm water discharges (SWRCB 2006). Coliform and *Enterococcus* bacteria provide an indication of the presence of fecal contamination, and some part of that fecal contamination may be from domestic animals. For some ASBS, discharge samples were analyzed for indicator bacteria (fecal coliform, total coliform, and enterococci). For fecal coliform, there was a minimum concentration of 1.1 MPN/100 mL, a median of 1,600 MPN/100 mL, and a maximum of 72,699 MPN/100 mL. For total coliform, there was a minimum concentration of 1.1 MPN/100 mL, a median of 4,673 MPN/100 mL, and a maximum of 160,000 MPN/100 mL. For enterococci, there was a minimum concentration of 1.1 MPN/100 mL, a median of 1,702 MPN/100 mL, and a maximum of 92,080 MPN/100 mL.

5.8.2 – Exception Application Toxicity Data

Toxicity tests evaluate the biological response of organisms to the effluent and measure the acceptability of waters for supporting a healthy marine biota. Acute aquatic toxicity tests result in endpoint referred to as a “lethal dose 50” (LC50). The LC50 is the dose that produces mortality in 50% of the test organisms. A high LC50 value indicates low acute toxicity and a low LC50 indicates high toxicity. “Toxicity Units Acute” (TUa) are inverses of the LC50s and are calculated by dividing 100 by the LC50 resulting from a 96-hour toxicity test. High TUa values indicate high toxicity. The Ocean Plan daily maximum objective is 0.3 TUa for acute toxicity.

Samples at various ASBS were measured for acute toxicity in storm water runoff. Eleven samples of storm water runoff were tested for acute toxicity to fish, and many exhibited acute toxic at only moderate levels at or below 1.0 TUa; the most toxic was at the James V. Fitzgerald ASBS with a TUa for two discharge samples of 1.0. Most storm water runoff was not acutely toxic to crustaceans (mysids). However, eight out of 18 samples did exhibit moderate levels of acute toxicity to mysids. The highest acute toxicity to mysids was found in two samples from the City of Pacific Grove runoff discharges into Pacific Grove ASBS, with both samples having a TUa of 1.0.

Thirty six (36) samples of ocean receiving water near storm runoff were also measured for acute toxicity to fish and/or mysids. Half of these samples exhibited no acute toxicity, with the other half exhibiting only slight or moderate acute toxicity. Of these receiving water samples the most toxic of these were at La Jolla ASBS, where two samples had an LC50 for mysids of >75% (95% survival in 65% concentration, 1.33 TUa). One sample of ocean background water offshore of the La Jolla ASBS also displayed slight acute toxicity, with an LC50 for mysids of >75% (1.33 TUa).

Regarding chronic toxicity, the “No Observed Effect Level” (NOEL) is the highest concentration of effluent or receiving water that causes no observable adverse effects on the test organisms in a critical life stage bioassay. NOELs of 100 percent indicate that there was no observed toxicity; NOELs less than 100 percent indicate increasing toxicity with decreasing percent concentration. “Toxicity Units Chronic” (TUc) are inverses of the NOELs and are calculated by dividing 100 by the NOEL resulting from a critical life stage toxicity test. High TUc values indicate high chronic toxicity. The Ocean Plan daily maximum objective is 1.0 TUc for chronic toxicity. The results of chronic toxicity tests on critical life stages of marine life are more sensitive than acute toxicity results and are therefore more informative for purposes of evaluating ASBS discharges.

Samples at various ASBS were tested for chronic toxicity in storm water runoff. Only one (1) of the 35 runoff samples exhibited slight chronic toxicity to fish. However, invertebrates and kelp displayed more sensitivity to runoff samples. Twenty one (21) out of 29 samples exhibited chronic toxicity to giant kelp greater than the Ocean Plan objective of 1.0 TUc, with the highest values of ≥16 TUc at Trinidad Head, Carmel Bay, Laguna Point to Latigo Point, and La Jolla ASBS. Twelve (12) out of 15 samples exhibited some chronic toxicity to mysids greater than the Ocean Plan objective of 1.0 Tuc, with the highest chronic toxicity (>16 TUc) at Heisler Park ASBS. Twelve (12) out of 12 samples exhibited chronic toxicity to sea urchins greater than the Ocean Plan objective of 1.0 TUc, with seven samples exhibiting the highest chronic toxicity of 32.0 TUc. Mollusks appeared to have sensitivity to runoff, with five (5) out of six (6) runoff samples tested with bivalves having TUc > 1.0 and the two (2) samples of runoff tested with abalone both had TUc > 1.0, (2.0 and 4.0, TUc, both Carmel Bay ASBS).
.
Thirty nine (39) samples at various ASBS were also tested for chronic toxicity to various species in ocean receiving water. Only two (2) 0out of 38 samples exhibited chronic toxicity to fish greater than the Ocean Plan objective of 1.0 TUc, with the highest chronic toxicity (4.0TUc) at Northwest Santa Catalina Island ASBS at the Isthmus Cove. Ten (10) out of 33 samples exhibited chronic toxicity to giant kelp greater than the Ocean Plan objective of 1.0 TUc, with the highest values of 8.0 TUc at Carmel Bay ASBS (Stillwater Cove Pier) and 16.0 TUc at La Jolla ASBS. Only two (2) out of nine (9) samples exhibited slight chronic toxicity to mysids just above the Ocean Plan objective of 1.0 Tuc. Five (5) out of eleven (11) samples exhibited chronic toxicity to sea urchin fertilization greater than the Ocean Plan objective of 1.0 TUc; notably two samples, at Northwest Santa Catalina Island ASBS at Isthmus Cove were very toxic with ≥16.0 TUc. Two (2) out of nine (9) receiving water samples tested with bivalves had TUc > 1.0, and none of the two samples of receiving water tested with abalone exhibited chronic toxicity.

5.8.3 - ASBS Application Water Quality Data – Staff Conclusions

It is clear that ASBS discharges generally contain some concentrations of anthropogenic waste. However, it appears that a majority of the ASBS waste discharges exhibited metal concentrations below instantaneous maximum objectives, and a majority of ASBS receiving waters had concentrations of ocean plan metals below the six-month median objective for the protection of marine aquatic life. While most of the discharge samples exhibited chronic toxicity to marine life, the majority of the receiving water samples met the daily maximum chronic toxicity objective. Based on its review of the above baseline chemistry and toxicity data, there is ample evidence to support an Ocean Plan exception for nonpoint source and storm water discharges, but only if such discharges are properly controlled to better maintain natural water quality in ASBS.

Still, a number of discharges had elevated metals and PAH concentrations, and exhibited toxicity, and a few receiving water samples were in violation of Ocean Plan objectives. The testing described above generally had very little replication. This indicates that current waste concentrations are temporally and/or spatially variable. In other words, a given waste discharge may meet objectives at least some of the time, but not necessarily all of the time; some other waste discharges definitely do not have adequate BMPs to prevent violation of objectives all of the time, as displayed by some of the minority samples described above. Therefore, BMPs should be designed and implemented to insure maintenance of natural water quality in ASBS receiving water during design storms. The adoption of Special Protections will reduce wastes in discharges to achieve and maintain natural water quality in ASBS. In addition, discharges and receiving water must be adequately monitored to insure compliance with the Special Protections, based on the range of natural water quality conditions at approved reference stations.

The background (away from the direct discharges) ocean water quality data indicated a majority of samples exhibited concentrations of certain metals above the Ocean Plan six month medians. This may be due to the small sample size, but some of the results may be inaccurate due to inadequate methods. Another possibility is that these elevated levels are real and represent pollution from indirect and possibly distant watershed sources. It is important to remember that these “background” ocean water samples were not approved reference sites (SCCWRP 2010) and therefore do not represent “natural water quality. ”Should post-exception sampling indicate that some ASBS have background water quality at levels above natural water quality, then further assessment should be performed to identify and control the sources where feasible.

As noted above there was a large variance in the data set. Some part of these large data ranges may represent true variability in the environment. However, staff believes that there was also a fair amount of inconsistency in the applicants’ sampling and analysis methodology, which may have contributed somewhat to the variance of the exception application results as well. Regional monitoring programs, with consistent methodology and statewide compatibility, were therefore employed to improve data quality and utility.

5.8.4 - ASBS Regional Monitoring

As described above, a better approach for future ASBS monitoring would be to take a collaborative and coordinated regional approach. Therefore, staff requested the Southern California Coastal Water Research Project to assist, with stakeholder participation, in developing a scientifically sound regional monitoring approach. The goal of this monitoring program is to answer three questions:

- What is the range of natural water quality at reference locations?
- How does water quality along ASBS coastline compare to the natural water quality at reference locations?
- How does the extent of natural quality compare among ASBS with or without discharges?

It was agreed that the regional programs would focus on ASBS ocean water quality. Marine samples would also be collected at reference watershed conditions to answer question number one. Reference conditions were determined as follows:

- At the mouth of a watershed with limited anthropogenic influences and with no offshore discharges in the vicinity.
- Limited anthropogenic influence is defined as a minimum of 95% open space. Preferably, the few anthropogenic sources in a reference watershed will be well attenuated (e.g., natural space buffers between a highway and the high tide line).
- There should be no 303(d) listed waterbodies either in the reference watershed or in the coastal zone.

In the 2007-2008 winter season, a pilot study (SCCWRP 2009) was performed on potential reference sites. Table 5.8.5 provides average results and data ranges for all potential reference site samples:

Table 5.8.5. Statewide Pilot Study Potential Reference Sites Average Results and Data Ranges for All Samples Winter Season 2007-2008

Constituent	Units	All Sites n = 8
TSS	mg/L	40.8 (2.3 - 180)
Ammonia	mg/L	0.02 (ND - 0.04)
Nitrate	mg/L	0.02 (ND - 0.06)
Nitrite	mg/L	0.005 (ND - 0.01)
Phosphorus	mg/L	0.19 (ND - 1.13)
Chromium	µg/L	0.87 (0.1 - 3.17)
Copper	µg/L	0.86 (ND - 2.76)
Lead	µg/L	0.98 (ND - 4.65)
Nickel	µg/L	1.53 (ND - 4.58)
Zinc	µg/L	2.13 (ND - 9.37)
Total PAH	µg/L	0.081 (0.001 - 0.444)
Total DDT	µg/L	ND
Total PCB	µg/L	ND
Toxicity Assay	% fertilization	96.8 (92 - 99)

It is clear from the above information (Table 5.8.5.) that the mean values for ammonia and metals were below Ocean Plan six-month medians objectives. The only constituents with maximum values slightly above the six month medians were chromium and lead; in the case of chromium the objective is based on hexavalent chromium, and the chromium value presented above was for total chromium. PAHs were present but are known to be naturally present in watersheds and submarine geological features. Most importantly there were no detectable levels of the synthetic pollutants DDT and PCB in the samples. Although there was a small sample size, and this work only represents one winter season, this first year pilot study may give us a good picture of nearshore ocean natural water quality.

Not all of the eight samples were collected when surface stream runoff entered ocean waters. However when comparing samples with surface drainage influence and with samples when no drainage was occurring, the average values for metals and PAH was slightly higher when there was no drainage. This indicates a likelihood that stream runoff provides some reduction of metal and PAH concentration due to natural dilution.

Table 5.8.6. Statewide Pilot Study Potential Reference Sites Regional Comparison of Potential Reference Stations

Constituent	Units	North Coast n = 1	Central Coast n = 2	South Coast n = 2
TSS	mg/L	12.3	5.35 (2.3 - 8.4)	34.5 (21.7 - 47.2)
Ammonia	mg/L	0.03	0.02 (ND - 0.04)	0.015 (ND - 0.03)
Nitrate	mg/L	0.06	0.01	0.005 (ND - 0.01)
Nitrite	mg/L	0.01	ND	0.005 (ND - 0.01)
Phosphorus	mg/L	ND	ND	0.016 (ND - 0.032)
Chromium	µg/L	1.12	0.11 (0.1 - 0.12)	0.76 (0.6 - 0.92)
Copper	µg/L	1.07	0.31 (ND - 0.62)	0.91 (0.28 - 1.54)
Lead	µg/L	0.15	0.20 (ND - 0.39)	1.11 (0.51 - 1.71)
Nickel	µg/L	1.56	0.66 (ND - 1.31)	1.88 (0.53 - 3.23)
Zinc	µg/L	ND	0.77 (0.1 - 1.45)	2.56 (2.44 - 2.69)
Total PAH	µg/L	0.003	0.003 (0.001 - 0.004)	0.018 (0.012 - 0.024)
Total DDT	µg/L	ND	ND	ND
Total PCB	µg/L	ND	ND	ND
Toxicity Assay	% fertilization	98	96.5 (96 - 97)	95.5 (92 - 99)

One concern voiced by stakeholders is that there may be differences in natural water quality in different regions of the state. Table 5.8.6. represents a regional comparison of the potential reference station results. There were only slight differences between regions with regard to individual constituents, but there are no clear trends overall. This may be due to the small sample size, so additional work should be performed regionally.

The State Water Board funded a statewide monitoring program during the winter of 2008-09 to assess water quality in ASBS near and far from direct discharges. Over 100 chemical constituents and toxicity were measured from 62 sites using a probabilistic study design; roughly half of sites were sampled in the ocean directly in front of a direct discharge into an ASBS and the other half were located in the ocean greater than 500 m from a direct discharge. Sample sites greater than 500 m from direct discharges may be influenced by other watershed drainages either into or outside of the ASBS, and therefore may represent background but not necessarily natural conditions. Samples at each site were collected less than 24 hr before rainfall and again less than 24 hr after rainfall. Ocean receiving water sites were sampled at most mainland ASBS in California.

The statewide survey illustrated generally good chemical water quality in mainland ASBS sites (Table 5.8.6). None of the constituents exceeded the instantaneous maximum objective in the California Ocean Plan. Seven constituents did not exceed the Ocean Plan's six month median or 30 day average (depending on the specific constituent) including strictly synthetic anthropogenic chemicals such as DDTs or PCBs.

Six constituents (arsenic, cadmium, copper, lead, nickel and zinc) exceeded the six month median but only for relatively small (< 15%) portions of mainland ASBS shoreline. Many of these constituents are common in urban stormwater, but also have natural sources. The lack of excessive chemical contamination in ASBS receiving waters was supported by infrequent (<5% of ASBS shoreline) chronic toxicity to a California endemic species (the purple sea urchin, *Strongylocentrotus purpuratus*).

There were two constituents, chromium and polycyclic aromatic hydrocarbons (PAHs), that exceeded Ocean Plan objectives over relatively large proportions of ASBS shoreline. Chromium exceeded objectives over 50% of ASBS mainland shoreline miles and PAHs exceeded objectives over 87% (Table 5.8.7.). The extent of Ocean Plan exceedence for these two constituents was similar near and far from discharges following storm events, and exceedances of the standards was similar between pre-storm and post-storm conditions near discharges. [9]

Both chromium and PAHs have natural and anthropogenic sources. The chromium objective is based on the more toxic form, hexavalent chromium, but total chromium was analyzed for the statewide probabilistic study. Chromium is a natural product of erosion including that from metamorphic rock, and there is no reason to believe that natural rock erosion products contain significant hexavalent chromium. Also, as mentioned previously, there are natural sources of PAHs (including hydrocarbon seeps, wildfires and plants) and direct atmospheric is another possible source. Furthermore, the objective for PAH is based on human health through bioaccumulation in seafood, and not on the protection of marine aquatic life. Since exceedences were similar between pre-storm and post-storm conditions near discharges, the sources of elevated PAHs may not only be storm related, and may include coastal and beach sediment.

[9] Report to the State Water Resources Control Board, Summation of Findings, Natural Water Quality Committee, 2006-2009, September 1, 2010.

Table 5.8.7. Statewide Probabilistic Study Percent of ASBS shoreline that exceeded State Water Board Ocean Plan objectives following storm events.

	Ocean Plan Objective	% Shoreline Greater Than OP Objective: All ASBS	<500 m from Discharge	>500 m from Discharge
Ammonia-N[1]	0.6 mg/L	--	--	--
Arsenic[1]	8 ug/L	1.6	2.7	--
Cadmium[1]	1 ug/L	2.1	3.6	--
Chromium[1]	2 ug/L	50	61	35
Copper[1]	3 ug/L	6.9	4.8	9.8

A collaborative ASBS effort was formed between several exception applicants, the State and Regional Water Boards, and SCCWRP in southern California as part of the Southern California Bight regional monitoring program (Bight'08). This study identified and sampled reference sites to measure natural water quality. Stakeholders agreed on reference site criteria that avoided anthropogenic sources by sampling in the surf zone at the mouth of streams located in watersheds having less than 90 % development. Reference site concentrations were then compared to concentrations measured near ASBS direct discharges. Similar to the statewide probabilistic survey described above, Bight'08 focused on wet weather.

Regional reference results had generally low concentrations of Ocean Plan constituents (Table 5.8.8) and a lack of chronic toxicity to sea urchin fertilization. Results were somewhat similar to the pilot reference study for most constituents, with the exception of total suspended solids (which was much higher in the Bight 08 study); this difference was likely due to the larger number of samples and different storm conditions in Bight 08. In the Bight 08 monitoring study, following storms, mean reference site concentrations for six out of eight Ocean Plan metals were at or below the six month median objective, with cadmium and lead having mean concentrations only slightly higher (less than 1.0 ug/L greater) than the objective. The maximum concentration for reference sites exceeded Ocean Plan objectives for seven metals (cadmium, chromium, copper, lead, nickel, silver and zinc). Maximum concentrations for four of these metals (cadmium, chromium, lead and silver) exceeded the daily maximum following storms, but none exceeded the instantaneous maximum. The mean concentration for PAHs at reference sites was also greater than the 30 day average objective. [10]

Table 5.8.8. Southern California Bight Study Minimum, maximum, median, and mean (± 95% confidence interval) of post-storm chemical concentrations at reference sites in the southern California Bight during 2009.

Parameter	Reference Site Concentrations							Ocean Plan Objective
	Units	%ND	Min	Median	Max	Mean	(±)95% CI	
TSS	mg/L	8	Nd	7.7	1692	140	171	-

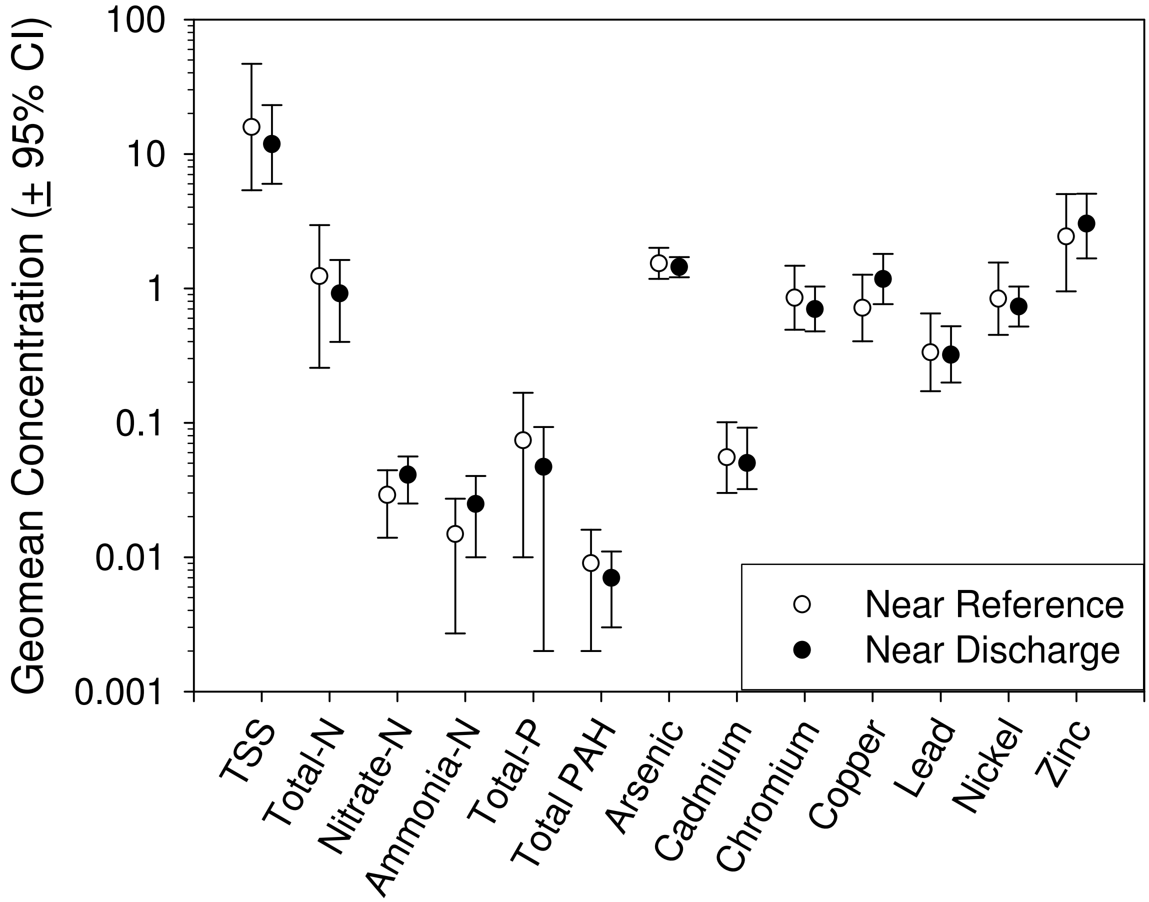
nd = not detected
95% CI = confidence interval
- = no objectives exist for this parameter

The results for ASBS discharge sites as a whole were generally similar to reference sites (Figure 5.8.7.) Mean concentrations at ASBS discharge sites following storm events were not significantly different from mean reference site concentrations for all constituents; however many for copper results at discharge sites were above the maximum reference site concentrations. In addition there were individual direct discharges with concentrations of certain other constituents that exceeded reference concentrations. For comparing discharge sites to a measure of natural water quality, a threshold level equivalent to the 85th percentile of the reference site post-storm concentrations was used. This 85th percentile level was chosen to represent natural water quality to eliminate uncertainty associated with outliers, thereby being protective of water quality.

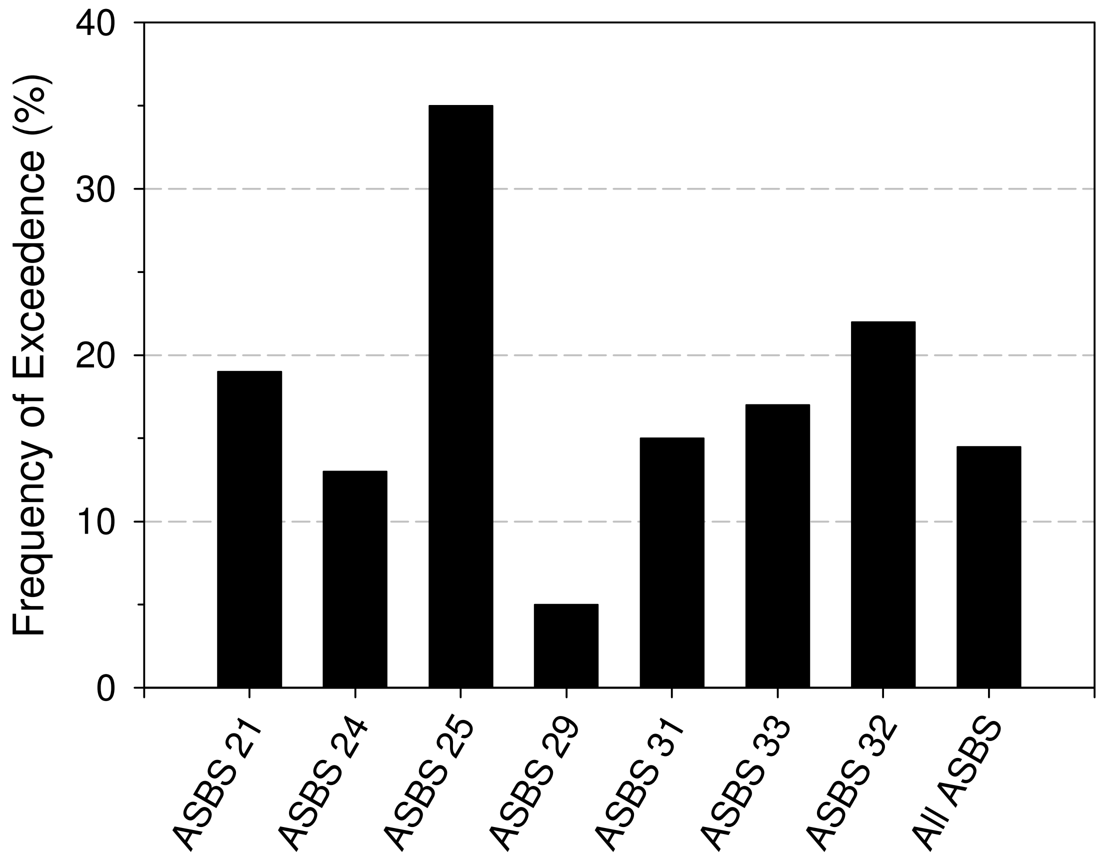
[10] Report to the State Water Resources Control Board, Summation of Findings, Natural Water Quality Committee, 2006-2009, September 1, 2010.

Figure 5.8.7. Southern California Bight Study Comparison of geometric mean (± 95% confidence interval) concentrations in ambient near-shore receiving waters following storm events at reference drainage and ASBS discharge sites. Total suspended solids (TSS) and nutrients in mg/L; Total Polycyclic Aromatic Hydrocarbons (Total PAHs) and total trace metals in µg/L



Exceedences of natural water quality were relatively infrequent at ASBS discharge sites (Figure 5.8.8.). Seven out of eight ASBS in southern California having exceedence rates of less than 25% for all constituents; Northwest Santa Catalina Island ASBS (ASBS 25) had the highest exceedence rate of 35%.

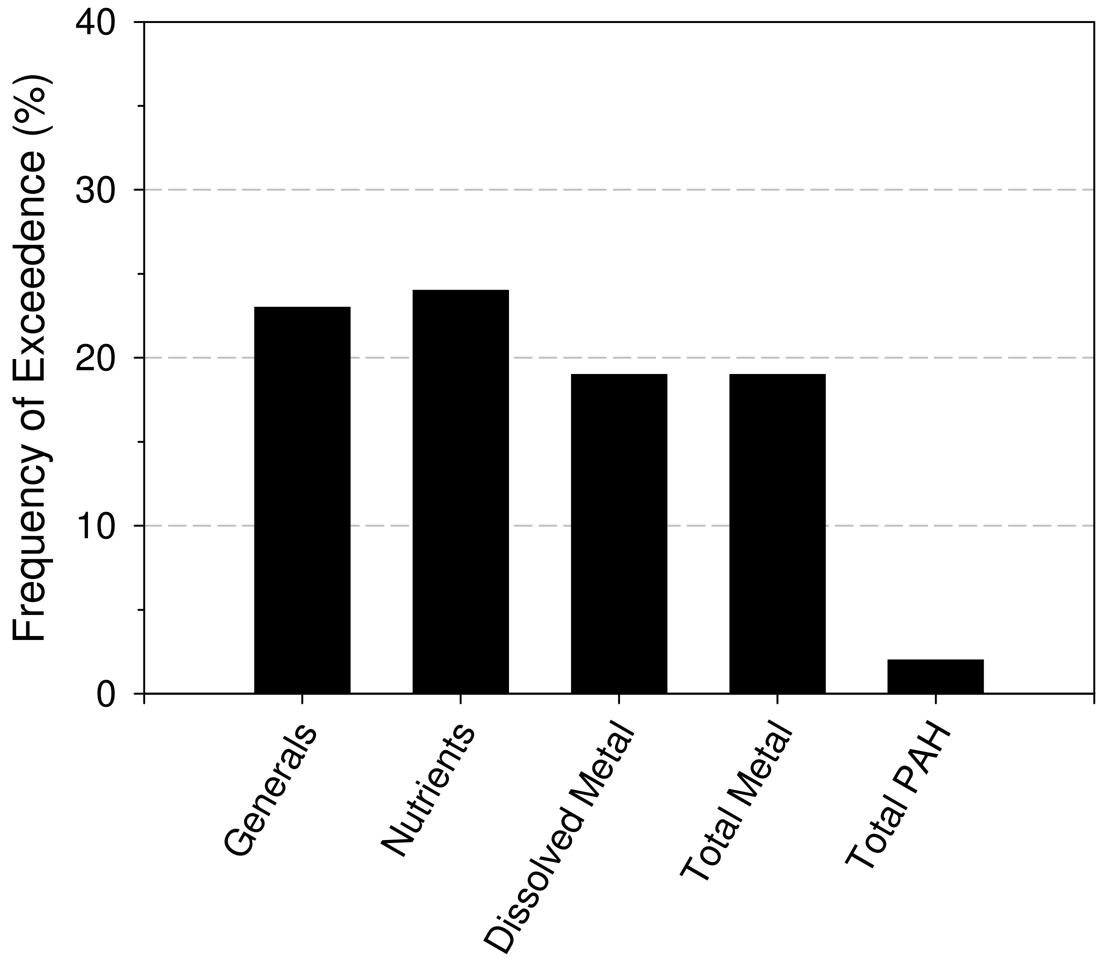
Figure 5.8.8. Frequency of natural water quality exceedences for all parameters during all storm events at each Area of Special Biological Significance (ASBS) in southern California



Where natural water quality was exceeded, general constituents (e.g. total suspended solids), nutrients and trace metals were the most frequent groups to exceed (Figure 5.8.9.). Total and dissolved metals had the same exceedence rate of 19% over the natural water quality thresholds identified in this study. PAHs exceeded the natural water quality threshold in only 2% of the samples. [11]

[11] Final Draft Report , Defining Natural Water Quality In Southern California's Areas Of Special Biological Significance, Kenneth Schiff, Brenda Luk, Dominic Gregorio, and Steve Gruber, 2010

Figure 5.8.9. Frequency of natural water quality exceedences by parameter group for all storm events and all Areas of Special Biological Significance (ASBS) in southern California



Regional and statewide monitoring in ASBS to date has proven very successful in providing scientific evidence of water quality conditions and indications of locations and certain constituents that require additional focus. The Bight'08 study represents the first comprehensive effort to determine natural water quality characteristics in the nearshore following storm events. The Natural Water Quality Committee stated that the Bight'08 program has provided sufficient information for the State Water Board to move forward, but prudent management should seek additional information. For example, Bight'08 quantified intra-annual (storm-to-storm) variability, but lacked inter-annual known to produce natural alterations in ocean water quality. Similarly, additional reference sites in central and northern California are necessary to quantify regional variability. However, in some instances, the reference site approach may be problematic, such as cases of widespread anthropogenic influence (i.e., PAHs and TCDDs) or where distant sources impinge on reference site water quality. (i.e., transport of large stormwater plumes from outside the ASBS). All of these causes of natural variability, and impacts from unanticipated anthropogenic contributions, should be investigated. Therefore staff recommends that where possible the regional approach to ASBS monitoring be designed and implemented to provide comparable and consistent information to manage ASBS discharges.

5.8.5 - Bioaccumulation

As part of their monitoring program for their ASBS exception and NPDES Permit, Scripps Institution of Oceanography (SIO), who performed a bioaccumulation study in receiving waters. This monitoring, which used both transplanted mussels and resident sand crabs, occurred in the vicinity of localized reference and ASBS discharge sites in the San Diego-Scripps ASBS and the La Jolla ASBS. SIO results indicated that:

1) most organic constituents were present at statistically nonsignificant levels relative to a reference sites during the study period;
2) certain pollutants were elevated in transplanted mussels near the SIO pier in the San Diego-Scripps ASBS (Cr, Ni, Fe, and Mn) and at the south end of the adjoining La Jolla ASBS (As) where the City of San Diego storm outfalls are located relative to other sites within the study area;
3) certain pollutants were elevated in transplanted mussels near the SIO pier (Cr and Ni) relative to historical statewide Mussel Watch results; and
4) large relative variability in tissue concentrations from sand crabs due to age/reproductive status precluded an assessment of spatial scale gradients and an evaluation of potential effects. [12]

Statewide mussel watch monitoring is an important tool in assessing bioaccumulation and water quality. Data collected by the National Ocean and Atmospheric Administration (NOAA) National Status and Trends (NS&T), and by the State Water Board Mussel Watch Program (SMWP) are provided below to assess spatial distributions and temporal trends in chemical contamination in or near certain ASBS.

5.8.5.1 <u>State Mussel Watch Program Data</u>

The SMWP was initiated in 1977 by the State Water Board to provide a uniform statewide approach to the detection and evaluation of toxic substances in California coastal waters, bays, harbors, and estuaries. The SMWP conducted a monitoring program using transplanted bivalve (*Mytilus californianus*) for trace elements and organic contaminants. The tissue samples were analyzed for the presence of trace elements and legacy pesticides.

An Elevated Data Level (EDL) is defined for the purposes of the SMWP as that concentration of a toxic substance in mussels or clams that equals or exceeds a specified percentile (such as 85 or 95 percent) of all measurements of the toxic substance in the same species and exposure condition (resident or transplant). Historical information on SMWP sites at ASBS are provided in Appendix 3)

---

[12] Report to the State Water Resources Control Board, Summation of Findings, Natural Water Quality Committee, 2006-2009, September 1, 2010.

The SMWP program has suffered from a lack of funding since 2000. The Department of Fish and Game at Moss Landing Laboratories collected and analyzed mussel samples since 2001 from a limited list of sites. Only 18 sites are currently being monitored for the Water Boards by the California Department of Fish and Game. SMWP primary targets areas with known or suspected impaired water quality. For this report, data from the following sites in or near ASBS have been reviewed: Pacific Grove ASBS, James V. Fitzgerald ASBS, Bodega Head (near but not within the ASBS), and Trinidad Head ASBS.

The available data for trace elements and organic constituents from 2001 to 2005 were reviewed and compared to the EDL 85 and EDL 95. Most trace elements were present at low concentration in all ASBS. However none of the elements exceeded the EDL 85 or EDL 95 in transplanted mussels at any of the ASBS during 2001-2005 sampling periods.

Certain synthetic chlorinated hydrocarbon compounds were elevated at some ASBS sites. Pesticide compounds including cis-chlordane, trans-chlordane, total chlordane, heptachlor epoxide, and dieldrine exceeded the EDL 85 in Trinidad Head, James V. Fitzgerald and Pacific Grove ASBS, and at Bodega Head, during one or more sampling events in 2001 to 2004. Data from James V. Fitzgerald and Pacific Grove ASBS also show exceedences of the EDL 95 for DDD, DDE, and PCB 1254.

Appendix 3 provides State Mussel Watch data at or near ASBS from 2001 to 2005.

5.8.5.2 <u>NOAA NS&T Mussel Watch Program Data</u>

To characterize the spatial distributions and trends in contaminant levels in the coastal ocean, NOAA NS&T Program was formed in 1986. The NOAA NS&T Mussel Watch Program measures the presence of concentrations of a broad suite of trace metals and organic chemicals in resident bivalves. The NS&T Mussel Watch Program is national in scale and the sampling sites are representative of a large area.

The NOAA NS&T Program analyzes bivalve tissue samples from the mussels *M. edulis and M. californianus* for trace metals, synthetic organic constituents, and histopathology. The NOAA NS&T sampling is conducted every two years.

There are several pre-2007 historical sites in the NOAA NS&T data base that are in or near ASBS. These were:

- Klamath River Flint Rock Head (Redwood National Park ASBS)
- Point Delgada Shelter Cove (King Range ASBS)

- Bodega Head (near Bodega ASBS)
- Farallon Islands East Landing (Farallon Islands ASBS)
- Pacific Grove Lovers Point (Pacific Grove ASBS)
- San Miguel Island Otter Harbor (San Miguel, Santa Rosa and Santa Cruz Islands ASBS)
- Santa Cruz Island Fraser Point (San Miguel, Santa Rosa and Santa Cruz Islands ASBS)
- Point Dume (Laguna Point to Latigo Point ASBS)
- Catalina Island Bird Rock (NW Santa Catalina Island ASBS)
- Newport Beach West Jetty (near Robert Badham ASBS)
- La Jolla (near the La Jolla ASBS).

Beginning in 2007, SCCWRP and the State Water Board entered into a partnership with the NOAA Status and Trends Mussel Watch Program. SCCWRP agreed to sample in southern California and the State Water Board staff agreed to sample in central and northern California. Samples are sent to NOAA contracted laboratories for analysis at no cost to the State. In exchange for providing sampling at existing NOAA sites several additional sampling sites were sampled and analyzed, many at ASBS. During the sampling period 2007-2009 the following sites were added in or near ASBS:

- Sea Ranch (near Del Mar Landing ASBS)
- Gerstle Cove (Gerstle Cove ASBS)
- Duxbury Reef (Duxbury Reef ASBS)
- Point Reyes (near Point Reyes Headlands ASBS)
- Ano Nuevo (Ano Nuevo ASBS)
- Partington Point (Julia Pfeiffer Burns ASBS)
- Anacapa (North Middle) Island (Santa Barbara and Anacapa Islands ASBS)
- Mugu Lagoon (adjacent to Laguna Point to Latigo Point ASBS)
- Old Stairs (Laguna Point to Latigo Point ASBS)
- San Nicolas Island (San Nicolas Island and Begg Rock ASBS)
- San Clemente Island (San Clemente Island ASBS)
- Crystal Cove State Park (Irvine Coast ASBS)
- Scripps Reef (San Diego-Scripps ASBS)

Concentrations of ten constituents (including trace metals and PAHs) in samples from 2007 to 2009 were assessed at all mussel watch sites statewide and at ASBS sites. It is important to mention that all of these constituents have both anthropogenic (e.g., polluted runoff) and natural sources. Natural sources for trace metals include natural background in seawater, sometimes accentuated by upwelling and coastal erosion. In fact, certain metals, including copper and zinc, are essential micronutrients that when present at naturally low concentrations are essential for marine life. Hydrocarbon seeps are an important potential source for PAHs. The following information is provided to give a general status of these constituents in mussel tissue in ASBS.

Arsenic
Mean and median arsenic concentrations for all mussel watch sites statewide were 10.53 µg/ dry g and 9.45 µg/ dry g, respectively. Mean and median arsenic concentrations for all ASBS sites were 13.35 µg/ dry g and 10.8 µg/ dry g, respectively. San Clemente Island ASBS has the highest concentration of arsenic in mussels (39.9 µg/ dry g) among all ASBS sites, and also had the highest concentration of all mussel watch stations statewide.

Cadmium
Mean and median cadmium concentrations for all mussel watch sites statewide were 5.163 µg/ dry g and 5.01µg/ dry g, respectively. Mean and median cadmium concentrations for all ASBS sites were 7.522 µg/ dry g and 6.825 µg/ dry g, respectively. The Carmel Bay ASBS at Arrowhead Point has the highest concentration of cadmium in mussels (14.4 µg/ dry g) among all ASBS sites, and also had the highest concentration of all mussel watch stations statewide.

Chromium
Mean and median chromium concentrations for all mussel watch sites statewide were 1.753 µg/ dry g and 1.46 µg/ dry g, respectively. Mean and median chromium concentrations for all ASBS sites were 1.76 µg/ dry g and 1.6 µg/ dry g, respectively. Bodega Head, near the Bodega Head ASBS, has the highest concentration of chromium in mussels (4.61 µg/ dry g) among all sites in or near ASBS.

Copper
Mean and median copper concentrations for all mussel watch sites statewide were 9.28 µg/ dry g and 8.36 µg/ dry g, respectively. Mean and median copper concentrations for all ASBS sites were 9.335 µg/ dry g and 8.195 µg/ dry g, respectively. The King Range ASBS, at Point Delgada (Shelter Cove) has the highest concentration of copper in mussels (15.5 µg/ dry g) among all ASBS sites, and also had the highest concentration of all mussel watch stations statewide (see Figure 5.8.10.).

Lead
Mean and median lead concentrations for all mussel watch sites statewide were 1.948 µg/ dry g and 1.36 µg/ dry g, respectively. Mean and median lead concentrations for all ASBS sites were 2.279 µg/ dry g and 1.345 µg/ dry g, respectively. The Farallon Islands ASBS, at East Landing, has the highest concentration of lead in mussels (17.8 µg/ dry g) among all ASBS sites, and also had the highest concentration of all mussel watch stations statewide.

Mercury
Mean and median mercury concentrations for all mussel watch sites statewide were 0.116 µg/ dry g and 0.074µg/ dry g, respectively. Mean and median mercury concentrations for all ASBS sites were 0.144 µg/ dry g and 0.106 µg/ dry g, respectively.

San Miguel Island (ASBS 17), at Otter Harbor, has the highest concentration of mercury in mussels (0.69 µg/ dry g) among all ASBS sites, and also had the highest concentration of all mussel watch stations statewide.

Nickel
Mean and median nickel concentrations for all mussel watch sites statewide were 2.913 µg/ dry g and 2.18 µg/ dry g, respectively. Mean and median nickel concentrations for all ASBS sites were 2.973 µg/ dry g and 2.5 µg/ dry g, respectively. The Redwoods National Park ASBS at the mouth of the Klamath River has the highest concentration of nickel in mussels (9.23 µg/ dry g) among all ASBS sites, and also had the highest concentration of all mussel watch stations statewide.

Silver
Mean and median silver concentrations for all mussel watch sites statewide were 0.166 µg/ dry g and 0.061µg/ dry g, respectively. Mean and median silver concentrations for all ASBS sites were 0.131µg/ dry g and 0.084µg/ dry g, respectively. The Laguna Point to Latigo Point ASBS, at Point Dume in Malibu, has the highest concentration of silver (0.842 µg/ dry g) among all the ASBS sites.

Zinc
Mean and median zinc concentrations for all mussel watch sites statewide were 144.98 µg/ dry g and 138 µg/ dry g, respectively. Mean and median zinc concentrations for all ASBS sites were 156.8 µg/ dry g and 160.5 µg/ dry g, respectively. San Miguel Island (ASBS 17), at Otter Harbor has the highest concentration of zinc in mussels (232 µg/ dry g) among all ASBS sites.

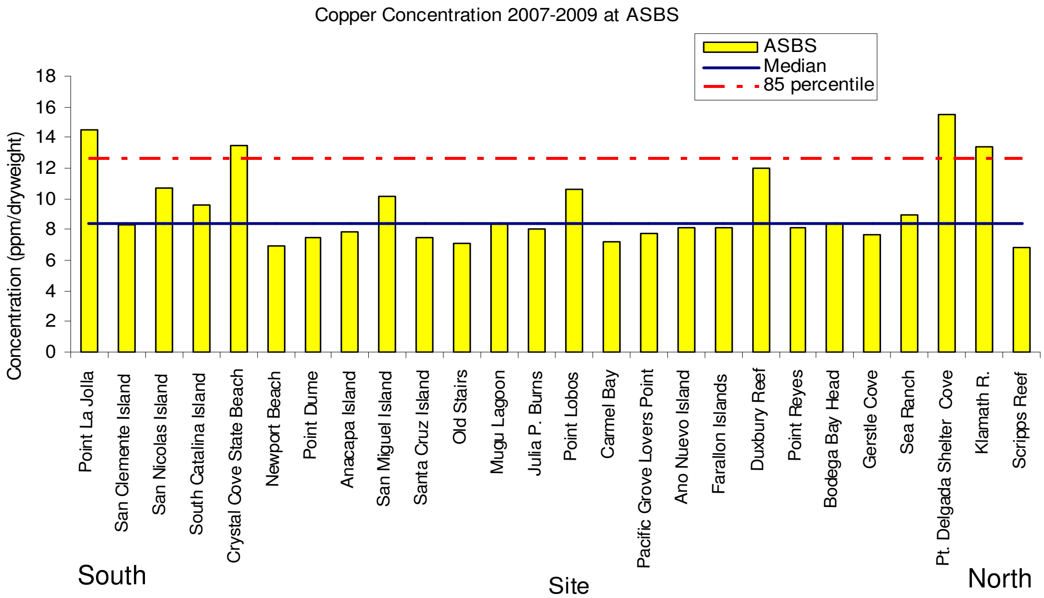
Total PAHs
Mean and median total PAH concentrations for all mussel watch sites statewide were 1139.17ng/ dry g and 122.2ng/ dry g, respectively. Mean and median total PAH concentrations for all ASBS sites were 128.68 ng/ dry g and 100.1 ng/ dry g, respectively. Ano Nuevo ASBS has the highest concentration of total PAHs in mussels (688.7ng/ dry g) among all the ASBS sites.

Trends for historical data (1986 – 2009) at several mussel watch sites at or near ASBS were assessed. Most organic pollutants are either staying the same or showing significant decreases in mussel tissues. Chlordane concentrations show a significant decrease at King Range ASBS, Laguna Point to Latigo Point ASBS, NW Catalina Island ASBS, and La Jolla ASBS. Butyltin concentrations show a significant decrease near the Robert Badham ASBS and in the Laguna Point to Latigo Point ASBS. DDT is also decreasing significantly at Laguna Point to Latigo Point ASBS.

Most trace metals are either staying the same or showing significant decreases in mussel tissues. Arsenic concentrations show a significant decrease at the Pacific Grove ASBS, NW Catalina Island ASBS and La Jolla ASBS. Lead concentrations show a significant decrease near in the Robert Badham ASBS and in the La Jolla ASBS.

Mercury concentrations show a significant decrease near in the Laguna Point to Latigo Point ASBS. Selenium concentrations are decreasing at Laguna Point to Latigo Point ASBS. Silver concentrations show a significant decrease near the Robert E. Badham ASBS and in the La Jolla ASBS. Tin concentrations are decreasing at the King Range ASBS, Pacific Grove ASBS, Laguna Point to Latigo Point ASBS, NW Catalina Island ASBS, and near the Robert Badham ASBS. However there were a few metals that were increasing at certain ASBS. Copper concentrations are increasing at the King Range ASBS; this increase in copper in mussels at the King Range ASBS is of concern because that site has the highest copper concentrations in resident mussels of any mussel watch site (Figure 5.8.10). Cadmium concentrations are increasing at the Pacific Grove ASBS and Laguna Point to Latigo Point ASBS. Mercury concentrations are increasing near the Robert Badham ASBS and in the La Jolla ASBS.

Appendix 3 provides the NOAA Mussel Watch data for ASBS.



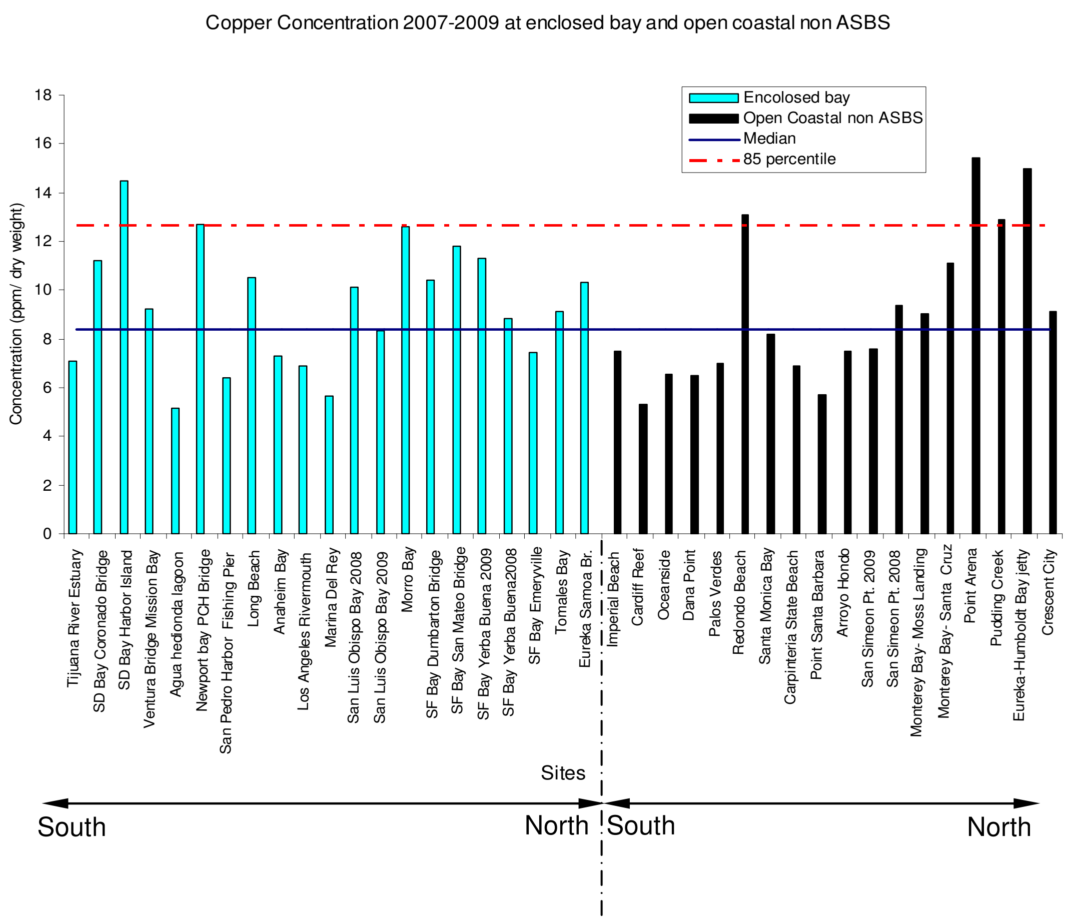


Figure 5.8.10. Mussel watch copper concentrations in ASBS and at other sites statewide.

6.0 ENVIRONMENTAL ANALYSIS

6.0 APPROACH TO THE ENVIRONMENTAL ANALYSIS

Sections 6.1 through 6.10 of this FEIR present a discussion of existing conditions, environmental impact associated with implementation of the proposed project, mitigation measures to reduce the level of impact, and residual significant impacts (i.e., impacts that would be significant and unavoidable despite the imposition of ay proposed mitigation measures). Issues evaluated in these sections consist of the range of environmental topics originally identified for review in the notice of preparation (NOP) and initial study (IS) prepared for the proposed project. Sections 6.1 through 6.10 each include the following components.

► **Environmental Impacts:** This subsection identifies the impacts of the proposed project on the existing environment, in accordance with State CEQA Guidelines Sections 15125 and 15143. Before presenting an evaluation of impacts, the section describes the analysis methodology used, and thresholds of significance used to identify impacts are then listed. Project impacts are identified alphanumerically and sequentially throughout this section. For example, impacts in Section 6.1 are identified as 6.1-1, 6.2-2, and so on. An impact statement preceded the discussion of each impact and provides a summary of the impact and its level of significance. The discussion that follows the impact statement included the evidence on which a conclusion is made regarding the level of impact. The discussions of cumulative impacts and growth-inducing impacts are presented in Section 8.0.

► **Mitigation Measures:** This subsection identifies potentially feasible mitigation measures to reduce significant and potentially significant impacts of the proposed project, in accordance with State CEQA Guidelines Sections 15002(a)(3), 15021(a)(2), and 15091(a)(1). Each mitigation measure is identified alphanumerically to correspond with the number of the impact being reduced by the measure. For example, Impact 6.1-1 would be mitigated with Mitigation Measure 6.1-1. This subsection also describes whether the mitigation measures would reduce impacts to less-that-significant levels. Significant and unavoidable impacts are identified as appropriate in this subsection, as well as in the "Residual Significant Impacts" subsection described below. Significant and unavoidable impacts are also summarized in Section 8.0.

► **Implementation:** This section identifies the agency responsible for the implementation of the mitigation measures.

► **Significance After Mitigation:** This section identifies impacts that would be reduced to less than significant and any significant impacts that would remain significant following implementation of the mitigation measures.

Any potential environmental impacts associated with the implementation of the General Exception Special Protections measures depend upon the specific compliance projects selected by the responsible parties identified herein, most of whom are public agencies subject to their own CEQA obligations. (See Pub. Res. Code § 21159.2, project-specific compliance projects). This program level EIR identifies broad mitigation approaches that could be considered at the program level for common selected BMPs. Consistent with PRC § 21159.2, this EIR does not engage in speculation or conjecture, but rather considers the reasonably foreseeable environmental impacts of the foreseeable methods of compliance, the reasonable foreseeable feasible mitigation measures, and the reasonable foreseeable alternative means of compliance, which would avoid or reduce the identified impacts.

Within each of the sections listed below, this EIR evaluated the impacts of each implementation alternative relative to the subject resource area. The physical scope of the environmental setting and the analysis in this EIR are the 26 ASBS potentially affected discharges arising from the 27 Responsible Parties identified previously in Section 1.0. Though this EIR governs potential impacts at 26 different geographic ASBS locations, generalizations are made about the impacts of different compliance measures (i.e. BMPs) and are expected to generate similar results. This is a reasonable assumption, given that the discharge of waste generated by the Responsible Parties is conveyed to the ocean waters of the ASBS primarily via storm drains and waste would be controlled and/or eliminated by any one of or a combination of the Special Protections implementation alternatives. Also, any potential impacts of implementing the proposed alternatives would be focused, short-term and ultimately produce long-term beneficial improvements to water quality and the removal of pollutants discharged to the ocean.

The implementation alternatives evaluated in this EIR are evaluated at a program level for impacts for each resource area. An assumption is made that a more detailed project-level analysis will be conducted by each Responsible Party once their mode of achieving compliance with the Special Protections has been determined. The analysis is this EIR assumes that, project proponents will design, install, and maintain implementation measures following all applicable laws, regulations, ordinances, and formally adopted municipal and/or agency codes, standards and practices. Several handbooks are available and currently used by municipal agencies that provide guidance for the selection and implementation of BMPs (Caltrans, CASQA, WERF).

As previously discussed in Section S.0 Executive Summary, the Special Protections would also be incorporated into the water quality control plans (basin plans) of six (6) coastal Regional Water Boards and into each Responsible Parties discharge permit. The Regional Water Boards would implement these regulations along with those authorized local agencies that would be given authority by the Regional Water Boards to implement and enforce the regulations, while the Responsible Parties are the lead agencies for any and all projects implemented within their jurisdiction, to comply with the program. The Regional Water Board does not specify the actual means of compliance by which responsible agencies choose to comply with the Special Protections.

Therefore, the implementation alternatives are mostly evaluated at a program level in this EIR. The alternatives assessed at a program level generally are projects that would be implemented as part of Special Protections compliance, PRC § 21159 places the responsibility of project-level analysis on the agencies that will implement the Special Protections.

6.01 DISCUSSION GENERAL EXCEPTION PROJECT MITIGATING TERMS AND SPECIAL CONDITIONS – SPECIAL PROTECTIONS

Since 1983, the Ocean Plan has prohibited the discharge of both point and nonpoint source waste to ASBS, unless the State Water Board grants an exception. The Ocean Plan allows the State Water Board to grant exceptions to plan requirements where the State Water Board determines that the exception "will not compromise protection of ocean waters for beneficial uses, and, [t]he public interest will be served." Prior to granting an exception, the State Water Board must hold a public hearing and comply with CEQA. In addition, the U.S. EPA must concur.

ASBS are also accorded special protection under the Marine Managed Areas Improvement Act (Act), PRC §36600 et seq. Under the Act, ASBS are a subset of state water quality protection areas and, as such, “require special protection as determined by the [State Water Board]” pursuant to the Ocean Plan (Public Resources Code §36700(f).) In all SWQPAs, waste discharges must be prohibited or limited by special conditions, in accordance with state water quality law, including the Ocean Plan (*Id.* §36710(f).)

On October 18, 2004, the State Water Board notified responsible parties to cease storm water and nonpoint source waste discharges into ASBS or to request an exception under the Ocean Plan. Several responsible parties submitted requests, or conditional requests, for exceptions. Subsequently, the State Water Board provided general instructions for exception application packages via its website. The State Water Board sent letters (in a few cases later in 2005) to responsible parties, providing specific instructions and a deadline for submission of the application package by May 31, 2006.

The State Water Board has received 27 applications for the general exception to the Ocean Plan prohibition against waste discharges to ASBS. The applications were filed by permitted storm water dischargers and nonpoint source dischargers, who are identified in Section 1.0. Staff recommends that the State Water Board grant the exceptions, provided that the dischargers comply with the Special Protections that are contained in this document.

Appendix 1 presents the staff draft proposal for State Water Board action on the exception applications that would establish “Special Protections” to address the applicants’ storm water and nonpoint source discharges into the affected ASBS. The proposed action is consistent with the Ocean Plan, which authorizes limited exceptions to the ASBS discharge prohibition, and with the Act, which authorizes waste discharges to ASBS only if they are limited by special conditions and conform to Ocean Plan requirements. The State Water Board will consider adoption of the Special Protections under the exception provisions of the Ocean Plan. The proposed special conditions in these Special Protections would limit waste discharges with prohibitions and special conditions to protect beneficial uses, including marine aquatic life and the maintenance of natural water quality within ASBS.

The 27 applicants have submitted extensive information. This FEIR is based on staff's review of that information, public comments received at the Board scoping meetings and subsequent stakeholder meetings.

This FEIR is in part modeled after State Water Board Resolution Nos. 2004-0052, 2006-0013, and 2007-0058, individual exceptions/Special Protections related to the Scripps Institution of Oceanography, Wrigley Marine Science Center, and Bodega Marine Lab discharges, respectively. The requirements in the draft Special Protections may be summarized generally to eliminate dry weather runoff, ensure that wet weather runoff does not alter natural water quality in the ASBS, and that adequate monitoring be conducted to determine if natural water quality and the marine life beneficial use is protected. The Special Protections are organized first according to applicability to permitted storm water or nonpoint source discharges. Each of these sections provides the applicable prohibitions and special conditions that limit waste discharges from each category. Requirements for storm water plans and compliance schedules are also provided. Special requirements are then given for parks and recreation facilities and waterfront and marine operations. Finally the terms and conditions for ASBS monitoring are provided.

6.1 ANALYSIS OF ENVIRONMENTAL IMPACTS - AESTHETICS

This section focuses on the existing visual resources at, or in the vicinity of, the proposed implementation locations of the General Exception Special Protections project. The potential impacts that could result to visual resources from installation and maintenance of each of the implementation alternatives are addressed, and the significance of those impacts, if anticipated, is analyzed for each of the implementation alternatives. Mitigation to reduce the impacts to the project is provided, where applicable. Visual resources include the aesthetics of the component sites and their surroundings, valued views, designated scenic highways, corridors or parkways, and lighting.

There are valuable scenic resources throughout all of the ASBS. Pacific Ocean view shed, surrounding hills and mountains in many ASBS provide a valuable scenic resource throughout the coastline. Additional resources include state-designated scenic and/or historic highways or roadways.

As part of the scoping and environmental analysis conducted for the General Exception project, sensitive visual resources were considered, but no potential for adverse impacts to these resources were identified. Depending on what measures each applicant uses to comply with the proposed exception, there may be an impact on aesthetics. However, the State Water Board believes that mitigation is available to reduce any potential impacts to aesthetics to less than significant levels. The mitigation measures would be implemented at the project-specific level.

CEQA establishes that it is the policy of the State to take all action necessary to provide the people of the state "with…enjoyment of aesthetic, natural, scenic and historic environmental qualities" [CA Public Resources Code § 21001 (b)].

It is anticipated that each applicant will assess sensitive visual resources on a project-by-project basis as part of compliance with the terms and conditions of the General Exception. If a proposed project is determined to have a significant visual resource impact under CEQA, then CEQA dictates that mitigation measures must be incorporated into the project unless such measures are not feasible. If it is determined that a project will have aesthetic impacts, then potential mitigation measures must be considered.

THRESHOLDS OF SIGNIFICANCE

For the purposes of this analysis, an aesthetic impact is considered significant if implementation of the proposed project would result in exceeding any of the thresholds identified below. These thresholds of significance are based on the State CEQA Guidelines. CEQA establishes that it is the policy of the State to take all action necessary to provide the people of the state "with…enjoyment of aesthetic, natural, scenic and historic environmental qualities" [CA Public Resources Code § 21001 (b)]. An aesthetic impact is considered significant in this analysis if implementation of the proposed project would result in potential:

- Substantial adverse effects on a scenic vista
- Substantial damage to scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway
- Substantial degradation of the existing visual character or quality of the site and its surroundings

IMPACTS OF THE PROPOSED PROJECT AND MITIGATION MEASURES

Impact 6.1-1 Direct Impacts Associated with Effects on a scenic vista.

The General Exception Project has the potential to have a substantial adverse effect on a scenic vista via construction disruption, which includes earth movement, distracting activities, and storing equipment and material; the effect is unavoidable, but not permanent.

► **Mitigation Measure:** As part of the scoping and environmental analysis conducted for the General Exception project, sensitive visual resources were considered, but no potential for long-term permanent adverse impacts to these resources were identified. Depending on what measures each applicant uses to comply with the proposed exception, there may be an impact on aesthetics. However, the State Water Board believes that mitigation is available to reduce any potential impacts to aesthetics to less than significant levels. The mitigation measures would be implemented at the project-specific level. Mitigation measures associated with specific BMPs are discussed below.

► **Implementation:** It is anticipated that each applicant will assess sensitive visual resources on a project-by-project basis as part of compliance with the terms and conditions of the General Exception. If, during the project analysis phase, a proposed project is determined to have a significant visual resource impact under CEQA, then CEQA dictates that mitigation measures must be incorporated into the project unless such measures are not feasible. If it is determined that a project will have aesthetic impacts, then potential mitigation measures must be considered.

► **Significance After Mitigation:** Less than significant.

Impact 6.1-2 Direct Impacts Associated with Damage to Scenic Resources

The General Exception Project has the potential to substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway.

► **Mitigation Measure:** As part of the scoping and environmental analysis conducted for the General Exception project, sensitive visual resources were considered, but no potential for adverse impacts to these resources was identified. Depending on what measures each applicant uses to comply with the proposed exception, there may be an impact on aesthetics. However, the State Water Board believes that mitigation is available to reduce any potential impacts to aesthetics to less than significant levels. Siting criteria of the local authority would continue to help establish appropriate locations for new structures or modifications to existing structures, including the installation of treatment systems, and would address, on a site-specific basis, the potential for systems or BMPs to affect designated scenic vistas or resources. The mitigation measures would be implemented at the project-specific level.

► **Implementation:** It is anticipated that each applicant will assess sensitive visual resources on a project-by-project basis as part of compliance with the terms and conditions of the General Exception. If during the project analysis phase, a proposed project is determined to have a significant visual resource impact under CEQA, then CEQA dictates that mitigation measures must be incorporated into the project unless such measures are not feasible. If it is determined that a project will have aesthetic impacts, then potential mitigation measures must be considered.

► **Significance After Mitigation:** Less than significant.

Impact 6.1-3 Direct Impacts Associated with Visual Character or Quality of the Site and Surroundings

The General Exception Project has the potential to substantially degrade the existing visual character or quality of the site and its surroundings. The proposed project could cause a gradual shift toward the use of more surface and subsurface treatment systems. Such systems could be installed in a variety of settings in many areas of the coastline including scenic vista, however, most elements of conventional treatment systems are located underground. This is also true for most elements of VSS treatment systems. While some systems have above-grade components, these elements have relatively low profile. These elements may also be small relative to the conveyance they serve. Special Protections BMP implementation projects and measures would eventually improve the overall aesthetic appeal within the ASBS identified herein and affected by trash and debris discharged to the shoreline, beaches and ocean, by the removal of visible trash, thus causing an overall long-term beneficial impact.

► **Mitigation Measure:** As part of the scoping and environmental analysis conducted for the General Exception project, sensitive visual resources were considered, but no potential for adverse impacts to these resources were identified. Depending on what measures each applicant uses to comply with the proposed exception, there may be an impact on aesthetics. However, the State Water Board believes that mitigation is available to reduce any potential impacts to aesthetics to less than significant levels. Low profile or subsurface treatment systems may be covered with soil and vegetation following a relatively short construction period. The mitigation measures would be implemented at the project-specific level. Mitigation measures associated with specific BMPs are discussed below.

► **Implementation:** It is anticipated that each applicant will assess sensitive visual resources on a project-by-project basis as part of compliance with the terms and conditions of the General Exception. If a proposed project is determined to have a significant visual resource impact under CEQA, then CEQA dictates that mitigation measures must be incorporated into the project unless such measures are not feasible. If it is determined that a project will have aesthetic impacts, then potential mitigation measures must be considered.

► **Significance After Mitigation:** Less than significant.

The following BMPs which may be potentially implemented by the Responsible Parties for the General Exception were evaluated for their potential to impact aesthetic resources either directly or indirectly.

ANALYSIS OF VARIOUS BMPs IMPACTS – VISUAL RESOURCES

Catch Basin Inserts
Catch basin inserts will have less than significant impact on any scenic vista or view. Curbside catch basin inserts are roadside devices. Installation of catch basin inserts would not foreseeably obstruct scenic vistas. Installation of catch basin inserts is a quick process and would not likely create an aesthetically offensive site during installation. Once completed, catch basin inserts will not result in an impairment of scenic views. Catch basin inserts themselves are unlikely to create an aseptically offensive site after installation because they are installed at street level. That notwithstanding, the creation of an aesthetically offensive site could be mitigated by improving the aesthetic characteristics of that device.

.

Vortex Separation System
Vortex separation systems (VSS) are subsurface devices and therefore installing them at a particular location is unlikely to result in an impairment of scenic vista. Since a VSS unit would be installed within already existing storm drain network, it is not foreseeable that the installation of VSS may substantially damage scenic resources and/or degrade the existing visual character or quality of any particular location and its surroundings. It is not foreseeable that the installation activities associated with siting VSS Units would result in any substantial adverse effect on the scenic vistas of the location. However, in the unlikely event that such activities should create aesthetically offensive impacts, these can be mitigated with screening and other construction BMPs. Screening can be used to reduce temporary impacts from aesthetically offensive installation activities.

Road and Parking Lot Street Sweeping
Increased street sweeping is unlikely to result in an impairment of scenic vistas. Increased street sweeping would not create an aesthetically offensive site. Rather, this alternative would pose a positive aesthetic impact by reducing visible litter instead.

Public Education
Public education would not result in an impairment of scenic vistas nor would it create an aesthetically offensive site. Public education would create a positive aesthetic, by reduction of litter and waste.

6.2 ANALYSIS OF ENVIRONMENTAL IMPACTS - AIR QUALITY

This section provides an overview of air quality, sensitive receptors and other conditions which may arise on potential project areas with the General Exception Special Protections implementation activities, including short term construction and installation activities and long term street sweeping activities. Federal, state, and regional regulations apply to air quality criteria. These criteria and each responsible party's compliance for their regional area is discussed below. Findings of the significance of impacts are presented. Mitigation to reduce the impacts associated with each activity is discussed where applicable.

There are two aspects of air pollution: daily emissions and pollutant concentrations. The term "emissions" means the quantity of pollutant released into the air and has unit of pounds per day (lbs/day). The term "concentrations" means the amount of pollutant material per volumetric unit of air and has unit of parts per million (ppm) or micrograms per cubic meter (µg/m3).

Criteria Pollutants

The State of California and the federal government have established ambient air quality standards for six pollutants to protect public health. The six air pollutants of concern, called criteria pollutants, are carbon monoxide (CO), ozone (O3), nitrogen dioxide (NO2), sulfur dioxide (SO2), respirable particulate matter (PM10), fine particulate matter (PM2.5), and lead (Pb). The criteria pollutants and associated adverse health effects are summarized below:

• **Carbon Monoxide.** Exposure to high concentrations of CO, a colorless and odorless gas, reduces the oxygen-carrying capacity of the blood, and therefore can cause dizziness and fatigue, impair central nervous system functions, and induce angina in persons with serious heart disease. CO is emitted almost exclusively from the incomplete combustion of fossil fuels. In urban areas, motor vehicles, power plants, refineries, industrial boilers, ships, aircraft, and trains emit CO. Motor vehicle exhaust releases most of the CO in urban areas. Vehicle exhaust contributes approximately 56 percent of all CO emissions nationwide and up to 95 percent in cities. CO is a non-reactive air pollutant that dissipates relatively quickly. As a result, ambient CO concentrations generally follow the spatial and temporal distributions of vehicular traffic. CO concentrations are influenced by local meteorological conditions; primarily wind speed, topography, and atmospheric stability. CO from motor vehicle exhaust can become locally concentrated when surface-based temperature inversions combine with calm atmospheric conditions. An inversion is an atmospheric condition in which a layer of warm air traps cooler air near the surface of the earth, preventing the normal rising of surface air.

• **Ozone.** While O3 serves a beneficial purpose in the upper atmosphere (stratosphere) by reducing potentially harmful ultraviolet radiation, when it reaches elevated concentrations in the lower atmosphere it can be harmful to the human and to sensitive species of plants. Short-term O3 exposure can reduce lung function, making persons susceptible to respiratory infection. Long-term exposure can impair lung defense mechanisms and lead to emphysema and chronic bronchitis. O3 concentrations build to peak levels during periods of light winds or stagnant air, bright sunshine, and high temperatures. Ideal conditions occur during summer and early autumn. Sensitivity to O3 varies among individuals. About 20 percent of the population is sensitive to O3, with exercising children being particularly vulnerable. O3 is formed in the atmosphere by a complex series of chemical reactions under sunlight that involve "ozone precursors." Ozone precursors are categorized into two families of pollutants: oxides of nitrogen (NOx) and reactive organic compounds (VOCs). NOx and VOCs are emitted from a variety of stationary and mobile sources. While NOx is considered a criteria pollutant, VOCs are not in this category, but are included in this discussion as O3 precursors. O3 is the chief component of urban smog and the damaging effects of photochemical smog generally relate to the concentration of O3, light winds or stagnant air, bright sunshine, and high temperatures. Ideal conditions occur during summer and early autumn. Sensitivity to O3 varies among individuals. About 20 percent of the population is sensitive to O3, with exercising children being particularly vulnerable. O3 is formed in the atmosphere by a complex series of chemical reactions under sunlight that involve "ozone precursors." Ozone precursors are categorized into two families of pollutants: oxides of nitrogen (NOx) and reactive organic compounds (VOCs). NOx and VOCs are emitted from a variety of stationary and mobile sources. While NOx is considered a criteria pollutant, VOCs are not in this category, but are included in this discussion as O3 precursors. O3 is the chief component of urban smog and the damaging effects of photochemical smog generally relate to the concentration of O3.

Where available, the significance criteria established by the applicable air quality management or air pollution control district may be relied upon to make the following determinations.

THRESHOLDS OF SIGNIFICANCE

The Clean Air Act (CAA), as amended in 1990, is the federal law that governs air quality. Its California counterpart is the California Clean Air Act (CCAA) of 1988. These laws set standards for the quantity of pollutants that can be in the air. At the federal level, these standards are called National Ambient Air Quality Standards (NAAQS). Standards have been established for six criteria pollutants that have been linked to potential health concerns; the criteria pollutants are: carbon monoxide (CO), nitrogen dioxide (NO2), ozone (O3), particulate matter (PM), lead (Pb), and sulfur dioxide (SO2). Conformity with CAA would be assessed in accordance with CEQA by each of the applicants identified in this General Exception as individual projects are planned and designed by applicants. Individual projects should discuss conformance at the regional level and at the project level. In general, projects must not cause the pollutant standard to be violated and must not cause any increase in the number and severity of violations. If a known violation is located in the project vicinity, the project must include measures to reduce or eliminate the existing violation(s). Each applicant's individual project would assess the affected environment under National and California Air Quality Standards as part or their air quality evaluation.

For the purposes of this analysis, an air quality impact is considered significant if implementation of the proposed project would result in exceeding any of the following thresholds identified below. These thresholds of significance are based on the State CEQA Guidelines and relevant air quality standards. Consistent with State CEQA Guidelines, an air quality impact is considered significant in this analysis if implementation of the proposed project would result in potential for exceeding any of these air quality objectives.

A significant air quality impact would occur if the alternative would: Result in a violation of any State of national ambient air quality standard or contribute substantially to an existing or projected air quality violation. The significance thresholds recommended by each regional Air Quality Management District would be the specific basis for determining significance of an impact for this project. Construction and operational emissions are considered by a regional AQMD to be significant if they exceed the thresholds identified for that Region.

Result in an increase in carbon monoxide concentrations where: (1) an increase in CO concentrations is sufficient to cause an exceedances of the most stringent State or national CO standard (20 ppm for 1-hour concentrations and 9 ppm for 8-hour concentrations); or (2) in an area that already exceeds national or State CO standards, the project increase exceeds 1 ppm for a 1-hour average or 0.45 ppm for an 8-hour average.

In addition, the CEQA Guidelines checklist provides the following thresholds for determining significance with respect to air quality. Implementation of the proposed project would also result in significant air quality impacts if it would:

- ► Conflict with or obstruct the implementation of an applicable regional air quality plan
- ► Violate any air quality standard or contribute substantially to an existing or projected air quality violation
- ► Expose sensitive receptors to substantial pollutant concentrations; or
- ► Create objectionable odors affecting a substantial number of people

IMPACTS OF THE PROPOSED PROJECT AND MITIGATION MEASURES

As part of the scoping and environmental analysis conducted for the General Exception project, these environmental resources were considered, but no potential for adverse impacts to these resources were identified. Depending on what measures each applicant uses to comply with the proposed exception, there may be an impact on air quality. However, the State Water Board believes that mitigation is available to reduce any potential impacts to air quality to less than significant levels. The mitigation measures would be implemented at the project-specific level.

Impact 6.2-1 Direct Impacts Associated with Air Quality Standards and/or Contributing to an Existing or Projected Air Quality Violation.

The General Exception Project has the potential to have a potentially significant adverse effect on air quality. A significant air quality impact would occur if it would result in a violation of any State or national ambient air quality standard or contribute substantially to an existing or projected air quality violation. Significance thresholds are recommended by each Air Quality District and the basis for determining significance of an impact for this project. Construction and operational emissions are considered by the Air District to be significant if they exceed the thresholds indentified in a Regional ambient air quality standard. They are also considered significant if they result in an increase in carbon monoxide concentrations where: (1) an increase in CO concentrations is sufficient to cause an exceedance of the most stringent State or national CO standard (20 –m for 1-hour concentrations and 9ppm for 8-hour concentrations): or (2) exceed 1 ppm for a 1-hour average of 0.45 ppm for an 8-hour average. Impacts from Special Protections implementation activities include both short term and long term activities. Impacts evaluation is based on a calculation of the total emissions from travel of construction and BMP related vehicles that might be affected by implementation of the Special Protections.

Comparative evaluation, instead of the examination of the emissions from each individual source alone is one method typically used. Vehicle emissions are calculated using forecasts of total vehicle miles traveled for each alternative based on data provided in MOBILE6, which is a vehicle emission software developed by USEPA. MOBILE6 is used for predicting gram per mile emissions of Hydrocarbons (HC), Carbon Monoxide (CO), Nitrogen Oxides (NOx), Carbon Dioxide (CO2), Particulate Matter (PM), and toxics from cars, trucks, and motorcycles under various conditions. The data which this calculation is based on are from technical documents of MOBILE6. Considering the type of work involved in implementation of the Special Protection, the calculation assumes that non-tampered heavy-duty diesel vehicles (HDDV Class 6) are used for installation/construction/maintenance activities. The mileage is assumed to be 50,000 miles, which is the median mileage for HDDVs. The year of Vehicle is assumed to be 2001+ for HC, CO, NOx, and SO2 and 1994+ for PM.

Based on assumptions above, the exhaust emission rates are found to be 2.1, 9.92, and 6.49 grams per mile for HC, CO, and NOx, respectively. The PM standard for HDDVs is 0.1 g/bhp-hr. By applying a conversion factor of

1.942 bhp-hr/mi (from Update Heavy-Duty Engine Emission Conversion Factors for Mobile6 – Analysis of BSFCs and Calculation of Heavy-Duty Engine Emission Conversion Factors), the exhaust emission rate for PM is found to be 0.1942 grams per mile. There is no exhaust emission rate information available for SOx in MOBILE6. Instead by using diesel fuel sulfur level of 8 ppm (from MOBILE6 for years after 2006), diesel fuel economy of 8.71 miles per gallon (from Update Heavy-Duty Engine Emission Conversion Factors for Mobile6 – Analysis of BSFCs and Calculation of Heavy-Duty Engine Emission Conversion Factors), and diesel fuel density of 7.099 pounds per gallon (from Update Heavy-Duty Engine Emission Conversion Factors for Mobile6 – Analysis of Fuel Economy, Non-Engine Fuel Economy Improvements and Fuel Densities), exhaust emissions rate for SO2 could be 0.00592 grams per mile, assuming all sulfur in fuel would be transformed to SO2.

► **Mitigation Measure:** Mitigation measures for increased air emissions due to increased vehicle trips or increased use of construction equipment include: 1) use of construction, and maintenance vehicles with lower-emission engines, 2) use of soot reduction traps or diesel particulate filters, and 3) use of emulsified diesel fuel.

► **Implementation:** The emissions generated by construction equipment could be lower than the local authority AQMD daily construction emissions thresholds. Detailed analysis can only be done at project level. In the case that daily construction emission exceeds significance threshold, construction projects for different structural BMPs can be conducted on different days to reduce emissions rates. Comparative evaluation, as discussed above, instead of the examination of the emissions from each individual source alone is one method typically used. Detailed analysis can only be done at project level. In case that daily construction emission exceeds significance threshold, which is unlikely, construction projects for various structural BMPs can be conducted on different days to reduce emissions rates. Mitigation measures implemented at the project level would reduce anticipated impacts to less than significant.

► **Significance After Mitigation:** Less Than Significant.

Impact 6.2-2 Expose sensitive receptors to substantial pollutant concentrations

The General Exception Project has the potential to have short-term temporary emission levels of criteria pollutants during installation and maintenance of various BMPs to implement the Special Protections. Emission levels of criteria pollutants during installation and maintenance of BMPs may be below the local authority AQMD Air Quality Significance thresholds. Long-term increases in traffic caused by ongoing maintenance of catch basin inserts (e.g., delivery of materials, street sweeping) are potential sources of increased air pollutant emissions. When evaluating

comparatively as discussed in the previous section emissions of toxic air contaminants are expected to be below the thresholds, The emissions generated by construction equipment is considered significant if it violates any air quality standards or contributes substantially to an existing or projected air quality violation, or results in a cumulatively considerable net increase of any criteria pollutants for the project region. Based on the relatively small project areas typical of BMP construction sites. It is likely that the emission of toxic air contaminants will be lower than AQMD daily construction emissions thresholds not be significant.

► **Mitigation Measure:** Potential mitigation measures which could be implemented at the project level for increased air emissions due to increased vehicle trips or for construction equipment due to the installation of structural BMPs include: 1) use of construction and maintenance vehicles with lower-emission engines, 2) use of soot reduction traps or diesel particulate filters, and 3) use of emulsified diesel fuel. In case that daily construction emission exceeds significance threshold, which is unlikely, construction projects can be conducted on different days to reduce emissions rates. These measures would reduce impacts to less than significant level.

► **Implementation:** The emissions generated by construction equipments could be lower than the local authority AQMD daily construction emissions thresholds. Detailed analysis can only be done at project level.

► **Significance After Mitigation:** Less than Significant

Impact 6.2-3 Create Objectionable Odors Affecting a Substantial Number of People

The General Exception Project has the potential to have direct short term temporary creation of odors during maintenance or construction of Special Protections implementation projects such as VSS units. It is possible that foul air could be temporarily released to the atmosphere while enclosed sources are uncovered or piping is reconfigured. These releases could create objectionable odors at the nearest receptors. These impacts are temporary and unpleasant odors, if any, will be at minimum with completion of the installation. VSS devices may be a source of objectionable odors if design allows for water stagnation or collection of water with sulfur-containing compounds. Storm water runoff is not likely to contain sulfur-containing compounds, but stagnant water could create objectionable odors.

► **Mitigation Measure:** Mitigation measures to eliminate odors caused by stagnation could include covers, aeration, filters, barriers, and/or odor suppressing chemical additives. Devices could be inspected to ensure that intake structures are not clogged or pooling water. During maintenance, odorous sources could be uncovered for as short of a time period as possible. To the extent possible, pollution removal devices could be designed to minimize stagnation of water (e.g., allow for complete drainage within 48 hours) and installed to increase the distance to sensitive receptors in the event of any stagnation. Notably, the current conditions result in significant impacts from odor, especially following storm events, where upstream trash may collect downstream of rivers and streams and at shoreline, and beaches. The potential re-suspension of sediments and associated pollutants during construction could also impact air quality.

► **Implementation:** At the localized project level, Responsible Parties performing a CEQA analysis could develop an operations plan for the specific construction and/or maintenance activities designed to address the variety of available measures to limit the air quality impacts. These could include vapor barriers and moisture control to reduce transfer of small sediments to air. Mitigation measures applied would eliminate or reduce these impacts to less than significant

► **Significance After Mitigation:** Less than significant.

ANALYSIS OF VARIOUS BMPs IMPACTS – AIR RESOURCES

Catch Basin Inserts

Long-term increases caused by ongoing maintenance of catch basin inserts (e.g., delivery of materials, street sweeping) are potential sources of increased air pollutant emissions. Mitigation measures to mitigate any potential impacts to air quality due to increased traffic could include 1) use of construction, maintenance, and street sweeper vehicles with lower-emission engines, 2) use of soot reduction traps or diesel particulate filters, 3) use of emulsified diesel fuel, 4) use of vacuum-assisted street sweepers to eliminate potential re-suspension of sediments during sweeping activity, and 5) the design of trash removal devices to minimize the frequency of maintenance trips. As a requirement of the MS4 permit, **catch basins** are cleaned out on varying schedules at a minimum frequency of once a year. This implementation measure does not require an increase in cleaning frequency above what is already required for existing permits, therefore no significant increase in air emissions is anticipated.

Nonetheless, mitigation measures are available to mitigate any potential impacts to air quality due to increased traffic. Mitigation measures could include 1) use of construction, maintenance, and street sweeper vehicles with lower-emission engines, 2) use of soot reduction traps or diesel particulate filters, 3) use of emulsified diesel fuel, 4) use of vacuum-assisted street sweepers to eliminate potential re-suspension of sediments during sweeping activity.

Vortex separation system

Short term increases in traffic during the construction and installation of VSS units and long-term increases in traffic caused by ongoing maintenance of these devices (e.g., delivery of materials and deployment of vacuum trucks) are potential sources of increased air pollutant emissions. A detailed analysis of emissions generated by construction equipment can only be done at the project level. If daily construction emissions exceed significance thresholds, construction projects for different VSS units can be conducted on different days to reduce emissions rates. Mitigation measures for increased emissions due to increased vehicle trips of increased use of construction equipment could include: 1) use of construction and maintenance vehicles with lower-emission engines, 2) use of soot reduction traps or diesel particulate filters, and 3) use of emulsified diesel fuel. VSS units may be a source of objectionable odors if design allows for water stagnation or collection of water with sulfur-containing compounds. Mitigation measures to eliminate odors caused by stagnation could include covers, aeration, filters, barriers, and/or odor suppressing chemical additives. Devices could be inspected to ensure that intake structures are not clogged or pooling water. During maintenance, odorous sources could be uncovered for as short of a time period as possible. The potential re-suspension of sediments and associated pollutants during construction could also impact air quality. An operations plan for the specific construction and/or maintenance activities could be completed to address the variety of available measures to limit the air quality impacts. These could include vapor barriers and moisture control to reduce transfer of small sediments to air.

Road and Parking Lot Street Sweeping
Increased road and parking lot sweeping would increase traffic and therefore increase air pollutant emissions. Applicants implementing the Special Protections would analyze the impacts of increased sweeping at the project level. Increased sweeping may increase objectionable odors and mitigation measures are available to mitigate any potential impacts to air quality due to increased sweeping. Mitigation measures could include 1) use of street sweeper vehicles with lower-emission engines, 2) use of soot reduction traps or diesel particulate filters, 3) use of emulsified diesel fuel, 4) use of vacuum-assisted street sweepers to eliminate potential re-suspension of sediments during sweeping activity.

Increased street sweeping would increase traffic and therefore increase air pollutant emissions. Increased street sweeping would not foreseeably be implemented alone for the Special Protections. It is not clear how often street sweeping would be increased to fulfill the requirements at this point. If the stakeholders make decisions on the frequency of street sweeping, the impacts on air quality caused by increased street sweeping could be analyzed at project level. Nevertheless, the impacts of increased street sweeping have been included in alternatives, such as catch basin inserts, that may also include increased street sweeping.

Public Education
Public education is not expected to have an impact on air quality, as it does not involve physical changes to the environment. There are no foreseeable impacts on air quality.

Each applicant, as part of their individual Special Protections BMP implementation project and CEQA analysis, may assess impact to air quality related to construction activities. Such impacts to be considered may include exhaust emissions and potential odors from construction equipment used on the construction site and vehicles used to transport materials to and from the site, and exhaust emissions from the motor vehicles of the construction crew. Stationary or mobile-powered on-site construction equipment may include trucks, tractors, signal boards, excavators, backhoes, concrete saws, crushing and/or processing equipment, graders, trenchers, pavers, and other equipment.

Installation and maintenance of structural BMPs to implement the Special Protections could result in potentially significant environmental effects with regard to air quality. However, mitigation measures which can be applied to reduce and/or eliminate these impacts are available. These mitigation measures are within the responsibility and jurisdiction of the applicants of this General Exception and can or should be adopted by them. The State Water Board does not direct which compliance measures be applied in order that potential environmental impacts be reduced or avoided. It is foreseeable that these mitigation measures may not always be capable of reducing these impacts to levels that are less than significant in every conceivable instance. In the event that a specific mitigation measure or alternative may not reduce impacts to levels that are less that significant, the project proponent may need to consider an alternative strategy or combination of strategies in their project CEQA analysis subsequent to comply with the Special Protections.

Depending on what measures each applicant uses to comply with the proposed exception, there may be an impact on air quality. However, the State Water Board staff believes that mitigation is available to reduce any potential impacts to air quality to less than significant levels. The mitigation measures would be implemented at the project-specific level.

6.3 ANALYSIS OF ENVIRONMENTAL IMPACTS - BIOLOGICAL RESOURCES

This section addresses biological resources that could be affected with implementation of the proposed project. The information presented is based on literature reviews and a review of existing documentation and research prepared explicitly for the project. As explained in the IS , impacts on marine biological resources range from “no impact” to “potentially significant. These issues are addressed in the impact analysis.

Water quality issues that may affect biological resources may be caused by a large spectrum of constituents which may be introduced by a number of different sources. Most impacts on biological resources occur indirectly as a result of degradation of surface water quality, whether a stream, creek, estuary or bay adjacent to ASBS.

The potential for the Responsible Parties’ existing discharges identified herein to cause water quality impacts that would affect biological resources is dependant on the magnitude of the contamination or mass loading from these flows. A single discharge would not likely have a substantial effect on the mass loading of contaminants to the

ASBS; however, the mass loading from high densities of discharges within a watershed together with inputs from other sources such as agricultural, recreational (golf courses, etc), storm, or urban runoff, can have a substantial effect on ASBS ocean water quality which could lead to adverse impacts on biological resources.

Many watersheds adjacent to the ASBS identified herein contain 303(d)-listed water bodies known to contribute sediment, pathogens, nutrients as well as other constituents to the marine environments located within an ASBS. Some impairment metrics to the nearshore waters of ASBS may be assessed visually such as eutrophication which results in excessive algal and aquatic plant growth, low oxygen levels. This type of contamination to marine life can also lead to human health advisories such as shellfish harvesting advisories or closure of a fishery area.

Though each of the 25 ASBS listed herein is unique in its characteristics, some generalized assumptions are made with regard to contaminant loading via discharges of the Responsible Parties. Impacts to marine life from pollutants including the effects of constituents listed in the Ocean Plan are well known. The impact analysis for aquatic biological resources here compares existing conditions to conditions that would exist with implementation of the proposed statewide Special Protections. These comparisons are based primarily on the water quality impact analysis in Section 6.7 “Analysis of Hydrology and Water Quality,” because impacts to aquatic biological resources would occur as a result of impacts from discharges on ocean water quality. The construction and operation of BMPs can cause a variety of impacts on biological resources. However, these impacts can be difficult to quantify. The Ocean Plan water quality standards are enforceable limits composed of two parts: (1) the designated beneficial uses of water and (2) criteria (i.e., numeric or narrative limits) to protect those beneficial uses.

Biological resources are among the “beneficial uses” as defined in Section 13050(f) of the Porter-Cologne Water Quality Control Act, which defines them as uses of surface water and groundwater that must be protected against water quality degradation (beneficial uses are discussed in Section 4.1-4, “Beneficial Uses,” of this document). California Ocean Plan water quality objectives (or “criteria” under the Clean Water Act) are found in the Basin Plans adopted by the State Water Board and each of the nine Regional Water Boards. Some of these standards, as they pertain to biological resources, may be site specific or vary by season, such as for dissolved oxygen. Ammonia is pH and temperature dependent.

Toxicity thresholds may vary depending on some of these parameters and depend on length of exposure as well (e.g., 4-day average, 1-hour average). Therefore numeric water quality standards are often not explicitly defined for biological resources under federal, state, or local plans and regulations as they are for human health thresholds. Therefore, much of this impact discussion is based on qualitative information.

Indirect impacts to biological resources may occur during the construction of BMPs, which typically involves the excavation of trenches and other ground-disturbing work that can cause the erosion of soil, habitat loss, and displacement of wildlife. Furthermore, off-site erosion and storm water runoff can pollute streams and other receiving waters, especially if best management practices (BMPs) for standard storm water and erosion controls are not followed or are not successful.

Operation of properly functioning BMPs generally would have no direct effects on terrestrial biological resources, but could still cause direct impacts on water quality in sensitive ASBS marine ecosystems, which in turn, could result in indirect adverse effects on aquatic habitat. Species that occupy aquatic systems or whose life cycles are interconnected to these systems could also be affected. Impacts would vary substantially because of many variables. These variables that control the potential for BMPs to affect surface water quality include storm water effluent quality and the reduction and subsequent elimination of discharges of wastes to ocean waters.

THRESHOLDS OF SIGNIFICANCE

The potential for the Special Protections to result in significant environmental effects was analyzed using information and criteria provided in the California Environmental Quality Act (CEQA) Guidelines. Pursuant to the suggested thresholds in Appendix G of the State CEQA Guidelines, the proposed project would have a significant impact on biological resources if it would:

► Have a substantial adverse effect, either directly or indirectly through habitat modifications, on the population of any species identified as a candidate, sensitive, or special-status species in regional or local plans, policies, or regulations, or by DFG or USFWS;

► Have a substantial adverse effect on any riparian or other sensitive natural community identified in local or regional plans, policies, or regulations or by DFG or USFWS;

► Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites;

► Conflict with local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance; or

► Conflict with the provisions of an adopted habitat conservation plan, natural communities conservation plan, or other approved local, regional, or state habitat conservation plan.

IMPACTS OF THE PROPOSED PROJECT AND MITIGATION MEASURES BIOLOGICAL RESOURCES

Impact 6.3-1 Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special

status species in local or regional plans, policies, or regulations, or by the DFG or USFWS.

> **As described under Impact 6.7 in "Hydrology and Water Quality," the proposed regulations could lead to an increase in BMP repairs, replacements, and upgrades. These changes would occur on sites that already have been disturbed and contain existing BMPs or other drainage conveyances and associated residential or commercial structures, and by virtue of their ongoing use are highly unlikely to support sensitive habitat that could be affected by repairs or replacement. With respect to new BMPs, as previously described these regulations do not alter the local land use agency process associated with ground-disturbing activities from residential and commercial development. A substantial adverse effect would occur if an individual project at the local level modified habitat of any species identified as a candidate, sensitive, or special status species. These effects would be significant. However, the implementation of Special Protections only affect the design of BMPs and their effectiveness to eliminate the discharge of waste to ASBS, not whether land uses associated with BMPs would be permitted. Therefore, impacts on biological resources related to typical ground-disturbing activities and water quality effects associated with the new BMPs regulations are considered less than significant with mitigation incorporated.**

► **Mitigation Measure:** Modify the proposed Special Protections to Require the Implementation of coordination with local or regional plans, policies, or regulations, or by the DFG or USFWS.

► **Implementation:** The application of Mitigation Measures is the responsibility of the Responsible Party implementing the project.

► **Significance After Mitigation:** Less than significant.

Impacts 6.3-2, 6.3-3, 6.3-4, and 6.3-5 are discussed together. The implementation of the Special Protections measures by the Responsible Parties identified herein may have the potential to; have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by the DFG or USFWS; interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory corridors, or impede the use of native wildlife nursery sites; conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance; conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan.

The implementation of the proposed Special Protections would require most Responsible Parties to assess their needs for waste discharge correction and potentially convert their existing conveyances to treatment BMPs, LID or with other supplemental treatment units. Such BMP upgrades or replacements would need to be completed within the time frame specified in the Special Protections. As discussed in the "Hydrology and Water Quality" section under Impact 6.7, construction of LID or BMPs could lead to the concentration of a large amount of construction activity within 600 feet of ASBS shoreline within a short time frame. Construction and replacement activities could cause sediment, storm water effluent, and debris to enter shoreline and/or perennial drainages, and ultimately the ocean waters of ASBS.

Additionally, storm events could cause newly constructed sites to erode, flushing sediment into receiving waters. As discussed previously, TSS and sediments could physically block sunlight, precipitate out of suspension and smother benthic macro invertebrates, fish and amphibian eggs, or aquatic plants, which could lead to suffocating fish and other aquatic life. TSS and turbidity are particularly problematic for fisheries, especially in those that are critical for recovery of a species (e.g., steelhead and Chinook salmon). Sediments could also transport other contaminants to receiving waters, including nutrients, pathogens, and other organic materials in storm water runoff. Nutrients may promote eutrophication and hypoxia within the receiving waters, which could increase the mortality of special status species, while pathogens that could be present in storm water runoff, such as *Toxoplasma* and *Cryptosporidium* could adversely affect mammals (i.e., harbor seals, sea otters) and other species as described above.

Where areas larger than 1 acre could be disturbed, the activities would be subject to the requirements of the statewide National Pollutant Discharge Elimination System General Permit for Storm water Discharges Associated with Construction Activity. However, in the majority of cases, construction activities at individual sites are not anticipated to affect more than 0.5 acre, and as discussed and addressed further in the "Hydrology and Water Quality" section under Impact 6.7, not all jurisdictions have local BMP requirements related to sedimentation and erosion control for construction activities disturbing less than 1 acre that are sufficient to avoid water quality impacts. Therefore, where targeted areas of impairment are located in jurisdictions with inadequate BMP requirements, compliance with implementation of the proposed draft Special Protection regulations could lead to sediments, erosion, or deposits of hazardous materials washing into adjacent waters, which could affect natural water quality and beneficial uses to the degree that it could degrade wetlands or sensitive aquatic habitat such as estuaries, bays, and marine aquatic life. The result would be harmful to fisheries and special status species. Therefore, this impact is considered **potentially significant**.

► **Mitigation Measure:** Modify the proposed implementations to require erosion and sediment control measures during BMP related construction activities. Erosion and sediment control measures are found in the Construction General Permit online at http://www.waterboards.ca.gov/water_issues/programs/stormwater/constpermits.shtml.

► **Implementation:** The application of the site specific mitigation measure is the responsibility of the discharger identified herein the General Exception. Appropriate measures would be identified in the project proponents CEQA analysis.

► **Significance After Mitigation:** Less than significant with mitigation incorporated.

The General Exception project has the potential to impact species, habitat, and sensitive natural communities within each of the 26 ASBS identified in this General Exception, if existing inadequate controls currently in force are allowed to continue. The applicants (Responsible Parties) submitted biological monitoring reports characterizing near shore marine biota. Four reports provided data sufficient to statistically compare impact from reference locations at San Clemente and San Nicolas Islands (Navy), Del Mar Landing, and Trinidad ASBS. Based on comparison of community composition, there is evidence that at three ASBS the impact locations are different from reference locations, but there is some question whether the differences are due to discharges or sample design. Caltrans reports for multiple ASBS locations include Redwood National Park, James V. Fitzgerald, Año Nuevo, Point Lobos, Carmel, and Irvine Coast ASBS. While certain ASBS sites within Caltrans area of impact differed from reference sites, there was no strong support that this was due to discharges. Differences between impact and reference locations were also found at Duxbury Reef ASBS (County of Marin) and at the Pillar Point area of James V. Fitzgerald ASBS (Air force). Again at these locations, the data was inadequate to attribute the variation to the impacts of the discharge.

The project, granting an exception with special mitigating conditions (i.e., special protections) will allow the continued discharge of wastes from various origins including storm water runoff into ASBS. It is anticipated that the mitigating terms and conditions of the special protections will result in improved water quality conditions. Further, the terms and conditions of the special protections provide for continued water quality improvements over time if all of the special protections designed to limit discharges of waste from the applicants are implemented.

It is anticipated that, as the applicants identified in this General Exception plan for and design individual control projects to comply with the terms and conditions or "Special Protections," each applicant will assess biological impacts on a project-by-project basis. If it is determined that a project will have biological impacts, then potential mitigation measures must be considered. A technical biological impact analysis may include evaluation of terrestrial and marine biota of an individual project. The impact analysis may assess mitigation measures that are determined to be reasonable and feasible, and at the time of final design would then be incorporated into projects' plans and specifications. Indirect effects to biological resources may extend throughout the duration of construction and may include increased erosion, siltation, and runoff. Projects should result in long-term, beneficial effects to biological resources within each individual project.

Thresholds of Significance:
1 - Indirect impacts on marine biological resources associated with existing baseline inadequate pollution and dry-weather flows control measures.

ANALYSIS FOR IMPACTS VARIOUS BMPs TO BIOLOGICAL RESOURCES

Catch Basin Inserts

Catch basin inserts fit directly into curbside catch basins typically in urbanized areas where native habitat or special status species may be absent. As such, potential impacts to biological resources would likely be avoided, including impacts to species diversity, impacts to special status species, impacts to habitat, or impacts to wildlife migration. Typically, installation of catch basin inserts requires no construction or ground disturbance which could impact biological resources. It is anticipated that the use of catch basin inserts will improve biological resources and no mitigation is required since no impact is anticipated. However, during a proposed site specific projects CEQA analysis, these issues would be assessed and coordinated with the appropriate agency, DFG, FWS, NMFS.

Vortex Separation System

It is anticipated that vortex separation system units would be implemented in currently urbanized areas. Because these areas are already urbanized it is unlikely that the installation of VSS systems would cause the removal, disturbance or change in diversity of any plant species or cause a change or reduction in the number of any unique, rare or endangered species of plants. However, depending on the final location of facilities, potential impacts to biological resources including special status species and habitat, wetlands, and trees protected under local ordinances or policies could occur where facilities are located.

It is not reasonably foreseeable that implementation of VSS units would result in the introduction of exotic or invasive plant species into an area. Nor will it result in a barrier to the normal replenishment of existing species. However, in the case that landscaping is incorporated into the specific project design, there is a possibility of disruption of resident species. It is possible that direct or indirect impacts to special status animal species may occur at the project level. Because these animal species are protected by state and/or federal Endangered Species Acts, impacts to them would be considered potentially significant, even though it is expected that potential projects would occur in what would generally be described as urban areas. If these species are present during activities associated with the potential projects, it could conceivably result in direct impacts to special status species, including; direct loss of a sensitive species; increased human disturbance in previously undisturbed habitats; mortality by construction or other human-related activity; impairing essential behavioral activities, such as breeding, feeding or shelter/refugia; destruction or abandonment of active nests/den sites; direct loss of occupied habitat. In addition, potential indirect impacts may include but are not limited to; displacement of wildlife by construction activities; disturbance in essential behavioral activities due to an increase in ambient noise levels and/or artificial light from outdoor lighting around facilities.

It is not reasonably foreseeable that implementation of VSS units will result in the introduction of a new animal species. In addition, because it is anticipated that potential projects would be established in existing developed areas it is not expected that potential project sites would act as a travel route or regional wildlife corridor. It is anticipated that construction of these facilities would not considerably restrict wildlife movement. A travel route is generally described as a landscape feature such as a ridgeline, canyon, or riparian strip within a larger natural habitat area that is used frequently by animals to facilitate movement and provide access to necessary resources such as food, water and den sites. Generally, wildlife corridors are found in areas of habitat which connect two or more habitat patches that would otherwise be fragmented or isolated from one another. It may be unlikely that VSS units would be construction in areas such as these.

VSS units may potentially impact wildlife crossings, where the crossing is small, narrow, short or constricted. Such an area allows wildlife to pass under or through obstacles that would otherwise hinder movement. Crossings may typically be manmade and include culverts, underpasses and drainage pipes to provide access across or under roads, highways, or other physical obstacles.

Migratory avian species potentially may be impacted by the construction activities associated with the implementation of VSS units. Avian species have the potential to utilize potential project sites, including ornamental vegetation during breeding and nesting season, and may be protected under the Migratory Bird Treaty Act (MBTA). The MBTA includes provisions for protection of migratory birds under the authority of the USFWS and CDFG. The MBTA protects over 800 species including geese, ducks, shorebirds, raptors, songbirds and many other relatively common species.

It is not reasonably foreseeable that the implementation of VSS will result in the deterioration of existing fish and or wildlife habitat. It is anticipated that potential VSS locations will be in already developed areas and would not result in the removal of sensitive biological habitats. VSS would not be sited within a stream course, but within a storm drain system.

6.3.6 Mitigation which should be implemented to reduce or avoid potential project level impacts to biological resources include:

1. If any unique plant species are present at the proposed installation site, plants could be preserved prior, during and after construction or by re-establishing and maintaining the plant communities affected, post-construction.

2. When proposed project sites are identified, a search of the California Natural Diversity Database (CNDDB) could be employed to confirm that any potentially sensitive plant species or biological habitats in the site area are properly

identified and protected. Plant surveys for special-status plant species could be conducted at each site location. If sensitive plant species occur on the project site, mitigation would be required in accordance with the Endangered Species Act. Mitigation measures shall be developed in consultation with the California Department of Fish and Game (CDFG) and the United States Fish and Wildlife Service (USFWS). Applicants should take steps to avoid impacts to unique, rare or endangered species or sensitive habitats.

3. Proposed project designs which incorporate the use of landscaping, should avoid or minimize the disruption of resident native species by using plants native to the area. The use of exotic invasive species or other plants listed in the Exotic Pest Plant of Greatest Ecological Concern in California should be prohibited (CalEPPC, 1999). As Applicants select measures or projects to comply with Special Protections which have the potential to significantly impact unique, rare or endangered (special status) species or sensitive habitat, such projects should be avoided. When specific projects are developed a search of the CNDDB would confirm that any potentially special status animal species in the site area are properly identified and protected. Focused animal protocol surveys for special status animal species shall be conducted at each site location.

4. If special status animal species are potentially near the project site area, as required by the Endangered Species Act (ESA), two weeks prior to grading or the construction of facilities and per applicable USFWS and/or CDFG protocols, pre-construction surveys to determine the presence or absence of special status species would be conducted. They should extend off-site to determine the presence or absence of any special status species adjacent to the project site. If special Status species are found to be present on the project site or within the project site buffer area, mitigation would be required under the ESA. Mitigation measures would be developed with the USFWS and CDFG to reduce potential impacts.

5. If VSS units are implemented at locations where they would foreseeably adversely impact species migration or movement patterns, mitigation measures shall be implemented to ensure that impacts which may result in a barrier to the migration or movement of animals is less than significant. Any site specific wildlife crossings shall be coordinated in consultation with CDFG. If a wildlife crossing would be significantly impacted, the project design shall include a new wildlife crossing in the same general location.

6. If a project is proposed for construction during the avian breeding season for special status species and/or MBTA protected species, then prior to (within 2 weeks) to the onset of construction activities, surveys for nesting migratory avian species shall be conducted on the site following USFWS and/or CDFG protocols. Active nests identified on or within a distance stipulated by USFWS and/or CDFG would require mitigation in consultation with these agencies.

Road and Parking Lot Street Sweeping
It is anticipated that road and parking lot sweeping would not involve a direct change to the physical environment. Indirect impacts could include an increase in ambient noise levels, but should not result in a significant impact to wildlife species adapted to a developed environment. No mitigation would be required since no impact is anticipated.

Public Education
It is anticipated that public education would involve no change to the physical environment either directly or indirectly and is not foreseeable to result in impacts to biological resources. Public education measures employed to comply with Special Protections, which include interpretive signage or kiosks, shall be evaluated at the project level and incorporate mitigation measures to a less than significant level.

Installation and maintenance of some structural BMP's could result in potentially significant environmental effects with regard to biological resources. However, mitigation measures which can be applied to reduce and/or eliminate these impacts are available as described. These mitigation measures are within the responsibility and jurisdiction of the responsible parties of the General Exception, and can or should be adopted by them. The project proponent would perform CEQA analysis on a project to determine measures appropriate for their location. The State Water Board does not direct which compliance measures applicants choose to adopt or which mitigation measures they employ. The State Water Board does, however, recommend that appropriate mitigation measures be applied in order that potential environmental impacts be reduced or avoided to ASBS. It is foreseeable that these mitigation measures may not always be capable of reducing these impacts to levels that are less than significant in every conceivable instance. In the event that a specific mitigation measure or alternative may not reduce impacts to levels that are less than significant, the project proponent may need to consider an alternative strategy or combination of strategies to comply with the Special Protections.

6.4 ANALYSIS OF ENVIRONMENTAL IMPACTS - CULTURAL RESOURCES

Regulations adopted pursuant to CEQA (Title 14; Chapter 3; Article 5; § 15064.5) establish rules for the analysis of historical resources, including archaeological resources, in order to determine whether a proposed project may have a substantial adverse effect on the significance of the resource.

The National Historic Preservation Act (NHPA) of 1966, as amended, sets forth national policy and procedures regarding historic properties, defined as districts, sites, buildings, structures, and objects included in or eligible for the National Register of Historic Places (NRHP).

CEQA and California Public Resources Code (PRC) §5024.1 established the California Register of Historical Resources. PRC §5024 requires state agencies to identify and protect State-owned resources that meet NRHP listing criteria. Sections 5024(f) and 5024.5 require state agencies to provide notice and consult with the State Historic Preservation Office (SHPO) before altering, transferring, relocating, or demolishing State-owned historical resources that are listed on or are eligible for inclusion in the National Register or are registered or eligible for registration as California Landmarks.

PRC §5097.9 established the Native American Heritage Commission (NAHC), which maintains a statewide list of sacred sites, designates the "most likely descendants" when human remains are encountered, and can mediate disputes relating to the treatment of human remains. PRC §5097.991 states that Native American remains and associated grave artifacts shall be repatriated. PRC §5097.5 makes it a misdemeanor for anyone to knowingly disturb any archaeological, paleontological, or historical feature situated on public lands.

If a proposed project is determined to have a significant cultural resource impact under CEQA, then CEQA dictates that mitigation measures must be incorporated into the project unless such measures are not feasible. It is anticipated that each applicant will assess cultural resource impacts on a project-by-project basis as part of compliance with the terms and conditions of the General Exception and part of their CEQA project analysis.

THRESHOLDS OF SIGNIFICANCE

For the purpose of this analysis an impact to cultural resources is considered significant if the project would result in the potential to:

► disturb any human remains, including those interred outside of formal cemeteries

IMPACTS OF THE PROPOSED PROJECT AND MITIGATION MEASURES

Impact 6.4-1 Direct Impacts Associated with Effects on a Cultural Resource

> **The General Exception Project has the potential to have a substantial adverse effect on cultural resources during construction of various Special Protections implementation measures and the possibility of disturbance of any human remains including those interred outside of formal cemeteries. A program level of analysis of the potential for impacts to cultural resources related to the implementation of the Special Protections and potential impacts are evaluated for various BMPs considered as a method of compliance.**

► **Mitigation Measure:** Upon determination of specific locations for BMPs, responsible agencies should complete further investigation, including consultation with Native American tribes, to make an accurate assessment of potential to affect historic, archaeological, or architectural resources or to impact any human remains. If potential impacts are identified, mitigation measures could include project redesign, such as the relocation of facilities outside the boundaries of archeological or historical sites. According to the California Office of Historic Preservation, avoidance and preservation in place are the preferable forms of mitigation for archeological sites. When avoidance is infeasible, a data recovery plan should be prepared which adequately provides for recovering scientifically consequential information from the site. Studies and reports resulting from excavations must be deposited with the California Historical Resources Regional Information Center (California Office of Historical Preservation, 2006). As such, with mitigation employed, it anticipated that any reasonably foreseeable impacts would be reduced to less than significant with mitigation.

► **Implementation:** Project-level impacts on cultural resources due to implementation of various BMPs would be similar.

► **Significance After Mitigation:** Less than significant

ANALYSIS OF VARIOUS BMPs IMPACTS - CULTURAL RESOURCES

Catch Basin Inserts

Catch basin inserts fit directly into curbside catch basins in urbanized areas and require no construction or ground disturbance. There is therefore no potential to impact cultural resources from this alternative means of compliance. No mitigation is required since no impact is anticipated**.**

Vortex Separation System

Vortex separation systems would be installed in currently urbanized areas where ground disturbance has previously occurred. Because these areas are already fully urbanized it is unlikely that their implementation would cause a substantial adverse change to historical or archeological resources, destroy paleontological resources, or disturb human remains. However, depending on the final location of facilities, potential impacts to cultural resources could occur. Paleontological resources can be found in areas of the coastal zone containing fossil-bearing formations. Archaeological resources have been found within the urbanized portions of the coastal zone. Historic and architectural resources have also been found within the coastal zone. The site-specific presence or absence of these resources is unknown because the specific locations for VSS will be determined by applicants at the project level. Installation of these systems could result in minor ground disturbances, which could impact cultural resources if they are sited in locations containing these resources and where disturbances have not previously occurred.

Upon determination of specific locations for VSS, applicants should complete further investigation, including consultation with Native American tribes, to make an accurate assessment of potential to affect historic, archaeological, or architectural resources or to impact any human remains. If potential impacts are identified, mitigation measures could include project redesign, such as the relocation of facilities outside the boundaries of archeological or historical sites. According to the California Office of Historic Preservation, avoidance and preservation in place are the preferable forms of mitigation for archeological sites. When avoidance is infeasible, a data recovery plan should be prepared which adequately provides for recovering scientifically consequential information from the site. Studies and reports resulting from excavations must be deposited with the California Historical Resources Regional Information Center. No impact is anticipated after mitigation.

Road and Parking Lot Street Sweeping
Road and parking lot sweeping would occur in areas along public rights of way and would have no potential to impact cultural resources. No mitigation is required since no impact is anticipated.

Public Education
Public education would involve no change to the physical environment either directly or indirectly and would have no impact on cultural resources. No mitigation is required since no impact is anticipated.

6.5 ANALYSIS OF ENVIRONMENTAL IMPACTS - GREENHOUSE GAS EMISSIONS

On June 1, 2005, the governor signed Executive Order S-3-05. The goal of this Executive Order is to reduce California's greenhouse gas (GHG) emissions to: (1) 200 levels by 2010; (2) 1990 levels by 2020; and (3) 80% below the 1990 levels by the 2050. In 2006, this goal was further reinforced with the passage of Assembly Bill 32 (AB 32), the Global Warming Solutions Act of 2006. AB 32 sets the same overall GHG emissions reduction goals while further mandating the California Air Resources Board create a plan. It is anticipated that an individual project planned and designed by each applicant would also be assessed under CEQA for climate change related impacts as part of the project's air quality assessment report.

For most Special Protections implementation projects of small to moderate size, GHG emissions could be to some extent quantified, but the analysis would focus on qualitative compliance with the emission reduction strategies contained in the California Climate Action Team's Report to the Governor. This report proposes a path to achieve the GHG reduction targets found in AB 32 and Executive Order S-3-05. While the report and Executive Order S-3-05 do not specifically mention CEQA, they do include a list of various measures that can be employed to achieve the GHG reduction targets. It can be easily argued that proposed projects that implement all appropriate actions listed in the emissions reduction strategies relevant to the proposed project would have a less than significant impact to global climate change. This same type of approach can be used for projects within counties that have an adopted GHG Reduction Plan (currently Marin County is the only one). In cases where quantifying emissions is not reasonable or possible, such as Specific Plans where the development is at a very programmatic approach, this approach could still be used and is defensible. For projects that have an established emissions inventory (such as cities, counties, or specific plans) the analysis can rely more heavily upon the quantitative analysis by estimating the existing GHG emissions inventory, the past GHG emissions invent ory for year 2000, year 1990, and the future year emissions inventory with the project. This approach can then quantitatively show how the project will (or will not) meet the GHG emissions targets (i.e. achieve the year 2000 GHG emissions inventory by year 2010, and the 1990 GHG emissions inventory by year 2020) found in Executive Order S-3-05. The types of projects that can rely upon the quantities of GHG emissions in determining significance is fairly limited, but lend themselves to General Plan updates.

By combining both a qualitative and quantitative approach, the analysis can be tailored to the particular type and size of the General Exception Special Protections project and still provide, to the fullest extent feasible, a comprehensive analysis of global climate change impacts that includes a comparison of significance criteria and mitigation methods. This is the most legally defensible method currently available.

Recommended Climate Change impact analysis process, as discussed earlier, the most defensible method to assess the significance of a project's indirect or direct and/or cumulative contribution to global climate change involved: 1) project compliance with emission reduction strategies, or when available and feasible comparison of emissions inventories; and 2) an inventory of project GHG emissions.

THRESHOLDS OF SIGNIFICANCE

For the purpose of this analysis an impact to greenhouse gas emissions is considered significant if the project would result in:

► generating greenhouse gas emissions, either directly or indirectly, that may have a significant impact on the environment.

IMPACTS OF THE PROPOSED PROJECT AND MITIGATION MEASURES

Impact 6.5-1 Direct Impacts Associated with Greenhouse Gas Emissions

The General Exception Project has the potential to have direct temporary short-term impacts from construction-related activities as associated with implementation of Special Protections. Construction activities and BMPs such as street sweeping have the potential to generate emissions related to GHG.

► **Mitigation Measure:** Onsite project mitigation. Project compliance with the greenhouse gas emission reduction strategies contained in the California Climate Action Team's Report to the Governor will be assessed. If new projects are consistent with those strategies, it follows that the project would not significantly contribute to a cumulative global climate change impact. To reduce California's greenhouse gas emissions to the levels proposed in Executive Order S-3-05, the California EPA Climate Action Team developed a report that outlines strategies for meeting the Governor's targets. Use of the strategies in the report to determine project consistency are the most appropriate to use at this time because the report "proposes a path to achieve the Governor's targets that will build on voluntary actions of California businesses, local government and community actions, and State incentive and regulatory programs" (CA 2006). AB 32 requires that a list of emission reduction strategies be published to achieve the goals set out in AB 32. However, until those reduction strategies are published, emission reduction strategies to meet Executive Order S-3-05 will be relied upon.

Emission strategies would be implemented by a Responsible Party and identified as part of a projects CEQA analysis. The strategies that CARB is to implement over the next two years are summarized in Appendix 9.

► **Implementation:** A project inventory of greenhouse gas emissions (carbon dioxide, ethane, nitrous oxide) forseeably generated by a local project would be presented for informational purposes and for full disclosure. The inventory would be compared to the California inventory and/or the County, when they become available. Emissions are typically estimated in tons per year, which are converted to teragrams of carbon dioxide equivalents (Tg CO2 Eq.) using the formula: Tg CO2 Eq. = (tons of gas) x (GWP) x (Tg / 1,000,000). One Tg is equal to one million metric tons. The global warming potential (GWP) for selected gases assessed are located in Appendix 9. The emissions are also compared with the current inventory for California, the air district, the county, and/or the city, as available. The Air Resources Board's website http://www.arb.ca.gov/homepage.htm provides additional AB32 information.

Motor vehicles emit carbon dioxide, methane, and nitrous oxide. URBEMIS2002 does not estimate emissions of carbon dioxide. However, URBEMIS2007 should estimate emissions of carbon dioxide. In the interim, carbon dioxide from motor vehicles can be manually calculated using emission factors from EMFAC2002 or EMFAC2007, whichever version of EMFAC the air district with jurisdiction over the basin in which the project is located has accepted. Emissions of methane from motor vehicles can also be calculated with EMFAC. Responsible Parties implementing a site specific project may, as part of their CEQA analysis utilize U.S. EPA emission factors available to calculate nitrous oxide and methane emissions from vehicles (EPA 2004, EPA 2004b).

► **Significance After Mitigation:** Less Than Significant.
Depending on what measures each applicant uses to comply with the proposed exception, there may be an impact on greenhouse gas emissions, either directly or indirectly. As such, since BMP construction projects are considered relatively small short-term and localized projects, the State Water Board believes that mitigation is

available to reduce any reasonably foreseeable potential GHG impacts to greenhouse gas emissions would be less than significant level.

6.6 ANALYSIS OF ENVIRONMENTAL IMPACTS - HAZARDS AND HAZARDOUS MATERIALS

CEQA requires an analysis to assess whether a proposed project would have a hazard or hazardous material impact. If a proposed project is determined to have a significant hazard or hazardous material impact under CEQA, then CEQA dictates that mitigation measures must be incorporated into the project unless such measures are not feasible. It is anticipated that each applicant will assess hazard or hazardous material impacts on a project-by-project basis as part of compliance with the terms and conditions of the General Exception. If it is determined that a project will have hazard or hazardous material impacts, then potential abatement measures must be considered. A hazards analysis may include materials or waste generated from construction of an individual project.

As part of the scoping and environmental analysis conducted for the General Exception project, the environmental resources and hazards were considered, but no potential for significant long-term adverse impacts were identified. Depending on what measures each applicant uses to comply with the proposed exception, there may be an impact from hazards and hazardous materials. However, the State Water Board believes that mitigation is available for the Responsible Parties to reduce any potential impacts from hazards and hazardous materials to less than significant levels.

THRESHOLDS OF SIGNIFICANCE

The potential for the Special Protections to result in significant environmental effects was analyzed using information and criteria provided in the State CEQA Guidelines. Pursuant to the suggested thresholds in Appendix G of the Guidelines, the proposed project would have a significant impact if it would:

- ► Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment;

- ► Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan.

IMPACTS OF THE PROPOSED PROJECT AND MITIGATION MEASURES

Impact 6.6-1 Direct Impacts Associated with Construction of General Exception Special Protections BMP Implementation.

The potential exists for Special Protections-related construction to create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment. Construction activities related to installation on various BMPs may include soil disturbance, potential involvement with aerially deposited lead, structures with lead-based paint and asbestos-containing materials, and hazardous materials. These activities may be considered reasonably foreseeably minimal and localized to the immediate area.

Hazards and hazardous materials have the potential to be located throughout more urbanized portions of the coastline and/or may occur as naturally occurring or man-made hazards. The potential for contaminated soil or associated groundwater from commercial and industrial sites such as gas stations, dry cleaners and manufacturing facilities also may occur in more urbanized portions adjacent to ASBS. Aboveground and underground storage tanks may contain hazardous substances and have the potential to leak petroleum fuels, solvents or other hazardous substances into the subsurface soils. Both naturally occurring hazards and anthropogenic contaminated soils could be encountered during the installation of structural treatment alternatives for implementation of the Special Protections. The California Department of Toxic Substances Control is the repository for cleanup sites and hazardous waste permitted facilities and their webpage http://www.envirostor.dtsc.ca.gov contains a searchable database to locate areas of potential hazardous materials concern.

In general, most BMP installation, replacement, repair, or upgrade projects would disturb less than 1 acre, and are regulated by the local land use agency with regard to implementation of appropriate siting and erosion control measures. Counties and cities have requirements in place that include sediment and erosion control measures. The Regional Water Boards, in addition to the cities and counties, also have requirements in place that include sediment and erosion control measures. While existing BMPs at the local level may be adequate to avoid significant water quality impacts in many or most situations, local agencies vary widely in the management measures required, and there may be some situations where those BMPs are not sufficient to avoid such impacts. Therefore, in instances where new BMPs are being installed, replaced, repaired, or upgraded would disturb less than 1 acre, the potential exists for construction to affect water quality related to sedimentation and erosion. However, the likelihood of uncontrolled releases of sediment from erosion or other releases of pollutants from such activities may be small. Furthermore, these impacts, as with the initial construction impacts potentially would be minimal and associated with other development on generally the same sites; for instance, a storm water conveyance system would be constructed on the same site, and future repairs would occur on that site. Water quality impacts relating to typical ground disturbance from BMP installation, repair, replacement, and upgrade in areas other than targeted areas of impairment are considered less than significant. In the few instances where the area of ground disturbance affected by construction of new facility infrastructure and construction of staging areas would exceed 1 acre, BMPs installation, replacement, repair and upgrade would be subject to the requirements of the statewide NPDES storm water general permit for construction activity (Order 99-08-DWQ). In these situations, before construction activities can be approved, the project applicant is required under existing state law to apply for permit coverage. This would result in the project applicant preparing a storm water pollution prevention plan (SWPPP) and any other necessary engineering plans and specifications for pollution prevention and control. The SWPPP would identify and specify BMPs that must be in place throughout all site work and construction.

Typical BMPs include the following:

1) Use erosion and sediment control measures, including construction techniques that would reduce the potential for runoff and minimize discharge of sediment into nearby drainage conveyances; these BMPs may include silt fences, staked straw bales or wattles, sediment/silt basins and traps, geofabric, sandbag dikes, and temporary vegetation.

2) Establish permanent vegetative cover to reduce erosion in areas disturbed by construction by slowing runoff velocities, trapping sediment, and enhancing filtration and transpiration.

3) Use drainage swales, ditches, and earth dikes to control erosion and runoff by conveying surface runoff down sloping land, intercepting and diverting runoff to a watercourse or channel, preventing sheet flow over sloped surfaces, preventing runoff accumulation at the base of a grade, and avoiding flood damage along roadways and facility infrastructure.

4) Identify the means of disposal of waste materials (i.e., brush, vegetation) removed from the site.

5) Identify pollutants that are likely to be involved in construction activities that could be present in storm water drainage and non-storm water discharges and in other types of materials used for equipment operation.

6) Establish spill prevention and contingency measures, including measures to prevent or clean up spills of hazardous waste and of hazardous materials used for equipment operation, and emergency procedures for responding to spills.

Several technical studies (California Storm water Quality Association 2003, Huffman & Carpenter 2003, and EPA 1999) have established that water quality control features such as revegetation, erosion control measures, and detention and infiltration basins are successful techniques for avoiding or minimizing construction-related water quality impacts (e.g., metals and organic compounds from storm water are typically filtered out within the first few feet of soil beneath retention basins for groundwater). Technical studies by Huffman and Carpenter (2003) demonstrated that the use of various BMPs, such as source control, detention basins, revegetation, and erosion control, have maintained surface water quality conditions in adjacent receiving waters. Given the adequacy of the existing NPDES, and SWPPP program where applicable (for areas of disturbance of 1 acre or more) and the effectiveness of BMPs when used appropriately in such situations, the project's potential construction-related impacts on water quality are also considered less than significant for BMPs construction disturbing 1 acre or more.

► **Mitigation Measure:** As discussed above, when hazardous materials are encountered during construction operations, formal procedures specified by a hazardous waste management plan, which are developed during a projects' CEQA analysis phase, would be implemented immediately, per a previously approved plan. Since most Special Protections BMP projects are anticipated to be site specific and localized, the CEQA threshold of significance that a project would reasonably foreseeable created a significant hazard to the public or the environment through release of hazardous materials, would be reduced to a less than significant level with mitigation.

► **Implementation:** All hazardous materials involvement would be coordinated with the appropriate federal, state, and local regulatory agencies. The plan should follow current laws and regulations governing hazardous waste. Relevant federal Resource Conservation and Recovery Act (RCRA) and California Hazardous Waste Control Law (HWCL) laws and regulations are relied upon when making any determinations about a waste. It is anticipated that each project implemented at a local level perform relevant CEQA site assessment prior to construction.

► **Significance After Mitigation:** Less than significant with mitigation employed

Impact 6.6-2 Indirect Impacts Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan.

> **Construction activities related to installation of various BMPs such as vortex separation systems could result in the temporary interference of emergency response or evacuation plans if construction equipment, road closures, or traffic interfered with emergency vehicles traveling through the installation area.**

► **Mitigation Measure:** Project-level emergency response plans and/or traffic and circulation plans would be prepared as part of a proposed projects' CEQA analysis and as recommended in accordance with local city or county ordinances.

► **Implementation:** Project-level by Applicant.

► **Significance After Mitigation:** Less than significant

ANALYSIS OF BMPS IMPACTS - HAZARDS AND HAZARDOUS MATERIALS
Catch Basin Inserts
Catch basin inserts fit directly into curbside catch basins and require no construction or ground disturbance. There is therefore no potential to encounter contaminated soils or groundwater or other hazards from this alternative means of compliance. Since no construction is required, the use of hazardous materials or potential for construction accidents is unlikely during installation. However, catch basin cleaning and maintenance could pose risks to maintenance workers. To the extent that catch basin cleaning and maintenance could pose risks to maintenance workers, mitigation measures to avoid these risks include requiring workers to obtain hazardous materials maintenance record keeping and disposal activities training. OSHA-required Health and Safety Training, and OSHA Confined Space Entry training.

Vortex Separation System
It is reasonably foreseeable that hazards or hazardous materials could be encountered during the installation of vortex separation systems. Contamination could exist depending on the current and historical land uses of the area. Depending on their location, VSS could be proposed in areas with contaminated soils or groundwater. The use of hazardous materials such as oil, gasoline and potential for accidents is also likely during installation. Debris that is trapped by VSS could become hazardous to the public or to maintenance workers who collect and transport the material if it is not handled in a timely manner and disposed of appropriately. Installation of VSS could result in the temporary interference of emergency response or evacuation plans if construction equipment, road closures, or traffic interfered with emergency vehicles traveling through the installation area. It is anticipated that VSS will be located in urbanized areas; it is not reasonably foreseeable that their installation would expose people too wild land fires. VSS would not result in a safety hazard for people residing or working within two miles of a public airport or public use airport.

To the extent that installation of VSS could involve work with of near hazards or hazardous materials, potential risks of exposure can be mitigated with proper handling and storage procedures. The health and safety plan prepared for any project should address potential effects from cross contamination and worker exposure to contaminated soils and water and should include a plan for temporary storage, transportation and disposal of contaminated soil and water. Compliance with the requirements of California Occupational Health and Safety Administration (Cal OSHA) and local safety regulations during installation, operation, and maintenance of these systems would prevent any worksite accidents or accidents involving the release of hazardous materials into the environment, which could harm the public, nearby residents and sensitive receptors such as schools. Systems can be redesigned and sites can be properly protected with fencing and signage to prevent accidental health hazards.

To the extent that trash and debris trapped by VSS could become hazardous, impacts to maintenance workers and the public could be avoided or mitigated by educating the local community of the effects of improper disposal of such wastes, enforcing litter ordinances, and timely cleaning out inserts and structural controls.

To the extent that installation of VSS interfered with emergency response or evacuation plans, traffic control plans could be used to manage traffic through installation zones.

To the extent that VSS become a source of standing water and vector production, design at the project-level can help mitigate vector production from standing water.

Road and Parking Lot Street Sweeping
Road and parking lot sweeping would occur in public rights of way and would have no potential impact related to hazards, hazardous material, or human health. No mitigation is required since no impact is anticipated.

Public Education
Public education would involve no change to the physical environment either directly or indirectly and would have no impact related to hazards, hazardous materials, or human health. No mitigation is required since no impact is anticipated.

Installation and maintenance of some structural BMP's could result in potentially significant INDIRECT SHORT-TERM environmental effects with regard to hazards and hazardous materials. However, mitigation measures which can be applied to reduce and/or eliminate these impacts are available as described. These mitigation measures are within the responsibility and jurisdiction of the applicants of the General Exception, and can or should be adopted by them. The State Water Board does not direct which compliance measures applicants choose to adopt nor which mitigation measures they employ. The State Water Board does, however, recommend that appropriate mitigation measures be applied in order that potential environmental impacts be reduced or avoided. As such, a Responsible Party's proposed project, in their CEQA analysis develop appropriate strategies to eliminate or reduce possible impacts. It is foreseeable that these mitigation measures may not always be capable of reducing these impacts to levels that are less than significant in every conceivable instance. In the event that a specific mitigation measure or alternative may not reduce impacts to levels that are less than significant, the project proponent may need to consider an alternative strategy or combination of strategies to comply with the Special Protections.

6.7 ANALYSIS OF ENVIRONMENTAL IMPACTS HYDROLOGY AND WATER QUALITY

The State Water Board's California Ocean Plan for Areas of Special Biological Significance

Section 13170.2 of the California Water Code directs the State Water Board to formulate and adopt a water quality control plan for ocean waters of California. The State Water Board first adopted this plan, known as the California Ocean Plan, in 1972. Over the years the plan and Public Resources Code have been amended to bolster the protection of important coastal and marine areas. The California Ocean Plan establishes water quality objectives for California's ocean waters and provides the basis for regulation of wastes discharged into the state's coastal waters. The plan applies to point and nonpoint source discharges and the plan provides numeric and narrative water quality objectives for discharges to marine environments (Table 6.7-1), including bacterial, physical, chemical, biological, and radioactivity standards for offshore water quality. For the most part, these standards, which are intended to protect aquatic resources, are more stringent than those for contact recreation, but are less stringent than those applied to drinking water to protect public health (see Ocean Plan, "Water Quality Objectives Addressing Bacteria or Pathogens").

THRESHOLDS OF SIGNIFICANCE

For the purpose of this analysis, a water quality impact is considered significant if implementation of the proposed project would result in exceeding any of the thresholds identified below and in Table B of the Ocean Plan. These thresholds of significance are based on the California Environmental Quality Act (CEQA) Guidelines (State CEQA Guidelines) and relevant adopted water quality objectives. Consistent with State CEQA Guidelines, a water quality impact is considered significant in this analysis if implementation of the proposed project would result in potential for exceeding any of these adopted water quality objectives related to State's ocean waters.

Implementation of the proposed project would also result in significant water quality impacts if it would:

► Violate federal, state, or local criteria concerning exposure to pollutants or pathogenic microorganisms;

► Violate any ambient natural ocean water quality objective, contribute substantially to an existing or projected water quality violation, or expose sensitive receptors to substantial waterborne pollutant concentrations; or

► Create a substantial water quality hazard or involve the use, production, or disposal of materials that pose a hazard to marine biota in the area affected.

ANALYSIS OF BMPS IMPACTS ON HYDOLOGY AND WATER QUALITY

The proper siting, construction, and operation of BMPs implemented as part of the Special Protections can affect water quality through various mechanisms. In general, these mechanisms are divided into three categories: construction, operation, and maintenance. Each of these mechanisms provides distinct avenues by which BMP's could affect water quality as described below.

Construction of BMPs is regulated by local agencies through the land use and development approval process (described in Chapter 3.0, "Regulatory Setting," and in Section 4.3, "Land Use and Planning"). The draft Special Protections do not alter the authority of local agencies to approve construction of BMP's or the processes by which local agencies determine whether to allow development of specific properties and construction of BMP's on those properties.

BMPs construction procedures typically involve the excavation of trenches and other earthwork that can cause the erosion of soil into nearby streams and other receiving waters, especially if standard BMPs for erosion control are not implemented successfully. This impact mechanism is evaluated below in Impacts 6.7-1 and 6.7-2. In addition, the draft Special Protections could affect the number of BMP's installed in areas that have been designated an ASBS SCCWRP discharge.

The potential increase in installation in these areas is addressed as well. After they are operating, different types of BMPs treat the pollutants found in the discharge to varying levels, and then discharge the treated flows during wet weather, or divert to dry weather flow unit or system. Some of these pollutants, if not adequately removed, may adversely affect beneficial uses.

The primary method used in the water quality and marine life health impact analysis consists of comparing water quality objectives (Ocean Plan Table B) to Natural Ocean Water Quality concentrations expected to result from the proposed project.

The impact headings below make a distinction between "**direct" and "indirect"** impacts. State CEQA Guidelines Section 15064(d) provides guidance on the definition of these terms and how to assess such effects in an EIR:

1. A direct physical change in the environment is a physical change in the environment that is caused by and immediately related to the project.

2. An indirect physical change in the environment is a physical change in the environment that is not immediately related to the project, but which is caused indirectly by the project and is still reasonably foreseeable.

3. An indirect physical change is to be considered only if that change is a reasonably foreseeable impact that may be caused by the project. A change that is speculative or unlikely to occur is not reasonably foreseeable.

It should be noted the key term “reasonably foreseeable” is not further defined in either CEQA or the State CEQA Guidelines.

IMPACTS OF THE PROPOSED PROJECT AND MITIGATION MEASURES

Environmental Impacts: This subsection identifies the impacts of the proposed project on the existing environment, in accordance with State CEQA Guidelines, Sections 15125 and 15143. Before presenting an evaluation of impacts, the section describes the analysis methodology used, and thresholds of significance used to identify impacts are then listed. Project impacts are identified alphanumerically and sequentially throughout this section. For example, impacts in Section 6.1 are identified as 6.1-1, 6.2-2, and so on. An impact statement preceded the discussion of each impact and provides a summary of the impact and its level of significance. The discussion that follows the impact statement included the evidence on which a conclusion is made regarding the level of impact. The discussions of cumulative impacts and growth-inducing impacts are presented in Section 8.0.

► **Mitigation Measures:** This subsection identifies potentially feasible mitigation measures to reduce significant and potentially significant impacts of the proposed project, in accordance with State CEQA Guidelines Sections 15002(a)(3), 15021(a)(2), and 15091(a)(1). Each mitigation measure is identified alphanumerically to correspond with the number of the impact being reduced by the measure. For example, Impact 6.1-1 would be mitigated with Mitigation Measure 6.1-1. This subsection also describes whether the mitigation measures would reduce impacts to less-that-significant levels. Significant and unavoidable impacts are identified as appropriate in this subsection, as well as in the “Residual Significant Impacts” subsection described below. Significant and unavoidable impacts are also summarized in Section 8.0.

► **Implementation:** This section identifies the agency responsible for the implementation of the mitigation measures.

► **Significance After Mitigation:** This section identifies impacts that would be reduced to less than significant and any significant impacts that would remain significant following implementation of the mitigation measures.

Impact 6.7.1 Direct Impacts Associated with Discharge of Waste by Existing inadequate Controls, with the reasonably foreseeable potential to violate federal, state, or local criteria concerning exposure to pollutants or pathogenic microorganisms; violate any ambient natural ocean water quality objective, contribute substantially to an existing or projected water quality violations, or expose sensitive receptors to substantial waterborne pollutant concentrations.

The General Exception Project has the potential to violate the ASBS waste discharge prohibition of the Ocean Plan if existing inadequate controls currently in force are allowed to continue. The project, granting an exception with special mitigating conditions (i.e., special protections) will allow the continued discharge of wastes from various origins including storm water runoff into ASBS. Existing ocean water quality conditions within ASBS have had measured concentrations of constituents which exceed the Table B water quality objectives of the Ocean Plan. Exceedances of the Table B Ocean Plan water quality objectives were also found in the storm water runoff of some of the applicants. It is expected that the mitigating terms and conditions of the special protections will result in improved water quality conditions. Further, the terms and conditions of the special protections provide for continued water quality improvements over time if all of the conditions designed to limit discharges of waste from the 27 applicants are implemented.

► **Mitigation Measure:** Granting the general exception will not violate federal antidegradation requirements because water quality will not be lowered, but rather, will be improved within the ASBS affected. Further, allowance of the General Exception will not violate the State Water Board's antidegradation policy (SWRCB 1968) since water quality conditions are anticipated to improve; the discharges will not unreasonably affect present and anticipated beneficial uses; the discharge will not result in water quality lower than that prescribed in the Ocean Plan; and beneficial uses will be protected and potential impacts will be less than significant with mitigation incorporated.

► **Implementation:** It is anticipated that the applicants identified in this General Exception project will implement various individual or collaborative projects to comply with the terms and conditions or "Special Protections." (See Special Protections Appendix 1).

► **Significance After Mitigation:** Less than significant with mitigation incorporated.

Impact 6.7.2 Direct Impacts Associated with Degradation of Water Quality otherwise substantially degrade water quality, or have the potential to reasonably and forseeably create a substantial water quality hazard or involve the use, production, or disposal of materials that pose a hazard to marine biota in the area affected.

It is anticipated that the applicants identified in this General Exception project will implement various individual or collaborative projects to comply with the terms and conditions or "Special Protections." As part of the scoping and environmental analysis conducted for the General Exception project, project types identified include: Low Impact

Development (LID); dry-weather flow diversions; and Best Management Practices (BMPs), such as Pollution Prevention BMPs and Treatment BMPs, such as infiltration basins and Gross Solids Removal Devices (GSRDs). Under the State Water Board's storm water program, these types of projects may require coverage under the General Permit for Discharges of Storm Water Associated with Construction Activity (Construction General Permit). Dischargers whose projects disturb 1 or more acres of soil or whose project disturbs less than 1 acre but are part of a larger common plan of development that in total disturbs 1 or more acres, are required to obtain coverage under this permit. The activity would include clearing, grading, and disturbances to the ground such as stockpiling, or excavation. Additional requirements of the Construction General Permit require the development and implementation of a Storm Water Pollution Prevention Plan (SWPPP). The SWPPP should contain a site map(s) which shows the construction site perimeter, existing and storm water collection and discharge points and drainage patterns across the project. The SWPPP includes a chemical monitoring program for "non-visible" pollutants to be implemented if there is a failure of BMPs during a project's construction.

► **Mitigation Measure:** Implementation of mitigation measures as applicable on a project by project basis in the Construction General Permit. These hydrology and water quality resource impacts were considered to be short-term and no potential for adverse impacts to these resources were identified.

► **Implementation:** Project-level by Applicant

► **Significance After Mitigation:** Less than significant with mitigation incorporated.

ANALYSIS VARIOUS BMPS IMPACTS - HYDROLOGY AND WATER QUALITY

Catch Basin Inserts

Catch basin inserts are manufactured frames that typically incorporate filters or fabric and placed in a curb opening or drop inlet to remove trash, sediment or debris. They can also be perforated metal screens placed horizontally or vertically within a catch basin. These devices have less hydraulic effect than the VSS systems, however, flooding is still a potential hazard if the filters or screens became blocked by trash and debris and prevent the discharge of storm water. This would be of particular concern in areas susceptible to high leaf litter rates. This potential impact can be mitigated through the use of inserts that are designed with automatic release mechanisms or retractable screens that allow flow-through during wet-weather and by performing regular maintenance to prevent the build up of trash and debris. Therefore the exposure of people and property to flooding hazards after mitigation should be less than significant.

Vortex separation system
VSS units are designed to allow the incoming flow of urban or storm water to pass through the device while capturing trash and other debris within the unit. These types of devices may result in a potentially significant impact due to flooding hazards if the screens became blocked by trash and debris and prevent the discharge of storm water, or it the VSS system was not properly designed and constructed to allow for bypass of storm water during storm events that exceed the design capacity. This potential impact can be mitigated through the design of the system with overflow/bypass structures and by performing regulate maintenance to prevent the build up of trash and debris. Therefore, the exposure of people and property to flooding hazards after mitigation is less than significant.

The VSS unit may cause a significant change in the drainage patterns, rate and amount of surface water runoff. These units may impede or slow overland flow to the storm drain system. Any device installed in a storm drain, especially in an older, under-capacity drain could have a negative effect on the drain's ability to convey surface waters including flood waters. This negative impact can be mitigated through design of the VSS system with overflow/bypass structures and by performing regular maintenance of these devices and if necessary enlargement of the storm drain upstream of the device.

Road and Parking Lot Street Sweeping
It is not reasonably foreseeable that increased road and parking lot sweeping would negatively impact hydrology or water quality.

Public Education
It is not reasonably foreseeable that public education would negatively impact hydrology or water quality.

Installation and maintenance of some structural BMP's could result in potentially significant environmental effects with regard to hydrology. However, mitigation measures which can be applied to reduce and/or eliminate these impacts are available as described. These mitigation measures are within the responsibility and jurisdiction of the applicants of the General Exception, and can or should be adopted by them. The State Water Board does not direct which compliance measures applicants choose to adopt or which mitigation measures they employ. The State Water Board does, however, recommend that appropriate mitigation measures be applied in order that potential environmental impacts be reduced or avoided. It is foreseeable that these mitigation measures may not always be capable of reducing these impacts to levels that are less than significant in every conceivable instance. In the event that a specific mitigation measure or alternative may not reduce impacts to levels that are less than significant, the project proponent may need to consider an alternative strategy or combination of strategies to comply with the Special Protections.

► **Significance After Mitigation:** Less than significant with mitigation incorporated.

DISCUSSION IMPACTS GENERAL EXCEPTION PROJECT

The General Exception Project has the potential to violate the ASBS waste discharge prohibition of the Ocean Plan if existing inadequate controls currently in force are allowed to continue. The project, granting an exception with special mitigating conditions (i.e., special protections) will allow the continued discharge of wastes from various origins including storm water runoff into ASBS. Existing ocean water quality conditions within ASBS have had measured concentrations of constituents which exceed the Table B water quality objectives of the Ocean Plan. Exceedances of the Table B Ocean Plan water quality objectives were also found in the storm water runoff of some of the applicants. It is expected that the mitigating terms and conditions of the special protections will result in improved water quality conditions. Further, the terms and conditions of the special protections provide for continued water quality improvements over time if all of the conditions designed to limit discharges of waste from the 27 applicants are implemented.

Granting the general exception will not violate federal antidegradation requirements because water quality will not be lowered, but rather, will be improved within the ASBS affected. Further, allowance of the General Exception will not violate the State Water Board's antidegradation policy (SWRCB 1968) since water quality conditions are anticipated to improve; the discharges will not unreasonably affect present and anticipated beneficial uses; the discharge will not result in water quality lower than that prescribed in the Ocean Plan; and beneficial uses will be protected and potential impacts will be less than significant with mitigation incorporated.

It is anticipated that the applicants identified in this General Exception project will implement various individual or collaborative projects to comply with the terms and conditions or "Special Protections." As part of the scoping and environmental analysis conducted for the General Exception project, project types identified include: Low Impact Development (LID); dry-weather flow diversions; and Best Management Practices (BMPs), such as Pollution Prevention BMPs and Treatment BMPs, such as infiltration basins and Gross Solids Removal Devices (GSRDs). Under the State Water Board's storm water program, these types of projects may require coverage under the General Permit for Discharges of Storm Water Associated with Construction Activity (Construction General Permit). Dischargers whose projects disturb 1 or more acres of soil or whose project disturbs less than 1 acre but are part of a larger common plan of development that in total disturbs 1 or more acres, are required to obtain coverage under this permit. The activity would include clearing, grading, and disturbances to the ground such as stockpiling, or excavation.

Additional requirements of the Construction General Permit require the development and implementation of a Storm Water Pollution Prevention Plan (SWPPP). The SWPPP should contain a site map(s) which shows the construction site perimeter, existing and storm water collection and discharge points and drainage patterns across the project. The SWPPP includes a chemical monitoring program for "non-visible" pollutants to be implemented if there is a failure of BMPs during a project's construction.

These hydrology and water quality resource impacts were considered to be short-term and no potential for adverse impacts to these resources were identified.

Thresholds of Significance:
1 - Exceedances of Table B water quality objectives in storm water
2 - Dry weather flows
3 - Violate federal antidegradation requirements
4 – Discharge of waste materials into the ASBS

6.8 ANALYSIS OF ENVIRONMENTAL IMPACTS - NOISE

The California Health and Safety Code Section 46022 defines noise as "excessive undesirable sound, including that produced by persons, pets and livestock, industrial equipment, construction, motor vehicles, boats, aircraft, home appliances, electric motors, combustion engines, and any other noise-producing objects "the degree to which noise can affect the human environment range from levels that interfere with speech and sleep (annoyance and nuisance) to levels that cause adverse health effects (hearing loss and psychological effects). Human response to noise is subjective and can vary greatly from person to person. Factors that influence individual response include the intensity, frequency, and pattern of noise; the amount of background noise present before the intruding noise; and the nature of work or human activity that is exposed to the noise source.

CEQA requires an analysis to assess whether a proposed project would have a noise impact. If a proposed project is determined to have a significant noise impact under CEQA, then CEQA dictates that mitigation measures must be incorporated into the project unless such measures are not feasible. It is anticipated that each applicant will assess noise impacts on a project by project basis as part of compliance with the terms and conditions of the General Exception. If it is determined that a project will have noise impacts, then potential abatement measures must be considered. A technical noise impact analysis may include evaluation of traffic and construction noise of an individual project. Other factors to consider as part of the analysis would be decibel, distance, and duration of construction. The impact analysis may assess noise abatement measures that are determined to be reasonable and feasible, and at the time of final design would then be incorporated into projects' plans and specifications.

Construction noise impacts and the degree of construction noise may vary depending on the location and type of construction activity.

THRESHOLDS OF SIGNIFICANCE

- ► Exposure of persons to, or generation of, noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies
- ► Exposure of persons to, or generation of, excessive ground borne vibration or ground borne noise levels
- ► A substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project
- ► A substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project

IMPACTS OF THE PROPOSED PROJECT AND MITIGATION MEASURES

Impact 6.8-1 Exposure of persons to, or generation of, noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies.

The General Exception Project has the potential to result in the generation of construction-related noise with the implementation of Special Protections.

Construction noise levels generated during construction must comply with applicable local, state, and federal regulations and all equipment must be fitted with adequate mufflers according to the manufacturers' specifications. Table 3.2.7-7 summarizes noise levels produced by construction equipment that is commonly used on construction projects. Construction equipment is expected to generate noise levels ranging from 70 to 90 dB at a distance of 50 feet, and noise produced by construction equipment would be reduced over distance at a rate of about 6 dB per doubling of distance.

Table 3.2.7-7. Construction Equipment Noise

Equipment	Maximum Noise Level (dBA at 50 feet)
Scrapers	89
Bulldozers	85
Heavy trucks	88
Backhoe	80
Pneumatic tools	85
Concrete pump	82

Source: Federal Transit Administration 2006.

No long-term adverse noise effects from construction are anticipated, because construction would be conducted in accordance with applicable local noise standards. Construction noise would be short-term, intermittent, and potentially masked by local traffic noise in some cases.

► **Mitigation Measure:** Minimize Construction Noise. It is anticipated that at the project-level, measures will be implemented to minimize noise effects from construction. In addition, the following measures may be implemented to further minimize noise effects from construction:

1) Use of equipment with sound-control devices that are no less effective than those provided on the original equipment.

2) Prohibition of the use of any equipment with an unmuffled exhaust.

3) Changing the location of stationary construction equipment to maximize the distance to noise sensitive uses.

4) Turning off idling equipment.

5) Rescheduling construction activity to non-sensitive hours of the day.

6) Notifying adjacent residents in advance of construction work.

7) Installing acoustic barriers around stationary construction noise sources.

► **Implementation:** It is anticipated that each applicant will assess noise levels on a project-by-project basis as part of compliance with the terms and conditions of the General Exception. Some of the Special Protections implementation alternatives have the potential to affect noise levels within the local project area. Noise within the counties and cities are regulated by noise ordinances, which are found in the municipal code of the county and each city. These noise ordinances limit intrusive noise and establish sound measurements and criteria, minimum ambient noise levels for different land use zoning classifications, sound emission levels for specific uses, hours of operation for certain activities (such as construction and trash collection), standards for determining noise deemed a disturbance of the peace, and legal remedies for violations. If a proposed project is determined to have a significant noise level impact under CEQA, then CEQA dictates that mitigation measures must be incorporated into the project unless such measures are not feasible. If it is determined that a project will have noise level impacts, then potential mitigation measures must be considered.

► **Significance After Mitigation:** Less than significant with mitigation incorporated.

The following impacts are discussed collectively: Impact 6.8-2,direct Impacts Associated with Construction of General Exception Special Protections; BMP Implementation as exposure of persons to, or generation of, excessive ground-borne vibration or ground-borne noise levels; Impact 6.8-3, substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project; Impact 6.8-4, substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project.

The General Exception Project has the potential to result in the generation of construction-related noise with the implementation of Special Protections. A certain degree of disruptive noise is inevitable during construction activities. Overall, installation noise levels are governed primarily by the noisiest pieces of equipment. For most construction equipment, the engine is the dominant noise source. Table 4.2-2 identifies the major pieces of construction equipment associated with the various stages of installation. Typical maximum noise emission levels (Lmax) are summarized, based on construction equipment operating at full power at a reference distance of 50 feet, and an estimated equipment usage factor based on experience with other similar installation projects. The usage factor is a fraction that accounts for the total time during an eight-hour day in which a piece of installation equipment is producing noise under full power. Although the noise levels in Table 7.17-3 represent typical values, there can be wide fluctuations in the noise emissions of similar equipment based on two important factors: (1) the operating condition of the equipment (e.g., age, presence of mufflers and engine cowlings); and (2) the technique used by the equipment operator (aggressive vs. conservative).

Table 7.13-3: Typical Installation Equipment Noise Emission Levels

Equipment	Maximum Noise Level, (dBA) 50 feet from source	Equipment Usage Factor	Total 8-hr Leq exposure (dBA) at various distances	
			50ft	100ft
Foundation Installation			83	77
Concrete Truck	*82*	*0.25*	76	70
Front Loader	*80*	*0.3*	75	69
Dump Truck	*71*	*0.25*	65	59
Generator to vibrate concrete	*82*	*0.15*	74	68
Vibratory Hammer	*86*	*0.25*	80	74
Equipment Installation			83	77
Flatbed truck	*78*	*0.15*	70	64
Forklift	*80*	*0.27*	74	69
Large Crane	*85*	*0.5*	82	76

Source; Caltrain, 2004

Special Protections BMP implementation projects would be short-term and localized. As such, the potential to expose persons, wildlife and marine life to substantial excessive permanent ground borne vibration of ground borne noise levels can be mitigated with common industry standard mitigation measures available. It is not anticipated that the potential for substantial, permanent increases in ambient noise levels would occur in the project area. Given the natural features of the landscape within each ASBS identified herein and its unique characteristics, during the CEQA analysis of each proposed implementation project by the Responsible Party appropriate consideration and mitigation must occur to eliminate or reduce impacts below threshold limits.

► **Mitigation Measure:** Noise and vibration abatement criteria would include the following measures to minimize impacts caused by construction.

1) Equipment Noise Control: Newer equipment that is quieter would be used. All equipment items would have intact and operational manufacturers' recommended noise abatement measures, such as mufflers, engine covers, and engine vibration isolators.

2) Administrative measures: Maintenance yard and other construction-oriented operations staging areas would be placed in the locations that would minimize disruption to the community.

3) Community Relations: Good public relations would be maintained with the community to minimize objections to the impact of unavoidable construction nose. Community members and visitors would be notified in advance of the construction schedule through the public awareness campaign.

► **Implementation:** Specific construction noise levels could be estimated for each project to be implemented by the Applicants of the General Exception. Noise level estimation is dependant on the type of activities and equipment expected to be employed during construction. Typical noise protocols would require consideration of noise abatement measures when predicted noise levels from a project substantially increase existing noise levels or when the project noise levels approach or exceed the individual project's local ordinances or noise abatement criteria for residences. Noise levels would be considered on a project-by-project basis and adjusted for urban or for passively used open spaces and evaluated as what is considered normally acceptable for that site.

► **Significance After Mitigation:** Less than significant with mitigation incorporated.

ANALYSIS OF VARIOUS BMPs IMPACTS NOISE

Catch Basin Inserts

Installation of catch basin inserts should not involve any construction activity or the use of major equipment, therefore no significant increase in ambient noise levels is anticipated. Catch Basins need to be cleaned regularly. Frequency of cleaning would be site specific and dependant on the amount of debris accumulated in the insert. Increased street sweeping efforts would help to reduce the amount of debris caught by the catch basin inserts. It is not anticipated that ambient noise levels will be adversely affected by the use of catch basin inserts.

Vortex Separator System

Installation of VSS units would potentially involve removal of asphalt and concrete from streets and sidewalks, excavation and shoring, installation of reinforced concrete pipe, installation of the unit, and repaving of the streets and sidewalks. It is anticipated that installation activities would occur in limited, discrete, and discontinuous areas over a short duration. No major construction activities are anticipated. It is anticipated that excavation, for the purposed of installation, and repaving would result in the greatest increase in noise levels during the period of installation. The manufacturer of the VSS unit recommends that the unit receive maintenance 2 to 4 times a year depending on amount and frequency of precipitation. Maintenance involves cleaning using vacuum trucks, which would increase ambient noise levels. The increase in noise levels would be dependent on the proximity of sensitive receptors to the site. Maintenance is also expected to generate 2-4 vehicle trips per year which is not expected to increase ambient noise levels noticeably.

Contractors and equipment manufacturers have been addressing noise problems for many years, and through design improvements, technological advances, and a better understanding of how to minimize exposures to noise, noise effects can be minimized. An operations plan for the specific construction and/or maintenance activities could be developed to address the variety of available measures to limit the impacts from noise to adjacent homes and businesses. To minimize noise and vibration impact at nearby sensitive site, installation activities should be conducted during daytime hours to the extent feasible. There are a number of measures that can be taken to reduce intrusion without placing unreasonable constraints on the installation process or substantially increasing costs. These include noise and vibration monitoring to ensure that contractors take all reasonable steps to minimize impacts when near sensitive areas; noise testing and inspections of equipment to ensure that all equipment on the site is in good condition and effectively muffled; and an active community liaison program. A community liaison program should keep residents informed about installation plans so they can plan around noise or vibration impacts; it should also provide a conduit for residents to express any concerns or complaints.

Measures that would minimize noise and vibration disturbances at sensitive areas during installation include:

1) The use of newer equipment with improved noise muffling and ensure that all equipment items have the manufacturers' recommended noise abatement devices, such as mufflers, engine covers, and engine vibration isolators intact and operational. Newer equipment will generally be quieter in operation than older equipment. All installation equipment should be inspected at periodic intervals to ensure proper maintenance and presence of noise control devices.

2) Perform all installation in a manner to minimize noise and vibration. Use installation methods or equipment that will provide the lowest level of noise and ground vibration impact near residences and consider alternative methods that are also suitable for the soil condition. The contractor should select installation processes and techniques that create the lowest noise levels.

3) Perform noise and vibration monitoring to demonstrate compliance with the noise limits. Independent monitoring should be performed to check compliance in particularly sensitive areas. Require contractors to modify and/or reschedule their installation activities if monitoring determines that maximum limits are exceeded at residential land uses.

4) Conduct truck loading, unloading and hauling operations so that noise and vibration are kept to a minimum by carefully selecting routes to avoid going through residential neighborhoods to the greatest possible extent. Ingress and egress to and from the staging area should be on collector streets or higher street designations (preferred).

5) Turn off idling equipment.

6) Temporary noise barriers shall be used and relocated, as practicable, to protect sensitive receptors against excessive noise from installation activities. Consider mitigation measures such as partial enclosures around continuously operating equipment or temporary barriers along installation boundaries.

7) The installation contractor should be required by contract specification to comply with all local noise and vibration ordinances and obtain all necessary permits and variances.

Road and Parking Lot Street Sweeping
Increased road and parking lot street sweeping would involve an increase in current street sweeping frequencies in order to reduce the amount of accumulated debris. Any increases in these sweeping frequencies would be focused in areas which generate higher amounts of trash and debris such as those with greater commercial and industrial land uses. The increase in ambient noise levels is expected to be limited in duration. In areas where noise levels have the potential to be considered a nuisance, efforts should be employed to reduce noise impacts.

Public Education
Public education efforts are not expected to create an increase in ambient noise levels, as such, no mitigation would be required.

Installation and maintenance of some structural BMP's could result in potentially significant environmental effects with regard to noise. However, mitigation measures which can be applied to reduce and/or eliminate these impacts are available as described. These mitigation measures are within the responsibility and jurisdiction of the responsible parties of the General Exception, and can or should be adopted by them. The State Water Board does not direct which compliance measures applicants choose to adopt or which mitigation measures they employ. The State Water Board does, however, recommend that appropriated mitigation measures be applied in order that potential environmental impacts be reduced or avoided. It is foreseeable that these mitigation measures may not always be capable of reducing these impacts to levels that are less than significant in every conceivable instance. In the event that a specific mitigation measure or alternative may not reduce impacts to levels that are less than significant, the project proponent may need to consider an alternative strategy or combination of strategies to comply with the Special Protections.

6.9 ANALYSIS OF ENVIRONMENTAL IMPACTS – PUBLIC SERVICES

CEQA requires an analysis to assess whether a proposed project would have public services impacts. If a proposed project is determined to have a significant public services impact under CEQA, then CEQA dictates that mitigation measures must be incorporated into the project unless such measures are not feasible. It is anticipated that each applicant will assess public services impacts on a project-by-project basis as part of compliance with the terms and conditions of the General Exception. If it is determined that a project will have public services impacts, then potential mitigation measures must be considered. A technical public services impact analysis may include evaluation of community facilities or services, or result in any removal or change of access to facilities or services, or create new demand for community services of an individual project. The impact analysis may assess mitigation measures that are determined to be reasonable and feasible, and at the time of final design would then be incorporated into projects' plans and specifications. Impacts to public services and the degree of impact may vary depending on the location and type of construction activity. Indirect effects to public services may extend throughout the duration of construction within the Project Limits.

Recreational resources include public parks, golf courses, beaches, wildlife areas. As part of the scoping and environmental analysis conducted for the General Exception project, impacts to these resources were considered for some structural and non-structural controls, but no potential for adverse impacts to these resources were identified. The General Exception project does not include recreational facilities or require the construction or expansion of recreational facilities.

THRESHOLDS OF SIGNIFICANCE

A public services impact is considered significant if implementation of the proposed project would result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service rations, response times or other performance objectives for any of the following public services:

► fire protection
► police protection
► recreational resources
► other public facilities

IMPACTS OF THE PROPOSED PROJECT AND MITIGATION MEASURES

Impact 6.9-1 Indirect Impacts Associated with Construction of General Exception Special Protections BMP Implementation.

> **While the potential exists for Special Protections-related construction to result in an impact to public services or facilities, it is reasonably foreseeable that these impacts would be temporary, short-term. Substantial adverse physical impacts associated with the provision of new or physically altered government facilities, is not foreseeable.**

► **Mitigation Measure:** None required due to less than significant impact.

► **Implementation:** None required.

► **Significance After Mitigation:** N/A.

As part of the scoping and environmental analysis conducted for the General Exception project, these resources were considered, but no potential for adverse impacts to these resources were identified and are not expected to result in permanent, direct, or indirect impacts to public services, nor would it create new demand for community services since no capital improvements are included in this General Exception project. Reasonably foreseeable impacts for some structural compliance measures such as vortex separation systems, catch basin inserts and non-structural alternatives such as road and parking lot sweeping and public education are analyzed. Depending on what measures each applicant uses to comply with the proposed exception, there may be an impact on public services. However, the State Water Board believes that mitigation is available to reduce any potential impacts to public services to less than significant levels.

APPROACH AND ANALYSIS OF VARIOUS BMPs IMPACTS PUBLIC SERVICES
Catch Basin Inserts
The environmental impacts associated with the installation, maintenance and monitoring of catch basin inserts are anticipated to be of a short duration and limited to traffic delays. It is not reasonably foreseeable that installation of catch basin inserts will not contribute to an increase in the cumulative demand for fire and police emergency services.

Vortex Separation System
There is potential for temporary delays in response times of fire and police vehicles due to road closure or traffic congestion during installation of the vortex separation systems. To mitigate potential delays the applicants identified in this General Exception could notify local emergency and police service providers of construction activities and road closures, if any, and coordinate with the local fire and police providers to establish alternative routes and traffic control during the installation activities. Most jurisdictions have in place guidelines to ensure safe passage of emergency and police vehicles during periods of road maintenance, construction, or other activities. It is anticipated that installation of a VSS unit would be subject to existing applicable building and safety codes and permits. Therefore, the potential delays in response times for fire and police vehicles after mitigation are less than significant. The installation of vortex separation systems will not result in development of land uses for residential, commercial, and/or industrial uses, nor will these units result in increased growth, it is reasonably foreseeable that the vortex separation systems would not result in a need for new or altered fire or police protection services. In addition, Emergency Preparedness Plans could be developed in consultation with local emergency providers to ensure that the new vortex separation systems will not contribute to an increase in the cumulative demand for fire and police emergency services.

Road and Parking Lot Street Sweeping
It is not reasonably foreseeable that road and parking lot street sweeping would result in an impact to fire and police emergency services.

Public Education
It is not reasonably foreseeable that public education would result in the need for new or altered government services.

Installation and maintenance of structural BMPs should not result in potentially significant effects with regard to public services. However, mitigation measures can be applied by the applicants identified in this General Exception to reduce and/or eliminate any potential impact. In the event that a specific mitigation measure or alternative may not reduce impacts to levels that are less than significant, the project proponent may need to consider an alternative to comply with the terms and conditions of the General Exception.

6.10 ANALYSIS OF ENVIRONMENTAL IMPACTS - TRANSPORTATION/TRAFFIC

As part of the scoping and environmental analysis conducted for the General Exception project, these resources were considered, but no potential for adverse impacts to these resources were identified and are not expected to result in permanent, direct, or indirect impacts to transportation and circulation. Depending on what measures each applicant uses to comply with the proposed exception, there may be an impact on transportation/traffic. However, the State Water Board believes that mitigation is available to reduce any potential impacts to transportation/traffic to less than significant levels.

THRESHOLDS OF SIGNIFICANCE

- ► Exceed the capacity of the existing circulation system, based on an applicable measure of effectiveness (as designated in a general plan policy, ordinance, etc.), taking into account all relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit

- ► Result in inadequate emergency access

IMPACTS OF THE PROPOSED PROJECT AND MITIGATION MEASURES

Impact 6.10-1 Direct Impacts Associated with Construction of General Exception Special Protections BMPs.

> **While the potential exists for Special Protections-related construction to create a potentially significant impact to transportation and circulation, these construction activities related to installation of various BMPs, may be considered foreseeably minimal and localized to the immediate area of the project.**

► **Mitigation Measure:** Implementation of a Traffic Management Plan would be developed to increase driver awareness, ease congestion, and minimize delay during construction. Depending on the localized project to be implemented, the Plan could be broadened to allow for consideration of recommendations resulting from consultation and feedback from a community advisory group. The community advisory group could potentially include representation from local tourist and commerce bureaus and businesses, representatives of the Sherriff’s Department, California Highway Patrol, local emergency service providers and others. Development of a Plan could be initiated during the design phase of a project and include agreements reached with the community advisory group that would inform and may constrain the construction contractor for the purpose of minimizing traffic impacts during construction. A Traffic Management Plan would cover construction scheduling, limitations of lane closures, noticing requirements, emergency response, and other topics as necessary. It would describe the manner in which to inform travelers of potential traffic delays and road closures and other construction-related activities that could inconvenience local businesses, residents and travelers, so that they could plan accordingly. The project contract could contain provisions required for emergency services (police, fire, and ambulances) to be notified before any required roadways or lane closures.

It is reasonably foreseeable that traffic impacts during construction may include impedance of traffic flow affected by any large amount of equipment and materials that would need to be transported over the roadway or highway and from lane closures needed to provide room for construction.

► **Implementation:** Transportation and circulation would be assessed in accordance with CEQA by each of the applicants identified in this General Exception as individual projects are planned and designed by each applicant. Individual projects should discuss the transportation and circulation concerns as they relate to project design and construction. Transportation and circulation are prime considerations within the coastal zone communities and each applicant would be responsible for assessing these impacts in concert with their individual projects to ensure sufficient levels of service.

► **Significance After Mitigation:** Less than significant.

Impact 6.10-2 Indirect Impacts associated with Construction of General Exception Special Protections BMP Implementation.

While the potential exists for Special Protections-related construction to create inadequate emergency access, it is reasonably foreseeable that these impacts would be short-term, temporary and localized.

► **Mitigation Measure:** None required.

► **Implementation:** N/A

► **Significance After Mitigation:** Less than significant.

ANALISIS OF POTENTIAL BMPs IMPACTS - TRANSPORTATION/TRAFFIC
Catch Basin Inserts

Installation of catch basin inserts is not anticipated to involve the use of heavy construction equipment, therefore additional vehicular movement during installation of the catch basin inserts is unlikely to be significant. Any potential impact would be limited and of short-term during the installation process, and not anticipated to have an adverse effect on traffic and transportation. Catch basins are required to be cleaned regularly at a minimum frequency or once per year. Mitigation measures which could be implemented would be the same as those used with vortex separation systems. It is anticipated that impacts after mitigation will be less than significant.

.

Vortex Separation Systems

During installation of these devices, additional vehicle movement will occur. However, these impacts will be temporary and limited in duration to the period of installation. Maintenance requirements for trash removal devices demonstrate that devices could be emptied when they reach 85% capacity. However, devices could be designed so that they need to be cleaned once per storm season. As site-specific projects are implemented, mitigation measures could include construction barricades, traffic-flow controls such as signals or personnel in compliance with authorized local police or California Highway Patrol requirements. These methods would be selected and implemented by responsible local agencies considering project level concerns. Standard safety measures should be employed including fencing, other physical safety structures, signage, and other physical impediments designed to promote safety and minimize pedestrian/bicyclists accidents. It is not foreseeable that implementation of VSS will result in significant increased in traffic hazards to motor vehicles, bicycles, or pedestrians.

To reduce the impact of construction traffic, implementation of a construction management plan for specified facilities could be developed to minimize traffic impacts upon the local circulation system. A construction traffic management plan could address traffic control for any street closure, detour, or other disruption to traffic circulation. The plan could identify the routes that construction vehicles will use to access the site, hours of construction traffic, and traffic controls and detours. The plan could also include plans for temporary traffic control, temporary signage and tripping, location points for ingress and egress of construction vehicles, staging areas, and timing of construction activity which appropriately limits hours during which large construction equipment may be brought on or off site. Potential impacts could also be reduced by, limiting or restricting hours of construction so as to avoid peak traffic times and by providing temporary traffic signals and flagging to facilitate traffic movement. It is anticipated that impacts after mitigation will be less than significant.

Road and Parking Lot Street Sweeping

The number of trips generated by increased road and parking lot sweeping will depend on the sweeping frequency determined by the applicant implementing this alternative. It is not anticipated that a significant impact will result; however, mitigation measures employed could include noticing any affected residents, businesses and property owners in the vicinity of the areas which this activity will occur.

Public Education
No adverse impacts to traffic or transportation is anticipated with this alternative.

6.11 CONCLUSION

Under the less stringent and somewhat inadequate controls currently in force, 27 applicants discharge waste into the 26 ASBS and are in violation of the ASBS discharge prohibition. The project, granting a general exception with special mitigating conditions (i.e., special protections), will allow the continued discharges from nonpoint sources and storm water runoff, and therefore has some potential to degrade water quality and biological resources unless mitigating conditions are implemented. However, under the mitigating conditions composing these special protections, the quality of the discharges will improve from current conditions, with an important reduction in the potential to degrade water quality. If all of the conditions designed to limit the discharge are met, the discharges will not compromise the protection of ocean waters of the ASBS for beneficial uses, and the public interest will be served.

Granting the conditional exception, likewise, will not violate federal antidegradation requirements because water quality will not be lowered, but rather will be improved. Further, allowance of the exception will not violate the State Water Board's antidegradation policy (SWRCB 1968) since water quality conditions will improve; the discharge will not unreasonably affect present and anticipated beneficial uses; the discharge will not result in water quality lower than that prescribed in the Ocean Plan; and the people of California benefit from the terms and conditions implemented while beneficial uses will still be protected.

7.0 ECONOMIC ANALYSIS OF SPECIAL PROTECTIONS

This section discusses a range of potential costs associated with the General Exception project implementation of the Special Protections and various selected monitoring and management practices which could be used by the dischargers identified herein.

7.1 MONITORING

One large problem faced by both ASBS dischargers and regulators is a lack of information. The lack of information falls into at least three categories. First, it is uncertain what constitutes natural water quality. Second, it is uncertain which discharges cause alterations in natural water quality. Finally, it is uncertain what the extent and magnitude of natural water quality impacts are on a statewide basis.

In response to the need for additional information, the State Water Board is working with ASBS dischargers to collaboratively conduct regional ASBS monitoring programs that are consistent statewide. The goal of this monitoring program is to determine water quality at each of the ASBS and analyze discharged water quality from applicants subject to these Special Protections. This will allow the State Water Board to assess potential impacts to the ASBS from specific discharges. Three regional monitoring groups are being established to perform the required core and regional monitoring requirement. The estimated costs for these monitoring programs are provided below. It should be noted that participation in the regional monitoring programs is an option and is not mandatory.

7.1.1 <u>Southern California Regional Monitoring Group</u>

In southern California, the regional monitoring group has been organized by SCCWRP and operated in conjunction with the Bight 08 program. This group will address the regional monitoring program required as part of the Special Protections. This monitoring group will include an extensive series of reference sites as part of their monitoring program as this fits nicely with the Bight 08 sampling project.

A. Wet Weather Chemistry and Toxicity

1) <u>Site Selection</u>
Since there is little or no historic water quality data available in ASBS sites prior to anthropogenic discharges, reference sites have been selected that will be used to determine the range of natural water quality and natural condition of marine life. The following primary criteria were established for reference sites:

- Located in receiving water at the mouth of watersheds with limited anthropogenic influences and with no offshore discharges in the vicinity.

- Limited anthropogenic influence defined as a minimum of 90% open space. Preferably, the few anthropogenic sources in a reference watershed will be well attenuated (e.g., natural space buffers between a highway and the high tide line).
- There should be no 303(d) listed waterbodies either in the reference watershed or in the coastal zone.

There are additional secondary criteria that are deemed important, but may not lead to complete exclusion:

- A range of reference watershed sizes that are inclusive of the ranges observed in watersheds that discharge to ASBS.
- A range of reference watershed geologies that are inclusive of the geologies observed in watersheds that discharge to ASBS.
- A range of reference beach substrate that includes sand, cobble, and rock.
- Reference watersheds that include channel island and mainland sites.

A minimum of eight reference sites have been selected for sampling as part of the regional monitoring survey.

In addition to reference sites, receiving water sites near ASBS discharges will also be sampled. These receiving water sites are located directly in front of discharges from regulated ASBS outfalls. The number of sites in ASBS was based on the following criteria:

- Minimum of 1 site/stakeholder/ASBS.
- Sample receiving waters near at least 10% of all regulated outfalls in an ASBS (> 18 inches opening).
- Discharge must reach receiving water (i.e., ocean).
- Approval by Regional Water Board and State Water Board.

A minimum of 10 receiving water sites near discharges have been targeted for sampling. Additional sites may be selected for contingency measures due to impaired sampling logistics or limited rainfall.

A cost estimate for each participant in the southern California regional receiving water monitoring effort is about $50,000 to $80,000 for chemistry and toxicity at one discharge and one reference station. For approximately 10 participants, receiving water chemistry and toxicity costs may cumulatively range from $500,000 to $800,000.

It is important to note that core monitoring will also be performed by the southern California dischargers and is not included in the costs of the regional receiving water study. Core monitoring is estimated to cost about $2,000 to $5,000 per outfall (sampling and analysis) per year, depending on size. It is estimated that in southern California, about 200 discharges may be sampled at $400,000 to $1,000,000 per year, depending on outfall size. Assuming a roughly equal distribution of outfalls > 18 inches and >36 inches, the cost would be about $700,000. Because southern California dischargers participated in the Bight "08 Regional Monitoring Program, core sampling for runoff will occur in only the first year, and there will be no additional runoff sampling for the remainder of the permit cycle for those parties.

B. Biological Monitoring

The Southern California regional monitoring program is focused on assessing the status of biological communities associated with rocky subtidal reefs located between one and 30 m (3 and 90 feet) depth. High and low relief substrates, nearshore and offshore reefs, as well as areas of persistent kelp are all included in this regional monitoring program. For the program to assess the spatial distribution among reefs, a probabilistic sampling design is used that consists of 60 sites stratified by mainland vs. islands and warm temperature vs. cold temperature marine habitats. The sampling methodology utilizes a modified PISCO/CRANE style biodiversity protocol that is conducted using trained scuba divers. The protocols include transects and unified point contact grids to quantify invertebrate, algal, and vertebrate species assemblages.

Bight 08 Rocky and Bight 08 ASBS investigators worked together to identify what sampling design specifics would be needed to integrate the two programs. Since the Bight 08 Rocky program is already a portion of the Bight Regional Survey, the primary data gap was site selection. Other important design specifics, such as sampling methods, have already been developed for the survey.

While 60 sites are targeted, many have yet to be sampled. In fact, approximately 40 sites are currently being sampled. Of these, 22 are located in or near an ASBS. This provides a broad base of coverage as a starting point for the Bight 08 ASBS program. Like the rocky intertidal program, there are at least three data gaps that still exist: (1) additional sites to ensure coverage for every ASBS in southern California; (2) additional sites to ensure adequate coverage for reference locations; and (3) resource matching to ensure the existing sites can be used for ASBS purposes. In order to address the first data gap, at least three additional mainland sites (Robert E. Badham ASBS, Heisler Park ASBS, La Jolla ASBS) and five Channel Island sites (East end Catalina, San Clemente, San Nicolas) will need to be added to cover the remaining ASBS locations. In order to address the second data gap, at least two additional mainland sites (Santa Barbara/Ventura Counties, Northern San Diego/Southern Orange Counties) and three additional Channel Island sites (Catalina, San Clemente, San Nicolas) will be needed to assess unsampled reference locations. Finally, the ASBS Planning Committee agreed to support nine of the existing sites to ensure these sites can be used for ASBS purposes.

Cost estimates for rocky subtidal monitoring are $12,500 per participant and for rocky intertidal monitoring is $22,000 per participant. For all participants combined, the collective costs for biological monitoring may total about $345,000.

In summary, for regional receiving water and biological monitoring, combined with core runoff monitoring, costs would be about $1,545,000.

7.1.2 <u>Central Coast ASBS Regional Monitoring</u>

In order to maintain comparability between regions, the basic questions, methods, and reference criteria will be the same for central and northern California as what was described above for southern California.

One proposal for central coast ASBS regional monitoring has been for the applicants to work with CCLEAN, which is a regional monitoring program that has been collecting, interpreting, and reporting water quality data in the Monterey Bay area since 2001. Currently, the participants in CCLEAN are the City of Santa Cruz, City of Watsonville (Lead Agency), Moss Landing Power Plant, Monterey Regional Water Pollution Control Agency, Carmel Area Wastewater District, and the Central Coast Regional Water Board. However, no decision has been made by the applicants to join CCLEAN or to initiate their own separate regional monitoring program.

Three scenarios have been developed for consideration that would provide for a regional monitoring program to monitor storm water runoff into ASBS in the Monterey Bay area. These scenarios have been developed with consideration of the Draft Special Protections for Selected Storm Water and Nonpoint Source Discharges into Areas of Special Biological Significance dated March 3, 2008.

The three scenarios that have been discussed by the dischargers are:

1) A regional monitoring program that is not part of CCLEAN,
2) A regional program that includes collection of data to allow estimates of contaminant loads, also not part of CCLEAN, and
3) A regional program that is part of CCLEAN.

These are presented and compared in the following sections. Implementation of either scenario would require the agreement of State and Regional Water Board. Scenario 3 would also require the agreement of current CCLEAN program participants. It should be emphasized that no agreement has been reached by the ASBS storm water/nonpoint source dischargers and CCLEAN participants.

This scenario makes use of the Monterey Bay National Marine Sanctuary's First Flush program to collect runoff samples, and includes funds to augment their effort by monitoring approximately 25 discharges currently not sampled by them. These additional sites include all discharges >18 inches, and those at Pebble Beach and Carmel Meadows. Biennial receiving water monitoring would be performed at seven sites and would include water sampling before and after a storm, and one-time sampling of benthic communities and bioaccumulation.

Table 7.1.1. Comparison of monitoring elements required by the Draft Special Protections and a proposed regional ASBS monitoring program that is not part of CCLEAN

Monitoring Element	Scenario 1 - Special Protections Requirements	Scenario 2 – Flow-proportioned Sampling
Runoff Flow Measurements	Estimate from rain gauges and % impervious surface with ground-truthing	Estimate from rain gauges and % impervious surface with ground-truthing
Runoff Samples	Annual in wet season at all discharges >18 inches (total of 37) Analyze for Table A; Table B acute toxicity annually at 1/5 outfalls (total of 7)	Annual in wet season at all discharges >18 inches (total of 37) Analyze for Table A; Table B acute toxicity annually at 1/5 outfalls (total of 7)
	Annual in wet season at all discharges >36 inches (total of 5) Table B for marine aquatic life, PAHs, pyrethroids, OP pesticides, nitrates, phosphates	Annual in wet season at 2 discharges >36 inches Table B for marine aquatic life, nitrates, phosphates, urea; and flow-proportioned samples for endosulfan, endrin, HCH, PAHs, PCBs, chlorinated pesticides, pyrethroids, OP pesticides, PBDEs
Receiving Water	Biennially in wet season at 2 reference sites and 5 ASBS sites, before and after a storm Table B for marine aquatic life, nitrates, phosphates, urea, endosulfan, endrin, HCH, PAHs, PCBs, chlorinated pesticides, pyrethroids, OP pesticides, PBDEs	Biennially in wet season at 2 reference sites and 5 ASBS sites, before and after a storm Table B for marine aquatic life, nitrates, phosphates, urea, endosulfan, endrin, HCH, PAHs, PCBs, chlorinated pesticides, pyrethroids, OP pesticides, PBDEs
Benthic Fauna	Biennially in wet season at 2 reference sites and 5 ASBS sites Infaunal abundance and sediment grain size and concentrations of TOC, endosulfan, endrin, HCH, PAHs, PCBs, chlorinated pesticides, pyrethroids, OP pesticides and PBDEs	Biennially in wet season at 2 reference sites and 2 ASBS sites on a rotating basis Infaunal abundance and sediment grain size and concentrations of TOC, endosulfan, endrin, HCH, PAHs, PCBs, chlorinated pesticides, pyrethroids, OP pesticides and PBDEs
Bioaccumulation	Biennially in wet season at 2 reference sites and 5 ASBS sites	Biennially in wet season at 2 reference sites and 2 ASBS sites on a rotating basis

Monitoring Element	Scenario 1 - Special Protections Requirements	Scenario 2 – Flow-proportioned Sampling
	Concentrations of endosulfan, endrin, HCH, PAHs, PCBs, chlorinated pesticides, pyrethroids, OP pesticides and PBDEs	Concentrations of endosulfan, endrin, HCH, PAHs, PCBs, chlorinated pesticides, pyrethroids, OP pesticides and PBDEs

There are seven ASBS dischargers on the central Coast that would be subject to the general exception. Cumulative cost estimates range from $325,000 per year under scenario 1 (ASBS discharges perform analysis within their own group) to $286,000 per year under scenario 2 (regional monitoring performed by group including ASBS dischargers and current NPDES monitoring group CCLEAN). Water quality monitoring will be required for only the first two storm seasons. Therefore the first permit cycle costs for runoff and receiving water monitoring are estimated to be $572,000 - $650,000. In addition, rocky intertidal monitoring would be required to be comparable with other regional monitoring efforts. It is estimated that rocky intertidal monitoring would collectively cost about $154,000. Using the above figures, the estimated total for central California would therefore be about $726,000 to $804,000.

7.1.3 <u>Northern California Regional Monitoring Group</u>

Unlike in other parts of the state, there is no existing regional monitoring organization. The Southern California Water Research Project (SCCWRP) has been retained by the Water Boards to initiate a regional monitoring program in central and northern California. There are twelve ASBS storm water/nonpoint source dischargers in northern California north of Point Año Nuevo.

The following is a cost estimate prepared by State Water Board staff based on available information. The estimate is based on requirements as outlined in the March 3, 2008 draft Special Protections document and February 3, 2012 updates and also includes before and after storm sampling events for receiving water and reference sites. As with other ASBS regional monitoring, applicants for individual point source exceptions, or holders of existing individual point source exceptions, would participate with applicants for the general exception; costs for parties with individual exceptions are not included below.

For this estimate, runoff flow measurement would use estimates from rain gauges and percent impervious surface, and checked with ground-truthing at selected sites. The core runoff monitoring would sample all discharges >18 inches three times annually for oil and grease, total suspended solids and indicator bacteria in the range of the southern sea otter, and once annually for Table B chronic toxicity (one species). This would be required for two storm seasons. Additional core runoff monitoring at larger discharges (>36 inches) would be done three times annually for Table B metals and ammonia, PAHs, pyrethroids, OP pesticides, nitrates, and phosphates, and once annually for Table B chronic toxicity (one species). This would also be required for two storm seasons. Core monitoring is estimated to cost about $2,000 to $5,000 per outfall per year depending on size. For the entire permit cycle (two storm seasons) for core monitoring, it is expected to cost $4,000 to $10,000 per outfall depending on outfall size. Staff estimates about 50 municipal and industrial outfalls in northern California of sufficient size to monitor runoff, with roughly an equal distribution of >18 inch and >36 inch sizes. Therefore we estimate core monitoring for runoff to be about $350,000 for a permit cycle.

For regional monitoring, receiving water would be sampled at twelve ASBS discharges and twelve reference sites, pre- and post-storm for the same constituents analyzed in southern California. Staff estimates that receiving water monitoring would cost about $500,000 during the first year and $500,000 in the second year, for a total of $1,000,000 for ocean water monitoring. In addition, intertidal monitoring would be required to be comparable with other regional monitoring efforts. It is estimated that intertidal monitoring would cost about $220,000.

The total program cost for northern California runoff and regional monitoring is estimated to be about $1,570,000.

7.1.4 Regional Monitoring Summary Costs

Combined, the Northern, Central, and Southern California regional monitoring efforts are estimated to cost as much as $3.92 million during their first permit cycle.

7.2 IMPLEMENTING THE ABSOLUTE DISCHARGE PROHIBITION (NO PROJECT ALTERNATIVE)

Caltrans has provided a cost estimate of eliminating all discharges from a set of properties into adjacent ASBS. Their estimate is based on eliminating all highway infrastructure and related discharges into ASBS.

Caltrans calculates that there are 57 miles (91.7 km) of State Coastal Highways, 1 and 101, that are adjacent to 10 ASBS. State Coastal Highways 1 and 101 are estimated to have 184 drainage conveyances that carry highway runoff into the ASBS. Of these, 85 carry runoff directly to ASBS. Caltrans estimates that 100% compliance with the ASBS absolute waste discharge prohibition would necessitate pumping storm water runoff to adjacent basins or discharge points outside of the ASBS. Initial calculations made in 2005 show that capital costs for installing the infrastructure to do this (e.g., drainage inlets, subsurface piping, pumping stations, power supply, etc.) may exceed $500 million.[13] For 184 discharges, it is estimated that this cost would be $2.7 million per Caltrans discharge.

There are approximately 1,673 total storm water and nonpoint source discharges from the applicants and property owners currently not subject to individual exceptions. Using the same figure used by Caltrans, installing infrastructure to eliminate all these discharges into ASBS would cost $4.5 billion. This is a minimum estimate, probably only applicable to storm drains and small nonpoint source runoff. Moving some discharges would involve completely removing entire businesses and infrastructure, as well as the complete disruption of military operations. Undoubtedly, the costs would actually be vastly greater than what is estimated above.

7.3 BEST MANAGEMENT PRACTICES (BMP) COSTS USING COMPARISON WITH CLEAN BEACHES INITIATIVE (CBI) PROJECTS

The CBI provides funding for infrastructure improvements with the end goal of improving water quality conditions at California's beaches. Examples of some of the costs associated with some of the projects which have successfully been implemented are listed in Table 22.

The State Water Board administers many innovative water bond projects. Over $1.5 billion in loans and grants managed by the State Water Board since 2006 are aimed, in whole or in part, at improving water quality and reducing sediment impacts to our coasts and ocean. Of this amount, almost $70 million dollars has been spent directly on projects to improve beach water quality in California. These projects have not been aimed at ASBS discharges but directed to improve beach water quality at the most impacted beaches. Still some CBI projects were performed at ASBS that were also contact recreation beaches.

These are a set of large projects that have been funded through California Bond funds administered by the State Water Board. In extreme cases of poor water quality in an ASBS that result from adjacent applicant facilities, these types of projects may be required. State Bond funds may be available at those places to help implement potentially required projects.

[13] Caltrans Memorandum from CTC meeting of December 14-15, 2005. Prepared by Jay Norvell for Cindy McKim regarding "Regulation by the State Water Quality Control Board for Discharge in Areas of Special Biological Significance".

Table 7.3.1. Costs - Clean Beaches Initiative Water Quality Projects 2006

CBI Projects	Diversions	Piers	Treatment	Wetlands
Number	34	3	18	2
Minimum	$ 350,000	$ 402,500	$ 272,000	$ 575,000
Maximum	$ 3,823,868	$1,800,000	$ 5,351,485	$ 600,000
Average	$ 1,160,647	$ 868,333	$ 1,546,275	$ 587,500
Total	$38,301,344	$2,605,000	$27,832,957	$1,175,000

7.4 STORM WATER RUNOFF BEST MANAGEMENT PRACTICES

BMP will be required to control discharge volume and quality from areas under the applicants' control in order to attain natural water quality. Examples of types of controls and relative costs provided by U.S. EPA are provided in Table 7.4.1. The costs of BMPs are highly dependent on the types of practices chosen, size of area to be controlled, and the volumes of water quality to be addressed. There are many references available to help choose which practices are appropriate in a given circumstance.

Table 7.4.1. Stormwater Best Management Practices in an Ultra-Urban Setting: Selection and Monitoring

Relative Rankings of Cost Elements and Effective Life of BMP Options			
BMP	**Capital Costs**	**O&M Costs**	**Effective Life[1]**
Structural BMPs			
Infiltration Trench	Moderate to High	Moderate	10 - 15 years
Infiltration Basin	Moderate	Moderate	5 - 10 years before deep tilling required
Bioretention	Moderate	Low	5 - 20 years[2]
Detention Ponds	Moderate	Low	20 - 50 years
Wetlands	Moderate to High	Moderate	20 - 50 years
Detention Tanks	Moderate to High	High	50 - 100 years
Underground Sand Filters	High	High	5 - 20 years
Surface Sand Filters	Moderate	Moderate	5 - 20 years
Organic Media Filters	High	High	5 - 20 years
Vegetated Swales	Low to Moderate	Low	5 - 20 years
Vegetated Filter Strips	Low	Low	20 - 50 years
Oil-Grit Separators	Moderate	High	50 - 100 years
Catch Basin Inserts	Low	Moderate - High	10 - 20 years
Manufactured Systems	Moderate	Moderate	50 - 100 years
Porous Pavement	Low	Moderate	15 - 20 years
Nonstructural BMPs			
Road and parking area street sweeping	Moderate	NA	4 - 8 years
Proper chemical and fuel storage, use, handling, containment, and spill response procedures	Moderate - High	Low	4 - 8 years
Vehicle and equipment, maintenance, storage and washing areas	Moderate	Low	long term
Bridge cleaning, maintenance and deck drainage (painting and sanding activities)	Moderate	NA	NA
Litter and debris management (dumpsters,	Low	Low	4 - 8 years

trash piles, equipment storage, waste management practices)			
Modification of existing nonstructural BMP programs or structural BMP maintenance schedule or procedure	Low to Moderate	Low to Moderate	long term
Nonstructural BMPs			
Education programs (employee, adopt-a-road, adopt-a-stream, outreach	Low	Low	long term
Elimination of illicit discharge and connections	Moderate	Low	long term
New and Innovative Practices			
Alum Injection	Moderate	Moderate	5 - 20 years[3]
MCTT	High	High	5 - 20 years[3]
Biofilters (e.g., StormTreat System)	Moderate	Moderate	5 - 20 years[3]
Vegetated Rock Filters	High	High	5 - 20 years
Adapted from Young et al. (1996); Claytor and Schueler (1996); U.S. EPA (1993); and others NA = Not Applicable or Not Available [1]Assumes regular maintenance, occasional removal of accumulated materials, and removal of any clogged media. [2]As a relatively new BMP, the effective life is uncertain. It is reasonable to assume an effective life at least as long as that of a vegetated swale. [3]Estimated based on best professional judgment.

7.5 TYPES OF BMPS APPROVED BY CALTRANS

Nine types of BMPs are being used in these studies representing a broad base of state-of-the-art BMP technology:

- Extended Detention Basin: These basins capture storm water runoff and allow for an extended drain time to remove particulates and other associated pollutants through sedimentation. http://www.dot.ca.gov/hq/env/stormwater/ongoing/pilot_studies/bmps/details/ed_basins/index.htm
- Drain Inlet Inserts: Devices are inserted into storm drain inlets to filter or absorb sediment, oil and grease, and other pollutants.

http://www.dot.ca.gov/hq/env/stormwater/ongoing/pilot_studies/bmps/details/di_inserts/index.htm

- Infiltration Basins and Trenches: Trenches are lined with filter fabric and filled with rock. Stormwater runoff captured in the trenches then infiltrates into the soil. Basins are excavated depressions that infiltrate captured storm water. http://www.dot.ca.gov/hq/env/stormwater/ongoing/pilot_studies/bmps/details/ib_trenches/index.htm
- Oil/Water Separator: These plate separators treat runoff from Caltrans facilities that generate oil and grease. Vertical plates separate oil from water, while a vault traps and collects sediments. http://www.dot.ca.gov/hq/env/stormwater/ongoing/pilot_studies/bmps/details/ow_separator/index.htm
- Media Filters: Fine sediments and pollutants are filtered through chambers containing sand or perlite/zeolite media. http://www.dot.ca.gov/hq/env/stormwater/ongoing/pilot_studies/bmps/details/m_filters/index.htm
- Multi-Chambered Treatment Trains (MCTT): Three vaults capture sediment and debris, remove oil and grease with absorbent pillows, and filter pollutants through fabric and a mixture of peat and sand. http://www.dot.ca.gov/hq/env/stormwater/ongoing/pilot_studies/bmps/details/mctt/index.htm
- Biofiltration Swales and Strips: Grassy pathways, also known as biofilters, filter and deposit pollutants from storm water when water flows through the vegetation. http://www.dot.ca.gov/hq/env/stormwater/ongoing/pilot_studies/bmps/details/bs_strips/index.htm
- Vortex seperation systems (VSS): VSS™ units treat runoff by screening sediment and debris and depositing the debris in a sump. Pre-cast VSS™ units create a vortex of water that allows water to escape through the screen, while pollutants are deflected into the storage sump. http://www.dot.ca.gov/hq/env/stormwater/ongoing/pilot_studies/bmps/details/cds/index.htm
- Wet Basin: A wet basin removes sediment, nutrients, and particulate metals from storm water runoff. An in-line permanent pool or basin enhances settling. http://www.dot.ca.gov/hq/env/stormwater/ongoing/pilot_studies/bmps/details/w_basin/index.htm

7.6 PROPOSITION 84 ASBS GRANT PROGRAM

In 2006, the Public Resources Code[14] required that the Proposition 84 ASBS Grant Program funds be used to provide matching grants to local public agencies to fund a variety of water quality improvement projects to assist local public agencies to comply with the discharge prohibition into ASBS. Following this legislation and in 2008, the

[14] Proposition 84- The Safe Drinking Water, Water Quality and Supply, Flood Control, River and Coastal Protection Bond Act of 2006 (§ 1. Division 43 Chapter 1)

Division of Financial Assistance solicited and received funding proposals from many of the Applicants included in this General Exception.

Proposals, which were approved by the State Water Board, include detailed analysis and project costs related to compliance with the ASBS discharge prohibition. Proposals submitted factored into their project's requirements contained in the March 3, 2008 "Draft Special Protections," considerations that only allowable discharges to the ASBS are those that occur during wet weather and are composed only of storm water runoff. As a result, many projects presented plans to build and operate diversion systems designed to eliminate the discharge of flows to the ASBS during dry weather (dry weather flows) when flows are composed largely of non-storm water.

Some projects consider eliminating runoff that would normally be discharged from the outfalls during non-rainfall periods, but would instead be captured by plugging the outfall pipes, and either diverting the non-storm water to the sanitary sewer. Alternatively, captured water may be vacuumed or removed by pump and then trucked to a treatment facility. Table 7.6.1 provides a summary of project related costs.

Table 7.6.1. Project Related Costs

ASBS AREA	PROJECT TYPE	PROJECT DESCRIPTION	OVERALL COST	COST PER DISCHARGE
Marin County	Catch basin treatment; LID	8 storm drains; 5 considered high threat, 3 moderated threat; LID parking lot retrofit	$1.48 million	~ $ 184,875
Carmel	Dry-weather flow diversions	17 storm drains; 10 considered high threat	$2.5 million	~ $ 147,000
Carmel	Dry-weather flow diversions	Multiple diversions	$2.5 million	~ $ 250,000
Carmel	Dry-weather flow diversion, multiple drainage treatments	Includes constructed wetland basin treatment and 6 dry-weather flow diversions	$ 2.4 million	--------
San Mateo County	Catch basin treatment; LID	10 storm drains considered high threat; LID parking lot retrofit	$2.5 million	----------
La Jolla	Dry-weather flow diversion; LID	1 large storm drain dry-weather flow diversion; parking lot LID retrofit	$1.69 million	

ASBS AREA	PROJECT TYPE	PROJECT DESCRIPTION	OVERALL COST	COST PER DISCHARGE
Latigo to Laguna	Catch basin treatments	2 major storm drains	$.54 million	--------
Latigo to Laguna	Catch basin treatments; linear highway facility LID	8 storm drains; 1 mile coastal hwy LID	$ 2.25 million	
Pacific Grove	Dry-weather flow diversions; parking lot bios wale	Multiple urban and roadway runoff treatment	$2.4 million	----------

Structural improvement costs vary and are dependant on project type, location, and number of storm water conveyances to be addressed (Table 24). Each applicant has a unique set of runoff issues within their ASBS. For example, at the Duxbury Reef ASBS, Marin County plans to begin work on correcting eight storm drains and address one asphalt parking lot immediately adjacent to the ASBS. Catch basin treatments are designed for each of the storm drains. The parking lot will be retrofitted into a LID structure. Marin County estimates that these projects, combined, will cost approximately $1.48 million, or about $185,000 per discharge. As another example, the City of Carmel by the Sea selected dry weather flows as a primary target for control. Seventeen storm drains were proposed for control, totaling $2.5 million or $147,000 per discharge.

The cost figures derived from the Prop 84 proposals may not represent all situations. For example, a more expensive large structural BMP (e.g., a moderate size VSS unit with a diversion) may cost $500,000 per priority discharge, and an inexpensive vegetated filter strip or small swale on a small discharge may cost only $10,000 to $20,000 per discharge. Still, an estimate of $147,000 to 185,000 per discharge is reasonable to assume as a general estimate, with some discharges being more or less expensive. There are about 294 total discharges greater than 18 inches in width or diameter. If all these discharges are controlled with structural BMPs, the total cost would range from $43 to $54 million statewide.

7.7 SUMMARY AND CONCLUSIONS OF SPECIAL PROTECTIONS COST

Combined, the costs for Northern, Central, and Southern California regional monitoring groups are estimated at about $3.9 million. Staff estimates the cost of BMPs on priority discharges would be about $43 to $54 million statewide. This is two orders of magnitude less than the minimum figure of $4.5 billion to eliminate ASBS discharges by moving all storm drains outside of ASBS into other ocean areas, an alternative that would have harmful environmental effects as well.

8.0 OTHER STATUTORY REQUIREMENTS

8.1 CUMULATIVE IMPACTS

According to Section 15355 of the State CEQA Guidelines:

> "cumulative impacts" refers to two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts.
>
> (a) The individual effects may be changes resulting from a single project or a number of separate projects.
>
> (b) The cumulative impact from several projects is the change in the environment which results from the incremental impact of the project when added to other closely related past, present, and reasonably foreseeable probable future projects. Cumulative impacts can result from individually minor but collectively significant projects taking place over a period of time.

An EIR must discuss cumulative impacts of a proposed project when the incremental effect of the project is "cumulatively considerable" (State CEQA Guidelines Section 15130[a]). This chapter provides information about past, present, and reasonably foreseeable future projects that could result in cumulative environmental impacts; describes the contribution of the proposed statewide Special Protections to those cumulative impacts; and determines whether the project's contribution to those cumulative impacts would be cumulatively considerable.

This cumulative impacts analysis evaluates existing statewide conditions and proposed implementation projects that could contribute to cumulative impacts along with the implementation of the proposed project. Where land-based discharges have been determined by local Regional Water Boards to be contributing to impairment (defined for purposes of this EIR as "targeted impaired areas"), extra attention is given to cumulative impacts where they correspond to the intersection of ASBS and 303(d)-listed impaired waters. Many of the 303[d] listed water bodies draining to ASBS are impaired for sediments and bacteria (i.e. Redwoods ASBS and James V. Fitzgerald ASBS).

Projects considered in this analysis consist of past, present, and probable future projects that may contribute to discharge-related cumulative impacts, including local projects outside of the regulatory purview of the state. These projects include regulatory programs and actions (e.g., the total maximum daily load [TMDL] process) in addition to other types of related projects such as general plans, specific plans, resource management plans, and other planning projects.

8.2 GROWTH INDUCING IMPACTS

The California Environmental Quality Act (CEQA) requires EIRs to address growth-inducement potential of a project and the related environmental effects. The General Exception project and Special Protections proposed by State Water Board staff would establish minimum requirements for the permitting and monitoring, of discharges into ASBS to prevent pollution and protect beneficial uses of ASBS including the protection of marine aquatic life within the ASBS throughout California. Therefore, this growth inducement analysis considers a broad context to characterize the potential effects of implementating the new ASBS regulations at a statewide level.

8.2.1 Basis for Analysis of Growth-Inducing Impacts

In accordance with Section 15126.2(d) of the State CEQA Guidelines, an EIR must discuss the growth-inducing impacts of the proposed project. The regulation states that the EIR shall: Discuss the ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth (a major expansion of a wastewater treatment plant might, for example, allow for more construction in service areas). Increases in the population may tax existing community service facilities, requiring construction of new facilities that could cause significant environmental effects. Also discuss the characteristics of some projects which may encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment.

Growth-inducing impacts would result from a project that would directly or indirectly foster (promote or encourage) additional economic or population growth or construction of additional housing. Growth can be fostered when an obstacle to growth is removed, as when expansion of infrastructure resolves growth-constraining capacity problems. In the case of the project, growth could be fostered if the Special Protections would allow the construction of discharge conveyances in locations where they currently cannot be constructed, or would otherwise reduce the cost or other barriers to the placement and re-direction of discharges to wastewater treatment plants. Development requires wastewater treatment, and regulations that would reduce barriers to construction of conveyances would remove one barrier to growth.

The State CEQA Guidelines do not distinguish between planned and unplanned growth for purposes of considering whether such growth could result in environmental impacts. Therefore, in order to reach the conclusion that a project is growth inducing as defined by CEQA, the EIR must find that it would foster (i.e., promote or encourage) additional growth in economic activity, population, or housing, regardless of whether the growth is already approved by and consistent with local plans. The conclusion does not determine that induced growth is beneficial or detrimental, consistent with Section 15126.2(d) of the State CEQA Guidelines.

If the EIR determines that a project is growth inducing, the next question is whether that growth may cause adverse effects on the environment. Environmental effects resulting from induced growth (i.e., growth-induced effects) fit the CEQA definition of "indirect" effects in Section 15358(a) (2) of the State CEQA Guidelines. These indirect or secondary effects of growth may result in significant environmental impacts. CEQA does not require that the EIR speculate unduly about the precise location and site-specific characteristics of significant, indirect effects caused by induced growth, but a good-faith effort is required to disclose what is feasible to assess.

Potential secondary effects of growth could include consequences—such as conversion of open space to developed uses, increased demand on community and public services and infrastructure, increased traffic and noise, degradation of air and water quality, or degradation or loss of plant and wildlife habitat—that are the result of the growth fostered by a project. If significant, indirect environmental effects of growth may occur, a final question to consider is whether those effects have already been considered and mitigated, or are appropriate for a statement of overriding considerations, if unavoidable, in a completed CEQA process.

If the induced growth is consistent with an approved general plan or community plan for the area, and a CEQA document on that plan adequately addresses the effects of growth in the plan, the environmental effects of growth induced by the proposed project should have already been evaluated and considered by the lead agency in which the growth could occur. In this circumstance, the EIR for a proposed project may incorporate the completed CEQA document by reference and need not re-evaluate previously identified impacts. A project that would induce growth that is not consistent with an adopted general plan or community plan could indirectly cause additional significant environmental impacts beyond those evaluated in the earlier CEQA document on the plan.

The decision to allow potentially induced growth is the subject of separate decision making by the lead agency responsible for allowing such projects to move forward. The proposed Special Protections specifically address how existing discharges, which already would be approved or operating under local land use authorities, would be cited and operated; they do not address or approve permits for development of projects, nor does it approve the discharges. Because the decision to allow growth is subject to separate discretionary decision making, and such decision making itself is subject to CEQA, the analysis of growth-inducing effects is not intended to determine site-specific environmental impacts and specific mitigation for the potentially induced growth. Rather, the discussion is intended to disclose the potential for environmental effects to occur more generally, such that decision makers are aware that additional environmental effects are a possibility if growth inducing projects are approved. The decision of whether impacts do occur, their extent, and the ability to mitigate them is appropriately left to consideration by the agency responsible for approving such projects, at such times as complete applications for development are submitted.

8.2.2 Growth Variables and Mechanisms of Growth Inducement

The timing, magnitude, and location of land development and population growth in a community or region are based on various interrelated land use and economic variables. Key variables include regional economic trends, market demand for residential and nonresidential uses, land availability and cost, the availability and quality of transportation facilities and public services, proximity to employment centers, the supply and cost of housing, and regulatory policies or conditions. As discussed in Chapter 3.0, "Regulatory Setting," the general plan of a community defines the location, type, and intensity of growth and it is the primary means of regulating development and growth in the State of California. Mechanisms by which a project may induce growth include creating jobs that attract economic or population growth to the area, promoting the construction of homes that would bring new residents to the area, or removing an existing obstacle that impedes growth in the area.

8.2.3 Potential for the Proposed Statewide Special Protections to Restrict Growth

Other comments submitted at public meetings and during the scoping period for the project suggested that approval and adoption of the proposed statewide regulations would restrict growth. The central idea expressed by these comments is as follows:

> ► The proposed Special Protections will render existing coastal lots and properties throughout the coastline of the state's ASBS unbuildable or prevent people from building in areas already designated for development i.e. impose a "building moratorium."

As discussed previously, the nine Regional Water Boards were established in their current form by the Porter-Cologne Water Quality Control Act of 1969 (Water Code Section 13000 et seq.). Six of these nine Regional Water Boards have coastal jurisdiction over the ASBS described in the General Exception and carry out the requirements of the Ocean Plan. In addition, development, adoption, and approval of Basin Plans followed during the 1970s. In some parts of California, legal lots of record were created preceding enactment of the Porter-Cologne Water Quality Control Act of 1969.

During the years that followed, the new water quality protection standards set forth in the Basin Plans in accordance with state and federal law rendered some existing legal lots unbuildable in places throughout California. As discussed above, six of the nine Regional Water Boards may include additional localized restrictions that are more protective of ocean water of ASBS than the proposed statewide Special Protections. Implementation of the proposed statewide Special Protections would not change the requirements and provisions contained in the Ocean Plan or approved Basin Plans for the respective Regional Water Boards. Ongoing enforcement of existing water quality protection standards that have been in effect since the 1970s would continue to render certain legal lots unbuildable.

It is not known where implementation of the proposed statewide Special Protections could inhibit growth. The proposed statewide Special Protections would likely increase the cost to install BMPs in some areas or re-direct existing waste discharge conveyances; consequently, in some instances it is probable that compliance costs could make development of some properties too costly. In those instances, it is likely that Special Protections could moderately reduce potential growth. It is not known, and there is no data available, to quantify the degree to which growth would be restricted by increased costs.

8.3 SIGNIFICANT AND UNAVOIDABLE IMPACTS

Section 6.0 of this draft EIR describes the potential environmental impacts of the proposed project and recommend various mitigation measures to reduce these impacts, to the extent feasible. After implementation of the recommended mitigation measures, most of the impacts associated with the proposed project would be reduced to a less-than-significant level. Impacts on ASBS ocean water quality and protection of marine biological resources and beneficial uses of the ASBS would remain significant and unavoidable if existing inadequate controls currently in force are allowed to continue. Summary discussions of significant and unavoidable impacts by issue are provided in the following text. Section 4.0, “Alternatives to the Proposed Project,” considers alternatives to the proposed project that may be capable of reducing or avoiding some of the impacts of the proposed project.

8.3.1. Determining Significance under CEQA

The *CEQA Guidelines* (§15000, et seq., California Code of Regulations, 2009) define a “significant effect” as:

“…*a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project including land, air, water, minerals, flora, fauna, ambient noise, and objects of historic and aesthetic significance. An economic or social change by itself shall not be considered a significant effect on the environment. A social or economic change related to a physical change may be considered in determining whether the physical change is significant” (CEQA Guidelines §15382, 2009).*

The *CEQA Guidelines* further state that “An ironclad definition of significant effect is not possible because the significance of an activity may vary with the setting. For example, an activity which may not be significant in an urban area may be significant in a rural area *(CEQA Guidelines §15064, 2009).* Appendix G of the *CEQA Guidelines* describes impacts that the California Resources Agency has determined are normally considered significant. These guidelines require that physical changes in the environment be evaluated based on factual evidence, reasonable assumptions supported by facts, and expert opinion based on fact.

8.3.2. Significance Criteria

Analysis of each project alternative was conducted to determine if there would be an impact to a particular environmental resource (Section 6.0 Environmental). This review included a determination of whether an impact occurring from the implementation of an alternative would be rated as “significant” under CEQA. Table 8.3.2 summarizes the significance of temporary, long-term, and cumulative environmental impacts of the General Exception/Special Protections Project alternatives under CEQA. Levels of significance stating “less than significant with mitigation incorporated” are based on the application of successful mitigation measures, meaning the impact would not be diminished until mitigation successfully accomplishes the desired goals.

Table 6.7.1 summarizes the Thresholds of Significance for Ocean Plan water quality objectives. For the purposes of this analysis, a water quality impact is considered significant if implementation of the proposed project would result in exceeding any of the Ocean Plan water quality objectives. Section 6.0 Environmental Analysis of this document provides a detailed discussion of the impacts for each resource category. Significant impacts were identified for the No—Project Alternative which is used as the baseline for comparison with other alternatives.

8.3.3. Thresholds of Significance

For the purposes of the Analysis of Environmental Impacts, a water quality impact is considered significant if implementation of the proposed project would result in exceeding any of the thresholds identified in Table B of the Ocean Plan (OP water quality objectives). These thresholds of significance are based on the CEQA Guidelines (State CEQA Guidelines) and relevant water quality objectives. Consistent with State CEQA Guidelines, a water quality impact is considered significant in this analysis if implementation of the proposed project would result in potential for exceeding any of these adopted water quality objectives related to ASBS.

8.3.4. Potential Impacts

This section discusses the resources which will experience potential impacts as a result of the General Exception/Special Protections Project.

The General Exception project has the potential to impact species, habitat, and sensitive natural communities within each of the 26 ASBS identified in this General Exception, if existing inadequate controls currently in force are allowed to continue. The applicants submitted biological monitoring reports characterizing near shore marine biota. Four reports provided data sufficient to statistically compare impact from reference locations at San Clemente and San Nicolas Islands (Navy), Del Mar Landing, and Trinidad ASBS. Based on comparison of community composition, there is evidence that at three ASBS the data show that sampled discharge locations are different from sampled reference locations. However, there is some question whether these differences are attributed to the discharges or an artifact of the sample design. For example, Caltrans reported data for their multiple ASBS discharge locations that include Redwood National Park, James V. Fitzgerald, Año Nuevo, Point Lobos, Carmel, and Irvine Coast ASBS. While data results from certain ASBS sites within Caltrans area of potential discharge impact differed from selected reference sites, there was no strong support that this was due to discharges. Differences between impact and reference locations were also found at Duxbury Reef ASBS (County of Marin) and at the Pillar Point area of James V. Fitzgerald ASBS (Air force). Again at these locations, the data was inadequate to attribute the variation to the impacts of the discharge.

The project, granting an exception with special mitigating conditions (i.e., special protections) will allow the continued discharge of wastes from various origins including storm water runoff into ASBS. It is anticipated that the mitigating terms and conditions of the special protections will result in improved water quality conditions. Further, the terms and conditions of the special protections provide for continued water quality improvements over time if all of the special protections designed to limit discharges of waste from the applicants are implemented.

It is anticipated that, as the applicants identified in this General Exception plan for and design individual control projects to comply with the terms and conditions or "Special Protections," each applicant will assess biological impacts on a project-by-project basis. If it is determined that a project will have biological impacts, then potential mitigation measures must be considered. A technical biological impact analysis may include evaluation of terrestrial and marine biota of an individual project. The impact analysis may assess mitigation measures that are determined to be reasonable and feasible, and at the time of final design would then be incorporated into projects' plans and specifications. Indirect effects to biological resources may extend throughout the duration of construction and may include increased erosion, siltation, and runoff. It is anticipated that cumulative proposed projects to implement Special Protections should result in long-term, beneficial effects to biological resources within each individual project.

Thresholds of Significance:
1 - Indirect impacts on marine biological resources associated with existing baseline inadequate pollution and dry-weather flows control measures.

The General Exception Project has the potential to violate the ASBS waste discharge prohibition of the Ocean Plan if existing inadequate controls currently in force are allowed to continue. The project, granting an exception with special mitigating conditions (i.e., special protections) will allow the continued discharge of wastes from various origins including storm water runoff into ASBS. Existing ocean water quality conditions within ASBS have had measured concentrations of constituents which exceed the Table B water quality objectives of the Ocean Plan. Exceedances of the Table B Ocean Plan water quality objectives were also found in the storm water runoff of some of the applicants. It is expected that the mitigating terms and conditions of the Special Protections will result in improved water quality conditions of ASBS. Further, the terms and conditions of the special protections provide for continued water quality improvements in storm water and nonpoint source discharges over time.

Granting the general exception will not violate federal antidegradation requirements because water quality will not be lowered, but rather, will be improved within the ASBS affected. Further, allowance of the General Exception will not violate the State Water Board's antidegradation policy (SWRCB 1968) since water quality conditions are anticipated to improve; the discharges will not unreasonably affect present and anticipated beneficial uses; the discharge will not result in water quality lower than that prescribed in the Ocean Plan; and beneficial uses will be protected and potential impacts will be less than significant with mitigation incorporated.

It is anticipated that the applicants identified in this General Exception project will implement various individual or collaborative projects to comply with the terms and conditions or "Special Protections." As part of the scoping and environmental analysis conducted for the General Exception project, project types identified include: Low Impact Development (LID); dry-weather flow diversions; and Best Management Practices (BMPs), such as Pollution Prevention BMPs and Treatment BMPs, such as infiltration basins and Gross Solids Removal Devices (GSRDs). Under the State Water Board's storm water program, these types of projects may require coverage under the General Permit for Discharges of Storm Water Associated with Construction Activity (Construction General Permit). Dischargers whose projects disturb 1 or more acres of soil or whose project disturbs less than 1 acre but are part of a larger common plan of development that in total disturbs 1 or more acres, are required to obtain coverage under this permit. The activity would include clearing, grading, and disturbances to the ground such as stockpiling, or excavation.

Additional requirements of the Construction General Permit require the development and implementation of a Storm Water Pollution Prevention Plan (SWPPP). The SWPPP should contain a site map(s) which shows the construction site perimeter, existing and storm water collection and discharge points and drainage patterns across the project. The SWPPP includes a chemical monitoring program for "non-visible" pollutants to be implemented if there is a failure of BMPs during a project's construction.

These hydrology and water quality resource impacts were considered to be short-term and no potential for adverse impacts to these resources were identified.

Thresholds of Significance:
1 - Exceedances of Table B water quality objectives in storm water
2 - Dry weather flows
3 - Violate federal antidegradation requirements
4 – Discharge of waste materials into the ASBS

8.4 DETERMINATION

The implementation of the General Exception to the Ocean Plan and associated terms and conditions, the Special Protections, will result in improved water quality in the waters of the State's 26 ASBS listed herein and will have significantly positive impacts to the environment, including preservation and enhancement of beneficial uses of the ASBS[15], and the economy over the long term. Enhancement of the beneficial uses will have positive social and economic effects by decreasing potential waste discharges and trash and increasing the aesthetic experience along the shoreline and waters of ASBS. Specific projects employed to implement Special Protections may have some adverse impacts to the environment, but these impacts are generally expected to be limited, short-term or may be mitigated through design and scheduling.

The FEIR, Initial Study and the Special Protections provide the necessary information pursuant to Public Resources Code section 21159 to conclude that properly designed and implemented BMPs or other waste discharge capture systems generally should not foreseeably have a significant adverse effect on the environment. Any potential impacts can be mitigated at the subsequent project level when specific sites and methods have been identified, and Responsible Parties identified herein can and should implement the recommended mitigation measures. These mitigation measures in most cases are routine measures to ease the expected and routine impacts attendant with ordinary minor construction projects and infrastructure maintenance in an urbanized environment. Routine construction and maintenance of power lines, sewers, streets, etc. are regular and expected incidents of living in urban and infrastructure improved environments (i.e. highways and roadways) along the coast. Sewer and power line maintenance, street sweeping, traffic alterations, and environmental impacts from them already occur and are expected.

This Special Protections project will foreseeably require many more such waste discharge prevention projects, but their individual impacts are not expected to be extraordinary in magnitude or severity. Specific projects, that may have a significant impact, would therefore be subject to a separate environmental review. The lead agency for subsequent projects would be obligated to mitigate any impacts they identify, for example by mitigating potential flooding impacts by designing the BMPs with adequate margins of safety. Notably, in almost all circumstances, where unavoidable or unmitigable impacts would present unacceptable hardship upon nearby receptors or venues, the Responsible Parties and/or associated local agencies have a variety of alternative implementation measures available instead. For instance, they can locate BMPs further down the storm drain system away from such receptors, or impose increased street sweeping or enforcement at that location instead.

All of the potential impacts discussed in this EIR must, however, be mitigated at the subsequent, project level because they involve specific sites and designs not specified at the program level. At this stage, any more particularized conclusions would be

---

[15] California Ocean Plan § I.A. Beneficial Uses

speculative. The State Board does not have legal authority to specify the manner of compliance with its orders or regulations (Wat. C. § 13360), and thus cannot dictate that an appropriate location be selected for any particular project. It is anticipated that compliance projects will be designed consistent with standard industry practices and that routine and ordinary mitigation measures be employed. These measures are all within the jurisdiction and authority of the Responsible Parties that will be responsible for implementing the Special Protections. The Responsible Parties can and should employ those alternatives and mitigation measures to reduce any impacts as much as feasible (14 Cal. Code Regs., §15091(a)(2).

Implementation of the General Exception Project and Special Protections is both necessary and beneficial. To the extent that the alternatives, mitigation measures, or both, that are examined in this analysis are not deemed feasible by those 27 Responsible Parties identified herein , the necessity of implementing the Project and removing the discharge of waste into ASBS (an action required to achieve the express, national policy of the Clean Water Act) remains.

On the basis of this evaluation and staff Program FEIR, which collectively provides the required information:

The State Water Board finds that the proposed General Exception and Special Protections could have a significant adverse effect on the environment. However, there are feasible alternatives and/or feasible mitigation measures that would substantially lessen any significant adverse impact. These alternatives are discussed above and in the Program FEIR.

Table 8.3.2. Summary of Project Impacts – (Refer to Section 6.0)			
Impacts	**Significance Before Mitigation**	**Mitigation Measures**	**Significance After Mitigation**
6.1 Aesthetics			
6.1-1: Direct Impacts Associated with Effects on a scenic vista	Potentially Significant, short-term temporary	Construction related mitigation project-by-project implemented by Applicant	Less than Significant
6.1-2: Direct Impacts Associated with effects on scenic highway	Potentially Significant, short-term temporary	Construction related mitigation project-by-project implemented by Applicant	Less than Significant
6.1-3: Direct Impacts Associated with Visual Character of site or surroundings	Potentially Significant, short-term temporary	Construction related mitigation project-by-project implemented by Applicant	Less than Significant
6.2 Air Quality			
6.2-1: Direct Impacts Associated with Air Quality Standards	Potentially Significant, short-term temporary	Construction related mitigation project-by-project implemented by Applicant	Less than Significant
6.2-2: Expose Sensitive Receptors to Substantial Pollutant concentrations	Potential short-term temporary	Construction and/or maintenance related mitigation project-by-project implemented by Applicant	Less than Significant
6.2-3: Create Objectionable Odors Affecting a Substantial Number of People	Potential direct short-term temporary	Construction and/or maintenance related mitigation project-by-project implemented by Applicant	Less than Significant
6.3 Biological Resources			
6.3-1: Substantial Direct/Indirect Adverse Effect to Candidate, sensitive or	Potential substantial adverse effect	Coordination by Applicant with local or regional plans, policies, or regulations and/or DFG or	Less than Significant

Special Status Species		USFWS	
6.3-2; 6.3-3; 6.3-4; 6.3-5: Substantial adverse effect on riparian habitat, interfere with fish passage, conflict with local resource protection, conflict with HCPs of NCCPs	Potentially significant short-term, temporary	Modify proposed implementations to require erosion and sediment control measures project-by-project implemented by Applicant	Less than Significant with mitigation incorporated
6.4 Cultural Resources			
6.4-1: Direct Impacts to Cultural Resources including historic, archaeological sites	Potential direct adverse impacts	Construction related mitigation project-by-project implemented by Applicant, coordination with SHPO	Less than Significant with mitigation incorporated
6.5 Greenhouse Gas Emissions			
6.5-1: Direct impacts associated with GHG emissions	Potential direct temporary short-term impacts	Construction and maintenance related equipment emissions mitigation implemented by Applicant	Less than Significant with mitigation incorporated
6.6 Hazards and Hazardous Materials			
6.6-1: Create a significant hazard via accidental release of hazardous materials	Potential direct temporary short-term impacts	Construction related mitigation project-by-project implemented by Applicant	Less than Significant with mitigation incorporated
6.6-2: Impair emergency response or evacuation	Potential direct temporary short-term impacts	Construction related mitigation project-by-project implemented by Applicant	Less than Significant
6.7 Hydrology and Water Quality			
6.7-1: Violate water quality criteria for pollutants and pathogens Violate ambient natural ocean water quality	Potential direct long-term impacts	Mitigating terms and conditions –Special Protections implemented by Applicant(s)	Less than Significant with mitigation incorporated
6.7-2: Create substantial water quality hazard to marine biota	Potential direct long-term impacts	Mitigating terms and conditions –Special Protections implemented by Applicant(s)	Less than Significant with mitigation incorporated

6.8 Noise			
6.8-1: Exposure to and generation of noise in excess of standards	Potential direct short-term	Construction and maintenance related equipment mitigation implemented by Applicant	Less than Significant with mitigation incorporated
6.9 Public Services			
6.9-1: Substantial adverse physical impacts to police, fire, recreational resources or public facilities	No reasonably foreseeable adverse impact	None required due to less than significant impact	N/A
6.10 Transportation/Traffic			
6.10-1: Adverse impact to transportation and circulation	Potential direct short-term	Construction and/or maintenance related mitigation project-by-project implemented by Applicant	Less than Significant with mitigation incorporated
6.10-2: Inadequate emergency access	Potential indirect short-term temporary	Non required due to less than significant impact	Less than Significant

GLOSSARY AND ACRONYMS

TERM/ABBREVIATION	DESCRIPTION
Areas of Special Biological Significance (ASBS)	Those areas designated by the State Water Board as ocean areas requiring protection of species or biological communities to the extent that alteration of natural water quality is undesirable. All Areas of Special Biological Significance are also classified as a subset of State Water Quality Protection Areas.
ASBS	Area(s) of Special Biological Significance
At the Point of Discharge(s)	In the surf zone, immediately where runoff from an outfall meets the ocean water (a.k.a. at point zero). For storm water discharges, outfall is defined in 40 CFR 122.26(b)(9).
BLM	Bureau of Land Management
BMPs	Best Management Practices
Caltrans	California Department of Transportation
CBI	Clean Beaches Initiative
CCC	California Coastal Commission
CCA	Critical Coastal Area
CCLEAN	Central Coast Long-term Environmental Assessment Network
CDO	Cease and Desist Order
CEQA	California Environmental Quality Act
COP	California Ocean Plan
CTR	California Toxics Rule
Cu	Copper
CWA	Clean Water Act
CWC	California Water Code
Design Storm	One inch of precipitation per day (for purposes of these Special Protections)
DFG	California Department of Fish and Game
DO	Dissolved Oxygen
FWS	United State Fish and Wildlife Service

TERM/ABBREVIATION	DESCRIPTION
LID	Low Impact Development:
Low Impact Development (LID)	A sustainable practice that benefits water supply and contributes to water quality protection. Unlike traditional storm water management, which collects and conveys storm water runoff through storm drains, pipes, or other conveyances to a centralized storm water facility, LID takes a different approach by using site design and storm water management to maintain the site's pre-development runoff rates and volumes. The goal of LID is to mimic a site's predevelopment hydrology by using design techniques that infiltrate, filter, store, evaporate, and detain runoff close to the source of rainfall.
MARINe	Multi-Agency Rocky Intertidal Network
MEP	Maximum Extent Practicable
MMA	Marine Managed Area
MMs	Management Measures
MS4	Municipal Separate Storm Sewer Systems
Municipal Separate Storm Sewer Systems (MS4)	A municipally-owned storm sewer system regulated under the Phase I or Phase II storm water program implemented in compliance with Clean Water Act section 402(p). Note that an MS4 program's boundaries are not necessarily congruent with the permittee's political boundaries.
Natural Water Quality	Determined by comparison to reference areas agreed upon via the regional monitoring programs(s).
Nonpoint Source (NPS)	Sources of pollution that arise over a comparatively large area rather than from a single point (Non-point pollution sources generally are sources that do not meet the definition of a point source). Non-point source pollution typically results from land runoff, precipitation (except those discharges regulated by an NPDES permit), atmospheric deposition, drainage, seepage, or hydrologic modification. Non-point sources, for purposes of these Special Protections, include storm water discharges that are not required to be regulated under an NPDES permit.
NPDES	National Pollutant Discharge Elimination System
NPS Policy	Policy for Implementation and Enforcement of the Nonpoint Source Pollution Control Program
OPP	Ocean Protection Projects
Parks and Recreation Facilities	State Parks
Person	"Person" is defined in Water code §13050(c)
Point Source	Defined in Clean Water Act §502(14)
POTWs	Publicly Owned Treatment Works

TERM/ABBREVIATION	DESCRIPTION
PRC	Public Resources Code
Regional Water Board	Regional Water Quality Control Board
SB	Senate Bill
SCCWRP	Southern California Coastal Water Research Project
SCI	San Clemente Island
SCICO	Santa Catalina Island Company
Sheet-Flow	Runoff that flows across land surfaces at a shallow depth relative to the cross-sectional width of the flow. These types of flow may or may not enter a storm drain system before discharge to receiving waters
Significant Difference	Statistically significant difference in the arithmetic means of two distributions of sampling results at the 95 percent confidence level.
SIO	Scripps Institution of Oceanography
SNI	San Nicholas Island
State Water Board	State Water Resources Control Board
Storm Water	Defined in 40 CFR 122.26(b)(13)
Surf Zone	The area between the breaking waves and the shoreline at any one time.
SWAMP	Storm Water Ambient Monitoring Program
SWMP	Storm Water Management Plan/Program
SWQPA	State Water Quality Protected Area
SWPPP	Storm Water Prevention Pollution Plan
TMDL	Total Maximum Daily Load
TSRA	The Sea Ranch Association
U.S. EPA	United States Environmental Protection Agency
Waterfront and Marine Operations	Activities that include boat launch, cleaning, maintenance, recreational, mooring , fishing and related infrastructure
Waste	Defined in Water Code §13050(d)
WDR	Waste Discharge Requirements

STATE WATER RESOURCES CONTROL BOARD
RESOLUTION NO. 2012-0012

APPROVING EXCEPTIONS TO THE CALIFORNIA OCEAN PLAN FOR SELECTED DISCHARGES INTO AREAS OF SPECIAL BIOLOGICAL SIGNIFICANCE, INCLUDING SPECIAL PROTECTIONS FOR BENEFICIAL USES, AND CERTIFYING A PROGRAM ENVIRONMENTAL IMPACT REPORT

WHEREAS:

1. The State Water Resources Control Board (State Water Board) adopted the California Ocean Plan (Ocean Plan) on July 6, 1972 and revised the Ocean Plan in 1978, 1983, 1988, 1990, 1997, 2000, 2005, and 2009.

2. The Ocean Plan prohibits the discharge of waste to designated Areas of Special Biological Significance (ASBS).

3. ASBS are designated by the State Water Board as ocean areas requiring protection of species or biological communities to the extent that alteration of natural water quality is undesirable.

4. Under the Marine Managed Areas Improvement Act, all ASBS are designated as a subset of state water quality protection areas and require special protection as determined by the State Water Board pursuant to the Ocean Plan and the Water Quality Control Plan for Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California (Thermal Plan).

5. In state water quality protection areas, waste discharges must be prohibited or limited by special conditions, in accordance with the Porter-Cologne Water Quality Control Act, California Water Code §13000 et seq., and implementing regulations, including the Ocean Plan and Thermal Plan.

6. The Ocean Plan authorizes the State Water Board to grant an exception to Ocean Plan provisions where the board determines that the exception will not compromise protection of ocean waters for beneficial uses and the public interest will be served.

7. On October 18, 2004, the State Water Board notified a number of parties that they must cease the discharge of storm water and nonpoint source waste into ASBS or request an exception to the Ocean Plan.

8. The State Water Board has now received 27 applications for an exception to the Ocean Plan prohibition against waste discharges into an ASBS. The applicants, who are listed in Attachment A to this resolution, discharge storm water and nonpoint source waste into ASBS.

9. The State Water Board finds that granting the requested exceptions will not compromise protection of ocean waters for beneficial uses, provided that the applicants comply with the prohibitions and special conditions that comprise the Special Protections contained in this resolution. The prohibitions and special conditions in the Special Protections, contained in Attachment B to this resolution, are intended to ensure that storm water

and nonpoint source discharges are controlled to protect the beneficial uses of the affected ASBS, including marine aquatic life and habitat, and to maintain natural water quality within ASBS. The Special Protections are also intended to maintain the natural hydrologic cycle and coastal ecology by allowing the flow of clean precipitation runoff into the ocean, while preserving coastal slope stability and preventing anthropogenic erosion.

10. The State Water Board finds that granting the requested exceptions is in the public interest because the various discharges are essential for flood control, slope stability, erosion prevention, and maintenance of the natural hydrologic cycle between terrestrial and marine ecosystems, public health and safety, public recreation and coastal access, commercial and recreational fishing, navigation, and essential military operations (national security).

11. The State Water Board staff conducted scoping meetings on August 1, 8, and 15, 2006. The comment period for CEQA scoping closed August 15, 2006. The State Water Board heard a status report on ASBS at the April 1, 2008 meeting.

12. The State Water Board staff prepared and circulated a Program Environmental Impact Report for the proposed exceptions, in accordance with the California Environmental Quality Act (CEQA) and implementing regulations.

13. The State Water Board held a public hearing on May 18, 2011, to receive comments on the proposed exceptions and the Program Environmental Impact Report. The written comment period ended on May 20, 2011. The State Water Board staff has considered the comments and prepared written response. The State Water Board finds, based on the whole record, including the applications, Draft Program Environmental Impact Report, comments, and responses, that there is no substantial evidence that approval of the exceptions will have a significant effect on the environment because of the terms and conditions incorporated into the project. The Program Environmental Impact Report reflects the State Water Board's independent judgment and analysis.

14. Granting the exceptions is consistent with federal and state antidegradation policies, in 40 C.F.R. §131.12 and State Water Board Resolution No. 68-16, respectively. The terms, special conditions, and prohibitions that comprise these Special Protections will not authorize a lowering of water quality, but rather will improve water quality conditions in the affected ASBS.

15. This resolution only grants an exception from the Ocean Plan prohibition against waste discharges into ASBS to the applicants listed in Attachment A. It does not authorize waste discharges to state waters. In order to legally discharge waste into an ASBS, the applicants must have both coverage under this resolution and an appropriate authorization to discharge. Authorization to discharge for point source waste discharges to navigable waters consists of coverage under the National Pollutant Discharge Elimination System (NPDES) permit program. Nonpoint source discharges of waste must be regulated under waste discharge requirements, a conditional waiver, or a conditional prohibition.

16. The exceptions will be reviewed during the next triennial review of the Ocean Plan. If the State Water Board finds cause to revoke or re-open the exceptions, the board may do so during the triennial review or at any other time. During the next triennial review period staff will also evaluate those aspects of the exception that are successfully protecting beneficial uses, to make recommendations on a potential Ocean Plan amendment to address storm runoff into ASBS.

17. The State Water Board's record of proceedings in this matter is located at 1001 I Street, Sacramento, California, 95814 and the custodian is the Division of Water Quality.

THEREFORE BE IT RESOLVED THAT:

The State Water Board:

1. The State Water Board certifies that the Final EIR has been completed in compliance with CEQA. The State Water Board has reviewed and considered the information contained in these documents, which reflect the State Water Board's independent judgment and analysis.

2. Approves the exceptions to the Ocean Plan prohibition against waste discharges to ASBS for discharges of storm water and nonpoint source waste by the applicants listed in Attachment A to this resolution provided that:

    a. The discharges are covered under an appropriate authorization to discharge waste to the ASBS, such as an NPDES permit and/or waste discharge requirements;
    b. The authorization incorporates all of the Special Protections, contained in Attachment B to this resolution, which are applicable to the discharge; and
    c. Only storm water and nonpoint source waste discharges by the applicants listed in Attachment A to this resolution are covered by this resolution. All other waste discharges to ASBS are prohibited, unless they are covered by a separate, applicable Ocean Plan exception.

3. Authorizes the Executive Director or designee to file the Notice of Determination with the Governor's Office of Planning and Research.

4. Authorizes the Executive Director or designee to transmit the exceptions to the United States Environmental Agency (U.S. EPA) for concurrence.

5. Directs staff to consider development of, and make recommendations for, an Ocean Plan amendment to address storm runoff into ASBS, during the next triennial review period.

6. Directs staff to propose for Board consideration up to $1 million from the Proposition 50 Coastal Nonpoint Source (CNPS) program for additional ASBS Regional Monitoring, starting in the fall of 2012.

7. Directs staff, pending budget authority, to propose for Board consideration the use of CNPS funds (approximately $10 million) in conjunction with the remaining Proposition 84 ASBS funds ($3.6 million) for additional ASBS BMP projects.

CERTIFICATION

The undersigned Clerk to the Board does hereby certify that the foregoing is a full, true, and correct copy of a resolution duly and regularly adopted at a meeting of the State Water Resources Control Board held on March 20, 2012.

Attachment B - Special Protections for Areas of Special Biological Significance, Governing Point Source Discharges of Storm Water and Nonpoint Source Waste Discharges

I. PROVISIONS FOR POINT SOURCE DISCHARGES OF STORM WATER AND NONPOINT SOURCE WASTE DISCHARGES

The following terms, prohibitions, and special conditions (hereafter collectively referred to as special conditions) are established as limitations on point source storm water and nonpoint source discharges. These special conditions provide Special Protections for marine aquatic life and natural water quality in Areas of Special Biological Significance (ASBS), as required for State Water Quality Protection Areas pursuant to California Public Resources Code Sections 36700(f) and 36710(f). These Special Protections are adopted by the State Water Board as part of the California Ocean Plan (Ocean Plan) General Exception.

The special conditions are organized by category of discharge. The State Water Resources Control Board (State Water Board) and Regional Water Quality Control Boards (Regional Water Boards) will determine categories and the means of regulation for those categories [e.g., Point Source Storm Water National Pollutant Discharge Elimination System (NPDES) or Nonpoint Source].

A. PERMITTED POINT SOURCE DISCHARGES OF STORM WATER

1. General Provisions for Permitted Point Source Discharges of Storm Water

   a. Existing storm water discharges into an ASBS are allowed only under the following conditions:

      (1) The discharges are authorized by an NPDES permit issued by the State Water Board or Regional Water Board;

      (2) The discharges comply with all of the applicable terms, prohibitions, and special conditions contained in these Special Protections; and

      (3) The discharges:

         (i) Are essential for flood control or slope stability, including roof, landscape, road, and parking lot drainage;

         (ii) Are designed to prevent soil erosion;

         (iii) Occur only during wet weather;

         (iv) Are composed of only storm water runoff.

   b. Discharges composed of storm water runoff shall not alter natural ocean water quality in an ASBS.

c. The discharge of trash is prohibited.

d. Only discharges from existing storm water outfalls are allowed. Any proposed or new storm water runoff discharge shall be routed to existing storm water discharge outfalls and shall not result in any new contribution of waste to an ASBS (i.e., no additional pollutant loading). "Existing storm water outfalls" are those that were constructed or under construction prior to January 1, 2005. "New contribution of waste" is defined as any addition of waste beyond what would have occurred as of January 1, 2005. A change to an existing storm water outfall, in terms of re-location or alteration, in order to comply with these special conditions, is allowed and does not constitute a new discharge.

e. Non-storm water discharges are prohibited except as provided below:

(1) The term "non-storm water discharges" means any waste discharges from a municipal separate storm sewer system (MS4) or other NPDES permitted storm drain system to an ASBS that are not composed entirely of storm water.

(2) (i) The following non-storm water discharges are allowed, provided that the discharges are essential for emergency response purposes, structural stability, slope stability or occur naturally:

(a) Discharges associated with emergency fire fighting operations.

(b) Foundation and footing drains.

(c) Water from crawl space or basement pumps.

(d) Hillside dewatering.

(e) Naturally occurring groundwater seepage via a storm drain.

(f) Non-anthropogenic flows from a naturally occurring stream via a culvert or storm drain, as long as there are no contributions of anthropogenic runoff.

(ii) An NPDES permitting authority may authorize non-storm water discharges to an MS4 with a direct discharge to an ASBS only to the extent the NPDES permitting authority finds that the discharge does not alter natural ocean water quality in the ASBS.

(3) Authorized non-storm water discharges shall not cause or contribute to a violation of the water quality objectives in Chapter II of the Ocean Plan nor alter natural ocean water quality in an ASBS.

2. Compliance Plans for Inclusion in Storm Water Management Plans (SWMP) and Storm Water Pollution Prevention Plans (SWPPP).

The discharger shall specifically address the prohibition of non-storm water runoff and the requirement to maintain natural water quality for storm water discharges to an ASBS in an ASBS Compliance Plan to be included in its SWMP or a SWPPP, as appropriate to permit type. If a statewide permit includes a SWMP, then the discharger shall prepare a stand-alone compliance plan for ASBS discharges. The ASBS Compliance Plan is subject to approval by the Executive Director of the State Water Board (statewide permits) or Executive Officer of the Regional Water Board (for permits issued by Regional Water Boards).

a. The Compliance Plan shall include a map of surface drainage of storm water runoff, showing areas of sheet runoff, prioritize discharges, and describe any structural Best Management Practices (BMPs) already employed and/or BMPs to be employed in the future. Priority discharges are those that pose the greatest water quality threat and which are identified to require installation of structural BMPs. The map shall also show the storm water conveyances in relation to other features such as service areas, sewage conveyances and treatment facilities, landslides, areas prone to erosion, and waste and hazardous material storage areas, if applicable. The SWMP or SWPPP shall also include a procedure for updating the map and plan when changes are made to the storm water conveyance facilities.

b. The ASBS Compliance Plan shall describe the measures by which all non-authorized non-storm water runoff (e.g., dry weather flows) has been eliminated, how these measures will be maintained over time, and how these measures are monitored and documented.

c. For Municipal Separate Storm Sewer System (MS4s), the ASBS Compliance Plan shall require minimum inspection frequencies as follows:

(1) The minimum inspection frequency for construction sites shall be weekly during rainy season;

(2) The minimum inspection frequency for industrial facilities shall be monthly during the rainy season;

(3) The minimum inspection frequency for commercial facilities (e.g., restaurants) shall be twice during the rainy season; and

(4) Storm water outfall drains equal to or greater than 18 inches (457 mm) in diameter or width shall be inspected once prior to the beginning of the rainy season and once during the rainy season and maintained to remove trash and other anthropogenic debris.

d. The ASBS Compliance Plan shall address storm water discharges (wet weather flows) and, in particular, describe how pollutant reductions in storm water runoff, that are necessary to comply with these special conditions, will be achieved through BMPs. Structural BMPs need not be installed if the discharger can document to the satisfaction of the State Water Board Executive Director (statewide permits) or Regional Water Board Executive Officer (Regional Water Board permits) that such installation would pose a threat to health or safety. BMPs to control storm water runoff discharges (at the end-of-pipe) during a design storm shall be designed to achieve on average the following target levels:

(1) Table B Instantaneous Maximum Water Quality Objectives in Chapter II of the Ocean Plan; or

(2) A 90% reduction in pollutant loading during storm events, for the applicant's total discharges.

The baseline for these determinations is the effective date of the Exception, except for those structural BMPs installed between January 1, 2005 and adoption of these Special Protections, and the reductions must be achieved and documented within four (4) years of the effective date.

e. The ASBS Compliance Plan shall address erosion control and the prevention of anthropogenic sedimentation in ASBS. The natural habitat conditions in the ASBS shall not be altered as a result of anthropogenic sedimentation.

f. The ASBS Compliance Plan shall describe the non-structural BMPs currently employed and planned in the future (including those for construction activities), and include an implementation schedule. The ASBS Compliance Plan shall include non-structural BMPs that address public education and outreach. Education and outreach efforts must adequately inform the public that direct discharges of pollutants from private property not entering an MS4 are prohibited. The ASBS Compliance Plan shall also describe the structural BMPs, including any low impact development (LID) measures, currently employed and planned for higher threat discharges and include an implementation schedule. To control storm water runoff discharges (at the end-of-pipe) during a design storm, permittees must first consider, and use where feasible, LID practices to infiltrate, use, or evapotranspirate storm water runoff on-site, if LID practices would be the most effective at reducing pollutants from entering the ASBS.

g. The BMPs and implementation schedule shall be designed to ensure that natural water quality conditions in the receiving water are achieved and maintained by either reducing flows from impervious surfaces or reducing pollutant loading, or some combination thereof.

h. If the results of the receiving water monitoring described in IV.B. of these special conditions indicate that the storm water runoff is causing or contributing to an alteration of natural ocean water quality in the ASBS, the discharger shall submit a report to the State Water Board and Regional Water Board within 30 days of receiving the results.

(1) The report shall identify the constituents in storm water runoff that alter natural ocean water quality and the sources of these constituents.

(2) The report shall describe BMPs that are currently being implemented, BMPs that are identified in the SWMP or SWPPP for future implementation, and any additional BMPs that may be added to the SWMP or SWPPP to address the alteration of natural water quality. The report shall include a new or modified implementation schedule for the BMPs.

(3) Within 30 days of the approval of the report by the State Water Board Executive Director (statewide permits) or Regional Water Board Executive Officer (Regional Water Board permits), the discharger shall revise its ASBS Compliance Plan to incorporate any new or modified BMPs that have been or will be implemented, the implementation schedule, and any additional monitoring required.

(4) As long as the discharger has complied with the procedures described above and is implementing the revised SWMP or SWPPP, the discharger does not have to repeat the same procedure for continuing or recurring exceedances of natural ocean water quality conditions due to the same constituent.

(5) The requirements of this section are in addition to the terms, prohibitions, and conditions contained in these Special Protections.

3. Compliance Schedule

a. On the effective date of the Exception, all non-authorized non-storm water discharges (e.g., dry weather flow) are effectively prohibited.

b. Within eighteen (18) months from the effective date of the Exception, the discharger shall submit a draft written ASBS Compliance Plan to the State Water Board Executive Director (statewide permits) or Regional Water Board Executive Officer (Regional Water Board permits) that describes its strategy to comply with these special conditions, including the requirement to maintain natural water quality in the affected ASBS. The ASBS Compliance Plan shall include a description of appropriate non-structural controls and a time schedule to implement structural controls (implementation schedule) to comply with these special conditions for inclusion in the discharger's SWMP or SWPPP, as appropriate to permit type. The final ASBS Compliance Plan, including a description and final schedule for structural controls based on the results of runoff and receiving water monitoring, must be submitted within thirty (30) months from the effective date of the Exception.

c. Within 18 months of the effective date of the Exception, any non-structural controls that are necessary to comply with these special conditions shall be implemented.

d. Within six (6) years of the effective date of the Exception, any structural controls identified in the ASBS Compliance Plan that are necessary to comply with these special conditions shall be operational.

e. Within six (6) years of the effective date of the Exception, all dischargers must comply with the requirement that their discharges into the affected ASBS maintain natural ocean water quality. If the initial results of post-storm receiving water quality testing indicate levels higher than the 85th percentile threshold of reference water quality data and the pre-storm receiving water levels, then the discharger must re-sample the receiving water, pre- and post-storm. If after re-sampling the post-storm levels are still higher than the 85th percentile threshold of reference water quality data, and the pre-storm receiving water levels, for any constituent, then natural ocean water quality is exceeded. See attached Flowchart.

f. The Executive Director of the State Water Board (statewide permits) or Executive Officer of the Regional Water Board (Regional Water Board permits) may only authorize additional time to comply with the special conditions d. and e., above if good cause exists to do so. Good cause means a physical impossibility or lack of funding.

If a discharger claims physical impossibility, it shall notify the Board in writing within thirty (30) days of the date that the discharger first knew of the event or circumstance that caused or would cause it to fail to meet the deadline in d. or e. The notice shall describe the reason for the noncompliance or anticipated noncompliance and specifically refer to this Section of this Exception. It shall describe the anticipated length of time the delay in compliance may persist, the cause or causes of the delay as well as measures to minimize the impact of the delay on water quality, the measures taken or to be taken by the discharger to prevent or minimize the delay, the schedule by which the measures will be implemented, and the anticipated date of compliance. The discharger shall adopt all reasonable measures to avoid and minimize such delays and their impact on water quality.

The discharger may request an extension of time for compliance based on lack of funding. The request for an extension shall require:

1. for municipalities, a demonstration of significant hardship to discharger ratepayers, by showing the relationship of storm water fees to annual household income for residents within the discharger's jurisdictional area, and the discharger has made timely and complete applications for all available bond and grant funding, and either no bond or grant funding is available, or bond and/or grant funding is inadequate; or

2. for other governmental agencies, a demonstration and documentation of a good faith effort to acquire funding through that agency's budgetary process, and a demonstration that funding was unavailable or inadequate.

B. NONPOINT SOURCE DISCHARGES

1. General Provisions for Nonpoint Sources

   a. Existing nonpoint source waste discharges are allowed into an ASBS only under the following conditions:

      (1) The discharges are authorized under waste discharge requirements, a conditional waiver of waste discharge requirements, or a conditional prohibition issued by the State Water Board or a Regional Water Board.

      (2) The discharges are in compliance with the applicable terms, prohibitions, and special conditions contained in these Special Protections.

      (3) The discharges:

         (i) Are essential for flood control or slope stability, including roof, landscape, road, and parking lot drainage;

         (ii) Are designed to prevent soil erosion;

         (iii) Occur only during wet weather;

         (iv) Are composed of only storm water runoff.

   b. Discharges composed of storm water runoff shall not alter natural ocean water quality in an ASBS.

c. The discharge of trash is prohibited.

d. Only existing nonpoint source waste discharges are allowed. “Existing nonpoint source waste discharges” are discharges that were ongoing prior to January 1, 2005. “New nonpoint source discharges” are defined as those that commenced on or after January 1, 2005. A change to an existing nonpoint source discharge, in terms of relocation or alteration, in order to comply with these special conditions, is allowed and does not constitute a new discharge.

e. Non-storm water discharges from nonpoint sources (those not subject to an NPDES Permit) are prohibited except as provided below:

(1) The term “non-storm water discharges” means any waste discharges that are not composed entirely of storm water.

(2) The following non-storm water discharges are allowed, provided that the discharges are essential for emergency response purposes, structural stability, slope stability, or occur naturally:

(i) Discharges associated with emergency fire fighting operations.

(ii) Foundation and footing drains.

(iii) Water from crawl space or basement pumps.

(iv) Hillside dewatering.

(v) Naturally occurring groundwater seepage via a storm drain.

(vi) Non-anthropogenic flows from a naturally occurring stream via a culvert or storm drain, as long as there are no contributions of anthropogenic runoff.

(3) Authorized non-storm water discharges shall not cause or contribute to a violation of the water quality objectives in Chapter II of the Ocean Plan nor alter natural ocean water quality in an ASBS.

f. At the San Clemente Island ASBS, discharges incidental to military training and research, development, test, and evaluation operations are allowed. Discharges incidental to underwater demolition and other in-water explosions are not allowed in the two military closure areas in the vicinity of Wilson Cove and Castle Rock. Discharges must not result in a violation of the water quality objectives, including the protection of the marine aquatic life beneficial use, anywhere in the ASBS.

g. At the San Nicolas Island and Begg Rock ASBS, discharges incidental to military research, development, testing, and evaluation of, and training with, guided missile and other weapons systems, fleet training exercises, small-scale amphibious warfare training, and special warfare training are allowed. Discharges incidental to underwater demolition and other in-water explosions are not allowed. Discharges must not result in a violation of the water quality objectives, including the protection of the marine aquatic life beneficial use, anywhere in the ASBS.

h. All other nonpoint source discharges not specifically authorized above are prohibited.

2. Planning and Reporting

a. The nonpoint source discharger shall develop an ASBS Pollution Prevention Plan, including an implementation schedule, to address storm water runoff and any other nonpoint source discharges from its facilities. The ASBS Pollution Prevention Plan must be equivalent in contents to an ASBS Compliance Plan as described in I (A)(2) in this document. The ASBS Pollution Prevention Plan is subject to approval by the Executive Director of the State Water Board (statewide waivers or waste discharge requirements) or Executive Officer of the Regional Water Board (Regional Water Board waivers or waste discharge requirements).

b. The ASBS Pollution Prevention Plan shall address storm water discharges (wet weather flows) and, in particular, describe how pollutant reductions in storm water runoff that are necessary to comply with these special conditions, will be achieved through Management Measures and associated Management Practices (Management Measures/Practices). Structural BMPs need not be installed if the discharger can document to the satisfaction of the State Water Board Executive Director or Regional Water Board Executive Officer that such installation would pose a threat to health or safety. Management Measures to control storm water runoff during a design storm shall achieve on average the following target levels:

(1) Table B Instantaneous Maximum Water Quality Objectives in Chapter II of the Ocean Plan; or

(2) A 90% reduction in pollutant loading during storm events, for the applicant's total discharges.

The baseline for these determinations is the effective date of the Exception, except for those structural BMPs installed between January 1, 2005 and adoption of these Special Protections, and the reductions must be achieved and documented within four (4) years of the effective date.

c. If the results of the receiving water monitoring described in IV.B. of these special conditions indicate that the storm water runoff or other nonpoint source pollution is causing or contributing to an alteration of natural ocean water quality in the ASBS, the discharger shall submit a report to the State Water Board and the Regional Water Board within 30 days of receiving the results.

(1) The report shall identify the constituents that alter natural water quality and the sources of these constituents.

(2) The report shall describe Management Measures/Practices that are currently being implemented, Management Measures/Practices that are identified in the ASBS Pollution Prevention Plan for future implementation, and any additional Management Measures/Practices that may be added to the Pollution Prevention Plan to address the alteration of natural water quality. The report shall include a new or modified implementation schedule for the Management Measures/Practices.

(3) Within 30 days of the approval of the report by the State Water Board Executive Director (statewide waivers or waste discharge requirements) or Executive Officer of the Regional Water Board (Regional Water Board waivers or waste discharge requirements), the discharger shall revise its ASBS Pollution Prevention Plan to incorporate any new or modified Management Measures/Practices that have been or will be implemented, the implementation schedule, and any additional monitoring required.

(4) As long as the discharger has complied with the procedures described above and is implementing the revised ASBS Pollution Prevention Plan, the discharger does not have to repeat the same procedure for continuing or recurring exceedances of natural water quality conditions due to the same constituent.

(5) The requirements of this section are in addition to the terms, prohibitions, and conditions contained in these Special Protections.

3. Compliance Schedule

a. On the effective date of the Exception, all non-authorized non-storm water discharges (e.g., dry weather flow) are effectively prohibited.

b. Within eighteen (18) months from the effective date of the Exception, the discharger~~s~~ shall submit a draft written ASBS Pollution Prevention Plan to the State Water Board Executive Director (statewide waivers or waste discharge requirements) or Executive Officer of the Regional Water Board (Regional Water Board waivers or waste discharge requirements) that describes its strategy to comply with these special conditions, including the requirement to maintain natural ocean water quality in the affected ASBS. The Pollution Prevention Plan shall include a description of appropriate non-structural controls and a time schedule to implement structural controls to comply with these special conditions for inclusion in the discharger's Pollution Prevention Plan. The final ASBS Pollution Prevention Plan, including a description and final schedule for structural controls based on the results of runoff and receiving water monitoring, must be submitted within thirty (30) months from the effective date of the Exception.

c. Within 18 months of the effective date of the Exception, any non-structural controls that are necessary to comply with these Special Protections shall be implemented.

d. Within six (6) years of the effective date of the Exception, any structural controls identified in the ASBS Pollution Prevention Plan that are necessary to comply with these special conditions shall be operational.

e. Within six (6) years of the effective date of the Exception, all dischargers must comply with the requirement that their discharges into the affected ASBS maintain natural ocean water quality. If the initial results of post-storm receiving water quality testing indicate levels higher than the 85th percentile threshold of reference water quality data and the pre-storm receiving water levels, then the discharger must re-sample the receiving water pre- and post-storm. If after re-sampling the post-storm levels are still higher than the 85th percentile threshold of reference water quality data and the pre-storm receiving water levels, for any constituent, then natural ocean water quality is exceeded. See attached Flowchart.

f. The Executive Director of the State Water Board (statewide waivers or waste discharge requirements) or Executive Officer of the Regional Water Board (Regional Water Board waivers or waste discharge requirements) may only authorize additional time to comply with the special conditions d. and e., above if good cause exists to do so. Good cause means a physical impossibility or lack of funding.

If a discharger claims physical impossibility, it shall notify the Board in writing within thirty (30) days of the date that the discharger first knew of the event or circumstance that caused or would cause it to fail to meet the deadline in d. or e. The notice shall describe the reason for the noncompliance or anticipated noncompliance and specifically refer to this Section of this Exception. It shall describe the anticipated length of time the delay in compliance may persist, the cause or causes of the delay as well as measures to minimize the impact of the delay on water quality, the measures taken or to be taken by the discharger to prevent or minimize the delay, the schedule by which the measures will be implemented, and the anticipated date of compliance. The discharger shall adopt all reasonable measures to avoid and minimize such delays and their impact on water quality.

The discharger may request an extension of time for compliance based on lack of funding. The request for an extension shall require:

1. a demonstration that the discharger has made timely and complete applications for all available bond and grant funding, and either no bond or grant funding is available, or bond and/or grant funding is inadequate; or

2. for governmental agencies, a demonstration and documentation of a good faith effort to acquire funding through that agency's budgetary process, and a demonstration that funding was unavailable or inadequate.

II. ADDITIONAL REQUIREMENTS FOR PARKS AND RECREATION FACILITIES

In addition to the provisions in Section I (A) or I (B), respectively, a discharger with parks and recreation facilities shall comply with the following:

A. The discharger shall include a section in an ASBS Compliance Plan (for NPDES dischargers) or an ASBS Pollution Prevention Plan (for nonpoint source dischargers) to address storm water runoff from parks and recreation facilities.

1. The plan shall identify all pollutant sources, including sediment sources, which may result in waste entering storm water runoff. Pollutant sources include, but are not limited to, roadside rest areas and vistas, picnic areas, campgrounds, trash receptacles, maintenance facilities, park personnel housing, portable toilets, leach fields, fuel tanks, roads, piers, and boat launch facilities.

2. The plan shall describe BMPs or Management Measures/Practices that will be implemented to control soil erosion (both temporary and permanent erosion controls) and reduce or eliminate pollutants in storm water runoff in order to achieve and maintain natural water quality conditions in the affected ASBS. The plan shall include BMPs or

Management Measures/Practices to ensure that trails and culverts are maintained to prevent erosion and minimize waste discharges to ASBS.

3. The plan shall include BMPs or Management Measures/Practices to prevent the discharge of pesticides or other chemicals, including agricultural chemicals, in storm water runoff to the affected ASBS.

4. The plan shall include BMPs or Management Measures/Practices that address public education and outreach. The goal of these BMPs or Management Measures/Practices is to ensure that the public is adequately informed that waste discharges to the affected ASBS are prohibited or limited by special conditions in these Special Protections. The BMPs or Management Measures/Practices shall include signage at camping, picnicking, beach and roadside parking areas, and visitor centers, or other appropriate measures, which notify the public of any applicable requirements of these Special Protections and identify the ASBS boundaries.

5. The plan shall include BMPs or Management Measures/Practices that address the prohibition against the discharge of trash to ASBS. The BMPs or Management Measures/Practices shall include measures to ensure that adequate trash receptacles are available for public use at visitor facilities, including parking areas, and that the receptacles are adequately maintained to prevent trash discharges into the ASBS. Appropriate measures include covering trash receptacles to prevent trash from being wind blown and periodically emptying the receptacles to prevent overflows.

6. The plan shall include BMPs or Management Measures/Practices to address runoff from parking areas and other developed features to ensure that the runoff does not alter natural water quality in the affected ASBS. BMPs or Management Measures/Practices shall include measures to reduce pollutant loading in runoff to the ASBS through installation of natural area buffers (LID), treatment, or other appropriate measures.

B. Maintenance and repair of park and recreation facilities must not result in waste discharges to the ASBS. The practice of road oiling must be minimized or eliminated, and must not result in waste discharges to the ASBS.

III. ADDITIONAL REQUIREMENTS – WATERFRONT AND MARINE OPERATIONS

In addition to the provisions in Section I (A) or I (B), respectively, a discharger with waterfront and marine operations shall comply with the following:

A. For discharges related to waterfront and marine operations, the discharger shall develop a Waterfront and Marine Operations Management Plan (Waterfront Plan). This plan shall contain appropriate Management Measures/Practices to address nonpoint source pollutant discharges to the affected ASBS.

1. The Waterfront Plan shall contain appropriate Management Measures/Practices for any waste discharges associated with the operation and maintenance of vessels, moorings, piers, launch ramps, and cleaning stations in order to ensure that beneficial uses are protected and natural water quality is maintained in the affected ASBS.

2. For discharges from marinas and recreational boating activities, the Waterfront Plan shall include appropriate Management Measures, described in The Plan for California's Nonpoint Source Pollution Control Program, for marinas and recreational boating, or equivalent practices, to ensure that nonpoint source pollutant discharges do not alter natural water quality in the affected ASBS.

3. The Waterfront Plan shall include Management Practices to address public education and outreach to ensure that the public is adequately informed that waste discharges to the affected ASBS are prohibited or limited by special conditions in these Special Protections. The management practices shall include appropriate signage, or similar measures, to inform the public of the ASBS restrictions and to identify the ASBS boundaries.

4. The Waterfront Plan shall include Management Practices to address the prohibition against trash discharges to ASBS. The Management Practices shall include the provision of adequate trash receptacles for marine recreation areas, including parking areas, launch ramps, and docks. The plan shall also include appropriate Management Practices to ensure that the receptacles are adequately maintained and secured in order to prevent trash discharges into the ASBS. Appropriate Management Practices include covering the trash receptacles to prevent trash from being windblown, staking or securing the trash receptacles so they don't tip over, and periodically emptying the receptacles to prevent overflow.

5. The discharger shall submit its Waterfront Plan to the by the State Water Board Executive Director (statewide waivers or waste discharge requirements) or Executive Officer of the Regional Water Board (Regional Water Board waivers or waste discharge requirements) within six months of the effective date of these special conditions. The Waterfront Plan is subject to approval by the State Water Board Executive Director or the Regional Water Board Executive Officer, as appropriate. The plan must be fully implemented within 18 months of the effective date of the Exception.

B. The discharge of chlorine, soaps, petroleum, other chemical contaminants, trash, fish offal, or human sewage to ASBS is prohibited. Sinks and fish cleaning stations are point source discharges of wastes and are prohibited from discharging into ASBS. Anthropogenic accumulations of discarded fouling organisms on the sea floor must be minimized.

C. Limited-term activities, such as the repair, renovation, or maintenance of waterfront facilities, including, but not limited to, piers, docks, moorings, and breakwaters, are authorized only in accordance with Chapter III.E.2 of the Ocean Plan.

D. If the discharger anticipates that the discharger will fail to fully implement the approved Waterfront Plan within the 18 month deadline, the discharger shall submit a technical report as soon as practicable to the State Water Board Executive Director or the Regional Water Board Executive Officer, as appropriate. The technical report shall contain reasons for failing to meet the deadline and propose a revised schedule to fully implement the plan.

E. The State Water Board or the Regional Water Board may, for good cause, authorize additional time to comply with the Waterfront Plan. Good cause means a physical impossibility or lack of funding.

If a discharger claims physical impossibility, it shall notify the Board in writing within thirty (30) days of the date that the discharger first knew of the event or circumstance that caused or would cause it to fail to meet the deadline in Section III.A.5. The notice shall describe the reason for the noncompliance or anticipated noncompliance and specifically refer to this Section of this Exception. It shall describe the anticipated length of time the delay in compliance may persist, the cause or causes of the delay as well as measures to minimize the impact of the delay on water quality, the measures taken or to be taken by the discharger to prevent or minimize the delay, the schedule by which the measures will be implemented, and the anticipated date of compliance. The discharger shall adopt all reasonable measures to avoid and minimize such delays and their impact on water quality. The discharger may request an extension of time for compliance based on lack of funding. The request for an extension shall require:

1. a demonstration of significant hardship by showing that the discharger has made timely and complete applications for all available bond and grant funding, and either no bond or grant funding is available, or bond and/or grant funding is inadequate.

2. for governmental agencies, a demonstration and documentation of a good faith effort to acquire funding through that agency's budgetary process, and a demonstration that funding was unavailable or inadequate.

IV. MONITORING REQUIREMENTS

Monitoring is mandatory for all dischargers to assure compliance with the Ocean Plan. Monitoring requirements include both: (A) core discharge monitoring, and (B) ocean receiving water monitoring. The State and Regional Water Boards must approve sampling site locations and any adjustments to the monitoring programs. All ocean receiving water and reference area monitoring must be comparable with the Water Boards' Surface Water Ambient Monitoring Program (SWAMP).

Safety concerns: Sample locations and sampling periods must be determined considering safety issues. Sampling may be postponed upon notification to the State and Regional Water Boards if hazardous conditions prevail.

Analytical Chemistry Methods: All constituents must be analyzed using the lowest minimum detection limits comparable to the Ocean Plan water quality objectives. For metal analysis, all samples, including storm water effluent, reference samples, and ocean receiving water samples, must be analyzed by the approved analytical method with the lowest minimum detection limits (currently Inductively Coupled Plasma/Mass Spectrometry) described in the Ocean Plan.

A. CORE DISCHARGE MONITORING PROGRAM

1. General sampling requirements for timing and storm size:

   Runoff must be collected during a storm event that is greater than 0.1 inch and generates runoff, and at least 72 hours from the previously measurable storm event. Runoff samples shall be collected during the same storm and at approximately the same time when post-storm receiving water is sampled, and analyzed for the same constituents as receiving water and reference site samples (see section IV B) as described below.

2. Runoff flow measurements

   a. For municipal/industrial storm water outfalls in existence as of December 31, 2007, 18 inches (457mm) or greater in diameter/width (including multiple outfall pipes in combination having a width of 18 inches, runoff flows must be measured or calculated, using a method acceptable to and approved by the State and Regional Water Boards.

   b. This will be reported annually for each precipitation season to the State and Regional Water Boards.

3. Runoff samples – storm events

   a. For outfalls equal to or greater than 18 inches (0.46m) in diameter or width:

      (1) samples of storm water runoff shall be collected during the same storm as receiving water samples and analyzed for oil and grease, total suspended solids, and, within the range of the southern sea otter indicator bacteria or some other measure of fecal contamination; and

      (2) samples of storm water runoff shall be collected and analyzed for critical life stage chronic toxicity (one invertebrate or algal species) at least once during each storm season when receiving water is sampled in the ASBS.

      (3) If an applicant has no outfall greater than 36 inches, then storm water runoff from the applicant's largest outfall shall be further collected during the same storm as receiving water samples and analyzed for Ocean Plan Table B metals for protection of marine life, Ocean Plan polynuclear aromatic hydrocarbons (PAHs), current use pesticides (pyrethroids and OP pesticides), and nutrients (ammonia, nitrate and phosphates).

   b. For outfalls equal to or greater than 36 inches (0.91m) in diameter or width:

      (1) samples of storm water runoff shall be collected during the same storm as receiving water samples and analyzed for oil and grease, total suspended solids, and, within the range of the southern sea otter indicator bacteria or some other measure of fecal contamination; and

      (2) samples of storm water runoff shall be further collected during the same storm as receiving water samples and analyzed for Ocean Plan Table B metals for protection of marine life, Ocean Plan polynuclear aromatic hydrocarbons (PAHs), current use pesticides (pyrethroids and OP pesticides), and nutrients (ammonia, nitrate and phosphates); and

      (3) samples of storm water runoff shall be collected and analyzed for critical life stage chronic toxicity (one invertebrate or algal species) at least once during each storm season when receiving water is sampled in the ASBS.

b. For an applicant not participating in a regional monitoring program [see below in Section IV (B)] in addition to (a.) and (b.) above, a minimum of the two largest outfalls or 20 percent of the larger outfalls, whichever is greater, shall be sampled (flow weighted composite samples) at least three times annually during wet weather (storm event) and analyzed for all Ocean Plan Table A constituents, Table B constituents for marine aquatic life protection (except for toxicity, only chronic toxicity for three species shall be required), DDT, PCBs, Ocean Plan PAHs, OP pesticides, pyrethroids, nitrates, phosphates, and Ocean Plan indicator bacteria. For parties discharging to ASBS in more than one Regional Water Board region, at a minimum, one (the largest) such discharge shall be sampled annually in each Region.

4. The Executive Director of the State Water Board (statewide permits) or Executive Officer of the Regional Water Board (Regional Water Board permits) may reduce or suspend core monitoring once the storm runoff is fully characterized. This determination may be made at any point after the discharge is fully characterized, but is best made after the monitoring results from the first permit cycle are assessed.

B. Ocean Receiving Water and Reference Area Monitoring Program

In addition to performing the Core Discharge Monitoring Program in Section II.A above, all applicants having authorized discharges must perform ocean receiving water monitoring. In order to fulfill the requirements for monitoring the physical, chemical, and biological characteristics of the ocean receiving waters within their ASBS, dischargers may choose either (1) an individual monitoring program, or (2) participation in a regional integrated monitoring program.

1. Individual Monitoring Program: The requirements listed below are for those dischargers who elect to perform an individual monitoring program to fulfill the requirements for monitoring the physical, chemical, and biological characteristics of the ocean receiving waters within the affected ASBS. In addition to Core Discharge Monitoring, the following additional monitoring requirements shall be met:

   a. Three times annually, during wet weather (storm events), the receiving water at the point of discharge from the outfalls described in section (IV)(A)(3)(c) above shall be sampled and analyzed for Ocean Plan Table A constituents, Table B constituents for marine aquatic life, DDT, PCBs, Ocean Plan PAHs, OP pesticides, pyrethroids, nitrates, phosphates, salinity, chronic toxicity (three species), and Ocean Plan indicator bacteria.

      The sample location for the ocean receiving water shall be in the surf zone at the point of discharges; this must be at the same location where storm water runoff is sampled. Receiving water shall be sampled prior to (pre-storm) and during (or immediately after) the same storm (post storm). Post storm sampling shall be during the same storm and at approximately the same time as when the runoff is sampled. Reference water quality shall also be sampled three times annually and analyzed for the same constituents pre-storm and post-storm, during the same storm seasons when receiving water is sampled. Reference stations will be determined by the State Water Board's Division of Water Quality and the applicable Regional Water Board(s).

   b. Sediment sampling shall occur at least three times during every five (5) year period. The subtidal sediment (sand or finer, if present) at the discharge shall be sampled and analyzed for Ocean Plan Table B constituents for marine aquatic life, DDT, PCBs, PAHs, pyrethroids, and OP pesticides. For sediment toxicity testing, only an acute toxicity test using the amphipod *Eohaustorius estuarius* must be performed.

c. A quantitative survey of intertidal benthic marine life shall be performed at the discharge and at a reference site. The survey shall be performed at least once every five (5) year period. The survey design is subject to approval by the Regional Water Board and the State Water Board's Division of Water Quality. The results of the survey shall be completed and submitted to the State Water Board and Regional Water Board at least six months prior to the end of the permit cycle.

d. Once during each five (5) year period, a bioaccumulation study shall be conducted to determine the concentrations of metals and synthetic organic pollutants at representative discharge sites and at representative reference sites. The study design is subject to approval by the Regional Water Board and the State Water Board's Division of Water Quality. The bioaccumulation study may include California mussels (*Mytilus californianus*) and/or sand crabs (*Emerita analoga* or *Blepharipoda occidentalis*). Based on the study results, the Regional Water Board and the State Water Board's Division of Water Quality, may adjust the study design in subsequent permits, or add or modify additional test organisms (such as shore crabs or fish), or modify the study design appropriate for the area and best available sensitive measures of contaminant exposure.

e. Marine Debris: Representative quantitative observations for trash by type and source shall be performed along the coast of the ASBS within the influence of the discharger's outfalls. The design, including locations and frequency, of the marine debris observations is subject to approval by the Regional Water Board and State Water Board's Division of Water Quality.

f. The monitoring requirements of the Individual Monitoring Program in this section are minimum requirements. After a minimum of one (1) year of continuous water quality monitoring of the discharges and ocean receiving waters, the Executive Director of the State Water Board (statewide permits) or Executive Officer of the Regional Water Board (Regional Water Board permits) may require additional monitoring, or adjust, reduce or suspend receiving water and reference station monitoring. This determination may be made at any point after the discharge and receiving water is fully characterized, but is best made after the monitoring results from the first permit cycle are assessed.

2. Regional Integrated Monitoring Program: Dischargers may elect to participate in a regional integrated monitoring program, in lieu of an individual monitoring program, to fulfill the requirements for monitoring the physical, chemical, and biological characteristics of the ocean receiving waters within their ASBS. This regional approach shall characterize natural water quality, pre- and post-storm, in ocean reference areas near the mouths of identified open space watersheds and the effects of the discharges on natural water quality (physical, chemical, and toxicity) in the ASBS receiving waters, and should include benthic marine aquatic life and bioaccumulation components. The design of the ASBS stratum of a regional integrated monitoring program may deviate from the otherwise prescribed individual monitoring approach (in Section IV.B.1) if approved by the State Water Board's Division of Water Quality and the Regional Water Boards.

a. Ocean reference areas shall be located at the drainages of flowing watersheds with minimal development (in no instance more than 10% development), and shall not be located in CWA Section 303(d) listed waterbodies or have tributaries that are 303(d) listed. Reference areas shall be free of wastewater discharges and anthropogenic non-storm water runoff. A minimum of low threat storm runoff discharges (e.g. stream highway overpasses and campgrounds) may be allowed on a case-by-case basis. Reference areas shall be located in the same region as the ASBS receiving water monitoring occurs. The reference areas for each Region are subject to approval by the participants in the regional monitoring program and the State Water Board's Division of Water Quality and the applicable Regional Water Board(s). A minimum of three ocean reference water samples must be collected from each station, each from a separate storm during the same storm season that receiving water is sampled. A minimum of one reference location shall be sampled for each ASBS receiving water site sampled per responsible party. For parties discharging to ASBS in more than one Regional Water Board region, at a minimum, one reference station and one receiving water station shall be sampled in each region.

b. ASBS ocean receiving water must be sampled in the surf zone at the location where the runoff makes contact with ocean water (i.e. at "point zero"). Ocean receiving water stations must be representative of worst-case discharge conditions (i.e. co-located at a large drain greater than 36 inches, or if drains greater than 36 inches are not present in the ASBS then the largest drain greater than18 inches.) Ocean receiving water stations are subject to approval by the participants in the regional monitoring program and the State Water Board's Division of Water Quality and the applicable Regional Water Board(s). A minimum of three ocean receiving water samples must be collected during each storm season from each station, each from a separate storm. A minimum of one receiving water location shall be sampled in each ASBS per responsible party in that ASBS. For parties discharging to ASBS in more than one Regional Water Board region, at a minimum, one reference station and one receiving water station shall be sampled in each region.

c. Reference and receiving water sampling shall commence during the first full storm season following the adoption of these special conditions, and post-storm samples shall be collected during the same storm event when storm water runoff is sampled. Sampling shall occur in a minimum of two storm seasons. For those ASBS dischargers that have already participated in the Southern California Bight 2008 ASBS regional monitoring effort, sampling may be limited to only one storm season.

d. Receiving water and reference samples shall be analyzed for the same constituents as storm water runoff samples. At a minimum, constituents to be sampled and analyzed in reference and discharge receiving waters must include oil and grease, total suspended solids, Ocean Plan Table B metals for protection of marine life, Ocean Plan PAHs, pyrethroids, OP pesticides, ammonia, nitrate, phosphates, and critical life stage chronic toxicity for three species. In addition, within the range of the southern sea otter, indicator bacteria or some other measure of fecal contamination shall be analyzed.

3. Waterfront and Marine Operations: In addition to the above requirements for ocean receiving water monitoring, additional monitoring must be performed for marinas and boat launch and pier facilities:

   a. For all marina or mooring field operators, in mooring fields with 10 or more occupied moorings, the ocean receiving water must be sampled for Ocean Plan indicator bacteria, residual chlorine, copper, zinc, grease and oil, methylene blue active substances (MBAS), and ammonia nitrogen.

(1) For mooring field operators opting for an individual monitoring program (Section IV.B.1 above), this sampling must occur weekly (on the weekend) from May through October.

(2) For mooring field operators opting to participate in a regional integrated monitoring program (Section IV.B.2 above), this sampling must occur monthly from May through October on a high use weekend in each month. The Water Boards may allow a reduction in the frequency of sampling, through the regional monitoring program, after the first year of monitoring.

b. For all mooring field operators, the subtidal sediment (sand or finer, if present) within mooring fields and below piers shall be sampled and analyzed for Ocean Plan Table B metals (for marine aquatic life beneficial use), acute toxicity, PAHs, and tributyltin. For sediment toxicity testing, only an acute toxicity test using the amphipod *Eohaustorius estuarius* must be performed. This sampling shall occur at least three times during a five (5) year period. For mooring field operators opting to participate in a regional integrated monitoring program, the Water Boards may allow a reduction in the frequency of sampling after the first sampling effort's results are assessed.

Glossary

At the point of discharge(s) – Means in the surf zone immediately where runoff from an outfall meets the ocean water (a.k.a., at point zero).

Areas of Special Biological Significance (ASBS) – Those areas designated by the State Water Board as ocean areas requiring protection of species or biological communities to the extent that alteration of natural water quality is undesirable. All Areas of Special Biological Significance are also classified as a subset of State Water Quality Protection Areas.

Design storm – For purposes of these Special Protections, a design storm is defined as the volume of runoff produced from one inch of precipitation per day or, if this definition is inconsistent with the discharger's applicable storm water permit, then the design storm shall be the definition included in the discharger's applicable storm water permit.

Development – Relevant to reference monitoring sites, means urban, industrial, agricultural, grazing, mining, and timber harvesting land uses.

Higher threat discharges - Permitted storm drains discharging equal to or greater than 18 inches, industrial storm drains, agricultural runoff discharged through an MS4, discharges associated with waterfront and marina operations (e.g., piers, launch ramps, mooring fields, and associated vessel support activities, except for passive discharges defined below), and direct discharges associated with commercial or industrial activities to ASBS.

Low Impact Development (LID) – A sustainable practice that benefits water supply and contributes to water quality protection. Unlike traditional storm water management, which entails collecting and conveying storm water runoff through storm drains, pipes, or other conveyances to a centralized storm water facility, LID focuses on using site design and storm water management to maintain the site's pre-development runoff rates and volumes. The goal of LID is to mimic a site's predevelopment hydrology by using design techniques that infiltrate, filter, store, evaporate, and detain runoff close to the source of rainfall.

Marine Operations – Marinas or mooring fields that contain slips or mooring locations for 10 or more vessels.

Management Measure (MM) - Economically achievable measures for the control of the addition of pollutants from various classes of nonpoint sources of pollution, which reflect the greatest degree of pollutant reduction achievable through the application of the best available nonpoint pollution control practices, technologies, processes, siting criteria, operating methods, or other alternatives. For example, in the "marinas and recreational boating" land-use category specified in the Plan for California's Nonpoint Source Pollution Control Program (NPS Program Plan) (SWRCB, 1999), "boat cleaning and maintenance" is considered a MM or the source of a specific class or type of NPS pollution.

Management Practice (MP) - The practices (e.g., structural, non-structural, operational, or other alternatives) that can be used either individually or in combination to address a specific MM class or classes of NPS pollution. For example, for the "boat cleaning and maintenance" MM, specific MPs can include, but are not limited to, methods for the selection of environmentally sensitive hull paints or methods for cleaning/removal of hull copper anti-fouling paints.

Municipal Separate Storm Sewer System (MS4) – A municipally-owned storm sewer system regulated under the Phase I or Phase II storm water program implemented in compliance with Clean Water Act section 402(p). Note that an MS4 program's boundaries are not necessarily congruent with the permittee's political boundaries.

Natural Ocean Water Quality - The water quality (based on selected physical, chemical and biological characteristics) that is required to sustain marine ecosystems, and which is without apparent human influence, *i.e.*, an absence of significant amounts of: (a) man-made constituents (*e.g.,* DDT); (b) other chemical (*e.g.,* trace metals), physical (temperature/thermal pollution, sediment burial), and biological (*e.g.*, bacteria) constituents at concentrations that have been elevated due to man's activities above those resulting from the naturally occurring processes that affect the area in question; and (c) non-indigenous biota (*e.g.,* invasive algal bloom species) that have been introduced either deliberately or accidentally by man. Discharges "*shall not alter natural ocean water quality*" as determined by a comparison to the range of constituent concentrations in reference areas agreed upon via the regional monitoring program(s). If monitoring information indicates that *natural ocean water quality* is not maintained, but there is sufficient evidence that a discharge is not contributing to the alteration of natural water quality, then the Regional Water Board may make that determination. In this case, sufficient information must include runoff sample data that has equal or lower concentrations for the range of constituents at the applicable reference area(s).

Nonpoint source – Nonpoint pollution sources generally are sources that do not meet the definition of a point source. Nonpoint source pollution typically results from land runoff, precipitation, atmospheric deposition, agricultural drainage, marine/boating operations or hydrologic modification. Nonpoint sources, for purposes of these Special Protections, include discharges that are not required to be regulated under an NPDES permit.

Non-storm water discharge – Any runoff that is not the result of a precipitation event. This is often referred to as "dry weather flow."

Non-structural control – A Best Management Practice that involves operational, maintenance, regulatory (e.g., ordinances) or educational activities designed to reduce or eliminate pollutants in runoff, and that are not structural controls (i.e. there are no physical structures involved).

Physical impossibility - Means any act of God, war, fire, earthquake, windstorm, flood or natural catastrophe; unexpected and unintended accidents not caused by discharger or its employees' negligence; civil disturbance, vandalism, sabotage or terrorism; restrain by court order or public authority or agency; or action or non-action by, or inability to obtain the necessary authorizations or approvals from any governmental agency other than the permittee.

Representative sites and monitoring procedures – Are to be proposed by the discharger, with appropriate rationale, and subject to approval by Water Board staff.

Sheet-flow – Runoff that flows across land surfaces at a shallow depth relative to the cross-sectional width of the flow. These types of flow may or may not enter a storm drain system before discharge to receiving waters.

Storm Season – Also referred to as rainy season, means the months of the year from the onset of rainfall during autumn until the cessation of rainfall in the spring.

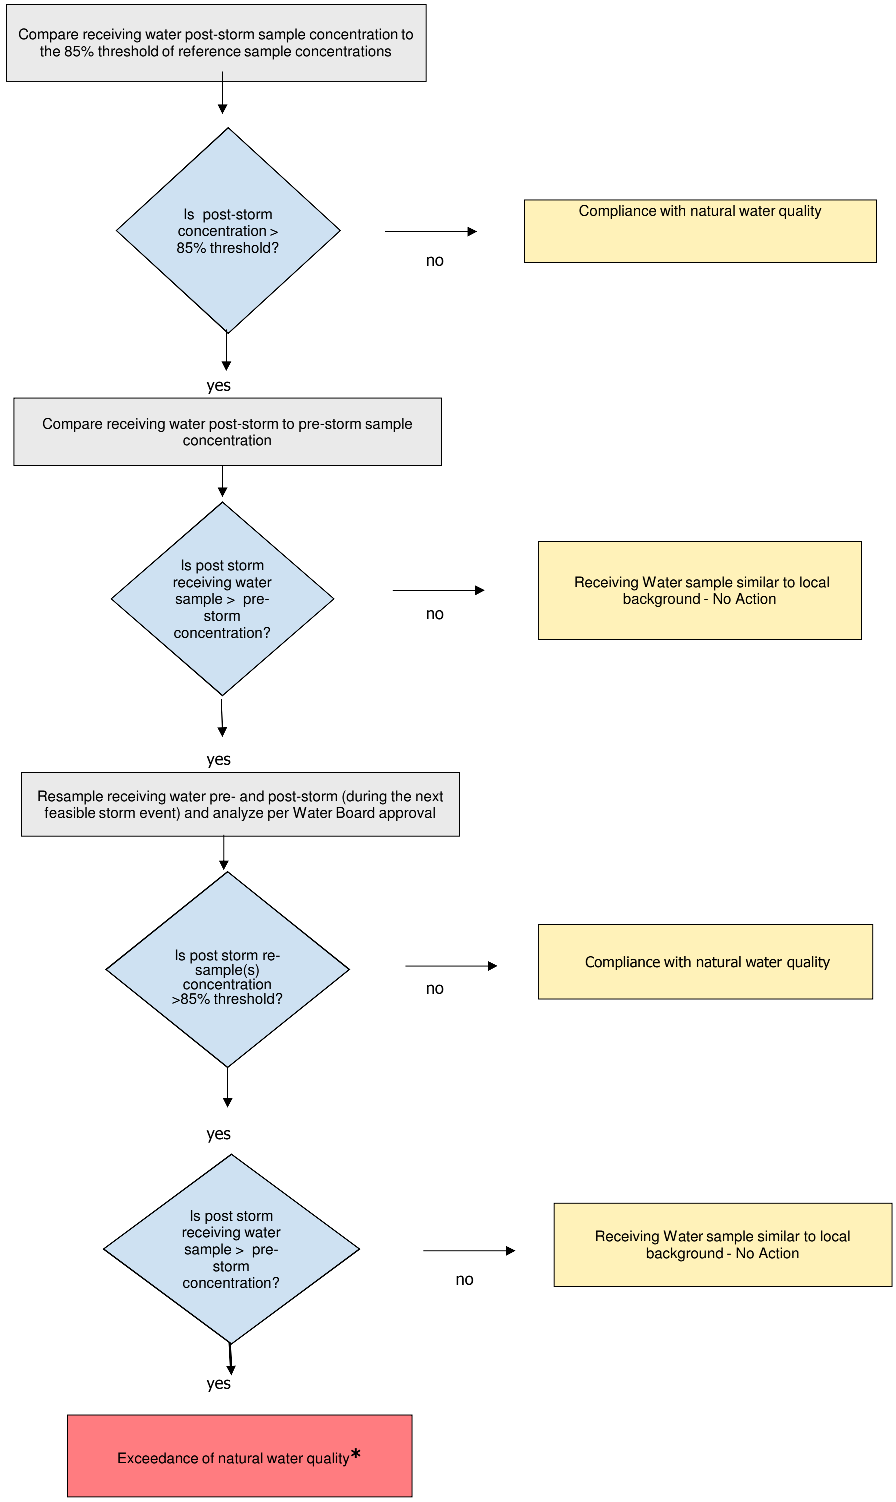
Structural control – A Best Management Practice that involves the installation of engineering solutions to the physical treatment or infiltration of runoff.

Surf Zone - The surf zone is defined as the submerged area between the breaking waves and the shoreline at any one time.

Surface Water Ambient Monitoring Program (SWAMP) comparable – Means that the monitoring program must 1) meet or exceed 2008 SWAMP Quality Assurance Program Management Plan (QAPP) Measurement Quality Objectives, or 2) have a Quality Assurance Project Plan that has been approved by SWAMP; in addition data must be formatted to match the database requirements of the SWAMP Information Management System. Adherence to the measurement quality objectives in the Southern California Bight 2008 ASBS Regional Monitoring Program QAPP and data base management comprises being SWAMP comparable.

Waterfront Operations - Piers, launch ramps, and cleaning stations in the water or on the adjacent shoreline.

Attachment 1
Special Protections Sections I(A)(3)(e) and I(B)(3)(e)
Flowchart to Determine Compliance with Natural Water Quality



*** When an exceedance of natural water quality occurs, the discharger must comply with section I.A.2.h (for permitted storm water) or section I.B.2.c (for nonpoint sources). Note, when sampling data is available, end-of-pipe effluent concentrations will be considered by the Water Boards in making this determination.**

Introduction

The regulatory environment

The California Ocean Plan defines water quality objectives for State waters and is the basis of regulation of discharges to marine environment. In 1972 there was recognition that certain areas had biological communities with ecological value or that were fragile. These areas were deemed to deserve enhanced protection to preserve and maintain natural (not affected by anthropogenic influences) water quality. These areas were designated Areas of Special Biological Significance (ASBS). As a result, regulations were enacted to prohibit discharges into ASBS as well as to any nearby waters that could affect the natural water quality in ASBS. In 1974 the State Water Board (SWB) designated 33 ASBS. An additional area was designated in 1975; there have been no subsequent designations.

ASBS have been designated to protect marine species or biological communities from an undesirable alteration in natural water quality. Furthermore ASBS provide intrinsic value or recognized value to man for scientific study, commercial use, recreational use, or esthetic reasons. Consistent with previous versions of the Ocean Plan, the 2009 Ocean Plan states: "Waste shall not be discharged to areas designated as being of special biological significance. Discharges shall be located a sufficient distance from such designated areas to assure maintenance of natural water quality conditions in these areas." This absolute waste discharge prohibition in the Ocean Plan stands, unless an "exception" is granted. The requirements for an exception are included in the Ocean Plan. When granting exceptions the State Water Board must determine that the public interest is served, and that protections of beneficial uses are not compromised. Despite the prohibition against waste discharges to ASBS, in 2003 there were approximately 1,658 outfalls to these marine water quality protected areas (SCCWRP 2003). As a result, the State Water Board has initiated regulatory actions, establishing special protections through the Ocean Plan's exception process.

The key attribute that underlies the ASBS water quality regulations is the standard of "natural water quality". The logic of the standard is that natural water quality is attainable using limited spatial regulations (prohibition of discharges in some areas) and essential for certain biological communities. Unfortunately, at least for southern California ASBS, coastal waters are no longer pristine. This is not simply due to discharges, as even if land based discharges were to be eliminated, aerial contaminants and pollutants carried by oceanic currents would influence water quality conditions.

Since a definition of natural water quality did not exist, a committee of scientists, termed the ASBS Natural Water Quality Committee, was formed to provide such a definition for the State Water Board. In 2010 the ASBS Natural Water Quality Committee provided the State Water Board with its findings (Dickson 2010), including an operational definition of natural water quality with the following criteria. These criteria address the two tenets of ASBS protections.

1) It should be possible to define a *reference* area or areas for each ASBS that currently approximate *natural water quality* and that are expected to exhibit the likely natural variability that would be found in that ASBS,

2) Any detectable human influence on the water quality must not hinder the ability of marine life to respond to natural cycles and processes. Such criteria will ensure that the beneficial uses identified by the Ocean Plan are protected for future generations.

This operational definition of natural water quality allows for the assessment of biological impacts related to water quality in ASBS and it provides the basic design elements for the assessment. In particular the use of reference areas for each ASBS allows for control of natural and temporal variability in biological communities.

The ecological environment

Because most discharges are into intertidal areas (defined as that area between low and high tides), there has been concern that impacts would be primarily manifested in ecological communities in sandy beach and rocky intertidal systems. Ecological communities in sandy beach habitats are extraordinarily dynamic (McLachlan 1993, Defeo 2008) and attribution of change to anthropogenic causes is quite difficult, mainly due to low statistical power. Species associated with rocky intertidal areas are also dynamic, but much less so than those in or on sandy beaches. As a result, attribution of the cause of change is easier for species or communities associated with rocky intertidal habitats (Littler and Murray 1975, Minchinton and Raimondi, 2005, Conway-Cranos and Raimondi 2007, Pinedo et al. 2007, Arevalo et al. 2007).

Within rocky intertidal communities, species have a variety of life histories that affect the assessment of potential causes of change. Shorter lived species like *Chthamalus*, *Ulva* and *Porphyra* often are associated with disturbance, while longer lived species like *Balanus*, fucoid algae and mussels tend to be associated with more stable environments. Hence, communities with higher cover of the more ephemeral species are often considered to be indicative of recent or ongoing perturbation. Clearly, perturbations can be due to both natural and anthropogenic causes and hence the design of the sampling program is critical for separating these two general mechanisms of change.

Here we report on a project designed to: (1) characterize the ecological community living on rocky intertidal habitats near discharges inside southern California ASBS, and at reference areas far from discharges and, (2) use the comparison between ASBS discharge and reference areas as a means to assess the likelihood that differences in ecological community structure that may be due to water quality degradation within ASBS.

Methods

Comprehensive sampling of ecological communities on rocky intertidal habitats was done using protocols developed by the coastal biodiversity surveys (http://cbsurveys.ucsc.edu/). The general approach is described below.

Site selection: ASBS and Reference – Based on the operational definition of natural water quality described above, along with the regulations prohibiting discharge in ASBS, we selected sites as follows. Sites were selected within ASBS that (1) had sufficient rocky intertidal habitat to be suited for sampling (as described below) and, (2) were located near to active discharge. Reference sites were selected following guideline (1) but instead of requiring proximity to an active discharge, we only used sites that were not near an active discharge. In addition we matched reference sites to discharge sites to control for spatial variance

The sampling procedure used was identical to that used by the coastal biodiversity survey (CBS) program housed at UCSC and administered by Peter Raimondi. In order to be cost-efficient, data from sites previously sampled by the CBS program were used in the analyses. New sampling was done to supplement existing data.

Selecting an appropriate location within a site - Within a site, the ideal location to do a CBS is on a bench that 1) is at least 30m wide, 2) gently slopes from the high to low zone, and most importantly 3) contains a representative sample of the intertidal community of the entire site. If it is not possible to find a contiguous 30m stretch of coastline, the survey can be split between two adjacent benches. When this is done, the survey should be divided as evenly as possible between the two benches.

***Set-Up* -** Once an appropriate area of shoreline was selected, it was sampled using a series of parallel transect lines extending from the high zone to the low zone. To facilitate the setup of these lines, two permanent 30m horizontal baselines (parallel to the ocean) were first established. The upper baseline was placed in the high zone above the upper limit of the organisms, while the lower baseline, which should be parallel to the upper baseline, was established farther down the shore. Depending on the amount of beach traffic or site regulations, the ends of these lines were permanently marked with either hex or carriage bolts.

Once these two baselines were established, parallel transect lines were run down the shore every three meters along the upper base line. To insure that these lines were parallel, they should intersect the appropriate meter mark on the lower baseline. In general the transect lines were allowed to follow the contours of the bench. When necessary, rocks were placed along the lines to prevent them from being shifted by heavy winds. It was noted where each transect crossed the lower baseline.

To facilitate resurveys of the site, a map was drawn of the site showing the location of the bolts relative to notable landmarks or other, pre-existing permanent plots. Photographs were also taken that include prominent visual reef characteristics for orientation (e.g. a large crack). The distance and bearing between the baseline endbolts were measured. When possible, measurements were also taken between the endbolts and any pre-existing permanent plots. Other pertinent information, such as the compass heading of the vertical transects, the sampling interval, weather conditions, site complications, and problems with taxonomic identification, was also recorded. All such information was used to make the mapping of the site more spatially explicit.

In addition to the spatial information described above, we also collected information about the site including bench type, relief, slope, extent of habitat and characteristics of surrounding coast. This information can be used to provide a spatial context for the site.

***Point-Contact Surveys* -** Each vertical transect was sampled using the point intercept method. An average of 100 points were sampled on each transect line. Hence, for example the interval between points would be 20cm for a 20m long transect, and 10cm for a 10m long transect. The basis of this design was to ensure that there was a similar density of sampled points per vertical unit of tidal elevation for all sites. For each point two types of data were collected: data that were used to determine relative abundance (% cover), and data that were used to describe spatial distributions. The relative abundance data were collected by identifying all taxa that fell directly under each point, including rock, sand, and tar. If there was layering of species, the taxa occupying the different layers were identified and assigned a letter; A for the top layer, B for the second layer, and C for the third. (Note: each layer must be a different taxa). If the point fell on an epibiont living on a host species, the epibiont was noted. Also recorded was whether the species under the point was in a pool, on cobble, or on boulders. A total of up to three taxa were identified under each point.

If fewer than three taxa were recorded under a point, then the next one or two species closest to that point were also noted. These 'nearby' species had to differ from those found under the point, and must fall within a circle centered over the point with a radius half the length of the sampling interval.

***Mobile Invertebrate Surveys* -** Although point-contact surveys are good at determining the abundance of spatially common species, particularly sessile species, they do not sample rare or spatially uncommon species very well. Because most mobile species are not spatially common, their abundances were sampled in 50 x 50 cm quadrats placed at three locations along each transect. Each transect was first divided into three zones; the low zone, defined as the area below the mussel zone, the mid-zone (including mussels and rock weeds, and the high zone (usually dominated by barnacles and littorines). Within each zone a quadrat was randomly placed on the transect, and all mobile species found within the quadrat were identified and counted. Sub-sampling was used when there was more than one hundred individuals of one species in a quadrat. If a quadrat landed in a deep pool or in an area dominated by sand, a new location within the defined zone was selected.

Vouchers–We collected field vouchers for all species that could not be identified in the field. Voucher samples were labeled with the date, site, name of sampler, transect line on which it was found.

***Specific hypotheses tested* -** The general goal of this project was to compare the ecological communities in ASBS and reference locations. To do this we developed the following specific (null) hypotheses

1) Species richness will not vary as function of site type (ASBS, Reference)
2) Community composition of sessile species will not vary as a function of site type
3) Community composition of mobile species will not vary as a function of site type
4) An integrated assessment of both mobile and sessile species will not identify particular sites as being substantially different from the expectation based on all sites. This is a way to look at specific sites rather than site types.

For questions 1-3 two forcing (independent) variables were used in the statistical approaches. First – whether the sites was considered to be an ASBS site (near to a discharge) or a reference site (that could also be in an ASBS). Second – we imposed a geographical group structure to match ASBS sites with appropriate reference sites (Figure 1). Point contact (mainly sessile or sedentary organisms) and Quadrat data (mobile organisms) were evaluated using a PERMANOVA approach to compare communities between ASBS and reference sites after accounting for geography. Species Richness was assessed using ANOVA. For hypotheses 1-3 we set the critical p-value at 0.05 (null hypothesis not rejected unless $p<0.05$).

For hypothesis 4 we generated site similarity matrices (using Bray Curtis values) then calculated Mahalanobis distances using values from the two matrices. Mahalanobis distances are the distance from a multivariate centroid accounting for the covariance structure among variables. Small values indicate that that sample is similar to a hypothetical typical sample, while large distances indicate samples very different from the hypothetical typical sample. Prediction limits (of the Mahalanobis distance) were used to assess the likelihood of inclusion of samples. For example, an 80% prediction limit would contain 80% of samples drawn from a pool of samples coming from the same population. This differs from confidence limits, which are used to assess the inclusion likelihood of means of samples from a population.

Results

Sites sampled and site attributes – Sampling locations are shown in Figure 1. Description of site metadata and site characteristics are in tables 1 and 2 respectively.

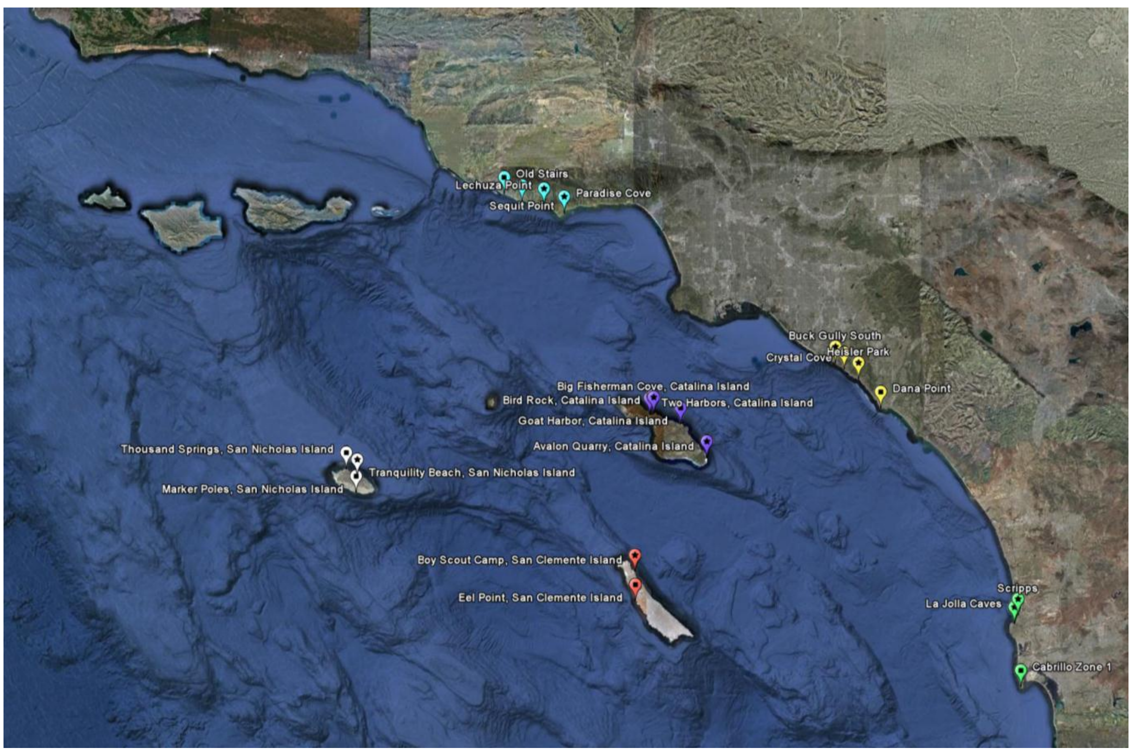

Figure 1: Map of sampling locations. Colors indicate geographic groups. Within each pointer the symbol represents site type: Star = Discharge site in ASBS, Square = reference site.

RB-AR 7078

1. **Primary Bench Type:** describes the dominant geology of the site
    a. **bedrock:** the primary bench type is consolidated bedrock at this site
    b. **bedrock/boulders:** the primary bench type is a mixture of consolidated bedrock and boulder fields at this site
    c. **bedrock/sand:** the primary bench type is a mixture of consolidated bedrock and sandy beach at this site
    d. **bedrock/boulders/sand:** the primary bench type is a mixture of consolidated bedrock, boulder fields, and sandy beach at this site
    e. **boulders:** the primary bench type is boulder fields at this site
2. **Slope:** describes the slope of the coastline at the site
    a. **0-5 degrees:** the slope of this site is between 0-5 degrees
    b. **5-15 degrees** the slope of this site is between 5-15 degrees
3. **Relief:** describes the rugosity of the site
    a. **high:** the relief of the site consists of extremely uneven terrain, containing many deep cracks and folds, such as in some mixed consolidated bedrock and boulder fields
    b. **moderate:** the relief of the site consists of moderately uneven terrain, containing few cracks and folds, such as in boulder or cobble fields and some consolidated bedrock
    c. **low:** the relief of the site consists of flat terrain, such as a sandy beach
4. **Extent:** describes the length of the intertidal area at the site, from the land to the ocean
    a. **long:** the extent of the site is greater than 15 meters
    b. **intermediate:** the extent of the site is between 5-15 meters
    c. **short:** the extent of the site is less than 5 meters
5. **Surrounding Coast:** describes the geology of the area surrounding the site
    a. **bedrock:** the surrounding coast is consolidated bedrock at this site
    b. **bedrock/boulders:** the surrounding coast is a mixture of consolidated bedrock and boulder fields at this site
    c. **bedrock/sand:** the surrounding coast is a mixture of consolidated bedrock and sandy beach at this site
    d. **bedrock/boulders/sand:** the surrounding coast is a mixture of consolidated bedrock, boulder fields, and sandy beach at this site
    e. **bedrock/boulders/cobble:** the surrounding coast is a mixture of consolidated bedrock, boulder fields, and cobble beach at this site
    f. **boulders/sand:** the surrounding coast is a mixture of boulder fields and sandy beach at this site
    g. **boulders/cobble/sand:** the surrounding coast is a mixture of boulder fields, cobble beach, and sandy beach at this site
    h. **boulders:** the surrounding coast is boulder fields at this site
    i. **sand:** the surrounding coast is sandy beach at this site
6. **Species Richness:** a count of the total number of species found at a given site, using existing protocols.

RB-AR 7081

Species Richness Analysis

There was no effect on species richness that was associated with geographic grouping, Site Type or interaction between Site Type and Geographic Group (see table 2) indicating no difference between ASBS discharge and reference sites (Table 3 and Figure 2).

Analysis of Variance - Species Richness					
Source	Type III SS	df	Mean Squares	F-Ratio	p-Value

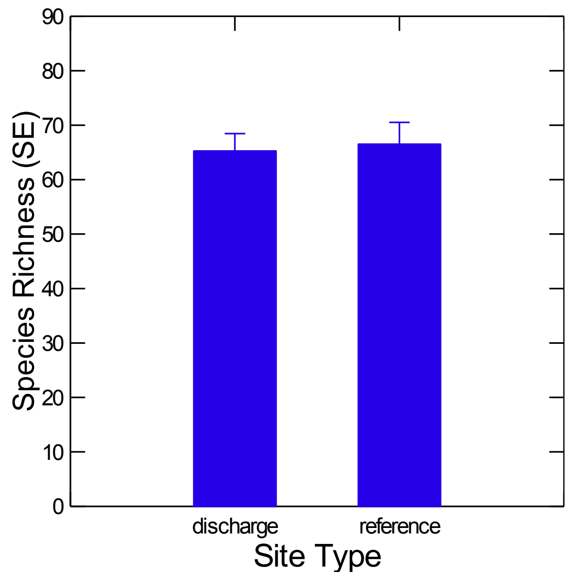
Error	846.16667	8	105.770833		

Table 3: ANOVA results for species richness.



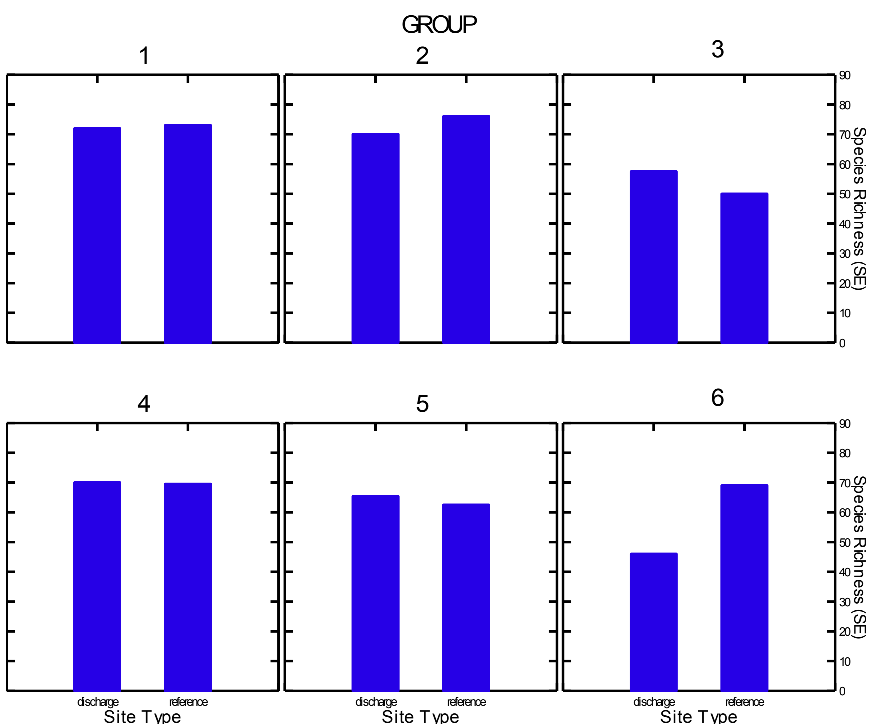


Figure 2: Top – Species richness as a function of site type. Bottom – Species richness as a function of geographic group and site type.

Community composition of sessile species

There was a large effect of geography (Gr=Group), which reflects the biogeography of the bight. There was no significant effect of either Site Type (Si) or any evidence of an interaction between Site Type and Group, indicating no difference between ASBS discharge and reference sites (Table 4, Figure 3). The results are shown below in the PERMANOVA table and MDS plot. (Groups are shown as numbers).

Table 5: PERMANOVA table for effect of site type and geographic group on the community composition of mobile species.

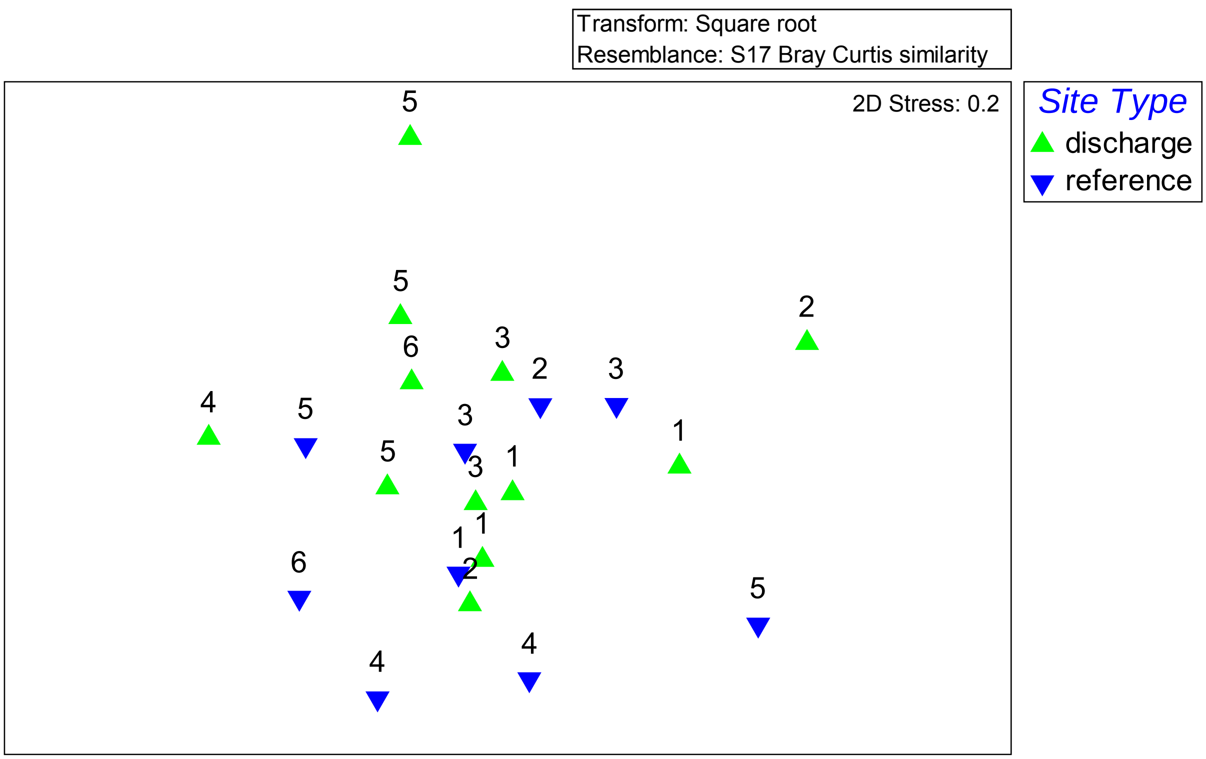

Figure 4: Multidimensional Scaling (MDS) figure for mobile species community composition. Numbers indicate geographic group.

While the PERMANOVA and MDS results are useful in a statistical assessment of the effect of discharges on intertidal communities, they don't convey information about the communities. Figures and tables showing species abundances are in APPENDIX 1 and 2.

An integrated assessment of both mobile and sessile species

In order to assess the relationships among sites when mobile and sedentary species were jointly considered, we calculated the prediction limit on site specific Mahalanobis distances (Figure 5). Two prediction limits are shown: 80 and 95%. Two sites, La Jolla Caves and Lechuza Point exceed the 95% prediction limit. An additional two sites, Avalon Quarry and Crystal Cove, exceed the 80% prediction limit. All four sites are discharge sites (ASBS).

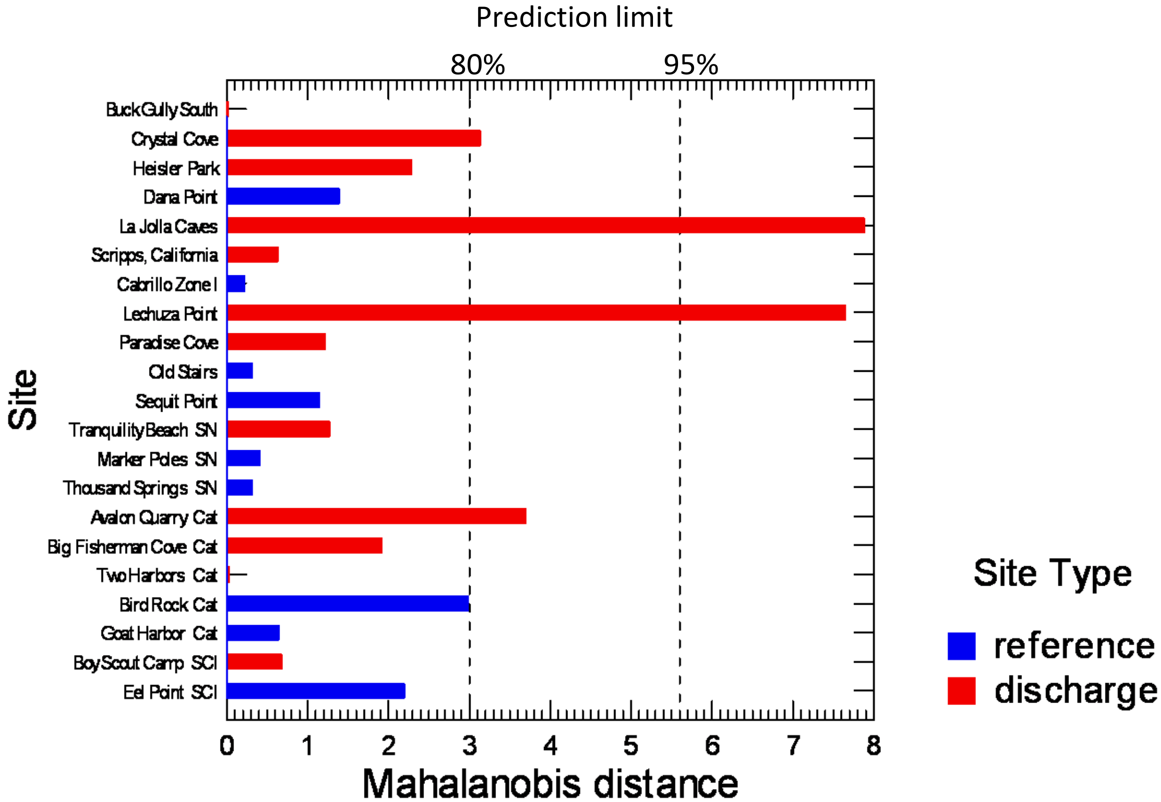

Figure 5: Mahalanobis distances for all sample sites. 80% and 95% prediction limits are also shown.

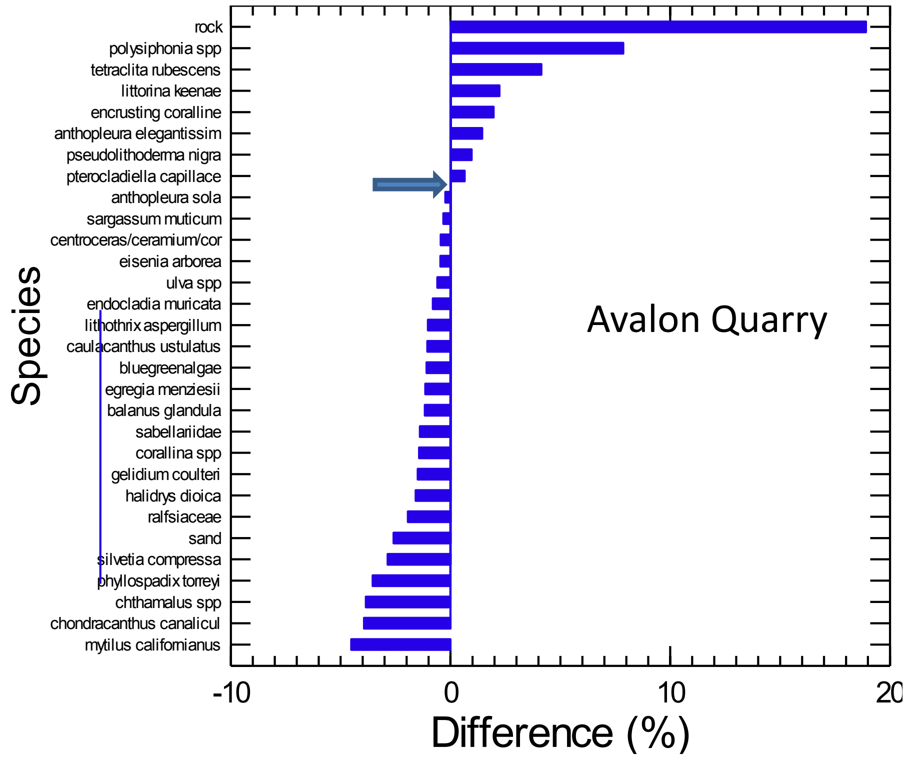
There is no way to specifically attribute the differences at these four sites to the effects of the discharge, however these results clearly indicate that the biological communities at these sites are different from that expected based on the regional analysis. Further analysis and field assays may help clarify the cause of these differences. In the figures shown below (Figures 6-9 and in appendix 1) the source of the differences can be seen. In these figures the biological communities at the four sites that exceeded the 80% prediction limit are compared to the 'expected' biological community, represented by the average across all sites.

There are several general points that can be made based on results.

(1) For all four sites and types of organisms (sessile, mobile) more species have below average than above average abundances.
(2) Avalon Quarry has a relatively impoverished biological community (particularly for mobile species) that is indicative of high levels of disturbance or impairment.

(3) Crystal Cove's sessile community is representative of an established bedrock community, although there is a high cover of the invasive species *Caulicanthus*. By contrast the mobile community is impoverished.
(4) La Jolla Caves is relatively species poor site. It's biological community is dominated by 'disturbance tolerant" species, which is an indication of natural or anthropogenic disturbance. It also has high representation of invasive species (*Sargassum and Caulicanthus*).
(5) Lechuza's community is characteristic of a sand influenced site with intermittent emergent rock



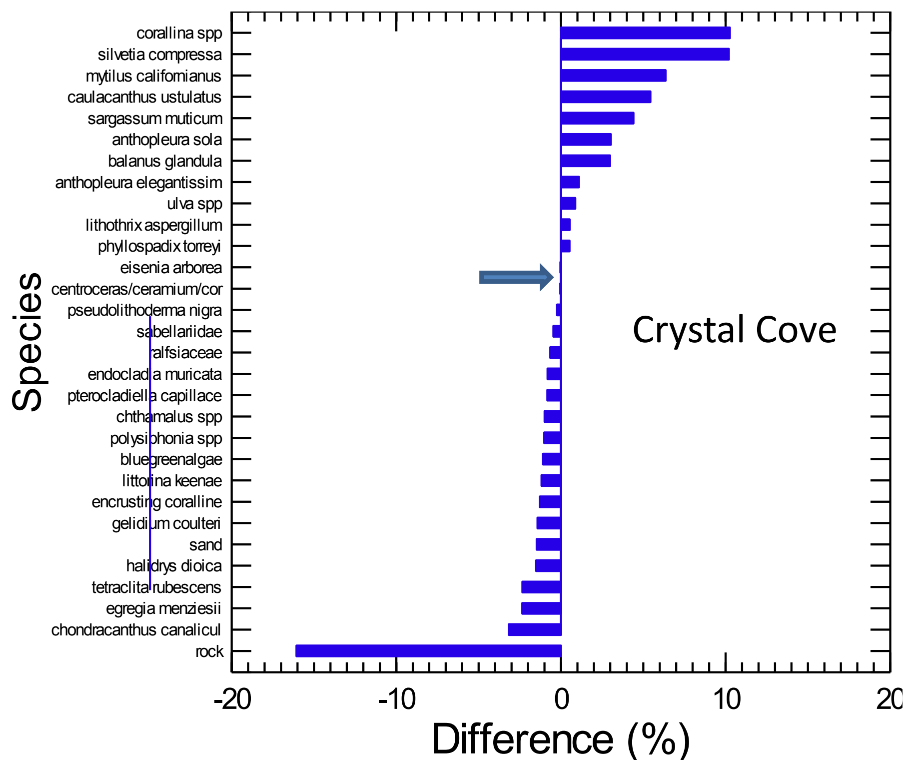


Figure 6: Differences in percent cover between specific sites (labeled) and expected values based on averages across all sites. Arrow indicates the transition between positive and negative differences.

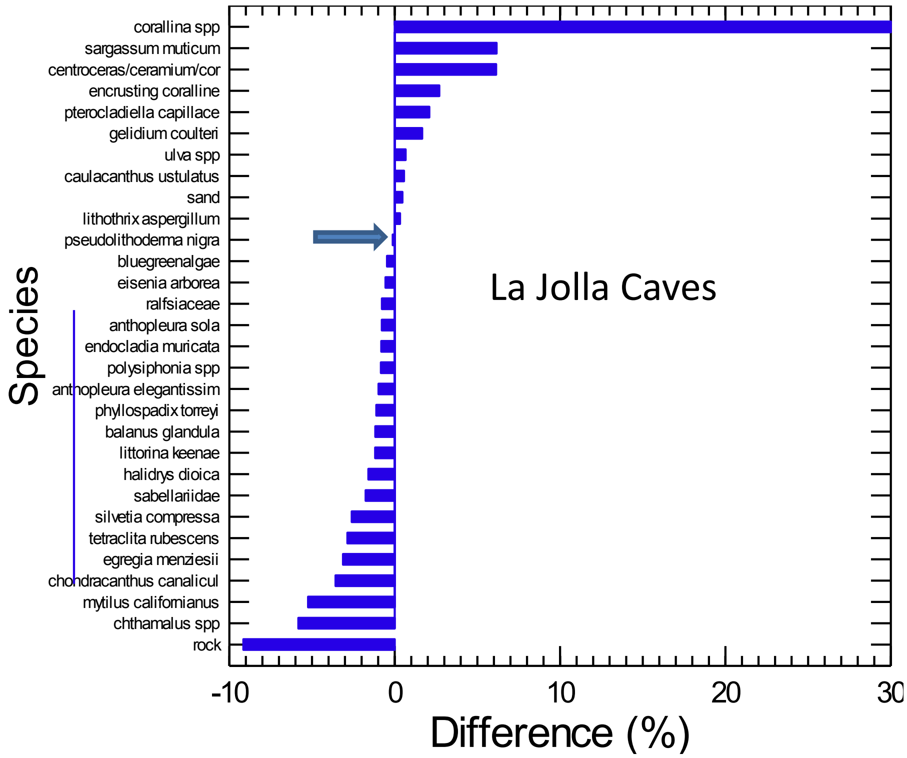

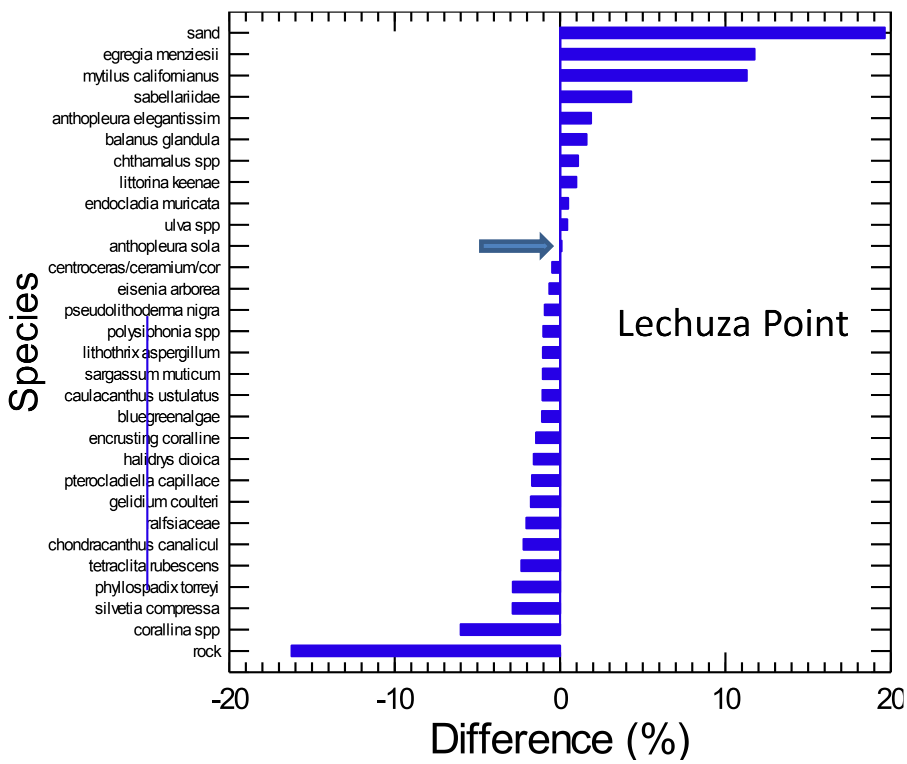

Figure 7: Differences in percent cover between specific sites (labeled) and expected values based on averages across all sites. Arrow indicates the transition between positive and negative differences.

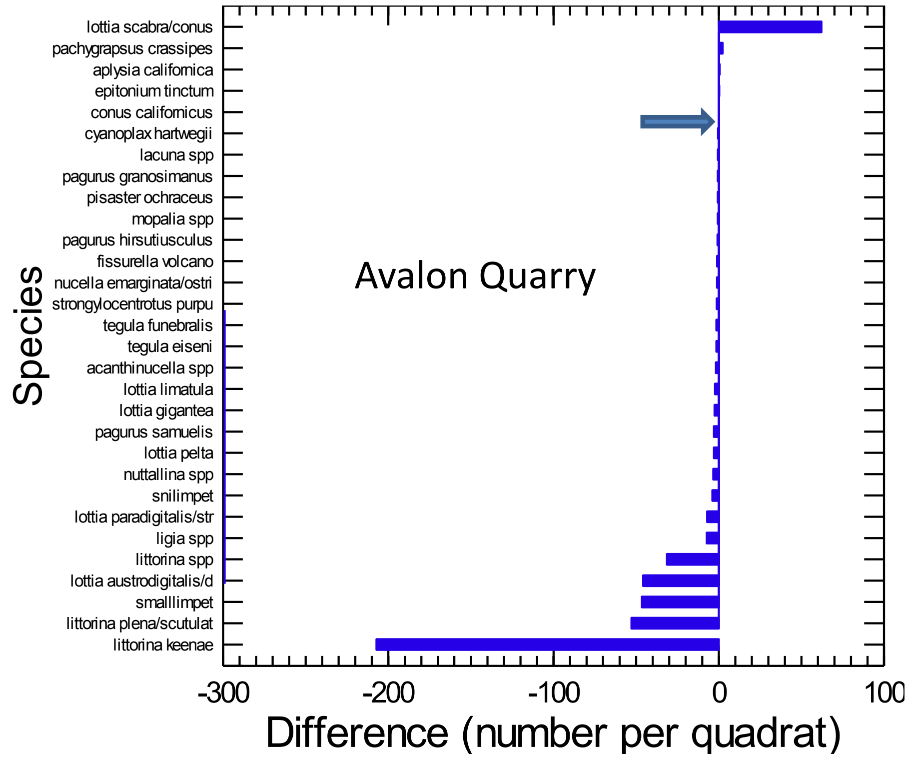

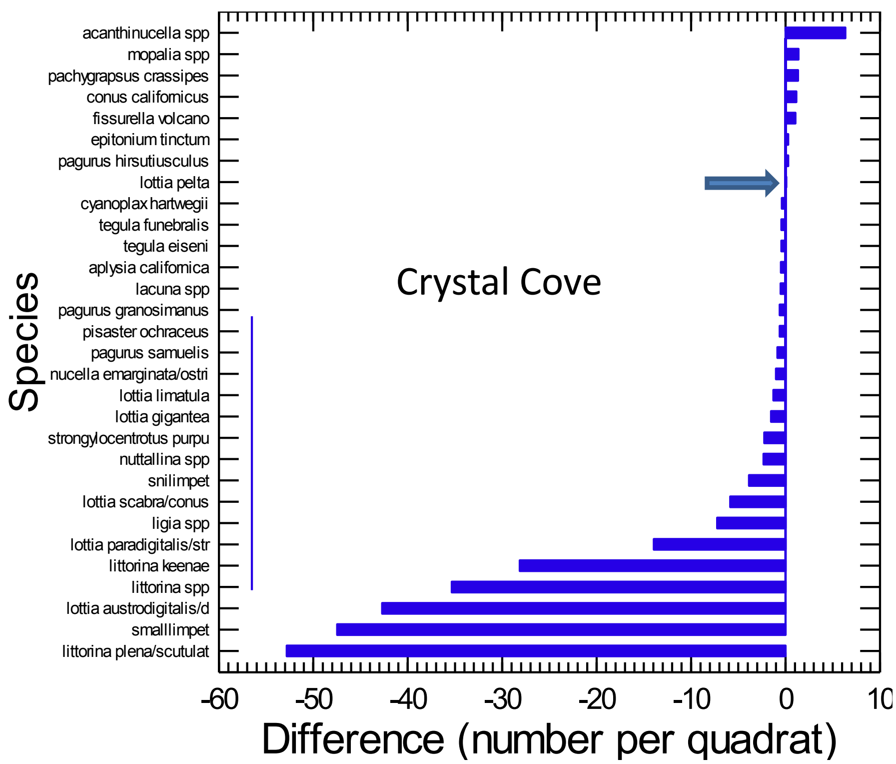

Figure 8: Differences in counts per quadrat between specific sites (labeled) and expected values based on averages across all sites. Arrow indicates the transition between positive and negative differences.

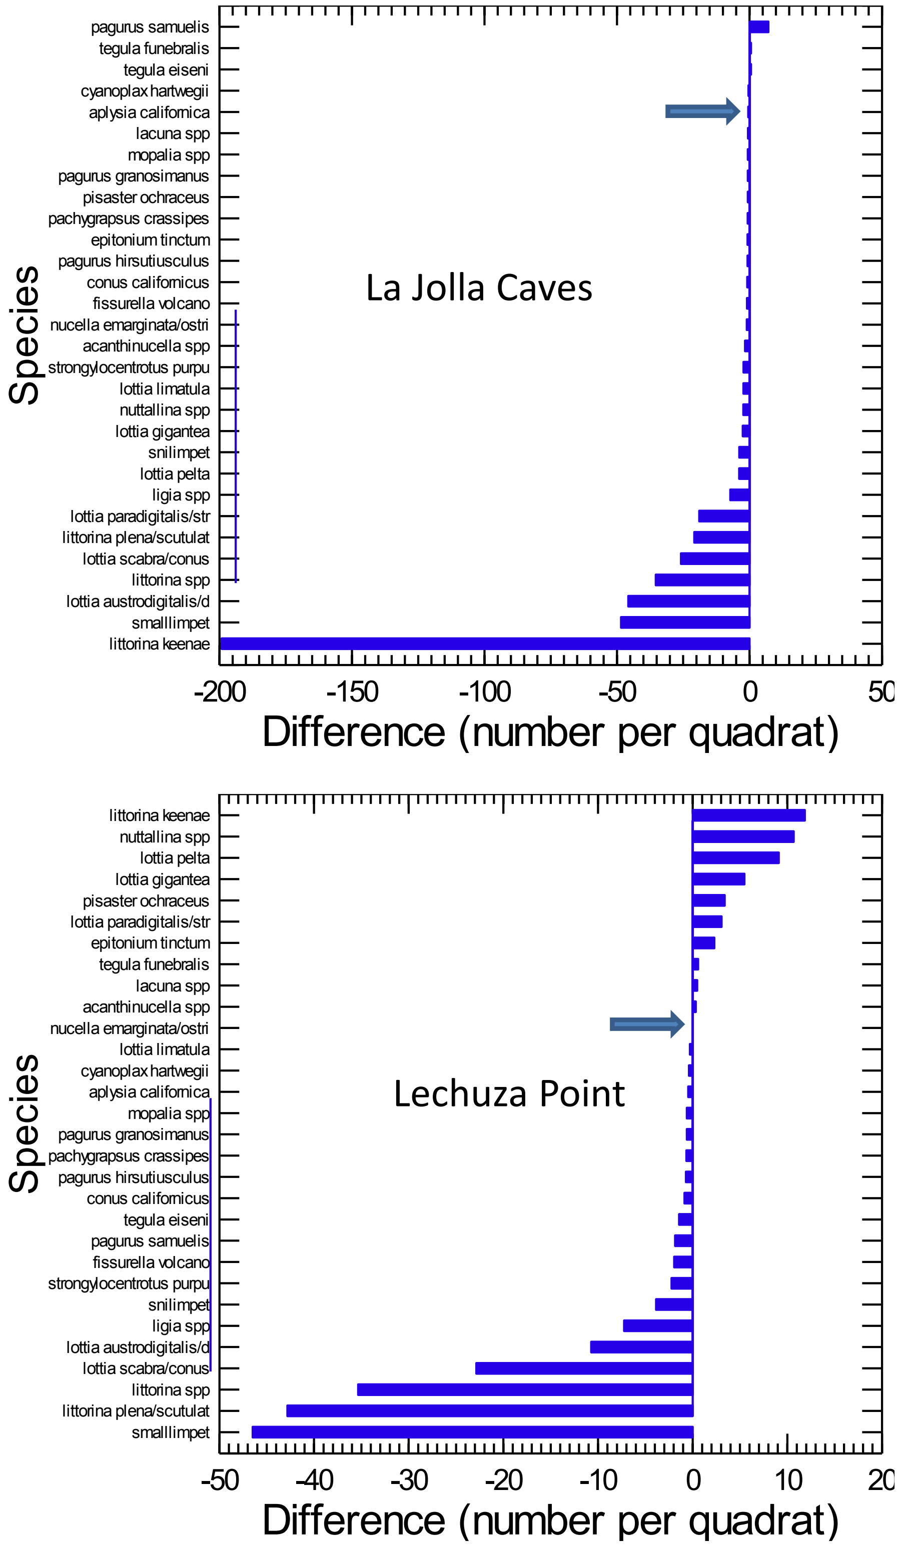

Figure 9: Differences in counts per quadrat between specific sites (labeled) and expected values based on averages across all sites. Arrow indicates the transition between positive and negative differences.

Discussion

There are many natural local (site scale) drivers of community structure including rock type, bedding orientation, sand influence, orientation of the rock surface to the prevailing swell direction, local swell height and period and upwelling. There are also many local human-induced drivers of community structure that do not involve discharges. These include collecting, trampling and non-point source pollution. The integration of these factors is the background driver of community structure against which the effect of discharge is measured. In this study we used a sampling program designed to minimize this integrated driver. We found that that there was no general difference in species richness or biological communities at discharge versus reference sites. This was also true when accounting for biogeographic differences present in the southern California Bight. These results strongly support the idea that there is no common impact associated with discharges. In part, this is consistent with earlier work (Blanchette, Raimondi, Littler), which showed considerable spatial variability in the biological communities in this region. The figures in Appendix 2 also show the tremendous spatial variability among biological communities.

While there was no indication of a general and similar impact of discharges on biological communities there was an indication that specific locations might be affected by compromised water quality. Using an analytical approach designed to assess site specific effects, we found that four sites exceeded the 80% prediction limit and 2 exceeded the 95% limit for community similarity (Figure 5). This means that they were substantially different from what would be expected based on all the rest of the sites. All 4 sites were associated with discharges and each characterized with lower than expected abundances of both mobile and sessile species as well as species composition different from expected. One has to be cautious in interpreting results of any community assessment, particularly when they come from surveys rather than experiments. No matter how carefully a survey is designed, there is no way to completely control for the contributions of extraneous factors. In such situations it is often useful to examine the details of the results to look for consistencies or deviations from patterns that would be expected under the posed hypothesis.

In this study we can look at the species composition associated with the four sites that differ from the expected species composition. The general question is whether the biological community is affected by discharge of water and associated components. Given a difference then specific expectations need to be evaluated. Here the specific expectations consistent with an impact due to compromised water quality are (Arevelo et al. 2007, Pineda et al. 2007):

1) Generally decreased abundance of species compared to reference areas. This expectation is true for all four sites
2) Communities characterized by disturbance associated species. This is true for Avalon Quarry, La Jolla Caves and Lechuza Point.
3) Of those communities characterized by disturbance associated species, there should be no other obvious of the pattern of species. This is true for Avalon Quarry and La Jolla Caves. By contrast, Lechuza Point has considerable sand influence, which is a clear driver of disturbance associated communities.

Based on the match between pattern and expectations, we can conclude that Avalon Quarry and La Jolla Caves are sites that are possibly affected by compromised water quality associated with discharges.

In addition to biological information collected from discharge and reference sites, water quality has been recently sampled as part of an ongoing program at The Southern California Coastal Water Research Project (SCCWRP). Results of this sampling relevant to this study are listed below:

1) Like biological communities, water quality near ASBS discharges following storm event was similar to the water quality observed near discharges at reference sites, no laboratory toxicity was observed any ASBS following storm events.
2) Lechuza Point is located in ASBS 25; while no water quality information was collected specifically near Lechuza Point discharge, water quality in ASBS 25 exceeded reference-based thresholds in 35% of the analyses conducted.
3) La Jolla Caves is located in ASBS 29; while no water quality information was collected specifically near La Jolla Caves discharge, water quality in ASBS 29 exceeded reference-based thresholds in 5% of the analyses conducted.
4) Crystal Cove is located in ASBS 33; water quality information was collected near Crystal Cove discharge, water quality in ASBS 25 exceeded reference-based thresholds in 15% of the analyses conducted.
5) No water quality information is available for Avalon Quarry

In summary, this project provided the first condition report for the rocky intertidal zone in Southern California Areas of Special Biological Significance and serves as a good trigger for focused additional work. In particular we recommend that water quality assessments be made concurrently with biological sampling at the discharge and reference areas for the Avalon Quarry and La Jolla Caves. Such additional and spatially explicit sampling should allow a more robust determination of the likelihood that discharge related impacts “hinder the ability of marine life to respond to natural cycles and processes” which by definition would be not be protective of the beneficial use of these areas.

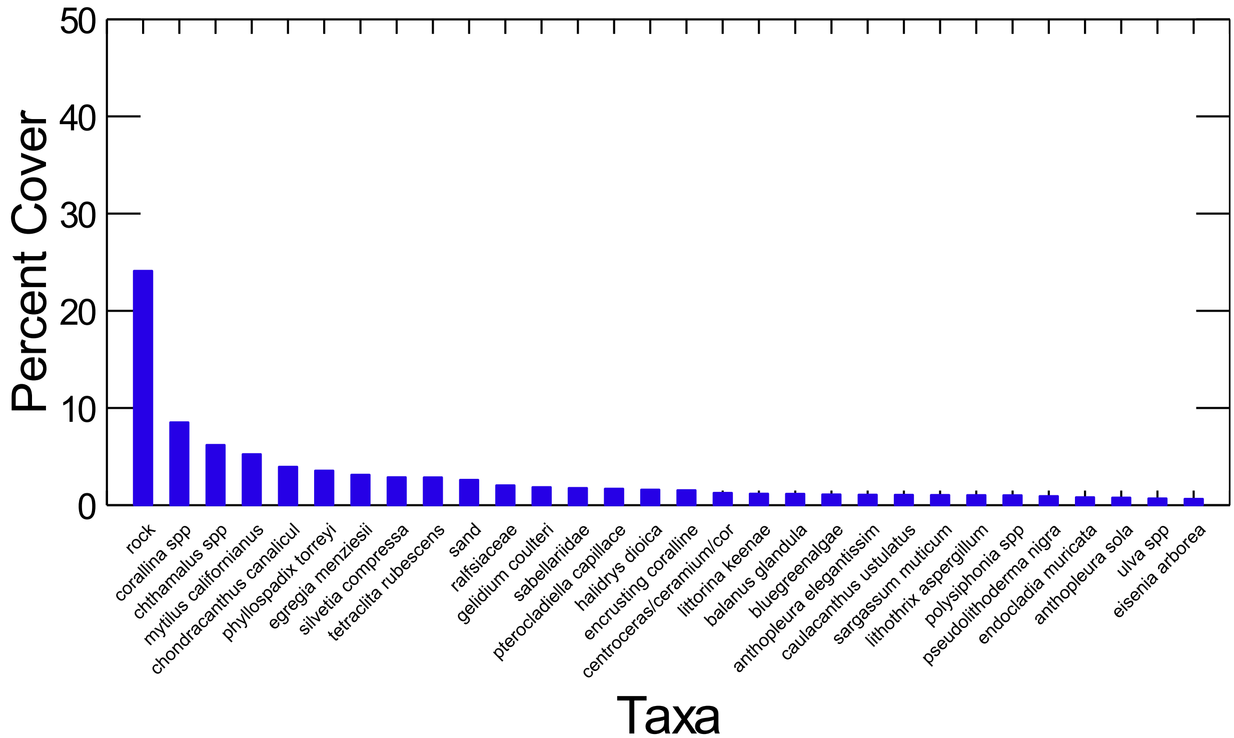
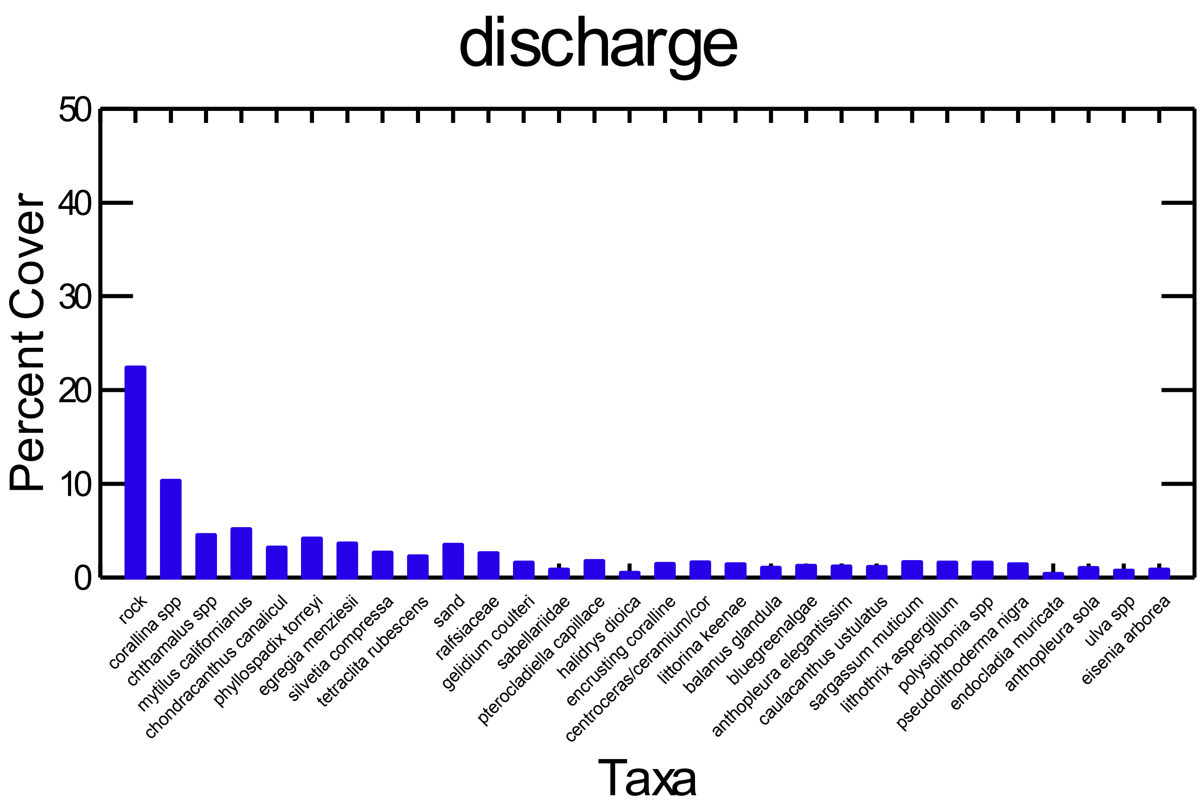
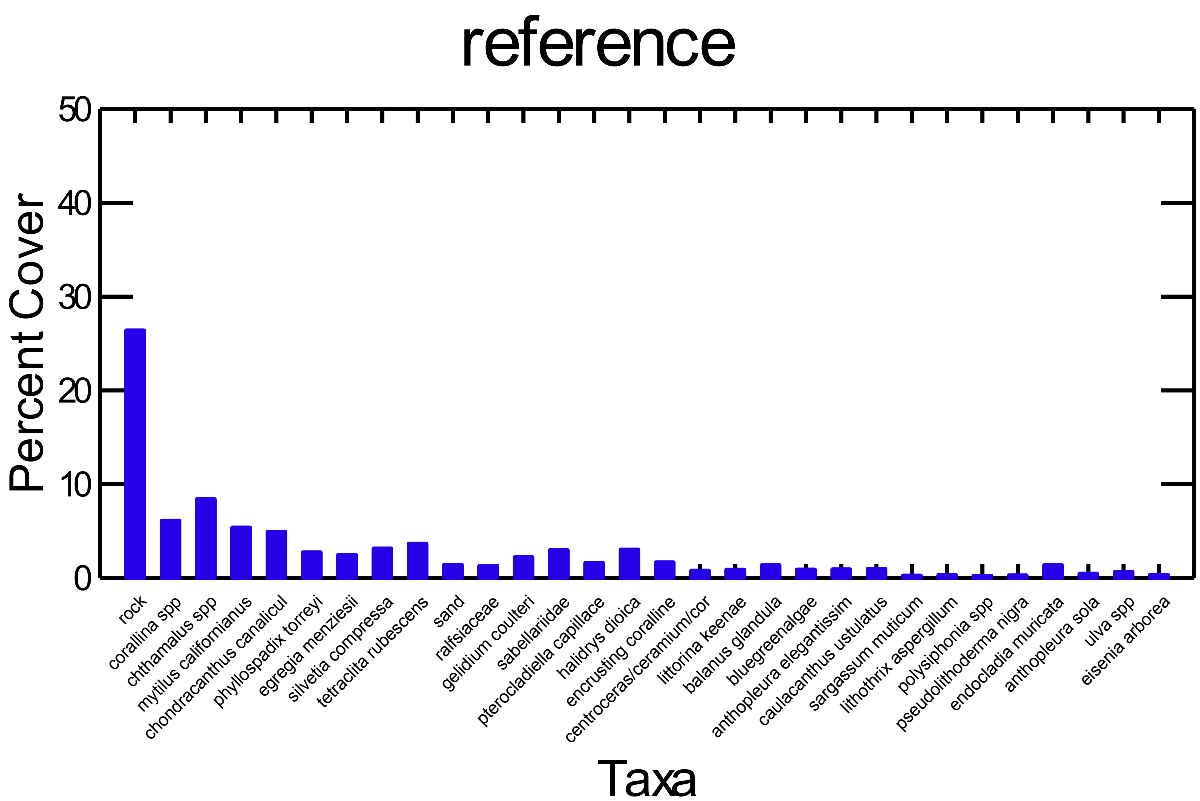
Appendix 1: additional figures

All sites – Point Contact (most common species)

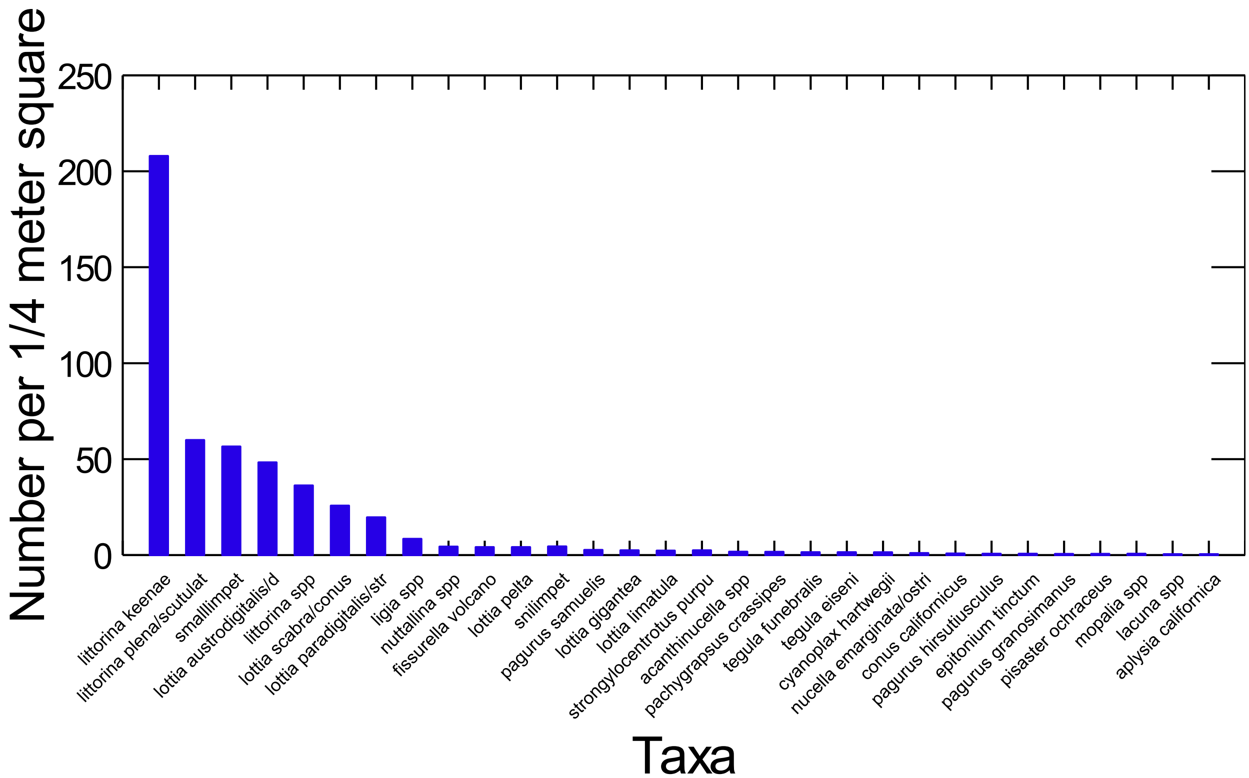


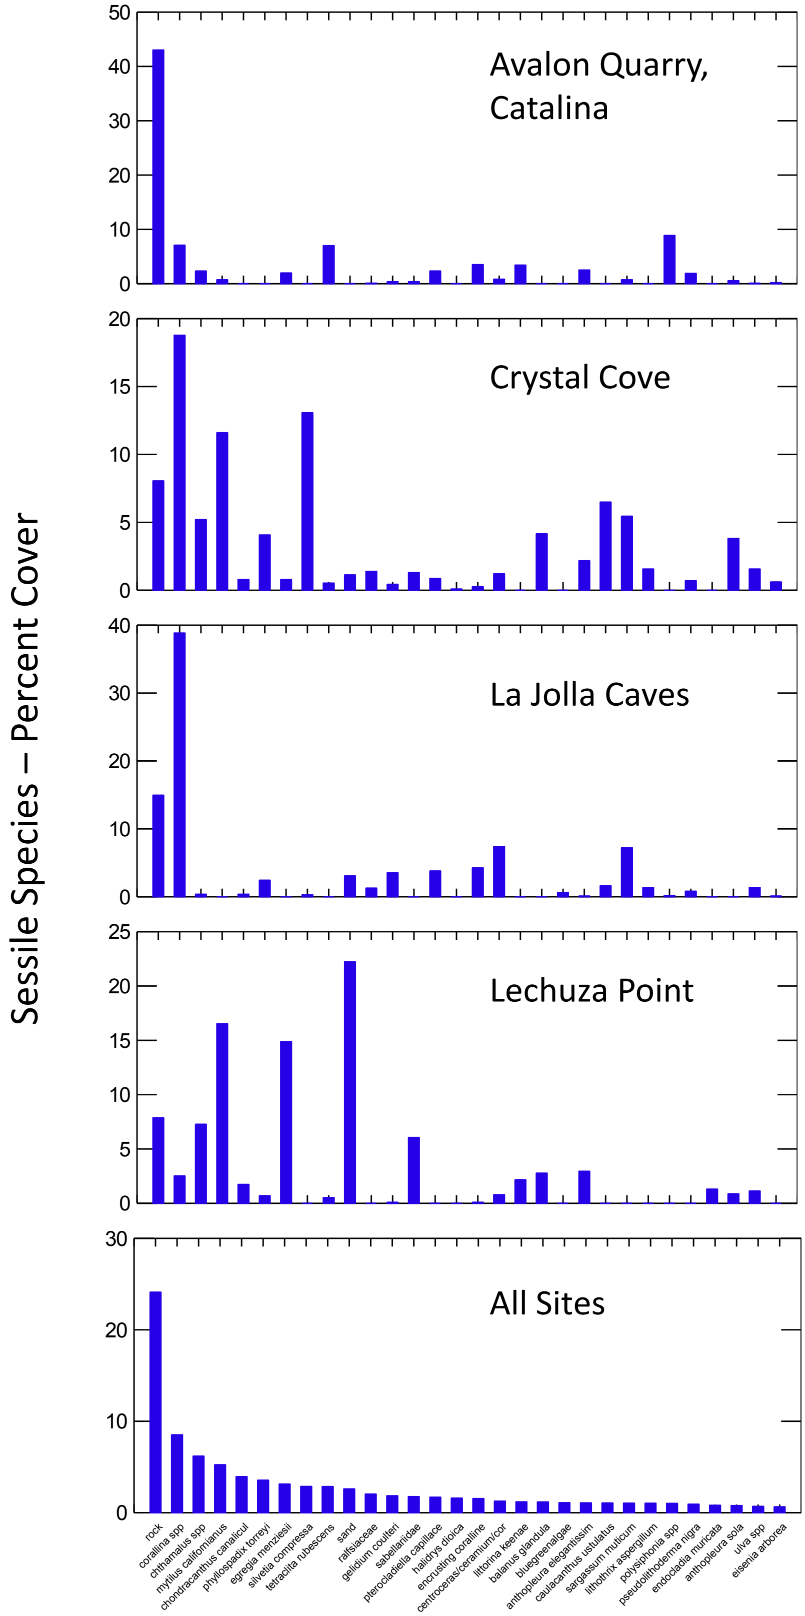
Across all sites – Point Contact (most common species)



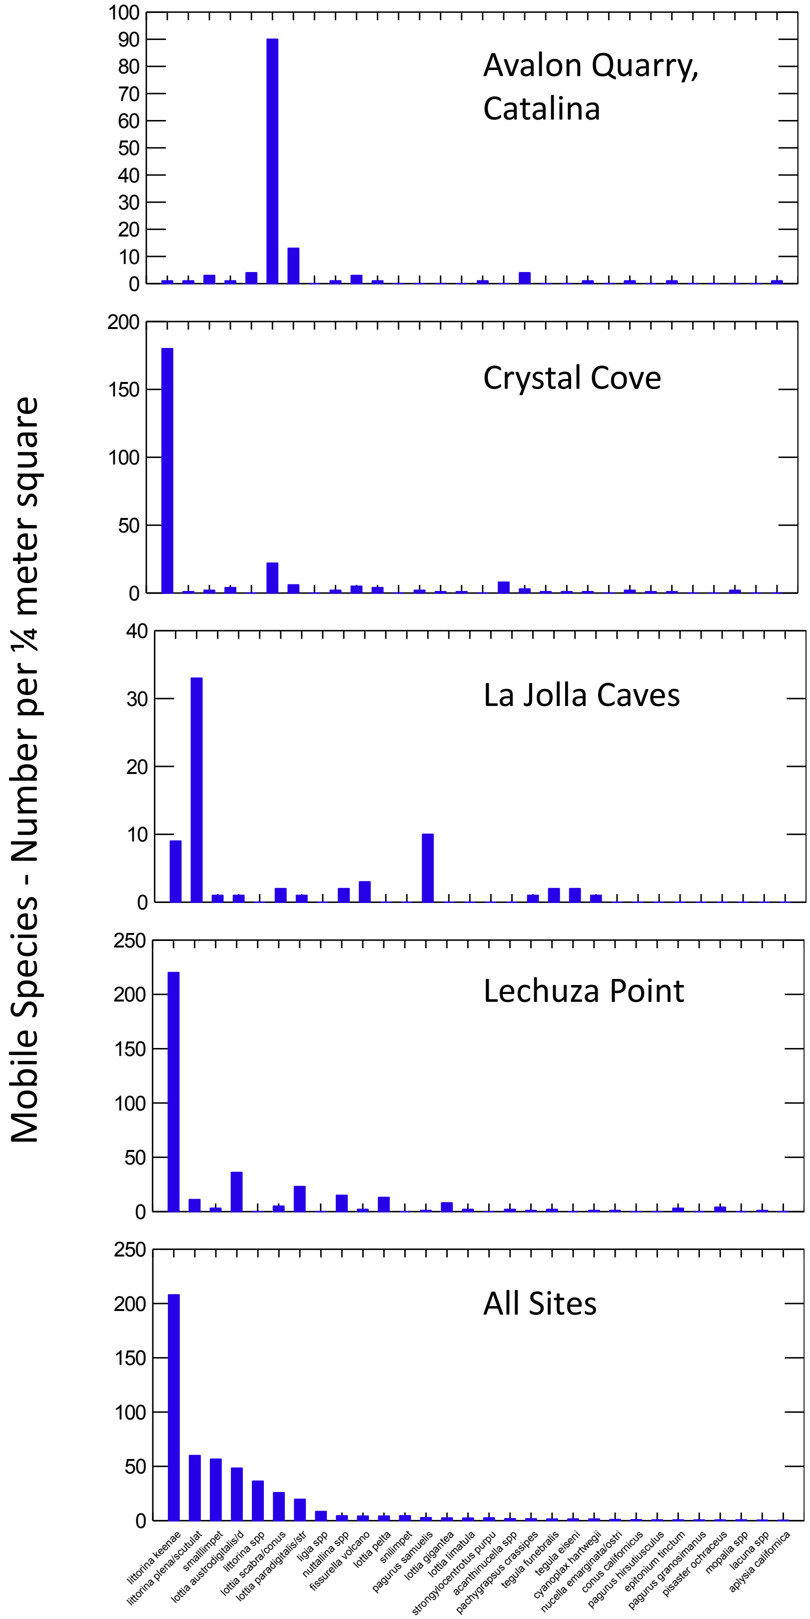


All sites – Mobile Species (most common species)





Percent cover of the most common sessile species across all sites and at the four sites that exceeded the prediction limit (Figure 5). Note differences in scale.



Density of most common mobile species across all sites and at the four sites that exceeded the prediction limit (Figure 5). Note differences in scale.

Appendix 2: Site locations, descriptions, pictures and site specific cover and density of species

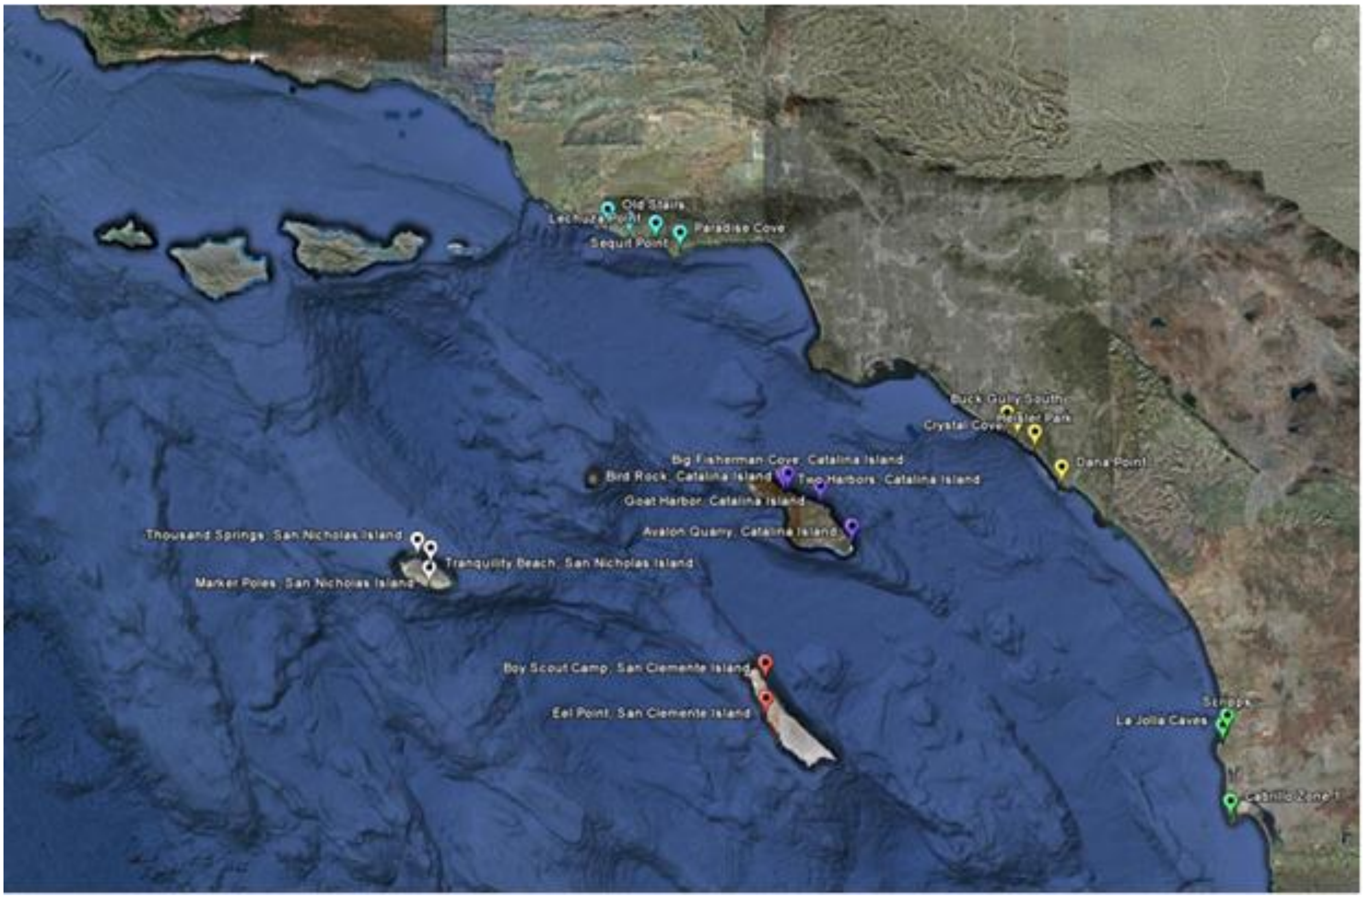


Figure A2-1: locations of ASBS and reference sites

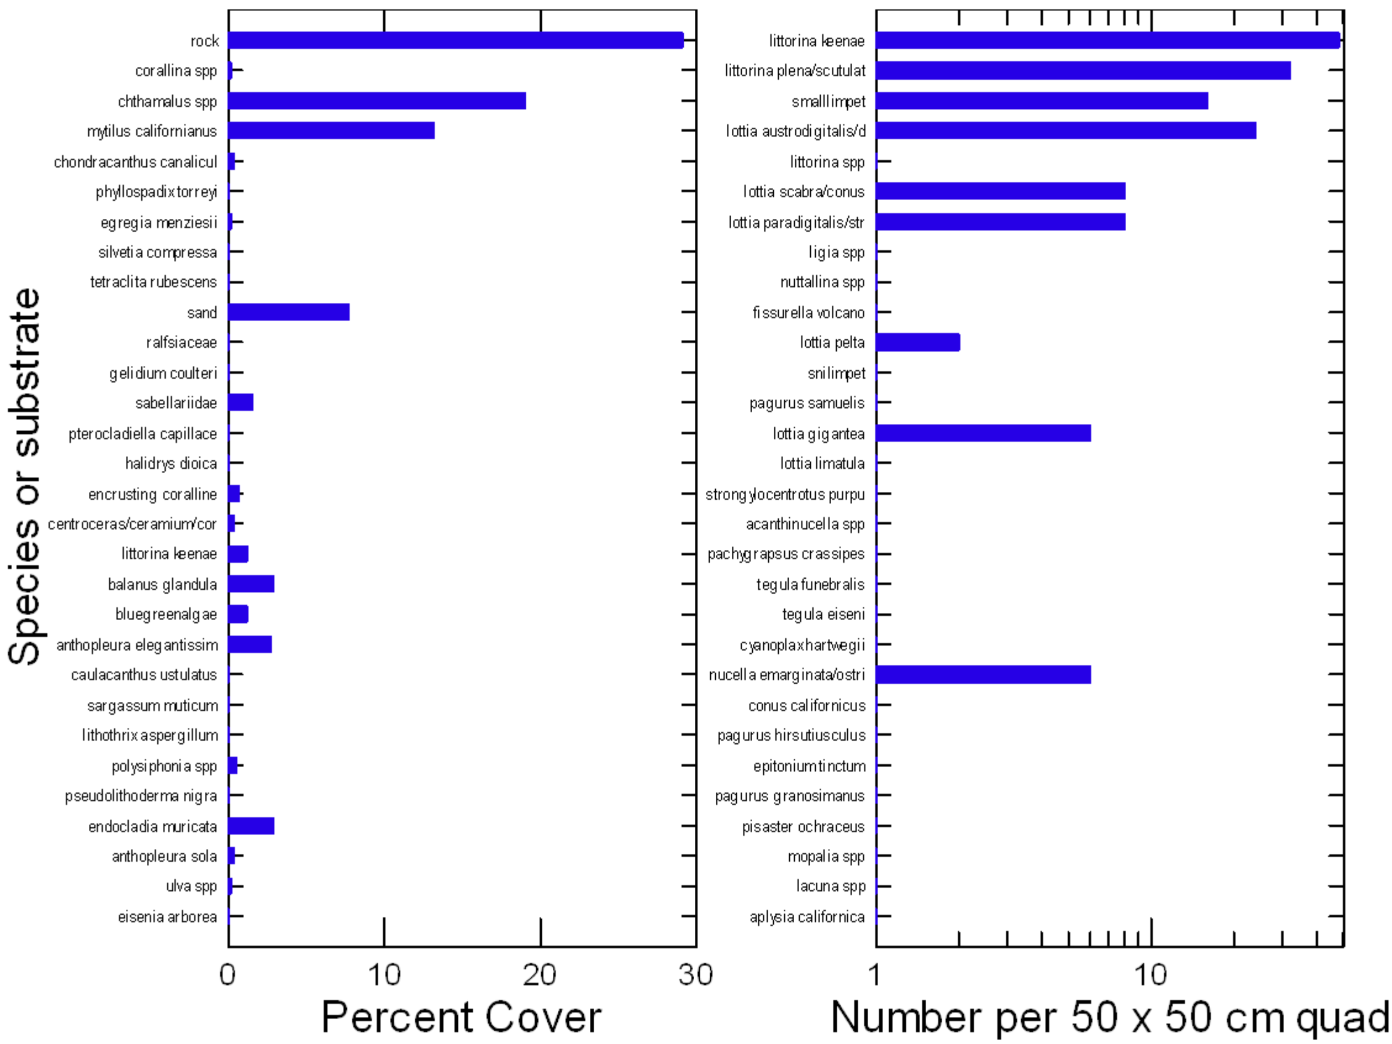
Magu Lagoon to Latigo Point

★ Discharge site in ASBS
■ Reference Site

Old Stairs is comprised of bedrock, boulders and sand with moderate relief. The surrounding coast is made up of boulders and sand. The survey area is divided into two sections. The up coast section is 6 meters wide and 20meters long.

The downcoast section is 21meters wide and 20meters long.

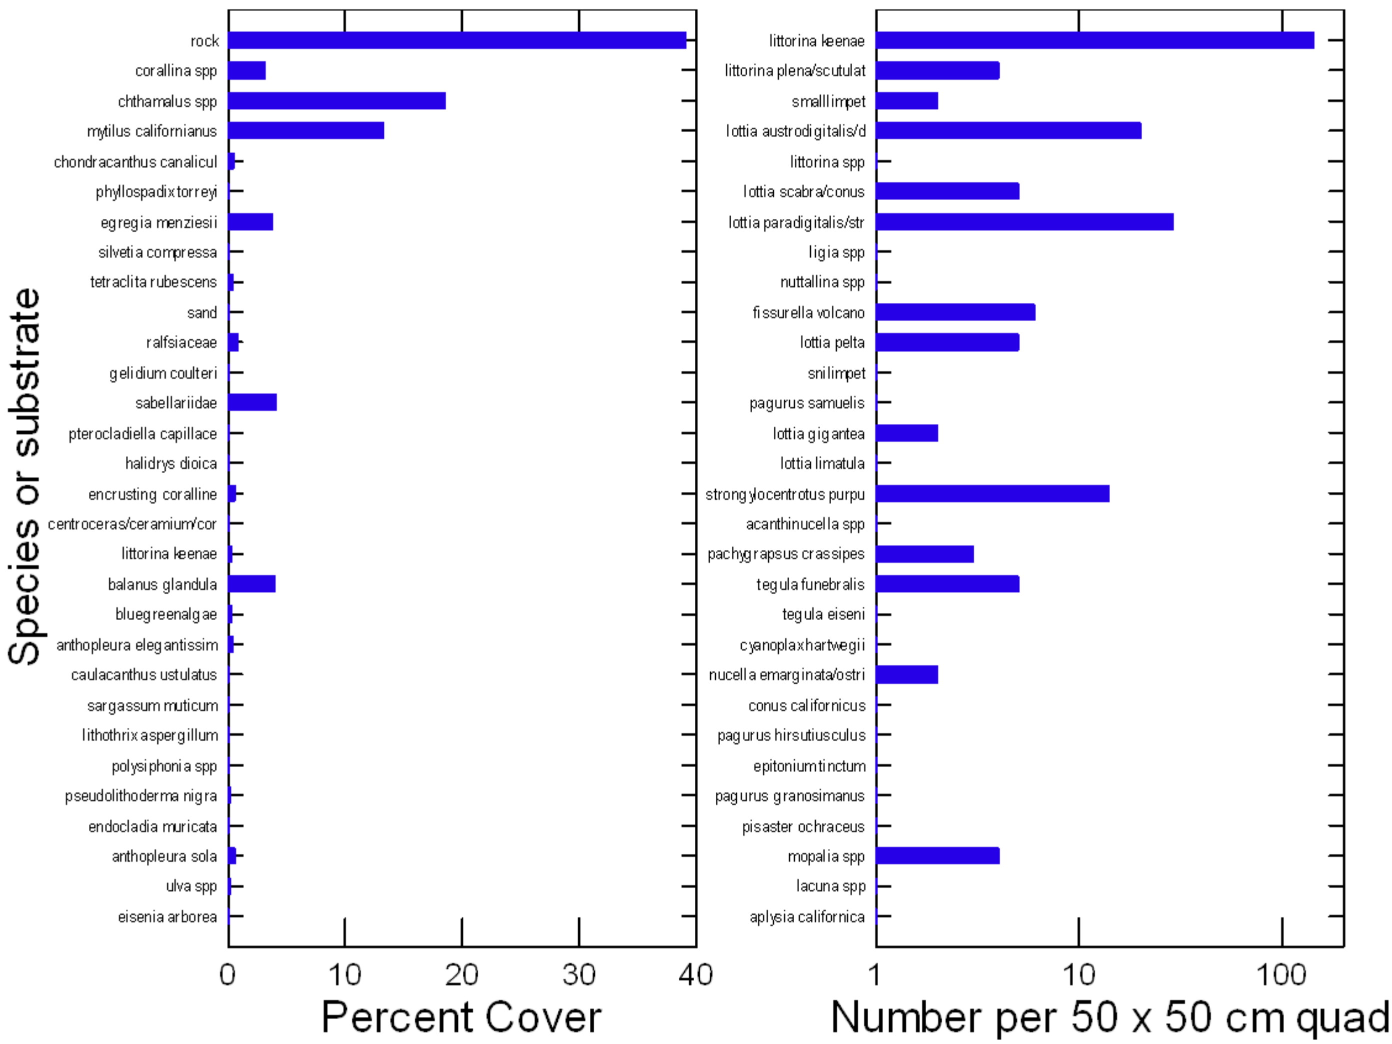
Old Stairs



Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

Sequit Point is comprised of bedrock with moderate relief. The surrounding coast is made up of bedrock, boulders and sand. The survey area is 20meters wide and 25meters long.

Sequit Point



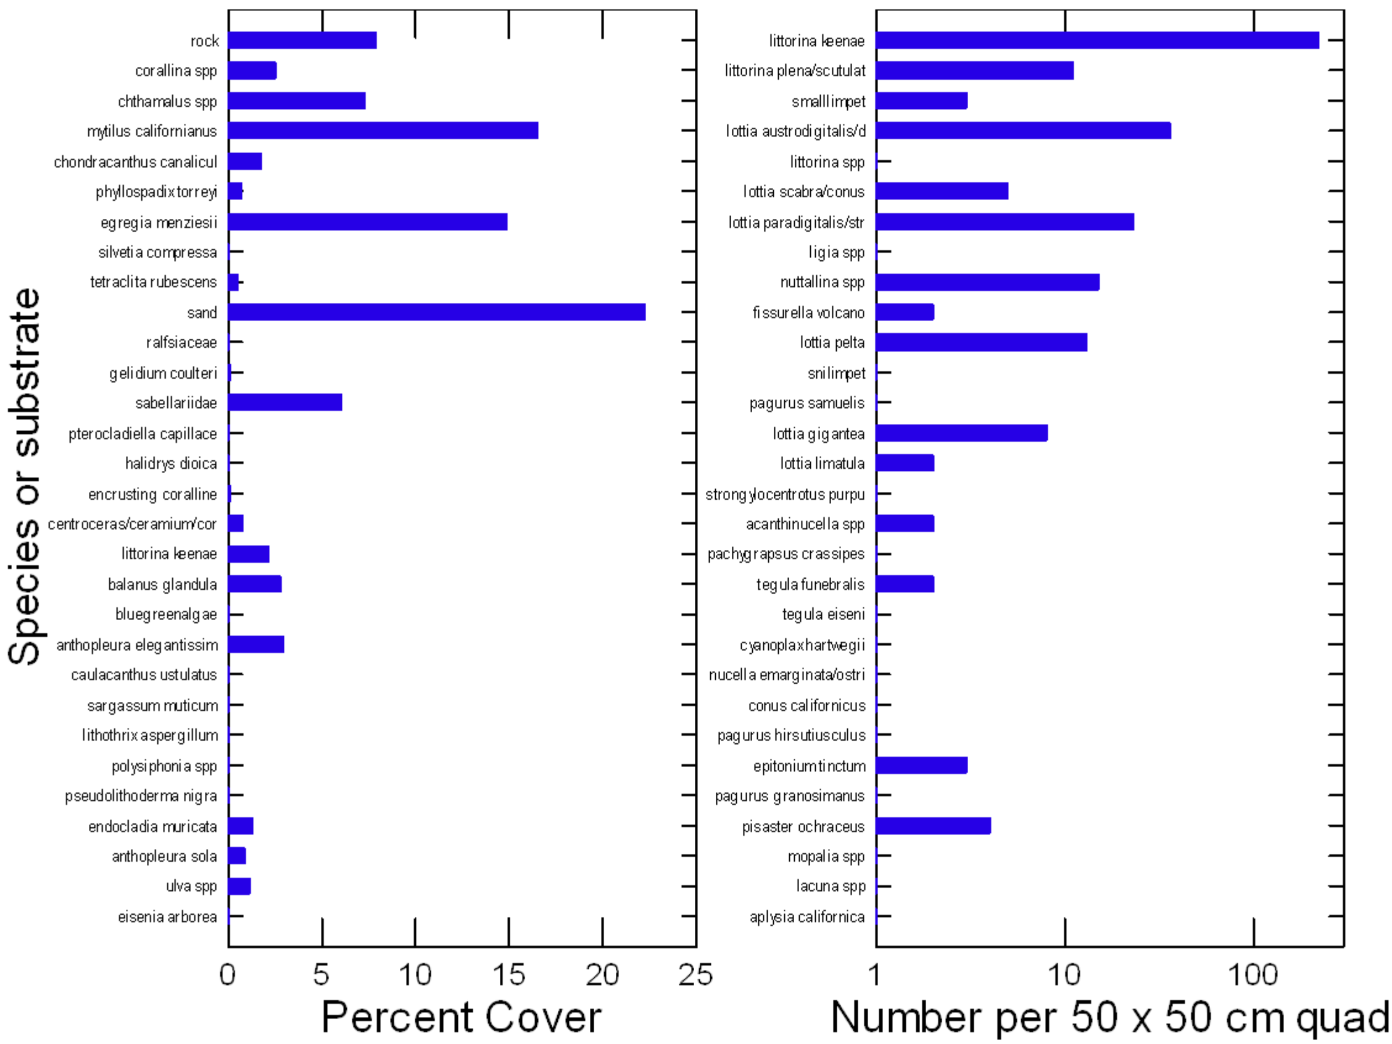
Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

Lechuza Point is comprised of bedrock and sand with moderate relief. The surrounding coast is made up of bedrock and sand. The survey area is divided into two sections. The upcoast section is 14meters wide and 45meters long. The biological community at this site differs from that expected based on other sites in the region. It is likely that this is due to the influence of sand burial and scour at the site.

The downcoast section is 4meters wide and 30meters long.

The nearest storm water discharge pipe is 25meters from survey bolt OT1.

Lechuza Point

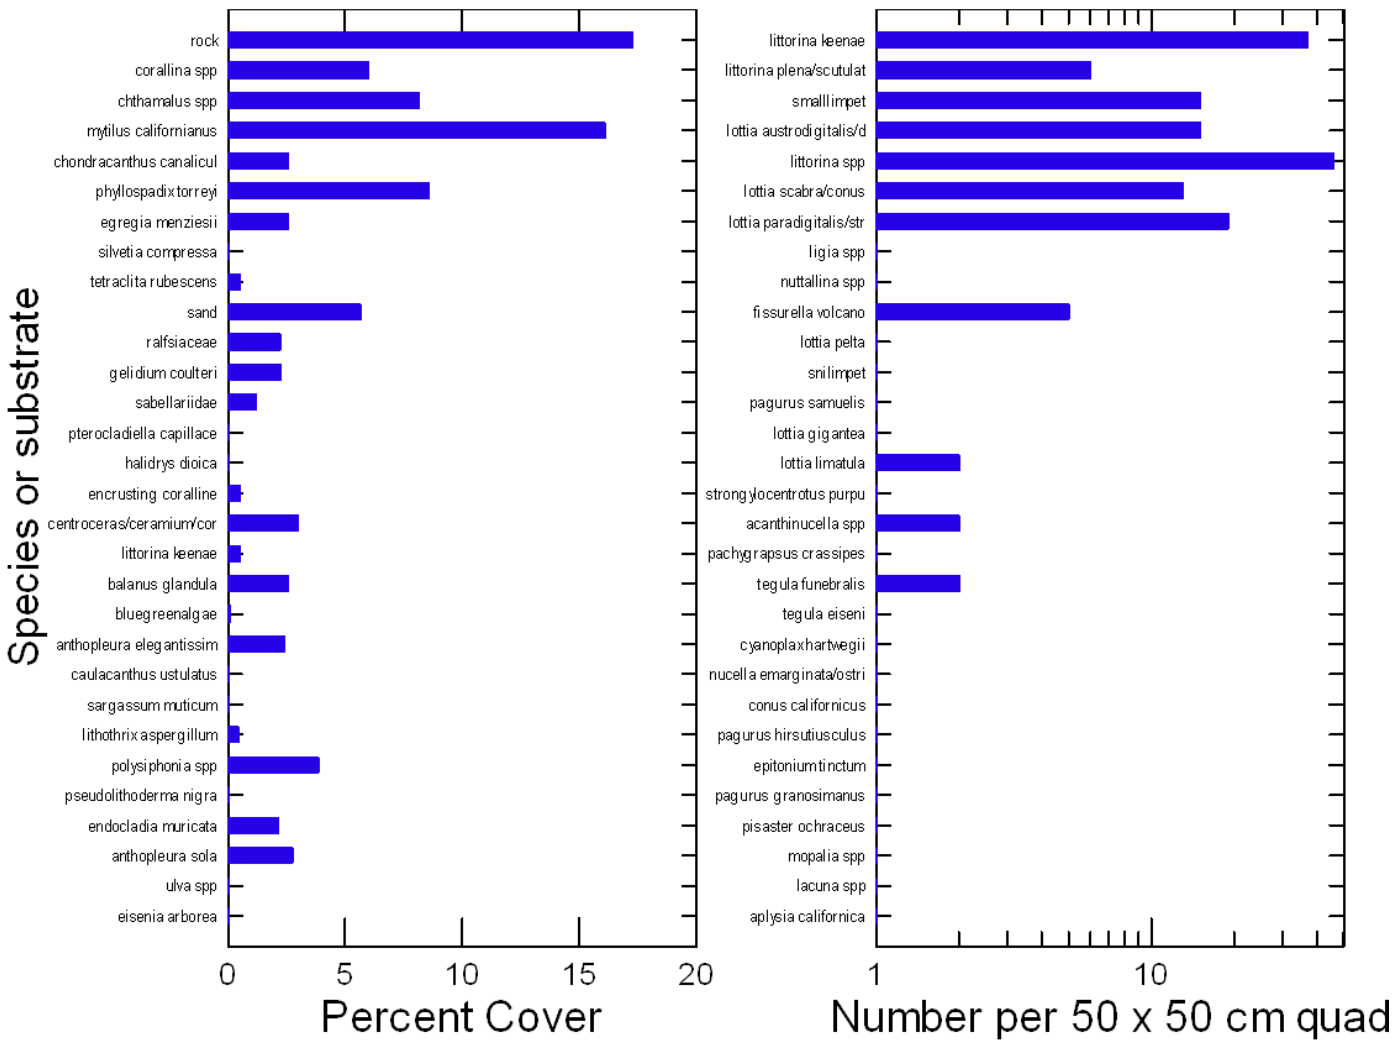


Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

Paradise Cove is comprised of bedrock and sand with low relief. The surrounding coast is made up of sand. The survey area is divided into two sections. The upcoast section is 12meters wide and 10meters long. The downcoast section is 15meters wide and 10meters long.

The nearest storm water discharge pipe (MUG379) is approximately 20meters from survey bolt R2.

Paradise Cove



Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

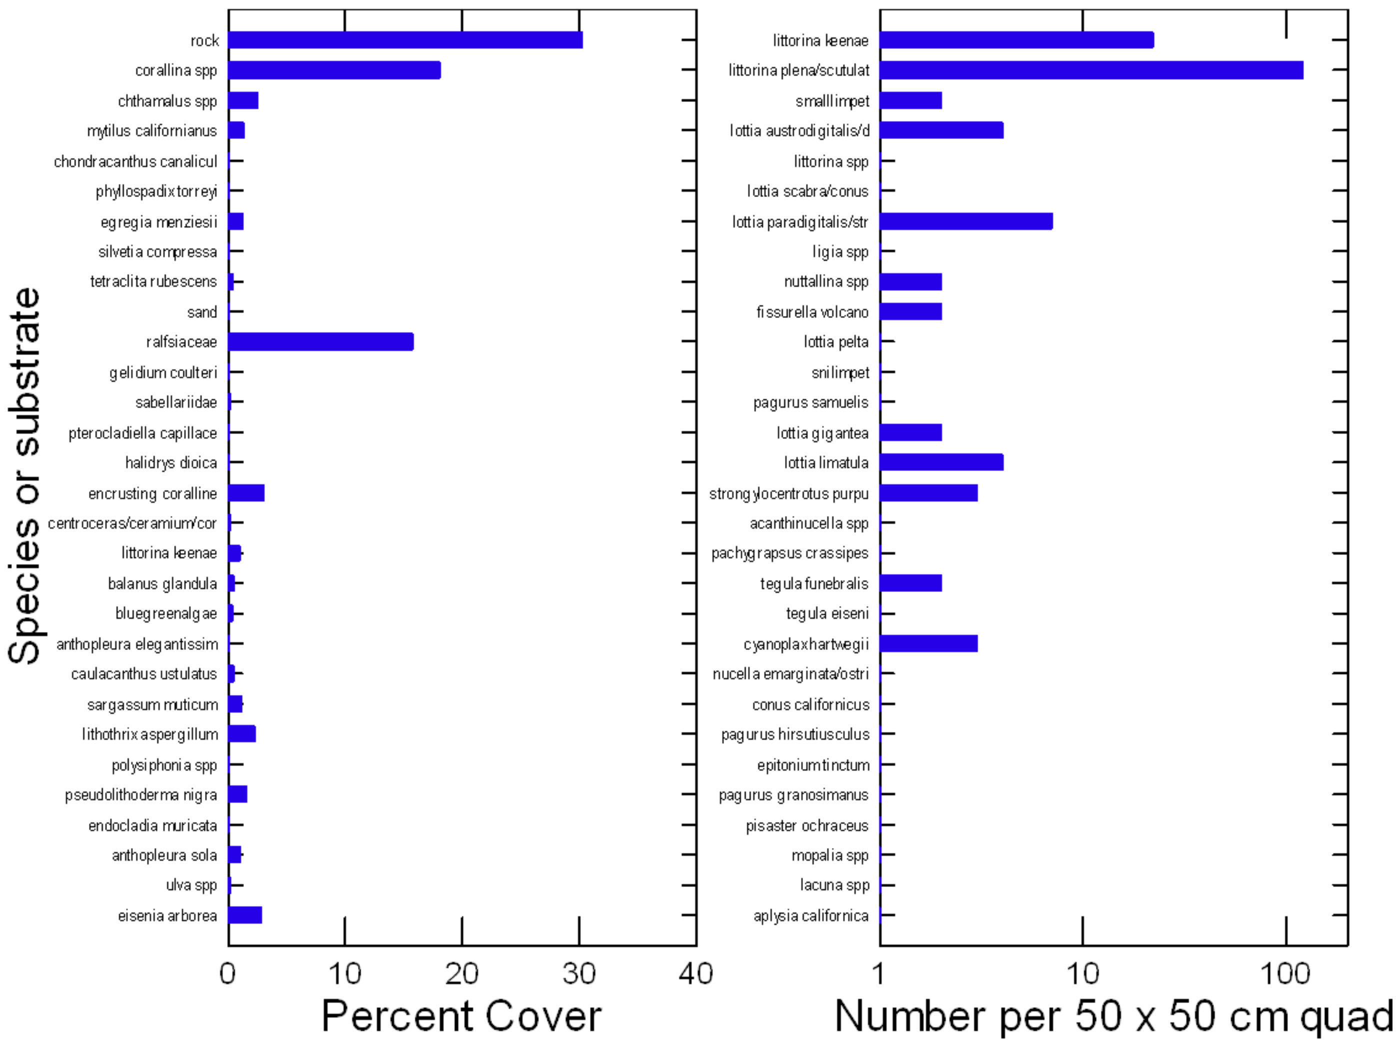
■ Reference Site

Buck Gulley South is comprised of bedrock and boulders with moderate relief. The surrounding coast is made up of bedrock, boulders and sand. The survey area is 30meters wide and 35meters long.

The nearest storm water discharge pipe (NEW016) is 5meters from survey bolt OT2.

RB-AR 7114

Buck Gully, south

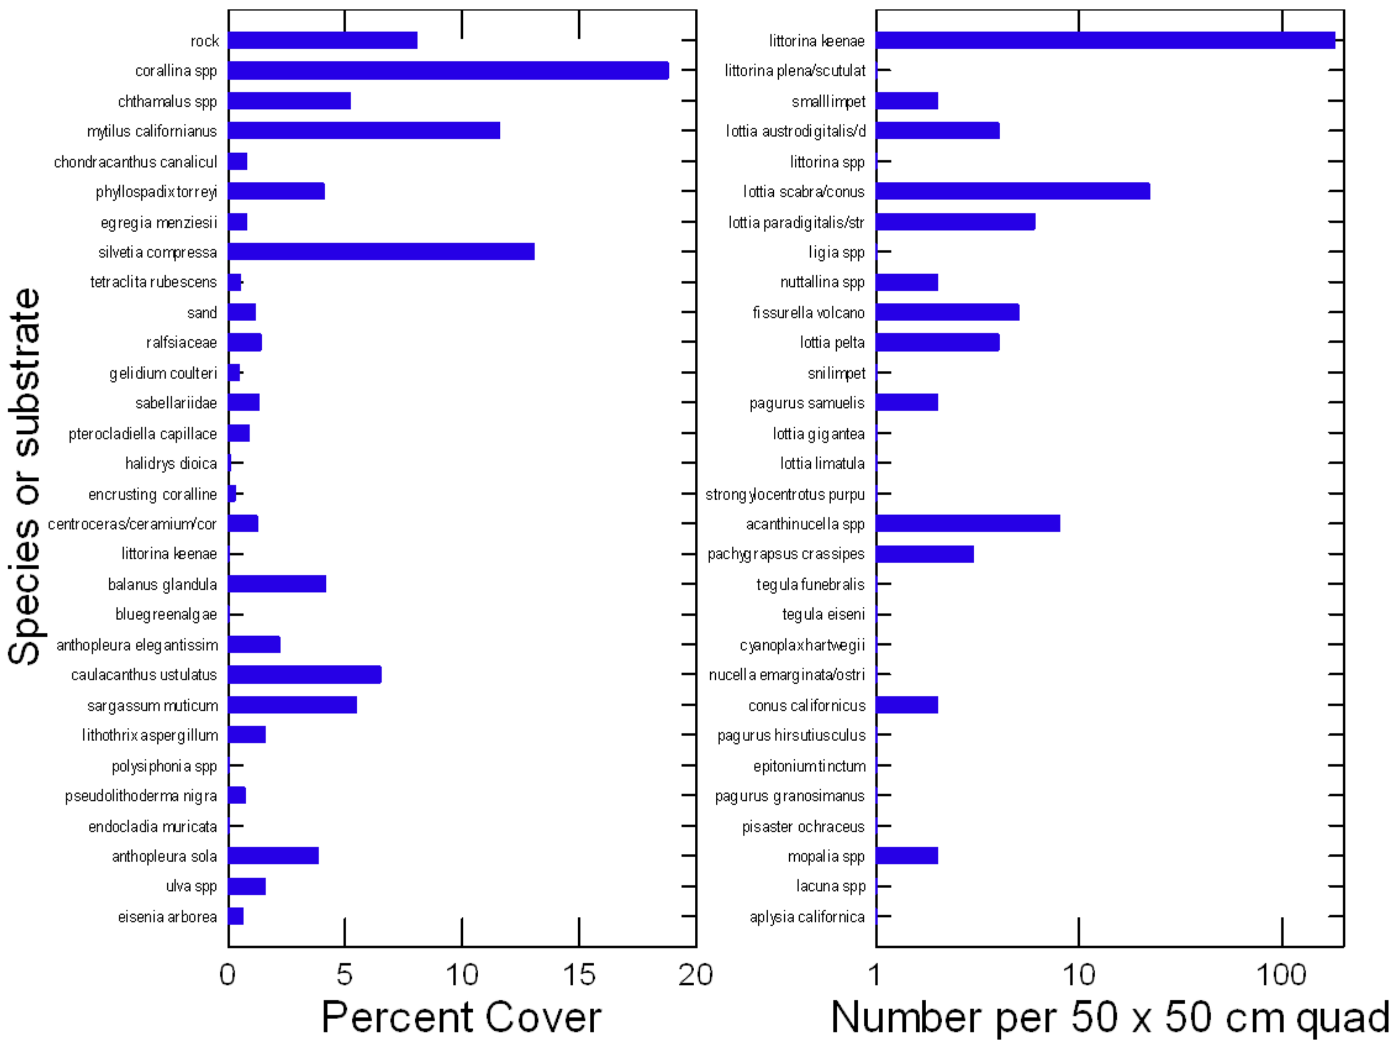


Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

RB-AR 7115

Crystal Cove is comprised of bedrock with low relief. The surrounding coast is made up of bedrock, boulders and sand. The survey area is 30meters wide and 35meters long. There is some sand influence at this site. The biological community, particularly mobile species differed considerably from that expected based on other sites in the region.

Crystal Cove

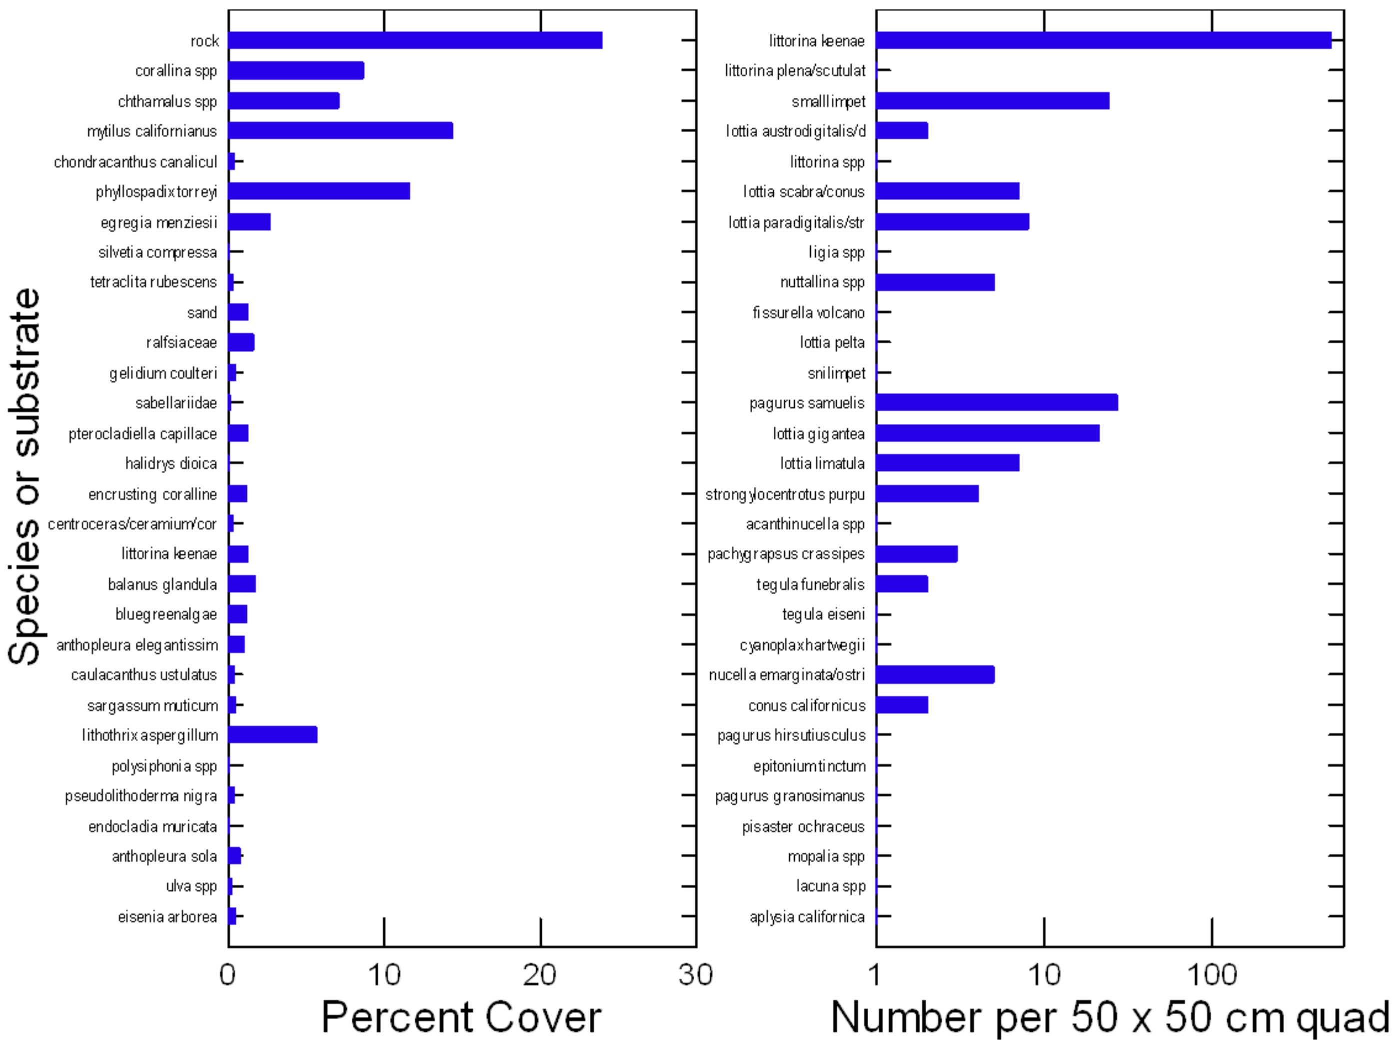


Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

Heisler Park is comprised of bedrock and sand with moderate relief. The surrounding coast is made up of bedrock, boulders and sand. The survey area is 20meters wide and 35meters long.

The nearest storm water discharge pipe (HSL013) is 52meters from survey bolt OT1.

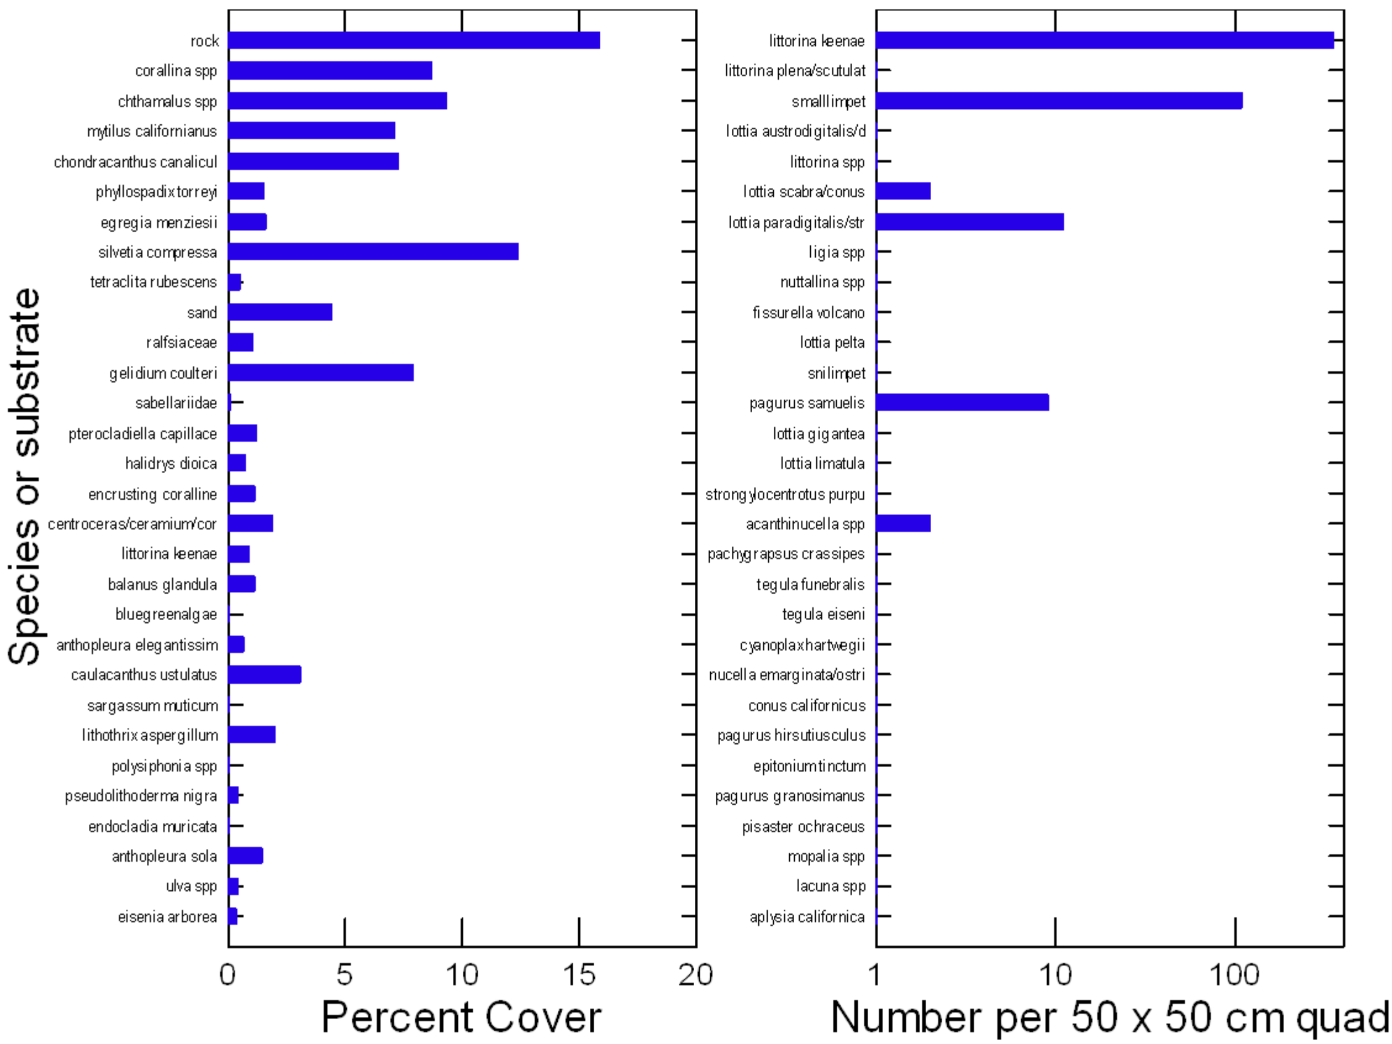
Heisler Park



Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

Dana Point is comprised of bedrock and boulders with moderate relief. The surrounding coast is made up of bedrock, boulders and sand. The survey area is 30meters wide and 29meters long.

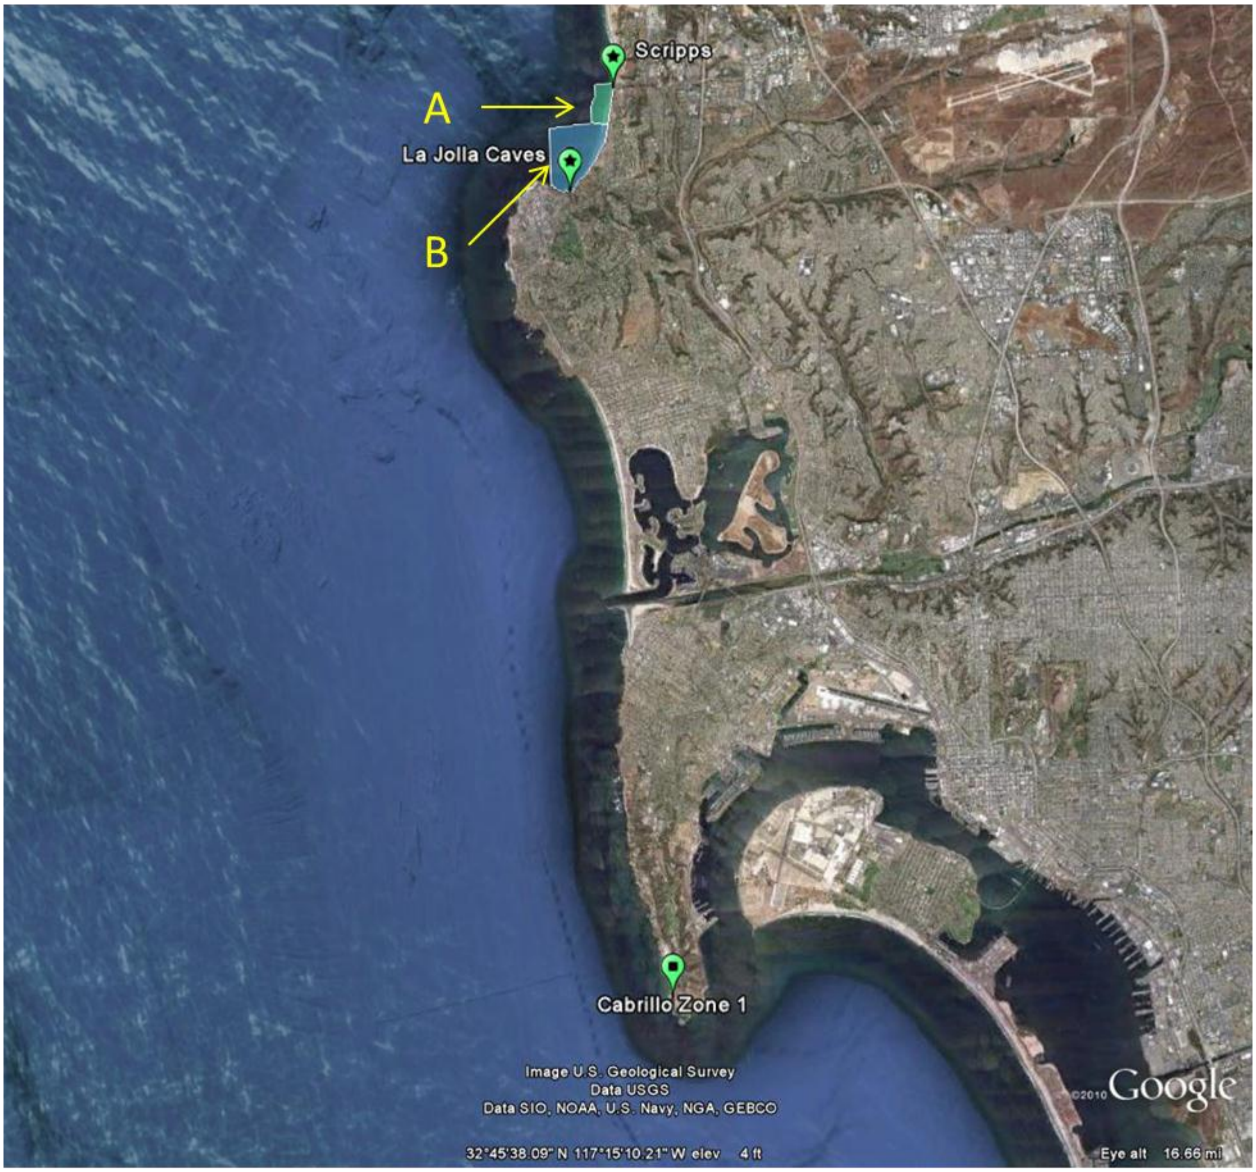
Dana Point



Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

RB-AR 7121

San Diego marine Life reserve (A) and San Diego-La Jolla ecological reserve (B)



★ Discharge site in ASBS

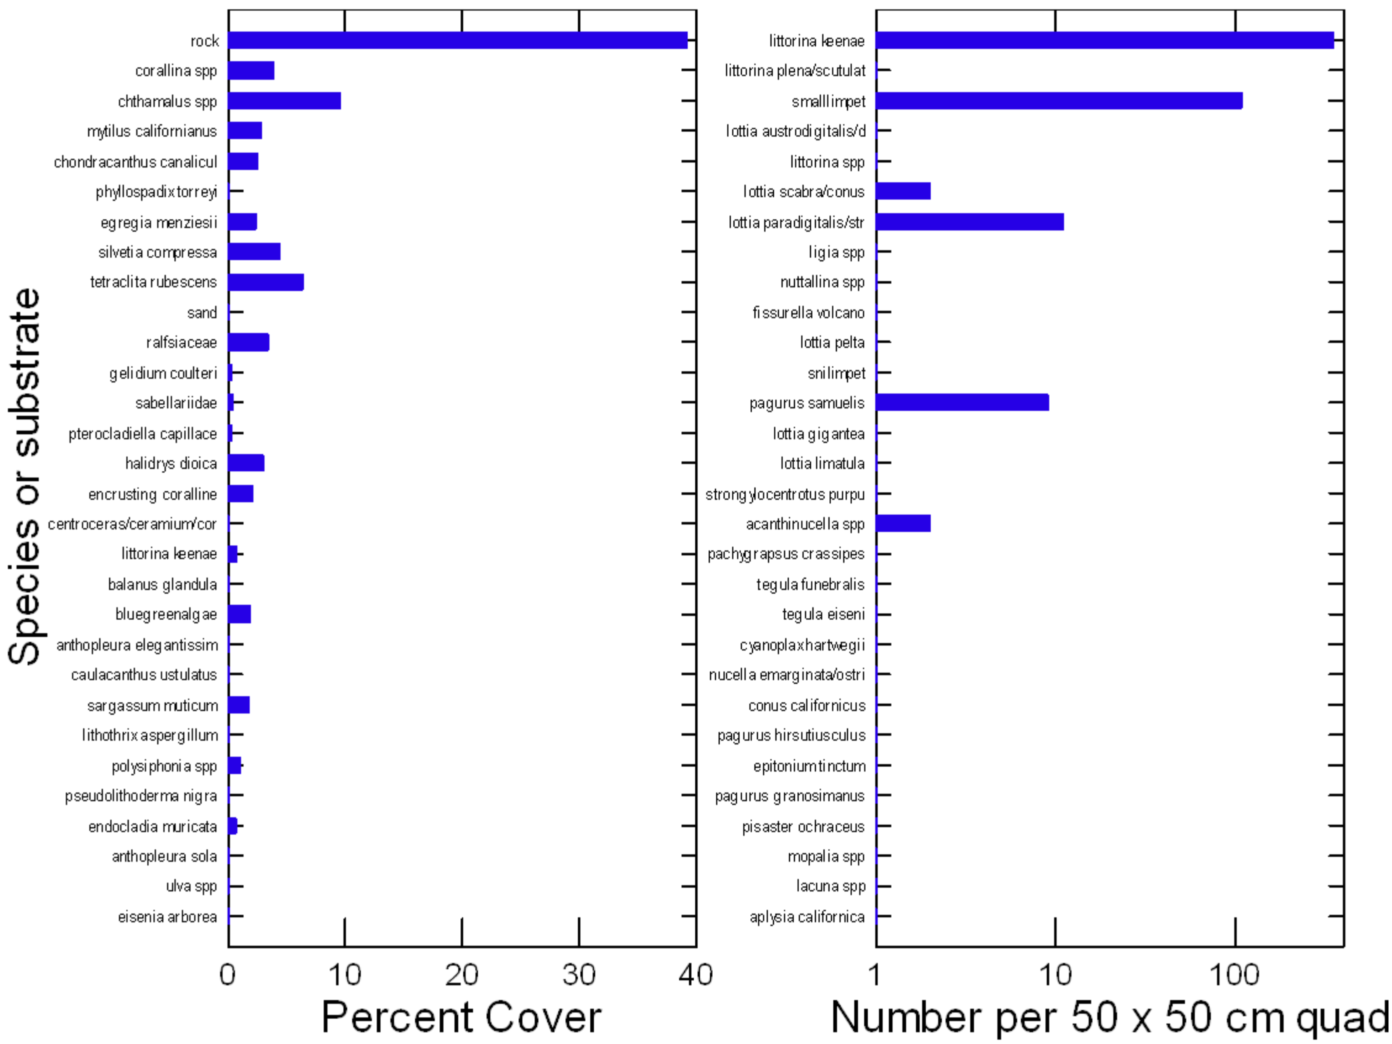
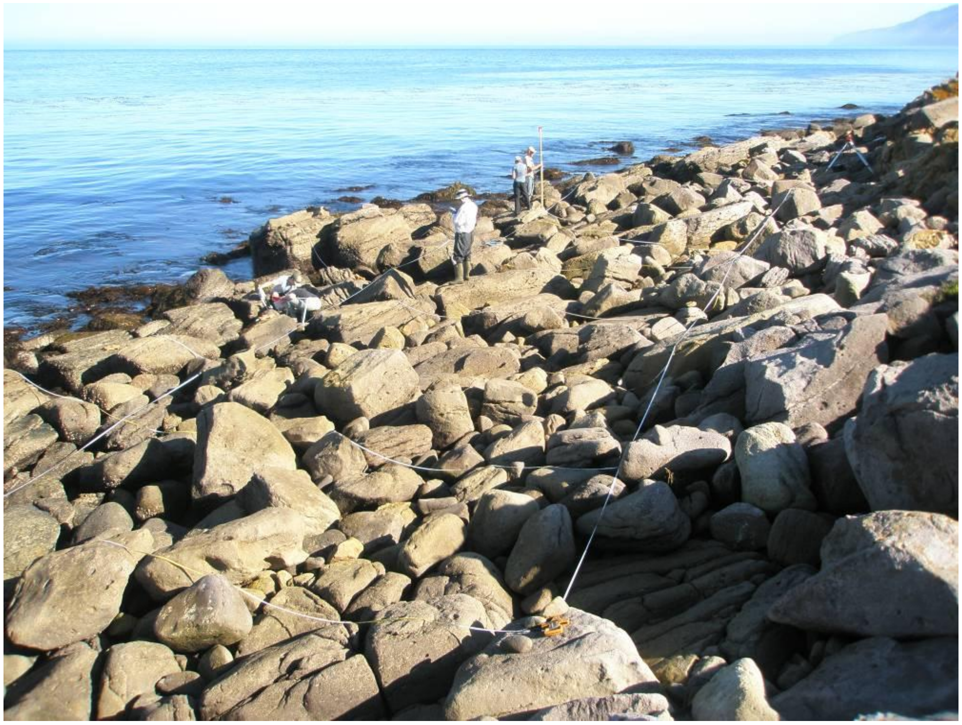
Eel Point is comprised of bedrock with moderate relief. The surrounding coast is made up of bedrock and boulders. The survey area is 20meters wide and 25meters long.

Eel Point

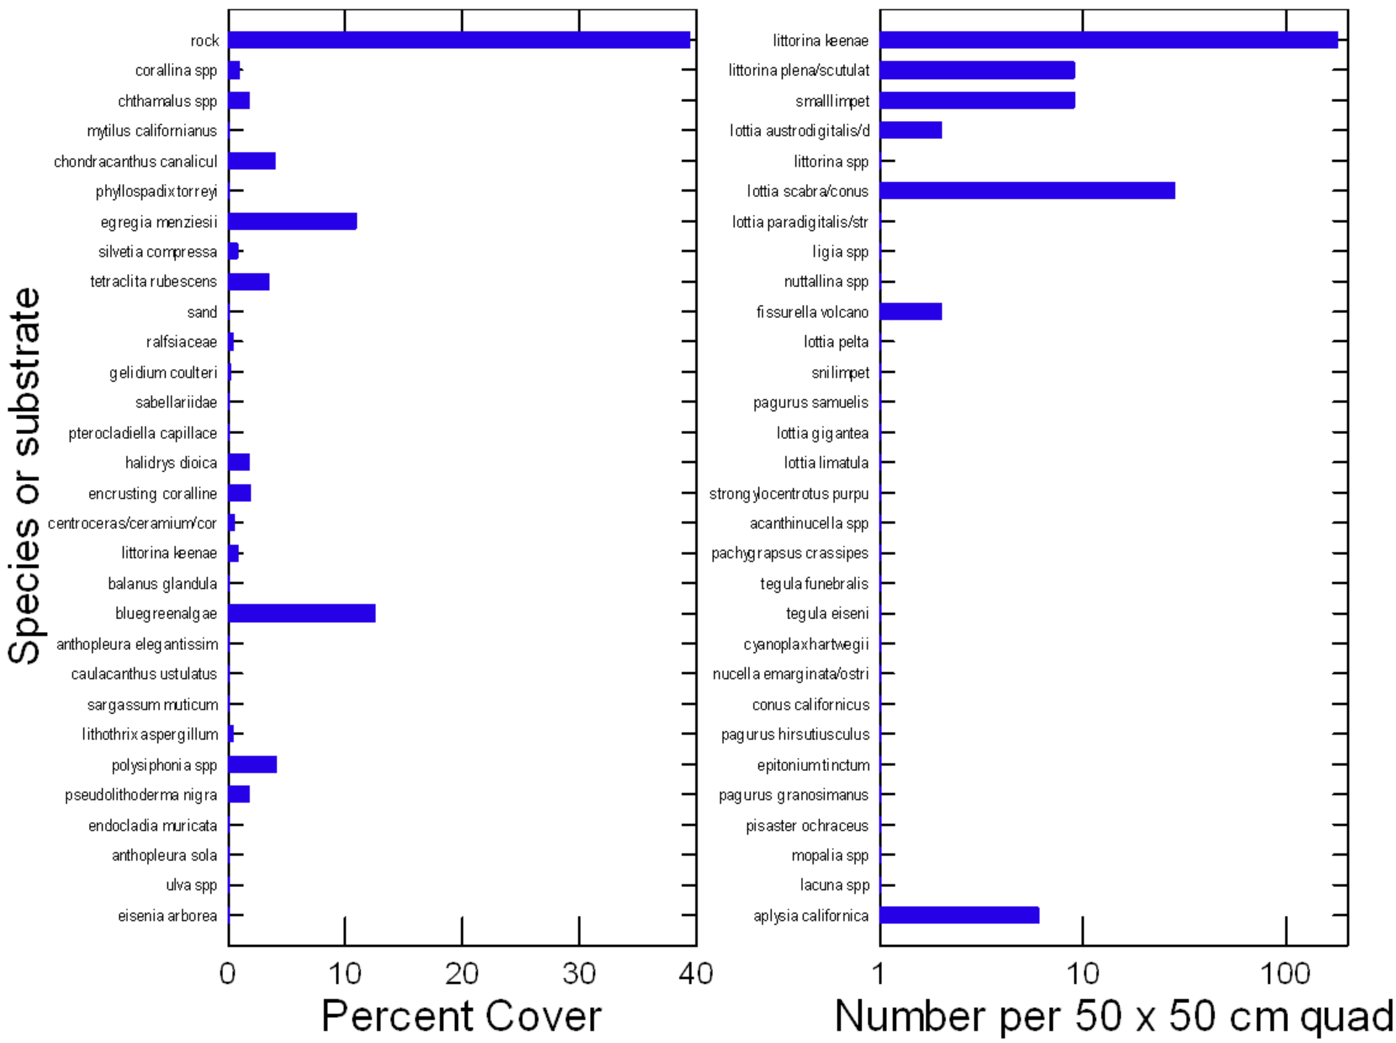


Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

Boy Scout Camp is comprised of bedrock and boulders with moderate relief. The surrounding coast is made up of bedrock and boulders. The survey area is 30meters wide and 15meters long.



Boy Scout Camp



Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

RB-AR 7140

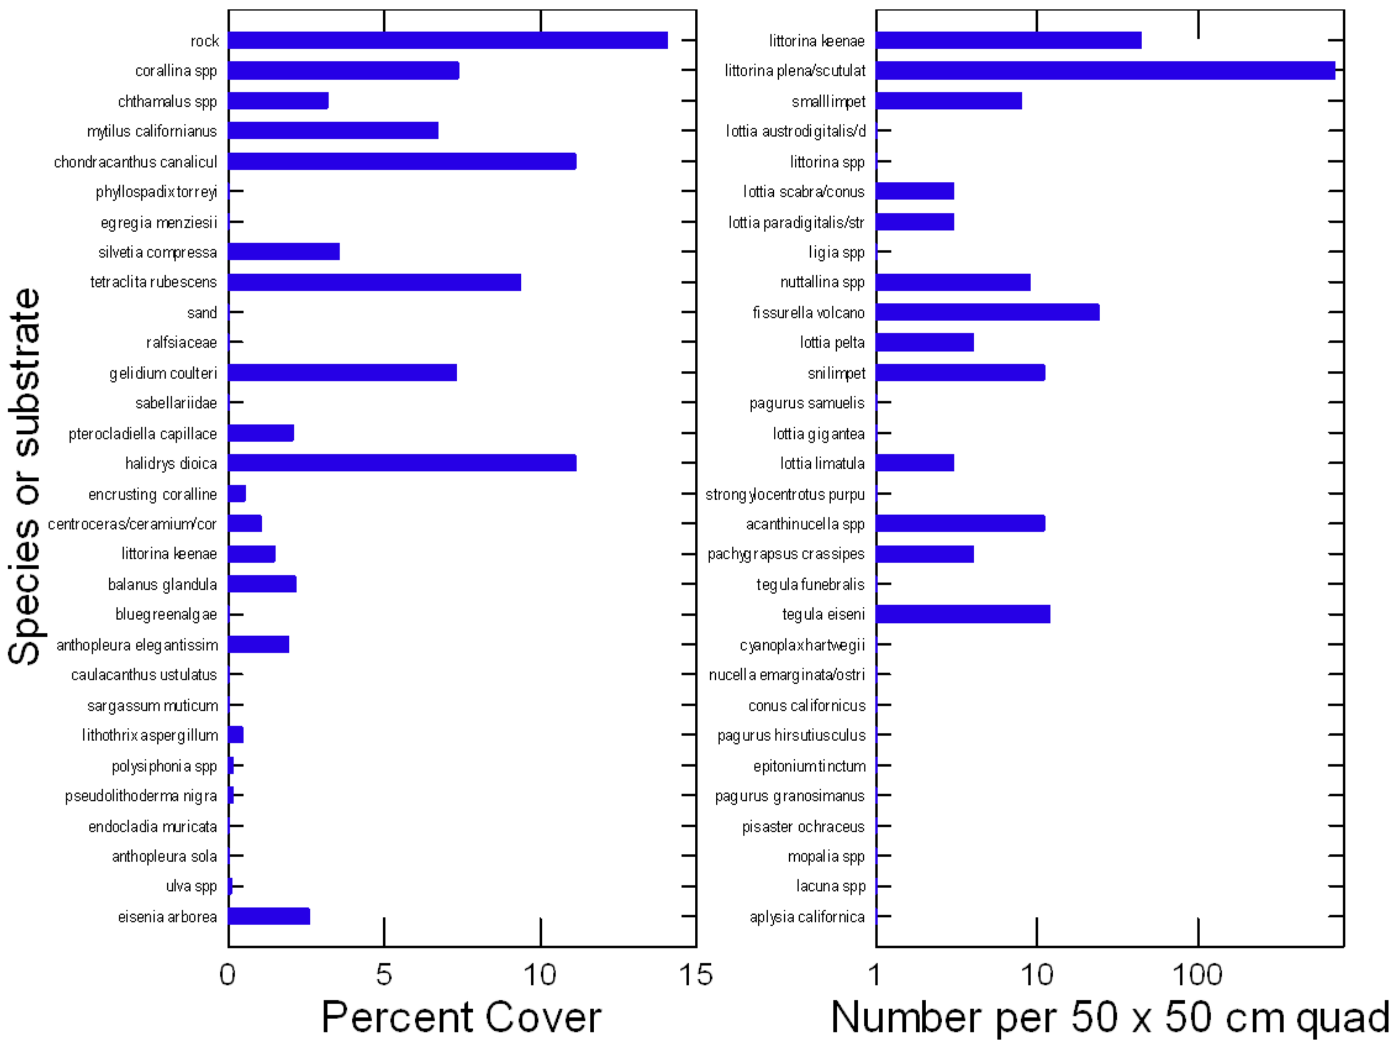
Santa Catalina Island

★ Discharge site in ASBS

■ Reference Site

Bird Rock is comprised of bedrock with moderate relief. The surrounding coast is made up of bedrock and boulders. The survey area is 30meters wide and 13meters long.

Bird Rock



Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

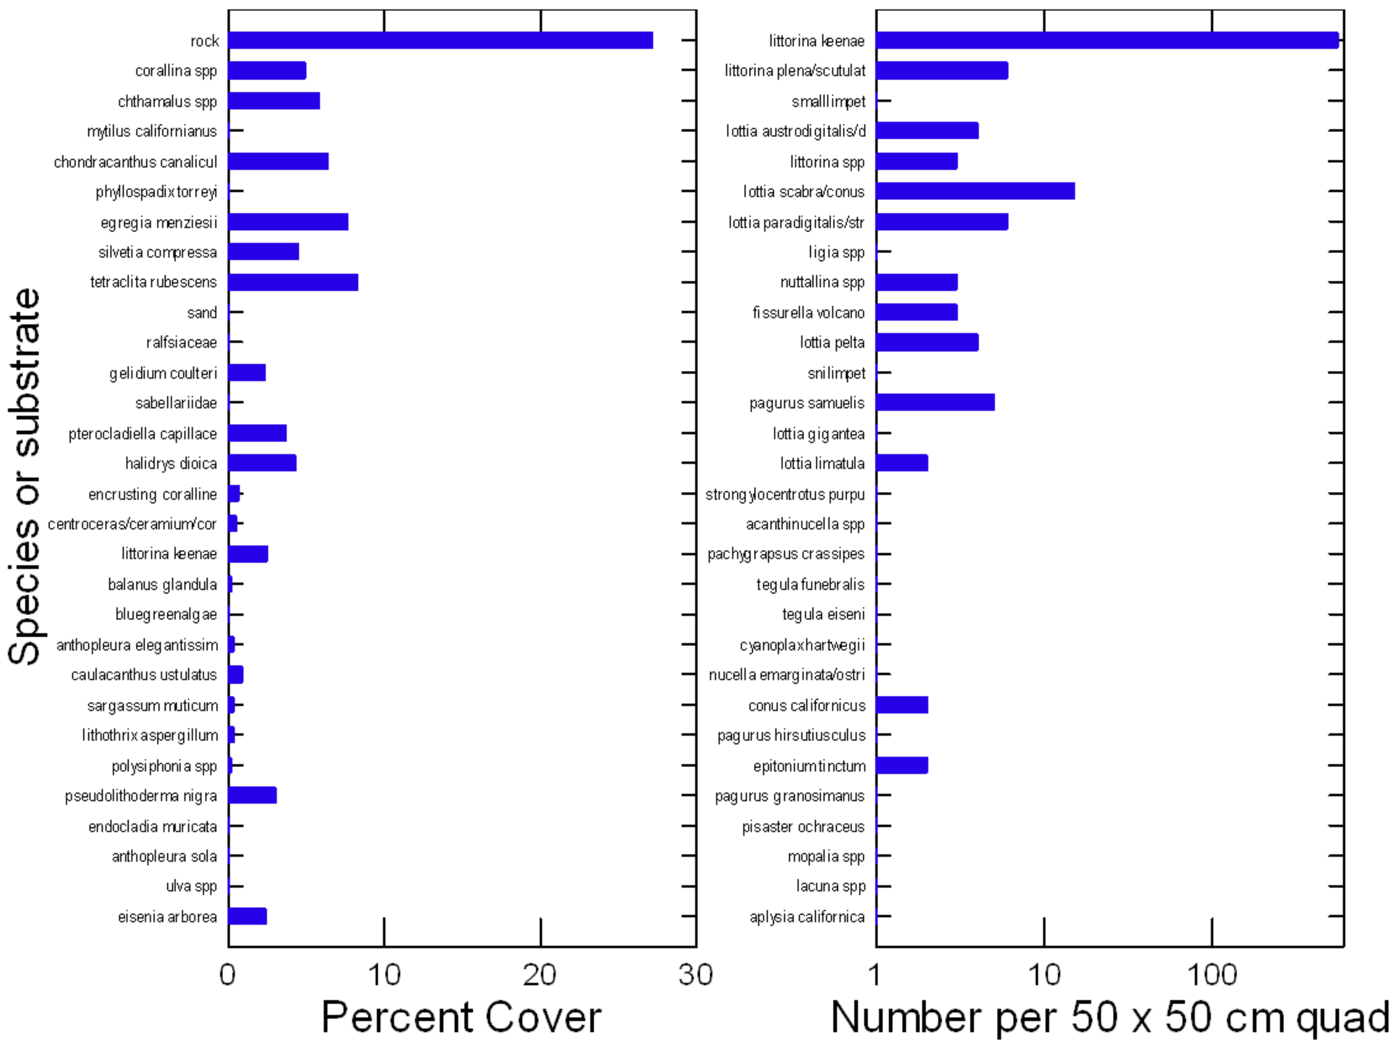
RB-AR 7143

Big Fisherman Cove is comprised of bedrock with moderate relief. The surrounding coast is made up of bedrock and boulders. The survey area is divided into two sections. The upcoast section is 8meters wide and 11meters long.

The downcoast section is 10meters wide and 12meters long. The nearest storm water discharge is approximately 100meters from survey bolt OT6.

RB-AR 7144

Big Fisherman Cove

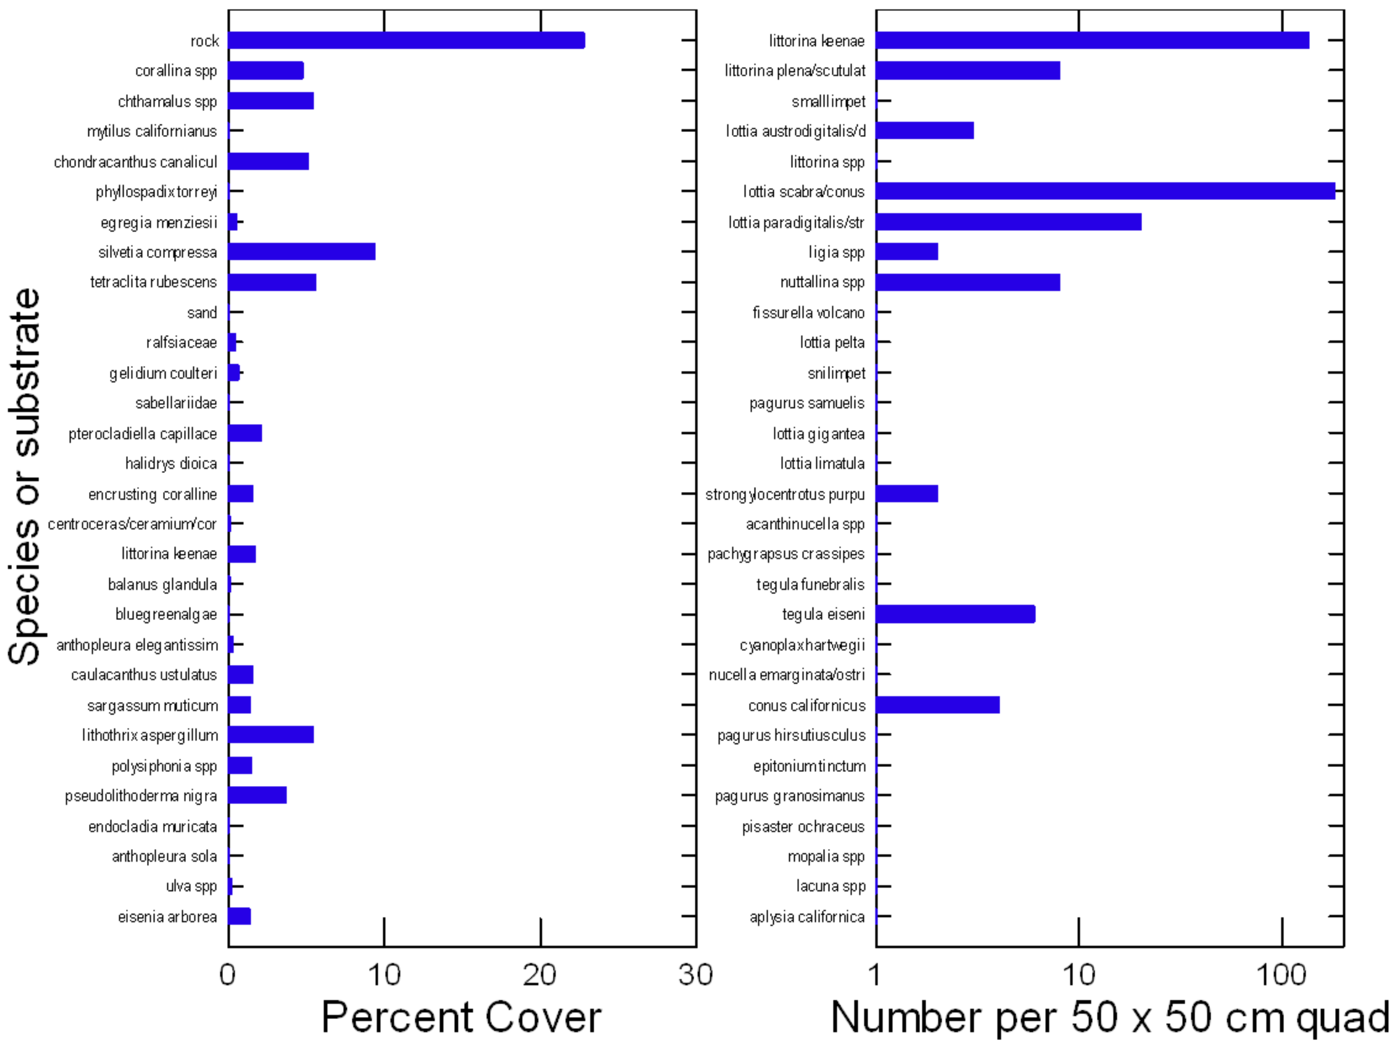


Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

Two Harbors is comprised of bedrock and boulders with moderate relief. The surrounding coast is made up of bedrock, boulders and sand. The survey area is 20meters wide and 10meters long.

The nearest storm water discharge pipe is approximately 150meters from survey bolt OT1.

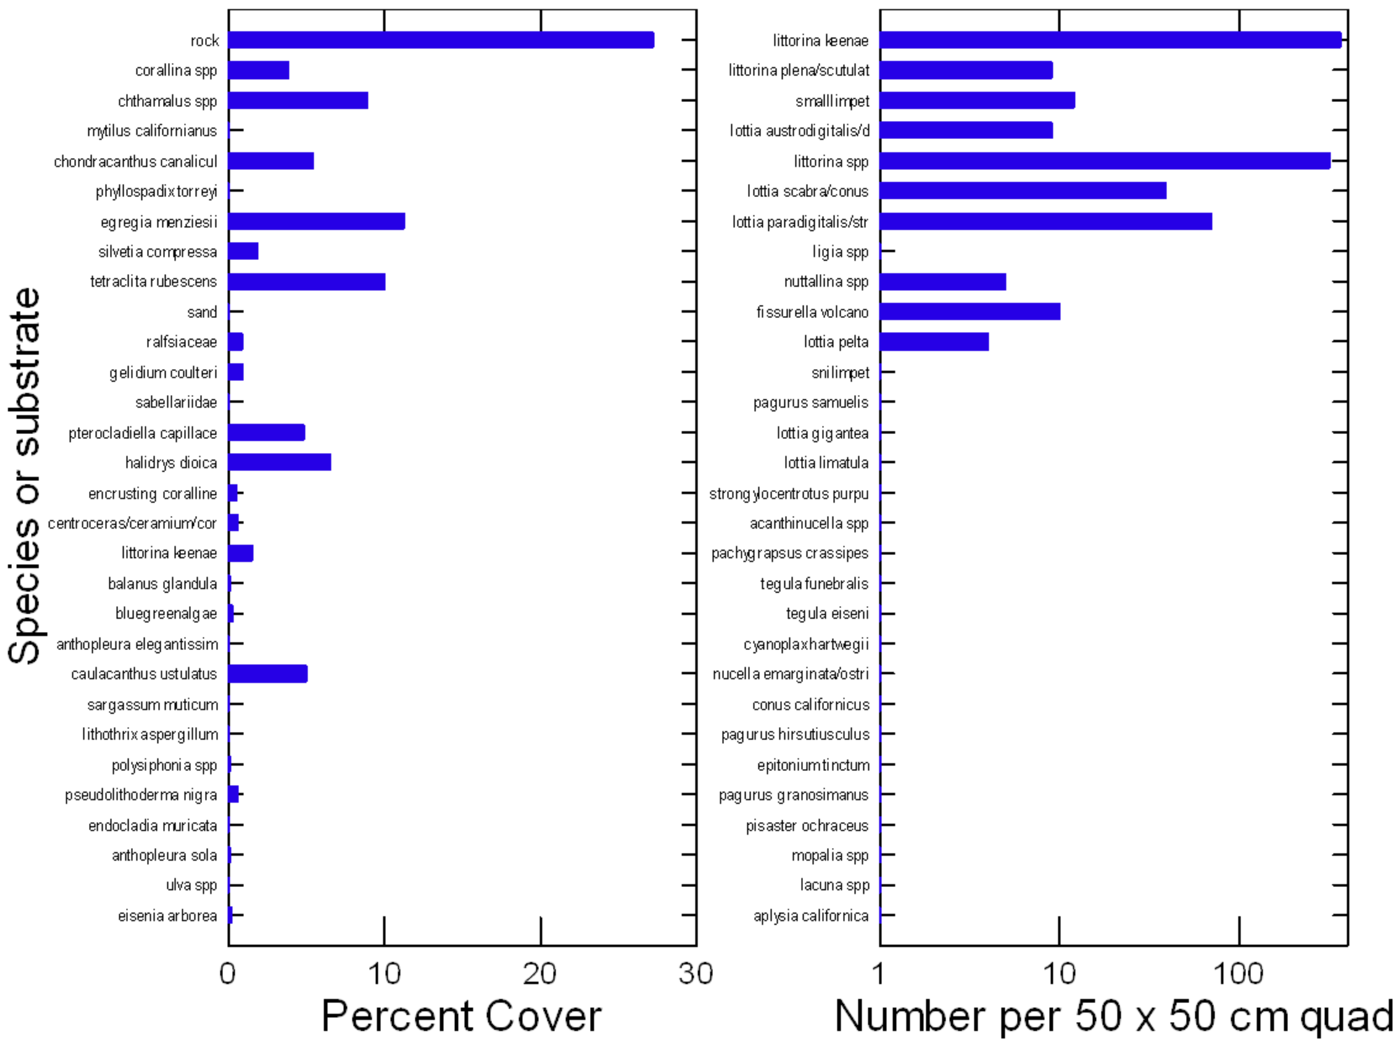
Two Harbors



Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

Goat Harbor is comprised of bedrock and boulders with moderate relief. The surrounding coast is made up of bedrock, boulders and cobble. The survey area is 20meters wide and 10meters long.

Goat Harbor



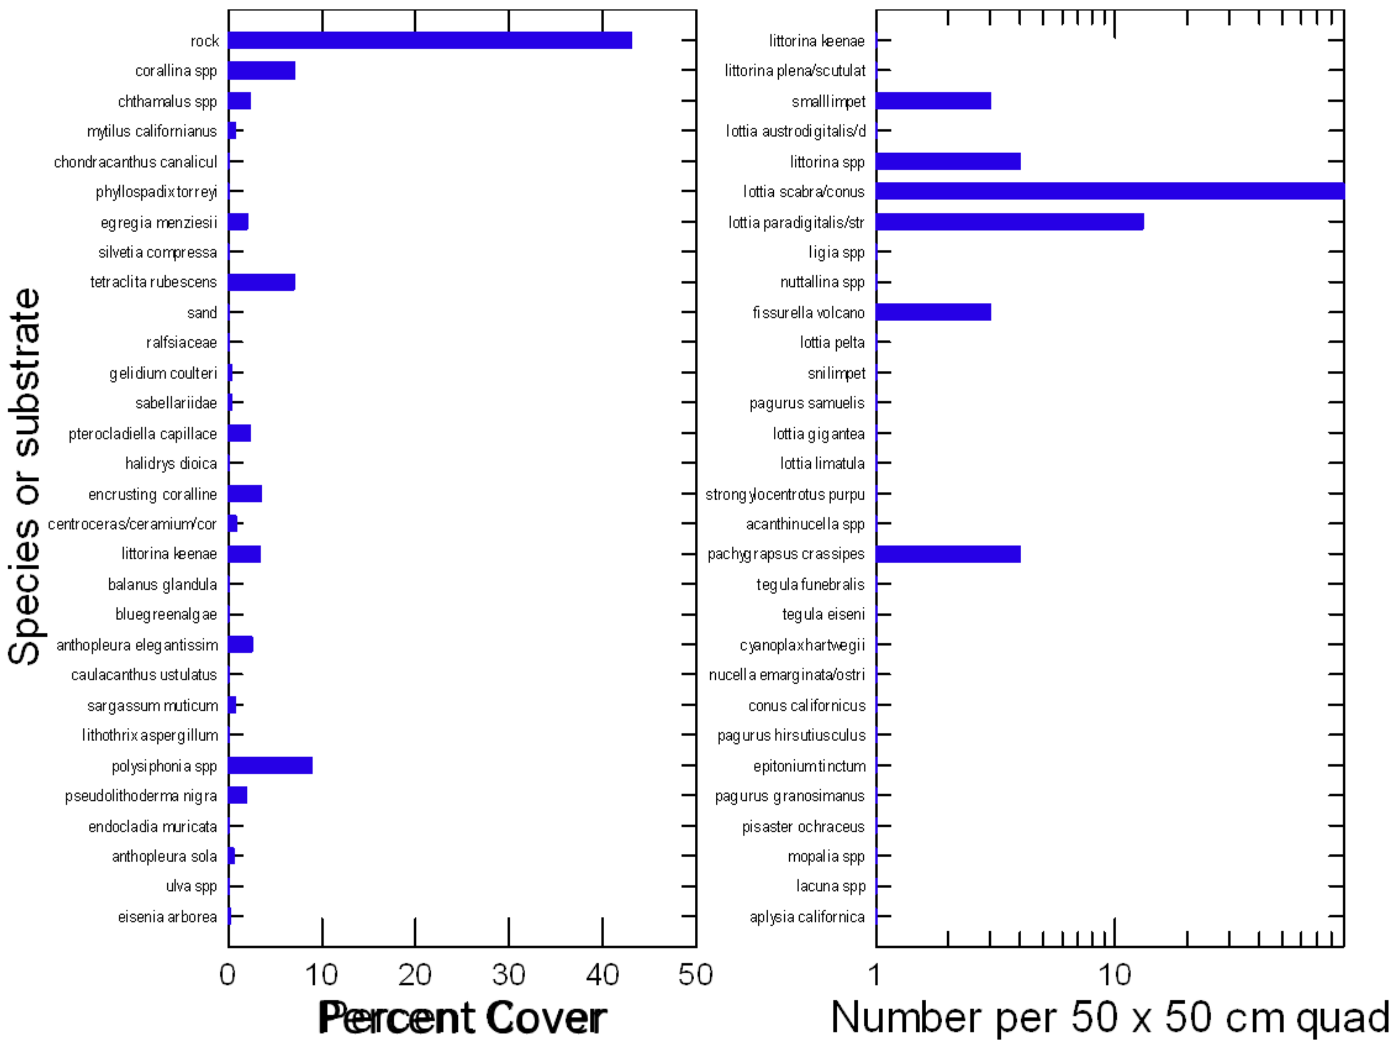
Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

RB-AR 7149

Avalon Quarry is comprised of boulders with moderate relief. The surrounding coast is made up of boulders. The survey area is 20meters wide and 10meters long. Based on the substrate and level of potential impact, this site was expected to differ from other sites. Our analyses confirmed this expectation.

The nearest storm water discharge is approximately 25meters from survey bolt OT1.

Avalon Quarry



Percent cover (from point contact surveys) and density (from mobile species surveys). Species order is based on ranking across all sites.

STATE WATER RESOURCES CONTROL BOARD
RESOLUTION NO. 2012-0031

AMENDING THE GENERAL EXCEPTION TO THE CALIFORNIA OCEAN PLAN FOR SELECTED DISCHARGES INTO AREAS OF SPECIAL BIOLOGICAL SIGNIFICANCE, INCLUDING SPECIAL PROTECTIONS FOR BENEFICIAL USES

WHEREAS:

1. The State Water Resources Control Board (State Water Board) adopted the California Ocean Plan (Ocean Plan) on July 6, 1972 and revised the Ocean Plan in 1978, 1983, 1988, 1990, 1997, 2000, 2005, and 2009.

2. The Ocean Plan prohibits the discharge of waste to designated Areas of Special Biological Significance (ASBS).

3. ASBS are designated by the State Water Board as ocean areas requiring protection of species or biological communities to the extent that alteration of natural water quality is undesirable.

4. Under the Marine Managed Areas Improvement Act, all ASBS are designated as a subset of state water quality protection areas and require special protection as determined by the State Water Board pursuant to the Ocean Plan and the Water Quality Control Plan for Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California (Thermal Plan).

5. In state water quality protection areas, waste discharges must be prohibited or limited by special conditions, in accordance with the Porter-Cologne Water Quality Control Act, (Wat. Code, §13000 et seq.) and implementing regulations, including the Ocean Plan and Thermal Plan.

6. The Ocean Plan authorizes the State Water Board to grant an exception to Ocean Plan provisions where the State Water Board determines that the exception will not compromise protection of ocean waters for beneficial uses and the public interest will be served.

7. On October 18, 2004, the State Water Board notified a number of parties that they must cease the discharge of storm water and nonpoint source waste into ASBS or request an exception to the Ocean Plan.

8. The State Water Board received 27 applications for an exception to the Ocean Plan prohibition against waste discharges into an ASBS. The applicants discharge storm water and nonpoint source waste into ASBS.

9. On March 20, 2012, in Resolution 2012-0012, the State Water Board adopted a General Exception to the Ocean Plan ASBS waste discharge prohibition, for storm water and nonpoint source discharges from these 27 applicants, including Special Protections for Beneficial Uses.

10. The State Water Board's stated intention when adopting the General Exception with Special Protections for Beneficial Uses was for compliance with natural ocean water quality within six years of the effective date.

11. Two sections in the Special Protections to ASBS Compliance Plans, section A. 2.d(2), and ASBS Pollution Prevention Plans, section B.2.b(2), were not corrected and retained a four year, instead of six year, compliance deadline.

THEREFORE BE IT RESOLVED THAT:

The State Water Board:

1. Amends sections A.2.d(2) and B.2.b(2) of the Special Protections in Attachment B to the General Exception, originally adopted in Resolution 2012-0012, to require pollutant reductions to be achieved within six years, to be consistent with the compliance schedules in sections I.A.3 and I.B.3.

2. Authorizes the Executive Director or designee to transmit the amended General Exception to the United States Environmental Agency (U.S. EPA) for concurrence.

CERTIFICATION

The undersigned Clerk to the Board does hereby certify that the foregoing is a full, true, and correct copy of a resolution duly and regularly adopted at a meeting of the State Water Resources Control Board held on June 19, 2012.

Attachment B - Special Protections for Areas of Special Biological Significance, Governing Point Source Discharges of Storm Water and Nonpoint Source Waste Discharges

I. PROVISIONS FOR POINT SOURCE DISCHARGES OF STORM WATER AND NONPOINT SOURCE WASTE DISCHARGES

The following terms, prohibitions, and special conditions (hereafter collectively referred to as special conditions) are established as limitations on point source storm water and nonpoint source discharges. These special conditions provide Special Protections for marine aquatic life and natural water quality in Areas of Special Biological Significance (ASBS), as required for State Water Quality Protection Areas pursuant to California Public Resources Code Sections 36700(f) and 36710(f). These Special Protections are adopted by the State Water Board as part of the California Ocean Plan (Ocean Plan) General Exception.

The special conditions are organized by category of discharge. The State Water Resources Control Board (State Water Board) and Regional Water Quality Control Boards (Regional Water Boards) will determine categories and the means of regulation for those categories [e.g., Point Source Storm Water National Pollutant Discharge Elimination System (NPDES) or Nonpoint Source].

A. PERMITTED POINT SOURCE DISCHARGES OF STORM WATER

1. General Provisions for Permitted Point Source Discharges of Storm Water

   a. Existing storm water discharges into an ASBS are allowed only under the following conditions:

      (1) The discharges are authorized by an NPDES permit issued by the State Water Board or Regional Water Board;

      (2) The discharges comply with all of the applicable terms, prohibitions, and special conditions contained in these Special Protections; and

      (3) The discharges:

         (i) Are essential for flood control or slope stability, including roof, landscape, road, and parking lot drainage;

         (ii) Are designed to prevent soil erosion;

         (iii) Occur only during wet weather;

         (iv) Are composed of only storm water runoff.

   b. Discharges composed of storm water runoff shall not alter natural ocean water quality in an ASBS.

c. The discharge of trash is prohibited.

d. Only discharges from existing storm water outfalls are allowed. Any proposed or new storm water runoff discharge shall be routed to existing storm water discharge outfalls and shall not result in any new contribution of waste to an ASBS (i.e., no additional pollutant loading). "Existing storm water outfalls" are those that were constructed or under construction prior to January 1, 2005. "New contribution of waste" is defined as any addition of waste beyond what would have occurred as of January 1, 2005. A change to an existing storm water outfall, in terms of re-location or alteration, in order to comply with these special conditions, is allowed and does not constitute a new discharge.

e. Non-storm water discharges are prohibited except as provided below:

(1) The term "non-storm water discharges" means any waste discharges from a municipal separate storm sewer system (MS4) or other NPDES permitted storm drain system to an ASBS that are not composed entirely of storm water.

(2) (i) The following non-storm water discharges are allowed, provided that the discharges are essential for emergency response purposes, structural stability, slope stability or occur naturally:

(a) Discharges associated with emergency fire fighting operations.

(b) Foundation and footing drains.

(c) Water from crawl space or basement pumps.

(d) Hillside dewatering.

(e) Naturally occurring groundwater seepage via a storm drain.

(f) Non-anthropogenic flows from a naturally occurring stream via a culvert or storm drain, as long as there are no contributions of anthropogenic runoff.

(ii) An NPDES permitting authority may authorize non-storm water discharges to an MS4 with a direct discharge to an ASBS only to the extent the NPDES permitting authority finds that the discharge does not alter natural ocean water quality in the ASBS.

(3) Authorized non-storm water discharges shall not cause or contribute to a violation of the water quality objectives in Chapter II of the Ocean Plan nor alter natural ocean water quality in an ASBS.

2. Compliance Plans for Inclusion in Storm Water Management Plans (SWMP) and Storm Water Pollution Prevention Plans (SWPPP).

The discharger shall specifically address the prohibition of non-storm water runoff and the requirement to maintain natural water quality for storm water discharges to an ASBS in an ASBS Compliance Plan to be included in its SWMP or a SWPPP, as appropriate to permit type. If a statewide permit includes a SWMP, then the discharger shall prepare a stand-alone compliance plan for ASBS discharges. The ASBS Compliance Plan is subject to approval by the Executive Director of the State Water Board (statewide permits) or Executive Officer of the Regional Water Board (for permits issued by Regional Water Boards).

a. The Compliance Plan shall include a map of surface drainage of storm water runoff, showing areas of sheet runoff, prioritize discharges, and describe any structural Best Management Practices (BMPs) already employed and/or BMPs to be employed in the future. Priority discharges are those that pose the greatest water quality threat and which are identified to require installation of structural BMPs. The map shall also show the storm water conveyances in relation to other features such as service areas, sewage conveyances and treatment facilities, landslides, areas prone to erosion, and waste and hazardous material storage areas, if applicable. The SWMP or SWPPP shall also include a procedure for updating the map and plan when changes are made to the storm water conveyance facilities.

b. The ASBS Compliance Plan shall describe the measures by which all non-authorized non-storm water runoff (e.g., dry weather flows) has been eliminated, how these measures will be maintained over time, and how these measures are monitored and documented.

c. For Municipal Separate Storm Sewer System (MS4s), the ASBS Compliance Plan shall require minimum inspection frequencies as follows:

(1) The minimum inspection frequency for construction sites shall be weekly during rainy season;

(2) The minimum inspection frequency for industrial facilities shall be monthly during the rainy season;

(3) The minimum inspection frequency for commercial facilities (e.g., restaurants) shall be twice during the rainy season; and

(4) Storm water outfall drains equal to or greater than 18 inches (457 mm) in diameter or width shall be inspected once prior to the beginning of the rainy season and once during the rainy season and maintained to remove trash and other anthropogenic debris.

d. The ASBS Compliance Plan shall address storm water discharges (wet weather flows) and, in particular, describe how pollutant reductions in storm water runoff, that are necessary to comply with these special conditions, will be achieved through BMPs. Structural BMPs need not be installed if the discharger can document to the satisfaction of the State Water Board Executive Director (statewide permits) or Regional Water Board Executive Officer (Regional Water Board permits) that such installation would pose a threat to health or safety. BMPs to control storm water runoff discharges (at the end-of-pipe) during a design storm shall be designed to achieve on average the following target levels:

(1) Table B Instantaneous Maximum Water Quality Objectives in Chapter II of the Ocean Plan; or

(2) A 90% reduction in pollutant loading during storm events, for the applicant's total discharges.

The baseline for these determinations is the effective date of the Exception, except for those structural BMPs installed between January 1, 2005 and adoption of these Special Protections, and the reductions must be achieved and documented within six (6) years of the effective date.

e. The ASBS Compliance Plan shall address erosion control and the prevention of anthropogenic sedimentation in ASBS. The natural habitat conditions in the ASBS shall not be altered as a result of anthropogenic sedimentation.

f. The ASBS Compliance Plan shall describe the non-structural BMPs currently employed and planned in the future (including those for construction activities), and include an implementation schedule. The ASBS Compliance Plan shall include non-structural BMPs that address public education and outreach. Education and outreach efforts must adequately inform the public that direct discharges of pollutants from private property not entering an MS4 are prohibited. The ASBS Compliance Plan shall also describe the structural BMPs, including any low impact development (LID) measures, currently employed and planned for higher threat discharges and include an implementation schedule. To control storm water runoff discharges (at the end-of-pipe) during a design storm, permittees must first consider, and use where feasible, LID practices to infiltrate, use, or evapotranspirate storm water runoff on-site, if LID practices would be the most effective at reducing pollutants from entering the ASBS.

g. The BMPs and implementation schedule shall be designed to ensure that natural water quality conditions in the receiving water are achieved and maintained by either reducing flows from impervious surfaces or reducing pollutant loading, or some combination thereof.

h. If the results of the receiving water monitoring described in IV.B. of these special conditions indicate that the storm water runoff is causing or contributing to an alteration of natural ocean water quality in the ASBS, the discharger shall submit a report to the State Water Board and Regional Water Board within 30 days of receiving the results.

(1) The report shall identify the constituents in storm water runoff that alter natural ocean water quality and the sources of these constituents.

(2) The report shall describe BMPs that are currently being implemented, BMPs that are identified in the SWMP or SWPPP for future implementation, and any additional BMPs that may be added to the SWMP or SWPPP to address the alteration of natural water quality. The report shall include a new or modified implementation schedule for the BMPs.

(3) Within 30 days of the approval of the report by the State Water Board Executive Director (statewide permits) or Regional Water Board Executive Officer (Regional Water Board permits), the discharger shall revise its ASBS Compliance Plan to incorporate any new or modified BMPs that have been or will be implemented, the implementation schedule, and any additional monitoring required.

(4) As long as the discharger has complied with the procedures described above and is implementing the revised SWMP or SWPPP, the discharger does not have to repeat the same procedure for continuing or recurring exceedances of natural ocean water quality conditions due to the same constituent.

(5) The requirements of this section are in addition to the terms, prohibitions, and conditions contained in these Special Protections.

3. Compliance Schedule

a. On the effective date of the Exception, all non-authorized non-storm water discharges (e.g., dry weather flow) are effectively prohibited.

b. Within eighteen (18) months from the effective date of the Exception, the discharger shall submit a draft written ASBS Compliance Plan to the State Water Board Executive Director (statewide permits) or Regional Water Board Executive Officer (Regional Water Board permits) that describes its strategy to comply with these special conditions, including the requirement to maintain natural water quality in the affected ASBS. The ASBS Compliance Plan shall include a description of appropriate non-structural controls and a time schedule to implement structural controls (implementation schedule) to comply with these special conditions for inclusion in the discharger's SWMP or SWPPP, as appropriate to permit type. The final ASBS Compliance Plan, including a description and final schedule for structural controls based on the results of runoff and receiving water monitoring, must be submitted within thirty (30) months from the effective date of the Exception.

c. Within 18 months of the effective date of the Exception, any non-structural controls that are necessary to comply with these special conditions shall be implemented.

d. Within six (6) years of the effective date of the Exception, any structural controls identified in the ASBS Compliance Plan that are necessary to comply with these special conditions shall be operational.

e. Within six (6) years of the effective date of the Exception, all dischargers must comply with the requirement that their discharges into the affected ASBS maintain natural ocean water quality. If the initial results of post-storm receiving water quality testing indicate levels higher than the 85th percentile threshold of reference water quality data and the pre-storm receiving water levels, then the discharger must re-sample the receiving water, pre- and post-storm. If after re-sampling the post-storm levels are still higher than the 85th percentile threshold of reference water quality data, and the pre-storm receiving water levels, for any constituent, then natural ocean water quality is exceeded. See attached Flowchart.

f. The Executive Director of the State Water Board (statewide permits) or Executive Officer of the Regional Water Board (Regional Water Board permits) may only authorize additional time to comply with the special conditions d. and e., above if good cause exists to do so. Good cause means a physical impossibility or lack of funding.

If a discharger claims physical impossibility, it shall notify the Board in writing within thirty (30) days of the date that the discharger first knew of the event or circumstance that caused or would cause it to fail to meet the deadline in d. or e. The notice shall describe the reason for the noncompliance or anticipated noncompliance and specifically refer to this Section of this Exception. It shall describe the anticipated length of time the delay in compliance may persist, the cause or causes of the delay as well as measures to minimize the impact of the delay on water quality, the measures taken or to be taken by the discharger to prevent or minimize the delay, the schedule by which the measures will be implemented, and the anticipated date of compliance. The discharger shall adopt all reasonable measures to avoid and minimize such delays and their impact on water quality.

The discharger may request an extension of time for compliance based on lack of funding. The request for an extension shall require:

1. for municipalities, a demonstration of significant hardship to discharger ratepayers, by showing the relationship of storm water fees to annual household income for residents within the discharger's jurisdictional area, and the discharger has made timely and complete applications for all available bond and grant funding, and either no bond or grant funding is available, or bond and/or grant funding is inadequate; or

2. for other governmental agencies, a demonstration and documentation of a good faith effort to acquire funding through that agency's budgetary process, and a demonstration that funding was unavailable or inadequate.

B. NONPOINT SOURCE DISCHARGES

1. General Provisions for Nonpoint Sources

   a. Existing nonpoint source waste discharges are allowed into an ASBS only under the following conditions:

      (1) The discharges are authorized under waste discharge requirements, a conditional waiver of waste discharge requirements, or a conditional prohibition issued by the State Water Board or a Regional Water Board.

      (2) The discharges are in compliance with the applicable terms, prohibitions, and special conditions contained in these Special Protections.

      (3) The discharges:

         (i) Are essential for flood control or slope stability, including roof, landscape, road, and parking lot drainage;

         (ii) Are designed to prevent soil erosion;

         (iii) Occur only during wet weather;

         (iv) Are composed of only storm water runoff.

   b. Discharges composed of storm water runoff shall not alter natural ocean water quality in an ASBS.

c. The discharge of trash is prohibited.

d. Only existing nonpoint source waste discharges are allowed. “Existing nonpoint source waste discharges” are discharges that were ongoing prior to January 1, 2005. “New nonpoint source discharges” are defined as those that commenced on or after January 1, 2005. A change to an existing nonpoint source discharge, in terms of relocation or alteration, in order to comply with these special conditions, is allowed and does not constitute a new discharge.

e. Non-storm water discharges from nonpoint sources (those not subject to an NPDES Permit) are prohibited except as provided below:

(1) The term “non-storm water discharges” means any waste discharges that are not composed entirely of storm water.

(2) The following non-storm water discharges are allowed, provided that the discharges are essential for emergency response purposes, structural stability, slope stability, or occur naturally:

(i) Discharges associated with emergency fire fighting operations.

(ii) Foundation and footing drains.

(iii) Water from crawl space or basement pumps.

(iv) Hillside dewatering.

(v) Naturally occurring groundwater seepage via a storm drain.

(vi) Non-anthropogenic flows from a naturally occurring stream via a culvert or storm drain, as long as there are no contributions of anthropogenic runoff.

(3) Authorized non-storm water discharges shall not cause or contribute to a violation of the water quality objectives in Chapter II of the Ocean Plan nor alter natural ocean water quality in an ASBS.

f. At the San Clemente Island ASBS, discharges incidental to military training and research, development, test, and evaluation operations are allowed. Discharges incidental to underwater demolition and other in-water explosions are not allowed in the two military closure areas in the vicinity of Wilson Cove and Castle Rock. Discharges must not result in a violation of the water quality objectives, including the protection of the marine aquatic life beneficial use, anywhere in the ASBS.

g. At the San Nicolas Island and Begg Rock ASBS, discharges incidental to military research, development, testing, and evaluation of, and training with, guided missile and other weapons systems, fleet training exercises, small-scale amphibious warfare training, and special warfare training are allowed. Discharges incidental to underwater demolition and other in-water explosions are not allowed. Discharges must not result in a violation of the water quality objectives, including the protection of the marine aquatic life beneficial use, anywhere in the ASBS.

h. All other nonpoint source discharges not specifically authorized above are prohibited.

2. Planning and Reporting

a. The nonpoint source discharger shall develop an ASBS Pollution Prevention ~~P~~lan, including an implementation schedule, to address storm water runoff and any other nonpoint source discharges from its facilities. The ASBS Pollution Prevention Plan must be equivalent in contents to an ASBS Compliance Plan as described in I (A)(2) in this document. The ASBS Pollution Prevention Plan is subject to approval by the Executive Director of the State Water Board (statewide waivers or waste discharge requirements) or Executive Officer of the Regional Water Board (Regional Water Board waivers or waste discharge requirements).

b. The ASBS Pollution Prevention Plan shall address storm water discharges (wet weather flows) and, in particular, describe how pollutant reductions in storm water runoff that are necessary to comply with these special conditions, will be achieved through Management Measures and associated Management Practices (Management Measures/Practices). Structural BMPs need not be installed if the discharger can document to the satisfaction of the State Water Board Executive Director or Regional Water Board Executive Officer that such installation would pose a threat to health or safety. Management Measures to control storm water runoff during a design storm shall achieve on average the following target levels:

(1) Table B Instantaneous Maximum Water Quality Objectives in Chapter II of the Ocean Plan; or

(2) A 90% reduction in pollutant loading during storm events, for the applicant's total discharges.

The baseline for these determinations is the effective date of the Exception, except for those structural BMPs installed between January 1, 2005 and adoption of these Special Protections, and the reductions must be achieved and documented within six (6) years of the effective date.

c. If the results of the receiving water monitoring described in IV.B. of these special conditions indicate that the storm water runoff or other nonpoint source pollution is causing or contributing to an alteration of natural ocean water quality in the ASBS, the discharger shall submit a report to the State Water Board and the Regional Water Board within 30 days of receiving the results.

(1) The report shall identify the constituents that alter natural water quality and the sources of these constituents.

(2) The report shall describe Management Measures/Practices that are currently being implemented, Management Measures/Practices that are identified in the ASBS Pollution Prevention Plan for future implementation, and any additional Management Measures/Practices that may be added to the Pollution Prevention Plan to address the alteration of natural water quality. The report shall include a new or modified implementation schedule for the Management Measures/Practices.

(3) Within 30 days of the approval of the report by the State Water Board Executive Director (statewide waivers or waste discharge requirements) or Executive Officer of the Regional Water Board (Regional Water Board waivers or waste discharge requirements), the discharger shall revise its ASBS Pollution Prevention Plan to incorporate any new or modified Management Measures/Practices that have been or will be implemented, the implementation schedule, and any additional monitoring required.

(4) As long as the discharger has complied with the procedures described above and is implementing the revised ASBS Pollution Prevention Plan, the discharger does not have to repeat the same procedure for continuing or recurring exceedances of natural water quality conditions due to the same constituent.

(5) The requirements of this section are in addition to the terms, prohibitions, and conditions contained in these Special Protections.

3. Compliance Schedule

a. On the effective date of the Exception, all non-authorized non-storm water discharges (e.g., dry weather flow) are effectively prohibited.

b. Within eighteen (18) months from the effective date of the Exception, the discharger~~s~~ shall submit a draft written ASBS Pollution Prevention Plan to the State Water Board Executive Director (statewide waivers or waste discharge requirements) or Executive Officer of the Regional Water Board (Regional Water Board waivers or waste discharge requirements) that describes its strategy to comply with these special conditions, including the requirement to maintain natural ocean water quality in the affected ASBS. The Pollution Prevention Plan shall include a description of appropriate non-structural controls and a time schedule to implement structural controls to comply with these special conditions for inclusion in the discharger's Pollution Prevention Plan. The final ASBS Pollution Prevention Plan, including a description and final schedule for structural controls based on the results of runoff and receiving water monitoring, must be submitted within thirty (30) months from the effective date of the Exception.

c. Within 18 months of the effective date of the Exception, any non-structural controls that are necessary to comply with these Special Protections shall be implemented.

d. Within six (6) years of the effective date of the Exception, any structural controls identified in the ASBS Pollution Prevention Plan that are necessary to comply with these special conditions shall be operational.

e. Within six (6) years of the effective date of the Exception, all dischargers must comply with the requirement that their discharges into the affected ASBS maintain natural ocean water quality. If the initial results of post-storm receiving water quality testing indicate levels higher than the 85^{th} percentile threshold of reference water quality data and the pre-storm receiving water levels, then the discharger must re-sample the receiving water pre- and post-storm. If after re-sampling the post-storm levels are still higher than the 85^{th} percentile threshold of reference water quality data and the pre-storm receiving water levels, for any constituent, then natural ocean water quality is exceeded. See attached Flowchart.

f. The Executive Director of the State Water Board (statewide waivers or waste discharge requirements) or Executive Officer of the Regional Water Board (Regional Water Board waivers or waste discharge requirements) may only authorize additional time to comply with the special conditions d. and e., above if good cause exists to do so. Good cause means a physical impossibility or lack of funding.

   If a discharger claims physical impossibility, it shall notify the Board in writing within thirty (30) days of the date that the discharger first knew of the event or circumstance that caused or would cause it to fail to meet the deadline in d. or e. The notice shall describe the reason for the noncompliance or anticipated noncompliance and specifically refer to this Section of this Exception. It shall describe the anticipated length of time the delay in compliance may persist, the cause or causes of the delay as well as measures to minimize the impact of the delay on water quality, the measures taken or to be taken by the discharger to prevent or minimize the delay, the schedule by which the measures will be implemented, and the anticipated date of compliance. The discharger shall adopt all reasonable measures to avoid and minimize such delays and their impact on water quality.

   The discharger may request an extension of time for compliance based on lack of funding. The request for an extension shall require:

   1. a demonstration that the discharger has made timely and complete applications for all available bond and grant funding, and either no bond or grant funding is available, or bond and/or grant funding is inadequate; or

   2. for governmental agencies, a demonstration and documentation of a good faith effort to acquire funding through that agency's budgetary process, and a demonstration that funding was unavailable or inadequate.

II. ADDITIONAL REQUIREMENTS FOR PARKS AND RECREATION FACILITIES

In addition to the provisions in Section I (A) or I (B), respectively, a discharger with parks and recreation facilities shall comply with the following:

A. The discharger shall include a section in an ASBS Compliance Plan (for NPDES dischargers) or an ASBS Pollution Prevention Plan (for nonpoint source dischargers) to address storm water runoff from parks and recreation facilities.

   1. The plan shall identify all pollutant sources, including sediment sources, which may result in waste entering storm water runoff. Pollutant sources include, but are not limited to, roadside rest areas and vistas, picnic areas, campgrounds, trash receptacles, maintenance facilities, park personnel housing, portable toilets, leach fields, fuel tanks, roads, piers, and boat launch facilities.

   2. The plan shall describe BMPs or Management Measures/Practices that will be implemented to control soil erosion (both temporary and permanent erosion controls) and reduce or eliminate pollutants in storm water runoff in order to achieve and maintain natural water quality conditions in the affected ASBS. The plan shall include BMPs or

Management Measures/Practices to ensure that trails and culverts are maintained to prevent erosion and minimize waste discharges to ASBS.

3. The plan shall include BMPs or Management Measures/Practices to prevent the discharge of pesticides or other chemicals, including agricultural chemicals, in storm water runoff to the affected ASBS.

4. The plan shall include BMPs or Management Measures/Practices that address public education and outreach. The goal of these BMPs or Management Measures/Practices is to ensure that the public is adequately informed that waste discharges to the affected ASBS are prohibited or limited by special conditions in these Special Protections. The BMPs or Management Measures/Practices shall include signage at camping, picnicking, beach and roadside parking areas, and visitor centers, or other appropriate measures, which notify the public of any applicable requirements of these Special Protections and identify the ASBS boundaries.

5. The plan shall include BMPs or Management Measures/Practices that address the prohibition against the discharge of trash to ASBS. The BMPs or Management Measures/Practices shall include measures to ensure that adequate trash receptacles are available for public use at visitor facilities, including parking areas, and that the receptacles are adequately maintained to prevent trash discharges into the ASBS. Appropriate measures include covering trash receptacles to prevent trash from being wind blown and periodically emptying the receptacles to prevent overflows.

6. The plan shall include BMPs or Management Measures/Practices to address runoff from parking areas and other developed features to ensure that the runoff does not alter natural water quality in the affected ASBS. BMPs or Management Measures/Practices shall include measures to reduce pollutant loading in runoff to the ASBS through installation of natural area buffers (LID), treatment, or other appropriate measures.

B. Maintenance and repair of park and recreation facilities must not result in waste discharges to the ASBS. The practice of road oiling must be minimized or eliminated, and must not result in waste discharges to the ASBS.

III. ADDITIONAL REQUIREMENTS – WATERFRONT AND MARINE OPERATIONS

In addition to the provisions in Section I (A) or I (B), respectively, a discharger with waterfront and marine operations shall comply with the following:

A. For discharges related to waterfront and marine operations, the discharger shall develop a Waterfront and Marine Operations Management Plan (Waterfront Plan). This plan shall contain appropriate Management Measures/Practices to address nonpoint source pollutant discharges to the affected ASBS.

1. The Waterfront Plan shall contain appropriate Management Measures/Practices for any waste discharges associated with the operation and maintenance of vessels, moorings, piers, launch ramps, and cleaning stations in order to ensure that beneficial uses are protected and natural water quality is maintained in the affected ASBS.

2. For discharges from marinas and recreational boating activities, the Waterfront Plan shall include appropriate Management Measures, described in The Plan for California's Nonpoint Source Pollution Control Program, for marinas and recreational boating, or equivalent practices, to ensure that nonpoint source pollutant discharges do not alter natural water quality in the affected ASBS.

3. The Waterfront Plan shall include Management Practices to address public education and outreach to ensure that the public is adequately informed that waste discharges to the affected ASBS are prohibited or limited by special conditions in these Special Protections. The management practices shall include appropriate signage, or similar measures, to inform the public of the ASBS restrictions and to identify the ASBS boundaries.

4. The Waterfront Plan shall include Management Practices to address the prohibition against trash discharges to ASBS. The Management Practices shall include the provision of adequate trash receptacles for marine recreation areas, including parking areas, launch ramps, and docks. The plan shall also include appropriate Management Practices to ensure that the receptacles are adequately maintained and secured in order to prevent trash discharges into the ASBS. Appropriate Management Practices include covering the trash receptacles to prevent trash from being windblown, staking or securing the trash receptacles so they don't tip over, and periodically emptying the receptacles to prevent overflow.

5. The discharger shall submit its Waterfront Plan to the by the State Water Board Executive Director (statewide waivers or waste discharge requirements) or Executive Officer of the Regional Water Board (Regional Water Board waivers or waste discharge requirements) within six months of the effective date of these special conditions. The Waterfront Plan is subject to approval by the State Water Board Executive Director or the Regional Water Board Executive Officer, as appropriate. The plan must be fully implemented within 18 months of the effective date of the Exception.

B. The discharge of chlorine, soaps, petroleum, other chemical contaminants, trash, fish offal, or human sewage to ASBS is prohibited. Sinks and fish cleaning stations are point source discharges of wastes and are prohibited from discharging into ASBS. Anthropogenic accumulations of discarded fouling organisms on the sea floor must be minimized.

C. Limited-term activities, such as the repair, renovation, or maintenance of waterfront facilities, including, but not limited to, piers, docks, moorings, and breakwaters, are authorized only in accordance with Chapter III.E.2 of the Ocean Plan.

D. If the discharger anticipates that the discharger will fail to fully implement the approved Waterfront Plan within the 18 month deadline, the discharger shall submit a technical report as soon as practicable to the State Water Board Executive Director or the Regional Water Board Executive Officer, as appropriate. The technical report shall contain reasons for failing to meet the deadline and propose a revised schedule to fully implement the plan.

E. The State Water Board or the Regional Water Board may, for good cause, authorize additional time to comply with the Waterfront Plan. Good cause means a physical impossibility or lack of funding.

If a discharger claims physical impossibility, it shall notify the Board in writing within thirty (30) days of the date that the discharger first knew of the event or circumstance that caused or would cause it to fail to meet the deadline in Section III.A.5. The notice shall describe the reason for the noncompliance or anticipated noncompliance and specifically refer to this Section of this Exception. It shall describe the anticipated length of time the delay in compliance may persist, the cause or causes of the delay as well as measures to minimize the impact of the delay on water quality, the measures taken or to be taken by the discharger to prevent or minimize the delay, the schedule by which the measures will be implemented, and the anticipated date of compliance. The discharger shall adopt all reasonable measures to avoid and minimize such delays and their impact on water quality. The discharger may request an extension of time for compliance based on lack of funding. The request for an extension shall require:

1. a demonstration of significant hardship by showing that the discharger has made timely and complete applications for all available bond and grant funding, and either no bond or grant funding is available, or bond and/or grant funding is inadequate.

2. for governmental agencies, a demonstration and documentation of a good faith effort to acquire funding through that agency's budgetary process, and a demonstration that funding was unavailable or inadequate.

IV. MONITORING REQUIREMENTS

Monitoring is mandatory for all dischargers to assure compliance with the Ocean Plan. Monitoring requirements include both: (A) core discharge monitoring, and (B) ocean receiving water monitoring. The State and Regional Water Boards must approve sampling site locations and any adjustments to the monitoring programs. All ocean receiving water and reference area monitoring must be comparable with the Water Boards' Surface Water Ambient Monitoring Program (SWAMP).

Safety concerns: Sample locations and sampling periods must be determined considering safety issues. Sampling may be postponed upon notification to the State and Regional Water Boards if hazardous conditions prevail.

Analytical Chemistry Methods: All constituents must be analyzed using the lowest minimum detection limits comparable to the Ocean Plan water quality objectives. For metal analysis, all samples, including storm water effluent, reference samples, and ocean receiving water samples, must be analyzed by the approved analytical method with the lowest minimum detection limits (currently Inductively Coupled Plasma/Mass Spectrometry) described in the Ocean Plan.

A. CORE DISCHARGE MONITORING PROGRAM

1. General sampling requirements for timing and storm size:

   Runoff must be collected during a storm event that is greater than 0.1 inch and generates runoff, and at least 72 hours from the previously measurable storm event. Runoff samples shall be collected during the same storm and at approximately the same time when post-storm receiving water is sampled, and analyzed for the same constituents as receiving water and reference site samples (see section IV B) as described below.

2. Runoff flow measurements

   a. For municipal/industrial storm water outfalls in existence as of December 31, 2007, 18 inches (457mm) or greater in diameter/width (including multiple outfall pipes in combination having a width of 18 inches, runoff flows must be measured or calculated, using a method acceptable to and approved by the State and Regional Water Boards.

   b. This will be reported annually for each precipitation season to the State and Regional Water Boards.

3. Runoff samples – storm events

   a. For outfalls equal to or greater than 18 inches (0.46m) in diameter or width:

      (1) samples of storm water runoff shall be collected during the same storm as receiving water samples and analyzed for oil and grease, total suspended solids, and, within the range of the southern sea otter indicator bacteria or some other measure of fecal contamination; and

      (2) samples of storm water runoff shall be collected and analyzed for critical life stage chronic toxicity (one invertebrate or algal species) at least once during each storm season when receiving water is sampled in the ASBS.

      (3) If an applicant has no outfall greater than 36 inches, then storm water runoff from the applicant's largest outfall shall be further collected during the same storm as receiving water samples and analyzed for Ocean Plan Table B metals for protection of marine life, Ocean Plan polynuclear aromatic hydrocarbons (PAHs), current use pesticides (pyrethroids and OP pesticides), and nutrients (ammonia, nitrate and phosphates).

   b. For outfalls equal to or greater than 36 inches (0.91m) in diameter or width:

      (1) samples of storm water runoff shall be collected during the same storm as receiving water samples and analyzed for oil and grease, total suspended solids, and, within the range of the southern sea otter indicator bacteria or some other measure of fecal contamination; and

      (2) samples of storm water runoff shall be further collected during the same storm as receiving water samples and analyzed for Ocean Plan Table B metals for protection of marine life, Ocean Plan polynuclear aromatic hydrocarbons (PAHs), current use pesticides (pyrethroids and OP pesticides), and nutrients (ammonia, nitrate and phosphates); and

      (3) samples of storm water runoff shall be collected and analyzed for critical life stage chronic toxicity (one invertebrate or algal species) at least once during each storm season when receiving water is sampled in the ASBS.

c. For an applicant not participating in a regional monitoring program [see below in Section IV (B)] in addition to (a.) and (b.) above, a minimum of the two largest outfalls or 20 percent of the larger outfalls, whichever is greater, shall be sampled (flow weighted composite samples) at least three times annually during wet weather (storm event) and analyzed for all Ocean Plan Table A constituents, Table B constituents for marine aquatic life protection (except for toxicity, only chronic toxicity for three species shall be required), DDT, PCBs, Ocean Plan PAHs, OP pesticides, pyrethroids, nitrates, phosphates, and Ocean Plan indicator bacteria. For parties discharging to ASBS in more than one Regional Water Board region, at a minimum, one (the largest) such discharge shall be sampled annually in each Region.

4. The Executive Director of the State Water Board (statewide permits) or Executive Officer of the Regional Water Board (Regional Water Board permits) may reduce or suspend core monitoring once the storm runoff is fully characterized. This determination may be made at any point after the discharge is fully characterized, but is best made after the monitoring results from the first permit cycle are assessed.

B. Ocean Receiving Water and Reference Area Monitoring Program

In addition to performing the Core Discharge Monitoring Program in Section II.A above, all applicants having authorized discharges must perform ocean receiving water monitoring. In order to fulfill the requirements for monitoring the physical, chemical, and biological characteristics of the ocean receiving waters within their ASBS, dischargers may choose either (1) an individual monitoring program, or (2) participation in a regional integrated monitoring program.

1. Individual Monitoring Program: The requirements listed below are for those dischargers who elect to perform an individual monitoring program to fulfill the requirements for monitoring the physical, chemical, and biological characteristics of the ocean receiving waters within the affected ASBS. In addition to Core Discharge Monitoring, the following additional monitoring requirements shall be met:

   a. Three times annually, during wet weather (storm events), the receiving water at the point of discharge from the outfalls described in section (IV)(A)(3)(c) above shall be sampled and analyzed for Ocean Plan Table A constituents, Table B constituents for marine aquatic life, DDT, PCBs, Ocean Plan PAHs, OP pesticides, pyrethroids, nitrates, phosphates, salinity, chronic toxicity (three species), and Ocean Plan indicator bacteria.

      The sample location for the ocean receiving water shall be in the surf zone at the point of discharges; this must be at the same location where storm water runoff is sampled. Receiving water shall be sampled prior to (pre-storm) and during (or immediately after) the same storm (post storm). Post storm sampling shall be during the same storm and at approximately the same time as when the runoff is sampled. Reference water quality shall also be sampled three times annually and analyzed for the same constituents pre-storm and post-storm, during the same storm seasons when receiving water is sampled. Reference stations will be determined by the State Water Board's Division of Water Quality and the applicable Regional Water Board(s).

   b. Sediment sampling shall occur at least three times during every five (5) year period. The subtidal sediment (sand or finer, if present) at the discharge shall be sampled and analyzed for Ocean Plan Table B constituents for marine aquatic life, DDT, PCBs, PAHs, pyrethroids, and OP pesticides. For sediment toxicity testing, only an acute toxicity test using the amphipod *Eohaustorius estuarius* must be performed.

c. A quantitative survey of intertidal benthic marine life shall be performed at the discharge and at a reference site. The survey shall be performed at least once every five (5) year period. The survey design is subject to approval by the Regional Water Board and the State Water Board's Division of Water Quality. The results of the survey shall be completed and submitted to the State Water Board and Regional Water Board at least six months prior to the end of the permit cycle.

d. Once during each five (5) year period, a bioaccumulation study shall be conducted to determine the concentrations of metals and synthetic organic pollutants at representative discharge sites and at representative reference sites. The study design is subject to approval by the Regional Water Board and the State Water Board's Division of Water Quality. The bioaccumulation study may include California mussels (*Mytilus californianus*) and/or sand crabs (*Emerita analoga* or *Blepharipoda occidentalis*). Based on the study results, the Regional Water Board and the State Water Board's Division of Water Quality, may adjust the study design in subsequent permits, or add or modify additional test organisms (such as shore crabs or fish), or modify the study design appropriate for the area and best available sensitive measures of contaminant exposure.

e. Marine Debris: Representative quantitative observations for trash by type and source shall be performed along the coast of the ASBS within the influence of the discharger's outfalls. The design, including locations and frequency, of the marine debris observations is subject to approval by the Regional Water Board and State Water Board's Division of Water Quality.

f. The monitoring requirements of the Individual Monitoring Program in this section are minimum requirements. After a minimum of one (1) year of continuous water quality monitoring of the discharges and ocean receiving waters, the Executive Director of the State Water Board (statewide permits) or Executive Officer of the Regional Water Board (Regional Water Board permits) may require additional monitoring, or adjust, reduce or suspend receiving water and reference station monitoring. This determination may be made at any point after the discharge and receiving water is fully characterized, but is best made after the monitoring results from the first permit cycle are assessed.

2. Regional Integrated Monitoring Program: Dischargers may elect to participate in a regional integrated monitoring program, in lieu of an individual monitoring program, to fulfill the requirements for monitoring the physical, chemical, and biological characteristics of the ocean receiving waters within their ASBS. This regional approach shall characterize natural water quality, pre- and post-storm, in ocean reference areas near the mouths of identified open space watersheds and the effects of the discharges on natural water quality (physical, chemical, and toxicity) in the ASBS receiving waters, and should include benthic marine aquatic life and bioaccumulation components. The design of the ASBS stratum of a regional integrated monitoring program may deviate from the otherwise prescribed individual monitoring approach (in Section IV.B.1) if approved by the State Water Board's Division of Water Quality and the Regional Water Boards.

   a. Ocean reference areas shall be located at the drainages of flowing watersheds with minimal development (in no instance more than 10% development), and shall not be located in CWA Section 303(d) listed waterbodies or have tributaries that are 303(d) listed. Reference areas shall be free of wastewater discharges and anthropogenic non-storm water runoff. A minimum of low threat storm runoff discharges (e.g. stream highway overpasses and campgrounds) may be allowed on a case-by-case basis. Reference areas shall be located in the same region as the ASBS receiving water monitoring occurs. The reference areas for each Region are subject to approval by the participants in the regional monitoring program and the State Water Board's Division of Water Quality and the applicable Regional Water Board(s). A minimum of three ocean reference water samples must be collected from each station, each from a separate storm during the same storm season that receiving water is sampled. A minimum of one reference location shall be sampled for each ASBS receiving water site sampled per responsible party. For parties discharging to ASBS in more than one Regional Water Board region, at a minimum, one reference station and one receiving water station shall be sampled in each region.

b. ASBS ocean receiving water must be sampled in the surf zone at the location where the runoff makes contact with ocean water (i.e. at "point zero"). Ocean receiving water stations must be representative of worst-case discharge conditions (i.e. co-located at a large drain greater than 36 inches, or if drains greater than 36 inches are not present in the ASBS then the largest drain greater than18 inches.) Ocean receiving water stations are subject to approval by the participants in the regional monitoring program and the State Water Board's Division of Water Quality and the applicable Regional Water Board(s). A minimum of three ocean receiving water samples must be collected during each storm season from each station, each from a separate storm. A minimum of one receiving water location shall be sampled in each ASBS per responsible party in that ASBS. For parties discharging to ASBS in more than one Regional Water Board region, at a minimum, one reference station and one receiving water station shall be sampled in each region.

c. Reference and receiving water sampling shall commence during the first full storm season following the adoption of these special conditions, and post-storm samples shall be collected during the same storm event when storm water runoff is sampled. Sampling shall occur in a minimum of two storm seasons. For those ASBS dischargers that have already participated in the Southern California Bight 2008 ASBS regional monitoring effort, sampling may be limited to only one storm season.

d. Receiving water and reference samples shall be analyzed for the same constituents as storm water runoff samples. At a minimum, constituents to be sampled and analyzed in reference and discharge receiving waters must include oil and grease, total suspended solids, Ocean Plan Table B metals for protection of marine life, Ocean Plan PAHs, pyrethroids, OP pesticides, ammonia, nitrate, phosphates, and critical life stage chronic toxicity for three species. In addition, within the range of the southern sea otter, indicator bacteria or some other measure of fecal contamination shall be analyzed.

3. Waterfront and Marine Operations: In addition to the above requirements for ocean receiving water monitoring, additional monitoring must be performed for marinas and boat launch and pier facilities:

   a. For all marina or mooring field operators, in mooring fields with 10 or more occupied moorings, the ocean receiving water must be sampled for Ocean Plan indicator bacteria, residual chlorine, copper, zinc, grease and oil, methylene blue active substances (MBAS), and ammonia nitrogen.

(1) For mooring field operators opting for an individual monitoring program (Section IV.B.1 above), this sampling must occur weekly (on the weekend) from May through October.

(2) For mooring field operators opting to participate in a regional integrated monitoring program (Section IV.B.2 above), this sampling must occur monthly from May through October on a high use weekend in each month. The Water Boards may allow a reduction in the frequency of sampling, through the regional monitoring program, after the first year of monitoring.

b. For all mooring field operators, the subtidal sediment (sand or finer, if present) within mooring fields and below piers shall be sampled and analyzed for Ocean Plan Table B metals (for marine aquatic life beneficial use), acute toxicity, PAHs, and tributyltin. For sediment toxicity testing, only an acute toxicity test using the amphipod *Eohaustorius estuarius* must be performed. This sampling shall occur at least three times during a five (5) year period. For mooring field operators opting to participate in a regional integrated monitoring program, the Water Boards may allow a reduction in the frequency of sampling after the first sampling effort's results are assessed.

Glossary

At the point of discharge(s) – Means in the surf zone immediately where runoff from an outfall meets the ocean water (a.k.a., at point zero).

Areas of Special Biological Significance (ASBS) – Those areas designated by the State Water Board as ocean areas requiring protection of species or biological communities to the extent that alteration of natural water quality is undesirable. All Areas of Special Biological Significance are also classified as a subset of State Water Quality Protection Areas.

Design storm – For purposes of these Special Protections, a design storm is defined as the volume of runoff produced from one inch of precipitation per day or, if this definition is inconsistent with the discharger's applicable storm water permit, then the design storm shall be the definition included in the discharger's applicable storm water permit.

Development – Relevant to reference monitoring sites, means urban, industrial, agricultural, grazing, mining, and timber harvesting land uses.

Higher threat discharges - Permitted storm drains discharging equal to or greater than 18 inches, industrial storm drains, agricultural runoff discharged through an MS4, discharges associated with waterfront and marina operations (e.g., piers, launch ramps, mooring fields, and associated vessel support activities, except for passive discharges defined below), and direct discharges associated with commercial or industrial activities to ASBS.

Low Impact Development (LID) – A sustainable practice that benefits water supply and contributes to water quality protection. Unlike traditional storm water management, which entails collecting and conveying storm water runoff through storm drains, pipes, or other conveyances to a centralized storm water facility, LID focuses on using site design and storm water management to maintain the site's pre-development runoff rates and volumes. The goal of LID is to mimic a site's predevelopment hydrology by using design techniques that infiltrate, filter, store, evaporate, and detain runoff close to the source of rainfall.

Marine Operations – Marinas or mooring fields that contain slips or mooring locations for 10 or more vessels.

Management Measure (MM) - Economically achievable measures for the control of the addition of pollutants from various classes of nonpoint sources of pollution, which reflect the greatest degree of pollutant reduction achievable through the application of the best available nonpoint pollution control practices, technologies, processes, siting criteria, operating methods, or other alternatives. For example, in the "marinas and recreational boating" land-use category specified in the Plan for California's Nonpoint Source Pollution Control Program (NPS Program Plan) (SWRCB, 1999), "boat cleaning and maintenance" is considered a MM or the source of a specific class or type of NPS pollution.

Management Practice (MP) - The practices (e.g., structural, non-structural, operational, or other alternatives) that can be used either individually or in combination to address a specific MM class or classes of NPS pollution. For example, for the "boat cleaning and maintenance" MM, specific MPs can include, but are not limited to, methods for the selection of environmentally sensitive hull paints or methods for cleaning/removal of hull copper anti-fouling paints.

Municipal Separate Storm Sewer System (MS4) – A municipally-owned storm sewer system regulated under the Phase I or Phase II storm water program implemented in compliance with Clean Water Act section 402(p). Note that an MS4 program's boundaries are not necessarily congruent with the permittee's political boundaries.

Natural Ocean Water Quality - The water quality (based on selected physical, chemical and biological characteristics) that is required to sustain marine ecosystems, and which is without apparent human influence, *i.e.*, an absence of significant amounts of: (a) man-made constituents (*e.g.,* DDT); (b) other chemical (*e.g.,* trace metals), physical (temperature/thermal pollution, sediment burial), and biological (*e.g.*, bacteria) constituents at concentrations that have been elevated due to man's activities above those resulting from the naturally occurring processes that affect the area in question; and (c) non-indigenous biota (*e.g.,* invasive algal bloom species) that have been introduced either deliberately or accidentally by man. Discharges "*shall not alter natural ocean water quality*" as determined by a comparison to the range of constituent concentrations in reference areas agreed upon via the regional monitoring program(s). If monitoring information indicates that *natural ocean water quality* is not maintained, but there is sufficient evidence that a discharge is not contributing to the alteration of natural water quality, then the Regional Water Board may make that determination. In this case, sufficient information must include runoff sample data that has equal or lower concentrations for the range of constituents at the applicable reference area(s).

Nonpoint source – Nonpoint pollution sources generally are sources that do not meet the definition of a point source. Nonpoint source pollution typically results from land runoff, precipitation, atmospheric deposition, agricultural drainage, marine/boating operations or hydrologic modification. Nonpoint sources, for purposes of these Special Protections, include discharges that are not required to be regulated under an NPDES permit.

Non-storm water discharge – Any runoff that is not the result of a precipitation event. This is often referred to as "dry weather flow."

Non-structural control – A Best Management Practice that involves operational, maintenance, regulatory (e.g., ordinances) or educational activities designed to reduce or eliminate pollutants in runoff, and that are not structural controls (i.e. there are no physical structures involved).

Physical impossibility - Means any act of God, war, fire, earthquake, windstorm, flood or natural catastrophe; unexpected and unintended accidents not caused by discharger or its employees' negligence; civil disturbance, vandalism, sabotage or terrorism; restrain by court order or public authority or agency; or action or non-action by, or inability to obtain the necessary authorizations or approvals from any governmental agency other than the permittee.

Representative sites and monitoring procedures – Are to be proposed by the discharger, with appropriate rationale, and subject to approval by Water Board staff.

Sheet-flow – Runoff that flows across land surfaces at a shallow depth relative to the cross-sectional width of the flow. These types of flow may or may not enter a storm drain system before discharge to receiving waters.

Storm Season – Also referred to as rainy season, means the months of the year from the onset of rainfall during autumn until the cessation of rainfall in the spring.

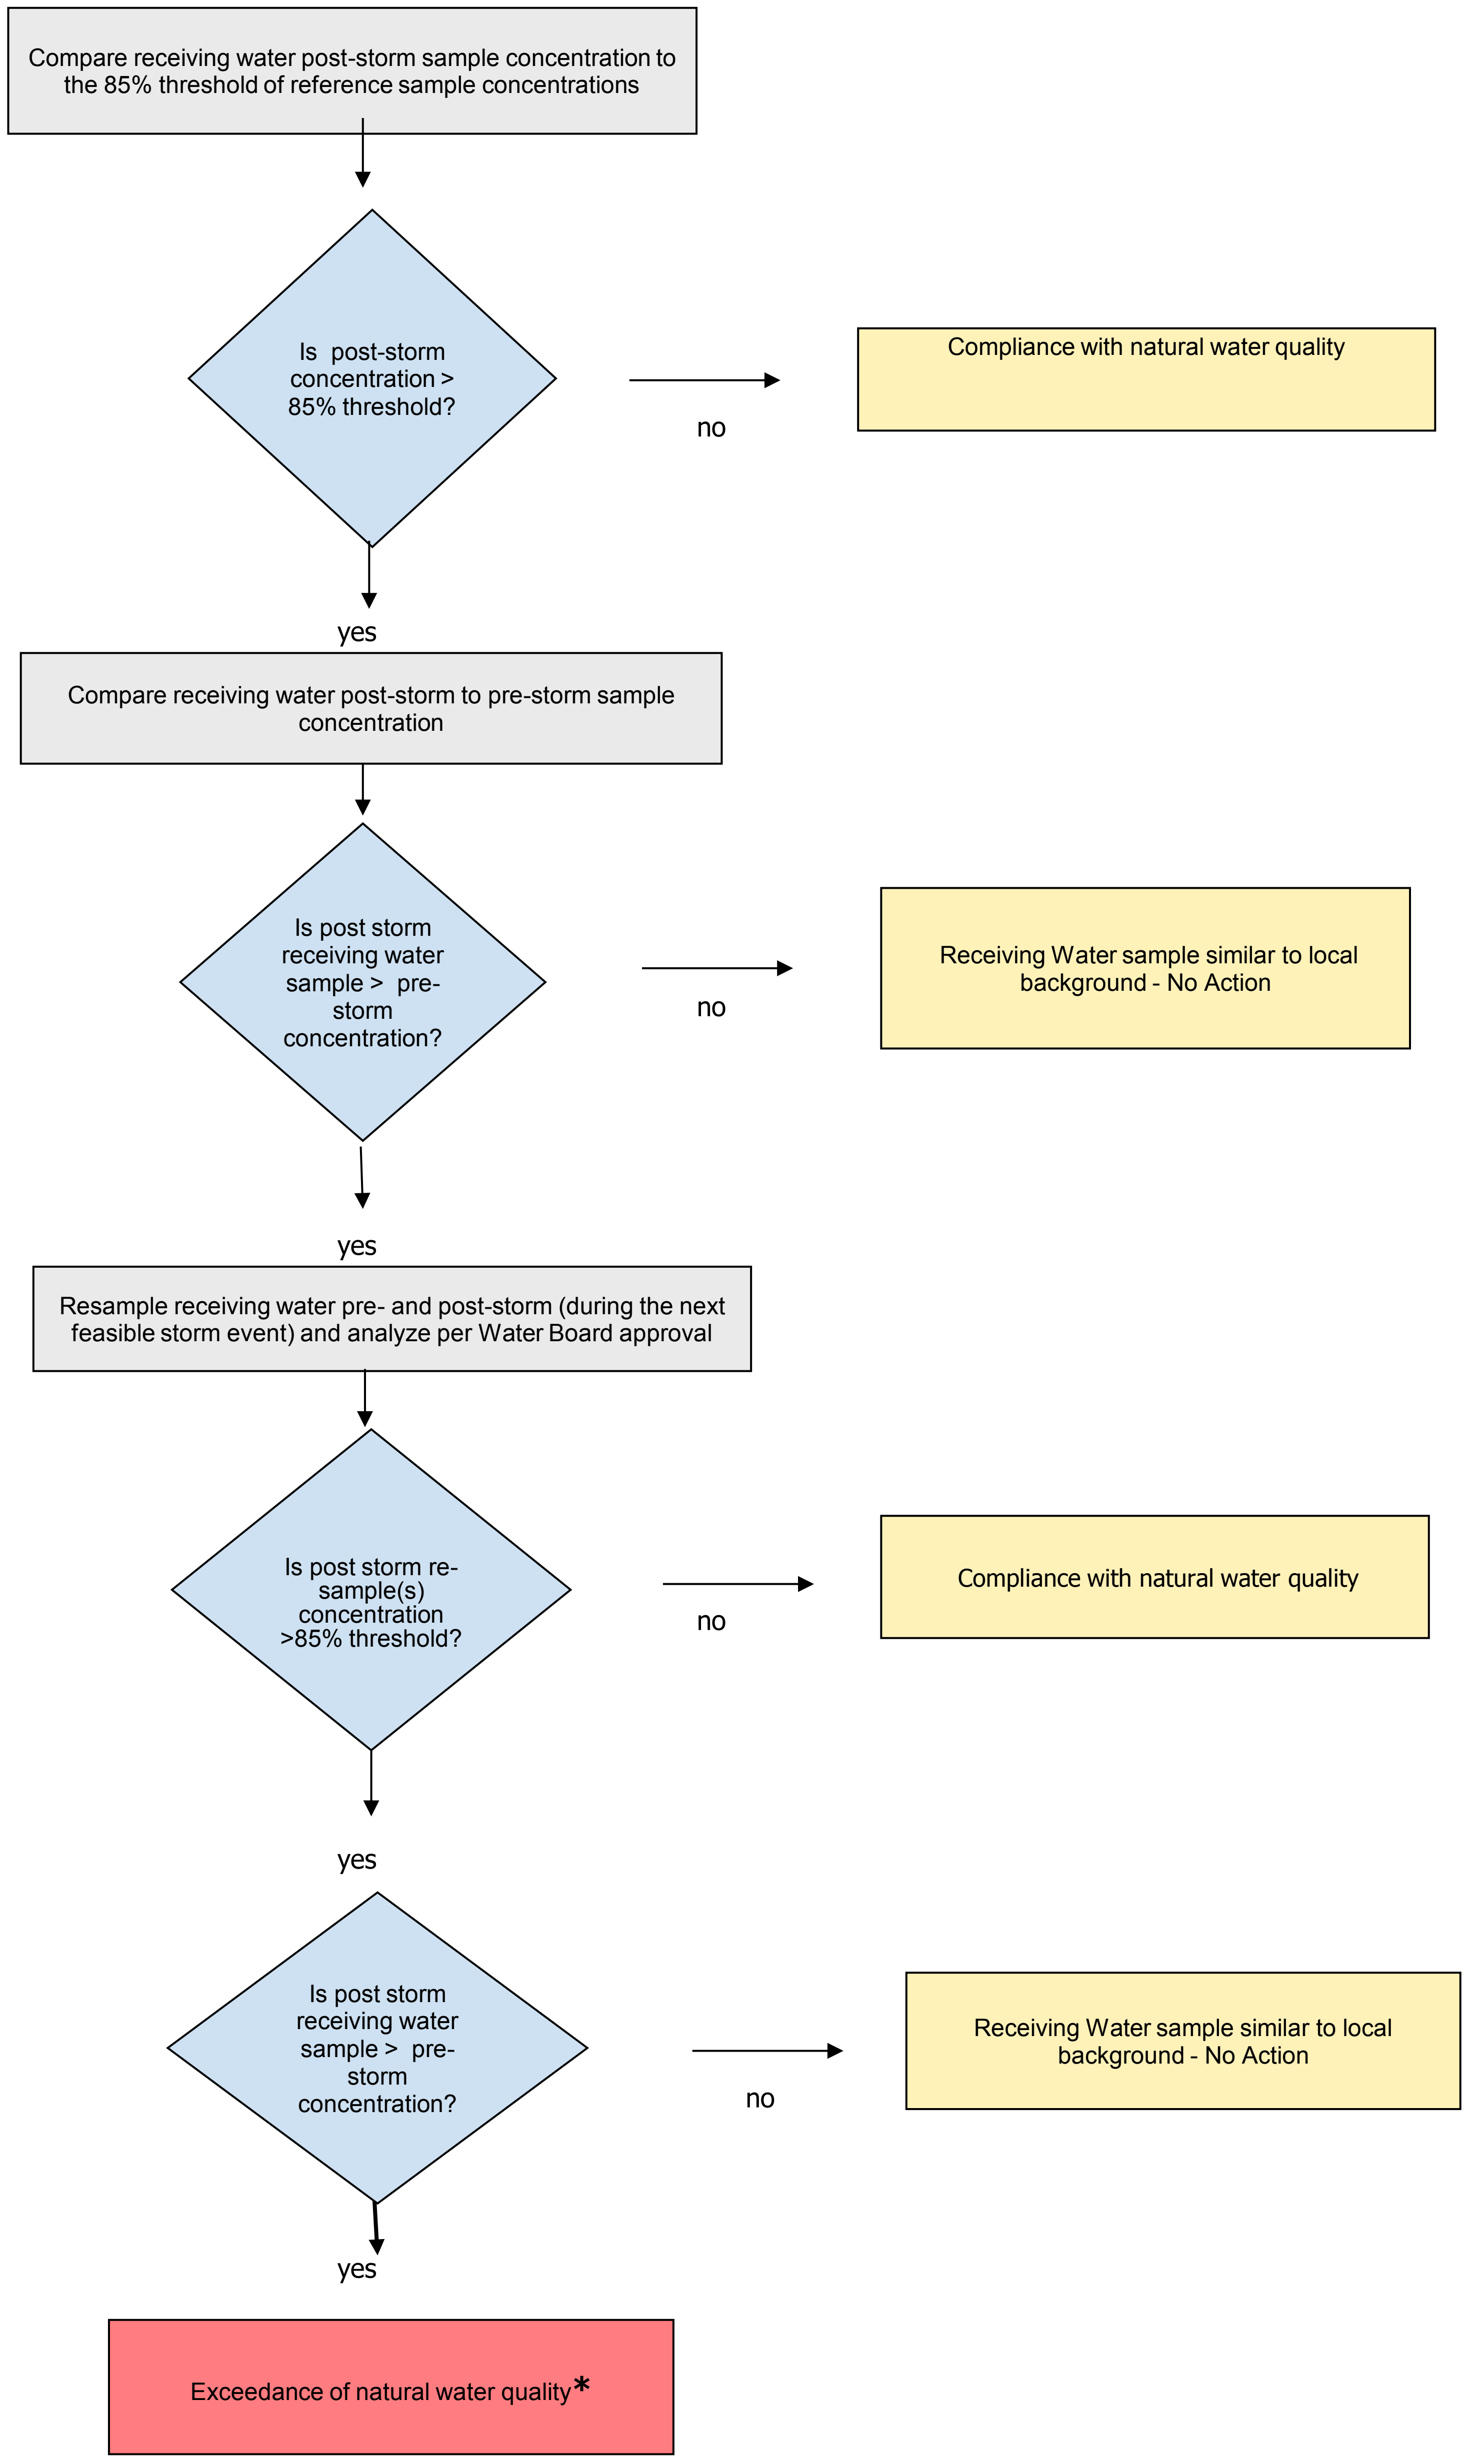
Structural control – A Best Management Practice that involves the installation of engineering solutions to the physical treatment or infiltration of runoff.

Surf Zone - The surf zone is defined as the submerged area between the breaking waves and the shoreline at any one time.

Surface Water Ambient Monitoring Program (SWAMP) comparable – Means that the monitoring program must 1) meet or exceed 2008 SWAMP Quality Assurance Program Management Plan (QAPP) Measurement Quality Objectives, or 2) have a Quality Assurance Project Plan that has been approved by SWAMP; in addition data must be formatted to match the database requirements of the SWAMP Information Management System. Adherence to the measurement quality objectives in the Southern California Bight 2008 ASBS Regional Monitoring Program QAPP and data base management comprises being SWAMP comparable.

Waterfront Operations - Piers, launch ramps, and cleaning stations in the water or on the adjacent shoreline.

Attachment 1
Special Protections Sections I(A)(3)(e) and I(B)(3)(e)
Flowchart to Deteremine Compliance with natural Water Quality



*** When an exceedance of natural water quality occurs, the discharger must comply with section I.A.2.h (for permitted storm water) or section I.B.2.c (for nonpoint sources). Note, when sampling data is available, end-of-pipe effluent concentrations will be considered by the Water Boards in making this determination.**

INTRODUCTION

The California Water Resources Control Board (SWRCB) has designated Areas of Special Biological Significance (ASBSs) as marine regions that require water quality protection. Discharges of waste into ASBSs, such as polluted storm water, are prohibited, but the State Water Resources Control Board (SWRCB) grants exceptions if it can be shown that the protection of marine life in ocean waters is not compromised. The standard for protection is that discharges “shall not alter natural ocean water quality in an ASBS” (SWRCB Resolution 2012-0012). In California, there are approximately 1,658 known discharges into ASBSs, nearly all of them storm water outfalls, which have a potential to impact ASBS water quality (SCCWRP 2003).

Wet-weather water column contamination in ASBS receiving waters was monitored in 2008 (Schiff et al. 2011). In order to define “natural”, the study used reference sites that were minimally impacted by human activities. The results from this survey found concentrations near discharges were, on average, similar to concentrations near reference sites. However, there were individual ASBS discharge sites that were greater than reference site based natural water quality thresholds. While these results were encouraging, the study did not focus on bioaccumulating compounds.

Driven by the needs of the SWRCB, the goal of this project was to answer the following questions for bioaccumulative contaminants. 1) What is the range of natural water quality for bioaccumulative compounds, as defined by mussel tissue sampled near reference stations? 2) Is the water quality for bioaccumulative compounds at ASBS discharge stations similar to that at reference stations representing natural water quality? Mussels are filter feeders that will accumulate contaminants over a longer period of time compared to storm water grab samples, and will bioconcentrate contaminants resulting in lower analytical method detection limits. Mussels have been used for decades in NOAA’s Mussel Watch Program to monitor bioaccumulative contaminants across the U.S. coastline (Kimbrough et al. 2008), but have not been previously utilized to assess ASBS water quality.

METHODS

Bioaccumulative contaminants in mussels were surveyed at 21 stations within 10 ASBSs in the Southern California Bight (Table 1 and Figure 1). Metals and synthetic organic contaminants were measured at locations representative of discharge and reference sites. The thirteen discharge sites received ASBS storm water discharge. The eight reference sites received drainage from a watershed determined to represent natural water quality. Station locations were selected by the ASBS Technical Committee and the SWRCB.

Sampling

Sample collection followed protocols established by the NOAA NS&T Mussel Watch Program (Lauenstein and Cantillo 1998, Diehl 2007). Mussels were collected from March to May 2013 at low tide by hand. Twenty individuals were collected at each of three sub-stations located along a 100 m transect of shoreline (60 individuals total per station). All intended stations were successfully sampled except at the following two locations. On Santa Catalina Island, reference station Goat Harbor could not be sampled due to field constraints (tide/weather); instead, nearby reference station Italian Gardens was sampled. On San Clemente Island, mussels were not present at discharge station Boy Scout Camp; instead, discharge station Boy Scout camp on Santa Catalina Island was sampled. As a result, San Clemente Island did not have a discharge station, only a reference station (Eel Point). *Mytilus californianus* was collected at all stations, except at Big Fisherman Cove, Two Harbors, and Boy Scout Camp on Catalina Island, where *Mytilus galloprovincialis* was collected. These two species have similar bioaccumulation potentials (Kimbrough et al. 2008). At the latter three stations, specimens were collected on man-made surfaces, whereas at all other stations specimens were collected from native habitats.

Upon collection, the shells were rinsed in water at the site to remove mud and debris, drained, and placed into individual plastic bags on ice. Samples were shipped cold to Physis Laboratories and the tissues were frozen after removal. Morphometric measurements were taken on each specimen and the individual tissues from each station were homogenized into a single sample. The sample was then split, with one portion sent for metal analysis at Physis Laboratories and one portion sent for organic analysis at SCCWRP.

Laboratory Analysis

Targeted contaminants were similar to those listed in the Ocean Plan and historically measured by the NOAA NS&T Mussel Watch Program (Table 2): metals, legacy organochlorine pesticides (OCP), polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs). Additional contaminants of emerging concern (CECs) were also measured. The polybrominated diphenyl ether (PBDE) flame retardants were recommended for monitoring in tissues by the recent expert panel on CECs in California marine ecosystems (Anderson et al. 2012), and were previously observed in Southern California mussel tissue (Dodder et al. 2013). Current use pesticides (CUP) included pyrethroids, fipronil, and fipronil degradates.

Organic contaminants were measured by gas chromatography coupled to mass spectrometry (GC/MS), and metals by inductively coupled plasma coupled to mass spectrometry (ICP/MS). The project used performance-based criteria for quality assurance. For metals, all laboratory blanks were non-detects, blank spike recoveries were 95%-108%, matrix spike recoveries were 95%-114%, the relative percent difference between duplicate matrix spikes was 0%-3%, certified reference material recoveries were 91%-109%, and the relative percent difference between replicate samples was 0%-14%. For organics, surrogate standard recoveries were 54%-116%, certified reference material recoveries were 50%-130%, and spiked matrix recoveries were 72%-110%. The relative percent difference between replicate samples was <45% for all detected organic analytes, except for 4 that were 56%-92% in one of two batches. All analytes were determined to pass the quality assurance criteria, except PCB-153/168 and PBDE-183, which were removed due to poor accuracy in the CRM. PBDE-66 passed the quality assurance criteria, but was unusually high in the mussel tissue relative to the known congener distribution in the technical mixture. This compound may have been a natural halogenated compound misidentified as a PBDE and was removed from the data set.

Data Analysis

Morphometric data was evaluated to compare mussel size and tissue mass among stations. Outlying morphometric parameter values at a particular station may indicate a difference in the age or health of the organisms, which in turn may affect contaminant concentrations relative to the other locations. The contaminant concentration data was evaluated in four steps. The results from steps 1-4 were compared and used to cross-check each other. Metals and organics were treated separately due to the higher concentration range of metals. First, the magnitude of each compound class at the reference and discharge stations were compared and outliers were noted. Second, the contaminant profiles (type and abundance of all individual compounds) were compared using clustering methods. Stations that clustered into separate groups were noted. Third, outlying reference stations were determined for each contaminant using Grubbs' test, and excluded when determining the reference threshold concentration in the next step. Fourth, a method for determining reference/discharge station equivalence was applied to each contaminant. This followed a procedure developed in the Bight '08 ASBS Study examining storm water, which used a reference-station based threshold as a proxy for distinguishing differences from natural water quality (Schiff et al. 2011). The threshold was calculated as the 85th percentile of the reference station concentrations after outliers were removed. Exceeding discharge stations were those with concentrations greater than the threshold. Threshold exceedance was determined on both a dry weight and lipid weight basis.

RESULTS

Morphometrics

The mean (± standard deviation) shell length was 61 ± 10 mm, mean total mass was 20 ± 9 g, and mean tissue mass was 5.2 ± 2.9 g. The mean shell length at each station varied among the total mean by < 2%. Shell length is a proxy for age; therefore, results indicated the mussels at each station had the same mean age and age was not a confounding variable when interpreting contaminant concentrations. The relationship between shell length and tissue mass for all 1260 individual mussels (Figure 2) can be used in future studies to predict the recoverable tissue mass given the size of collected mussels.

Contaminant Magnitude

Contaminant magnitudes are shown in Figures 3a (metals) and 3b (organics). Outlying concentrations and/or discharge stations with relatively high values are labeled. For metals, discharge station Avalon Quarry, Santa Catalina Island, had copper, silver, and molybdenum concentrations that exceeded reference station levels. Discharge station Boy Scout Camp, Santa Catalina Island, had cadmium, copper, lead, and selenium concentrations that exceeded reference station levels. Reference station Thousand Springs, San Nicholas Island, had relatively high levels of arsenic and nickel that exceeded discharge station levels.

For organics, discharge station Barge Landing, San Nicholas Island, had DDT, PCB, PBDE, and Other Pesticides concentrations that exceeded reference station levels (except Thousand Springs for PCB; Figure 4). Discharge station Two Harbors, Santa Catalina Island, had PAH concentrations that exceeded reference station levels. Discharge station Muddy Canyon, Irvine Coast, had DDT and Other Pesticide concentrations that exceeded reference station concentrations. Three Orange County discharge stations, Buck Gully South, Muddy Canyon, and Heisler Park, had elevated fipronil concentrations relative to the reference stations. Reference station Thousand Springs, San Nicholas Island, had relatively high levels of PCB that exceeded discharge station levels.

Contaminant Profile Clustering

Clustering methods compare the relative abundances of the contaminants. Stations that have a shorter "distance" to one another (i.e., cluster together) have similar contaminant profiles. Stations that have a further "distance" from one another have dissimilar contaminant profiles. Clustering methods consider the relative abundances, not absolute magnitudes, of the contaminants. For the organics, individual compound concentrations were used, not the compound class concentrations. Three clustering algorithms were applied and the results are summarized in Figures 5a (metals) and 5b (organics). The methods were hierarchical analysis, *k*-means clustering, and principal components analysis (PCA). Conclusions were based on a weight of evidence approach, where the highest confidence was reached if all three algorithms had the same result.

For metals, results from the three clustering algorithms showed Eel Point and Bird Rock (reference stations on San Clemente Island and Santa Catalina Island, respectively) formed a separate cluster due to low aluminum concentrations. This is visualized in the PCA plot, where the first two principal components (PC1 and PC2) represent 73% of the variation in the data. In the PCA plot, Boy Scout Camp on Santa Catalina Island appears distinct from the other stations due to a higher cadmium concentration, but this result was not corroborated by the other clustering algorithms.

For organics, results from the three clustering algorithms showed Two Harbors and Big Fisherman Cove (discharge stations on Santa Catalina Island) formed a separate cluster due to high PAH concentrations. Thousand Springs and Barge Landing (the reference and discharge stations on San Nicholas Island, respectively) formed a second separate cluster due to high PCB concentrations. The remaining stations may be considered as one cluster. This is visualized in the PCA plot, where the first two principal components (PC1 and PC2) represent 71% of the variation in the data.

Reference Outlier Detection

Outlier reference concentrations are shown in Table 3. Thousand Springs, San Nicholas Island, was found to have multiple outlying contaminants and may not be suitable as a reference station in future surveys. For some contaminants, the normality assumption of Grubbs' test was questionable due to only one or two detects among the reference stations. In this case, if the detect was at Thousand Springs, it was considered an outlier since multiple lines of evidence (contaminant magnitudes and clustering) indicated it may not have reference conditions. Otherwise, the station was not considered an outlier.

Reference Threshold Exceedance

The 85th percentile of the reference station concentrations for a given analyte, with outliers removed, was used to set the exceedance threshold. This threshold concentration was applied to each discharge station, and the number of exceeding contaminants at each station was determined. Figures 6a (metals) and 6b (organics) show the frequency of exceeding contaminants at each station. Fifteen percent exceedance was expected due to the 85th percentile threshold that was applied. Stations close to or below 15% exceedance were determined to have natural water quality.

For metals, stations on Santa Catalina Island with a greater than 15% exceedance frequency were Avalon Quarry (50%), Boy Scout Camp (42%), Big Fisherman Cove (25%), and Two Harbors (25%). Other exceeding stations were Buck Gully South (42%), and Scripps Reef (25%). There is a greater uncertainty in the exceedance of Big Fisherman Cove, Two Harbors, and Scripps Reef because their values are closer to the 15% threshold. The metals responsible for exceeding stations are described in Table 4a. Copper was responsible for all 6 exceeding stations and manganese for 4 of the 6 stations.

For organics, island stations with a greater than 15% exceedance frequency were Barge Landing on San Nicolas (36%), and Two Harbors (36%) and Big Fisherman Cove (32%) on Santa Catalina. Mainland stations were Buck Gully South (33%) and Crystal Cove (33%). Other stations had an exceedance frequency of 15%-25% and therefore a greater uncertainty in the result. The organic contaminants responsible for the five highest exceeding stations are described in Table 4b. PAHs were primarily responsible for exceedances on Santa Catalina Island. PCBs and PBDEs were primarily responsible for exceedances on San Nicholas Island.

Tables 5a, 5b, 6a and 6b give the full set of concentrations for each contaminant at both reference and discharge stations.

DISCUSSION

All reference stations were determined to be suitable except for Thousand Springs on San Nicholas Island. This station had a similar contaminant profile to its paired discharge station, Barge Landing, and had unusually high PCB concentrations relative to the other reference stations. In this study, outlying reference concentrations for individual contaminants were removed. Future surveys should consider excluding Thousand Springs as a reference location.

Three methods were used to analyze the contaminant data: 1) compare the concentration magnitudes at reference and discharge locations, 2) compare the relative profiles using clustering algorithms, and 3) determine if the discharge station concentration exceeds a reference threshold. These three methods generally agreed on both the discharge stations that were different from reference conditions, and on the contaminants responsible for the differences. Agreement among the methods increased the confidence in the results. The exception was the clustering results for metals, which did not identify exceeding stations observed by the other methods. For example, Avalon Quarry, Santa Catalina Island, had the highest exceedance frequency at 50% (Figure 6a), but was not identified as different from reference conditions by the clustering methods. This is because the clustering algorithms compare abundances of contaminants relative to one another, not the absolute magnitudes, and can miss magnitude differences if the relative abundances of contaminants are similar.

The concentration basis is a potentially confounding factor in the interpretation of the organic contaminant results. Organic contaminant concentrations may be calculated on either a dry weight basis or a lipid weight basis. We reported concentrations on a dry weight basis because this is the more common format for mussel tissue data (Lauenstein and Cantillo 1998, Kimbrough et al. 2008, Dodder et al. 2013), but many of the bioaccumulative contaminants are known to be positively correlated with increasing lipid mass. Therefore, the reference threshold exceedance was also calculated with concentrations on a lipid weight basis. Table 7 compares the results using both normalization methods. There was agreement that Barge Landing (San Nicholas Island), Two Harbors and Big Fisherman Cove (Santa Catalina Island), and Buck Gully South (mainland) are different than reference conditions. Other stations that exceeded on a dry weight basis did not exceed on a lipid weight basis.

Taking into account the results from the three data analysis methods, with preference given to the reference threshold exceedance method, and the dry weight/lipid weight comparison for organics, the following stations were determined to be different from natural water quality. 1) Barge Landing in the San Nicholas Island ASBS (due to organics); 2) Two Harbors (organics), Big Fisherman Cove (organics), and Boy Scout Camp (metals) in the NW Santa Catalina Island ASBS; 3) Avalon Quarry (metals) in the SE Santa Catalina ASBS; and 4) Buck Gully South (metals and organics) in the Robert Badham ASBS. Note that mussels at Two Harbors and Big Fisherman Cove were collected on man-made structures (see Table 1 for the types of structures) and had relatively high PAH concentrations. Boy Scout Camp was also collected on a man-made structure and had relatively high metal concentrations. The results for these three stations may have been influenced by their close proximity to boating activity in addition to possible storm water influence.

In 2010, NOAA, the State Water Resources Control Board, and SCCWRP collaborated to sample mussel tissues across the California coast (Dodder et al. 2013). This was in part a continuation of NOAA's Mussel Watch program, but was exclusive to California, included more stations within the state, and expanded the list of measured compounds to include contaminants of emerging concern. This data set, which includes stations intentionally selected to have the highest contaminant loads in California, can be used to put the ASBS contaminant concentrations in perspective; see Table 8 for a list of representative compounds. ASBS stations measured in the present study were lower than the maximum concentrations observed at non-ASBS stations in the 2010 study. Maximum metal concentrations in the present study were within an order of magnitude of the maximum concentration at non-ASBS stations. However, maximum organic contaminant concentrations were one to two orders of magnitude higher in the non-ASBS stations.

CONCLUSIONS AND RECOMMENDATIONS

The goal of this project was to answer the following questions for bioaccumulative contaminants. 1) What is the range of natural water quality for bioaccumulative compounds, as defined by mussel tissue sampled near reference stations? 2) Is the water quality for bioaccumulative compounds at ASBS discharge stations similar to that at reference stations representing natural water quality? The conclusions were:

- **Cumulatively, the differences between reference and discharge stations were small.**
  Median contaminant concentrations were similar between reference stations and discharge stations for both metals and organic contaminants. Contaminant profiles (types and relative abundances) among all stations were also similar based on cluster analysis.

- **Despite the similarity in average concentrations between reference and discharge stations, there were differences in concentrations at individual sites.**
  For organic contaminants, the four discharge stations determined to be different from natural water quality were Barge Landing (San Nicholas Island ASBS), Two Harbors and Big Fisherman Cove (NW Santa Catalina Island ASBS), and Buck Gully South (Robert Badham ASBS).
  For metals, the three discharge stations determined to be different from natural water quality were Avalon Quarry (SE Santa Catalina Island ASBS), Boy Scout Camp (NW Santa Catalina Island ASBS), and Buck Gully South (Robert Badham ASBS)

- **The compounds that exceeded natural water quality thresholds most frequently were copper and PAHs.**
  Of those discharge stations that exceeded natural water quality thresholds, copper was the only metal of concern at every station. Similarly, PAHs were the only organic compound of concern at every station that exceeded natural water quality thresholds. While this survey was intended to examine storm water discharges, proximity to boating activity may be a contributing factor for PAH and/or copper concentrations observed in the NW Santa Catalina Island ASBS.

- **Thousand Springs on San Nicholas Island may not be a suitable reference station.**
  The Thousand Springs reference site had high PCB concentrations relative to the other reference stations, and also had a contaminant profile similar to the discharge station on San Nicholas Island (Barge Landing). As a result, multiple PCB congeners from Thousand Springs were removed as outliers prior to establishing reference threshold values.

- **Concentrations at ASBS discharge stations were lower than maximum values observed at non-ASBS stations in the 2010 California Mussel Watch survey.**
  The most recent Mussel Watch survey in California occurred in 2010. Compared to concentrations of representative compounds in the current survey, median ASBS concentrations are lower for PAH, PCB, DDT, and PBDE.

Future recommendations include:

- **Bioaccumulation results should be connected to the other concurrent ASBS surveys on aqueous-phase storm water contaminants and biodiversity.**
  The bioaccumulation results in this report are not the only indicator of natural water quality being measured near ASBS discharges. Storm water discharges and adjacent receiving waters are being measured for pollutant concentrations and toxicity. Also, biodiversity surveys that identify and enumerate rocky intertidal biological communities are being conducted at many of the same discharge and reference stations sampled for bioaccumulation. These different indicators of

environmental stress and biological response should be integrated in a synthesis report of ASBS condition.

- **Resample San Nicholas and NW Santa Catalina Island ASBSs to confirm the contaminant concentrations observed in this study.**
  While mussels are a valuable indicator because they integrate pollutant concentrations over time, re-sampling at these sites is recommended as a confirmation step. Re-sampling efforts should investigate the use of an alternate San Nicholas Island reference station. Additionally, the NW Santa Catalina Island discharge stations should be collected at locations near the storm water discharge, but away from boating activity and on non-anthropogenic substrates in an effort to isolate the different sources of potential pollutants.

Figure 1. Map of discharge and reference stations sampled for bioaccumulative contaminants in mussels.

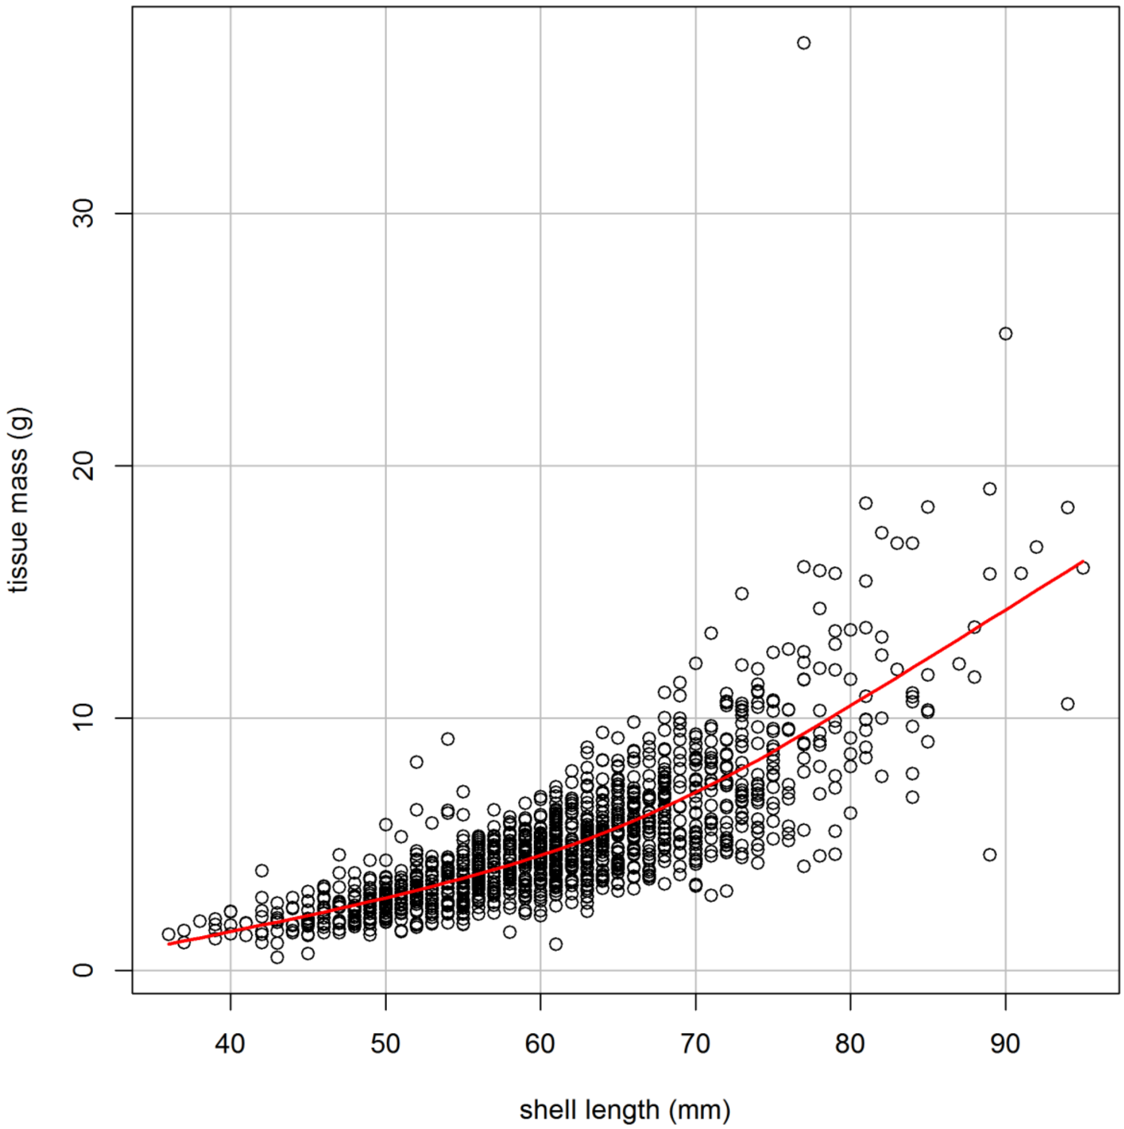

Figure 2. Shell length as a predictor of tissue mass. The data set is primarily *Mytilus californianus*, but 14% of the mussels (3 of the 21 stations) were *Mytilus galloprovincialis*. The fitted line is a cubic smoothing spline.

Table 4a. Metal threshold exceedance by station. Check marks indicate metals that exceeded the reference threshold concentration.

Metal	Avalon Quarry	Boy Scout Camp	Buck Gully South	Big Fisherman Cove	Scripps Reef	Two Harbors
Copper	✓	✓	✓	✓	✓	✓
Manganese	✓	✓	✓		✓	
Selenium	✓	✓		✓		✓
Cadmium		✓		✓		✓
Zinc	✓		✓			
Molybdenum	✓					
Silver	✓					
Lead		✓				
Arsenic			✓			
Nickel			✓			

Table 4b. Organic contaminant threshold exceedance by station. Values are the number of individual compounds that exceeded the reference threshold concentrations. The value in parentheses is the percent of exceeding contaminants within the compound class.

Contaminant Class	Barge Landing	Two Harbors	Big Fisherman Cove	Crystal Cove	Buck Gully South
PAH	2	22 (81%)	19 (70%)	4	13 (48%)
PCB	12 (28%)	0	0	7 (16%)	1
PBDE	8 (57%)	2	2	8 (57%)	3
Fipronil	1	0	1	1	3 (75%)
DDT	1	0	0	4 (50%)	0
Other Pesticides	2	0	0	0	0

Table 5a. Discharge station metal concentrations (µg/g dry weight).

Metal	Reference Threshold	Avalon Quarry	Barge Landing	Big Fisherman Cove	Boy Scout Camp	Buck Gully South	Crystal Cove	Deer Creek	Heisler Park	Lechuza Point	Muddy Canyon	Paradise Cove	Scripps Reef	Two Harbors

EXECUTIVE SUMMARY

Over 280 km of shoreline have been designated as marine water quality protected areas, termed Areas of Special Biological Significance (ASBS), in southern California, USA. While the standard for water quality protection in an ASBS is “natural water quality”, there are at least 271 documented coastal discharges that potentially threaten this important ecological resource. The goal of this study was to assess the water quality status of ASBS by answering two questions: 1) What is the range of natural water quality near reference drainage locations? and 2) How does water quality near ASBS discharges compare to the natural water quality near reference drainage locations? Previous monitoring of southern California ASBS in 2008-09 was able to produce natural water quality guidelines, and ASBS water quality was generally comparable to these guidelines without widespread, dramatic alterations. The work detailed in this report, describes a second survey in 2012-14, which aims to increase confidence in the natural water quality guidelines and confirm the lack of demonstrative impacts to water quality in ASBS.

The sample design focused exclusively on receiving water (not effluents) and wet weather, which are the locations and times where natural and anthropogenic contributions can mix making pollutants difficult to identify and control. Twenty-seven locations encompassing 57 site-events were sampled immediately prior to (<48 hours), then immediately following (<24 hours) storm events ranging from 0.09 to 2.58 inches rainfall. Mean concentrations of total suspended solids (TSS), nutrients (ammonia, nitrate, nitrite, total phosphorus), total trace metals (arsenic, cadmium, chromium, copper, nickel, lead, silver, and zinc), pyrethroid and organophosphorus pesticides, and polycyclic aromatic hydrocarbons (PAH) from post-storm samples were similar at reference drainage and ASBS discharge sites. The average concentration difference between post-storm geometric mean concentrations at reference drainage vs. ASBS discharge sites across all parameters was <10%. Concentrations of pesticides were infrequent and post-storm samples rarely exhibited significant toxicity despite testing with three different endemic species. In addition, there was no consistent increase from pre- to post-storm concentrations at either reference drainage or ASBS discharge locations. Most post-storm concentrations did not correlate well with storm parameters (i.e., rainfall quantity, duration, intensity) or stormwater tracers (i.e., salinity, TSS), decreasing the utility of these tools for predicting impacts. A reference drainage site based threshold was used as a proxy for distinguishing differences from natural water quality. The reference based threshold included a two-step process: 1) was the individual chemical post-storm discharge concentration greater than the 85th percentile of the reference drainage site post-storm concentrations; and then 2) was the individual post-storm discharge concentration greater than the pre-storm concentration for the same storm event. While the concentrations near ASBS discharges were on average similar to reference site concentrations, there were some individual ASBS discharge sites that were greater than the reference site based threshold. Cumulatively across all ASBS, the constituents that were most frequently greater than the reference site based threshold were PAHs, pesticides, and nutrients.

TABLE OF CONTENTS

INTRODUCTION

Environmental managers face a tremendous challenge trying to maintain water quality in the face of urban development. Nowhere is this more apparent than in southern California. Population in the three coastal counties has increased from roughly 10 million in 1970 to 24 million in 2010; an increase of 140% in just 40 years (US Census 2009). Along with this increase in urban development, are commensurate increases in habitat loss, flow modification, and pollutant inputs from surface runoff (Lyon and Stein 2009, Schiff and Sutula 2004, Tiefenthaler *et al.* 2008).

In the early to mid-1970's, perhaps in anticipation of the urbanizing coastline, the State Water Resources Control Board (SWRCB) created a series of water quality protected areas, termed Areas of Special Biological Significance (ASBS). The language in the SWRCB's Ocean Plan (2010) states that ASBS shall not have any "discharge of waste" and shall maintain "natural water quality". There are 14 ASBS in southern California covering approximately 280 km of shoreline in southern California (Figure 1).

Since the mid-1970's, the SWRCB has effectively prevented the construction of treated municipal or industrial wastewater outfalls in ASBS. However, there are at least 271 storm drain outfalls that discharge to ASBS (SCCWRP 2003). These storm drain outfalls likely discharge natural constituents (i.e., suspended solids, nutrients or trace metals) as well as the possibility of anthropogenic pollutant contributions of these natural constituents and some human synthesized pollutants (i.e., pesticides).

In order to address the dilemma between water quality protected areas and development in the coastal zone, the goal of this study was to assess the water quality in southern California ASBS. Specifically, the study was designed to answer two questions: 1) what is the range of natural water quality near reference drainage locations? and 2) how does water quality near ASBS discharges compare to the natural water quality at reference drainage locations? The first question aims to quantify what is meant by "natural water quality" by visiting locations presumptively free of anthropogenic contributions. The second question compares the natural water quality levels derived from the first question to water quality near ASBS discharges to determine the level of existing water quality protection.

In 2008-09, the dischargers to ASBS in southern California and their state regulators collaborated on a first-of-its-kind regional monitoring program in an attempt to answer these questions (Schiff *et al.* 2011). After collecting 35 storm-event samples in the ocean from Malibu to San Diego, the water quality measured in ASBS receiving water near storm drain discharges was similar to the water quality at reference locations. However, one of the primary limitations from that study was a concern that the data set was too sparse. The regional monitoring collaborative recommended collecting additional data to capture the range of variability inherent between storms, between wet seasons, and between additional sites. The goal of this study fulfills these recommendations, collecting additional storms to quantify the range of variability from reference locations and near ASBS discharges, and to confirm that water quality in ASBS is being protected.

METHODS

There are 34 ASBS in California, 14 of which occur in southern California (Figure 1). The majority (78%) of ASBS shoreline in southern California surrounds the offshore Channel Islands, but a significant fraction (35 km) occur along the six mainland ASBS.

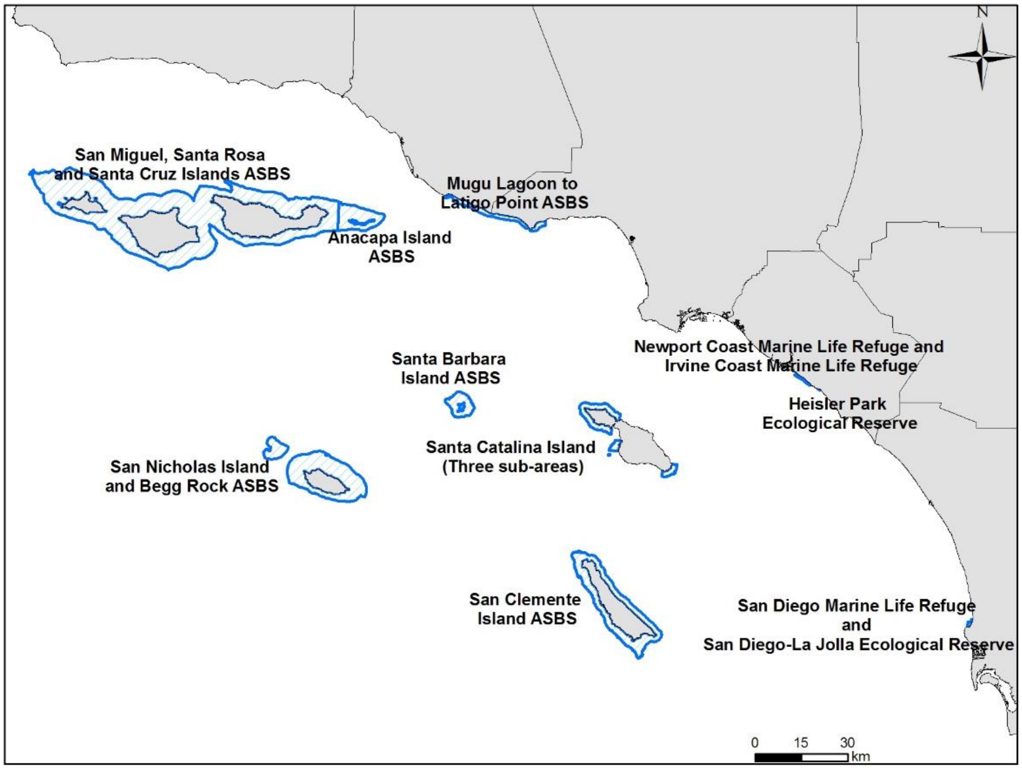

Figure 1. Southern California Areas of Special Biological Significance.

This study had two primary design elements. The first design element was a focus on receiving water. All samples were collected in receiving waters near reference drainage or ASBS discharges; no effluent discharge samples were collected as part of this study. The second design element was a focus on wet weather. Dry weather was not addressed in this study assuming that all non-storm discharges are, or soon will be, remediated.

Sampling

Twenty-seven sites were selected for wet weather sampling in this study (Table 1). Fourteen of the sampling locations were reference drainage sites (representing natural water quality) and 13 were ASBS discharge sites. Reference site selection followed five criteria: 1) the site must be an open beach with breaking waves (i.e., no embayments); 2) the beach must have drainage from a watershed that produces flowing surface waters during storm events; 3) the reference watershed should be similar in size to the watersheds that discharge to ASBS; 4) the watershed must be comprised of primarily (>90%) open space; and 5) neither the shoreline nor any segment within the contributing watershed can be on the State's 2006 list of impaired waterbodies (e.g., §303d list). All but one of the reference drainage sites was located within an ASBS.

Table 1. Sampling sites and sample inventory.

		Total No. Reference Site-Events				**26**	**27**
		Total No. Discharge Site-Events				**33**	**30**
		Total No. Site-Events				**59**	**57**

A total of 57 site-events were sampled (Table 1). Twenty-seven site-events were sampled near reference drainage locations, and another 30 site-events were sampled near ASBS discharge locations. Up to three storm events were sampled per site. A storm was defined as any wet weather event that resulted in surface flow across the beach into the ocean receiving water. Rainfall during sampled events ranged from 0.09 to 2.58 inches. Pre-storm samples were collected prior to (<48 hours) rainfall, and post-storm samples were collected immediately following (<24 hours) rainfall, with most post-storm samples collected less than 6 hours after rainfall cessation. All post-storm samples also had a pre-storm sample collected. Samples were collected in the ocean at the initial mixing location in the receiving water. Both pre- and post-storm samples were collected by filling pre-cleaned intermediate container just below the water surface and then pouring sequential aliquotes into sample containers to ensure homogeneity.

Laboratory Analysis

All water samples were analyzed for 18 parameters: 1) general constituents including total suspended solids (TSS), oil and grease, and salinity; 2) nutrients including nitrate (NO3-N), ammonia (NH3-N), and ortho-phophate (PO4-P); 3) total [unfiltered] trace metals (arsenic, cadmium, chromium, copper, mercury, nickel, lead, selenium, silver, zinc); 3) pyrethroid (8 pyrethroids) and organophosphorus (2 OPs) pesticides; 4) total polycyclic aromatic hydrocarbons (28 PAHs); and 5) three different short-term chronic toxicity tests using endemic species (successful egg fertilization of purple sea urchin *Strongylocentrotus purpuratus*, normal germination and tube growth using the giant kelp *Macrocycstis pyrifera*, and normal growth and development of the California mussel *Mytilus californianus*). All sample analysis followed standard methods and/or EPA approved procedures (APHA 2006, USEPA 1995). Trace metals were prepared for analysis using ammonium pyrrolidine dithiocarbamate (APDC), a chelation method that concentrates trace metals and removes matrix interferences (USEPA 1996).

The project focused on performance-based measures of quality assurance. In general, laboratory data quality was quite good: 100% sample completeness, no laboratory blank samples were greater than the method detection limit; 90% success meeting data quality objectives (DQOs) for precision using laboratory duplicates; 96% success meeting DQOs for accuracy using spiked samples. All toxicity tests indicated 100% success meeting DQOs for negative and positive control response.

Data Analysis

Data analysis followed four steps. The first step was determining the validity of reference drainage site selection. This was achieved by examining the data for known anthropogenic contamination (i.e., synthetic pesticides such as pyrethroids and fipronyl), testing for outlier samples in the reference drainage data set, and the presence of toxicity. The second data analysis step compared the average concentration of post-storm ambient concentrations at reference drainage sites to ASBS discharge sites. Differences between these concentrations were evaluated using a studentized T-test. The third data analysis step examined potential relationships among parameters looking for explanatory variables that derive differences both within reference drainage sites and between reference drainage and ASBS discharge sites. Rainfall quantity, TSS and salinity concentrations were correlated with all of the post-storm chemical concentrations. For the final data analysis, a reference site based threshold was used as a proxy for distinguishing differences from natural water quality (Table 2). The reference based threshold included a two-step process: 1) was the individual chemical post-storm discharge concentration greater than the 85th percentile of the reference drainage site post-storm concentrations; and then 2) was the individual post-storm discharge concentration greater than the pre-storm concentration for the same storm event.

Table 2. Reference drainage site based thresholds (85th percentile of reference drainage site distribution) used as proxies of natural water quality in south coast areas of special biological significance.

Analyte	Reference Drainage Site Thresholds (85th Percentile)
Ammonia as N (mg/L)	0.015
Nitrate as N (mg/L)	0.34
Oil and Grease (mg/L)	0.5
Orthophosphate as P (mg/L)	0.10
Total Suspended Solids (mg/L)	48
Arsenic (µg/L)	1.8
Cadmium (µg/L)	0.15
Chromium (µg/L)	1.9
Copper (µg/L)	1.5
Lead (µg/L)	0.5
Mercury (µg/L)	0.0006
Nickel (µg/L)	1.3
Selenium (µg/L)	0.0025
Silver (µg/L)	0.08
Zinc (µg/L)	18.6
Total PAHs (µg/L)	0.0125
Total Organophosphorus pesticides (µg/L)	0.006
Total Pyrethroid pesticides (µg/L)	0.00675

Minimum detection limits for each compound are listed in Appendix B. For all calculations, one-half the detection limit was used when samples were non-detectable. Organic analyses flagged as quantifiable estimates below the reporting level, but above the detection limit, were used as reported.

RESULTS

There was a wide range of rainfall characteristics of the storms sampled across the Southern California region during the 2013-14 study year (Table 3). Storm rainfall totals ranged from 0.09 to 2.58 inches per storm event, with an event median of 0.16 inches. The greatest rainfall generally occurred in the north. For example, Malibu had triple the amount of rain measured at San Onofre on March 1, 2014 (2.58 vs. 0.91 inches) and double the amount of rain measured at Laguna on February 27, 2014 (0.79 vs. 0.32 inches). Storm rainfall intensity ranged from 0.06 to 0.66 inches per hour, with a median of 0.16. In general, the islands tended to have the least intense rainfall, never exceeding 0.27 inches per hour and the majority of storm events less than 0.11 inches per hour. Storm durations ranged from 2.9 to 50 hours, with a median of 9.4 hours. Except for Laguna, every site had at least one storm that exceeded 20 hours.

Table 3. Rainfall by region within southern California.

Region	Sampling Dates	Maximum Intensity (inches/hr)	Storm Total (inches)	Storm Duration (hr)
Malibu	2/19/2013	0.14	0.20	2.9
	3/8/2013	0.20	0.33	33.3
	2/27/2014	0.28	0.79	8.7
	3/1/2014	0.53	2.58	20.0
Laguna	2/19/2013	0.66	0.30	11.5
	3/8/2013	0.64	0.36	3.6
	2/27/2014	0.29	0.32	4.0
San Onofre	3/1/2014	0.15	0.91	50.0
La Jolla	1/25/2013	0.10	0.43	22.3
	2/8/2013	0.11	0.19	6.5
	2/20/2013	0.16	0.37	8.5
Catalina Island	2/20/2013	0.11	0.20	4.0
	3/8/2013	0.11	0.17	4.1
	2/28/2014	0.27	1.08	32.8
San Nicolas Island	1/25/2013	0.06	0.33	32.0
	2/20/2013	0.07	0.09	8.0
	3/8/2013	0.13	0.22	8.0
	2/28/2014	0.25	0.41	10.0
San Clemente Island	1/25/2013	0.07	0.21	26.2
	2/28/2014	0.17	0.91	32.0
	Min	0.06	0.17	2.9
	Max	0.66	2.58	50.0
	Median	0.16	0.33	9.4

Post-storm reference drainage site concentrations were similar to post-storm ASBS discharge site concentrations (Table 4). For 18 parameters (including TSS, nutrients, total PAH, total pyrethroids, and total trace metals), none were significantly different between reference and discharge sites following storm events ($p < 0.05$). No constituent differed by more than an order of magnitude between mean reference and discharge site concentration; half of the constituents differed by less than a factor of two. The two largest differences were for mercury, where 95% of all samples were below detection limits and TSS, which had roughly three times greater concentration at reference drainage sites than ASBS discharge sites.

In general, there was no consistent increase or decrease in concentrations pre- to post-storm at reference drainage or ASBS discharge sites (Figure 2). Pre:Post-storm concentration ratios were not significantly different between reference drainage and ASBS discharge sites for any of the trace metals. Nearly every trace metal, whether from reference drainage or ASBS discharge sites, encompassed unity within its interquartile distribution indicating that pre- and post-storm concentrations were similar. The only exception was copper, with over 75% of the ASBS discharge site distribution greater than 1. This would indicate that receiving water concentrations of copper increased following storm events. However, the maximum pre:post storm ratio at reference drainage sites was greater than the ratio at ASBS discharge sites.

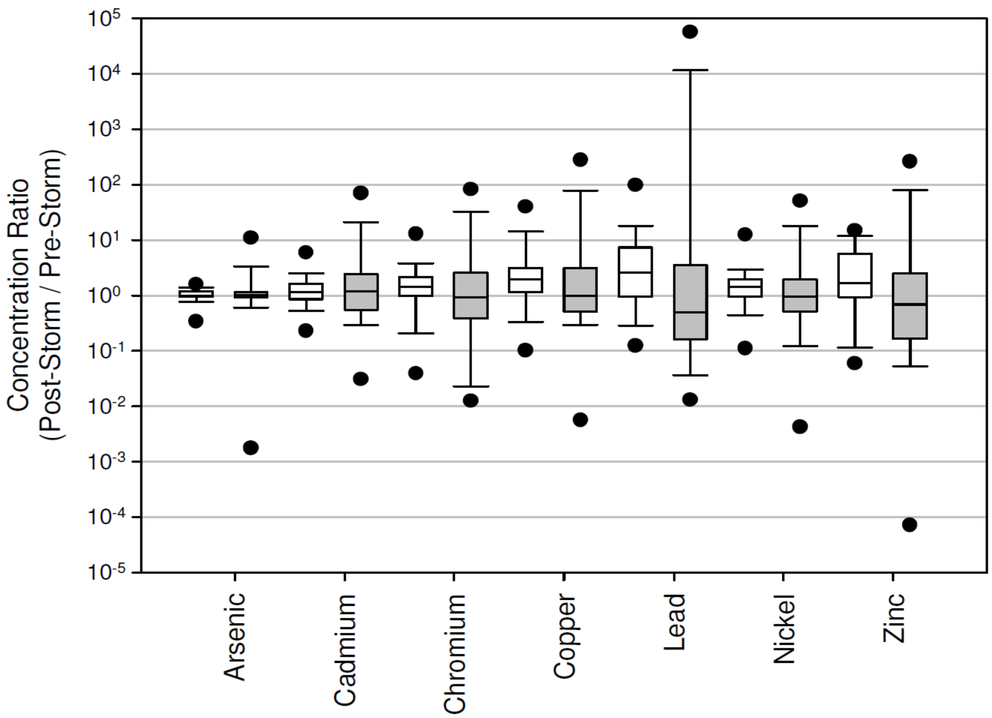

Figure 2. Box plot of pre/post-storm concentrations at reference drainage (grey) and ASBS discharge (white) sites for total trace metals.

Most relationships of discharge post-storm concentrations with storm characteristics were poor (Table 5). Correlation coefficients of constituent concentrations with storm characteristics were generally low and most were non-significant. No significant correlation was observed between storm duration and receiving water concentration. Three of 16 constituents had significant relationships with rainfall quantity, with correlation coefficients ranging from -0.37 to 0.40. Zinc concentrations increased with increasing rainfall, while nitrate and oil and grease had decreased with increasing rainfall. Eight of 16 constituents had significant relationships between constituent concentration and rainfall intensity. While most significantly correlated constituents had positive relationships with rainfall intensity, correlation coefficients ranged from -0.39 to 0.61.

Table 5. Relationships (correlation r-values) between storm characteristics or conservative tracers [salinity and total suspended solids (TSS)] and pollution concentrations at southern California discharge sites. Bold values are significant (p <0.05).

Salinity, a conservative marker of freshwater inputs, was not well correlated with constituent concentrations. Only organophosphorus pesticides and PAHs were significantly correlated, but both relationships were positive indicating runoff plumes were not the source of these constituents. Perhaps the strongest and most consistently correlated parameters were between TSS and constituent concentrations, particularly for trace metals that ranged from 0.44 to 0.54

Exceedance of reference drainage site based thresholds ranged from 35 to 32% of all analyses at each ASBS (Figure 3). ASBS 32 (Robert Badham) had the greatest proportion of analyses that were greater than reference site based thresholds (33% of all analyses). ASBS 31 (San Diego-Scripps) had the smallest proportion of analyses that were greater than reference site based thresholds (3% of all analyses). Cumulatively across all ASBS, 14% of all analyses were greater than reference site based thresholds.

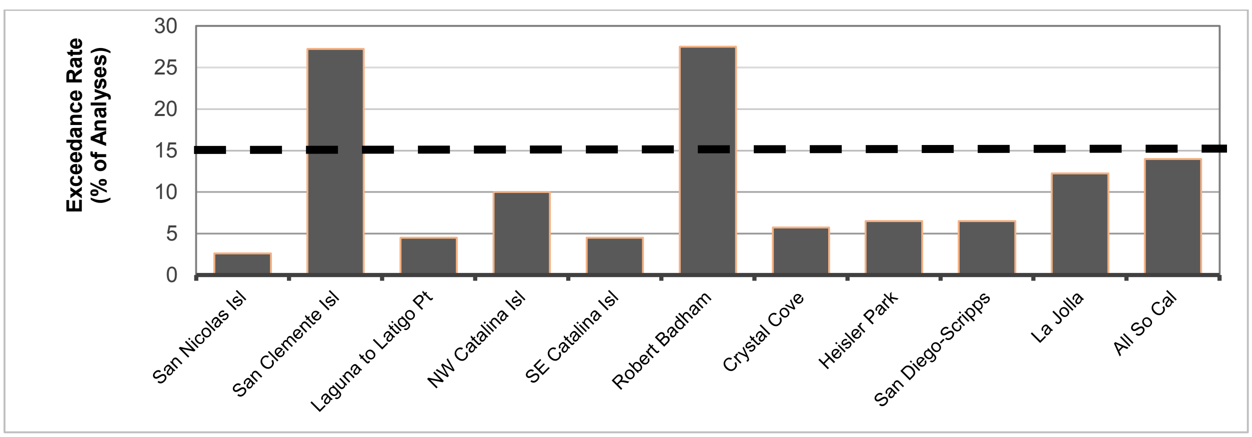

Figure 3. Exceedance of reference site based thresholds by ASBS. The 15% reference line is the expected exceedance rate for reference sites.

There were relatively minor differences in exceedance rate among constituent types (Figure 4). Total PAH (19% of all analyses) and nutrients (17% of all analyses) exceeded reference site based thresholds most frequently. TSS exceeded reference site based thresholds least frequently (10% of all analyses). Significant toxicity was rarely observed during this study. No toxicity was observed with either the mussel embryo development or sea urchin fertilization tests. Only three ASBS discharge samples exhibited toxicity utilizing the kelp germination and growth test, and none of these appeared correlated with maximum contaminant concentrations (see Appendix A).

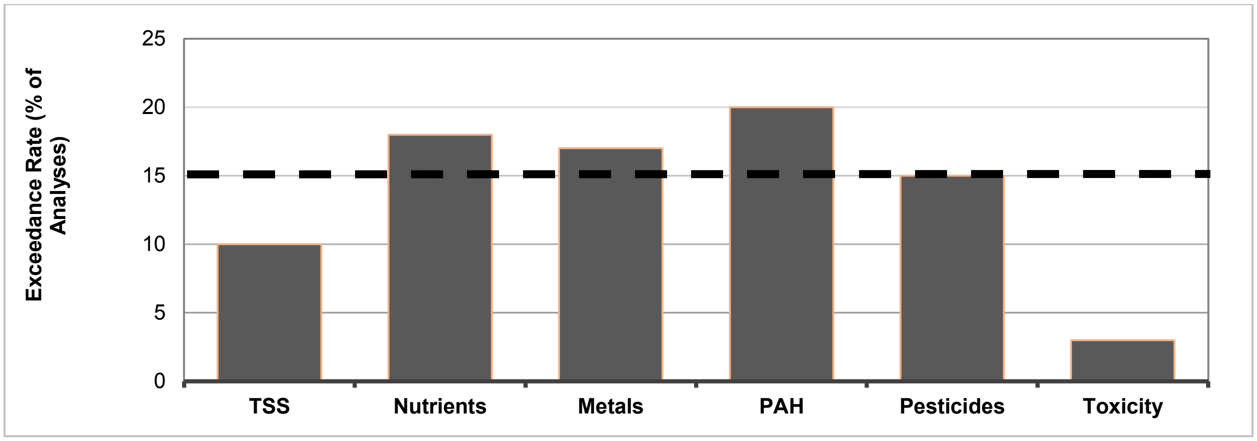

Figure 4. Exceedance of reference site based thresholds by parameter group. The 15% reference line is the expected exceedance rate for reference sites.

DISCUSSION

Based on the data reported in this study, water quality in southern California ASBS was generally comparable to natural water quality following storm events. On average, the range of post-storm pollutant concentrations in receiving waters sampled near ASBS discharge sites were not significantly different from post-storm concentrations at reference drainage sites, which included stormwater inputs free of (or minimally influenced by) anthropogenic sources. When comparing cutpoint exceedances, which focused on the 85th percentile of the reference site distribution, the southern California ASBS discharge sites cumulatively exceeded these thresholds 14% of the time for all chemical and toxicological analysis. This is similar to the 15% expected from a reference drainage site distribution (e.g., inverse of the 85th percentile). Moreover, few relationships with storm characteristics such as rainfall quantity, or with conservative tracers in the receiving water such as salinity or TSS, were observed in large part because pollutant concentrations were so low. Furthermore, synthetic anthropogenic contaminants such as organophosphorus and pyrethroid pesticides were not detectable across the wide variety of reference drainage sample locations in ASBS, and were infrequently detectable at discharge sites in ASBS. Moreover, toxicity in post-storm samples collected near ASBS discharges was rare even though multiple species were tested.

Although ASBS on average were maintaining natural water quality, there were some individual ASBS sites that appeared to have anthropogenic contributions. ASBS 32 (Robert Badham) had an unusually large proportion of analyses that were greater than reference site based thresholds. This site recently had a large structural BMP installed to help reduce constituent concentrations including a large infiltration gallery and a small restoration project near the terminus of the discharge. As a result, samples collected from the discharge to the ASBS during storm events should be examined to assess the potential for local and direct stormwater discharges to cause or contribute to the exceedances of reference site thresholds. These results should also be compared to other nearby sources that could be impacting the ASBS. For example, a recent study identified that this site potentially receives influence from the nearby Newport Harbor (Rogowski *et al.* 2014), which includes several 303d listed waterbodies. However, Newport Harbor does not discharge directly to ASBS 32 and is not subject to ASBS Special Protection regulatory requirements.

Supplementary studies examining bioaccumulation have largely supported the finding that natural water quality is being supported in southern California ASBS (Dodder *et al.* 2014). Bioaccumulation measurements were taken in mussels (*Mytilus californianus*), often considered a sentinel organism by state and federal agencies (Sericano *et al.* 1995, O'Connor 1998). Samples were collected at reference sites (to generate reference based thresholds similar to the water column sampling study design) and then compared to mussels collected near ASBS discharges. The results indicated that the number and magnitude of reference threshold exceedances were quite small. Interestingly, only San Clemente Island exceeded reference drainage site bioaccumulation and water column chemistry thresholds. This site drains a naval installation with limited development including municipal and industrial land uses, and exceeded reference based thresholds for several contaminants in mussel tissues. The exceedances could be a result of runoff from these land-based activities, or they could be associated with local geology associated with naturally high levels of metals (Weigand 1994). Repeated mussel sampling is being conducted at San Clemente Island to confirm these results.

Supplementary studies examining biodiversity have also supported the general finding that natural water quality is being supported in southern California ASBS (Raimondi *et al.* 2014). Similar in study design to the water column and tissue chemistry, rocky intertidal habitats were quantitatively surveyed near reference and ASBS discharges following the wet season. Results indicated that these biological communities, which are perhaps the habitat most at risk from direct storm drain discharges, were largely similar to reference site communities. Where sites near ASBS discharges did appear to be different from reference sites, resampling has indicated that these differences are relatively short-lived.

This study in 2012-14 was not the first regional survey of water concentrations in ASBS of southern California. The previous regional survey in 2008-09 listed several recommendations that the current study has addressed (Schiff *et al.* 2011). The primary recommendation was to increase sample size to confirm and provide greater confidence in the reference-based thresholds. Interestingly, reference-based thresholds changed little even though the sample size more than doubled, and included new sites and a wider range of storm conditions. The second recommendation from 2008-09 was to better define the extent and magnitude of exceedances at ASBS discharge locations. In 2008-09, the cumulative exceedance rate was 15% of all chemical and toxicological analysis. In 2012-14, the same cumulative exceedance rate was 14%. The similarities of these results, separated by five years, should provide managers with added confidence for making environmental decisions.

State Water Resources Control Board

MAR 17 2015

Ms. Gail Farber
Director of Public Works
County of Los Angeles
900 South Fremont Avenue
Alhambra, CA 91803

Dear Ms. Farber:

COMMENTS ON DRAFT COMPLIANCE PLAN FOR LAGUNA POINT TO LATIGO POINT (NO. 24) AREA OF SPECIAL BIOLOGICAL SIGNIFICANCE FROM THE COUNTY OF LOS ANGELES, THE LOS ANGELES COUNTY FLOOD CONTROL DISTRICT, AND THE CITY OF MALIBU

The State Water Resources Control Board (State Water Board) received the Areas of Special Biological Significance (ASBS) draft Compliance Plan and draft Pollution Prevention Plan from the County of Los Angeles, the Los Angeles County Flood Control District, and the City of Malibu dated September 20, 2014. A draft compliance plan and draft pollution prevention plan are required under sections I.A.3.b and I.B.2.a of Attachment B of the State Water Board's Resolution No. 2012-0012 *Approving Exceptions to the California Ocean Plan for Selected Discharges into ASBS, Including Special Protections for Beneficial Uses, and Certifying a Program Environmental Impact Report* (General Exception). Attachment B in the General Exception contains the *Special Protections for ASBS, Governing Point Source Discharges of Storm Water and Nonpoint Source Waste Discharges* (Special Protections), which describes special conditions required of the discharger.

State Water Board staff has reviewed the draft Compliance Plan and draft Pollution Prevention Plan and provides the following comments:

1. **Map of storm water runoff**: Section I.A.2.a. of the Special Protections requires a map of storm water runoff that highlights the prioritized discharges and a description of any structural Best Management Practices (BMPs) already employed or to be employed. Priority discharges are those that pose the greatest water quality threat and which are identified to require installation of structural BMPs. Section I.A.2.f. states that the ASBS Compliance Plan shall describe structural BMPs, including any low impact development (LID) measures, currently employed and planned for higher threat discharges and shall include an implementation schedule. Higher threat discharges include permitted storm drains equal to or greater than 18 inches in diameter or width.

   Appendix A in the draft Compliance Plan includes a map of storm water runoff and the planned structural BMP at Broad Beach Road. However, the draft Compliance Plan does not identify priority discharges, stating that none of the evaluated outfalls fall into this category, since receiving water monitoring results met the Table B Instantaneous Maximum Water Quality Objectives in Chapter II of the Ocean Plan, and consequently that additional structural BMPs are not necessary. To clarify, in determining exceedances of the natural water quality and identifying priority discharge locations, receiving water monitoring data is compared to the 85th percentile of the threshold of reference water quality data, not to Ocean Plan Table B Instantaneous Maximum Water Quality Objectives. In the draft Compliance Plan, the receiving water monitoring results show levels of constituents higher than the 85th percentile threshold of reference water quality data, indicating that additional structural BMPs are required. Staff noted similarities in elevated levels of constituents at core discharge ASBS-028 and its associated receiving water site ASBS-S02. Therefore, core discharge ASBS-028 should be identified as a priority discharge location. In the final Compliance Plan, please identify priority discharges on the map, describe additional structural BMPs and explain how they will reduce pollutants in storm water runoff, and update the implementation schedule accordingly.

2. **Non-authorized non-storm water runoff**: Section I.A.2.b. of the Special Protections requires a description of the measures by which all non-authorized non-storm water runoff has been eliminated, how the measures will be maintained over time, and how these measures are monitored and documented.

   The draft Compliance Plan describes actions being taken to eliminate flows that reach the surf. Although dry weather flows that did not reach the surf were observed during dry weather inspections of outfalls, there is no explanation of how these flows will be eliminated. In the final Compliance Plan, please address how dry weather flows will be eliminated as well as how these measures will be maintained over time and how they will be monitored and documented.

3. **Implementation schedule**: Section I.A.3.d. of the Special Protections stipulates that any structural controls identified in the final Compliance Plan be operational within six years of the effective date. Section I.A.3.e. specifies that all dischargers must comply with the requirement that their discharges into the affected ASBS maintain natural ocean water quality within six years of the effective date.

   The draft Compliance Plan lists March 20, 2019 as the date by which necessary structural controls shall be operational and by which all discharges must be in compliance with the General Exception requirements. The 12-month extension that was granted by the State Water Board applies to the deadlines for the draft and final Compliance Plans. This extension does not apply to the March 20, 2018 deadline for necessary structural controls or compliance with the General Exception requirements. Please be aware that the correct date is March 20, 2018 and that this is the date that should be listed in the implementation schedule.

4. **Exceedances in natural water quality**: Section I.A.3.e. of the Special Protections requires that, if initial results of post-storm receiving water quality testing indicate levels higher than the 85th percentile threshold of reference water quality data and the pre-storm receiving water levels, then the discharger must re-sample the receiving water pre- and post-storm.

   The results for receiving water site ASBS-S02 indicate that exceedances in water quality were detected for multiple constituents during receiving water monitoring. Therefore, ASBS-S02 must be re-sampled pre- and post-storm for an additional storm event. If after re-sampling the post-storm levels are still higher than the 85th percentile threshold of reference water quality data and pre-storm receiving water levels for any constituent, then natural ocean water quality is exceeded, and consequently an exceedance report must be submitted as stipulated in Section I.A.2.h of the Special Protections.

5. **Ocean receiving water monitoring**: Section IV.B.2.b. of the Special Protections requires that a minimum of three ocean receiving water samples must be collected during each storm season from each station, each from a separate storm. It further specifies that a minimum of one receiving water location shall be sampled in each ASBS per responsible party in that ASBS.

   Due to participation in the Southern California Bight 2008 regional monitoring effort, monitoring requirements for the County of Los Angeles, the Los Angeles County Flood Control District, and the City of Malibu were limited to only one storm season. The data from the remaining storm season were included in the draft Compliance Plan and indicate that only one receiving water site (ASBS-S02) was sampled successfully for three storm events. The remaining two sites (ASBS-S01 and 24-BB-03R) were only successfully sampled pre- and post-storm during one storm event. Staff understands that the City of Malibu will continue wet weather monitoring into the 2014-2015 wet season and that this sampling may be performed before submittal of the final Compliance Plan. Additionally, receiving water site ASBS-S01 and its associated core discharge ASBS-016 must be sampled for two additional storm events, to account for the incomplete previous monitoring events.

   Also, staff noticed that outfall 24-BB-01Z is included on the map and the outfall descriptions, yet there were no results presented for this outfall, even though the draft Compliance Plan states that it was successfully sampled during the February 28, 2014 storm event. Please include results from that sampling event in the final Compliance Plan.

Staff appreciates the efforts of the County of Los Angeles, the Los Angeles County Flood District, and the City of Malibu on the draft Compliance Plan and will continue to collaborate to resolve the comments mentioned in this letter as needed. Please submit the final Compliance Plan addressing these comments for approval by the State Water Board Executive Director by September 20, 2015.

For further questions pertaining to this subject matter, please contact Dr. Kimberly Tenggardjaja at (916) 341-5473 or Kimberly.Tenggardjaja@waterboards.ca.gov or Dr. Maria de la Paz Carpio-Obeso, Ocean Unit Chief, at (916) 341-5858 or MarielaPaz.Carpio-Obeso@waterboards.ca.gov.

Sincerely,

Victoria A. Whitney

Victoria A. Whitney, Deputy Director
Division of Water Quality

CALIFORNIA OCEAN PLAN

WATER QUALITY CONTROL PLAN

OCEAN WATERS OF CALIFORNIA

Amendments to the Water Quality Control Plan for the Ocean Waters of California

Name	Date Adopted	Resolution Number	Effective Date
1. Amendment to the statewide for the Ocean Plan of California addressing desalination facility intakes, brine discharges, and to incorporate other non-substantive changes	5/06/2015	2015-0033	1/28/2016
2. Amendment to the Water Quality Control Plan for Ocean Waters of California to control trash and part 1 trash provisions of the Water Quality Control Plan for inland surface waters, enclosed bays, and estuaries in California	4/7/2015	2015-0019	1/12/2016
3. Adoption of the California Ocean Plan Amendments regarding model monitoring, vessel discharges, and non-substantive changes	10/16/2012	2012-0057	7/01/2013
4. Adopting the California Ocean Plan Amendment implementing State Water Board resolutions 2010-0057 and 2011-013 regarding State Water Quality Protection Areas and Marine Protected Areas	10/16/2012	2012-0056	7/01/2013
5. Adoption of Proposed Amendments to the California Ocean Plan regarding total recoverable metals, compliance schedules, toxicity definitions, and the list of exceptions	9/15/2009	2009-0072	3/10/2010
6. Amendment to the California Ocean Plan: (1) Reasonable Potential, Determining When California Ocean Plan Water Quality-Based Effluent Limitations are Required, and (2) Minor Changes to the Areas of Special Biological Significance, and Exception Provisions	4/21/2005	2005-0035	10/12/2005
7. Amendment to California Ocean Plan Water Contact Bacterial Standards	1/20/2005	2005-0013	10/12/2005
8. Adoption of the Proposed Amendments to the California Ocean Plan regarding Table A, chemical water quality objectives, provisions of compliance, special protection for water quality and designated uses, and administrative changes	11/16/2000	2000-108	12/03/2001
9. Adoption of an Amendment to the Water Quality Control Plan for Ocean Waters of California regarding revisions to the list of critical life stage protocols used in testing the toxicity of waste discharges	3/20/1997	97-026	7/23/1997
10. Approval of Amendment to the Water Quality Control Plan for Ocean Waters of California regarding new water quality objectives in Table B	3/22/1990	90-027	3/22/1990

11. Water Quality Control Plan for Ocean Waters of California, California Ocean Plan	9/22/1988	88-111	9/22/1988
12. Water Quality Control Plan for Ocean Waters of California	11/17/1983	83-087	11/17/1983
13. Water Quality Control Plan for Ocean Waters of California	1/19/1978	78-002	1/19/1978
14. Water Quality Control Plan for Ocean Waters of California	7/06/1972	72-045	7/06/1972

CALIFORNIA OCEAN PLAN

TABLE OF CONTENTS

CALIFORNIA OCEAN PLAN

WATER QUALITY CONTROL PLAN FOR
OCEAN WATERS OF CALIFORNIA

INTRODUCTION

A. Purpose and Authority

1. In furtherance of legislative policy set forth in section 13000 of Division 7 of the California Water Code (CWC) (Stats. 1969, Chap. 482) pursuant to the authority contained in section 13170 and 13170.2 (Stats. 1971, Chap. 1288) the State Water Resources Control Board (State Water Board) hereby finds and declares that protection of the quality of the ocean* waters for use and enjoyment by the people of the State requires control of the discharge of waste* to ocean* waters and control of intake seawater* in accordance with the provisions contained herein. The Board finds further that this plan shall be reviewed at least every three years to guarantee that the current standards are adequate and are not allowing degradation* to marine species or posing a threat to public health.

B. Principles

1. Harmony Among Water Quality Control Plans and Policies.

   a. In the adoption and amendment of water quality control plans, it is the intent of this Board that each plan will provide for the attainment and maintenance of the water quality standards of downstream waters.*

   b. To the extent there is a conflict between a provision of this plan and a provision of another statewide plan or policy, or a regional water quality control plan (basin plan), the more stringent provision shall apply except where pursuant to Chap. III.J of this Plan, the State Water Board has approved an exception to the Plan requirements, and except in chapter III.M, in which the provisions of this plan shall govern.

C. Applicability

1. This plan is applicable, in its entirety, to point source discharges to the ocean.* Nonpoint sources of waste* discharges to the ocean* are subject to Chapter I Beneficial Uses, Chapter II - WATER QUALITY OBJECTIVES (wherein compliance with water quality objectives shall, in all cases, be determined by direct measurements in the receiving waters*) and Chapter III - PROGRAM OF IMPLEMENTATION Parts A.2, D, E, and I.

2. This plan is not applicable to discharges to enclosed* bays and estuaries* or inland waters or the control of dredged material.*

* See Appendix I for definition of terms.

3. Provisions regulating the thermal aspects of waste* discharged to the ocean* are set forth in the Water Quality Control Plan for the Control of Temperature in the Coastal and Interstate Waters and Enclosed* Bays and Estuaries* of California.

4. Provisions regulating the intake of seawater* for desalination facilities* are established pursuant to the authority contained in section 13142.5 subdivision (b) of the California Water Code (Stats. 1976, Chap. 1330).

5. Within this Plan, references to the State Board or State Water Board shall mean the State Water Resources Control Board. References to a Regional Board or Regional Water Board shall mean a California Regional Water Quality Control Board. References to the Environmental Protection Agency, USEPA, or EPA shall mean the federal Environmental Protection Agency.

* See Appendix I for definition of terms.

I. BENEFICIAL USES

A. The beneficial uses of the ocean* waters of the State that shall be protected include industrial water supply; water contact and non-contact recreation, including aesthetic enjoyment; navigation; commercial and sport fishing; mariculture*; preservation and enhancement of designated Areas* of Special Biological Significance (ASBS); rare and endangered species; marine habitat; fish migration; fish spawning and shellfish* harvesting.

* See Appendix I for definition of terms.

II. WATER QUALITY OBJECTIVES

A. General Provisions

1. This chapter sets forth limits or levels of water quality characteristics for ocean* waters to ensure the reasonable protection of beneficial uses and the prevention of nuisance. The discharge of waste* shall not cause violation of these objectives.

2. The Water Quality Objectives and Effluent Limitations are defined by a statistical distribution when appropriate. This method recognizes the normally occurring variations in treatment efficiency and sampling and analytical techniques and does not condone poor operating practices.

3. Compliance with the water quality objectives of this chapter shall be determined from samples collected at stations representative of the area within the waste* field where initial* dilution is completed.

B. Bacterial Characteristics

1. Water-Contact Standards

   Both the State Water Board and the California Department of Public Health (CDPH) have established standards to protect water contact recreation in coastal waters from bacterial contamination. Subsection a of this section contains bacterial objectives adopted by the State Water Board for ocean* waters used for water contact recreation. Subsection b describes the bacteriological standards adopted by CDPH for coastal waters adjacent to public beaches and public water contact sports areas in ocean waters.

   a. State Water Board Water-Contact Standards

   (1) Within a zone bounded by the shoreline and a distance of 1,000 feet from the shoreline or the 30-foot depth contour, whichever is further from the shoreline, and in areas outside this zone used for water contact sports, as determined by the Regional Board (i.e., waters designated as REC-1), but including all kelp beds,* the following bacterial objectives shall be maintained throughout the water column:

   30-day Geometric Mean – The following standards are based on the geometric mean of the five most recent samples from each site:

   i. Total coliform density shall not exceed 1,000 per 100 mL;
   ii. Fecal coliform density shall not exceed 200 per 100 mL; and
   iii. Enterococcus density shall not exceed 35 per 100 mL.

   Single Sample Maximum:

   i. Total coliform density shall not exceed 10,000 per 100 mL;
   ii. Fecal coliform density shall not exceed 400 per 100 mL;
   iii. Enterococcus density shall not exceed 104 per 100 mL; and

* See Appendix I for definition of terms.

iv. Total coliform density shall not exceed 1,000 per 100 mL when the fecal coliform/total coliform ratio exceeds 0.1.

(2) The “Initial Dilution* Zone” of wastewater outfalls shall be excluded from designation as kelp beds* for purposes of bacterial standards, and Regional Boards should recommend extension of such exclusion zone where warranted to the State Water Board (for consideration under chapter III. J). Adventitious assemblages of kelp on waste discharge structures (e.g.,outfall pipes and multiport diffusers*) do not constitute kelp beds* for purposes of bacterial standards.

b. CDPH Standards

CDPH has established minimum protective bacteriological standards for coastal waters adjacent to public beaches and for public water-contact sports areas in ocean* waters. These standards are found in the California Code of Regulations, title 17, section 7958, and they are identical to the objectives contained in subsection a. above. When a public beach or public water-contact sports area fails to meet these standards, CDPH or the local public health officer may post with warning signs or otherwise restrict use of the public beach or public water-contact sports area until the standards are met. The CDPH regulations impose more frequent monitoring and more stringent posting and closure requirements on certain high-use public beaches that are located adjacent to a storm drain that flows in the summer.

For beaches not covered under AB 411 regulations, CDPH imposes the same standards as contained in Title 17 and requires weekly sampling but allows the county health officer more discretion in making posting and closure decisions.

2. Shellfish* Harvesting Standards

a. At all areas where shellfish* may be harvested for human consumption, as determined by the Regional Board, the following bacterial objectives shall be maintained throughout the water column:

(1) The median total coliform density shall not exceed 70 per 100 mL, and not more than 10 percent of the samples shall exceed 230 per 100 mL.

C. Physical Characteristics

1. Floating particulates and grease and oil shall not be visible.

2. The discharge of waste* shall not cause aesthetically undesirable discoloration of the ocean* surface.

3. Natural light* shall not be significantly* reduced at any point outside the initial* dilution zone as the result of the discharge of waste.*

4. The rate of deposition of inert solids and the characteristics of inert solids in ocean* sediments shall not be changed such that benthic communities are degraded.*

* See Appendix I for definition of terms.

5. Trash* shall not be present in ocean waters, along shorelines or adjacent areas in amounts that adversely affect beneficial uses or cause nuisance.

D. Chemical Characteristics

1. The dissolved oxygen concentration shall not at any time be depressed more than 10 percent from that which occurs naturally, as the result of the discharge of oxygen demanding waste* materials.*
2. The pH shall not be changed at any time more than 0.2 units from that which occurs naturally.
3. The dissolved sulfide concentration of waters in and near sediments shall not be significantly* increased above that present under natural conditions.
4. The concentration of substances set forth in chapter II, Table 1, in marine sediments shall not be increased to levels which would degrade* indigenous biota.
5. The concentration of organic materials* in marine sediments shall not be increased to levels that would degrade* marine life.
6. Nutrient materials* shall not cause objectionable aquatic growths or degrade* indigenous biota.
7. Numerical Water Quality Objectives
   a. Table 1 water quality objectives apply to all discharges within the jurisdiction of this Plan. Unless otherwise specified, all metal concentrations are expressed as total recoverable concentrations.
   b. Table 1 Water Quality Objectives

* See Appendix I for definition of terms.

TABLE 1 (formerly TABLE B)
WATER QUALITY OBJECTIVES

	Units of Measurement	Limiting Concentrations: 6-Month Median	Daily Maximum	Instantaneous Maximum
OBJECTIVES FOR PROTECTION OF MARINE AQUATIC LIFE				
Arsenic	µg/L	8.	32.	80.
Cadmium	µg/L	1.	4.	10.
Chromium (Hexavalent) (see below, a)	µg/L	2.	8.	20.
Copper	µg/L	3.	12.	30.
Lead	µg/L	2.	8.	20.
Mercury	µg/L	0.04	0.16	0.4
Nickel	µg/L	5.	20.	50.
Selenium	µg/L	15.	60.	150.
Silver	µg/L	0.7	2.8	7.
Zinc	µg/L	20.	80.	200.
Cyanide (see below, b)	µg/L	1.	4.	10.
Total Chlorine Residual (For intermittent chlorine sources see below, c)	µg/L	2.	8.	60.
Ammonia (expressed as nitrogen)	µg/L	600.	2400.	6000.
Acute* Toxicity	TUa	N/A	0.3	N/A
Chronic* Toxicity	TUc	N/A	1.	N/A
Phenolic Compounds (non-chlorinated)	µg/L	30.	120.	300.
Chlorinated Phenolics	µg/L	1.	4.	10.
Endosulfan*	µg/L	0.009	0.018	0.027
Endrin	µg/L	0.002	0.004	0.006
HCH*	µg/L	0.004	0.008	0.012
Radioactivity	Not to exceed limits specified in Title 17, Division 1, Chapter 5, Subchapter 4, Group 3, Article 3, section 30253 of the California Code of Regulations. Reference to section 30253 is prospective, including future changes to any incorporated provisions of federal law, as the changes take effect.			

* See Appendix I for definition of terms.

TABLE 1 (formerly TABLE B) Continued

Chemical	30-day Average (µg/L) Decimal Notation	Scientific Notation
OBJECTIVES FOR PROTECTION OF HUMAN HEALTH – NONCARCINOGENS		
acrolein	220.	2.2×10^{2}
antimony	1,200.	1.2×10^{3}

tetrachloroethylene	2.0	2.0×10^{0}
toxaphene	0.00021	2.1×10^{-4}
trichloroethylene	27.	2.7×10^{1}
1,1,2-trichloroethane	9.4	9.4×10^{0}
2,4,6-trichlorophenol	0.29	2.9×10^{-1}
vinyl chloride	36.	3.6×10^{1}

* See Appendix I for definition of terms.

Table 1 Notes:

a) Dischargers may at their option meet this objective as a total chromium objective.

b) If a discharger can demonstrate to the satisfaction of the Regional Water Board (subject to EPA approval) that an analytical method is available to reliably distinguish between strongly and weakly complexed cyanide, effluent limitations for cyanide may be met by the combined measurement of free cyanide, simple alkali metal cyanides, and weakly complexed organometallic cyanide complexes. In order for the analytical method to be acceptable, the recovery of free cyanide from metal complexes must be comparable to that achieved by the approved method in 40 CFR PART 136, as revised May 14, 1999.

c) Water quality objectives for total chlorine residual applying to intermittent discharges not exceeding two hours, shall be determined through the use of the following equation:

$$\log y = -0.43 (\log x) + 1.8$$

where: y = the water quality objective (in µg/L) to apply when chlorine is being discharged;
x = the duration of uninterrupted chlorine discharge in minutes.

E. Biological Characteristics

1. Marine communities, including vertebrate, invertebrate, algae, and plant species, shall not be degraded.*

2. The natural taste, odor, and color of fish, shellfish,* or other marine resources used for human consumption shall not be altered.

3. The concentration of organic materials* in fish, shellfish* or other marine resources used for human consumption shall not bioaccumulate to levels that are harmful to human health.

F. Radioactivity

1. Discharge of radioactive waste* shall not degrade* marine life.

* See Appendix I for definition of terms.

III. PROGRAM OF IMPLEMENTATION

A. General Provisions

1. Effective Date

a. The *Water Quality Control Plan, Ocean Waters of California, California Ocean Plan* was adopted and has been effective since 1972. There have been multiple amendments of the Ocean Plan since its adoption.

2. General Requirements For Management Of Waste Discharge To The Ocean*

a. Waste* management systems that discharge to the ocean* must be designed and operated in a manner that will maintain the indigenous marine life and a healthy and diverse marine community.

b. Waste* discharged to the ocean* must be essentially free of:

(1) Material* that is floatable or will become floatable upon discharge.

(2) Settleable material* or substances that may form sediments which will degrade* benthic communities or other aquatic life.

(3) Substances which will accumulate to toxic levels in marine waters, sediments or biota.

(4) Substances that significantly* decrease the natural light* to benthic communities and other marine life.

(5) Materials* that result in aesthetically undesirable discoloration of the ocean* surface.

c. Waste* effluents shall be discharged in a manner which provides sufficient initial* dilution to minimize the concentrations of substances not removed in the treatment.

d. Location of waste* discharges must be determined after a detailed assessment of the oceanographic characteristics and current patterns to assure that:

(1) Pathogenic organisms and viruses are not present in areas where shellfish* are harvested for human consumption or in areas used for swimming or other body-contact sports.

(2) Natural water quality conditions are not altered in areas designated as being of special biological significance or areas that existing marine laboratories use as a source of seawater.*

(3) Maximum protection is provided to the marine environment.

---

* See Appendix I for definition of terms.

e. Waste* that contains pathogenic organisms or viruses should be discharged a sufficient distance from shellfishing* and water-contact sports areas to maintain applicable bacterial standards without disinfection. Where conditions are such that an adequate distance cannot be attained, reliable disinfection in conjunction with a reasonable separation of the discharge point from the area of use must be provided. Disinfection procedures that do not increase effluent toxicity and that constitute the least environmental and human hazard should be used.

3. Areas of Special Biological Significance*

a. ASBS* shall be designated by the State Water Board following the procedures provided in Appendix IV. A list of ASBS* is available in Appendix V.

4. Combined Sewer Overflow: Not withstanding any other provisions in this plan, discharges from the City of San Francisco's combined sewer system are subject to the US EPA's Combined Sewer Overflow Policy.

B. Table 2 Effluent Limitations

TABLE 2 (formerly TABLE A)
EFFLUENT LIMITATIONS

		Limiting Concentrations		
	Unit of Measurement	Monthly (30-day Average)	Weekly (7-day Average)	Maximum at any time
Grease and Oil	mg/L	25.	40.	75.
Suspended Solids			See below +	
Settleable Solids	mL/L	1.0	1.5	3.0
Turbidity	NTU	75.	100.	225.
pH	Units		Within limit of 6.0 to 9.0 at all times	

Table 2 Notes:

\+ Suspended Solids: Dischargers shall, as a 30-day average, remove 75% of suspended solids from the influent stream before discharging wastewaters to the ocean,* except that the effluent limitation to be met shall not be lower than 60 mg/l. Regional Boards may recommend that the State Water Board (chapter III section J), with the concurrence of the Environmental Protection Agency, adjust the lower effluent concentration limit (the 60 mg/l above) to suit the environmental and effluent characteristics of the discharge. As a further consideration in making such recommendation for adjustment, Regional Water Boards should evaluate effects on existing and potential water* reclamation projects.

If the lower effluent concentration limit is adjusted, the discharger shall remove 75% of suspended solids from the influent stream at any time the influent concentration exceeds four times such adjusted effluent limit.

---

1. Table 2 effluent limitations apply only to publicly owned treatment works and industrial discharges for which Effluent Limitations Guidelines have not been established pursuant to sections 301, 302, 304, or 306 of the Federal Clean Water Act.

* See Appendix I for definition of terms.

2. Table 2 effluent limitations shall apply to a discharger's total effluent, of whatever origin (i.e., gross, not net, discharge), except where otherwise specified in this Plan.

3. The State Water Board is authorized to administer and enforce effluent limitations established pursuant to the Federal Clean Water Act. Effluent limitations established under sections 301, 302, 306, 307, 316, 403, and 405 of the aforementioned Federal Act and administrative procedures pertaining thereto are included in this plan by reference. Compliance with Table 2 effluent limitations, or Environmental Protection Agency Effluent Limitations Guidelines for industrial discharges, based on Best Practicable Control Technology, shall be the minimum level* of treatment acceptable under this plan, and shall define reasonable treatment and waste* control technology.

4. Compliance with Table 2 effluent limitations for brine discharges from desalination facilities that commingle brine and wastewater prior to discharge to the ocean may be measured after the brine has been commingled with wastewater, provided that the permittee for the commingled discharge accepts responsibly for any exceedances of the Table 2 effluent limitations.

C. Implementation Provisions for Table 1

1. Effluent concentrations calculated from Table 1 water quality objectives shall apply to a discharger's total effluent, of whatever origin (i.e., gross, not net, discharge), except where otherwise specified in this Plan.

2. If the Regional Water Board determines, using the procedures in Appendix VI, that a pollutant is discharged into ocean* waters at levels which will cause, have the reasonable potential to cause, or contribute to an excursion above a Table 1 water quality objective, the Regional Water Board shall incorporate a water quality-based effluent limitation in the Waste Discharge Requirement for the discharge of that pollutant.

3. Effluent limitations shall be imposed in a manner prescribed by the State Water Board such that the concentrations set forth below as water quality objectives shall not be exceeded in the receiving water* upon completion of initial* dilution, except that objectives indicated for radioactivity shall apply directly to the undiluted waste* effluent.

4. Calculation of Effluent Limitations

a. Effluent limitations for water quality objectives listed in Table 1, with the exception of acute toxicity and radioactivity, shall be determined through the use of the following equation:

Equation 1: $Ce = Co + Dm (Co - Cs)$

where:

Ce = the effluent concentration limit, µg/L

Co = the concentration (water quality objective) to be met at the completion of initial* dilution, µg/L

Cs = background seawater* concentration (see Table 3 below, with all metals expressed as total recoverable concentrations), µg/L

Dm = minimum probable initial* dilution expressed as parts seawater* per part wastewater.

* See Appendix I for definition of terms.

TABLE 3 (formerly TABLE C)
BACKGROUND SEAWATER* CONCENTRATIONS (Cs)

Waste Constituent	Cs (µg/L)
Arsenic	3.
Copper	2.
Mercury	0.0005
Silver	0.16
Zinc	8.
For all other Table 1 parameters, Cs = 0.	

b. Determining a Mixing Zone for the Acute Toxicity* Objective

The mixing zone for the acute toxicity* objective shall be ten percent (10%) of the distance from the edge of the outfall structure to the edge of the chronic mixing zone (zone of initial dilution*). There is no vertical limitation on this zone. The effluent limitation for the acute toxicity* objective listed in Table 1 shall be determined through the use of the following equation:

Equation 2: $Ce = Ca + (0.1)\ Dm\ (Ca)$

where:

Ca = the concentration (water quality objective) to be met at the edge of the acute mixing zone.

Dm = minimum probable initial* dilution expressed as parts seawater* per part wastewater (This equation applies only when $Dm > 24$).

c. Toxicity Testing Requirements based on the Minimum Initial* Dilution Factor for Ocean Waste* Discharges

(1) Dischargers shall conduct acute toxicity* testing if the minimum initial* dilution of the effluent is greater than 1,000:1 at the edge of the mixing zone.

(2) Dischargers shall conduct either acute or chronic toxicity* testing if the minimum initial* dilution ranges from 350:1 to 1,000:1 depending on the specific discharge conditions. The Regional Water Board shall make this determination.

(3) Dischargers shall conduct chronic toxicity* testing for ocean waste* discharges with minimum initial* dilution factors ranging from 100:1 to 350:1. The Regional Water Board may require that acute toxicity* testing be conducted in addition to chronic as necessary for the protection of beneficial uses of ocean* waters.

(4) Dischargers shall conduct chronic toxicity* testing if the minimum initial* dilution of the effluent falls below 100:1 at the edge of the mixing zone.

* See Appendix I for definition of terms.

d. For the purpose of this Plan, minimum initial* dilution is the lowest average initial* dilution within any single month of the year. Dilution estimates shall be based on observed waste* flow characteristics, observed receiving water* density structure, and the assumption that no currents, of sufficient strength to influence the initial* dilution process, flow across the discharge structure.

e. The Executive Director of the State Water Board shall identify standard dilution models for use in determining Dm, and shall assist the Regional Board in evaluating Dm for specific waste* discharges. Dischargers may propose alternative methods of calculating Dm, and the Regional Board may accept such methods upon verification of its accuracy and applicability.

f. The six-month median shall apply as a moving median of daily values for any 180-day period in which daily values represent flow weighted average concentrations within a 24-hour period. For intermittent discharges, the daily value shall be considered to equal zero for days on which no discharge occurred.

g. The daily maximum shall apply to flow weighted 24 hour composite samples.

h. The instantaneous maximum shall apply to grab sample determinations.

i. If only one sample is collected during the time period associated with the water quality objective (e.g., 30-day average or 6-month median), the single measurement shall be used to determine compliance with the effluent limitation for the entire time period.

j. Discharge requirements shall also specify effluent limitations in terms of mass emission rate limits utilizing the general formula:

Equation 3: lbs/day = 0.00834 x Ce x Q

where:

Ce = the effluent concentration limit, µg/L

Q = flow rate, million gallons per day (MGD)

k. The six-month median limit on daily mass emissions shall be determined using the six-month median effluent concentration as Ce and the observed flow rate Q in millions of gallons per day. The daily maximum mass emission shall be determined using the daily maximum effluent concentration limit as Ce and the observed flow rate Q in millions of gallons per day.

l. Any significant* change in waste* flow shall be cause for reevaluating effluent limitations.

5. Minimum* Levels

For each numeric effluent limitation, the Regional Board must select one or more Minimum* Levels (and their associated analytical methods) for inclusion in the permit. The "reported" Minimum* Level is the Minimum* Level (and its associated analytical

* See Appendix I for definition of terms.

method) chosen by the discharger for reporting and compliance determination from the Minimum* Levels included in their permit.

a. Selection of Minimum* Levels from Appendix II

The Regional Water Board must select all Minimum* Levels from Appendix II that are below the effluent limitation. If the effluent limitation is lower than all the Minimum* Levels in Appendix II, the Regional Board must select the lowest Minimum* Level from Appendix II.

b. Deviations from Minimum* Levels in Appendix II

The Regional Board, in consultation with the State Water Board's Quality Assurance Program, must establish a Minimum* Level to be included in the permit in any of the following situations:

1. A pollutant is not listed in Appendix II.
2. The discharger agrees to use a test method that is more sensitive than those described in 40 CFR 136 (revised May 14, 1999).
3. The discharger agrees to use a Minimum* Level lower than those listed in Appendix II.
4. The discharger demonstrates that their calibration standard matrix is sufficiently different from that used to establish the Minimum* Level in Appendix II and proposes an appropriate Minimum* Level for their matrix.
5. A discharger uses an analytical method having a quantification practice that is not consistent with the definition of Minimum* Level (e.g., US EPA methods 1613, 1624, 1625).

6. Use of Minimum* Levels

a. Minimum* Levels in Appendix II represent the lowest quantifiable concentration in a sample based on the proper application of method-specific analytical procedures and the absence of matrix interferences. Minimum* Levels also represent the lowest standard concentration in the calibration curve for a specific analytical technique after the application of appropriate method-specific factors.

Common analytical practices may require different treatment of the sample relative to the calibration standard. Some examples are given below:

Substance or Grouping	Method-Specific Treatment	Most Common Factor
Volatile Organics	No differential treatment	1
Semi-Volatile Organics	Samples concentrated by extraction	1000
Metals	Samples diluted or concentrated	½ , 2 , and 4
Pesticides	Samples concentrated by extraction	100

b. Other factors may be applied to the Minimum* Level depending on the specific sample preparation steps employed. For example, the treatment typically applied when there are matrix effects is to dilute the sample or sample aliquot by a factor of ten. In such cases, this additional factor must be applied during the

* See Appendix I for definition of terms.

computation of the reporting limit. Application of such factors will alter the reported Minimum* Level.

c. Dischargers are to instruct their laboratories to establish calibration standards so that the Minimum* Level (or its equivalent if there is differential treatment of samples relative to calibration standards) is the lowest calibration standard. At no time is the discharger to use analytical data derived from *extrapolation* beyond the lowest point of the calibration curve. In accordance with section 4b, above, the discharger's laboratory may employ a calibration standard lower than the Minimum* Level in Appendix II.

7. Sample Reporting Protocols

a. Dischargers must report with each sample result the reported Minimum* Level (selected in accordance with section 4, above) and the laboratory's current MDL.*

b. Dischargers must also report the results of analytical determinations for the presence of chemical constituents in a sample using the following reporting protocols:

(1) Sample results greater than or equal to the reported Minimum* Level must be reported "as measured" by the laboratory (i.e., the measured chemical concentration in the sample).

(2) Sample results less than the reported Minimum* Level, but greater than or equal to the laboratory's MDL,* must be reported as "Detected, but Not Quantified", or DNQ. The laboratory must write the estimated chemical concentration of the sample next to DNQ as well as the words "Estimated Concentration" (may be shortened to "Est. Conc.").

(3) Sample results less than the laboratory's MDL* must be reported as "Not Detected", or ND.

8. Compliance Determination

Sufficient sampling and analysis shall be required to determine compliance with the effluent limitation.

a. Compliance with Single-Constituent Effluent Limitations

Dischargers are out of compliance with the effluent limitation if the concentration of the pollutant (see section 7c, below) in the monitoring sample is greater than the effluent limitation and greater than or equal to the reported Minimum* Level.

b. Compliance with Effluent Limitations expressed as a Sum of Several Constituents

Dischargers are out of compliance with an effluent limitation which applies to the sum of a group of chemicals (e.g., PCBs*) if the sum of the individual pollutant concentrations is greater than the effluent limitation. Individual pollutants of the group will be considered to have a concentration of zero if the constituent is reported as ND or DNQ.

* See Appendix I for definition of terms.

c. Multiple Sample Data Reduction

The concentration of the pollutant in the effluent may be estimated from the result of a single sample analysis or by a measure of central tendency (arithmetic mean, geometric mean, median, etc.) of multiple sample analyses when all sample results are quantifiable (i.e., greater than or equal to the reported Minimum* Level). When one or more sample results are reported as ND or DNQ, the central tendency concentration of the pollutant shall be the median (middle) value of the multiple samples. If, in an even number of samples, one or both of the middle values is ND or DNQ, the median will be the lower of the two middle values.

d. Powerplants and Heat Exchange Dischargers

Due to the large total volume of powerplant and other heat exchange discharges, special procedures must be applied for determining compliance with Table 1 objectives on a routine basis. Effluent concentration values (Ce) shall be determined through the use of equation 1 considering the minimal probable initial* dilution of the combined effluent (in-plant waste* streams plus cooling water flow). These concentration values shall then be converted to mass emission limitations as indicated in equation 3. The mass emission limits will then serve as requirements applied to all in-plant waste* streams taken together which discharge into the cooling water flow, except that limits for total chlorine residual, acute (if applicable per section (3)(c)) and chronic* toxicity* and instantaneous maximum concentrations in Table 1 shall apply to, and be measured in, the combined final effluent, as adjusted for dilution with ocean water. The Table 1 objective for radioactivity shall apply to the undiluted combined final effluent.

9. Pollutant Minimization Program

a. Pollutant Minimization Program Goal

The goal of the Pollutant Minimization Program is to reduce all potential sources of a pollutant through pollutant minimization (control) strategies, including pollution prevention measures, in order to maintain the effluent concentration at or below the effluent limitation.

Pollution prevention measures may be particularly appropriate for persistent bioaccumulative priority pollutants where there is evidence that beneficial uses are being impacted. The completion and implementation of a Pollution Prevention Plan, required in accordance with CA Water Code section 13263.3 (d) will fulfill the Pollution Minimization Program requirements in this section.

b. Determining the need for a Pollutant Minimization Program

1. The discharger must develop and conduct a Pollutant Minimization Program if all of the following conditions are true:

(a) The calculated effluent limitation is less than the reported Minimum Level*

(b) The concentration of the pollutant is reported as DNQ

* See Appendix I for definition of terms.

(c) There is evidence showing that the pollutant is present in the effluent above the calculated effluent limitation.

2. Alternatively, the discharger must develop and conduct a Pollutant Minimization Program if all of the following conditions are true:

   (a) The calculated effluent limitation is less than the Method Detection Limit.*

   (b) The concentration of the pollutant is reported as ND.

   (c) There is evidence showing that the pollutant is present in the effluent above the calculated effluent limitation.

c. Regional Water Boards may include special provisions in the discharge requirements to require the gathering of evidence to determine whether the pollutant is present in the effluent at levels above the calculated effluent limitation. Examples of evidence may include:

   1. health advisories for fish consumption,
   2. presence of whole effluent toxicity,
   3. results of benthic or aquatic organism tissue sampling,
   4. sample results from analytical methods more sensitive than methods included in the permit (in accordance with section 4b, above).
   5. the concentration of the pollutant is reported as DNQ and the effluent limitation is less than the MDL*

d. Elements of a Pollutant Minimization Program

   The Regional Board may consider cost-effectiveness when establishing the requirements of a Pollutant Minimization Program. The program shall include actions and submittals acceptable to the Regional Board including, but not limited to, the following:

   1. An annual review and semi-annual monitoring of potential sources of the reportable pollutant, which may include fish tissue monitoring and other bio-uptake sampling;
   2. Quarterly monitoring for the reportable pollutant in the influent to the wastewater treatment system;
   3. Submittal of a control strategy designed to proceed toward the goal of maintaining concentrations of the reportable pollutant in the effluent at or below the calculated effluent limitation;
   4. Implementation of appropriate cost-effective control measures for the pollutant, consistent with the control strategy; and,
   5. An annual status report that shall be sent to the Regional Board including:

      (a) All Pollutant Minimization Program monitoring results for the previous year;

      (b) A list of potential sources of the reportable pollutant;

      (c) A summary of all action taken in accordance with the control strategy; and,

* See Appendix I for definition of terms.

(d) A description of actions to be taken in the following year.

10. Toxicity Reduction Requirements

a. If a discharge consistently exceeds an effluent limitation based on a toxicity objective in Table 1, a toxicity reduction evaluation (TRE) is required. The TRE shall include all reasonable steps to identify the source of toxicity. Once the source(s) of toxicity is identified, the discharger shall take all reasonable steps necessary to reduce toxicity to the required level.

b. The following shall be incorporated into waste* discharge requirements: (1) a requirement to conduct a TRE if the discharge consistently exceeds its toxicity effluent limitation, and (2) a provision requiring a discharger to take all reasonable steps to reduce toxicity once the source of toxicity is identified.

D. Implementation Provisions for Bacterial Characteristics

1. Water-Contact Monitoring

a. Weekly samples shall be collected from each site. The geometric mean shall be calculated using the five most recent sample results.

b. If a single sample exceeds any of the single sample maximum (*SSM*) standards, repeat sampling at that location shall be conducted to determine the extent and persistence of the exceedance. Repeat sampling shall be conducted within 24 hours of receiving analytical results and continued until the sample result is less than the SSM standard or until a sanitary survey is conducted to determine the source of the high bacterial densities.

i) Total coliform density will not exceed 10,000 per 100 mL; or
ii) Fecal coliform density will not exceed 400 per 100 mL; or
iii) Total coliform density will not exceed 1,000 per 100 mL when the ratio of fecal/total coliform exceeds 0.1;
iv) enterococcus density will not exceed 104 per 100 mL.

When repeat sampling is required because of an exceedance of any one single sample density, values from all samples collected during that 30-day period will be used to calculate the geometric mean.

c. It is state policy that the geometric mean bacterial objectives are strongly preferred for use in water body assessment decisions, for example, in developing the Clean Water Act section 303(d) list of impaired waters, because the geometric mean objectives are a more reliable measure of long-term water body conditions. In making assessment decisions on bacterial quality, single sample maximum data must be considered together with any available geometric mean data. The use of only single sample maximum bacterial data is generally inappropriate unless there is a limited data set, the water is subject to short-term spikes in bacterial concentrations, or other circumstances justify the use of only single sample maximum data.

* See Appendix I for definition of terms.

d. For monitoring stations outside of the defined water-contact recreation zone (REC-1), samples will be analyzed for total coliform only.

E. Implementation Provisions for Marine Managed Areas*

1. Section E addresses the following Marine Managed Areas*:

(a) State Water Quality Protection Areas (SWQPAs)* consisting of:

(1) SWQPA – Areas of Special Biological Significance (ASBS)* designated by the State Water Board that require special protections as defined under section 4 below.

(2) SWQPA – General Protection (GP) designated by the State Water Board to protect water quality within Marine Protected Areas (MPAs) that require protection under the provisions described under section 5 below.

(b) Marine Protected Areas as defined in the California Public Resources Code as State Marine Reserves, State Marine Parks and State Marine Conservation Areas, established by the Fish and Game Commission, or the Parks and Recreation Commission.

2. The designation of State Marine Parks and State Marine Conservation Areas may not serve as the sole basis for new or modified limitations, substantive conditions, or prohibitions upon existing municipal point source wastewater discharge outfalls. This provision does not apply to State Marine Reserves.

3. The State Water Board may designate SWQPAs* to prevent the undesirable alteration of natural water quality within MPAs. These designations may include either SWQPA-ASBS or SWQPA-GP or in combination. In considering the designation of SWQPAs over MPAs, the State Water Board will consult with the affected Regional Water Quality Control Board, the Department of Fish and Game and the Department of Parks and Recreation, in accordance with the requirements of Appendix IV.

4. Implementation Provisions For SWQPA-ASBS*

(a) Waste* shall not be discharged to areas designated as being of special biological significance. Discharges shall be located a sufficient distance from such designated areas to assure maintenance of natural water quality conditions in these areas.

(b) Regional Water Boards may approve waste* discharge requirements or recommend certification for limited-term (i.e. weeks or months) activities in ASBS.* Limited-term activities include, but are not limited to, activities such as maintenance/repair of existing boat facilities, restoration of sea walls, repair of existing storm water pipes, and replacement/repair of existing bridges. Limited-term activities may result in temporary and short-term changes in existing water quality. Water quality degradation shall be limited to the shortest possible time. The activities must not permanently degrade* water quality or result in water quality

* See Appendix I for definition of terms.

lower than that necessary to protect existing uses, and all practical means of minimizing such degradation shall be implemented.

5. Implementation Provisions for SWQPAs-GP*

(a) Implementation provisions for existing point source wastewater discharges (NPDES)

(1) An SWQPA-GP shall not be designated over existing permitted point source wastewater outfalls or encroach upon the zone of initial dilution* associated with an existing discharge. This requirement does not apply to discharges less than one million gallons per day.

(2) Designation of an SWQPA-GP shall not include conditions to move existing point source wastewater outfalls.

(3) Where a new SWQPA-GP is established in the vicinity of existing municipal wastewater outfalls, there shall be no new or modified limiting condition or prohibitions for the SWQPA-GP relative to those wastewater outfalls.

(4) Regulatory requirements for discharges from existing treated municipal wastewater outfalls shall be derived from the Chapter II – Water Quality Objectives and Chapter III – Program of Implementation.

(b) Implementation provisions for existing seawater* intakes

(1) Existing permitted seawater* intakes other than those serving desalination facilities* must be controlled to minimize entrainment and impingement by using best technology available. Existing permitted seawater* intakes with a capacity less than one million gallons per day are excluded from this requirement.

(2) Existing permitted seawater* intakes serving desalination facilities are governed by the provisions set forth in chapter III.M of this Plan.

(c) Implementation provisions for permitted separate storm sewer system (MS4) discharges and nonpoint source discharges.

(1) Existing waste* discharges are allowed, but shall not cause an undesirable alteration in natural water quality. For purposes of SWQPA-GP, an undesirable alteration in natural water quality means that for intermittent (e.g. wet weather) discharges, Table 1 instantaneous maximum concentrations for chemical constituents, and daily maximum concentrations for chronic toxicity,* must not be exceeded in the receiving water.*

(2) An NPDES permitting authority* may authorize NPDES-permitted non-storm water discharges* to an MS4 with a direct discharge to an SWQPA-GP only to the extent the NPDES permitting authority* finds that the discharge does not cause an undesirable alteration in natural water quality in an SWQPA-GP.

(3) Non-storm water (dry weather) flows are effectively prohibited as required by the applicable permit. Where capacity and infrastructure exists, all dry weather flows

* See Appendix I for definition of terms.

shall be diverted to municipal sanitary sewer systems. The permitting authority* may allow discharges essential for emergency response purposes, structural stability, and slope stability, which may include but are not limited the following:

a. Discharges associated with emergency fire-fighting operations.
b. Foundation and footing drains
c. Water from crawl space or basement pumps.
d. Hillside dewatering.

(4) The following naturally occurring discharges are allowed:

a. Naturally occurring groundwater seepage via a storm drain
b. Non-anthropogenic flows from a naturally occurring stream via a culvert or storm drain, as long as there are no contributions of anthropogenic runoff.

(5) Existing storm water discharges into an SWQPA-GP shall be characterized and assessed to determine what effect if any these inputs are having on natural water quality in the State Water Quality Protection Area. Such assessments shall include an evaluation of cumulative impacts as well as impacts stemming from individual discharges. Information to be considered shall include:

a. Water quality;
b. Flow;
c. Watershed pollutant sources; and
d. Intertidal and/ or subtidal biological surveys.

Within each SWQPA-GP the assessment shall be used to rank these existing discharges into low, medium and high threat impact categories. Cumulative impacts will be ranked similarly as well.

(6) An initial analysis shall be performed for pre- and post-storm receiving water* quality of Table 1 constituents and chronic toxicity.* If post-storm receiving water* quality has larger concentrations of constituents relative to pre-storm, and Table 1 instantaneous maximum concentrations for chemical constituents, and daily maximum concentrations for chronic toxicity,* are exceeded, then receiving water* shall be re-analyzed along with storm runoff (end of pipe) for the constituents that are exceeded.

(7) If undesirable alterations of natural water quality and/or biological communities are identified, control strategies/measures shall be implemented for those dischargers characterized as a high threat or those contributing to higher threat cumulative impacts first.

(8) If those strategies fail, additional control strategies/measures will be implemented for dischargers characterized as medium impact dischargers. If these strategies do not result in improvement of water quality, those discharges classified as low threat shall also implement control strategies/measures.

(d) Implementation Provisions for New Discharges

* See Appendix I for definition of terms.

(1) Point Source Wastewater Outfalls
No new point source wastewater outfalls shall be established within an SWQPA-GP.

(2) Seawater* intakes
No new surface water seawater* intakes shall be established within an SWQPA-GP. This does not apply to subsurface* intakes where studies are prepared showing there is no predictable entrainment, impingement, or construction-related marine life mortality.

(3) All Other New Discharges
There shall be no increase in nonpoint sources or permitted storm drains directly into an SWQPA-GP.

6. Impaired Tributaries to MPAs, SWQPA-ASBS and SWQPA-GP

All water bodies draining to, or that are designated as, MPAs and SWQPAs that appear on the State's CWA section 303(d) list shall be given a high priority to have a TMDL developed and implemented.

F. Revision of Waste* Discharge Requirements

1. The Regional Water Boards may establish more restrictive water quality objectives and effluent limitations than those set forth in this Plan as necessary for the protection of beneficial uses of ocean* waters.

2. Regional Water Boards may impose alternative less restrictive provisions than those contained within Table 1 of the Plan, provided an applicant can demonstrate that:

   a. Reasonable control technologies (including source control, material* substitution, treatment and dispersion) will not provide for complete compliance; or

   b. Any less stringent provisions would encourage water* reclamation;

3. Provided further that:

   a. Any alternative water quality objectives shall be below the conservative estimate of chronic toxicity,* as given in Table 4 (with all metal concentrations expressed as total recoverable concentrations), and such alternative will provide for adequate protection of the marine environment;

   b. A receiving water* quality toxicity objective of 1 TUc is not exceeded; and

   c. The State Water Board grants an exception (chapter III.J) to the Table 1 limits as established in the Regional Board findings and alternative limits.

G. Compliance Schedules in National Pollutant Discharge Elimination System (NPDES) Permits

1. Compliance schedules in NPDES permits are authorized in accordance with the provisions of the State Water Board's Policy for Compliance Schedules in [NPDES] Permits (2008).

* See Appendix I for definition of terms.

TABLE 4 (formerly TABLE D)
CONSERVATIVE ESTIMATES OF CHRONIC* TOXICITY

Constituent	**Estimate of Chronic* Toxicity (µg/L)**
Arsenic	19.
Cadmium	8.
Hexavalent Chromium	18.
Copper	5.
Lead	22.
Mercury	0.4
Nickel	48.
Silver	3.
Zinc	51.
Cyanide	10.
Total Chlorine Residual	10.0
Ammonia	4000.0
Phenolic Compounds (non-chlorinated)	a) (see below)
Chlorinated Phenolics	a)
Chlorinated Pesticides and PCBs*	b)

Table 4 Notes:

a) There are insufficient data for phenolics to estimate chronic* toxicity levels. Requests for modification of water quality objectives for these waste* constituents must be supported by chronic* toxicity data for representative sensitive species. In such cases, applicants seeking modification of water quality objectives should consult the Regional Water Quality Control Board to determine the species and test conditions necessary to evaluate chronic effects.

b) Limitations on chlorinated pesticides and PCBs* shall not be modified so that the total of these compounds is increased above the objectives in Table 1.

H. Monitoring Program

1. The Regional Water Boards shall require dischargers to conduct self-monitoring programs and submit reports necessary to determine compliance with the waste* discharge requirements, and may require dischargers to contract with agencies or persons acceptable to the Regional Water Board to provide monitoring reports. Monitoring provisions contained in waste* discharge requirements shall be in accordance with the Monitoring Procedures provided in Appendices III and VI.

2. The Regional Water Board may require monitoring of bioaccumulation of toxicants in the discharge zone. Organisms and techniques for such monitoring shall be chosen by the Regional Water Board on the basis of demonstrated value in waste* discharge monitoring.

* See Appendix I for definition of terms.

I. Discharge Prohibitions

1. <u>Hazardous Substances</u>

   a. The discharge of any radiological, chemical, or biological warfare agent or high-level radioactive waste* into the ocean* is prohibited.

2. <u>Areas Designated for Special Water Quality Protection</u>

   a. Waste* shall not be discharged to designated Areas* of Special Biological Significance except as provided in chapter III.E Implementation Provisions for Marine Managed Areas.*

3. <u>Sludge</u>

   a. Pipeline discharge of sludge to the ocean* is prohibited by federal law; the discharge of municipal and industrial waste* sludge directly to the ocean,* or into a waste* stream that discharges to the ocean,* is prohibited by this Plan. The discharge of sludge digester supernatant directly to the ocean,* or to a waste* stream that discharges to the ocean* without further treatment, is prohibited.

   b. It is the policy of the State Water Board that the treatment, use and disposal of sewage sludge shall be carried out in the manner found to have the least adverse impact on the total natural and human environment. Therefore, if federal law is amended to permit such discharge, which could affect California waters, the State Water Board may consider requests for exceptions to this section under Chapter III. J of this Plan, provided further that an Environmental Impact Report on the proposed project shows clearly that any available alternative disposal method will have a greater adverse environmental impact than the proposed project.

4. <u>By-Passing</u>

   a. The by-passing of untreated wastes* containing concentrations of pollutants in excess of those of Table 2 or Table 1 to the ocean* is prohibited.

5. <u>Vessels</u>

   a. Discharges of hazardous waste (as defined in California Health and Safety Code § 25117 et seq. [but not including sewage]), oily bilge water,* medical waste (as defined in § 117600 et seq. of the California Health and Safety Code) dry-cleaning waste, and film-processing waste from large passenger vessels* and oceangoing vessels* are prohibited.

   b. Discharges of graywater* and sewage* from large passenger vessels* are prohibited.

   c. Discharges of sewage and sewage sludge from vessels are prohibited in No Discharge Zones* promulgated by U.S. EPA.

---
* See Appendix I for definition of terms.

6. Trash*

The discharge of Trash* to surface waters of the State or the deposition of Trash* where it may be discharged into surface waters of the State is prohibited. Compliance with this prohibition of discharge shall be achieved as follows:

a. Dischargers with NPDES permits that contain specific requirements for the control of Trash* that are consistent with these Trash Provisions* shall be determined to be in compliance with this prohibition if the dischargers are in full compliance with such requirements.

b. Dischargers with non-NPDES waste discharge requirements (WDRs) or waivers of WDRs that contain specific requirements for the control of Trash* shall be determined to be in compliance with this prohibition if the dischargers are in full compliance with such requirements.

c. Dischargers with NPDES permits, WDRs, or waivers of WDRs that do not contain specific requirements for the control of Trash* are exempt from these Trash Provisions*.

d. Dischargers without NPDES permits, WDRs, or waivers of WDRs must comply with this prohibition of discharge.

e. Chapter III.I.6.b and Chapter III.L.3 notwithstanding, this prohibition of discharge applies to the discharge of preproduction plastic* by manufacturers of preproduction plastics*, transporters of preproduction plastics*, and manufacturers that use preproduction plastics* in the manufacture of other products to surface waters of the State, or the deposition of preproduction plastic* where it may be discharged into surface waters of the State, unless the discharger is subject to a NPDES permit for discharges of storm water* associated with industrial activity.

J. State Board Exceptions to Plan Requirements

1. The State Water Board may, in compliance with the California Environmental Quality Act, subsequent to a public hearing, and with the concurrence of the Environmental Protection Agency, grant exceptions where the Board determines:

   a. The exception will not compromise protection of ocean* waters for beneficial uses, and,

   b. The public interest will be served.

2. All exceptions issued by the State Water Board and in effect at the time of the Triennial Review will be reviewed at that time. If there is sufficient cause to re-open or revoke any exception, the State Water Board may direct staff to prepare a report and to schedule a public hearing. If after the public hearing the State Water Board decides to re-open, revoke, or re-issue a particular exception, it may do so at that time.

* See Appendix I for definition of terms.

K. Implementation Provisions for Vessel Discharges

1. Vessel discharges must comply with State Lands Commission (SLC) requirements for ballast water discharges and hull fouling to control and prevent the introduction of non-indigenous species, found in the Public Resources Code sections 71200 et seq. and title 2, California Code of Regulations, section 22700 et. seq.

2. Discharges incidental to the normal operation large passenger vessels* and ocean-going vessels must be covered and comply with an individual or general NPDES permit.

3. Vessel discharges must not result in violations of water quality objectives in this plan.

4. Vessels subject to the federal NPDES Vessel General Permit (VGP) which are not large passenger vessels* must follow the best management practices for graywater* as required in the VGP, including the use of only those cleaning agents (e.g., soaps and detergents) that are phosphate-free, non-toxic, and non-bioaccumulative.

L. Implementation Provisions for Trash* [(Section L only) effective January 12, 2016]

1. Applicability

a. These Trash Provisions* shall be implemented through a prohibition of discharge (Chapter III.I.6) and through NPDES permits issued pursuant to section 402(p) of the Federal Clean Water Act, waste discharge requirements (WDRs), or waivers of WDRs (as set forth in Chapter III.L.2 and Chapter III.L.3 below).

b. These Trash Provisions* apply to all surface waters of the State, with the exception of those waters within the jurisdiction of the Los Angeles Regional Water Quality Control Board (Los Angeles Water Board) for which trash Total Maximum Daily Loads (TMDLs) are in effect prior to the effective date of these Trash Provisions*[1]; provided, however, that:

(1) Upon the effective date of these Trash Provisions*, the Los Angeles Water Board shall cease its full capture system* certification process and provide that any new full capture systems* shall be certified by the State Water Board in accordance with these Trash Provisions*.

(2) Within one year of the effective date of these Trash Provisions*, the Los Angeles Water Board shall convene a public meeting to reconsider the scope of its trash TMDLs, with the exception of those for the Los Angeles River and Ballona Creek watersheds, to particularly consider an approach

[1] In the Los Angeles Region, there are fifteen (15) trash TMDLs for the following watersheds and water bodies: Los Angeles River Watershed, Ballona Creek, Malibu Creek Watershed, Santa Monica Bay Nearshore and Offshore, San Gabriel River East Fork, Revolon Slough and Beardsley Wash, Ventura River Estuary, Machado Lake, Lake Elizabeth, Lake Hughes, Munz Lake, Peck Road Park Lake, Echo Park Lake, Lincoln Park Lake and Legg Lake. Three of these were established by the U.S. EPA: Peck Road Park Lake, Echo Park Lake and Lincoln Park Lake.

* See Appendix I for definition of terms.

that would focus MS4* permittees' trash-control efforts on high-trash generation areas within their jurisdictions.

2. Dischargers Permitted Pursuant to Federal Clean Water Act Section 402(p)

Permitting authorities* shall include the following requirements in NPDES permits issued pursuant to Federal Clean Water Act section 402(p):

a. MS4* permittees with regulatory authority over priority land uses* shall be required to comply with the prohibition of discharge in Chapter III.I.6.a herein by either of the following measures:

(1) Track 1: Install, operate, and maintain full capture systems* for all storm drains that captures runoff from the priority land uses* in their jurisdictions; or

(2) Track 2: Install, operate, and maintain any combination of full capture systems*, multi-benefit projects*, other treatment controls*, and/or institutional controls* within either the jurisdiction of the MS4* permittee or within the jurisdiction of the MS4* permittee and contiguous MS4* permittees. The MS4* permittee may determine the locations or land uses within its jurisdiction to implement any combination of controls. The MS4* permittee shall demonstrate that such combination achieves full capture system equivalency*. The MS4* permittee may determine which controls to implement to achieve compliance with full capture system equivalency*. It is, however, the State Water Board's expectation that the MS4* permittee will elect to install full capture systems* where such installation is not cost-prohibitive.

b. The California Department of Transportation (Department) shall be required to comply with the prohibition of discharge in Chapter III.I.6.a herein in all significant trash generating areas* by installing, operating, and maintaining any combination of full capture systems*, multi-benefit projects*, other treatment controls*, and/or institutional controls* for all storm drains that captures runoff from significant trash generating areas*. The Department shall demonstrate that such combination achieves full capture system equivalency*. In furtherance of this provision, the Department and MS4* permittees that are subject to the provisions of Chapter III.L.2.a herein shall coordinate their efforts to install, operate, and maintain full capture systems*, multi-benefit projects*, other treatment controls*, and/or institutional controls* in significant trash generating areas* and/or priority land uses*.

c. Dischargers that are subject to NPDES permits for discharges of storm water* associated with industrial activity (including construction activity) shall be required to comply with the prohibition of discharge in Chapter III.I.6.a herein by eliminating Trash* from all storm water* and authorized non-storm water* discharges consistent with an outright prohibition of the discharge of Trash* contained within the applicable NPDES permit regulating the industrial or construction facility. If the discharger can satisfactorily demonstrate to the permitting authority* its inability to comply with the outright prohibition of the

* See Appendix I for definition of terms.

discharge of Trash* contained within the applicable NPDES permit, then the permitting authority* may require the discharger to either:

(1) Install, operate, and maintain full capture systems* for all storm drains that captures runoff from the facility or site regulated by the NPDES permit; or,

(2) Install, operate, and maintain any combination of full capture systems*, multi-benefit projects*, other treatment controls*, and/or institutional controls* for the facility or site regulated by the NPDES permit. The discharger shall demonstrate that such combination achieves full capture system equivalency*.

Termination of permit coverage for industrial and construction storm water* dischargers shall be conditioned upon the proper operation and maintenance of all controls (e.g., full capture systems*, multi-benefit projects*, other treatment controls*, and/or institutional controls*) used at their facility(ies).

d. A permitting authority* may determine that specific land uses or locations (e.g., parks, stadia, schools, campuses, or roads leading to landfills) generate substantial amounts of Trash*. In the event that the permitting authority* makes that determination, the permitting authority* may require the MS4* to comply with Chapter III.L.2.a.1 or Chapter III.L.2.a.2, as determined by the permitting authority*, with respect to such land uses or locations.

3. Other Dischargers

A permitting authority* may require dischargers, described in Chapter III.I.6.c or Chapter III.I.6.d, that are not subject to Chapter III.L.2 herein, to implement any appropriate Trash* controls in areas or facilities that may generate Trash*. Such areas or facilities may include (but are not limited to) high usage campgrounds, picnic areas, beach recreation areas, parks not subject to an MS4* permit, or marinas.

4. Time Schedule

The permitting authority* shall modify, re-issue, or newly adopt NPDES permits issued pursuant to section 402(p) of the Federal Clean Water Act that are subject to the provisions of Chapter III.L.2 herein to include requirements consistent with these Trash Provisions*. The permitting authorities* shall abide by the following time schedules:

a. NPDES Permits Regulating MS4* Permittees that have Regulatory Authority over Priority Land Uses*.[2]

[2] The time schedule requirement in Chapter III.L.4.a.1 requiring MS4* permittees to elect Chapter III.L.2.a.1 (Track 1) or Chapter III.L.2.a.2 (Track 2) does not apply to MS4* permittees subject to the Municipal Regional Stormwater NPDES Permit (MRP) issued by the San Francisco Bay Regional Water Quality Control Board (San Francisco Bay Water Board) or the East Contra Costa Municipal Storm Water Permit issued by the Central Valley Regional Water Quality Control Board (Central Valley Water Board) because those permits already require control requirements substantially equivalent to Track 2. The time schedule requirement in Chapter III.L.4.a.1 requiring MS4* permittees to submit an implementation plan

* See Appendix I for definition of terms.

(1) Within eighteen (18) months of the effective date of these Trash Provisions*, for each permittee, each permitting authority* shall either:

A. Modify, re-issue, or adopt the applicable MS4* permit to add requirements to implement these Trash Provisions*. The implementing permit shall require written notice from each MS4* permittee stating whether it has elected to comply under Chapter III.L.2.a.1 (Track 1) or Chapter III.L.2.a.2 (Track 2) and such notice shall be submitted to the permitting authority* no later than three (3) months from the effective date of the implementing permit, or for MS4s* designated after the effective date of these Trash Provisions*, three (3) months from the effective date of that designation. The implementing permit shall also require that within eighteen (18) months of the effective date of the implementing permit or new designation, MS4* permittees that have elected to comply with Track 2 shall submit an implementation plan to the permitting authority*. The implementation plan shall describe: (i) the combination of controls selected by the MS4* permittee and the rationale for the selection, (ii) how the combination of controls is designed to achieve full capture system equivalency*, and (iii) how full capture system equivalency* will be demonstrated. The implementation plan is subject to approval by the permitting authority*.

B. Issue an order pursuant to Water Code section 13267 or 13383 requiring the MS4* permittee to submit, within three (3) months from receipt of the order, written notice to the permitting authority* stating whether such MS4* permittee will comply with the prohibition of discharge under Chapter III.L.2.a.1 (Track 1) or Chapter III.L.2.a.2 (Track 2). For MS4s* designated after the effective date of these Trash Provisions*, the order pursuant to Water Code section 13267 or 13383 shall be issued at the time of designation. Within eighteen (18) months of the receipt of the Water Code section 13267 or 13383 order, MS4* permittees that have elected to comply with Track 2 shall submit an implementation plan to the permitting authority* that describes: (i) the combination of controls selected by the MS4* permittee and the rationale for the selection, (ii) how the combination of controls is designed to achieve full capture system equivalency*, and (iii) how full capture system equivalency* will be demonstrated. The implementation plan is subject to approval by the permitting authority*.

(2) For MS4* permittees that elect to comply with Chapter III.L.2.a.1 (Track1), the implementing permit shall state that full compliance shall occur within

---

does not apply to the above permittees if the pertinent permitting authority* determines that such permittee has already submitted an implementation plan prior to the effective date of the Trash Provisions* that is equivalent to the implementation plan required by Chapter III.L.4.a.1. In the aforementioned permits, the pertinent permitting authority* may establish an earlier full compliance deadline than that specified in Chapter III.L.4.a.3.

---

* See Appendix I for definition of terms.

ten (10) years of the effective date of the first implementing permit except as specified in Chapter III.L.4.a.5. The permit shall also require these permittees to demonstrate achievement of interim milestones such as average load reductions of ten percent (10%) per year or other progress to full implementation. In no case may the final compliance date be later than fifteen (15) years from the effective date of these Trash Provisions*.

(3) For MS4* permittees that elect to comply with Chapter III.L.2.a.2 (Track 2), the implementing permit shall state that full compliance shall occur within ten (10) years of the effective date of the first implementing permit except as specified in Chapter III.L.4.a.5. The permit shall also require these permittees to demonstrate achievement of interim milestones such as average load reductions of ten percent (10%) per year or other progress to full implementation. In no case may the final compliance date be later than fifteen (15) years from the effective date of these Trash Provisions*.

(4) The implementing permit shall state that for MS4* permittees designated after the effective date of the implementing permit, full compliance shall occur within ten (10) years of the effective date of the designation. The permit shall also require such designations to demonstrate achievement of interim milestones such as average load reductions of ten percent (10%) per year or other progress to full implementation.

(5) Where a permitting authority* makes a determination pursuant to Chapter III.L.2.d that a specific land use generates a substantial amount of Trash*, that permitting authority* has discretion to determine the time schedule for full compliance. In no case may the final compliance date be later than ten (10) years from the determination.

b. NPDES Permits Regulating the Department.

(1) Within eighteen (18) months of the effective date of these Trash Provisions*, the State Water Board shall issue an order pursuant to Water Code section 13267 or 13383 requiring the Department to submit an implementation plan to the Executive Director of the State Water Board that: (i) describes the specific locations of its significant trash generating areas*, (ii) the combination of controls selected by the Department and the rationale for the selections, and (iii) how it will demonstrate full capture system equivalency*.

(2) The Department must demonstrate full compliance with Chapter III.L.2.b herein within ten (10) years of the effective date of the first implementing NPDES permit, along with achievements of interim milestones such as average load reductions of ten percent (10%) per year. In no case may the final compliance date be later than fifteen (15) years from the effective date of these Trash Provisions*.

c. NPDES Permits Regulating the Discharges of Storm Water* Associated with Industrial Activity (Including Construction Activity). Dischargers that are subject

---

* See Appendix I for definition of terms.

to the provisions of Chapter III.L.2.c herein must demonstrate full compliance in accordance with the deadlines contained in the first implementing NPDES permits. Such deadlines may not exceed the terms of the first implementing permits.

5. Monitoring and Reporting

The permitting authority* must include monitoring and reporting requirements in its implementing permits. The following monitoring and reporting provisions are the minimum requirements that must be included within the implementing permits:

a. MS4* permittees that elect to comply with Chapter III.L.2.a.1 (Track 1) shall provide a report to the applicable permitting authority* demonstrating installation, operation, maintenance, and the Geographic Information System- (GIS-) mapped location and drainage area served by its full capture systems* on an annual basis.

b. MS4* permittees that elect to comply with Chapter III.L.2.b.2 (Track 2) shall develop and implement monitoring plans that demonstrate the effectiveness of the full capture systems*, multi-benefit projects*, other treatment controls*, and/or institutional controls* and compliance with full capture system equivalency*. Monitoring reports shall be provided to the applicable permitting authority* on an annual basis, and shall include GIS-mapped locations and drainage area served for each of the full capture systems*, multi-benefit projects*, other treatment controls*, and/or institutional controls* installed or utilized by the MS4* permittee. In developing the monitoring reports the MS4* permittee should consider the following questions:

(1) What type of and how many treatment controls*, institutional controls*, and/or multi-benefit projects* have been used and in what locations?

(2) How many full capture systems* have been installed (if any), in what locations have they been installed, and what is the individual and cumulative area served by them?

(3) What is the effectiveness of the total combination of treatment controls*, institutional controls*, and multi-benefit projects* employed by the MS4* permittee?

(4) Has the amount of Trash* discharged from the MS4* decreased from the previous year? If so, by how much? If not, explain why.

(5) Has the amount of Trash* in the MS4's* receiving water(s) decreased from the previous year? If so, by how much? If not, explain why.

c. The Department, as subject to the provisions of Chapter III.L.2.b, shall develop and implement monitoring plans that demonstrate the effectiveness of the controls and compliance with full capture system equivalency*. Monitoring reports shall be provided to the State Water Board on an annual basis, and shall include GIS-mapped locations and drainage area served for each of the full

* See Appendix I for definition of terms.

capture systems*, multi-benefit projects*, other treatment controls*, and/or institutional controls* installed or utilized by the Department. In developing the monitoring report, the Department should consider the following questions:

(1) What type of and how many treatment controls* institutional controls*, and/or multi-benefit projects* have been used and in what locations?

(2) How many full capture systems* have been installed (if any), in what locations have they been installed, and what is the individual and cumulative area served by them?

(3) What is the effectiveness of the total combination of treatment controls*, institutional controls*, and multi-benefit projects* employed by the Department?

(4) Has the amount of Trash* discharged from the Department's MS4* decreased from the previous year? If so, by how much? If not, explain why.

(5) Has the amount of Trash* in the receiving waters decreased from the previous year? If so, by how much? If not, explain why.

d. Dischargers that are subject to the provisions of Chapter III.L.2.c herein shall be required to report the measures used to comply with Chapter III.L.2.c.

M. Implementation Provisions for Desalination Facilities*

1. Applicability and General Provisions

a. Chapter III.M applies to desalination facilities* using seawater.* Chapter III.M.2 does not apply to desalination facilities* operated by a federal agency. Chapter III.M.2, M.3, and M.4 do not apply to portable desalination facilities* that withdraw less than 0.10 million gallons per day (MGD) of seawater* and are operated by a governmental agency. These standards do not alter or limit in any way the authority of any public agency to implement its statutory obligations. The Executive Director of the State Water Board may temporarily waive the application of chapter III.M to desalination facilities* that are operating to serve as a critical short-term water supply during a state of emergency as declared by the Governor.

b. Definitions of New, Expanded, and Existing Facilities:

(1) For purposes of chapter III.M, "existing facilities" means desalination facilities* that have been issued an NPDES permit and all building permits and other governmental approvals necessary to commence construction for which the owner or operator has relied in good faith on those previously-issued permits and approvals and commenced construction of the facility beyond site grading prior to January 28, 2016.

* See Appendix I for definition of terms.

(2) For purposes of chapter III.M, “expanded facilities” means existing facilities for which, after January 28, 2016, the owner or operator does either of the following in a manner that could increase intake or mortality of all forms of marine life * beyond that which was originally approved in any NPDES permit or Water Code section 13142.5, subdivision (b) (hereafter Water Code section 13142.5(b)) determination: 1) increases the amount of seawater* used either exclusively by the facility or used by the facility in conjunction with other facilities or uses, or 2) changes the design or operation of the facility. To the extent that the desalination facility* is co-located with another facility that withdraws water for a different purpose and that other facility reduces the volume of water withdrawn to a level less than the desalination facility’s* volume of water withdrawn, the desalination facility* is considered to be an expanded facility.

(3) For purposes of chapter III.M, “new facilities” means desalination facilities* that are not existing facilities or expanded facilities.

c. Chapter III.M.2 (Water Code §13142.5(b) Determinations for New and Expanded Facilities: Site, Design, Technology, and Mitigation Measures) applies to new and expanded desalination facilities* withdrawing seawater.*

d. Chapter III.M.3 (Receiving Water Limitation for Salinity*) applies to all desalination facilities* that discharge into ocean waters* and wastewater facilities that receive brine* from seawater* desalination facilities* and discharge into ocean waters.*

e. Chapter III.M.4 (Monitoring and Reporting Programs) applies to all desalination facilities* that discharge into ocean waters.* Chapter III.M.4 shall not apply to a wastewater facility that receives brine* from a seawater* desalination facility* and discharges a positively buoyant commingled effluent through an existing wastewater outfall that is covered under an existing NPDES permit, as long as the owner or operator monitors for compliance with the receiving water limitation set forth in chapter III.M.3. For the purposes of chapter III.M.4, a positively buoyant commingled effluent shall mean that the commingled plume rises when it enters the receiving water body due to salinity* levels in the commingled discharge being lower than the natural background salinity.*

f. References to the regional water board include the regional water board acting under delegated authority. For provisions that require consultation between regional water board and State Water Board staff, the regional water board shall notify and consult with the State Water Board staff prior to making a final determination on the item requiring consultation.

g. All desalination facilities must comply with all other applicable sections of the Ocean Plan.

2. Water Code section 13142.5(b) Determinations for New and Expanded Facilities: Site, Design, Technology, and Mitigation Measures Feasibility Considerations

* See Appendix I for definition of terms.

a. General Considerations

(1) The owner or operator shall submit a request for a Water Code section 13142.5(b) determination to the appropriate regional water board as early as practicable. This request shall include sufficient information for the regional water board to conduct the analyses described below. The regional water board in consultation with the State Water Board staff may require an owner or operator to provide additional studies or information if needed, including any information necessary to identify and assess other potential sources of mortality to all forms of marine life. All studies and models are subject to the approval of the regional water board in consultation with State Water Board staff. The regional water board may require an owner or operator to hire a neutral third party entity to review studies and models and make recommendations to the regional water board.

(2) The regional water board shall conduct a Water Code section 13142.5(b) analysis of all new and expanded desalination facilities.* A Water Code section 13142.5(b) analysis may include future expansions at the facility. The regional water board shall first analyze separately as independent considerations a range of feasible* alternatives for the best available site, the best available design, the best available technology, and the best available mitigation measures to minimize intake and mortality of all forms of marine life.* Then, the regional water board shall consider all four factors collectively and determine the best combination of feasible* alternatives to minimize intake and mortality of all forms of marine life.* The best combination of alternatives may not always include the best alternative under each individual factor because some alternatives may be mutually exclusive, redundant, or not feasible* in combination.

(3) The regional water board's Water Code section 13142.5(b) analysis for expanded facilities may be limited to those expansions or other changes that result in the increased intake or mortality of all forms of marine life,* unless the regional water board determines that additional measures that minimize intake and mortality of all forms of marine life* are feasible* for the existing portions of the facility.

(4) In conducting the Water Code section 13142.5(b) determination, the regional water boards shall consult with other state agencies involved in the permitting of that facility, including, but not limited to: California Coastal Commission, California State Lands Commission, and California Department of Fish and Wildlife. The regional water board shall consider project-specific decisions made by other state agencies; however, the regional water board is not limited to project-specific requirements set forth by other agencies and may include additional requirements in a Water Code section 13142.5(b) determination.

---
* See Appendix I for definition of terms.

(5) A regional water board may expressly condition a Water Code section 13142.5(b) determination based on the expectation of the occurrence of a future event. Such future events may include, but are not limited to, the permanent shutdown of a co-located power plant with intake structures shared with the desalination facility,* or a reduction in the volume of wastewater available for the dilution of brine.* The regional water board must make a new Water Code section 13142.5(b) determination if the foreseeable future event occurs.

(a) The owner or operator shall provide notice to the regional water board as soon as it becomes aware that the expected future event will occur, and shall submit a new request for a Water Code section 13142.5(b) determination to the regional water board at least one year prior to the event occurring. If the owner or operator does not become aware that the event will occur at least one year prior to the event occurring, the owner or operator shall submit the request as soon as possible.

(b) The regional water board may allow up to five years from the date of the event for the owner or operator to make modifications to the facility required by a new Water Code section 13142.5(b) determination, provided that the regional water board finds that 1) any water supply interruption resulting from the facility modifications requires additional time for water users to obtain a temporary replacement supply, or 2) such a compliance period is otherwise in the public interest and reasonably required for modification of the facility to comply with the determination.

(c) If the regional water board makes a Water Code section 13142.5(b) determination for a desalination facility* that will be co-located with a power plant, the regional water board shall condition its determination on the power plant remaining in compliance with the Water Quality Control Policy on the Use of Coastal and Estuarine Waters for Power Plant Cooling.

b. Site is the general onshore and offshore location of a new or expanded facility. There may be multiple potential facility design configurations within any given site. The regional water board shall require that the owner or operator evaluate a reasonable range of nearby sites, including sites that would likely support subsurface intakes. For each potential site, in order to determine whether a proposed facility site is the best available site feasible* to minimize intake and mortality of all forms of marine life,* the regional water board shall require the owner or operator to:

(1) Consider whether subsurface intakes* are feasible.*

(2) Consider whether the identified need for desalinated* water is consistent with an applicable adopted urban water management plan

* See Appendix I for definition of terms.

prepared in accordance with Water Code section 10631, or if no urban water management plan is available, other water planning documents such as a county general plan or integrated regional water management plan.

(3) Analyze the feasibility of placing intake, discharge, and other facility infrastructure in a location that avoid impacts to sensitive habitats* and sensitive species.

(4) Analyze the direct and indirect effects on all forms of marine life* resulting from facility construction and operation, individually and in combination with potential anthropogenic effects on all forms of marine life* resulting from other past, present, and reasonably foreseeable future activities within the area affected by the facility.

(5) Analyze oceanographic geologic, hydrogeologic, and seafloor topographic conditions at the site, so that the siting of a facility, including the intakes and discharges, minimizes the intake and mortality of all forms of marine life.*

(6) Analyze the presence of existing discharge infrastructure, and the availability of wastewater to dilute the facility's brine* discharge.

(7) Ensure that the intake and discharge structures are not located within a MPA or SWQPA* with the exception of intake structures that do not have marine life mortality associated with the construction, operation, and maintenance of the intake structures (e.g. slant wells). Discharges shall be sited at a sufficient distance from a MPA or SWQPA* so that the salinity* within the boundaries of a MPA or SWQPA* does not exceed natural background salinity.* To the extent feasible,* surface intakes shall be sited so as to maximize the distance from a MPA or SWQPA.*

c. Design is the size, layout, form, and function of a facility, including the intake capacity and the configuration and type of infrastructure, including intake and outfall structures. The regional water board shall require that the owner or operator perform the following in determining whether a proposed facility design is the best available design feasible* to minimize intake and mortality of all forms of marine life:*

(1) For each potential site, analyze the potential design configurations of the intake, discharge, and other facility infrastructure to avoid impacts to sensitive habitats* and sensitive species.

(2) If the regional water board determines that subsurface intakes* are not feasible* and surface water intakes are proposed instead, analyze potential designs for those intakes in order to minimize the intake and mortality of all forms of marine life.*

* See Appendix I for definition of terms.

(3) Design the outfall so that the brine mixing zone* does not encompass or otherwise adversely affect existing sensitive habitat.*

(4) Design the outfall so that discharges do not result in dense, negatively-buoyant plumes that result in adverse effects due to elevated salinity* or hypoxic conditions occurring outside the brine mixing zone.* An owner or operator must demonstrate that the outfall meets this requirement through plume modeling and/or field studies. Modeling and field studies shall be approved by the regional water board in consultation with State Water Board staff.

(5) Design outfall structures to minimize the suspension of benthic sediments.

d. Technology is the type of equipment, materials,* and methods that are used to construct and operate the design components of the desalination facility.* The regional water board shall apply the following considerations in determining whether a proposed technology is the best available technology feasible* to minimize intake and mortality of all forms of marine life:*

(1) Considerations for Intake Technology:

(a) Subject to chapter M.2.a.(2), the regional water board in consultation with State Water Board staff shall require subsurface intakes* unless it determines that subsurface intakes* are not feasible* based upon a comparative analysis of the factors listed below for surface and subsurface intakes.* A design capacity in excess of the need for desalinated* water as identified in chapter III.M.2.b.(2) shall not be used by itself to declare subsurface intakes* as not feasible.*

i. The regional water board shall consider the following factors in determining feasibility of subsurface intakes:* geotechnical data, hydrogeology, benthic topography, oceanographic conditions, presence of sensitive habitats,* presence of sensitive species, energy use for the entire facility; design constraints (engineering, constructability), and project life cycle cost. Project life cycle cost shall be determined by evaluating the total cost of planning, design, land acquisition, construction, operations, maintenance, mitigation, equipment replacement and disposal over the lifetime of the facility, in addition to the cost of decommissioning the facility. Subsurface intakes* shall not be determined to be economically infeasible solely because subsurface intakes* may be more expensive than surface intakes. Subsurface intakes* may be determined to be economically infeasible if the additional costs or lost profitability associated with subsurface intakes,* as compared to surface intakes, would render the desalination facility* not economically viable. In

* See Appendix I for definition of terms.

addition, the regional water board may evaluate other site- and facility-specific factors.

ii. If the regional water board determines that subsurface intakes* are not feasible* for the proposed intake design capacity, it shall determine whether subsurface intakes* are feasible* for a reasonable range of alternative intake design capacities. The regional water board may find that a combination of subsurface* and surface intakes is the best feasible* alternative to minimize intake and mortality of marine life and meet the identified need for desalinated water as described in chapter III.M.2.b.(2).

(b) Installation and maintenance of a subsurface intake* shall avoid, to the maximum extent feasible,* the disturbance of sensitive habitats* and sensitive species.

(c) If subsurface intakes* are not feasible,* the regional water board may approve a surface water intake, subject to the following conditions:

i. The regional water board shall require that surface water intakes be screened. Screens must be functional while the facility is withdrawing seawater.*

ii. In order to reduce entrainment, all surface water intakes must be screened with a 1.0 mm (0.04 in) or smaller slot size screen when the desalination facility* is withdrawing seawater.*

iii. An owner or operator may use an alternative method of preventing entrainment so long as the alternative method results in intake and mortality of eggs, larvae, and juvenile organisms that is less than or equivalent to a 1.0 mm (0.04 in) slot size screen. The owner or operator must demonstrate the effectiveness of the alternative method to the regional water board. The owner or operator must conduct a study to demonstrate the effectiveness of the alternative method, and use an Empirical Transport Model* (ETM)/ Area of Production Forgone* (APF) approach* to estimate entrainment. The study period shall be at least 12 consecutive months. Sampling for environmental studies shall be designed to account for variation in oceanographic or hydrologic conditions and larval abundance and diversity such that abundance estimates are reasonably accurate. Samples must be collected using a mesh size no larger than 335 microns and individuals collected shall be identified to the lowest taxonomical level practicable. The ETM/APF analysis* shall evaluate entrainment for a broad range of species, species morphologies, and sizes under the environmental and operational conditions that are representative of the entrained species and the conditions at

* See Appendix I for definition of terms.

the full-scale desalination facility.* At their discretion, the regional water boards may permit the use of existing entrainment data to meet this requirement.

iv. In order to minimize impingement, through-screen velocity at the surface water intake shall not exceed 0.15 meters per second (0.5 feet per second).

(2) Considerations for Brine* Discharge Technology:

(a) The preferred technology for minimizing intake and mortality of all forms of marine life* resulting from brine* discharge is to commingle brine* with wastewater (e.g., agricultural, municipal, industrial, power plant cooling water, etc.) that would otherwise be discharged to the ocean. The wastewater must provide adequate dilution to ensure salinity* of the commingled discharge meets the receiving water limitation for salinity* in chapter III.M.3. Nothing in this section shall preclude future recycling of the wastewater.

(b) Multiport diffusers* are the next best method for disposing of brine* when the brine* cannot be diluted by wastewater and when there are no live organisms in the discharge. Multiport diffusers* shall be engineered to maximize dilution, minimize the size of the brine mixing zone,* minimize the suspension of benthic sediments, and minimize mortality of all forms of marine life.*

(c) Brine* discharge technologies other than wastewater dilution and multiport diffusers,* may be used if an owner or operator can demonstrate to the regional water board that the technology provides a comparable level of intake and mortality of all forms of marine life* as wastewater dilution if wastewater is available, or multiport diffusers* if wastewater is unavailable. The owner or operator must evaluate all of the individual and cumulative effects of the proposed alternative discharge method on the intake and mortality of all forms of marine life,* including (where applicable); intake-related entrainment, osmotic stress, turbulence that occurs during water conveyance and mixing, and shearing stress at the point of discharge. When determining the intake and mortality associated with a brine* discharge technology or combination of technologies, the regional water board shall require the owner or operator to use empirical studies or modeling to:

i. Estimate intake entrainment impacts using an ETM/APF approach.*

ii. Estimate degradation of all forms of marine life* from elevated salinity* within the brine mixing zone,* including osmotic stresses, the size of impacted area, and the duration that all forms of marine life* are exposed to the

* See Appendix I for definition of terms.

toxic conditions. Considerations shall be given to the most sensitive species, and community structure and function.

iii. Estimate the intake and mortality of all forms of marine life* that occurs as a result of water conveyance, in-plant turbulence or mixing, and waste* discharge.

iv. Within 18 months of beginning operation, submit to the regional water board an empirical study that evaluates intake and mortality of all forms of marine life* associated with the alternative brine* discharge technology. The study must evaluate impacts caused by any augmented intake volume, intake and pump technology, water conveyance, waste brine* mixing, and effluent discharge. Unless demonstrated otherwise, organisms entrained by the alternative brine* discharge technology are assumed to have a mortality rate of 100 percent. The study period shall be at least 12 consecutive months. If the regional water board requires a study period longer than 12 months, the final report must be submitted to the regional water board within 6 months of the completion of the empirical study.

v. If the empirical study shows that the alternative brine* discharge technology results in more intake and mortality of all forms of marine life* than a facility using wastewater dilution or multiport diffusers,* then the facility must either: (1) cease using the alternative brine* discharge technology and install and use wastewater dilution or multiport diffusers* to discharge brine* waste, or (2) re-design the alternative brine* discharge technology system to minimize intake and mortality of all forms of marine life* to a level that is comparable with wastewater dilution if wastewater is available, or multiport diffusers* if wastewater is unavailable,* subject to regional water board approval.

(d) Flow augmentation* as an alternative brine* discharge technology is prohibited with the following exceptions:

i. At facilities that use subsurface intakes* to supply augmented flow water for dilution. Facilities that use subsurface intakes* to supply augmented flow water for dilution are exempt from the requirements of chapter III.M.2.d.(2)(c) if the facility meets the receiving water limitation for salinity* in chapter III.M.3.

ii. At a facility that has received a conditional Water Code section 13142.5(b) determination and is over 80 percent constructed by January 28, 2016. If the owner or operator of the facility proposes to use flow augmentation* as an

* See Appendix I for definition of terms.

alternative brine* discharge technology, the facility must: use low turbulence intakes (e.g., screw centrifugal pumps or axial flow pumps) and conveyance pipes; convey and mix dilution water in a manner that limits thermal stress, osmotic stress, turbulent shear stress, and other factors that could cause intake and mortality of all forms of marine life*; comply with chapter III.M.2.d.(1); and not discharge through multiport diffusers.*

e. Mitigation for the purposes of this section is the replacement of all forms of marine life* or habitat that is lost due to the construction and operation of a desalination facility* after minimizing intake and mortality of all forms of marine life* through best available site, design, and technology. The regional water board shall ensure an owner or operator fully mitigates for the operational lifetime of the facility and uses the best available mitigation measures feasible* to minimize intake and mortality of all forms of marine life.* The owner or operator may choose whether to satisfy a facility's mitigation measures pursuant to chapter III.M.2.e.(3) or, if available, M.2.e.(4), or a combination of the two.

(1) *Marine Life Mortality Report.* The owner or operator of a facility shall submit a report to the regional water board estimating the marine life mortality resulting from construction and operation of the facility after implementation of the facility's required site, design, and technology measures.

(a) For operational mortality related to intakes, the report shall include a detailed entrainment study. The entrainment study period shall be at least 12 consecutive months and sampling shall be designed to account for variation in oceanographic or hydrologic conditions and larval abundance and diversity such that abundance estimates are reasonably accurate. At their discretion, the regional water boards may permit the use of existing entrainment data from the facility to meet this requirement. Samples must be collected using a mesh size no larger than 335 microns and individuals collected shall be identified to the lowest taxonomical level practicable. The ETM/APF analysis* shall be representative of the entrained species collected using the 335 micron net. The APF* shall be calculated using a one-sided, upper 95 percent confidence bound for the 95th percentile of the APF distribution. An owner or operator with subsurface intakes* is not required to do an ETM/APF analysis* for their intakes and is not required to mitigate for intake-related operational mortality. The regional water board may apply a one percent reduction to the APF* acreage calculated in the Marine Life Mortality Report to account for the reduction in entrainment of all forms of marine life* when using a 1.0 mm slot size screen.

* See Appendix I for definition of terms.

(b) For operational mortality related to discharges, the report shall estimate the area in which salinity* exceeds 2.0 parts per thousand above natural background salinity* or a facility-specific alternative receiving water limitation (see chapter III.M.3). The area in excess of the receiving water limitation for salinity* shall be determined by modeling and confirmed with monitoring. The report shall use any acceptable approach approved by the regional water board for evaluating mortality that occurs due to shearing stress resulting from the facility's discharge, including any incremental increase in mortality resulting from a commingled discharge.

(c) For construction-related mortality, the report shall use any acceptable approach approved by the regional water board for evaluating the mortality that occurs within the area disturbed by the facility's construction. The regional water board may determine that the construction-related disturbance does not require mitigation because the disturbance is temporary and the habitat is naturally restored.

(d) Upon approval of the report by the regional water board in consultation with State Water Board staff, the calculated marine life mortality shall form the basis for the mitigation provided pursuant to this section.

(2) The owner or operator shall mitigate for the mortality of all forms of marine life* determined in the report above by choosing to either complete a mitigation project as described in chapter III.M.2.e.(3) or, if an appropriate fee-based mitigation program is available, provide funding for the program as described in chapter III.M.2.e.(4). The mitigation project or the use of a fee-based mitigation program and the amount of the fee that the owner or operator must pay is subject to regional water board approval.

(3) *Mitigation Option 1: Complete a Mitigation Project.* The mitigation project must satisfy the following provisions:

(a) The owner or operator shall submit a Mitigation Plan. Mitigation Plans shall include: project objectives, site selection, site protection instrument (the legal arrangement or instrument that will be used to ensure the long-term protection of the compensatory mitigation project site), baseline site conditions, a mitigation work plan, a maintenance plan, a long-term management plan, an adaptive management plan, performance standards and success criteria, monitoring requirements, and financial assurances.

(b) The mitigation project must meet the following requirements:

i. Mitigation shall be accomplished through expansion, restoration or creation of one or more of the following:

* See Appendix I for definition of terms.

kelp beds,* estuaries,* coastal wetlands, natural reefs, MPAs, or other projects approved by the regional water board that will mitigate for intake and mortality of all forms of marine life* associated with the facility.

ii. The owner or operator shall demonstrate that the project fully mitigates for intake-related marine life mortality by including expansion, restoration, or creation of habitat based on the APF* acreage calculated in the Marine Life Mortality Report above. The owner or operator using surface water intakes shall do modeling to evaluate the areal extent of the mitigation project's production area to confirm that it overlaps the facility's source water body.* Impacts on the mitigation project due to entrainment by the facility must be offset by adding compensatory acreage to the mitigation project.

iii. The owner or operator shall demonstrate that the project also fully mitigates for the discharge-related marine life mortality projected in the Marine Life Mortality Report above.

iv. The owner or operator shall demonstrate that the project also fully mitigates for the construction-related marine life mortality identified in the Marine Life Mortality Report above.

v. The regional water board may permit out-of-kind mitigation* for mitigation of open water or soft-bottom species. In-kind mitigation* shall be done for all other species whenever feasible.*

vi. For out-of-kind mitigation,* an owner or operator shall evaluate the biological productivity of the impacted open water or soft-bottom habitat calculated in the Marine Life Mortality Report and the proposed mitigation habitat. If the mitigation habitat is a more biologically productive habitat (e.g. wetlands, estuaries,* rocky reefs, kelp beds,* eelgrass beds,* surfgrass beds*), the regional water boards may apply a mitigation ratio based on the relative biological productivity of the impacted open water or soft-bottom habitat and the mitigation habitat. The mitigation ratio shall not be less than one acre of mitigation habitat for every ten acres of impacted open water or soft-bottom habitat.

vii. For in-kind mitigation,* the mitigation ratio shall not be less than one acre of mitigation habitat for every one acre of impacted habitat.

---
* See Appendix I for definition of terms.

viii. For both in-kind* and out-of-kind mitigation,* the regional water boards may increase the required mitigation ratio for any species and impacted natural habitat calculated in the Marine Life Mortality Report when appropriate to account for imprecisions associated with mitigation including, but not limited to, the likelihood of success, temporal delays in productivity, and the difficulty of restoring or establishing the desired productivity functions.

ix. The rationale for the mitigation ratios must be documented in the administrative record for the permit action.

(c) The Mitigation Plan is subject to approval by the regional water board in consultation with State Water Board staff and with other agencies having authority to condition approval of the project and require mitigation.

(4) *Mitigation Option 2: Fee-based Mitigation Program*. If the regional water board determines that an appropriate fee-based mitigation program has been established by a public agency, and that payment of a fee to the mitigation program will result in the creation and ongoing implementation of a mitigation project that meets the requirements of chapter M.2.e.(3), the owner or operator may pay a fee to the mitigation program in lieu of completing a mitigation project.

(a) The agency that manages the fee-based mitigation program must have legal and budgetary authority to accept and spend mitigation funds, a history of successful mitigation projects documented by having set and met performance standards for past projects, and stable financial backing in order to manage mitigation sites for the operational life of the facility.

(b) The amount of the fee shall be based on the cost of the mitigation project, or if the project is designed to mitigate cumulative impacts from multiple desalination facilities or other development projects, the amount of the fee shall be based on the desalination facility's* fair share of the cost of the mitigation project.

(c) The manager of the fee-based mitigation program must consult with the California Department of Fish and Wildlife, Ocean Protection Council, Coastal Commission, State Lands Commission, and State and regional water boards to develop mitigation projects that will best compensate for intake and mortality of all forms of marine life* caused by the desalination facility.* Mitigation projects that increase or enhance the viability and sustainability of all forms of marine life* in Marine Protected Areas are preferred, if feasible.*

* See Appendix I for definition of terms.

(5) California Department of Fish and Wildlife, the regional water board, and State Water Board may perform audits or site inspections of any mitigation project.

(6) An owner or operator, or a manager of a fee-based mitigation program, must submit a mitigation project performance report to the regional water board 180 days prior to the expiration date of their NPDES permit.

(7) For conditionally permitted facilities or expanded facilities, the regional water boards may:

(a) Account for previously-approved mitigation projects associated with a facility when making a new Water Code section 13142.5(b) determination.

(b) Require additional mitigation when making a new Water Code section 13142.5(b) determination for any additional mortality of all forms of marine life resulting from the occurrence of the conditional event or the expansion of the facility. The additional mitigation must be to compensate for any additional construction, discharge, or other increases in intake or impacts or an increase in intake and mortality of all forms of marine life.*

3. Receiving Water Limitation for Salinity*

a. Chapter III.M.3 is applicable to all desalination facilities discharging brine* into ocean waters,* including facilities that commingle brine* and wastewater.

b. The receiving water limitation for salinity* shall be established as described below:

(1) Discharges shall not exceed a daily maximum of 2.0 parts per thousand (ppt) above natural background salinity* measured no further than 100 meters (328 ft) horizontally from each discharge point. There is no vertical limit to this zone.

(2) In determining an effluent limit necessary to meet this receiving water limitation, permit writers shall use the formula in chapter III.C.4 that has been modified for brine* discharges as follows:

Equation 1: $Ce = Co + Dm(2.0 \text{ ppt})$
$Ce = (2.0 \text{ ppt} + Cs) + Dm(2.0 \text{ ppt})$

Where:

Ce= the effluent concentration limit, ppt
Co= the salinity* concentration to be met at the completion of initial* dilution= 2.0 ppt + Cs
Cs= the natural background salinity,* ppt
Dm= minimum probable initial dilution* expressed as parts

* See Appendix I for definition of terms.

seawater* per part brine* discharge

(a) The fixed distance referenced in the initial dilution* definition shall be no more than 100 meters (328 feet).

(b) In addition, the owner or operator shall develop a dilution factor (Dm) based on the distance of 100 meters (328 feet) or initial dilution,* whichever is smaller. The dilution factor (Dm) shall be developed within the brine mixing zone* using applicable water quality models that have been approved by the regional water boards in consultation with State Water Board staff.

(c) The value 2.0 ppt in Equation 1 is the maximum incremental increase above natural background salinity* (Cs) allowed at the edge of the brine mixing zone.* A regional water board may substitute an alternative numeric value for 2.0 ppt in Equation 1 based upon the results of a facility-specific alternative salinity* receiving water limitation study, as described in chapter III.M.3.c below.

c. An owner or operator may submit a proposal to the regional water board for approval of an alternative (other than 2 ppt) salinity* receiving water limitation to be met no further than 100 meters horizontally from the discharge. There is no vertical limit to this zone.

(1) To determine whether a proposed facility-specific alternative receiving water limitation is adequately protective of beneficial uses, an owner or operator shall:

(a) Establish baseline biological conditions at the discharge location and at reference locations over a 12-month period prior to commencing brine* discharge. The biologic surveys must characterize the ecologic composition of habitat and marine life using measures established by the regional water board. At their discretion, the regional water boards may permit the use of existing data to meet this requirement.

(b) Conduct at least the following chronic toxicity* Whole Effluent Toxicity (WET) tests: germination and growth for giant kelp (*Macrocystis pyrifera)*; development for red abalone (*Haliotis refescens)*; development and fertilization for purple urchin (*Strongleocentrotus purpuratus)*; development and fertilization for sand dollar (*Dendraster excentricus)*; larval growth rate for topsmelt (*Atherniops affinis)*. WET tests shall be performed by an Environmental Laboratory Accreditation Program (ELAP) certified laboratory.

* See Appendix I for definition of terms.

(c) The regional water board in consultation with State Water Board staff may require an owner or operator to do additional toxicity studies if needed.

(2) The regional water board in consultation with the State Water Board staff may require an owner or operator to provide additional studies or information in order to approve a facility-specific alternative receiving water limitation for salinity.*

(3) The facility-specific alternative receiving water limitation shall be based on the lowest observed effect concentration (LOEC)* for the most sensitive species and toxicity endpoint as determined in the chronic toxicity* studies. The regional water board in consultation with State Water Board staff has discretion to approve the proposed facility-specific alternative receiving water limitation for salinity.*

(4) The regional water board shall review a facility's monitoring data, the studies as required in chapter III.M.4 below, or any other information that the regional water board deems to be relevant to periodically assess whether the facility-specific alternative receiving water limitation for salinity* is adequately protective of beneficial uses. The regional water board may eliminate or revise a facility-specific alternative receiving water limitation for salinity* based on its assessment of the data.

d. The owner or operator of a facility that has received a conditional Water Code section 13142.5(b) determination and is over 80 percent constructed by January 28, 2016 that proposes flow augmentation* using a surface water intake may submit a proposal to the regional water board in consultation with the State Water Board staff for approval of an alternative brine mixing zone* not to exceed 200 meters laterally from the discharge point and throughout the water column. The owner or operator of such a facility must demonstrate, in accordance with chapter III.M.2.d.(2)(c), that the combination of the alternative brine mixing zone* and flow augmentation* using a surface water intake provide a comparable level of intake and mortality of all forms of marine life* as the combination of the standard brine mixing zone* and wastewater dilution if wastewater is available, or multiport diffusers* if wastewater is unavailable. In addition to the analysis of the effects required by chapter III.M.2.d.(2)(c), the owner or operator must also evaluate the individual and cumulative effects of the alternative brine mixing zone* on the intake and mortality of all forms of marine life.* In no case may the discharge result in hypoxic conditions outside of the alternative brine mixing zone.* If an alternative brine mixing zone* is approved, the alternative distance and the areal extent of the alternative brine mixing zone* shall be used in lieu of the standard brine mixing zone* for all purposes, including establishing an effluent limitation and a receiving water limitation for salinity, in chapter III.M.

e. Existing facilities that do not meet the receiving water limitation at the edge of the brine mixing zone* and throughout the water column by January 28, 2016 must either: 1) establish a facility-specific alternative receiving water limitation

* See Appendix I for definition of terms.

for salinity* as described in chapter III.M.3.c; or, 2) upgrade the facility's brine* discharge method in order to meet the receiving watr limitation in chapter III.M.3.b in accordance with the State Water Board's Compliance Schedule Policy, as set forth in chapter III.M.3.f below. An owner or operator that chooses to upgrade the facility's method of brine* discharge:

(1) Must demonstrate to the regional water board that the brine* discharge does not negatively impact sensitive habitats,* sensitive species, MPAs, or SWQPAs.*

(2) Is subject to the Considerations for Brine* Discharge Technology described in chapter III.M.2.d.(2).

f. The regional water board may grant compliance schedules for the requirements for brine* waste discharges for desalination facilities.* All compliance schedules shall be in accordance with the State Water Board's Compliance Schedule Policy, except that the salinity* receiving water limitation set forth in chapters III.M.3.b and III.M.3.c shall be considered to be a "new water quality objective" as used in the Compliance Schedule Policy.

g. The regional water board in consultation with the State Water Board staff may require an owner or operator to provide additional studies or information if needed. All studies and models are subject to the approval of the regional water board in consultation with State Water Board staff. The regional water board may require an owner or operator to hire a neutral third party entity to review studies and models and make recommendations to the regional water board.

4. Monitoring and Reporting Programs

a. The owner or operator of a desalination facility* must submit a Monitoring and Reporting Plan to the regional water board for approval. The Monitoring and Reporting Plan shall include monitoring of effluent and receiving water characteristics and impacts to all forms of marine life.* The Monitoring and Reporting Plan shall, at a minimum, include monitoring for benthic community health, aquatic life toxicity, hypoxia, and receiving water characteristics consistent with Appendix III of this Plan and for compliance with the receiving water limitation in chapter III.M.3. Receiving water monitoring for salinity* shall be conducted at times when the monitoring locations are most likely affected by the discharge. For new or expanded facilities the following additional requirements apply:

(1) An owner or operator must perform facility-specific monitoring to demonstrate compliance with the receiving water limitation for salinity,* and evaluate the potential effects of the discharge within the water column, bottom sediments, and the benthic communities. Facility-specific monitoring is required until the regional water board determines that a regional monitoring program is adequate to ensure compliance with the receiving water limitation. The monitoring and

* See Appendix I for definition of terms.

reporting plan shall be reviewed, and revised if necessary, upon NPDES permit renewal.

(2) Baseline biological conditions shall be established at the discharge location and at a reference location prior to commencement of construction. The owner or operator is required to conduct biological surveys (e.g., Before-After Control-Impact study), that will evaluate the differences between biological communities at a reference site and at the discharge location before and after the discharge commences. The regional water board will use the data and results from the surveys and any other applicable data for evaluating and renewing the requirements set forth in a facility's NPDES permit.

* See Appendix I for definition of terms.

APPENDIX I
DEFINITION OF TERMS

ACUTE TOXICITY

a. Acute Toxicity (TUa)

Expressed in Toxic Units Acute (TUa)

$$TUa = \frac{100}{96\text{-hr LC } 50\%}$$

b. Lethal Concentration 50% (LC 50)

LC 50 (percent waste giving 50% survival of test organisms) shall be determined by static or continuous flow bioassay techniques using standard marine test species as specified in Appendix III. If specific identifiable substances in wastewater can be demonstrated by the discharger as being rapidly rendered harmless upon discharge to the marine environment, but not as a result of dilution, the LC 50 may be determined after the test samples are adjusted to remove the influence of those substances.

When it is not possible to measure the 96-hour LC 50 due to greater than 50 percent survival of the test species in 100 percent waste, the toxicity concentration shall be calculated by the expression:

$$TUa = \frac{\log (100 - S)}{1.7}$$

where:

S = percentage survival in 100% waste. If S > 99, TUa shall be reported as zero.

ALL FORMS OF MARINE LIFE includes all life stages of all marine species.

AREA PRODUCTION FOREGONE (APF), also known as habitat production foregone, is an estimate of the area that is required to produce (replace) the same amount of larvae or propagules* that are removed via entrainment at a desalination facilities* intakes. APF is calculated by multiplying the proportional mortality* by the source water body,* which are both determined using an empirical transport model.*

AREAS OF SPECIAL BIOLOGICAL SIGNIFICANCE (ASBS) are those areas designated by the State Water Board as ocean areas requiring protection of species or biological communities to the extent that maintenance of natural water quality is assured. All Areas of Special Biological Significance are also classified as a subset of STATE WATER QUALITY PROTECTION AREAS.* ASBS are also referred to as State Water Quality Protection Areas* – Areas of Special Biological Significance (SWQPA-ASBS).

BRINE is the byproduct of desalinated* water having a salinity* concentration greater than a desalination facility's* intake source water.

* See Appendix I for definition of terms.

BRINE MIXING ZONE is the area where salinity* may exceed 2.0 parts per thousand above natural background salinity,* or the concentration of salinity* approved as part of an alternative receiving water limitation. The standard brine mixing zone shall not exceed 100 meters (328 feet) laterally from the points of discharge and throughout the water column. An alternative brine mixing zone, if approved as described in chapter III.M.3.d, shall not exceed 200 meters (656 feet) laterally from the points of discharge and throughout the water column. The brine mixing zone is an allocated impact zone where there may be toxic effects on marine life due to elevated salinity.

CHLORDANE shall mean the sum of chlordane-alpha, chlordane-gamma, chlordene-alpha, chlordene-gamma, nonachlor-alpha, nonachlor-gamma, and oxychlordane.

CHRONIC TOXICITY: This parameter shall be used to measure the acceptability of waters for supporting a healthy marine biota until improved methods are developed to evaluate biological response.

a. Chronic Toxicity (TUc)

Expressed as Toxic Units Chronic (TUc)

$$TUc = \frac{100}{NOEL}$$

b. No Observed Effect Level (NOEL)

The NOEL is expressed as the maximum percent effluent or receiving water* that causes no observable effect on a test organism, as determined by the result of a critical life stage toxicity test listed in Appendix III, Table III-1.

DDT shall mean the sum of 4,4'DDT, 2,4'DDT, 4,4'DDE, 2,4'DDE, 4,4'DDD, and 2,4'DDD.

DEGRADE: Degradation shall be determined by comparison of the waste field and reference site(s) for characteristic species diversity, population density, contamination, growth anomalies, debility, or supplanting of normal species by undesirable plant and animal species. Degradation occurs if there are significant* differences in any of three major biotic groups, namely, demersal fish, benthic invertebrates, or attached algae. Other groups may be evaluated where benthic species are not affected, or are not the only ones affected.

DESALINATION FACILITY is an industrial facility that processes water to remove salts and other components from the source water to produce water that is less saline than the source water.

DICHLOROBENZENES shall mean the sum of 1,2- and 1,3-dichlorobenzene.

DOWNSTREAM OCEAN WATERS shall mean waters downstream with respect to ocean currents.

DREDGED MATERIAL: Any material* excavated or dredged from the navigable waters of the United States, including material* otherwise referred to as "spoil".

EELGRASS BEDS are aggregations of the aquatic plant species of the genus *Zostera*.

* See Appendix I for definition of terms.

EMPIRICAL TRANSPORT MODEL (ETM) is a methodology for determining the spatial area known as the source water body* that contains the source water population, which are the organisms that are at risk of entrainment as determined by factors that may include but are not limited to biological, hydrodynamic, and oceanographic data. ETM can also be used to estimate proportional mortality,* P_m.

ENCLOSED BAYS are indentations along the coast which enclose an area of oceanic water within distinct headlands or harbor works. Enclosed bays include all bays where the narrowest distance between headlands or outermost harbor works is less than 75 percent of the greatest dimension of the enclosed portion of the bay. This definition includes but is not limited to: Humboldt Bay, Bodega Harbor, Tomales Bay, Drakes Estero, San Francisco Bay, Morro Bay, Los Angeles Harbor, Upper and Lower Newport Bay, Mission Bay, and San Diego Bay.

ENDOSULFAN shall mean the sum of endosulfan-alpha and -beta and endosulfan sulfate.

ESTUARIES AND COASTAL LAGOONS are waters at the mouths of streams that serve as mixing zones for fresh and ocean* waters during a major portion of the year. Mouths of streams that are temporarily separated from the ocean by sandbars shall be considered as estuaries. Estuarine waters will generally be considered to extend from a bay or the open ocean to the upstream limit of tidal action but may be considered to extend seaward if significant* mixing of fresh and salt water occurs in the open coastal waters. The waters described by this definition include but are not limited to the Sacramento-San Joaquin Delta as defined by section 12220 of the California Water Code, Suisun Bay, Carquinez Strait downstream to Carquinez Bridge, and appropriate areas of the Smith, Klamath, Mad, Eel, Noyo, and Russian Rivers.

ETM/APF APPROACH or ANALYSIS. For guidance on how to perform an ETM/APF analysis please see Appendix E of the Staff Report for Amendment to the Water Quality Control Plan For Ocean Waters of California Addressing Desalination Facility Intakes, Brine Discharges, And The Incorporation Of Other Non-substantive Changes.

FEASIBLE for the purposes of chapter III.M, shall mean capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, social, and technological factors.

FLOW AUGMENTATION is a type of in-plant dilution and occurs when a desalination facility* withdraws additional source water for the specific purpose of diluting brine* prior to discharge.

FULL CAPTURE SYSTEM is a treatment control*, or series of treatment controls*, including but not limited to, a multi-benefit project* or a low-impact development control* that traps all particles that are 5 mm or greater, and has a design treatment capacity that is either: a) of not less than the peak flow rate, Q, resulting from a one-year, one-hour, storm in the subdrainage area, or b) appropriately sized to, and designed to carry at least the same flows as, the corresponding storm drain.

[Rational equation is used to compute the peak flow rate: $Q = C \bullet I \bullet A$, where Q = design flow rate (cubic feet per second, cfs); C = runoff coefficient (dimensionless); I = design rainfall

* See Appendix I for definition of terms.

intensity (inches per hour, as determined per the rainfall isohyetal map specific to each region, and A = subdrainage area (acres).]

Prior to installation, full capture systems* must be certified by the Executive Director, or designee, of the State Water Board. Uncertified full capture systems* will not satisfy the requirements of these Trash Provisions*. To request certification, a permittee shall submit a certification request letter that includes all relevant supporting documentation to the State Water Board's Executive Director. The Executive Director, or designee, shall issue a written determination approving or denying the certification of the proposed full capture system* or conditions of approval, including a schedule to review and reconsider the certification. Full capture systems* certified by the Los Angeles Regional Water Board prior to the effective date of these Trash Provisions* and full capture systems* listed in Appendix I of the Bay Area-wide Trash Capture Demonstration Project, Final Project Report (May 8, 2014) will satisfy the requirements of these Trash Provisions*, unless the Executive Director, or designee, of the State Water Board determines otherwise.

FULL CAPTURE SYSTEM EQUIVALENCY is the Trash* load that would be reduced if full capture systems* were installed, operated, and maintained for all storm drains that capture runoff from the relevant areas of land (priority land uses*, significant trash generating areas*, facilities or sites regulated by NPDES permits for discharges of storm water* associated with industrial activity, or specific land uses or areas that generate substantial amounts of Trash*, as applicable). The full capture system equivalency* is a Trash* load reduction target that the permittee quantifies by using an approach, and technically acceptable and defensible assumptions and methods for applying the approach, subject to the approval of permitting authority*. Examples of such approaches include, but are not limited to, the following:

(1) Trash Capture Rate Approach. Directly measure or otherwise determine the amount of Trash* captured by full capture systems* for representative samples of all similar types of land uses, facilities, or areas within the relevant areas of land over time to identify specific trash capture rates. Apply each specific Trash* capture rate across all similar types of land uses, facilities, or areas to determine full capture system equivalency*. Trash* capture rates may be determined either through a pilot study or literature review. Full capture systems* selected to evaluate Trash* capture rates may cover entire types of land uses, facilities, or areas, or a representative subset of types of land uses, facilities, or areas. With this approach, full capture system equivalency* is the sum of the products of each type of land use, facility, or area multiplied by Trash* capture rates for that type of land use, facility, or area.

(2) Reference Approach. Determine the amount of Trash* in a reference receiving water in a reference watershed where full capture systems* have been installed for all storm drains that capture runoff from all relevant areas of land. The reference watershed must be comprised of similar types and extent of sources of trash* and land uses (including priority land uses* and all other land uses), facilities, or areas as the permittee's watershed. With this approach, full capture system equivalency* would be demonstrated when the amount of Trash* in the receiving water is equivalent to the amount of Trash* in the reference receiving water.

* See Appendix I for definition of terms.

<u>GRAYWATER</u> is drainage from galley, dishwasher, shower, laundry, bath, and lavatory wash basin sinks, and water fountains, but does not include drainage from toilets, urinals, hospitals, or cargo spaces.

<u>HALOMETHANES</u> shall mean the sum of bromoform, bromomethane (methyl bromide) and chloromethane (methyl chloride).

<u>HCH</u> shall mean the sum of the alpha, beta, gamma (lindane) and delta isomers of hexachlorocyclohexane.

<u>INDICATOR BACTERIA</u> includes total coliform bacteria, fecal coliform bacteria (or *E. coli*), and/or Enterococcus bacteria.

<u>IN-KIND MITIGATION</u> is when the habitat or species lost is the same as what is replaced through mitigation.

<u>INSTITUTIONAL CONTROLS</u> are non-structural best management practices (i.e., no structures are involved) that may include, but not be limited to, street sweeping, sidewalk Trash* bins, collection of the Trash*, anti-litter educational and outreach programs, producer take-back for packaging, and ordinances.

<u>INITIAL DILUTION</u> is the process which results in the rapid and irreversible turbulent mixing of wastewater with ocean water around the point of discharge.

For a submerged buoyant discharge, characteristic of most municipal and industrial wastes that are released from the submarine outfalls, the momentum of the discharge and its initial buoyancy act together to produce turbulent mixing. Initial dilution in this case is completed when the diluting wastewater ceases to rise in the water column and first begins to spread horizontally.

For shallow water submerged discharges, surface discharges, and nonbuoyant discharges, characteristic of cooling water wastes and some individual discharges, turbulent mixing results primarily from the momentum of discharge. Initial dilution, in these cases, is considered to be completed when the momentum induced velocity of the discharge ceases to produce significant* mixing of the waste, or the diluting plume reaches a fixed distance from the discharge to be specified by the Regional Board, whichever results in the lower estimate for initial dilution.

<u>KELP BEDS</u>, are aggregations of marine algae of the order Laminariales, including species in the genera *Macrocystis, Nereocystis, and Pelagophycus*. Kelp beds include the total foliage canopy throughout the water column.

<u>LARGE PASSENGER VESSELS</u> are vessels of 300 gross registered tons or greater engaged in carrying passengers for hire. The following vessels are not large passenger vessels:
(1) Vessels without berths or overnight accommodations for passengers;
(2) Noncommercial vessels, warships, vessels operated by nonprofit entities as determined by the Internal Revenue Service, and vessels operated by the state, the United States, or a foreign government;
(3) Oceangoing vessels,* as defined below (e.g. those used to transport cargo).

* See Appendix I for definition of terms.

<u>LOW-IMPACT DEVELOPMENT CONTROLS</u> are treatment controls* that employ natural and constructed features that reduce the rate of storm water* runoff, filter out pollutants, facilitate storm water* storage onsite, infiltrate storm water* into the ground to replenish groundwater supplies, or improve the quality of receiving groundwater and surface water. (See Water Code § 10564.)

<u>LOEC</u> is the lowest observed effect concentration or the lowest concentration of effluent that causes observable adverse effects in exposed test organisms.

<u>MARICULTURE</u> is the culture of algae, plants, and animals in marine waters independent of any pollution source.

<u>MARINE MANAGED AREAS</u> are named, discrete geographic marine or estuarine areas along the California coast designated by law or administrative action, and intended to protect, conserve, or otherwise manage a variety of resources and their uses. According to the California Public Resources Code (§§ 36600 et seq.) there are six classifications of marine managed areas, including State Marine Reserves, State Marine Parks and State Marine Conservation Areas, State Marine Cultural Preservation Areas, State Marine Recreational Management Areas, and State Water Quality Protection Areas.*

<u>MARKET SQUID NURSURIES</u> are comprised of numerous egg capsules, each containing approximately 200 developing embryos, attached in clusters or mops to sandy substrate with moderate water flow. Market squid (*Doryteuthis opalescens*) nurseries occur at a wide range of depths; however, mop densities are greatest in shallow, nearshore waters between ten and 100 meters (328 feet) deep.

<u>MATERIAL</u>: (a) In common usage: (1) the substance or substances of which a thing is made or composed (2) substantial; (b) For purposes of this Ocean Plan relating to waste disposal, dredging and the disposal of dredged material* and fill, MATERIAL means matter of any kind or description which is subject to regulation as waste, or any material dredged from the navigable waters of the United States. See also, DREDGED MATERIAL.* For the purposes of chapter III.M.2.d, materials relates to the common usage in (a).

<u>METHOD DETECTION LIMIT</u> (MDL) is the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero, as defined in 40 CFR PART 136 Appendix B.

<u>MINIMUM LEVEL (ML)</u> is the concentrations at which the entire analytical system must give a recognizable signal and acceptable calibration point. The ML is the concentration in a sample that is equivalent to the concentration of the lowest calibration standard analyzed by a specific analytical procedure, assuming that all the method-specified sample weights, volumes and processing steps have been followed.

<u>MULTI-BENEFIT PROJECT</u> is a treatment control* project designed to achieve any of the benefits set forth in section 10562, subdivision (d) of the Water Code. Examples include projects designed to: infiltrate, recharge or store storm water* for beneficial reuse; develop or enhance habitat and open space through storm water* and non-storm water management; and/or reduce storm water* and non-storm water runoff volume.

* See Appendix I for definition of terms.

MULTIPORT DIFFUSERS are linear structures consisting of spaced ports or nozzles that are installed on submerged marine outfalls. For the purposes of chapter III.M, multiport diffusers discharge brine* waste into an ambient receiving water body and enable rapid mixing, dispersal, and dilution of brine* within a relatively small area.

MUNICIPAL SEPARATE STORM SEWER SYSTEM (MS4) has the same meaning set forth in 40 Code of Federal Regulations section 122.26(b)(8).

NATURAL BACKGROUND SALINITY is the salinity* at a location that results from naturally occurring processes and is without apparent human influence. For purposes of determining natural background salinity, the regional water board may approve the use of:

(1) the mean monthly natural background salinity. Mean monthly natural background salinity shall be determined by averaging 20 years of historical salinity* data in the proximity of the proposed discharge location and at the depth of the proposed discharge, when feasible.* For historical data not recorded in parts per thousand, the regional water boards may accept converted data at their discretion. When historical data are not available, natural background salinity shall be determined by measuring salinity* at depth of proposed discharge for three years, on a weekly basis prior to a desalination facility* discharging brine,* and the mean monthly natural salinity* shall be used to determine natural background salinity; or

(2) the actual salinity at a reference location, or reference locations, that is representative of natural background salinity at the discharge location. The reference locations shall be without apparent human influence, including wastewater outfalls and brine discharges.

Either method to establish natural background salinity may be used for the purpose of determining compliance with the receiving water limitation or an effluent limitation for salinity. If a reference location(s) is used for compliance monitoring, the permit should specify that historical data shall be used if reference location data becomes unavailable. An owner or operator shall submit to the regional water board all necessary information to establish natural background salinity.

NATURAL LIGHT: Reduction of natural light may be determined by the Regional Board by measurement of light transmissivity or total irradiance, or both, according to the monitoring needs of the Regional Board.

NO DISCHARGE ZONE (NDZ) is an area in which both treated and untreated sewage discharges from vessels are prohibited. Within NDZ boundaries, vessel operators are required to retain their sewage discharges onboard for disposal at sea (beyond three miles from shore) or onshore at a pump-out facility.

NON-STORM WATER DISCHARGE is any runoff that is not the result of a precipitation event. This is often referred to as “dry weather flow.”

OCEAN WATERS are the territorial marine waters of the State as defined by California law to the extent these waters are outside of enclosed bays,* estuaries, and coastal lagoons.* If a discharge outside the territorial waters of the State could affect the quality of the waters of the State, the discharge may be regulated to assure no violation of the Ocean Plan will occur in ocean waters.

* See Appendix I for definition of terms.

OCEANGOING VESSELS (i.e., oceangoing ships) means commercial vessels of 300 gross registered tons or more calling on California ports or places, excluding active military vessels.

OILY BILGE WATER includes bilge water that contains used lubrication oils, oil sludge and slops, fuel and oil sludge, used oil, used fuel and fuel filters, and oily waste.

OUT-OF-KIND MITIGATION is when the habitat or species lost is different than what is replaced through mitigation.

PAHs (polynuclear aromatic hydrocarbons) shall mean the sum of acenaphthylene, anthracene, 1,2-benzanthracene, 3,4-benzofluoranthene, benzo[k]fluoranthene, 1,12-benzoperylene, benzo[a]pyrene, chrysene, dibenzo[ah]anthracene, fluorene, indeno[1,2,3-cd]pyrene, phenanthrene and pyrene.

PCBs (polychlorinated biphenyls) shall mean the sum of chlorinated biphenyls whose analytical characteristics resemble those of Aroclor-1016, Aroclor-1221, Aroclor-1232, Aroclor-1242, Aroclor-1248, Aroclor-1254 and Aroclor-1260.

PERMITTING AUTHORITY means the State Water Board or Regional Water Board, whichever issues the permit.

PREPRODUCTION PLASTIC has the same meaning set forth in section 13367(a) of the Water Code.

PRIORITY LAND USES are those developed sites, facilities, or land uses (i.e., not simply zoned land uses) within the MS4* permittee's jurisdiction from which discharges of Trash* are regulated by this Ocean Plan as follows:

(1) **High-density residential:** all land uses with at least ten (10) developed dwelling units/acre.
(2) **Industrial**: land uses where the primary activities on the developed parcels involve product manufacture, storage, or distribution (e.g., manufacturing businesses, warehouses, equipment storage lots, junkyards, wholesale businesses, distribution centers, or building material sales yards).
(3) **Commercial**: land uses where the primary activities on the developed parcels involve the sale or transfer of goods or services to consumers (e.g., business or professional buildings, shops, restaurants, theaters, vehicle repair shops, etc.)
(4) **Mixed urban**: land uses where high-density residential, industrial, and/or commercial land uses predominate collectively (i.e., are intermixed).
(5) **Public transportation stations**: facilities or sites where public transit agencies' vehicles load or unload passengers or goods (e.g., bus stations and stops).

Equivalent alternate land uses: An MS4* permittee with regulatory authority over priority land uses* may issue a request to the applicable permitting authority* that the MS4* permittee be allowed to substitute one or more land uses identified above with alternates land use within the MS4* permittee's jurisdiction that generates rates of Trash* that are equivalent to or greater than the priority land use(s)* being substituted. The land use area

* See Appendix I for definition of terms.

requested to substitute for a priority land use* need not be an acre-for-acre substitution but may involve one or more priority land uses*, or a fraction of a priority land use*, or both, provided the total trash* generated in the equivalent alternative land use is equivalent to or greater than the total Trash* generated from the priority land use(s)* for which substitution is requested. Comparative Trash* generation rates shall be established through the reporting of quantification measures such as street sweeping and catch basin cleanup records; mapping; visual trash presence surveys, such as the "Keep America Beautiful Visible Litter Survey"; or other information as required by the permitting authority*.

PROPAGULES are structures that are capable of propagating an organism to the next stage in its life cycle via dispersal. Dispersal is the movement of individuals from their birth site to their reproductive grounds.

PROPORTIONAL MORTALITY, P_m, is percentage of larval organisms or propagules* in the source water body* that is expected to be entrained at a desalination facility's* intake. It is assumed that all entrained larvae or propagules* die as a result of entrainment.

RECEIVING WATER, for permitted storm water discharges and nonpoint sources, should be measured at the point of discharge(s), in the surf zone immediately where runoff from an outfall meets the ocean water (a.k.a., at point zero).

SALINITY is a measure of the dissolved salts in a volume of water. For the purposes of this Plan, salinity shall be measured using a standard method approved by the regional water board (e.g. Standard Method 2520 B, EPA Method 120.1, EPA Method 160.1) and reported in parts per thousand (ppt). For historical salinity data not recorded in parts per thousand, the regional water boards may accept converted data at their discretion.

SEAWATER is salt water that is in or from the ocean. For the purposes chapter III.M, seawater includes tidally influenced waters in coastal estuaries and coastal lagoons* and underground salt water beneath the seafloor, beach, or other contiguous land with hydrologic connectivity to the ocean.

SENSITIVE HABITATS, for the purposes of this Plan, are kelp beds,* rocky substrate, surfgrass beds,* eelgrass beds,* oyster beds, spawning grounds for state or federally managed species, market squid nurseries,* or other habitats in need of special protection as determined by the Water Boards.

SHELLFISH are organisms identified by the California Department of Public Health as shellfish for public health purposes (i.e., mussels, clams and oysters).

SIGNIFICANT difference is defined as a statistically significant difference in the means of two distributions of sampling results at the 95 percent confidence level.

SIGNIFICANT TRASH GENERATING AREAS means all locations or facilities within the Department's jurisdiction where Trash* accumulates in substantial amounts, such as:

(1) Highway on- and off-ramps in high density residential, commercial, and industrial land uses (as such land uses are defined under priority land uses* herein).
(2) Rest areas and park-and-rides.

* See Appendix I for definition of terms.

(3) State highways in commercial and industrial land uses (as such land uses are defined under priority land uses* herein).
(4) Mainline highway segments to be identified by the Department through pilot studies and/or surveys.

SOURCE WATER BODY is the spatial area that contains the organisms that are at risk of entrainment at a desalination facility* as determined by factors that may include, but are not limited to, biological, hydrodynamic, and oceanographic data.

STATE WATER QUALITY PROTECTION AREAS (SWQPAs) are nonterrestrial marine or estuarine areas designated to protect marine species or biological communities from an undesirable alteration in natural water quality. All Areas of Special Biological Significance (ASBS)* that were previously designated by the State Water Board in Resolutions 74-28, 74-32, and 75-61 are now also classified as a subset of State Water Quality Protection Areas and require special protections afforded by this Plan.

STATE WATER QUALITY PROTECTION AREAS – GENERAL PROTECTION (SWQPA-GP) designated by the State Water Board to protect marine species and biological communities from an undesirable alteration in natural water quality within State Marine Parks and State Marine Conservation Areas.

STORM WATER has the same meaning set forth in 40 Code of Federal Regulations section 122.26(b)(13) (Nov. 16, 1990).

SUBSURFACE INTAKE, for the purposes of chapter III.M, is an intake withdrawing seawater* from the area beneath the ocean floor or beneath the surface of the earth inland from the ocean.

SURFGRASS BEDS are aggregations of marine flowering plants of the genus *Phyllospadix*.

TCDD EQUIVALENTS shall mean the sum of the concentrations of chlorinated dibenzodioxins (2,3,7,8-CDDs) and chlorinated dibenzofurans (2,3,7,8-CDFs) multiplied by their respective toxicity factors, as shown in the table below.

* See Appendix I for definition of terms.

Isomer Group	Toxicity Equivalence Factor
2,3,7,8-tetra CDD	1.0
2,3,7,8-penta CDD	0.5
2,3,7,8-hexa CDDs	0.1
2,3,7,8-hepta CDD	0.01
octa CDD	0.001
2,3,7,8 tetra CDF	0.1
1,2,3,7,8 penta CDF	0.05
2,3,4,7,8 penta CDF	0.5
2,3,7,8 hexa CDFs	0.1
2,3,7,8 hepta CDFs	0.01
octa CDF	0.001

<u>TRASH</u> means all improperly discarded solid material from any production, manufacturing, or processing operation including, but not limited to, products, product packaging, or containers constructed of plastic, steel, aluminum, glass, paper, or other synthetic or natural materials.

<u>TRASH PROVISIONS</u> are the water quality objective for Trash*, as well as the prohibition of discharge set forth in Chapter III.I and implementation requirements set forth in Chapter III.L herein.

<u>TREATMENT CONTROLS</u> are structural best management practices to either (a) remove pollutants and/or solids from storm water* runoff, wastewater, or effluent, or (b) capture, infiltrate or reuse storm water* runoff, wastewater, or effluent. Treatment controls include full capture systems* and low-impact development controls*.

<u>WASTE</u>: As used in this Plan, waste includes a discharger's total discharge, of whatever origin, <u>i.e</u>., gross, not net, discharge.

<u>WATER RECLAMATION</u>: The treatment of wastewater to render it suitable for reuse, the transportation of treated wastewater to the place of use, and the actual use of treated wastewater for a direct beneficial use or controlled use that would not otherwise occur.

* See Appendix I for definition of terms.

APPENDIX II
MINIMUM* LEVELS

The Minimum* Levels identified in this appendix represent the lowest concentration of a pollutant that can be quantitatively measured in a sample given the current state of performance in analytical chemistry methods in California. These Minimum* Levels were derived from data provided by state-certified analytical laboratories in 1997 and 1998 for pollutants regulated by the California Ocean Plan and shall be used until new values are adopted by the State Water Board. There are four major chemical groupings: volatile chemicals, semi-volatile chemicals, inorganics, pesticides & PCBs.* "No Data" is indicated by "--".

TABLE II-1
MINIMUM* LEVELS – VOLATILE CHEMICALS

		Minimum* Level (μg/L)	
Volatile Chemicals	**CAS Number**	**GC Method [a]**	**GCMS Method [b]**
Acrolein	107028	2.	5
Acrylonitrile	107131	2.	2
Benzene	71432	0.5	2
Bromoform	75252	0.5	2
Carbon Tetrachloride	56235	0.5	2
Chlorobenzene	108907	0.5	2

APPENDIX III
STANDARD MONITORING PROCEDURES

1. INTRODUCTION

The purpose of this appendix is to provide guidance to the Regional Water Boards on implementing the Ocean Plan and to ensure the reporting of useful information. Monitoring should be question driven rather than just gathering data and should be focused on assuring compliance with narrative and numeric water quality standards, the status and attainment of beneficial uses, and identifying sources of pollution.

It is not feasible to prescribe requirements in the Ocean Plan that encompass all circumstances and conditions that could be encountered by all dischargers, nor is it desirable to limit the flexibility of the Regional Water Boards in the monitoring of ocean* waters. This appendix should therefore be considered the basic framework for the design of an ocean discharger monitoring program. The Regional Water Boards are responsible for issuing monitoring and reporting programs (MRPs) that will implement this monitoring guidance. Regional Water Boards can deviate from the procedures required in the appendix only with the approval of the State Water Resources Control Board.

This monitoring guidance utilizes a model monitoring framework. The model monitoring framework has three components that comprise a range of spatial and temporal scales: (1) core monitoring, (2) regional monitoring, and (3) special studies.

1) Core monitoring consists of the basic site-specific monitoring necessary to measure compliance with individual effluent limits and/or impacts to receiving water* quality. Core monitoring is typically conducted in the immediate vicinity of the discharge by examining local scale spatial effects.

2) Regional monitoring provides information necessary to make assessments over large areas and serves to evaluate cumulative effects of all anthropogenic inputs. Regional monitoring data also assists in the interpretation of core monitoring studies. It is recommended that the Regional Water Boards require participation by the discharger in an approved regional monitoring program, if available, for the receiving water.* In the event that a regional monitoring effort takes place during a permit cycle in which the MRP does not specifically address regional monitoring, a Regional Water Board may allow relief from aspects of core monitoring components in order to encourage participation.

3) Special studies are directed monitoring efforts designed in response to specific management or research questions identified through either core or regional monitoring programs. Often they are used to help understand core or regional monitoring results, where a specific environmental process is not well understood, or to address unique issues of local importance. Regional Water Boards may require special studies as appropriate. Special studies are not addressed further in this guidance because they are beyond its scope.

The Ocean Plan does not address all site-specific monitoring issues and allows the Regional Water Boards to select alternative protocols with the approval of the State Water Board. If no direction is given in this appendix for a specific provision of the Ocean Plan, it is within the

* See Appendix I for definition of terms.

discretion of the Regional Water Boards to establish the monitoring requirements for that provision.

2. QUALITY ASSURANCE

All receiving* and ambient water monitoring conducted in compliance with MRPs must be comparable with the Quality Assurance requirements of the Surface Water Ambient Monitoring Program (SWAMP).

SWAMP comparable means all sample collection and analyses shall meet or exceed the measurement quality objectives (MQOs) – including all sample types, frequencies, control limits and holding time requirements – as specified in the SWAMP Quality Assurance Project Plan (QAPrP)

The SWAMP QAPrP is located at: http://www.waterboards.ca.gov/water_issues/programs/swamp/tools.shtml#qa.

For those measurements that do not have SWAMP MQOs available, then MQOs shall be at the discretion of the Regional Water Board. Refer to the USEPA guidance document (EPA QA/G-4) for selecting data quality objectives, located at http://www.epa.gov/quality/qs-docs/g4-final.pdf.

Water Quality data must be reported according to the California Environmental Data Exchange Network (CEDEN) "Data Template" format for all constituents that are monitored in receiving and ambient water. CEDEN Data Template are available at: http://ceden.org.

3. TYPE OF WASTE DISCHARGE SOURCES

Discharges to ocean waters* are highly diverse and variable, exhibiting a wide range of constituents, effluent quality and quantity, location and frequency of discharge. Different types of discharges will require different approaches. This Appendix provides specific direction for three broad types of discharges: (1) Point Sources, (2) Storm Water Point Sources and (3) Non-point Sources.

3.1. Point Sources

Industrial, municipal, marine laboratory and other traditional point sources of pollution that discharge wastewater directly to surface waters and are required to obtain NPDES permits.

3.2. Storm Water Point Sources

Storm Water Point Sources, hereafter referred to as Storm Water Sources, are those NPDES permitted discharges regulated by Construction or Industrial Storm Water General Permits or municipal separate storm sewer system (MS4s) Permits. MS4 Permits are further divided into Phase I and II Permits. A Phase I MS4 Permit is issued by a Regional Water Board for medium (serving between 100,000 and 250,000 people) and large (serving 250,000 or more people) municipalities. A Phase II MS4 General Permit is issued by the State Water Resources Control Board for the discharge of storm water for smaller municipalities, and includes nontraditional Small MS4s, which are governmental facilities such as military bases, public campuses, prison and hospital complexes.

* See Appendix I for definition of terms.

3.3. Non-point Sources

A Non-point Source is any source of pollutants that is not a Point Source described in section 3.1 or a Storm Water Source as described in section 3.2. Land use categories contributing to non-point sources include but are not limited to:

a. Agriculture
b. Grazing
c. Forestry/timber harvest
d. Urban not covered under an NPDES permit
e. Marinas and mooring fields
f. Golf Courses not covered under an NPDES Permit

Only agricultural and golf course related non-point source discharge monitoring is addressed in this Appendix, but Regional Water Boards may issue MRPs for other non-point sources at their discretion. Agriculture includes irrigated lands. Irrigated lands are where water is applied for the purpose of producing crops, including, but not limited to, row and field crop, orchards, vineyard, rice production, nurseries, irrigated pastures, and managed wetlands.

4. INDICATOR BACTERIA*

4.1. Point Sources

Primary questions to be addressed:

1. Does the effluent comply with the water quality standards in the receiving water*?
2. Does the sewage effluent reach water contact zones or commercial shellfish* beds?

To answer these questions, core monitoring shall be conducted in receiving water* on the shoreline for the indicator bacteria* at a minimum weekly for any point sources discharging treated sewage effluent:

a. within one nautical mile of shore, or
b. within one nautical mile of a commercial shellfish* bed, or
c. if the discharge is in excess of 10 million gallons per day (MGD).

Alternatively, these requirements may be met through participation in a regional monitoring program to assess the status of marine contact recreation water quality. If the permittee participates in a regional monitoring program, in conjunction with local health organization(s), core monitoring may be suspended for that period at the discretion of the Regional Water Board. Regional monitoring should be used to answer the above questions, and may be used to answer additional questions. These additional questions may include, but are not limited to, questions regarding the extent and magnitude of current or potential receiving water* indicator bacteria* problems, or the sources of indicator bacteria.*

4.2. Storm Water

Primary questions to be addressed:

1. Does the receiving water* comply with water quality standards?

* See Appendix I for definition of terms.

2. Is the condition of the receiving water* protective of contact recreation and shellfish* harvesting beneficial uses?
3. Are the indicator bacteria* levels in receiving water* getting better or worse?
4. What is the relative contribution of indicator bacteria* to the receiving water* from storm water runoff?

To answer these questions, core monitoring for indicator bacteria* shall be required periodically for storm water discharges representative of the area of concern. At a minimum, for municipal storm water discharges, all receiving water* at outfalls greater than 36 inches in diameter or width must be monitored (ankle depth, point zero) at the following frequencies:

a. During wet weather with a minimum of three storms per year, and
b. When non-storm water discharges* occur (flowing during dry weather), and if located at an AB 411 beach, at least weekly. (An AB 411 Beach is defined as a beach visited by more than 50,000 people annually and located on an area adjacent to a storm drain that flows in the summer. (Health & Saf. Code § 115880.)).

Regional Water Boards may waive monitoring once structural best management practices have been installed, evaluated and determined to have successfully controlled indicator bacteria.*

Alternatively, these requirements may be met through participation in a regional monitoring program to assess the status of marine contact recreation water quality. If the permittee participates in a regional monitoring program, in conjunction with local health organization(s), core monitoring may be suspended for that period at the discretion of the Regional Water Board. Regional monitoring should be used to answer the above questions, and may be used to answer additional questions. These additional questions may include, but are not limited to, questions regarding the extent and magnitude of current or potential receiving water* indicator bacteria* problems, or the sources of indicator bacteria.*

4.3. Non-point Sources

Primary questions to be addressed:

1. Does the receiving water* comply with water quality standards?
2. Do agricultural and golf course non-point source discharges reach water contact or shellfish* harvesting zones?
3. Are the indicator bacteria* levels in receiving water* getting better or worse?
4. What is the relative contribution of indicator bacteria* to the receiving water* from agricultural and golf course non-point sources?

To answer these questions, core monitoring of representative agricultural irrigation tail water and storm water runoff, at a minimum, will be conducted in receiving water* (ankle depth, point zero) for indicator bacteria*:

a. During wet weather, at a minimum of two storm events per year, and
b. When non-storm water discharges* occur (flowing during dry weather), and if located at an AB 411 beach or within one nautical mile of shellfish* bed, at least weekly.

Alternatively, these requirements may be met through participation in a regional monitoring program to assess the status of marine contact recreation water quality. If the discharger

* See Appendix I for definition of terms.

participates in a regional monitoring program, in conjunction with local health organization(s), core monitoring may be suspended for that period at the discretion of the Regional Water Board. Regional monitoring should be used to answer the above questions, and may be used to answer additional questions. These additional questions may include, but are not limited to, questions regarding the extent and magnitude of current or potential receiving water* indicator bacteria* problems, or the sources of indicator bacteria.*

5. CHEMICAL CONSTITUENTS

5.1. Point Sources

Primary questions addressed:

1. Does the effluent meet permit effluent limits thereby ensuring that water quality standards are achieved in the receiving water*?
2. What is the mass of the constituents that are discharged annually?
3. Is the effluent concentration or mass changing over time?

Consistent with Appendix VI, the core monitoring for the substances in Table 1 and Table 2 shall be required periodically. For discharges less than 10 MGD, the monitoring frequency shall be at least one complete scan of the Table 1 substances annually. Discharges greater than 10 MGD shall be required to monitor at least semiannually.

5.2. Storm Water

Primary questions addressed:

1. Does the receiving water* meet the water quality standards?
2. Are the conditions in receiving water* getting better or worse?
3. What is the relative runoff contribution to pollution in the receiving water*?

For Phase I and Phase II MS4 dischargers, core receiving water* monitoring will be required at a minimum for 10 percent of all outfalls greater than 36 inches in diameter or width once per year. If a discharger has less than five outfalls exceeding 36 inches in diameter or width, they shall conduct monitoring at a minimum of only once per outfall during a five year period. Monitoring shall be for total suspended solids, oil & grease, total organic carbon, pH, temperature, biochemical oxygen demand, turbidity, Table 1 metals, PAHs,* and pesticides determined by the Regional Water Boards. Regional Water Boards may waive monitoring once structural best management practices have been installed, evaluated and determined to have successfully controlled pollutants.

For industrial storm water discharges, runoff monitoring must be conducted at all outfalls at least two storm events per year. In addition, at least one representative receiving water* sample must be collected per industrial storm water permittee during two storm events per year. Monitoring shall be conducted for total suspended solids, oil & grease, total organic carbon, pH, temperature, biochemical oxygen demand, turbidity, and Table 1 metals and PAHs.*

The requirements for individual core monitoring for Table 1 metals, PAHs* and pesticides may be waived at the discretion of the Regional Water Board, if the permittee participates in a regional program for monitoring runoff and/or receiving water* to answer the above questions as

* See Appendix I for definition of terms.

well as additional questions. Additional questions may include, but are not limited to, questions regarding the extent and magnitude of current or potential receiving water* problems from storm water runoff, or sources of any runoff pollutants.

5.3. Non-point Sources

The primary questions are:

1. Does the agricultural or golf course runoff meet water quality standards in the receiving water*?
2. Are nutrients present that would contribute to objectionable aquatic algal blooms or degrade* indigenous biota?
3. Are the conditions in receiving water* getting better or worse?
4. What is the relative agricultural runoff or golf course contribution to pollution in the receiving water*?

To answer these questions, a statistically representative sample (determined by the Regional Water Board) of receiving water* at the sites of agricultural irrigation tail water and storm water runoff, and golf course runoff in each watershed will be monitored for Ocean Plan Table 1 metals, ammonia as N, nitrate as N, phosphate as P, and pesticides determined by the Regional Board:

a. During wet weather, at a minimum of two storm events per year, and
b. During dry weather, when flowing, at a frequency determined by the Regional Boards.

This requirement may be satisfied by core monitoring individually, or through participation in a regional program for monitoring runoff and receiving water* at the discretion of the Regional Water Board to answer the above questions as well as additional questions. Additional questions may include, but are not limited to, questions regarding the sources of agricultural pollutants.

6. SEDIMENT MONITORING

All Sources:

1. Is the dissolved sulfide concentration of waters in sediments significantly* increased above that present under natural conditions?
2. Is the concentration of substances set forth in Table 1, for protection of marine aquatic life, in marine sediments at levels which would degrade* the benthic community?
3. Is the concentration of organic pollutants in marine sediments at levels that would degrade* the benthic community?

6.1. Point Sources

For discharges greater than 10 MGD, acid volatile sulfides, OP Pesticides, Table 1 metals, ammonia N, PAHs,* and chlorinated hydrocarbons will be measured in sediments annually in a core monitoring program approved by the Regional Water Board. Sediment sample locations will be determined by the Regional Water Board. If sufficient data exists from previous water column monitoring for these parameters, the Regional Water Board at its discretion may reduce the frequency of monitoring, or may allow this requirement to be satisfied through participation in a regional monitoring program.

* See Appendix I for definition of terms.

6.2. Storm Water

For Phase I MS4 permittees, discharges greater than 72 inches in diameter or width discharging to low energy coastal environments with the likelihood of sediment deposition, acid volatile sulfides, OP Pesticides, Ocean Plan Table 1 metals, ammonia N, PAHs,* and chlorinated hydrocarbons will be measured in sediments once per permit cycle.

Regional Water Boards may waive monitoring once structural best management practices have been installed, evaluated and determined to have successfully controlled pollutants.

This requirement may be satisfied by core monitoring individually or through participation in a regional monitoring program at the discretion of the Regional Water Board. Sediment sample locations will be determined by the Regional Water Board.

7. AQUATIC LIFE TOXICITY

Toxicity tests are another method used to assess risk to aquatic life. These tests assess the overall toxicity of the effluent, including the toxicity of unmeasured constituents and/or synergistic effects of multiple constituents.

7.1. Point Sources

1. Does the effluent meet permit effluent limits for toxicity thereby ensuring that water quality standards are achieved in the receiving water*?
2. If not:
   a. Are unmeasured pollutants causing risk to aquatic life?
   b. Are pollutants in combinations causing risk to aquatic life?

Core monitoring for Table 1 effluent toxicity shall be required periodically. For discharges less than 0.1 MGD the monitoring frequency for acute and/or chronic toxicity* shall be twice per permit cycle. For discharges between 0.1 and 10 MGD, the monitoring frequency for acute and/or chronic toxicity* of the effluent should be at least annually. For discharges greater than 10 MGD, the monitoring frequency for acute and/or chronic toxicity* of the effluent should be at least semiannually.

For discharges greater than 10 MGD in a low energy coastal environment with the likelihood of sediment deposition, Core monitoring for acute sediment toxicity is required and will utilize alternative amphipod species (*Eohaustorius estuarius, Leptocheirus plumulosus, Rhepoxynius abronius*).

If an exceedance is detected, six additional toxicity tests are required within a 12-week period. If an additional exceedance is detected within the 12-week period, a toxicity reduction evaluation (TRE) is required, consistent with chapter III.C.10 that requires a TRE if a discharge consistently exceeds an effluent limitation based on a toxicity objective in Table 1.

7.2. Storm Water

1. Does the runoff meet objectives for toxicity in the receiving water*?
2. Are the conditions in receiving water* getting better or worse with regard to toxicity

* See Appendix I for definition of terms.

3. What is the relative runoff contribution to the receiving water* toxicity?
4. What are the causes of the toxicity* and the sources of the constituents responsible?

For Phase I MS4, Phase II MS4, and industrial storm water discharges, core toxicity monitoring will be required at a minimum for 10 percent of all outfalls greater than 36 inches in diameter or width at a minimum of once per year. Receiving water* monitoring shall be for Table 1 critical life stage chronic toxicity* for a minimum of one invertebrate species.

For storm water discharges greater than 72 inches in diameter or width in a low energy coastal environment with the likelihood of sediment deposition, core sediment monitoring for acute sediment toxicity is required and will utilize alternative amphipod species (*Eohaustorius estuarius, Leptocheirus plumulosus, Rhepoxynius abronius*).

Regional Water Boards may waive monitoring once structural best management practices have been installed, evaluated and determined to have successfully controlled toxicity.

If an exceedence is detected, an additional toxicity test is required during the subsequent storm event. If an additional exceedance is detected at that time, a TRE is required, consistent with chapter III.C.10 that requires a TRE if a discharge consistently exceeds an effluent limitation based on a toxicity objective in Table 1. A sufficient volume must be collected to conduct a TIE, if necessary, as a part of a TRE.

The requirement for core toxicity monitoring may be waived at the discretion of the Regional Water Board, if the permittee participates in a regional monitoring program to answer the above questions, as well as any other additional questions that may be developed by the regional monitoring program.

7.3. Non-point Sources

1. Does the agricultural and golf course runoff meet water quality standards for toxicity in the receiving water*?
2. Are the conditions in receiving water* getting better or worse with regard to toxicity?
3. What is the relative agricultural and golf course runoff contribution to receiving water* toxicity?
4. What are the causes of the toxicity, and the sources of the constituents responsible?

To answer these questions, a statistically representative sample (determined by the Regional Water Board) of receiving water* at the sites of agricultural irrigation tail water and storm water runoff, and golf course runoff, in each watershed will be monitored:

a. During wet weather, at a minimum of two storm events per year, and
b. During dry weather, when flowing, at a frequency determined by the Regional Boards.

Core receiving water* monitoring shall include Table 1 critical life stage chronic toxicity* for a minimum of one invertebrate species.

For runoff in a low energy coastal environment with the likelihood of sediment deposition, core sediment monitoring shall include acute sediment toxicity utilizing alternative amphipod species (*Eohaustorius estuarius, Leptocheirus plumulosus, Rhepoxynius abronius*) at a minimum once per year.

---
* See Appendix I for definition of terms.

If an exceedence is detected, an additional toxicity test is required during the subsequent storm event. If an additional exceedance is detected, a TRE is required, consistent with chapter III.C.10 that requires a TRE if a discharge consistently exceeds an effluent limitation based on a toxicity objective in Table 1. A sufficient volume must be collected to conduct a TIE, if necessary, as a part of a TRE.

The requirement for core monitoring may be waived at the discretion of the Regional Water Board, if the permittee participates in a regional monitoring program to answer the above questions, as well as any other additional questions that may be developed by the regional monitoring program.

8. BENTHIC COMMUNITY HEALTH

8.1. Point Sources

1. Are benthic communities degraded* as a result of the discharge?

To answer this question, benthic community monitoring shall be conducted
   a. for all discharges greater than 10 MGD, or
   b. those discharges greater than 0.1 MGD and one nautical mile or less from shore, or
   c. discharges greater than 0.1 MGD and one nautical mile or less from a State Water Quality Protection Area* or a State Marine Reserve.

The minimum frequency shall be once per permit cycle, except for discharges greater than 100 MGD the minimum frequency shall be at least twice per permit cycle.

This requirement may be satisfied by core monitoring individually or through participation in a regional monitoring program at the discretion of the Regional Board.

9. BIOACCUMULATION

9.1. Point Sources

1. Does the concentration of pollutants in fish, shellfish,* or other marine resources used for human consumption bioaccumulate to levels that are harmful to human health?
2. Does the concentration of pollutants in marine life bioaccumulate to levels that degrade* marine communities?

To answer these questions, bioaccumulation monitoring shall be conducted, at a minimum, once per permit cycle for:

   a. discharges greater than 10 MGD, or
   b. those discharges greater than 0.1 MGD and one nautical mile or less from shore, or
   c. discharges greater than 0.1 MGD and one nautical mile or less from a State Water Quality Protection Area* or a State Marine Reserve, Park or Conservation Area.

Constituents to be monitored must include pesticides (at the discretion of the Regional Board), Table 1 metals, and PAHs.* Bioaccumulation may be monitored by a mussel watch program or a fish tissue program. Resident mussels are preferred over transplanted mussels. Sand crabs

---
* See Appendix I for definition of terms.

and/or fish may be added or substituted for mussels at the discretion of the Regional Water Board.

This requirement may be satisfied individually as core monitoring or through participation in a regional monitoring program at the discretion of the Regional Water Board.

9.2. Storm Water

1. Does the concentration of pollutants in fish, shellfish,* or other marine resources used for human consumption bioaccumulate to levels that are harmful to human health?
2. Does the concentration of pollutants in marine life bioaccumulate to levels that degrade* marine communities?

For Phase I MS4 dischargers, bioaccumulation monitoring shall be conducted, at a minimum, once per permit cycle. Constituents to be monitored must include OP Pesticides, Ocean Plan Table 1 metals, Table 1 PAHs,* Table 1 chlorinated hydrocarbons, and pyrethroids. Bioaccumulation may be monitored by a mussel watch program or a fish tissue program. Sand crabs, fish, and/or Solid Phase Microextraction may be added or substituted for mussels at the discretion of the Regional Water Board.

This requirement may be satisfied individually as core monitoring or through participation in a regional monitoring program at the discretion of the Regional Water Board.

10. RECEIVING WATER* CHARACTERISTICS

All Sources:

1. Is natural light* significantly* reduced at any point outside the zone of initial dilution* as the result of the discharge of waste*?
2. Does the discharge of waste* cause a discoloration of the ocean surface?
3. Does the discharge of oxygen demanding waste* cause the dissolved oxygen concentration to be depressed at any time more than 10 percent from that which occurs naturally, as the result of the discharge of oxygen demanding* waste* materials*?
4. Does the discharge of waste* cause the pH to change at any time more than 0.2 units from that which occurs naturally?
5. Does the discharge of waste* cause the salinity* to become elevated in the receiving water*?
6. Do nutrients cause objectionable aquatic growth or degrade* indigenous biota?

10.1. Point Sources

For discharges greater than 10 MGD, turbidity (alternatively light transmissivity or surface water transparency), color [Chlorophyll-A and/or color dissolved organic matter (CDOM)], dissolved oxygen and pH shall be measured in the receiving water* seasonally, at a minimum, in a core monitoring program approved by the Regional Water Board. If sufficient data exists from previous water column monitoring for these parameters, the Regional Water Board, at its discretion, may reduce the frequency of water column monitoring, or may allow this requirement to be satisfied through participation in a regional monitoring program. Use of regional ocean observing programs, such as the Southern California Coastal Ocean Observing System

* See Appendix I for definition of terms.

(SCCOOS) and the Central and Northern California Ocean Observing System (CeNCCOOS) is encouraged.

Salinity* must also be monitored by all point sources discharging brine* as part of their core monitoring program. Seawater desalination facilities* discharging brine* into ocean waters* and wastewater facilities that receive brine from seawater desalination facilities and discharge into ocean waters shall monitor salinity as described in chapter III.M.4.

10.2. Storm Water

At a minimum, 10 percent of Phase I MS4 discharges greater than 36 inches, receiving water* turbidity, color, dissolved oxygen, pH, nitrate, phosphate, and ammonia shall be measured annually in a core monitoring program approved by the Regional Water Board.

Regional Water Boards may waive monitoring once structural best management practices have been installed, evaluated and determined to have successfully controlled pollutants. The Regional Water Board, at its discretion, may also allow this requirement to be satisfied through participation in a regional monitoring program.

10.3. Non-point Sources

Representative agricultural and golf course discharges shall be measured, at a minimum twice annually (during two storm season and irrigation season) for receiving water* turbidity, color, dissolved oxygen, pH, nitrate, phosphate, ammonia in a core monitoring program approved by the Regional Water Board. The Regional Water Board, at its discretion, may allow this requirement to be satisfied through participation in a regional monitoring program.

<u>11. ANALYTICAL REQUIREMENTS</u>

Procedures, calibration techniques, and instrument/reagent specifications shall conform to the requirements of 40 CFR PART 136. Compliance monitoring shall be determined using an US EPA approved protocol as provided in 40 CFR PART 136. All methods shall be specified in the monitoring requirement section of waste* discharge requirements.

Where methods are not available in 40 CFR PART 136, the Regional Water Boards shall specify suitable analytical methods in waste* discharge requirements. Acceptance of data should be predicated on demonstrated laboratory performance.

Laboratories analyzing monitoring data shall be certified by the California Department of Public Health, in accordance with the provisions of Water Code section 13176, and must include quality assurance quality control data with their reports.

Sample dilutions for total and fecal coliform bacterial analyses shall range from 2 to 16,000. Sample dilutions for enterococcus bacterial analyses shall range from 1 to 10,000 per 100 mL. Each test method number or name (e.g., EPA 600/4-85/076, Test Methods for *Escherichia coli* and *Enterococci* in Water by Membrane Filter Procedure) used for each analysis shall be specified and reported with the results.

---
* See Appendix I for definition of terms.

Test methods used for coliforms (total and fecal) shall be those presented in Table 1A of 40 CFR PART 136, unless alternate methods have been approved in advance by U.S. EPA pursuant to 40 CFR PART 136.

Test methods used for enterococcus shall be those presented in U.S. EPA publication EPA 600/4-85/076, Test Methods for *Escherichia coli* and *Enterococci* in Water by Membrane Filter Procedure or any improved method determined by the Regional Board to be appropriate. The Regional Water Board may allow analysis for *Escherichia coli* (*E. coli)* by approved test methods to be substituted for fecal coliforms if sufficient information exists to support comparability with approved methods and substitute the existing methods.

The State or Regional Water Board may, subject to U.S. EPA approval, specify test methods which are more sensitive than those specified in 40 CFR PART 136. Because storm water and non-point sources are not assigned a dilution factor, sufficient sampling and analysis shall be required to determine compliance with Table 1 Water Quality Objectives. Total chlorine residual is likely to be a method detection limit effluent limitation in many cases. The limit of detection of total chlorine residual in standard test methods is less than or equal to 20 µg/L.

Toxicity monitoring requirements in permits prepared by the Regional Water Boards shall use marine test species instead of freshwater species when measuring compliance. The Regional Water Board shall require the use of critical life stage toxicity tests specified in this Appendix to measure TUc. For Point Sources, a minimum of three test species with approved test protocols shall be used to measure compliance with the toxicity objective. If possible, the test species shall include a fish, an invertebrate, and an aquatic plant. After a screening period, monitoring can be reduced to the most sensitive species.

Dilution and control water should be obtained from an unaffected area of the receiving waters.* The sensitivity of the test organisms to a reference toxicant shall be determined concurrently with each bioassay test and reported with the test results.

Use of critical life stage bioassay testing shall be included in waste* discharge requirements as a monitoring requirement for all Point Source discharges greater than 100 MGD

Procedures and methods used to determine compliance with benthic monitoring should use the following federal guidelines when applicable: Macroinvertebrate Field and Laboratory Methods for Evaluating the Biological Integrity of Surface Waters (1990) -- EPA/600/4-90/030 (PB91-171363). This manual describes guidelines and standardized procedures for the use of macroinvertebrates in evaluating the biological integrity of surface waters.

Procedures used to determine compliance with bioaccumulation monitoring should use the U.S. EPA. Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories (November 2000, EPA 823-B-00-007), NOAA Technical Memorandum NOS ORCA 130, Sampling and Analytical Methods of the National Status and Trends Program Mussel Watch Project (1998 update), and/or State Mussel Watch Program, 1987-1993 Data Report, State Water Resources Control Board 94-1WQ.

* See Appendix I for definition of terms.

TABLE III-1
APPROVED TESTS – CHRONIC TOXICITY* (TUc)

Species	Effect	Tier	Reference
giant kelp, *Macrocystis pyrifera*	percent germination; germ tube length	1	1,3
red abalone, *Haliotis rufescens*	Abnormal shell development	1	1,3
oyster, *Crassostrea gigas*; mussels, *Mytilus spp.*	Abnormal shell development; percent survival	1	1,3
urchin, *Strongylocentrotus purpuratus*; sand dollar, *Dendraster excentricus*	Percent normal development	1	1,3
urchin, *Strongylocentrotus purpuratus*; sand dollar, *Dendraster excentricus*	Percent fertilization	1	1,3
shrimp, *Holmesimysis costata*	Percent survival; growth	1	1,3
shrimp, *Mysidopsis bahia*	Percent survival; growth; fecundity	2	2,4
topsmelt, *Atherinops affinis*	Larval growth rate; percent survival	1	1,3
Silversides, *Menidia beryllina*	Larval growth rate; percent survival	2	2,4

Table III-1 Notes

The first tier test methods are the preferred toxicity tests for compliance monitoring. A Regional Water Board can approve the use of a second tier test method for waste* discharges if first tier organisms are not available.

* See Appendix I for definition of terms.

APPENDIX IV
PROCEDURES FOR THE NOMINATION AND DESIGNATION OF STATE WATER QUALITY PROTECTION AREAS.*

1. Any person may nominate areas of ocean* waters for designation as SWQPA-ASBS or SWQPA-GP by the State Water Board. Nominations shall be made to the appropriate Regional Water Board and shall include:

   (a) Information such as maps, reports, data, statements, and photographs to show that:

      (1) Candidate areas are located in ocean* waters as defined in the "Ocean Plan".

      (2) Candidate areas are intrinsically valuable or have recognized value to man for scientific study, commercial use, recreational use, or esthetic reasons.

      (3) Candidate areas need protection beyond that offered by waste* discharge restrictions or other administrative and statutory mechanisms.

   (b) Data and information to indicate whether the proposed designation may have a significant* effect on the environment.

      (1) If the data or information indicate that the proposed designation will have a significant* effect on the environment, the nominee must submit sufficient information and data to identify feasible changes in the designation that will mitigate or avoid the significant* environmental effects.

2. The State Water Board or a Regional Water Board may also nominate areas for designation as SWQPA-ASBS or SWQPA-GP on their own motion.

3. A Regional Water Board may decide to (a) consider individual SWQPA-ASBS or SWQPA-GP nominations upon receipt, (b) consider several nominations in a consolidated proceeding, or (c) consider nominations in the triennial review of its water quality control plan (basin plan). A nomination that meets the requirements of 1. above may be considered at any time but not later than the next scheduled triennial review of the appropriate basin plan or Ocean Plan.

4. After determining that a nomination meets the requirements of paragraph 1. above, the Executive Officer of the affected Regional Water Board shall prepare a Draft Nomination Report containing the following:

   (a) The area or areas nominated for designation as SWQPA-ASBS or SWQPA-GP.

   (b) A description of each area including a map delineating the boundaries of each proposed area.

   (c) A recommendation for action on the nomination(s) and the rationale for the recommendation. If the Draft Nomination Report recommends approval of the proposed designation, the Draft Nomination Report shall comply with the CEQA documentation requirements for a water quality control plan amendment in section 3777, title 23, California Code of Regulations.

---
* See Appendix I for definition of terms.

5. The Executive Officer shall, at a minimum, seek informal comment on the Draft Nomination Report from the State Water Board, Department of Fish and Game, other interested state and federal agencies, conservation groups, affected waste dischargers, and other interested parties. Upon incorporation of responses from the consulted agencies, the Draft Nomination Report shall become the Final Nomination Report.

6. (a) If the Final Nomination Report recommends approval of the proposed designation, the Executive Officer shall ensure that processing of the nomination complies with the CEQA consultation requirements in section 3778, Title 23, California Code of Regulations and proceed to step 7 below.

   (b) If the Final Nomination Report recommends against approval of the proposed designation, the Executive Officer shall notify interested parties of the decision. No further action need be taken. The nominating party may seek reconsideration of the decision by the Regional Water Board itself.

7. The Regional Water Board shall conduct a public hearing to receive testimony on the proposed designation. Notice of the hearing shall be published three times in a newspaper of general circulation in the vicinity of the proposed area or areas and shall be distributed to all known interested parties 45 days in advance of the hearing. The notice shall describe the location, boundaries, and extent of the area or areas under consideration, as well as proposed restrictions on waste* discharges within the area.

8. The Regional Water Board shall respond to comments as required in section 3779, Title 23, California Code of Regulations, and 40 C.F.R. Part 25 (July 1, 1999).

9. The Regional Water Board shall consider the nomination after completing the required public review processes required by CEQA.

   (a) If the Regional Water Board supports the recommendation for designation, the board shall forward to the State Water Board its recommendation for approving designation of the proposed area or areas and the supporting rationale. The Regional Water Board submittal shall include a copy of the staff report, hearing transcript, comments, and responses to comments.

   (b) If the Regional Water Board does not support the recommendation for designation, the Executive Officer shall notify interested parties of the decision, and no further action need be taken.

10. After considering the Regional Water Board recommendation and hearing record, the State Water Board may approve or deny the recommendation, refer the matter to the Regional Water Board for appropriate action, or conduct further hearing itself. If the State Water Board acts to approve a recommended designation, the State Water Board shall amend Appendix V, Table V-1, of this Plan. The amendment will go into effect after approval by the Office of Administrative Law and US EPA. In addition, after the effective date of a designation, the affected Regional Water Board shall revise its water quality control plan in the next triennial review to include the designation.

* See Appendix I for definition of terms.

12. The State Water Board Executive Director shall advise other agencies to whom the list of designated areas is to be provided that the basis for an SWQPA-ASBS or SWQPA-GP designation is limited to protection of marine life from waste* discharges.

* See Appendix I for definition of terms.

APPENDIX V
STATE WATER QUALITY PROTECTION AREAS*
AREAS OF SPECIAL BIOLOGICAL SIGNIFICANCE*

TABLE V-1
STATE WATER QUALITY PROTECTION AREAS*
AREAS OF SPECIAL BIOLOGICAL SIGNIFICANCE*
(DESIGNATED OR APPROVED BY THE STATE WATER RESOURCES CONTROL BOARD)

No.	ASBS Name	Date Designated	State Water Board Resolution No.	Region No.
1.	Jughandle Cove	March 21, 1974,	74-28	1
2.	Del Mar Landing	March 21, 1974,	74-28	1
3.	Gerstle Cove	March 21, 1974,	74-28	1
4.	Bodega	March 21, 1974,	74-28	1
5.	Saunders Reef	March 21, 1974,	74-28	1
6.	Trinidad Head	March 21, 1974,	74-28	1
7.	King Range	March 21, 1974,	74-28	1
8.	Redwoods National Park	March 21, 1974,	74-28	1
9.	James V. Fitzgerald	March 21, 1974,	74-28	2

APPENDIX VI

REASONABLE POTENTIAL ANALYSIS PROCEDURE FOR DETERMINING WHICH TABLE 1 OBJECTIVES REQUIRE EFFLUENT LIMITATIONS

In determining the need for an effluent limitation, the Regional Water Board shall use all representative information to characterize the pollutant discharge using a scientifically defensible statistical method that accounts for the averaging period of the water quality objective, accounts for and captures the long-term variability of the pollutant in the effluent, accounts for limitations associated with sparse data sets, accounts for uncertainty associated with censored data sets, and (unless otherwise demonstrated) assumes a lognormal distribution of the facility-specific effluent data.

The purpose of the following procedure (see also Figure VI-1) is to provide direction to the Regional Water Boards for determining if a pollutant discharge causes, has the reasonable potential to cause, or contributes to an excursion above Table 1 water quality objectives in accordance with 40 CFR 122.44 (d)(1)(iii). The Regional Water Board may use an alternative approach for assessing reasonable potential such as an appropriate stochastic dilution model that incorporates both ambient and effluent variability. The permit fact sheet or statement of basis will document the justification or basis for the conclusions of the reasonable potential assessment. This appendix does not apply to permits or any portion of a permit where the discharge is regulated through best management practices (BMP) unless such discharge is also subject to numeric effluent limitations.

Step 1: Identify C_o, the applicable water quality objective from Table 1 for the pollutant.

Step 2: Does information about the receiving water* body or the discharge support a reasonable potential assessment (RPA) without characterizing facility-specific effluent monitoring data? If yes, go to *Step 13* to conduct an RPA based on best professional judgment (BPJ). Otherwise, proceed to *Step 3*.

Step 3: Is facility-specific effluent monitoring data available? If yes, proceed to *Step 4.* Otherwise, go to *Step 13.*

Step 4: Adjust all effluent monitoring data C_e, including censored (ND or DNQ) values to the concentration X expected after complete mixing. For Table 1 pollutants use $X = (C_e + D_m C_s) / (D_m + 1)$; for acute toxicity* use $X = C_e / (0.1 D_m + 1)$; where D_m is the minimum probable initial dilution* expressed as parts seawater* per part wastewater and C_s is the background seawater* concentration from Table 3. For ND values, C_e is replaced with "<MDL*;" for DNQ values C_e is replaced with "<ML.*" Go to *Step 5*.

Step 5: Count the total number of samples n, the number of censored (ND or DNQ) values, c and the number of detected values, d, *such that* $n = c + d$.

Is any *detected* pollutant concentration after complete mixing greater than C_o? If yes, the discharge causes an excursion of C_o; go to *Endpoint 1*. Otherwise, proceed to *Step 6*.

Step 6: Does the effluent monitoring data contain three or more detected observations ($d \geq 3$)? If yes, proceed to *Step 7* to conduct a parametric RPA. Otherwise, go to *Step11* to conduct a nonparametric RPA.

---

* See Appendix I for definition of terms.

Step 7: Conduct a parametric RPA. Assume data are lognormally distributed, unless otherwise demonstrated. Does the data consist entirely of detected values ($c/n = 0$)? If yes,

- calculate summary statistics M_L and S_L, the mean and standard deviation of the natural logarithm transformed effluent data expected after complete mixing, $\ln(X)$,
- go to *Step 9*.

Otherwise, proceed to *Step 8*.

Step 8: Is the data censored by 80% or less ($c/n \leq 0.8$)? If yes,

- calculate summary statistics M_L and S_L using the censored data analysis method of Helsel and Cohn (1988),
- go to *Step 9*.

Otherwise, go to Step 11.

Step 9: Calculate the UCB i.e., the one-sided, upper 95 percent confidence bound for the 95th percentile of the effluent distribution after complete mixing. For lognormal distributions, use $UCBL_{(.95,.95)} = \exp(M_L + S_L\, g'_{(.95,.95,n)})$, where g' is a normal tolerance factor obtained from the table below (Table VI-1). Proceed to *Step 10*.

Step 10: Is the UCB greater than C_o? If yes, the discharge has a reasonable potential to cause an excursion of C_o; go to *Endpoint 1*. Otherwise, the discharge has no reasonable potential to cause an excursion of C_o; go to *Endpoint 2*.

Step 11: Conduct a non-parametric RPA. Compare each data value *X* to C_o. Reduce the sample size *n* by 1 for each tie (i.e., inconclusive censored value result) present. An adjusted ND value having C_o < MDL* is a tie. An adjusted DNQ value having C_o < ML* is also a tie.

Step 12: Is the adjusted *n* > 15? If yes, the discharge has no reasonable potential to cause an excursion of C_o; go to *Endpoint 2*. Otherwise, go to *Endpoint 3*.

Step 13: Conduct an RPA based on BPJ. Review all available information to determine if a water quality-based effluent limitation is required, notwithstanding the above analysis in *Steps 1* through *12*, to protect beneficial uses. Information that may be used includes: the facility type, the discharge type, solids loading analysis, lack of dilution, history of compliance problems, potential toxic impact of discharge, fish tissue residue data, water quality and beneficial uses of the receiving water,* CWA 303(d) listing for the pollutant, the presence of endangered or threatened species or critical habitat, and other information.

Is data or other information unavailable or insufficient to determine if a water quality-based effluent limitation is required? If yes, go to *Endpoint 3.* Otherwise, go to either *Endpoint 1* or *Endpoint 2* based on BPJ.

Endpoint 1: An effluent limitation must be developed for the pollutant. Effluent monitoring for the pollutant, consistent with the monitoring frequency in Appendix III, is required.

Endpoint 2: An effluent limitation is not required for the pollutant. Appendix III effluent monitoring is not required for the pollutant; the Regional Board, however, may require occasional monitoring for the pollutant or for whole effluent toxicity as appropriate.

---

* See Appendix I for definition of terms.

Endpoint 3: The RPA is inconclusive. Monitoring for the pollutant or whole effluent toxicity testing, consistent with the monitoring frequency in Appendix III, is required. An existing effluent limitation for the pollutant shall remain in the permit, otherwise the permit shall include a reopener clause to allow for subsequent modification of the permit to include an effluent limitation if the monitoring establishes that the discharge causes, has the reasonable potential to cause, or contributes to an excursion above a Table 1 water quality objective.

ADDRESS ALL CORRESPONDENCE TO:
P.O. BOX 1460
ALHAMBRA, CALIFORNIA 91802-1460

IN REPLY PLEASE
REFER TO FILE: WM-7

September 17, 2015

Dr. Maria de la Paz Carpio-Obeso
Chief, Ocean Standards Unit
California State Water Resources Control Board
Division of Water Quality
Watersheds, Ocean, and Wetlands Section
P.O. Box 100
Sacramento, CA 95812-0100

Dear Dr. Carpio-Obeso:

AREA OF SPECIAL BIOLOGICAL SIGNIFICANCE 24
FINAL COMPLIANCE PLAN

The County of Los Angeles, the Los Angeles County Flood Control District, and the City of Malibu, collectively referred to as the Agencies, are submitting the enclosed Final Compliance Plan. The document is submitted in response to the March 17, 2015, comment letter from the State Water Resources Control Board. A response to comments and the field data sheet for the February 2014 event at site 24-BB-01Z are enclosed as Attachment A.

The enclosed Final Compliance Plan fulfills the requirements provided under Sections I.A.3.b and I.B.2.a of the State Water Board's Resolution No. 2012-0012.

If you have any questions, please contact me at (626) 458-4300 or ageorge@dpw.lacounty.gov or your staff may contact Mr. Paul Alva at (626) 458-4325 or palva@dpw.lacounty.gov.

Very truly yours,

GAIL FARBER
Director of Public Works

Angela R. George

ANGELA R. GEORGE
Assistant Deputy Director
Watershed Management Division

Attachment A: Response to Comments

Comment 1 - Map of storm water runoff:

Section I.A.2.a. of the Special Protections requires a map of storm water runoff that highlights the prioritized discharges and a description of any structural Best Management Practices (BMPs) already employed or to be employed. Priority discharges are those that pose the greatest water quality threat and which are identified to require installation of structural BMPs. Section I.A.2.f. states that the ASBS Compliance Plan shall describe structural BMPs, including any low impact development (LID) measures, currently employed and planned for higher threat discharges and shall include an implementation schedule. Higher threat discharges include permitted storm drains equal to or greater than 18 inches in diameter or width.

Appendix A in the draft Compliance Plan includes a map of storm water runoff and the planned structural BMP at Broad Beach Road. However, the draft Compliance Plan does not identify priority discharges, stating that none of the evaluated outfalls fall into this category, since receiving water monitoring results met the Table B Instantaneous Maximum Water Quality Objectives in Chapter II of the Ocean Plan, and consequently that additional structural BMPs are not necessary. To clarify, in determining exceedances of the natural water quality and identifying priority discharge locations, receiving water monitoring data is compared to the 85th percentile of the threshold of reference water quality data, not to Ocean Plan Table B Instantaneous Maximum Water Quality Objectives. In the draft Compliance Plan, the receiving water monitoring results show levels of constituents higher than the 85th percentile threshold of reference water quality data, indicating that additional structural BMPs are required. Staff noted similarities in elevated levels of constituents at core discharge ASBS-028 and its associated receiving water site ASBS-502. Therefore, core discharge ASBS-028 should be identified as a priority discharge location. In the final Compliance Plan, please identify priority discharges on the map, describe additional structural BMPs and explain how they will reduce pollutants in storm water runoff, and update the implementation schedule accordingly.

Response:

The Compliance Plan Map has been modified to indicate ASBS-028 is a priority outfall. As discussed with State Water Board Staff, and in compliance with the Special Protections, since discharges from ASBS-028 are already within the Ocean Plan Instantaneous Maximum, structural BMPs will not be installed. Instead, the Agencies will continue to implement non-structural BMPs as discussed in the Plan.

Comment 2 - Non-authorized non-storm water runoff:

Section I.A.2.b. of the Special Protections requires a description of the measures by which all non-authorized non-storm water runoff has been eliminated, how the measures will be maintained over time, and how these measures are monitored and documented.

The draft Compliance Plan describes actions being taken to eliminate flows that reach the surf. Although dry weather flows that did not reach the surf were observed during dry weather inspections of outfalls, there is no explanation of how these flows will be eliminated. In the final Compliance Plan, please address how dry weather flows will be *eliminated as well as how these measures will be maintained over time and how they will be monitored and documented.*

Response:

Section 3.0 of the Compliance Plan has been modified to enhance the discussion of monitoring, documenting, and reporting of dry weather elimination activities by the City of Malibu in cooperation with the County of Los Angeles (County) and Flood Control District (FCD).

Comment 3 - Implementation schedule:

Section I.A.3.d. of the Special Protections stipulates that any structural controls identified in the final Compliance Plan be operational within six years of the effective date. Section I.A.3.e. specifies that all dischargers must comply with the requirement that their discharges into the affected ASBS maintain natural ocean water quality within six years of the effective date.

The draft Compliance Plan lists March 20, 2019 as the date by which necessary structural controls shall be operational and by which all discharges must be in compliance with the General Exception requirements. The 12-month extension that was granted by the State Water Board applies to the deadlines for the draft and final Compliance Plans. This extension does not apply to the March 20, 2018 deadline for necessary structural controls or compliance with the General Exception requirements. Please be aware that the correct date is March 20, 2018 and that this is the date that should be listed in the implementation schedule.

Response:

The dates in the Compliance Plan have been corrected to reflect the March 2018 compliance schedule.

Comment 4 - Exceedances in natural water quality:

Section I.A.3.e. of the Special Protections requires that, if initial results of post-storm receiving water quality testing indicate levels higher than the 85th percentile threshold of reference water quality data and the pre-storm receiving water levels, then the discharger must re-sample the receiving water pre- and post-storm.

The results for receiving water site ASBS-502 indicate that exceedances in water quality were detected for multiple constituents during receiving water monitoring. Therefore, ASBS-S02 must be re-sampled pre- and post-storm for an additional storm event. If after re-sampling the post-storm levels are still higher than the 85th percentile threshold of reference water quality data and pre-storm receiving water levels for any constituent, then natural ocean water quality is exceeded, and consequently an exceedance report must be submitted as stipulated in Section I.A.2.h of the Special Protections.

Response:

The FCD will resample ASBS-S02 and ASBS-028 for one additional event and will report the results in accordance with Special Protections Section I.A.2.h.

Comment 5 - Ocean receiving water monitoring:

Section IV.B.2.b. of the Special Protections requires that a minimum of three ocean receiving water samples must be collected during each storm season from each station, each from a separate storm. It further specifies that a minimum of one receiving water *location shall be sampled in each ASBS per responsible party in that ASBS.*

Due to participation in the Southern California Bight 2008 regional monitoring effort, monitoring requirements for the County of Los Angeles, the Los Angeles County Flood Control District, and the City of Malibu were limited to only one storm season. The data from the remaining storm season were included in the draft Compliance Plan and indicate that only one receiving water site (ASBS-S02) was sampled successfully for three storm events. The remaining two sites (ASBS-S01 and 24-BB-03R) were only successfully sampled pre- and post-storm during one storm event. Staff understands that the City of Malibu will continue wet weather monitoring into the 2014-2015 wet season and that this sampling may be performed before submittal of the final Compliance Plan. Additionally, receiving water site ASBS-S01 and its associated core discharge ASBS-016 must be sampled for two additional storm events, to account for the incomplete previous monitoring events.

Also, staff noticed that outfall 24-BB-01Z is included on the map and the outfall descriptions, yet there were no results presented for this outfall, even though the draft Compliance Plan states that it was successfully sampled during the February 28, 2014 storm event. Please include results from that sampling event in the final Compliance Plan.

Response:

The City of Malibu sampled a December 1, 2014 storm event at sites 24-BB-03R, 24-BB-03Z, and 24-BB-02Z. Data and discussions resulting from these events have been included in the Compliance Plan (Section 4.1.4, Table 4.4, and various discussion locations).

The City of Malibu will continue its monitoring at site 24-BB-3-03R and its associated outfall 24-BB-03Z until it has completed three sampling events. The City will report the results of this monitoring in accordance with Special Protections Section I.A.2.h.

The County was not able to sample these two additional events prior to submitting the Final Compliance Plan and will sample two additional storm events at ASBS-S01 and its associated outfall ASBS-016. The County will report the results of this monitoring in accordance with Special Protections Section I.A.2.h.

The Compliance Plan inaccurately states that 24-BB-01Z was sampled during the Feb, 2014 event. The site was visited, but not sampled during this event, due to a lack of discharge, and a copy of the field report documenting the lack of discharge has been included with this response to comments.

Attachment A: Response to Comments

Comment 1 - Map of storm water runoff:

Section I.A.2.a. of the Special Protections requires a map of storm water runoff that highlights the prioritized discharges and a description of any structural Best Management Practices (BMPs) already employed or to be employed. Priority discharges are those that pose the greatest water quality threat and which are identified to require installation of structural BMPs. Section I.A.2.f. states that the ASBS Compliance Plan shall describe structural BMPs, including any low impact development (LID) measures, currently employed and planned for higher threat discharges and shall include an implementation schedule. Higher threat discharges include permitted storm drains equal to or greater than 18 inches in diameter or width.

Appendix A in the draft Compliance Plan includes a map of storm water runoff and the planned structural BMP at Broad Beach Road. However, the draft Compliance Plan does not identify priority discharges, stating that none of the evaluated outfalls fall into this category, since receiving water monitoring results met the Table B Instantaneous Maximum Water Quality Objectives in Chapter II of the Ocean Plan, and consequently that additional structural BMPs are not necessary. To clarify, in determining exceedances of the natural water quality and identifying priority discharge locations, receiving water monitoring data is compared to the 85th percentile of the threshold of reference water quality data, not to Ocean Plan Table B Instantaneous Maximum Water Quality Objectives. In the draft Compliance Plan, the receiving water monitoring results show levels of constituents higher than the 85th percentile threshold of reference water quality data, indicating that additional structural BMPs are required. Staff noted similarities in elevated levels of constituents at core discharge ASBS-028 and its associated receiving water site ASBS-502. Therefore, core discharge ASBS-028 should be identified as a priority discharge location. In the final Compliance Plan, please identify priority discharges on the map, describe additional structural BMPs and explain how they will reduce pollutants in storm water runoff, and update the implementation schedule accordingly.

Response:

The Compliance Plan Map has been modified to indicate ASBS-028 is a priority outfall. As discussed with State Water Board Staff, and in compliance with the Special Protections, since discharges from ASBS-028 are already within the Ocean Plan Instantaneous Maximum, structural BMPs will not be installed. Instead, the Agencies will continue to implement non-structural BMPs as discussed in the Plan.

Comment 2 - Non-authorized non-storm water runoff:

Section I.A.2.b. of the Special Protections requires a description of the measures by which all non-authorized non-storm water runoff has been eliminated, how the measures will be maintained over time, and how these measures are monitored and documented.

The draft Compliance Plan describes actions being taken to eliminate flows that reach the surf. Although dry weather flows that did not reach the surf were observed during dry weather inspections of outfalls, there is no explanation of how these flows will be eliminated. In the final Compliance Plan, please address how dry weather flows will be *eliminated as well as how these measures will be maintained over time and how they will be monitored and documented.*

Response:

Section 3.0 of the Compliance Plan has been modified to enhance the discussion of monitoring, documenting, and reporting of dry weather elimination activities by the City of Malibu in cooperation with the County of Los Angeles (County) and Flood Control District (FCD).

Comment 3 - Implementation schedule:

Section I.A.3.d. of the Special Protections stipulates that any structural controls identified in the final Compliance Plan be operational within six years of the effective date. Section I.A.3.e. specifies that all dischargers must comply with the requirement that their discharges into the affected ASBS maintain natural ocean water quality within six years of the effective date.

The draft Compliance Plan lists March 20, 2019 as the date by which necessary structural controls shall be operational and by which all discharges must be in compliance with the General Exception requirements. The 12-month extension that was granted by the State Water Board applies to the deadlines for the draft and final Compliance Plans. This extension does not apply to the March 20, 2018 deadline for necessary structural controls or compliance with the General Exception requirements. Please be aware that the correct date is March 20, 2018 and that this is the date that should be listed in the implementation schedule.

Response:

The dates in the Compliance Plan have been corrected to reflect the March 2018 compliance schedule.

Comment 4 - Exceedances in natural water quality:

Section I.A.3.e. of the Special Protections requires that, if initial results of post-storm receiving water quality testing indicate levels higher than the 85th percentile threshold of reference water quality data and the pre-storm receiving water levels, then the discharger must re-sample the receiving water pre- and post-storm.

The results for receiving water site ASBS-502 indicate that exceedances in water quality were detected for multiple constituents during receiving water monitoring. Therefore, ASBS-S02 must be re-sampled pre- and post-storm for an additional storm event. If after re-sampling the post-storm levels are still higher than the 85th percentile threshold of reference water quality data and pre-storm receiving water levels for any constituent, then natural ocean water quality is exceeded, and consequently an exceedance report must be submitted as stipulated in Section I.A.2.h of the Special Protections.

Response:

The FCD will resample ASBS-S02 and ASBS-028 for one additional event and will report the results in accordance with Special Protections Section I.A.2.h.

Comment 5 - Ocean receiving water monitoring:

Section IV.B.2.b. of the Special Protections requires that a minimum of three ocean receiving water samples must be collected during each storm season from each station, each from a separate storm. It further specifies that a minimum of one receiving water *location shall be sampled in each ASBS per responsible party in that ASBS.*

Due to participation in the Southern California Bight 2008 regional monitoring effort, monitoring requirements for the County of Los Angeles, the Los Angeles County Flood Control District, and the City of Malibu were limited to only one storm season. The data from the remaining storm season were included in the draft Compliance Plan and indicate that only one receiving water site (ASBS-S02) was sampled successfully for three storm events. The remaining two sites (ASBS-S01 and 24-BB-03R) were only successfully sampled pre- and post-storm during one storm event. Staff understands that the City of Malibu will continue wet weather monitoring into the 2014-2015 wet season and that this sampling may be performed before submittal of the final Compliance Plan. Additionally, receiving water site ASBS-S01 and its associated core discharge ASBS-016 must be sampled for two additional storm events, to account for the incomplete previous monitoring events.

Also, staff noticed that outfall 24-BB-01Z is included on the map and the outfall descriptions, yet there were no results presented for this outfall, even though the draft Compliance Plan states that it was successfully sampled during the February 28, 2014 storm event. Please include results from that sampling event in the final Compliance Plan.

Response:

The City of Malibu sampled a December 1, 2014 storm event at sites 24-BB-03R, 24-BB-03Z, and 24-BB-02Z. Data and discussions resulting from these events have been included in the Compliance Plan (Section 4.1.4, Table 4.4, and various discussion locations).

The City of Malibu will continue its monitoring at site 24-BB-3-03R and its associated outfall 24-BB-03Z until it has completed three sampling events. The City will report the results of this monitoring in accordance with Special Protections Section I.A.2.h.

The County was not able to sample these two additional events prior to submitting the Final Compliance Plan and will sample two additional storm events at ASBS-S01 and its associated outfall ASBS-016. The County will report the results of this monitoring in accordance with Special Protections Section I.A.2.h.

The Compliance Plan inaccurately states that 24-BB-01Z was sampled during the Feb, 2014 event. The site was visited, but not sampled during this event, due to a lack of discharge, and a copy of the field report documenting the lack of discharge has been included with this response to comments.

EXECUTIVE SUMMARY

Background

The Laguna Point to Latigo Point Area of Special Biological Significance (ASBS), also referred to as ASBS 24, was established in 1974 by the State Board to preserve sensitive marine habitat (SWRCB, 1979). It stretches 24 miles, contains 11,842 marine acres, and is the largest ASBS along the mainland of Southern California. A wide range of sandy substrate, rocky reef, and coastal pelagic species can be found within ASBS 24. Figure ES-1-1 shows a small portion of ASBS 24 east of Point Dume.

Figure ES-1-1. ASBS 24 Looking East Across Dume Cove

Since 1983, the California Ocean Plan (Ocean Plan) has prohibited the discharge of waste into ASBS along the California Coast, unless the State Water Resources Control Board (State Board) grants an exception to dischargers. The southern and central portions of ASBS 24 that are located in Los Angeles County (County) are subject to direct discharges from roads, urban landscape runoff, homes, and small businesses. In general, the near-coast storm water runoff along ASBS 24 within the County is conveyed through storm drain systems and / or natural drainage courses before it is discharged at multiple locations along the beach. In 2004, the City of Malibu (City), County of Los Angeles, and the Los Angeles County Flood Control District (District) requested exceptions for storm water discharges to ASBS 24 from the State Board. The State Board received requests from numerous other applicants for an exception to the Ocean Plan. In 2012, the State Board adopted a General Exception.

The General Exception includes Special Protections which specify prohibited discharges and other requirements that dischargers covered under the General Exception must comply with. The County, the District, and the City were included in the list of responsible entities required to prepare a Draft and Final ASBS Compliance Plan for point source discharges of storm water in ASBS 24. This Compliance Plan has been prepared by the County, District, and City (collectively the Parties) in accordance with the General Exception

Point Source Discharge Locations (Outfalls Equal to and Greater Than 18 Inches)

Los Angeles County Department of Public Works (LACDPW) has identified 12 storm drain outfalls having a diameter equal to or greater than 18 inches that drain to ASBS 24 and are owned and maintained by the County. Nine storm drain outfalls that have a diameter greater than or equal to 18 inches and drain to ASBS 24 are owned and maintained by the District. These nine outfalls occur along Broad Beach and Escondido Beach and convey runoff from upstream neighborhoods. The City identified eight storm drain outfalls that are privately owned and maintained and have diameters equal to or greater than 18 inches. These storm drains convey runoff from City owned and maintained inlets on Broad Beach Road and Wildlife Road to the storm drain outfalls located along Broad Beach and the seaside cliffs of Point Dume. An additional 10 storm drain outfalls are currently of undetermined ownership. These storm drains with undetermined ownership convey flow from the Pacific Coast Highway, and upstream neighborhoods. These 39 storm drain outfalls are considered point source discharges of storm water to ASBS 24. Figure ES-1-2 shows the locations of point source discharges along the County shoreline of ASBS-24. The Compliance Plan Map is included in the Appendix A.

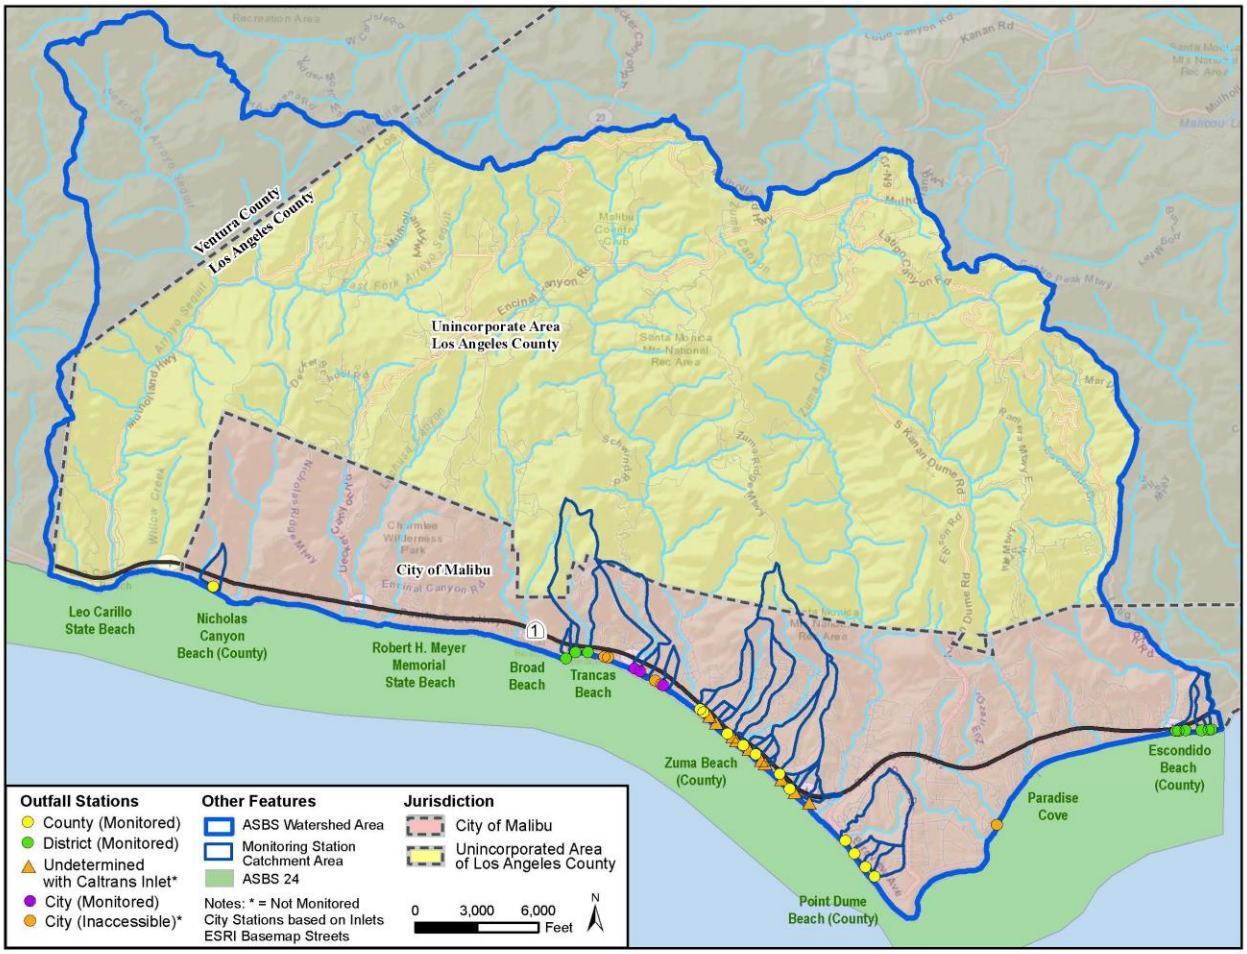

Figure ES-1-2. ASBS-24 Point Source Discharge Locations

Compliance Plan Map

A Compliance Plan Map for the ASBS 24 watershed area has been created and can be updated using Environmental Systems Research Institute (ESRI) ArcMap 10 and is provided in Appendix A. This map shows storm water conveyances and other storm drain features associated with surface drainage of storm water runoff, including catch basins, inlets/outlets, outfalls, storm drain lines, channels, and creeks. The map identifies core monitoring stations and shows the location of other outfalls equal to or greater than 18 inches that are private, state, or federal and not monitored by the Parties. Drainage areas for the core monitoring stations, watershed sub-basins and flow directions within these sub-basins are depicted, as well as the overall ASBS 24 watershed area. The map includes the locations of waste and hazardous material storage areas, sewage conveyances and treatment facilities, landslide zones, and roads. Jurisdictional boundaries for the unincorporated area of the County, the City, and state and federal lands within these areas are shown. This Plan provides information regarding the Compliance Plan Map datasets and the procedures for updating applicable GIS files and the map.

Dry Weather Requirement

The General Exception prohibits all non-authorized non-storm water (dry weather) discharges into the ASBS. Dry weather runoff is any runoff that is not the result of a precipitation event. This is also referred to as "non-storm water discharges" (SWRCB, 2012a). The Parties have implemented nonstructural measures that are designed to eliminate non-authorized, non-storm water runoff. These measures include public information and participation programs (PIPPs), operations and maintenance (O&M) programs, and enforcement programs. A discussion of these activities is provided in Section 3, and a list of existing programs with brief descriptions is provided in Appendix B.

Dry weather monitoring of outfalls has been performed to ensure compliance with the requirements of the General Exception. A summary of these outfall inspections for 2012 and 2013 is provided within the main body of the Plan on Table 3-3 and Table 3-4, respectively. Of the inspected outfalls, only ASBS-002 had flow reaching the surf, and this occurred only once out of the 13 times in 2012 and once out of the three times in 2013. Subsequent inspections performed in March and May, 2013, at ASBS-002 indicated that flow was not present. Some other outfalls were observed with flows or ponded water; however, due to the distances between the outfalls and the surf zones, these flows did not reach the surf zones. Inspections will continue to ensure that discharges of non-storm, non-authorized runoff do not occur.

Receiving Water Assessment

In 2008, a study was conducted as part of Bight 2008 to assess water quality in southern California ASBS (Schiff et al., 2011). The study was designed to evaluate the range of natural water quality near reference drainage locations and to compare water quality near ASBS discharges to these natural water quality conditions. The 2008 study provided initial estimates of reference thresholds, set at 85th percentile, based on data collected at reference sites. As part of the Bight 2013 Regional Monitoring Program, additional reference monitoring was performed under the Regional Monitoring Program, and the 85th percentile reference thresholds were revised.

Wet weather monitoring was performed by LACDPW at two receiving water locations: 1) S01, located off Zuma Beach directly out from ASBS-016, a 60-inch storm drain; and 2) S02, located off Escondido Beach directly out from ASBS-028, a 36-inch storm drain. The City performed monitoring at receiving water Site 24-BB-03R The assessment of compliance with natural water quality was primarily performed for receiving water station S02, which was the only site that had samples collected during three wet weather events. Receiving water station S02 is associated with ASBS-028, which is a 36-inch outfall that drains a mixture of developed and vacant land. Receiving water station S02 is considered to be representative of the typical to worst case scenario of the potential impact that storm water runoff may have on the water quality within the ASBS. The receiving water quality assessment is presented in Section 4.0, and a summary of the assessment is presented below.

In samples collected in the receiving water (Site S02), selenium, mercury, and total polynuclear aromatic hydrocarbons (PAHs) concentrations were above the 85th percentile reference threshold and had post-storm concentrations that exceeded those of the pre-storm samples collected during two consecutive monitored storm events. Based on the guidance found in Attachment 1 of the General Exception, this indicates an exceedance of natural water quality in the ASBS for these constituents.

Receiving water samples collected (Site S02) during one event, but not in subsequent events, that had concentrations above both the 85th percentile threshold and pre-storm concentrations include pyrethroids, nitrate as N, copper, lead, and zinc. These constituents do not meet the guidance criteria and are not considered an exceedance of the natural water quality in the ASBS.

During the three monitored events flow from ASBS-016 only reach the receiving water once at Site S01 and thus, receiving water chemistry data was only obtained once at S01 as part of the General Exception monitoring. Mercury, silver, zinc, and total PAHs concentrations in the receiving water were greater than both the 85th percentile threshold and pre-storm concentrations for Site S01. Receiving water concentrations above both the 85th percentile thresholds and pre-storm concentrations occurring during only one event is not considered to be an exceedance of natural water quality.

Pre-storm and post-storm samples were collected and analyzed at Site 24-BB-03R for two events. The post-storm selenium concentration in the receiving water was greater than both the 85th percentile threshold and pre-storm concentrations for only the first event (see Table 4-3). The post-storm ammonia as N, silver, and total PAHs concentrations in the receiving water were greater than both the 85th percentile threshold and pre-storm concentrations for only the second event. The concentration of selenium, ammonia, silver, and PAHs being above the 85th percentile threshold and pre-storm concentrations in one event is not considered an exceedance of natural water quality at Site 24-BB-03R. However, the selenium result at Site 24-BB-03R is consistent with the results at Site S02 where selenium is considered to be an exceedance of natural water quality based on first and second event results.

Pollution Loading Reduction Assessment

The General Exception states that the ASBS Compliance Plan shall describe how the necessary pollutant reductions in storm water runoff will be achieved through prioritization of outfalls and implementation of BMPs to achieve end-of-pipe pollutant concentrations targets during a design storm to below either the Table 1 Instantaneous Maximum Water Quality Objectives (WQOs) in Chapter II of the Ocean Plan or a 90% reduction in pollutant loading during storm events for the applicant's total discharge. Constituents that are currently in exceedance of the natural water quality threshold of the ASBS, and that also have an associated Ocean Plan Table 1 Instantaneous Maximum WQO value (mercury and selenium), were compared with the Table 1 Instantaneous Maximum WQOs in order to determine the appropriate pollutant load reduction in accordance with the General Exception.

Monitoring Results

Chemistry results obtained from monitoring outfall discharges to ASBS 24 are presented in the main body of the Plan in Table 5-1 through Table 5-4 respectively. The Ocean Plan Table 1 Instantaneous Maximum WQOs for mercury and selenium are 0.4 µg/L and 150 µg/L, respectively. The Ocean Plan Table 1 does not list Instantaneous Maximum WQOs for PAHs. During the three monitored events the sampling results were all below these Ocean Plan Table 1 Instantaneous Maximum values. A summary of the highest measured values in comparison with the Ocean Plan Table 1 Instantaneous Maximum values as well as other Ocean Plan Table 1 WQOs is provided on Table ES-1-1.

Table ES-1-1. Summary of Ocean Plan WQOs Comparison to Maximum Outfall Results

Parameter	Ocean Plan Table 1 Values (Receiving Water Mixing Zone)			Maximum Measured Value (in Outfall Prior to Mixing Zone)		
	6-Month Median	Daily Maximum	Instantaneous Maximum	February 2013, Event 1	March 2013, Event 2	February 2014, Event 3
Mercury	0.04	0.16	0.4	0.16	0.06	<0.0012
Selenium	15	60	150	0.79	1.0	5.1

Outfall Assessment Conclusions

Following the guidance found in the Special Protections an assessment of outfalls was performed to determine where structural controls may be required to achieve the specified pollutant loading limitations on point source discharges into ASBS 24. The outfall assessment included comparing the mercury and selenium monitoring data results obtained to Ocean Plan Table 1 Instantaneous Maximum WQOs. The Ocean Plan Table 1 does list Instantaneous Maximum values for the protection of marine aquatic life for total PAHs. (The Ocean Plan Table 1 only lists a 30-day Average PAHs WQO for the protection of human health.) As shown in Table ES-1 the results of the comparison indicated the discharges to the ASBS from point sources (outfalls) are currently achieving, and significantly below, the target levels. Therefore, based on available data, and in accordance with the Special Protections of the General Exception, the outfalls being evaluated in this Plan do not require additional controls (e.g., BMPs) to achieve pollutant load reductions in the drainage areas tributary to the Parties' outfalls. However, due to the identified exceedanace of natural water quality, outfall ASBS-28 is currently considered a priority outfall.

Anthropogenic Sedimentation Assessment

In accordance with the requirements of the General Exception, the natural habitat conditions in the ASBS shall not be altered as a result of anthropogenic sedimentation (SWRCB, 2012a). An assessment of the potential areas prone to anthropogenic sedimentation was performed as part of this Compliance Plan for the purpose of identifying areas where sediment control BMPs may be required. The general assessment process included first performing a desktop analysis of geological conditions, topography, land use, and aerial imagery for the applicable area. Next, a reconnaissance of the area was performed to verify desktop findings and further analyze the drainage areas. Finally, the desktop and reconnaissance data collected were then complied into this Plan.

Geologic processes, beginning as far back as 80 million years, created the sedimentary formations predominantly found along the coast shoreline and Point Dume upland mesa area, which include siltstone and sandstone. Approximately 16 million years ago, seismic activity began and continued for 3 million years to form the Santa Monica Mountains, which are composed of a combination of sedimentary and igneous rock formations (City, 1995). Land use zoning and development have occurred predominantly along the coast within the flatter areas at lower elevations. Some development has occurred inland within the Santa Monica Mountains, but for the most part, development in the mountainous areas of the ASBS 24 watershed has been restricted due to the conservation of the area at the federal, state, and local levels.

The desktop analysis included determining the general sediment risk for the area based on the procedures outlined in the Construction General Permit. These procedures included determining the rainfall erosivity (R factor), which is based on data collected over several years to determine the annual storm kinetic energy, on average, for the area. That factor, combined with properties of common soils and various slopes (up to 50%) and heights (up to 50 ft.), were used to determine the potential annual disturbed loose soil areas within the watershed. Calculation results indicated that the potential for soil loss within disturbed areas increases rapidly for areas having slopes greater than 10% and heights greater than a few feet. These results were used during the field reconnaissance to aid in determining if areas have the potential to contribute anthropogenic sedimentation to ASBS 24.

Field reconnaissance was performed with a focus on the areas that drain to the identified outfalls that discharge to ASBS 24. In general, the drainage areas primarily consisted of larger lots (0.25 to approximately 1 acre) with existing residential structures, hardscape improvements, and landscaping. Landscape vegetation of sloped areas within developed areas, including residential properties and roadway rights-of-way, were observed to have fairly good cover. No signs of erosion as a result of manmade improvements (e.g., rills, gullies caused by runoff from impervious surfaces) were observed in sloped areas, alongside secondary roads, or the PCH.

The sedimentation assessment indicates that currently there are no areas prone to anthropogenic sedimentation within the drainage areas to the identified outfalls that discharge to ASBS 24. Land use in the drainage areas consists predominantly of residential and vacant (open space) designations with associated roadway connections. The sloped areas associated with residential properties were observed to have good vegetation cover and appeared to be regularly maintained by landscaping professionals (see Figure 7-9). Areas where cuts (excavation) were made during the construction of roadways were observed to have either good vegetation cover that has been maintained by responsible property owners or consist of hard coastal bluff materials resistant to erosive forces (e.g., large bluff along the southeast portion of Zuma County Beach, as shown on Figure 7-11). Therefore, at this time, no additional sediment BMPs are required by this plan.

Conclusions

The assessments performed in the preparation of this Compliance Plan indicate that no additional structural controls (BMPs) are required based on the guidance presented within the Special Protections. However, the Parties recognize that the ABSB 24 is one of most valued resources in the region and that wherever possible and feasible additional reductions in pollutant loading should be achieved. Accordingly, various existing nonstructural programs will continue to be implemented in order to maintain compliance with the requirements of the Special Protections and possibly achieve further reductions in pollutant loading. The Parties are considering implementing additional nonstructural controls and enhancements to existing controls for the purpose of further reducing pollutant loading to the ASBS. Additionally, in July 2015, the City deemed construction complete for structural BMPs for the areas of Broad Beach Road and Wildlife Road where City inlets drain to private outlets in the ASBS area.

Cost Estimate

The Parties have implemented numerous nonstructural controls and related programs in order to eliminate non-storm water, non-authorized discharges to ASBS 24. The Parties continue to maintain these measures, and the annual estimated costs associated with the key programs, which are detailed in Section 3.0, are provided on Table ES-1-2. Appendix B contains a list along with brief descriptions of various existing nonstructural measures implemented by the Parties.

Structural controls are being proposed and currently in the planning and permitting phase for the areas of Broad Beach Road and Wildlife Road. These structural controls will provide additional reduction of pollutant loading into the ASBS but are not directly connected to the Compliance Plan (i.e., not a result of the assessments performed for this document and not a requirement of this document). The costs for these structural controls are not included on Table ES-1-2. More information on these structural controls, included estimated costs, is included in Appendix C.

Table ES-1-2. Annual Nonstructural Programs Costs

Program Type	Approximate Cost ($/year)
PIPP Subtotal	$228,407
O&M Subtotal	$1,182,500
Enforcement Subtotal	$111,752
Total	$1,522,659

1.0 INTRODUCTION

In 1974 and 1975, the California State Water Resources Control Board (SWRCB) designated 34 coastal areas in California as Areas of Biological Significance (ASBS). The ASBSs are ocean areas requiring protection of species or biological communities to the extent that alteration of natural water quality is undesirable. One of these ASBS, known as ASBS 24, is located along 24 miles of the Ventura and Los Angeles County coastline, from Laguna Point to Latigo Point (SWRCB, 1979).

The California Ocean Plan (Ocean Plan) prohibition on discharges of waste to ASBS has been in place since 1983. The SWRCB may grant exceptions to this prohibition if the exception will not compromise the protection of ocean waters for beneficial uses and the public interest will be served (SWRCB, 2012a). On March 20, 2012, the SWRCB adopted a General Exception to the Ocean Plan ASBS waste discharge prohibition. The General Exception was amended and adopted as Resolution 2012-0031 on June 19, 2012 (SWRCB, 2012b).

The General Exception includes Special Protections that dischargers covered under the General Exception must comply with. For ASBS 24, the County of Los Angeles (County), the Los Angeles County Flood Control District (District), and the City of Malibu (City) were included in the list of responsible entities required to prepare an ASBS Compliance Plan for point source discharges of storm water and a Pollution Prevention Plan for non-point source waste discharges by September 30, 2013. An extension of one year was granted due to the lack of rainfall and water quality monitoring opportunities. This Compliance Plan has been prepared by the County, District, and City (the Parties) as specified in the General Exception. The Pollution Prevention Plan has been prepared under a separate cover.

1.1 Compliance Plan Objective and Scope

This Compliance Plan (Plan) documents the existing ASBS and ASBS watershed conditions and policies within the Parties' jurisdiction for the purpose of demonstrating either compliance with the point source discharges of storm water requirements specified in the General Exception Attachment B – *Special Protection for Areas of Special Biological Significance, Governing Point Source Discharges of Storm Water and Nonpoint Source Waste Discharge* (Special Protections), or describing the steps necessary to achieve compliance within the time frame allotted. This Plan focuses on point source discharges, which by this document are defined as outfalls that have associated storm networks that drain significant areas and that are entirely or partially maintained by an agency. Using this definition, point sources identified in this document coincide with conveyances that are equal to or greater than 18 inches in size (diameter or width) that discharge directly to the ASBS shoreline and the Parties maintain the outfall and/or inlets. Potential discharges from smaller pipes and conveyances (not defined as point sources) are defined in the Special Protections as nonpoint sources, and discussed in the Pollution Prevention Plan.

The following tasks associated with point source discharge locations and drainage areas were performed as part of the process to prepare this Plan:

- Preparing a map of the ASBS watershed showing surface drainage of storm water runoff and outfall locations (18 inches or greater in size).
- Preparing procedures to allow for future updates to the Compliance Plan map.
- Evaluations of compliance with the permitted point source discharges of storm water, which includes the prohibition of non-storm water discharges (i.e., discharges not composed entirely of storm water and not specifically allowed in accordance with Special Protections Section I.A.1.e).
- Assessment of the Parties' inspection policies.
- Collection and analysis of water quality samples in accordance with Section IV of the Special Protections.
- Assessment, using water quality sample results, of whether the storm water discharges are altering the natural water quality of the ASBS.
- Assessment of pollutant load reduction targets and outfall prioritization.
- Assessment of potential sources of anthropogenic sedimentation.
- Compilation of assessment and data into this Compliance Plan.
- Description of the nonstructural controls currently employed and planned in the future and implementation schedule

1.2 ASBS 24 Watershed Responsible Agencies

The Laguna Point to Latigo Point ASBS, also referred to as ASBS 24, stretches 24 miles, contains 11,842 marine acres, and is the largest ASBS along the mainland of Southern California. The boundary of ASBS 24 extends out from the mean high tide line at Laguna Point in Ventura County to either 1,000 ft. from shore or to the 100-ft isobath (whichever is greater) in a southwesterly direction to Latigo Point in Malibu, Los Angeles County.

This Plan includes the applicable drainage areas and point discharges that are the Parties' purview (i.e., drainage area is within either the jurisdiction of the City or Unincorporated County and/or the outfall ownership is either the County's or District's). These include the areas of the unincorporated County and City of Malibu along the coast south the Los Angeles County boundary and west of Latigo Point. Figure 1-1 shows the overall ASBS watershed within Los Angeles County, along with jurisdictional boundaries. Properties within the ASBS watershed in which the Parties do not have jurisdictional authority and thus are excluded from this Plan include, but are not limited to, federal lands, state parks, and state rights-of-way (see Section 2.1.2 for more information on these excluded properties).

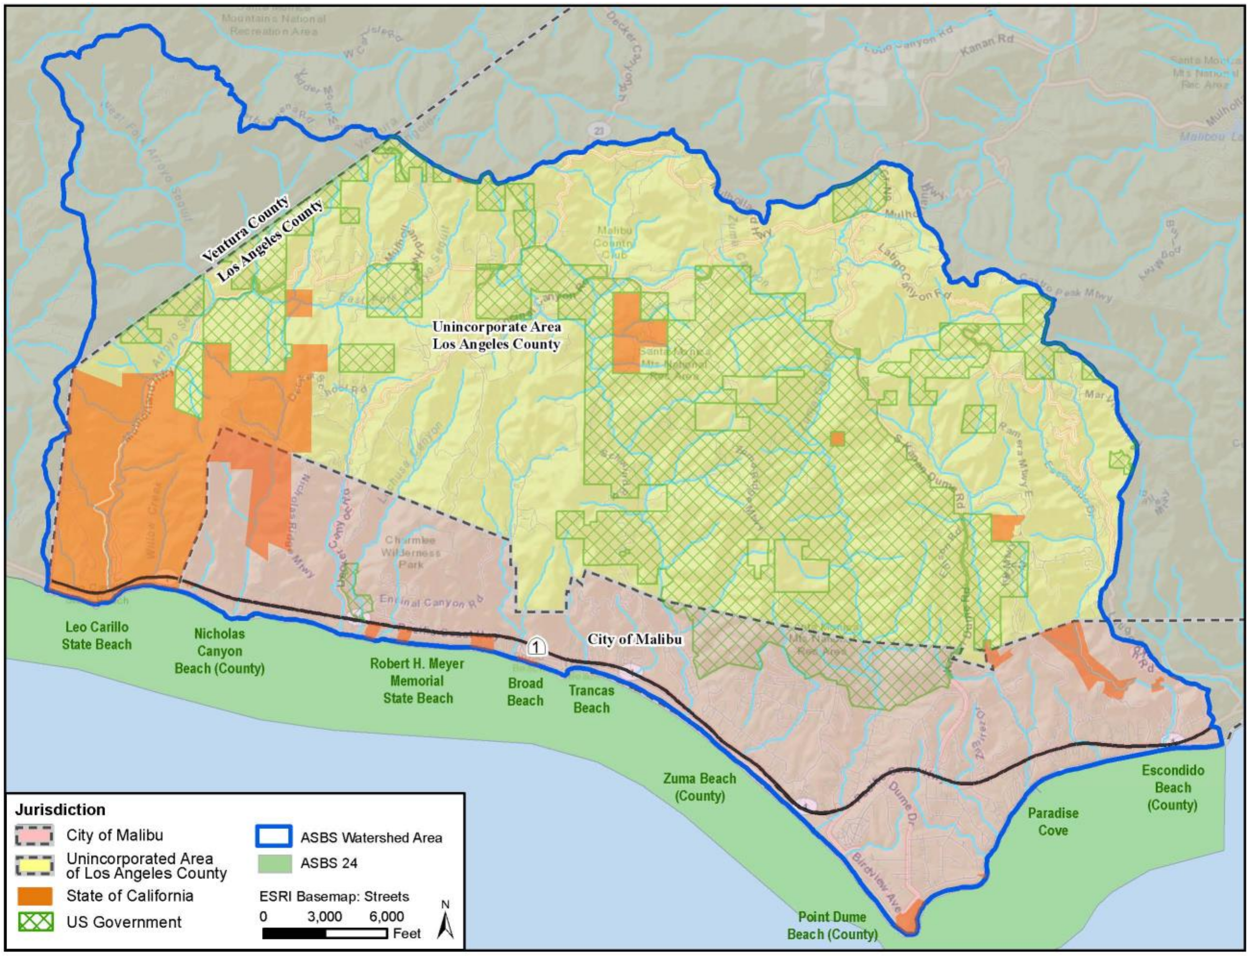

Figure 1-1. ASBS 24 Watershed and Jurisdictional Boundaries

2.0 ASBS 24 WATERSHED

2.1 General Site Conditions and Land Use

2.1.1 Topography

In general, the elevations within the ASBS 24 drainage area vary from sea level to 1,700 ft. above mean sea level (AMSL). Areas within the Santa Monica Mountains, typically north of the Pacific Coast Highway (PCH), contain steep hills, canyons, and valleys that drain to ASBS 24. These mountains consist of steep slopes with a 20% or greater gradient (SWRCB, 1979). Most of the developed areas along the coast lie below 100 ft., with the exception of the Point Dume and Malibu Park areas, which reach an elevation of approximately 500 ft. The hillsides and coastal mesas, such as Big Rock and Las Flores (both on the eastern end of town well outside of the ASBS), have elevations ranging from 300 to 400 ft. AMSL (City, 1995).

North of Broad Beach, extending to the County jurisdictional boundary, the coastal topography consists of narrow beaches adjacent to near-vertical natural bluffs that extend between 50 ft. to 200 ft. above mean sea level (alms). The mesas above the bluffs slope towards the coast at approximately 2% to 10%. The mesas extend inland and merge with the Santa Monica Mountains, which as previously stated are characterized by steep and rugged hillsides and valleys and canyons. The mesas have various valleys and canyons that coincide with the mountain valleys and canyons that provide the area with natural drainage to the ocean.

The area of Broad Beach south to Zuma County Beach is characterized, in general, by gentle seaward sloping natural topography (approximately 2 to 4%) with some near-vertical bluffs located further inland at varying distances from the ocean between approximately 1,000 ft. to 3,500 ft. and similar to those bluffs previously described.

The Point Dume area consists of narrow beaches followed by near vertical bluffs that extend from approximately 200 ft. northwest of the point to approximately 500 ft. northeast of the point. The mesa area above the beach is large and consists of sloping terrain which has formed high and low areas as well as valley and canyons that drain the area to the ocean. This topography continues northeast to approximately Escondido Beach, where the area has an approximately 10% gradient towards Escondido Creek.

South of Escondido Creek, the topography is similar to that of Broad Beach, with an area of gentle seaward sloping terrain along the ocean followed by relatively small inland bluffs and upland sloped areas.

2.1.2 Current Land Use

Land use data within the drainage area to the portion of ASBS 24 located south of the LA-Ventura County jurisdictional boundary were compiled and analyzed using GIS software and available land use data sources, including data provided by the City (2010 data for the City portion) and LACDPW (2008 data for the County portion). Both of these sources use Southern California Association of Governments (SCAG) land use codes. The SCAG classifications were generalized for inclusion into this document and for mapping purposes. Roads were not included in the land use; however, data were filled in with the mapping and analysis software.

Along the coast, the location of the County jurisdictional boundary coincides with a natural high point in the topography, and thus, the drainage area boundary follows the County jurisdiction boundary fairly well for a couple of miles inland. The land use analysis indicated that the overall drainage area to ASBS 24 includes approximately 31,400 acres, of which approximately 28,480 acres are located within the County jurisdictional boundary, and 2,900 acres are located in Ventura County.

The portion of the drainage area located within Ventura County is composed primarily of natural open space, mountainous terrain. The drainage area within the LA County portion is under the jurisdiction of multiple entities, including national parks, state parks, Unincorporated County, City of Malibu and Caltrans. The properties located south of the jurisdictional boundary are within the Unincorporated County and City's jurisdiction. However, several parcels have federal, state, or conservation authority ownership and are designated as National or State Parks. Table 2-1 summarizes land areas associated with the County and City and includes information on federal- and state-owned properties.

Table 2-1. Property Ownership Summary

Ownership	Unincorporated County Area (acres)	City of Malibu Area (acres)	Total (acres)
Federal	7,490	740	8,230
State	2,330	520	2,850
Conservation Authority/Conservancy	300	10	310
Remainder (Non-specified)	10,140	6,950	17,090
Total	**20,260**	**8,220**	**28,480**

The general land use within the drainage area is approximately 86.1% open space public lands; 4.9% low-density residential; 4.8% very-low-density residential; 2.6% medium-density residential; and about 1.6% either low-density commercial, industrial, high-density residential, planned development, high-density commercial, water, urban reserve, and mixed use (SWRCB, 2012c).

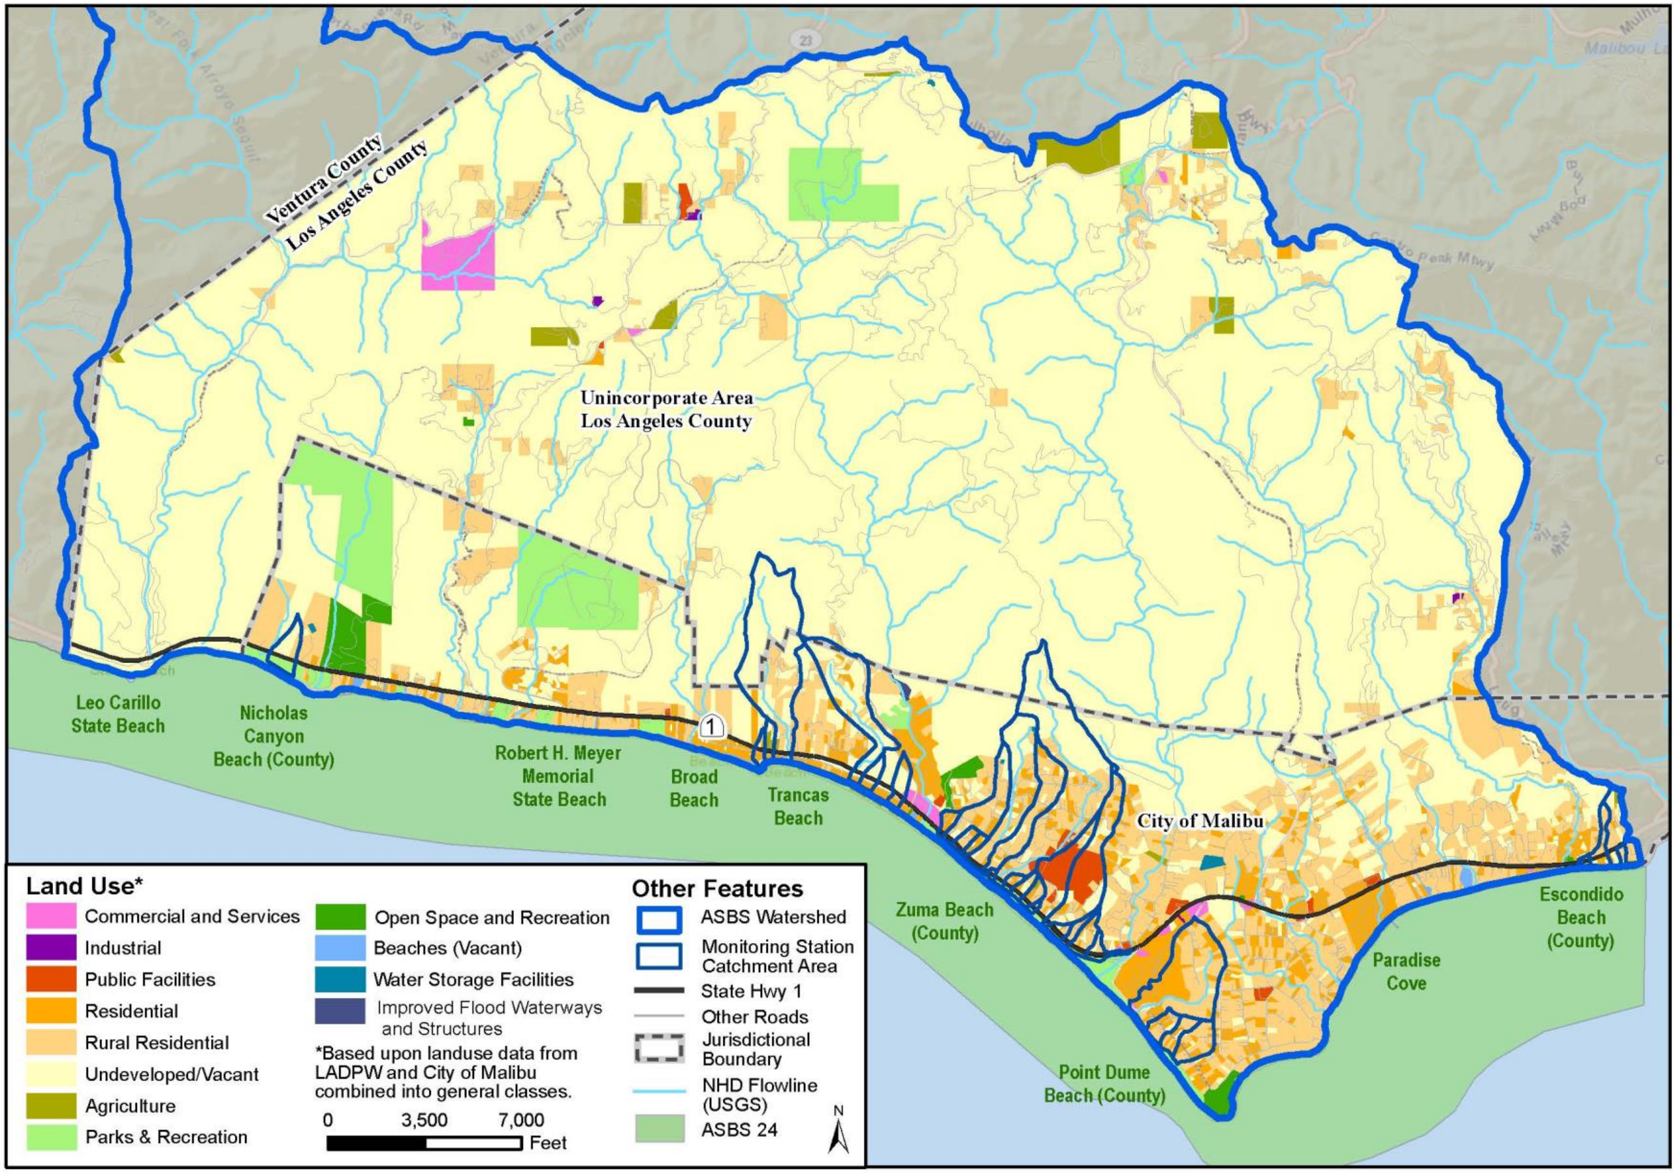

Figure 2-1. ASBS 24 Drainage Area Land Use Map

2.2 Geological Setting

2.2.1 Regional Geology

The ASBS 24 coastal drainage area is composed of an extremely complex geology that has resulted from the geologic uplift which formed the Santa Monica Mountains. The area is located within the northwestern corner of the Los Angeles basin, which lies at the boundary or juncture between two major geomorphic or structural provinces of southern California: 1) the Peninsular Ranges province, consisting primarily of a northwest-oriented structural grain; and 2) the Transverse Ranges structural province, which features a predominantly east-west-oriented structural grain. The Los Angeles structural basin originated roughly 16 million years ago in what is designated the Miocene geologic epoch. However, the Los Angeles basin area, in general, has been a site of continuous sedimentary deposition for at least the past 80 million years. The sedimentary rocks underlying the Santa Monica Mountains in the ASBS 24 drainage area are generally highly folded and complexly faulted (City, 1995).

2.2.2 ASBS 24 Geology

The Malibu Coast fault runs in an east-west alignment within the ASBS 24 drainage area. The fault is a boundary between two very different geologic terranes: to the south, Catalina Schist is overlain by Miocene and younger deposits; and to the north, Santa Monica Slate and plutonic granodiorite is overlain by Upper Cretaceous through upper Miocene deposits (i.e., Santa Monica Mountains) (Yerkes and Campbell, 1979). The fault is aligned in a near east-west direction following the coast line from the County’s north jurisdictional boundary east to Lechuza Point. East of Lechuza Point the fault continues in a near east-west alignment to Corral Beach (east of ASBS 24). The fault continues east along the coastline (NPS, 2007). North of the Malibu Coast fault, the local bedrock structure of the Santa Monica Mountains can be modeled as an asymmetric, south-vergent, westward-plunging anticline, including sandstone and siltstone bedrock (e.g., Tuna Canyon Formation, Sespe Formation, Vaqueros Formation, and Topanga Group). South of the Malibu Coast fault, the ductile bedrock units, Trancas and Monterey Formations, contain a high percentage of shales, mudstones, and diatomaceous rocks that exhibit complex folding and pervasive shearing (City, 1995).

The majority of the area along the Malibu coast comprises the Santa Monica Mountains. The portion of the ASBS 24 and uplands areas between Point Mugu, which is north of the County’s jurisdictional boundary and La Piedra State Beach, comprise the Santa Monica Mountains formations. North of Point Mugu, the coastal area consists of low-lying land that comprises the Ventura-Oxnard Alluvial Plain. The Malibu Coast fault separates the Santa Monica Mountains from the coastal formations between La Piedra State Beach and Corral Beach. The portion of ASBS 24 between La Piedra State Beach area and the south extents of Broad Beach, south of the Malibu Coast Fault, consists of Malibu Bluff Coast Trancas Formation. The Trancas Formation consists chiefly of sandstone, mudstone, silty shale, and claystone. This formation extends north (upland from the ocean), varying distances between a few hundred feet to a few thousand feet. Southeast of Broad Beach, the ASBS and entire upland coastal area, bound to the north by the Malibu Coast Fault, comprise the Malibu Bluff Coast Monterey/Modelo Formation (SWRCB, 1979). The Monterey Formation consists of marine clay shale and laminated to platy siltstone that are variably diatomaceous, bituminous, phosphatic, siliceous, or cherty, and interbedded altered vitric tuffs and fine- to medium-grained sandstone that locally is schist bearing.

The Malibu bluff coast is triangular with its widest point at Point Dume. This region is structurally the most complex within the ASBS. The rocks are highly folded and steeply dipping so that very different rock types lie next to each other. The western part of this bluff coast from little Sycamore Canyon to Trancas Beach is made up of older Tertiary (Miocene) erosion-resistant rocks of the Trancas Formation. The white cliffs of Paradise Cove are outcrops of the Miocene age Modelo Formation which forms steep inclined bids from Zuma Beach eastward to Corral Beach. This formation is predominantly siliceous shale and was probably formed in the deep sea. The headland at Point Dume is highly resistant igneous breccia which has protected the softer sedimentary shale behind it from erosion. In addition to the Miocene deposits, there is an irregular veneer of Pleistocene marine terrace deposits on the bluff between the ocean and the mountains adjacent to the eastern section of the ASBS. This is a reddish, poorly stratified, and sorted material, which is soft and easily dissected. It tends to form steep-sided stream gullies and sea cliffs (SWRCB, 2008).

The geologic features within the ASBS 24 drainage area are shown in Figure 2-2. Map symbols used along the coastal area were defined using the National Geologic Map Database. Pleistocene marine terrace deposits along the shoreline include the Trancas and Monterey Formations. The symbols used to depict general costal geologic features in Figure 2-2 include the following:

- Qa – Alluvial gravel, sand, and clay of flood plains.
- Qaf – Artificial cut and fill.
- Qao – Older dissected alluvial gravel, sand and clay; on coastal area deposited in part on a wave-cut platform, forms several terraces.
- Qg – Gravel and sand of major stream channels.
- Qls – Landslide debris.
- Qos – Old dune sand at Point Dume.
- Qs – Beach Sand.
- Tr – Trancas Formation composed of marine sandstone, mudstone, silty shale, and claystone.
- Tmt – Modelo/Monterey Formation composed of marine clay shale and laminated to platy siltstone with sandstone.

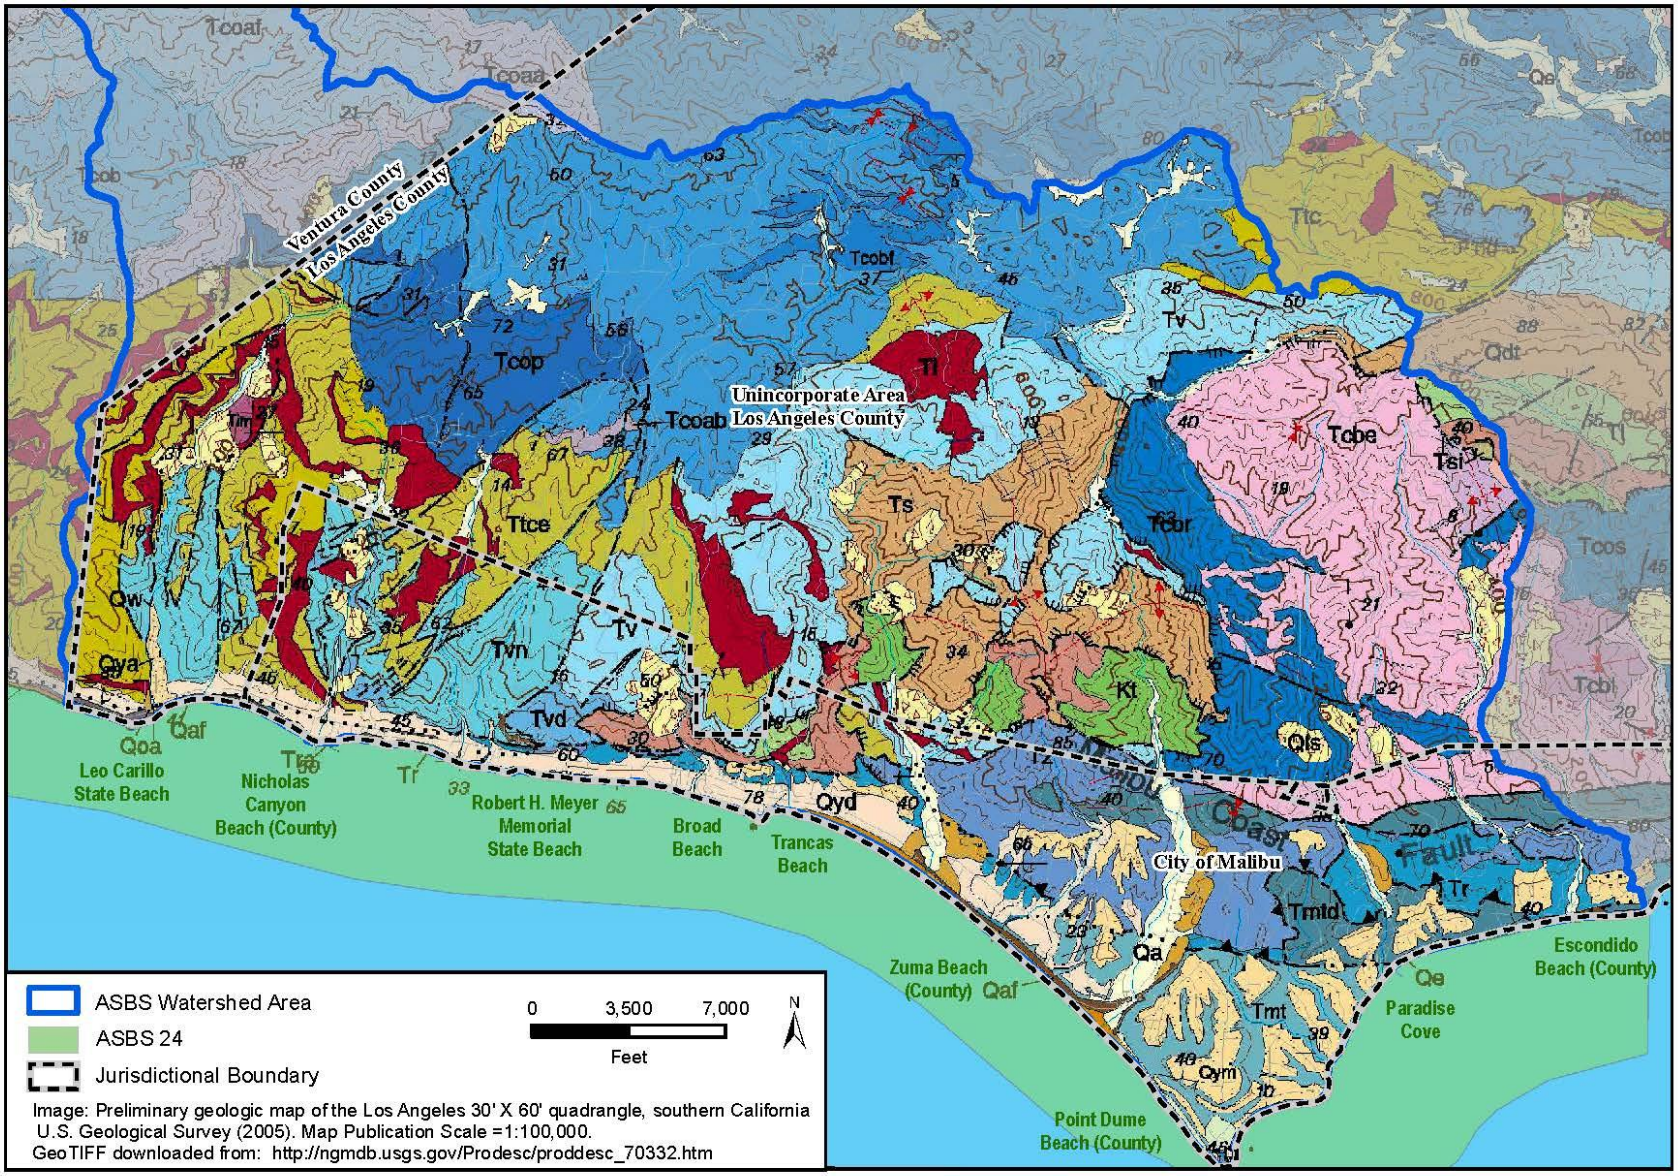

Figure 2-2. Geology Map of Overall ASBS 24 Drainage Area

2.3 Site Hydrology

The Santa Monica Mountains within the ASBS watershed generally slope towards the south to southwest. Except for the lower laying and relatively flat portion of the coast north of Point Dume extending to Broad Beach, the coast is lined with a steep bluff area that varies in height. Slopes along the coast above the bluff are gentle to moderate, with gradients typically between 2% and 20%. Inland, the watershed consists of much steeper terrain (typically 3:1 or steeper) covered with native coastal vegetation.

The Santa Monica Mountains have formed various peaks and valleys that collect runoff into 21 natural streams and gullies that drain to ASBS 24. Outside of this network of natural streams, 39 storm drain outfalls 18 inches in diameter or larger fall under the Parties' responsibility. Typically, the drainage areas to these outfalls consist of open space and/or development. The areas of development primarily include residential properties occupied by single-family dwellings surrounded by maintained landscaping along with associated roadways. The state-maintained PCH with various associated storm drain inlets extends across the length of the watershed near the coastline.

2.4 Monitoring Activities

2.4.1 2013 Regional Monitoring Program

As part of the exception process, LACDPW and the City participated in the Bight 2008 and Bight 2013 ASBS Planning Committee (Committee) with the State Board, the Southern California Coastal Water Research Project (SCCWRP), and other ASBS dischargers in Southern California. Together, the Committee developed a Regional ASBS Work Plan that is based on the Special Protections document. The Regional ASBS Work Plan is intended to provide compliance guidance to applicants of the General Exception in Southern California that wish to participate in the Southern California Bight 2013 Regional Monitoring Program (Bight 2013).

All outfalls that are equal to or greater than 18 inches in diameter are required to be monitored for oil and grease, total suspended solids (TSS), and toxicity, while outfalls that are equal to or greater than 36 inches in diameter are required to be monitored for metals, polynuclear aromatic hydrocarbons (PAHs), pyrethroids, organophosphorus pesticides, and nutrients (ammonia, nitrate, and phosphates) in addition to oil and grease, TSS, and toxicity. Furthermore, each discharger participating in the Regional Monitoring Program is required to monitor one ocean receiving water station which is representative of worst-case discharge conditions (i.e., co-located at a large drain greater than 36 inches, if possible).

As participants in the Bight 2013, LACDPW monitored 21 storm drains along ASBS 24, nine of which are operated by LACFCD, and 12 of which are operated by the County. Additionally, the City of Malibu, which owns storm drain inlets that drain to ASBS 24 via outfalls that are privately owned, monitor three outfalls located along Broad Beach; other private outfalls with City maintained inlets were not proposed to be monitored due to being inaccessible.

The ASBS Special Protections monitoring data used in this document were collected and analyzed during the 2012-2013 and 2013-2014 wet seasons. The monitoring performed complies with the monitoring requirements of the Regional Monitoring Program through the identification of water quality impacts to ASBS 24 during storm events. The Special Protections document describes the following two types of monitoring programs:

1. **Core Discharge Monitoring** – collecting and analyzing wet weather runoff from the discharge of outfalls during a storm event.
2. **Ocean Receiving Water Monitoring** – collecting and analyzing samples from the ocean before and after a storm event at two locations (i.e., directly in front of the discharge and at a reference site removed from the discharge). For the monitoring performed during the 2012-2014 wet weather season, ocean receiving water monitoring at the discharge site was the responsibility of the discharger, while reference station monitoring was performed by SCCWRP.

2.5 ASBS 24 OUTFALL DESCRIPTIONS

A description of the point source outfalls is provided that includes the location, size, ownership, and tributary general land use. LACDPW identified 11 storm drain outfalls having a diameter equal to or greater than 18 inches that drain to ASBS 24 and are owned and maintained by the County. Nine storm drain outfalls that have a diameter greater than or equal to 18 inches and drain to ASBS 24 are owned and maintained by the District. These nine outfalls occur along Broad Beach and Escondido Beach and convey runoff from upstream neighborhoods and PCH. The City identified eight privately owned storm drain outfalls with City maintained inlets that have diameters equal to or greater than 18 inches. These storm drains convey runoff from Broad Beach Road and Wildlife Road to the storm drain outfalls located along Broad Beach and the seaside cliffs of Little Dume Cove. An additional 10 storm drain outfalls are currently of undetermined ownership. These storm drains with undetermined ownership convey flow from PCH and upstream neighborhoods. These 39 storm drain outfalls are considered point source discharges of storm water to ASBS 24 and are described in the following section. Figure 2-3 shows the outfall locations.

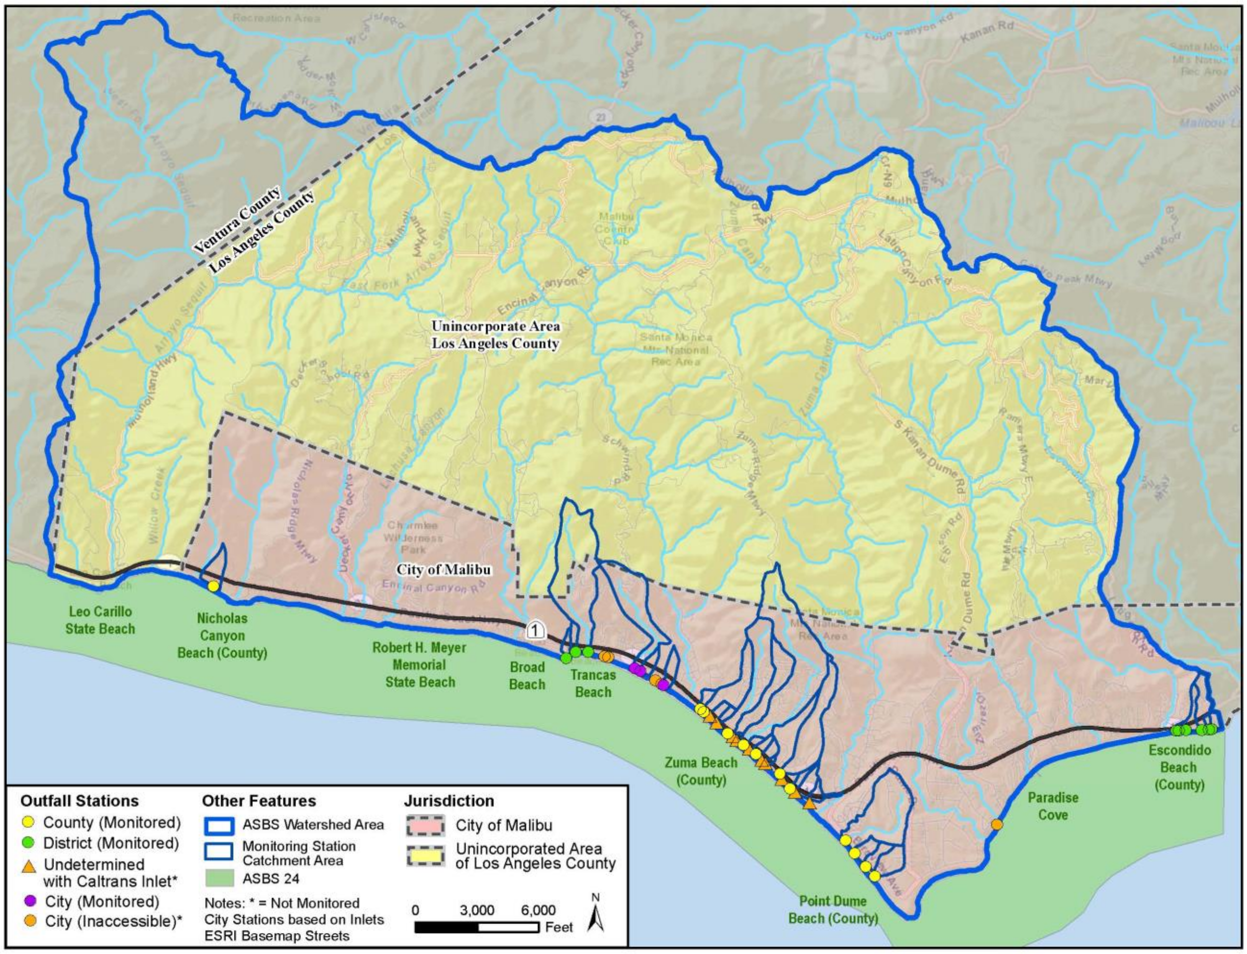

Figure 2-3. ASBS Outfall Location Map

2.5.1 County Outfalls

The 11 outfalls that fall under the jurisdiction of the County are located along Zuma Beach (six outfalls), Westward Beach (four outfalls) and Nicholas Beach (one outfall). The location of each County outfall is provided on Table 2-2 and show in Figure 2-4. A summary, including the diameter, monitoring data collected at each outfall pipe, and the observed flow connection (or absence), is provided on Table 2-3. A description of each outfall is provided in the text following Figure 2-4.

Table 2-2. County Outfall Locations and Diameters

Beach Location	Site Name	Latitude	Longitude	Pipe Diameter (inches)
Zuma Beach	ASBS-004	34.028038	-118.840179	24
	ASBS-005	34.027683	-118.839637	36
	ASBS-008	34.024833	-118.835784	24
	ASBS-011	34.023258	-118.833213	24

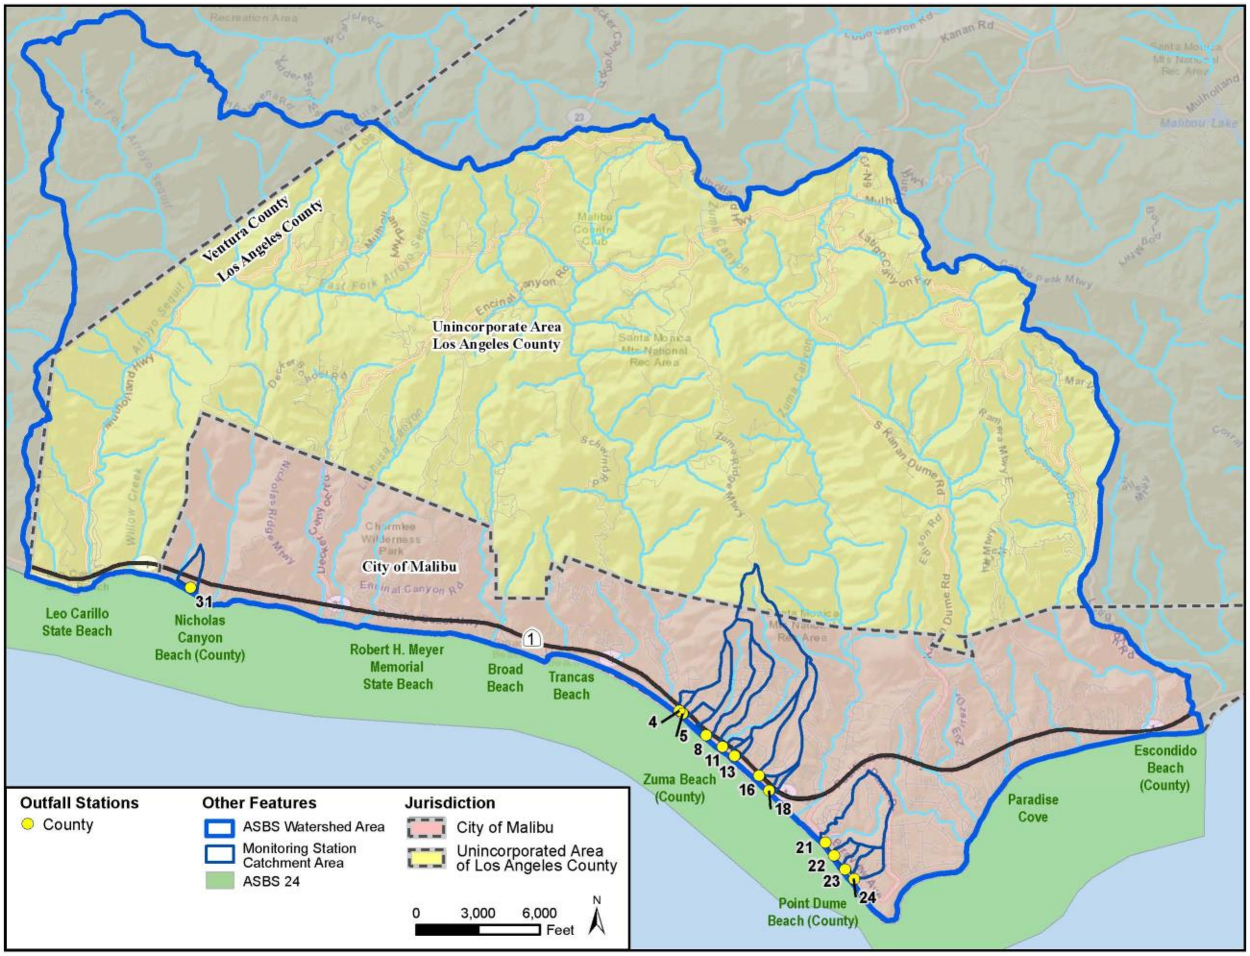

Figure 2-4. County ASBS Outfall Location Map

Zuma Beach Outfalls

ASBS-004 is a 24-inch outfall located at the northern end of Zuma Beach, adjacent to the northernmost parking lot along Zuma Beach Access Road (Figure 2-5). This outfall is accessible during all tides and was sampled during three monitored storm events (February 19 and March 8, 2013 and February 28, 2014). The watershed draining to ASBS-004 is 9.8 acres in size and the surrounding landscape at ASBS-004 consists of a gradually sloping, broad sandy beach.

Figure 2-5. ASBS-004 Outfall

ASBS-005 is a 36-inch outfall located at the northern end of Zuma Beach, adjacent to the northernmost parking lot along Zuma Beach Access Road, and directly across from the intersection of Guernsey Avenue with PCH (Figure 2-6). This outfall is accessible during all tides and was sampled during the February 19, March 8, 2013, and February 28, 2014, storm events. The watershed draining to ASBS-005 is 65.8 acres in size and the surrounding landscape at ASBS-005 consists of a gradually sloping, broad sandy beach.

Figure 2-6. ASBS-005 Outfall

ASBS-008 is a 24-inch outfall located at the northern end of Zuma Beach, near a parking lot along Zuma Beach Access Road (Figure 2-7). This outfall is accessible during all tides and was sampled during the March 8, 2013, storm event (it was added to the list of monitored sites following the February 19, 2013, storm event). The watershed draining to ASBS-008 is 114.8 acres in size and the surrounding landscape at ASBS-008 consists of a gradually sloping, broad sandy beach.

Figure 2-7. ASBS-008 Outfall

ASBS-011 is a 24-inch outfall located in middle portion of Zuma Beach, adjacent to a parking lot along Zuma Beach Access Road (Figure 2-8). This outfall is accessible during all tides and was sampled during three monitored storm events (February 19 and March 8, 2013, and February 28, 2014). The watershed draining to ASBS-011 is 7.0 acres in size and the surrounding landscape at ASBS-011 consists of a gradually sloping, broad sandy beach.

Figure 2-8. ASBS-011 Outfall

ASBS-013 is an 18-inch outfall located in middle portion of Zuma Beach, adjacent to a parking lot along Zuma Beach Access Road (Figure 2-9). This outfall is accessible during all tides and was sampled during only the March 8, 2013, and February 28, 2014, storm events, as it did not flow during the February 19, 2013, storm event. The watershed draining to ASBS-013 is 10.4 acres in size and the surrounding landscape at ASBS-013 consists of a gradually sloping, broad sandy beach.

Figure 2-9. ASBS-013 Outfall

ASBS-016 is a 60-inch outfall located in middle portion of Zuma Beach, adjacent to a parking lot along Zuma Beach Access Road (Figure 2-10). This box culvert outfall is accessible during all tides and was sampled during only the March 8, 2013, and February 28, 2014, storm events, as it did not flow during the February 19, 2013, storm event. Flow monitoring equipment was installed in this outfall. The watershed draining to ASBS-016 is 115.1 acres in size and the surrounding landscape at ASBS-016 consists of a gradually sloping, broad sandy beach.

Figure 2-10. ASBS-016 Outfall

ASBS-018 is a 24-inch outfall located at the southern end of Zuma Beach, adjacent to a lifeguard station in the middle of the beach off Zuma Beach Access Road (Figure 2-11). This outfall is accessible during all tides and was sampled during three monitored storm events (February 19 and March 8, 2013, and February 28, 2014). The watershed draining to ASBS-018 is 10.0 acres in size and the surrounding landscape consists of a gradually sloping, broad sandy beach.

Figure 2-11. ASBS-018 Outfall

Westward Beach Outfalls

ASBS-021 is a 48-inch outfall located at the northern end of Westward Beach, adjacent to an entrance gate near the intersection of Birdview Ave. and Westward Beach Road (Figure 2-12). This outfall is accessible during all tides and was sampled during three monitored storm events (February 19 and March 8, 2013, and February 28, 2014).The watershed draining to ASBS-021 is 170 acres in size and the surrounding landscape at ASBS-021 consists of a gradually sloping, broad sandy beach.

Figure 2-12. ASBS-021 Outfall

ASBS-022 is a 36-inch outfall located at the northern end of Westward Beach, midway between the entrance gate and the edge of the parking lot on Westward Beach Road (Figure 2-13). This outfall is accessible during all tides and was sampled during three monitored storm events (February 19 and March 8, 2013, and February 28, 2014).. The watershed draining to ASBS-022 is 18.4 acres in size and the surrounding landscape at ASBS-022 consists of a gradually sloping, broad sandy beach.

Figure 2-13. ASBS-022 Outfall

ASBS-023 is a 42-inch outfall located in the middle portion of Westward Beach, approximately 100 meters (m) north of the parking lot on Westward Beach Road (Figure 2-14). This outfall is difficult to find since it is hidden by ice plant. ASBS-023 is accessible during all tides and was sampled during three monitored storm events (February 19 and March 8, 2013, and February 28, 2014). The watershed draining to ASBS-023 is 18.4 acres in size and the surrounding landscape at ASBS-023 consists of a gradually sloping, broad sandy beach.

Figure 2-14. ASBS-023 Outfall

ASBS-024 is a 24-inch outfall located in the middle portion of Westward Beach, approximately 100 m south of the edge of the parking lot on Westward Beach Road (Figure 2-15). This outfall is accessible during all tides and was sampled during three monitored storm events (February 19 and March 8, 2013, and February 28, 2014). The watershed draining to ASBS-024 is 34.9 acres in size and the surrounding landscape at ASBS-024 consists of a gradually sloping, broad sandy beach.

Figure 2-15. ASBS-024 Outfall

Nicholas Beach Outfall

ASBS-031 is a 22-inch outfall located in the middle portion of Nicholas Beach, at the base of Nicholas Beach Road (Figure 2-16). This outfall is accessible during all tides; however, no flow was observed during either of the monitored storm events. The watershed draining to ASBS-031 is 30.1 acres in size and the surrounding landscape at ASBS-031 consists of a gradually sloping, broad sandy beach.

Figure 2-16. ASBS-031 Outfall

2.5.2 Outfalls Whose Ownership is Undetermined [With Inlets Owned by Caltrans]

Along Zuma Beach, 10 outfalls drain to ASBS 24 and are equal to or greater than 18 inches in diameter; however, ownership has not been determined. These outfalls have inlets maintained by Caltrans. A brief summary of the location and diameter of each of these outfalls with undetermined ownership is provided on Table 2-4, and Figure 2-17 shows the outfall locations. A description of each outfall is provided in the text that follows Figure 2-17.

Table 2-4. Locations and Diameters of Outfalls with Undetermined Ownership

Beach Location	Site Name	Latitude	Longitude	Pipe diameter (inches)
Zuma Beach	ASBS-006	34.027069	-118.838623	24
	ASBS-007	34.026184	-118.837539	24
	ASBS-009	34.024349	-118.834899	24
	ASBS-010	34.023872	-118.834304	18
	ASBS-012	34.022735	-118.832267	24
	ASBS-014	34.021247	-118.830307	24
	ASBS-015	34.02082	-118.829696	18
	ASBS-017	34.018711	-118.827049	30
	ASBS-019	34.016979	-118.824882	24
	ASBS-020	34.015602	-118.822525	36

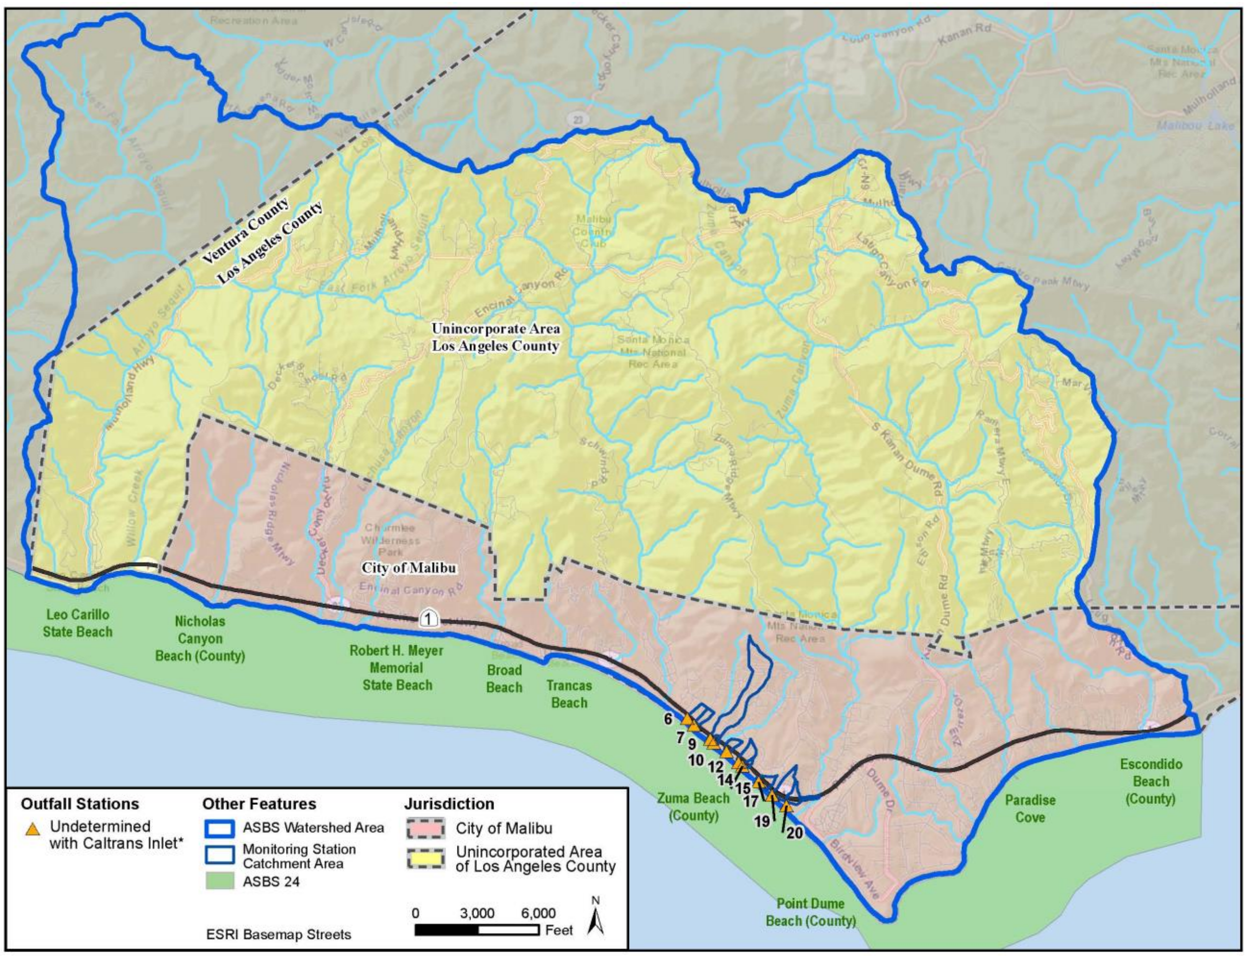

Figure 2-17. Undetermined Ownership (with Caltrans Inlets) ASBS Outfall Location Map

Zuma Beach Outfalls

ASBS-006 is a 24-inch outfall located in the northern portion of Zuma Beach, adjacent to a parking lot along Zuma Beach Access Road (Figure 2-18). The watershed draining to ASBS-006 is 10.2 acres in size and the surrounding landscape at ASBS-006 consists of a gradually sloping, broad sandy beach.

Figure 2-18. ASBS-006 Outfall

ASBS-007 is a 24-inch outfall located in the northern portion of Zuma Beach, adjacent to a parking lot along Zuma Beach Access Road (Figure 2-19). The watershed draining to ASBS-007 is 7.8 acres in size and the surrounding landscape at the outfall consists of a gradually sloping, broad sandy beach.

Figure 2-19. ASBS-007 Outfall

ASBS-009 is a 24-inch outfall located in the middle portion of Zuma Beach, adjacent to a parking lot along Zuma Beach Access Road, approximately 90 m south of Seadrift Cove (Figure 2-20). The watershed draining to ASBS-009 is 78.6 acres in size and the surrounding landscape at ASBS-009 consists of a gradually sloping, broad sandy beach.

Figure 2-20. ASBS-009 Outfall

ASBS-010 is an 18-inch outfall located in the middle portion of Zuma Beach, adjacent to a parking lot along Zuma Beach Access Road, approximately 170 m south of Seadrift Cove (Figure 2-21). The watershed draining to ASBS-010 is 2.4 acres in size and the surrounding landscape at ASBS-010 consists of a gradually sloping, broad sandy beach.

Figure 2-21. ASBS-010 Outfall

ASBS-012 is a 24-inch outfall located in the middle portion of Zuma Beach, adjacent to a parking lot along Zuma Beach Access Road, approximately 400 m south of Seadrift Cove (Figure 2-22). The watershed draining to ASBS-012 is 7.0 acres in size and the surrounding landscape at ASBS-012 consists of a gradually sloping, broad sandy beach.

Figure 2-22. ASBS-012 Outfall

ASBS-014 is a 24-inch outfall located in the middle portion of Zuma Beach, adjacent to a parking lot along Zuma Beach Access Road, directly in front of the Beaches and Harbors maintenance yard (Figure 2-23). The watershed draining to ASBS-014 is 12.1 acres in size and the surrounding landscape at ASBS-014 consists of a gradually sloping, broad sandy beach.

Figure 2-23. ASBS-014 Outfall

ASBS-015 is an 18-inch outfall located in the middle portion of Zuma Beach, adjacent to a parking lot along Zuma Beach Access Road, approximately 65 m south of the Beaches and Harbors maintenance yard (Figure 2-24). The watershed draining to ASBS-015 is 3.0 acres in size and the surrounding landscape at ASBS-015 consists of a gradually sloping, broad sandy beach.

Figure 2-24. ASBS-015 Outfall

ASBS-017 is an 18-inch outfall located in the southern portion of Zuma Beach, adjacent to a parking lot along Zuma Beach Access Road, directly in front of a helicopter landing pad (Figure 2-25). The watershed draining to ASBS-017 is 8.8 acres in size and the surrounding landscape at ASBS-017 consists of a gradually sloping, broad sandy beach.

Figure 2-25. ASBS-017 Outfall

ASBS-019 is a 24-inch outfall located in the southern portion of Zuma Beach, adjacent to a parking lot along Zuma Beach Access Road, approximately 420 m north of the Zuma Beach entrance gate (Figure 2-26). The watershed draining to ASBS-019 is 20.8 acres in size and the surrounding landscape at the outfall consists of a gradually sloping, broad sandy beach.

Figure 2-26. ASBS-019 Outfall

ASBS-020 is a 36-inch outfall located in the southern portion of Zuma Beach, adjacent to a parking lot along Zuma Beach Access Road, approximately 200 m north of the Zuma Beach entrance gate, in the center of the beach (Figure 2-27). The watershed draining to ASBS-020 is 12.3 acres in size and the surrounding landscape at ASBS-020 consists of a gradually sloping, broad sandy beach.

Figure 2-27. ASBS-020 Outfall

2.5.3 District Outfalls

The nine outfalls that fall under the jurisdiction of the District are located along Broad Beach (three outfalls) and Escondido Beach (six outfalls). The location of each County Outfall is provided on Table 2-5 and shown on Figure 2-28. A summary, including the diameter, monitoring data collected at each outfall pipe, and the observed flow connection (or absence), is provided on Table 2-6. A description of each outfall is provided in the text following Figure 2-28.

Table 2-5. District Outfall Locations and Diameters

Beach Location	Site Name	Latitude	Longitude	Pipe Diameter (inches)
Broad Beach	ASBS-001	34.034702	-118.861846	24
	ASBS-002	34.035556	-118.860328	18
	ASBS-003	34.035526	-118.858276	51
Escondido Beach	ASBS-025	34.025646	-118.763717	18
	ASBS-026	34.025653	-118.763336	24
	ASBS-027	34.025726	-118.762153	24
	ASBS-028	34.025772	-118.75962	36
	ASBS-029	34.025856	-118.758468	18
	ASBS-030	34.025897	-118.757987	18

Table 2-6. District Outfall Locations, Diameters, and Monitoring Information

Beach Location	Site Name	Pipe Diameter (in)	Analyses Performed	Storm Events Analyzed			Did flow reach receiving water?		
				2/19/2013	3/8/2013	2/28/2014	2/19/2013	3/8/2013	2/28/2014
Broad Beach	ASBS-001	24	TSS, O&G, Bivalve Toxicity	x	x	x	Yes	Yes	Yes

	ASBS-028**	36	Full Chem. List*; Bivalve Toxicity	x	x	x	Yes	Yes	Yes
	ASBS-029	18	TSS, O&G, Bivalve Toxicity	x	x	x	Yes	No	Yes
	ASBS-030	18	TSS, O&G, Bivalve Toxicity	x	x	x	No	No	Yes
Ocean Receiving Water	S02	N/A	Full Chem. List*; Kelp, Bivalve, and Echinoderm Toxicity	x	x	x	Not applicable		

*Full chemistry list= TSS, oil and grease, metals, PAHs, pyrethroids, OP pesticides, ammonia, nitrate and total phosphorus.

* *Flow monitoring equipment installed in this outfall pipe.

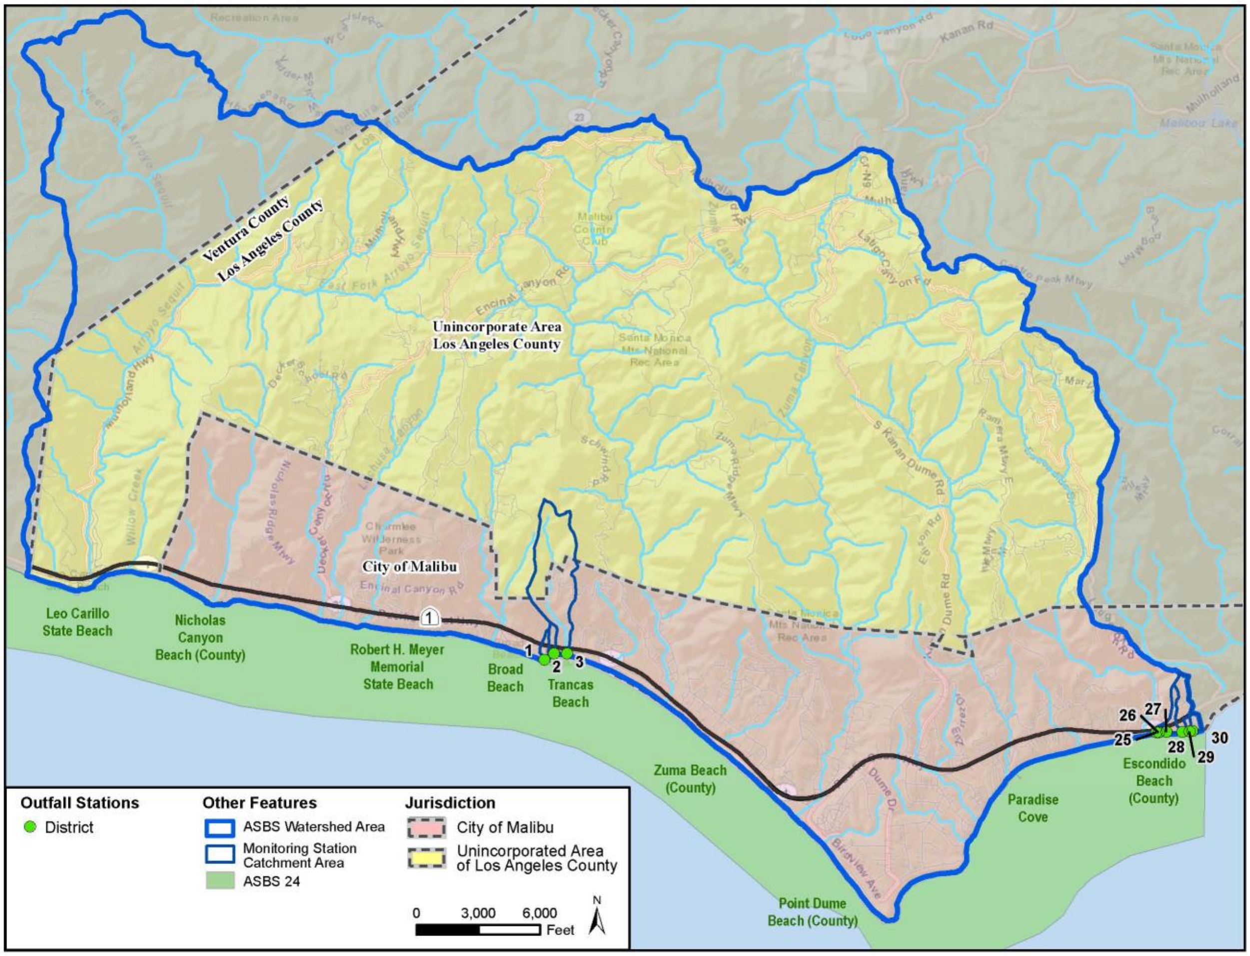

Figure 2-28. District ASBS Outfall Location Map

Broad Beach Outfalls

ASBS-001 is a 24-inch outfall located at the northern end of Broad Beach, along Point Lechuza, beneath a large residence (Figure 2-29). This outfall is inaccessible during high tide and was sampled during three monitored storm events (February 19 and March 8, 2013, and February 28, 2014) from a manhole located approximately 140 ft. from the beach on Point Lechuza Drive. The watershed draining to ASBS-001 is 9.4 acres in size and the area surrounding the outfall consists of a rocky intertidal area interspersed along a narrow, sandy beach.

Figure 2-29. ASBS-001 Outfall

ASBS-002 is an 18-inch outfall located at the northern end of Broad Beach, south of Point Lechuza, adjacent to a residence that was undergoing construction (Figure 2-30). This outfall is inaccessible during high tide but was successfully sampled during three monitored storm events (February 19 and March 8, 2013, and February 28, 2014).The watershed draining to ASBS-002 is 11.0 acres in size and the area surrounding the outfall consists of a narrow, sandy beach with intermittent rocky reef.

Figure 2-30. ASBS-002 Outfall

ASBS-003 is a 51-inch outfall located at the northern end of Broad Beach, south of Point Lechuza, between two residences (Figure 2-31). This outfall is inaccessible during high tide but was successfully sampled during three monitored storm events (February 19 and March 8, 2013 and February 28, 2014). The watershed draining to ASBS-003 is 253.5 acres in size and a rocky intertidal area is located directly west of the outfall.

Figure 2-31. ASBS-003 Outfall

Escondido Beach Outfalls

ASBS-025 is an 18-inch outfall located at the southern end of Escondido Beach, south of the Malibu Cove Colony Drive entrance off PCH (Figure 2-32). The outfall is integrated with the foundation of a residence and discharges directly onto the sand between two residences. This outfall is inaccessible during high tide but was successfully sampled during three monitored storm events (February 19 and March 8, 2013, and February 28, 2014). The watershed draining to ASBS-025 is 0.8 acres in size and the landscape surrounding the outfall is composed of a steep, sandy beach.

Figure 2-32. ASBS-025 Outfall

ASBS-026 is a 24-inch outfall located at the southern end of Escondido Beach, south of the Malibu Cove Colony Drive entrance off PCH (approximately 30 m southeast of ASBS-025). The outfall is integrated with the foundation of a residence and discharges directly onto the sand beneath the residence (Figure 2-33). This outfall is inaccessible during high tide but was successfully sampled during three monitored storm events (February 19 and March 8, 2013, and February 28, 2014). The watershed draining to ASBS-026 is 2.5 acres in size and the landscape surrounding the outfall is composed of a steep, sandy beach.

Figure 2-33. ASBS-026 Outfall

ASBS-027 is a 24-inch outfall located at the southern end of Escondido Beach, approximately 300 m east of the Malibu Cove Colony Drive entrance off PCH (Figure 2-34). The outfall is integrated with the foundation of a residence and discharges directly onto the sand beneath the residence. This outfall is inaccessible during high tide but was successfully sampled during three monitored storm events (February 19 and March 8, 2013, and February 28, 2014). The watershed draining to ASBS-027 is 18.9 acres in size and the landscape surrounding the outfall is composed of a steep, sandy beach.

Figure 2-34. ASBS-027 Outfall

ASBS-028 is a 36-inch outfall located at the southern end of Escondido Beach, approximately 500 m east of the Malibu Cove Colony Drive entrance off PCH (Figure 2-35). The outfall is integrated with the foundation of a residence and discharges directly onto the sand beneath the residence. Flow monitoring equipment was installed in this outfall near the inlet on Malibu Cove Colony Drive. This outfall is inaccessible during high tide but was successfully sampled during three monitored storm events (February 19 and March 8, 2013, and February 28, 2014). The watershed draining to ASBS-028 is 36.0 acres in size and the landscape surrounding the outfall is composed of a steep, sandy beach.

Figure 2-35. ASBS-028 Outfall

ASBS-029 is an 18-inch outfall located at the southern end of Escondido Beach, near the end of Malibu Cove Colony Drive (Figure 2-36). The outfall lies between two residences and discharges directly onto the sand. This outfall is inaccessible during high tide but was successfully sampled three monitored storm events (February 19 and March 8, 2013, and February 28, 2014). The watershed draining to ASBS-029 is 3.8 acres in size and the landscape surrounding the outfall is composed of a steep, sandy beach.

Figure 2-36. ASBS-029 Outfall

ASBS-030 is an 18-inch outfall located at the southern end of Escondido Beach, near the end of Malibu Cove Colony Drive (approximately 45 m east of ASBS-029). The outfall is integrated with the foundation of a residence and discharges directly onto the sand beneath the residence (Figure 2-37). This outfall is inaccessible during high tide but was successfully sampled during three monitored storm events (February 19 and March 8, 2013, and February 28, 2014). The watershed draining to ASBS-030 is 8.9 acres in size and the landscape surrounding the outfall is composed of a steep, sandy beach.

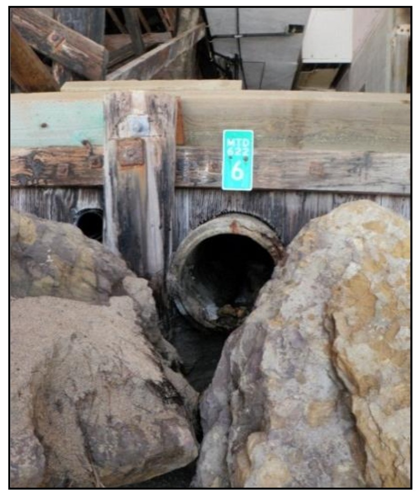

Figure 2-37. ASBS-030 Outfall

2.5.4 Private Outfalls with Inlets Owned by the City

Eight outfalls that are greater than, or equal to, 18 inches in diameter and located along Broad Beach and Little Dume Beach are privately owned with inlets maintained by the City. Currently, three of the outfalls along Broad Beach are being monitored as part of Bight 2013 and the compliance requirements of the General Exception. Although the City maintains ownership of the inlets for each of these storm drains, the ownership status of the outfalls is privately owned. The other five private outfalls with City maintained inlets along Broad Beach and Little Dume Cove that are greater than, or equal to, 18 inches in diameter are not being monitored due to inaccessibility during storm events or due to locations high on Bluffs. A brief summary of the location and diameter for each of these outfall pipes is provided on Table 2-7. Figure 2-38 shows the locations of these private outfalls with City maintained inlets, and a description of each outfall is provided in the text following Figure 2-38.

Table 2-7. City Outfall Locations, Diameters, and Monitoring Information

Beach Location	Site Name	City Outfall ID	City Inlet ID	Latitude	Longitude	Pipe diameter (inches)
Broad Beach	24-BB-01*	24-BB-01Z	24-BB-01A	34.03118	-118.84615	24
	24-BB-02*	24-BB-02Z	24-BB-02B	34.03302	-118.84988	18
	24-BB-03*	24-BB-03Z	24-BB-03A	34.0334	-118.85082	30
	ASBS-B	ASBS-B-Z**	ASBS-B-A	34.03499	-118.85567	18
	ASBS-C	ASBS-C-Z	ASBS-C-A	34.03485	-118.85502	30
	ASBS-F	ASBS-F-Z**	ASBS-F-A	34.03186	-118.84748	24
	ASBS-G	ASBS-G-Z	ASBS-G-A	34.03134	-118.84649	24
Little Dume Beach	ASBS-I	ASBS-I-Z	ASBS-I-A	34.01292	-118.79237	18

*Site currently undergoing monitoring in accordance with the General Exception.
**Site with no visible outfall.

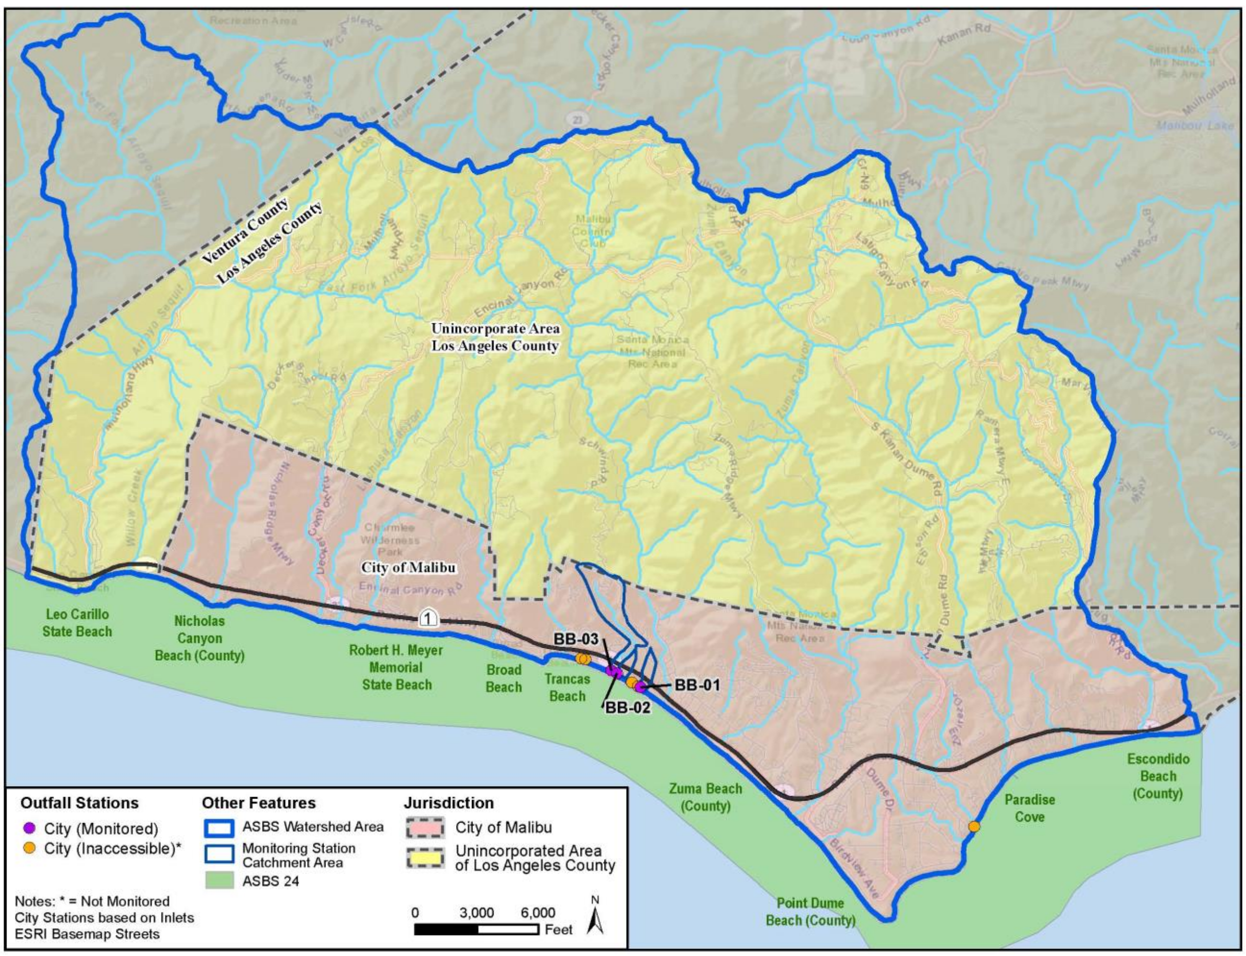

Figure 2-38. City ASBS Outfall Location Map

Broad Beach Outfalls

Site 24-BB-01Z is a 24-inch outfall located at the southern end of Broad Beach, near the intersection of Trancas Canyon Road and PCH (Figure 2-39). The outfall is located behind rock revetment and is inaccessible during high tide or dangerous surf conditions. This outfall was successfully visited during the February 28, 2014, storm event, but no flow was observed. The watershed draining to 24-BB-01Z is 19.9 acres in size and consists primarily of single family residences, commercial, transportation right-of-way (ROW), and PCH ROW land uses. The landscape surrounding the outfall is composed of a rock revetment and narrow, sandy beach with near-shore reef and kelp.

Figure 2-39. 24-BB-01Z Outfall

Site 24-BB-02Z is an 18-inch outfall located at the southern end of Broad Beach, approximately 200 meters south of the intersection of Lunita Road and PCH (Figure 2-40), when viewed on an aerial. This outfall was successfully sampled during the February 28, 2014 and December 1, 2014 storm events. The outfall is located among the shoreline rock revetment and is inaccessible during high tide or dangerous surf conditions. The watershed draining to 24-BB-02Z is 13.9 acres in size and consists primarily of single family residences, vacant, transportation ROW, and PCH ROW land uses. The landscape surrounding the outfall is composed of rock revetment a narrow, sandy beach.

Figure 2-40. 24-BB-02Z Outfall

Figure 2-41. 24-BB-03Z Outfall

Site 24-BB-03Z is a 30-inch outfall located at the southern end of Broad Beach, approximately 100 meters south of the intersection of Lunita Road and PCH (Figure 2-41), when viewed on an aerial. This outfall was successfully sampled during the February 28, 2014 and December 1, 2014 storm events The outfall is located among the shoreline rock revetment and is inaccessible during high tide or dangerous surf conditions. The watershed draining to 24-BB-03Z is 127.6 acres in size and consists primarily of rural residential, vacant, single family residences, transportation ROW, and PCH ROW land uses. The landscape surrounding the outfall is composed of rock revetment and a narrow, sandy beach.

Site ASBS-B-Z (outfall has a potential correlation to the SWQCB list as SAD790, although not confirmed) is an 18-inch outfall located at the northern end of Broad Beach, directly across from the intersection of La Herran Road and PCH, when viewed on an aerial. The City owns the inlet to this site, but existence and ownership of the outfall has not been determined, as the outlet may have been reconfigured during installation of the private rock revetment. The outfall may be located among shoreline riprap; however, the outfall is currently not visible and thus, considered inaccessible. No sampling has been performed at this site. The landscape surrounding the outfall is composed of rock revetment and a narrow, sandy beach with some near-shore reef.

Figure 2-42. ASBS-C Outfall

Site ASBS-C-Z is a 30-inch outfall located at the northern end of Broad Beach, approximately 30 meters south of the intersection of La Herran Road and PCH (Figure 2-42), when viewed on an aerial. While the City owns the inlet to this outfall, the outfall is considered private. The outfall is located behind and partially buried by the rock revetment and is inaccessible at all times due to the steep rock revetment that surrounds the outfall. No sampling has been performed at this site. The watershed draining to ASBS-C is 66.8 acres in size and consists primarily of single family residences, vacant, transportation ROW, and PCH ROW land uses. The landscape surrounding the outfall is composed of rock revetment and a narrow, sandy beach with some near-shore reef.

Site ASBS-F is a 24-inch outfall located at the southern end of Broad Beach, approximately 350 meters northeast of the intersection of Trancas Canyon Road and PCH. The outfall is located among shoreline riprap; however, the outfall is currently not visible and thus, considered inaccessible. No sampling has been performed at this site, and the landscape surrounding the outfall is composed of a rock revetment and narrow, sandy beach.

Site ASBS-G (outfall has a potential correlation to SWQCB list as MUG232 or SAD900, although not confirmed) has a 24-inch outfall located at the southern end of Broad Beach, approximately 200 meters northeast of the intersection of Trancas Canyon Road and PCH. The outfall is located among shoreline riprap; however, the outfall is currently not visible and thus, considered inaccessible. No sampling has been performed at this site. The landscape surrounding the outfall is composed of a narrow, sandy beach.

Little Dume Beach Outfalls

Site ASBS-I (also referred to as PC02 in other documents) is an 18-inch outfall located on Little Dume Beach, approximately 100 m east of the end of Wildlife Drive (Figure 2-43). The outfall is located on a cliff-side bluff and is inaccessible. No sampling has been performed at this site. The watershed draining to ASBS-I is 6.7 acres in size and the landscape surrounding the outfall is composed of a narrow, sandy beach with near-shore reef and kelp.

Figure 2-43. ASBS-I Outfall

2.6 ASBS 24 Compliance Plan Map

A Compliance Plan Map for the ASBS 24 watershed area has been created and can be updated using ESRI ArcMap 10. This map shows storm water conveyances and other storm drain features associated with surface drainage of storm water runoff, including catch basins, inlets/outlets, outfalls, storm drain lines, channels, and creeks. The map identifies core monitoring stations and shows the location of other outfalls equal to or greater than 18 inches that are private, state, or federal and not monitored by the Parties. Drainage areas for the core monitoring stations, areas of potential sheet flow, the planned Broad Beach Road biofiltration best management practices (BMPs), watershed sub-basins and flow directions within these sub-basins are depicted, as well as the overall ASBS 24 watershed area. The map includes the locations of waste and hazardous material storage areas (located on private commercial properties), sewage conveyances and treatment facilities, landslide zones, and roads. Jurisdictional boundaries for the unincorporated area of the County, the City, and state and federal lands within these areas are shown. This subsection of the Compliance Plan provides information regarding the Compliance Plan Map datasets and the procedures for updating applicable GIS files and the map.

2.6.1 Compliance Plan Map Files

The Compliance Plan Map includes several types of files, organized by file type, in the following folders:

- MXD – MXD files are the map documents produced in ESRI ArcMap. An MXD contains the map template (e.g., size, layout) and calls upon ESRI GIS shapefiles that are stored in the Shapefiles folder. The MXD contains a table of contents, text, and graphic elements, and specifies how data will be displayed. The MXD establishes relative file paths to the shapefiles. Currently, the MXD folder contains only one file: Compliance_Plan_Map.MXD. Additional versions of the map can be saved in this folder, as needed.

- Shapefiles – Shapefiles are GIS format data files that are called upon by the map. Changes to shapefiles will be reflected in the map if the map calls upon the data stored in the shapefile. A spreadsheet listing all of the shapefiles, contents, and sources is provided as Table 2-8.

- Data Files – Data files contain MS Excel spreadsheets, including those added as tables to the MXD. Changes to MS Excel files do not update the map. New or revised tables must be added to the MXD, and can be used to create XY events (based on latitude and longitude data in the table), or joined to existing shapefiles through a common field ID to append additional data fields to the GIS features.

Table 2-8 lists the GIS shapefiles used in the Compliance Plan Map by filename, and provides GIS feature types (e.g., points, lines, polygons), descriptions of the contents of the GIS file, information regarding the original source, and how to update the data in the Compliance Plan Map as needed. The file order in this table is based on the order of the items in the map legend (Figure 2-44).

2.6.2 Compliance Plan Map Update Procedures

Update procedures are provided by GIS shape file on Table 2-8 and are dependent upon original source and other considerations. Many of the original source GIS files were provided by LACDPW, some files by the City, and were received in GIS shapefile format; therefore, files have been maintained in shapefile format (i.e., not converted to geodatabase format). The County possesses a complete set of the files used to prepare the map (Compliance Plan Map dataset). As these base data layers are updated by the Parties in their primary GIS database, the revised GIS files can be provided to the County and copied in the local Compliance Plan Map dataset, processed, and used to replace the older file versions. The City and County/District Outfall Stations (and Other Outfalls) locations are maintained in separate shapefiles such that this information can be updated independently by each party and then reinserted into the GIS database without overwriting another parties' information. If the new filename is the same as the previous version, the new data should display within ArcMap when the file is replaced in the Shapefile folder. However, if the data attribute options have been updated, the symbology for the data layer should be checked in the table of contents to ensure that all values have a symbol and will be drawn. If the map layer does not display (i.e., a red exclamation point will appear in the table of contents next to the filename), check the data source file path and update as needed. GIS shapefiles should be clipped to the overall ASBS watershed area (GIS file), and geometry recalculated to update line lengths and polygon areas. All GIS data should be maintained in the following projected coordinate system: CA State Plane, Datum NAD83, Zone V, units Survey Feet for consistency.

In addition, GIS files can be edited within ESRI ArcMap to update map features and attribute data, such as a change in monitoring stations, a revision to the monitoring station catchment areas, the inclusion of monitoring data results to outfall locations, or the addition of new BMPs to the BMP shapefile. This process can be performed in an edit session using the Editing toolbar. Note that map labels on the map are currently static (i.e., have been converted to annotation stored in the map) to better control their placement. Therefore, text labels will need to be created for new features that are added to existing shapefiles or for new shapefile features for which map labeling is appropriate.

Facilities with hazardous material storage areas should be updated on an annual basis by requesting the Active Facility Inventory List from LA County Fire for Zip Code 90265. The address information can be formatted in an MS Excel spreadsheet for the geocoding process. After adding the table to ArcMap, run the geocoder tool, and clip the resulting shapefile to the ASBS 24 watershed area.

Updates can also be made to the MXD, such as adding new features layers, revising the layout, or other map template items to change the look of the map. New GIS files can also be easily added to the map as additional data become available related to compliance activities. Note that the map legend is static and will not automatically update when new GIS files are added to the MXD. The legend can be manually updated using the drawing and text tools or a new legend inserted. An MXD can be saved as a new file to maintain previous versions in the database.

Table 2-8. GIS Shapefiles Used in Compliance Plan Map

Filename	Type	Description	Original Source	To Update
LAC_ASBS24_Outfalls	Point	County and District Monitoring Stations in ASBS 24 Monitoring Program, including Core MS4 Outfalls, Outfalls that have Caltrans Inlets but undetermined ownership of Outfalls (not monitored) and Ocean Receiving Water Stations, and creek reference station. Includes ownership information.	Core Monitoring Stations provided by LADPW in table format and imported into GIS from an MS Excel spreadsheet using latitude and longitude data provided in file to map locations.	Station locations and attribute data can be edited in GIS to update file (i.e., add, remove, or change location or attribute data associated with monitoring stations).
City_Outfalls	Point	Outfalls identified for the City's ASBS 24 Monitoring Program. City has jurisdiction of inlets but outfalls were determined by City to be privately owned. Three of these eight Outfalls are monitored, and five are considered inaccessible. Includes the City's Ocean Receiving Water station.	Field notes in an MS PowerPoint file provided by the City. GIS file created using latitude and longitude data. Other outfalls ≥ 18 inches that were listed in the field notes but not included in monitoring program are provided in file called "Other_Outfalls_City_Recon".	Edit or replace GIS file as needed to add, remove, or change location or attribute data associated with monitoring stations.
Other_Outfalls_County_Recon	Point	This file contains outfalls that were identified in field reconnaissance activities by the County for which ownership is private or undetermined. These outfalls are not in the monitoring program. Not all outfalls were visible or could be verified.	Provided by LADPW in table format and imported into GIS from an MS Excel spreadsheet using latitude and longitude data fields provided in file.	Station locations and attribute data can be edited in GIS to update file. This file complements the LAC_ASBS24_Outfalls file as the outfalls ≥ 18 inches but not in County monitoring program as ownership is private or undetermined.
Other_Outfalls_City_Recon	Point	This file contains outfalls that were identified in field reconnaissance activities by the City of Malibu and were determined to be privately owned and were not included in the monitoring program. Not all outfalls were visible or could be verified.	Field notes in an MS PowerPoint file provided by the City. Tabular data imported into GIS using latitude and longitude data from field notes.	Station locations and attribute data can be edited in GIS to update file. This file complements the City_Outfalls that were also identified in the City recon activities, found to be privately owned but chosen for compliance monitoring.
Catchbasins_ws	Point	Catch basin locations within the ASBS 24 watershed area. Ownership or maintenance of catch basins given in file as: LACFCD for District, City, Road Maintenance Division or not listed (blank).	Based on integrating data from two different catch basin files and removing duplicates. One file provided by LADPW (used as primary data source), the other found on LA County GIS data portal (supplementary).	Replace GIS file with updated one (LADPW source) as available and clip to the ASBS 24 watershed boundary. Record catch basin cleaning frequency attribute data.
Inlet_Outlet_from_LADPW_ws	Point	Inlet and outlet locations clipped to ASBS 24 watershed.	Provided by LADPW. Feature type (inlet or outlet) attribute data was blank, so features could not be symbolized differently.	Replace GIS file with updated one (LADPW source) as available and clip to the ASBS 24 watershed boundary. Improve data by completing data fields.
City_inlets_ASBS_Drainage	Point	Point locations for inlets identified by the City as owned by the City.	Table provided by the City.	Locations and attribute information can be edited in GIS or a new table imported into GIS.
Lateral_Lines_SD_from_LADPW_ws	Line	Lateral line storm drains clipped to ASBS 24 watershed.	Provided by LADPW.	Replace GIS file with updated one (LADPW source) as available and clip to the ASBS 24 watershed boundary.
Gravity_Main_SD_from_LADPW_ws	Line	Storm drain mains clipped to ASBS 24 watershed.	Provided by LADPW.	Replace GIS file with updated one (LADPW source) as available and clip to ASBS 24 watershed boundary.
Storm_Drains_LADPW_clip_ws	Line	Includes pipes, channels, and creeks that convey stormwater runoff clipped to the watershed boundary.	LA County GIS data portal.	Replace GIS file with updated one (LADPW source) as available and clip to the ASBS 24 watershed boundary.
Prelimin_drain_areas_core_mon_outfalls	Polygon	Catchment areas delineated for the Core Monitoring Stations.	Delineated by Weston based on desktop data review using 2-ft contour data, sub-basins, and storm drain data. Not field-verified and should be considered preliminary.	Catchment areas and attribute data can be edited in GIS to update file. New drainage areas will need to be delineated as stations are added.
BMP_Areas	Polygon	Shows structural BMPs that can be mapped, and currently displays the Planned Biofiltration BMP at Broad Beach Rd. Does not include non-structure BMPS or Operations and Maintenance Activities (See compliance plan for details).	Based upon project boundary shown in Biofiltration Project report.	Edit or replace GIS file as needed to add, remove, or change location or attribute data associated with these features.
ASBS_24_Watershed	Polygon	An overall boundary watershed based on the eight watersheds that drain to the ASBS 24 area.	Based on sub-basins GIS file from LADPW with internal boundaries dissolved for the eight watersheds.	Edit boundary in GIS as needed.

Table 2-8. GIS Shapefiles Used in Compliance Plan Map

Filename	Type	Description	Original Source	To Update
Subbasins_ws	Polygon	Watershed sub-basins clipped to the ASBS 24 watershed boundary	Provided by LADPW.	Replace GIS file with updated one (LADPW source) as available and clip to the ASBS 24 watershed boundary.
Subbasins_flow_dir_ws	Line	Watershed sub-basins clipped to the ASBS 24 watershed boundary.	Provided by LADPW.	Replace GIS file with updated one (LADPW source) as available and clip to the ASBS 24 watershed boundary.
Sewer_Treatment_Plant_ws	Point	Sewer treatment plant locations within the ASBS 24 watershed area.	Provided by LADPW.	Replace GIS file with updated one (LADPW source) as available and clip to the ASBS 24 watershed boundary.
Sewer_Pump_Station_ws	Point	Sewer pump station locations within the ASBS 24 watershed area.	Provided by LADPW.	Replace GIS file with updated one (LADPW source) as available and clip to the ASBS 24 watershed boundary.
Areas_potential_sheet_flow	Polygon	Areas identified as having potential sheet flow are the parking lots at Nicholas Canyon, Zuma, and Westward Beaches.	Parking lot areas were digitized from aerial imagery to create the polygon file.	Edit or replace GIS file as needed to add, remove, or change location or attribute data associated with these features.
Sewer_Pipe_ws	Line	Sewer pump station locations within the ASBS 24 watershed area.	Provided by LADPW.	Replace GIS file with updated one (LADPW source) as available and clip to the ASBS 24 watershed boundary.
Sewer_Maintenance_Service_Area_ws	Polygon	Sewer maintenance service area within the ASBS 24 watershed area.	Provided by LADPW.	Replace GIS file with updated one (LADPW source) as available and clip to the ASBS 24 watershed boundary.
Pacific_Coast_Highway_ws	Line	Centerline feature of PCH (State Hwy 1) extracted from CAMS 2011 GIS file and clipped to the ASBS 24 watershed boundary.	LA County GIS data portal: http://egis3.lacounty.gov/dataportal/2011/12/09/2011-la-county-street-centerline-street-address-file/.	As updated versions of file become available, extract PCH lines from the new shapefile and clip to the ASBS 24 watershed.
Roads_ws	Line	Non-private road centerline features extracted from the CAMS 2011 GIS file and clipped to the ASBS 24 watershed boundary.	LA County GIS data portal: http://egis3.lacounty.gov/dataportal/2011/12/09/2011-la-county-street-centerline-street-address-file/.	Replace road file with updated versions as available and clip to the ASBS 24 watershed.
Facilities_with_haz_materials	Point	Geocoded addressed for facilities that generate or store hazardous materials within the ASBS 24 watershed.	Facility addresses provided by LA County Fire Dept in excel spreadsheet.	Request the annual update of Facility (Active) Inventory List from LA County Fire for Zip Code 90265. Format address data in Excel spreadsheet for geocoder. Geocode in ArcMap and clip the shapefile to the ASBS24 watershed.
County_Bndry	Polygon	Boundary of the County.	Los Angeles County GIS Data Portal.	No update expected.
Jurisdictional_Boundary_ws	Polygon	Jurisdictional boundaries for the unincorporated portion of the County and the City clipped to the ASBS 24 watershed.	Los Angeles County GIS Data Portal.	Replace GIS file with updated one (LADPW source) as available and clip to the ASBS 24 watershed boundary.
State_and_Federal_Lands_ws	Polygon	Land areas identified as in state or rederal ownership clipped to the ASBS watershed area.	Based on parcels in state or federal ownership extracted from Parcel GIS data file provided by LADPW.	Process updated parcel file (LADPW source) to extract parcels with state or federal ownership; dissolve boundaries by owner type/code; clip to the ASBS 24 watershed boundary.
ASBS_24_Boundary	Polygon	ASBS 24 watershed boundary.	CA State Water Resources Control Board.	To be updated only if boundary is changed. Replace GIS file if new one is published by agency.
USGS_Landslides_zone_clipped_ws	Polygon	Landslide zones for 1:24k USGS sheets of Point Dume and Trifuno Pass merged into a single GIS file.	Provided by the City, available from USGS.	Update GIS file as new data are published by USGS or if County revises data based on landslide activity.

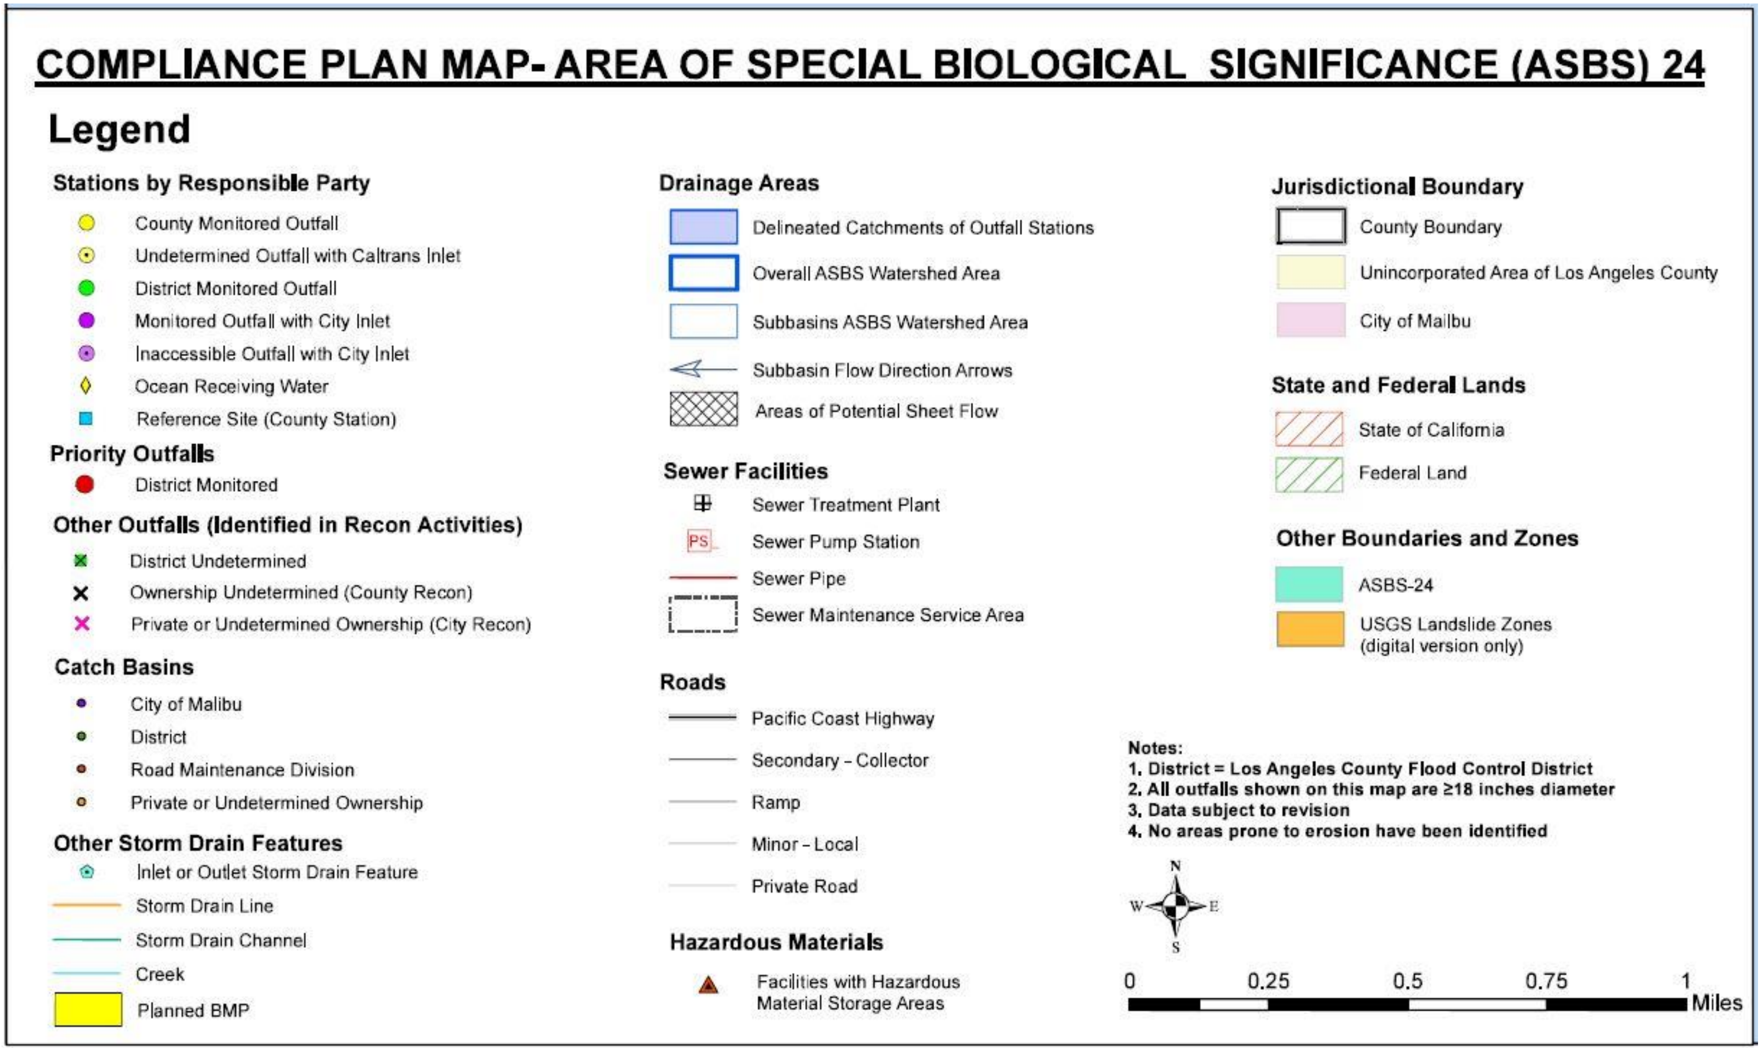

Figure 2-44. Compliance Plan Map Legend

3.0 DRY WEATHER COMPLIANCE

Section I.A.2.b of the General Exception states that the ASBS Compliance Plan will describe measures taken by the Parties to eliminate non-authorized, non-storm water runoff (e.g., dry weather flows), how these measures will be maintained over time, and how these measures are monitored and documented (SWRCB, 2012b).

As discussed in more detail in the following sections, the Parties' existing dry weather elimination programs have been effective in eliminating non-exempt discharges. However, conditionally exempt hillside dewatering and natural creek flows are expected to continue to be a source of discharges from MS4 outfalls. The County, FCD, and City will continue to implement the non-structural programs, identified in this document, that have been designed to prevent non-exempt dry weather discharges. Two key components of these programs are the City's dry weather runoff elimination and water conservation programs.

The ASBS dry weather runoff elimination program was originally established as part of a State Proposition 84 grant-funded ASBS focused outreach project. This program included creating the Coastal Preservation Specialist (CPS) position to educate residents and business owners about dry weather runoff elimination, pollution prevention, and water conservation within the City of Malibu in areas potentially tributary to the ASBS. As the need for drought education grew, coordination of the local water conservation program was expanded and integrated more thoroughly into the runoff elimination program.

Elimination of non-stormwater runoff to the entire MS4 system within the City, and thus all potential dry weather discharges to the ASBS, was targeted through these programs. In addition to the CPS position, the programs also provide education, resources, and tools, such as opportunities for site evaluations, rebates, and incentives. Having shown that additional resources and focused staff were necessary for successful runoff elimination and public awareness about the ASBS, the CPS position was permanently established as the Environmental Programs Specialist (Specialist) to conduct citywide monitoring, documentation, and reporting on dry weather discharges, among other assignments.

The City will continue to respond to reports of runoff and over-irrigation; most reports are received either directly by staff at City Hall, the City's 24-hour Pollution Prevention Hotline, online water waster reporting form, or as observations by staff in the field. The City will also periodically proactively patrol neighborhoods with a history of over-irrigation, and will address or prevent non-stormwater discharges by meeting with property owners and home/property owner associations within the entire area tributary to ASBS 24 within the City limits. Ongoing efforts include property owner education regarding discharge prevention and source control with enforcement actions when necessary.

The City also continues to conduct a PIPP by providing educational information about the ASBS and BMPs to the beach going community at large. The City's multi-platform educational outreach campaign, *Keep It Clean, Malibu,* continues to be promoted throughout the community. The community has been receptive and enthusiastic about the program. The *Keep It Clean, Malibu* campaign and relevant videos may be found at www.KeepItCleanMalibu.com and ASBS

education in general at www.MalibuCity.org/ASBS. To date, Malibu's *Keep It Clean* Campaign has won five awards and received both national and statewide recognition.
The City provides a 24-hour Pollution Prevention Hotline for the community to report any environmental concerns, including runoff. The hotline is advertised on the City's website and in a display at City Hall.

The City also maintains a website (www.malibucity.org/waterwaster) for reporting water wasting activities including, but not limited to, excessive irrigation and overspray. Though focused on water conservation, this website also serves to receive information about runoff from community members who may not normally be aware of water quality issues, but, due to public information programs on California's current severe drought, may be more engaged in water issues. With additional eyes on the street, the City can be promptly notified if any dry weather discharges are observed, and coordinate with the County when any of their FCD or Public Works MS4 is affected. Since implementing the hotline and *waterwaster* website, response to complaints and enforcement actions to cease runoff or discharges have improved citywide and enhanced the ability to more effectively document incidents.

The following sections identify the nonstructural measures the Parties have implemented that are designed to eliminate non-authorized, non-storm water runoff, including public information and participation programs (PIPPs), operations and maintenance (O&M) programs, and enforcement programs. A list of existing programs is provided in Appendix B. When used in combination, nonstructural controls have been proven to provide improved effectiveness in load and flow reduction, at a lower cost, than many structural solutions (Brown et al., 2010; Pohl, 2010; Cac and Ogawa, 2010; Krieger et al., 2010). Ongoing dry weather elimination program activities will be documented and the results will be submitted in the MS4 Annual Report to the Los Angeles Regional Water Quality Control Board.

Dry weather monitoring of outfalls has been performed to ensure compliance with the requirements of the General Exception. This document summarizes those monitoring activities and results.

3.1 Nonstructural Controls

Nonstructural controls are designed to prevent dry weather runoff and pollution generation, control sources of dry weather runoff and pollution once generated, and eliminate the true source of pollutants, if appropriate. This document identifies nonstructural controls used by the Parties in order to meet the requirements of the General Exception and Special Protections of the California Ocean Plan (SWRCB, 2012a).

3.1.1 Nonstructural Program Terms and Definitions

Nonstructural programs are designed to prevent pollution generation, control sources of pollution once generated, and eliminate the true source of pollutants. The following common terms and definitions are related to nonstructural controls, which are used throughout the document, including:

- Pollution Prevention Measures target pollutants and wastes before they are generated. These measures typically emphasize conserving or reusing resources to prevent pollution.
- Source Controls target specific sources of pollution to reduce or eliminate pollutants from entering the municipal separate storm sewer system (MS4) and / or ultimately the receiving water. Source controls may include institutional controls (e.g., codes, ordinances, and regulations), outreach, education, incentive programs, and enforcement measures.
- True Source Controls recognize that the source pollutant may be the physical design of a product, such as copper-based pesticides or copper break-pads. In this instance, product regulation and true source control can only be achieved at the state or national level. True source controls support regulatory change outside the local jurisdiction.

Nonstructural programs have been classified in this document using a "three-legged stool" approach where the three legs of the stool consist of PIPPs, Enforcement Programs, and O&M Programs (see Figure 3-1). When used in combination, nonstructural controls have been proven to provide improved effectiveness in load and flow reduction, at a lower cost, than many structural solutions (Brown et al., 2010; Pohl, 2010; Cac and Ogawa, 2010; Krieger et al., 2010).

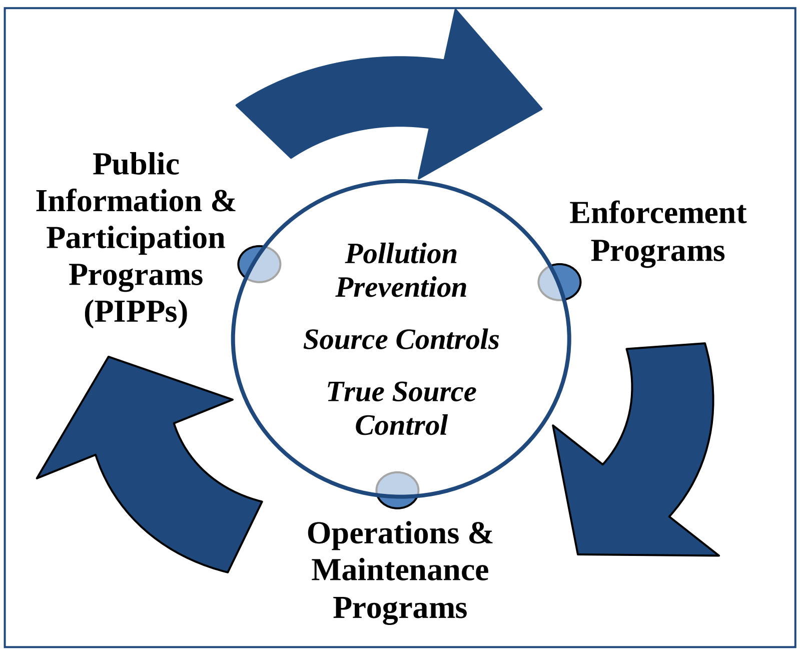

Figure 3-1. ASBS 24 Nonstructural Programs

3.1.2 Nonstructural Program Adaptive Management Process

The ASBS 24 PIPPs, enforcement, and O&M nonstructural programs have been implemented using adaptive management (

Figure 3-2) to plan, implement, assess, and refine individual nonstructural controls. Nonstructural programs implemented to date have ensured compliance with the zero dry weather discharge criteria of the Special Protections. Receiving water data collected under the 2013 Regional Monitoring Program represent the initial assessment of wet weather loading to ASBS 24. Some nonstructural programs implemented to date, identified in this document, also have the potential to help reduce wet weather pollutant loads. Effectiveness assessments will play a key role in ongoing implementation of the nonstructural program by identifying the optimal enhanced programs and establishing a process for planning subsequent phases of nonstructural implementation.

Figure 3-2. Adaptive Management Process

3.2 Existing Nonstructural Programs

The Parties proactively participate in regional nonstructural planning efforts and implement nonstructural controls to protect the receiving water quality of ASBS 24. A detailed list of existing PIPPs, enforcement programs, and O&M programs is provided in Appendix B. This section contains a description of key nonstructural programs related to compliance with the prohibited discharges listed in the General Exception.

3.2.1 Public Information and Participation Programs

PIPPs encompass the education, outreach efforts, and rebate / incentive programs implemented by the Parties which encourage positive behavior changes that eliminate or reduce potential polluting behaviors, encourage reporting and cleanup of discharges, and reduce water consumption. Waste management and water conservation PIPPs have been implemented by the County and the City and are described in the following sub-sections.

3.2.1.1 Waste Management PIPPs – Outreach Programs

Clean LA is the County's main PIPP. Clean LA offers online and hotline resources to residents, businesses, and local governments to answer questions related to household hazardous and electronic waste collection, composting, recycling, illegal dumping prevention, and water quality impacts of proper waste management. The Clean LA hotline, which is shared with the District, fielded 34,064 calls throughout Los Angeles County during the fiscal year covered under the 2011-2012 Annual Report (LACDPW, 2012). Within the Clean LA tool box, the Rethink LA program encourages "rethinking" about opportunities to implement reduction, recycling, and reuse, and offers the Los Angeles County Materials Exchange (LACoMAX) as a unique Web platform for buying recycled products, exchanging materials, and advertising garage sales. These online educational resources are interlinked and represent the types of programmatic tiering possible within a PIPP.

Similarly, the Malibu Green Room Web page, a one-stop resource for all things "green" in the City, is one of the City's key PIPP resources. The Web page includes information related to environmental protection ordinances, the City's 24-Hour Pollution Prevention Hotline (initiated in June 2012), special waste collection events, the ocean friendly gardens (OFG) and California (CA) Friendly Landscapes programs and examples of properties where such gardens are installed, design and implementation of structural BMPs, and environmental events, as well as examples of what actions the City has taken to become more sustainable. This Web page is linked with other City-managed Web pages, such as the ASBS Web page, the *Keep it Clean, Malibu* campaign and projects and programs offered by partner agencies.

3.2.1.2 Water Conservation PIPPs – Incentive Programs

Three incentive programs are managed regionally by the Los Angeles County Waterworks and local water districts and are advertised within the ASBS 24 watershed by the County and City. The programs are used to encourage water conservation for outdoor landscaping, thereby preventing dry weather runoff to ASBS 24 from over-irrigation. These programs vary based on available funding, but have included the Landscape Irrigation Efficiency Program (completed in 2013), which offered installation of free, efficient sprinkler heads and an irrigation survey at qualified properties; the Water Saving Devices Rebate Program, a residential rebate program for water saving devices such as rotary sprinkler nozzles and irrigation controllers; and Cash for Grass, a residential rebate program for replacing grass with water-efficient landscaping.

3.2.1.3 Water Conservation PIPP – Surfrider Ocean Friendly Garden (OFG) Program

The Surfrider OFG Program is a regional effort to promote water conservation and eliminate dry weather runoff from over-irrigation and other urban sources. The County and City manage webpages identifying OFG "case studies" within their jurisdiction and frequently host educational and outreach events at OFGs located at public facilities. The City also promotes the Metropolitan Water District-funded California Friendly Landscapes program, which is a reimagining of the OFG program intended to engage a broader audience who might not otherwise resonate with the concept of "ocean friendly".

3.2.1.4 Water Conservation PIPP – CA Friendly Landscaping Program

The CA Friendly Landscaping Program targets residences and businesses to promote water conservation and eliminate non-point source pollution from landscaping. It is a reimagining of the OFG Program by the Metropolitan Water District in an attempt to engage a broader audience statewide. Similarly to the OFG Program, it is promoted by its local water Districts and agencies. The program includes educational workshops, training events, and incentives such as landscape water efficiency rebates. The City hosted two CA Friendly Landscaping Workshops from 2013-2014.

3.2.1.5 Water Conservation PIPP – City of Malibu ASBS Focused Outreach Program

The City of Malibu Focused ASBS Outreach Program included a CPS position that was created by the City under a Proposition 84 grant to perform direct and focused outreach to residents and to develop an outreach campaign to reach the community at large raising awareness of ASBS 24. One of the roles of the CPS was to develop and implement PIPPs that prevent dry weather flows. The CPS mailed a general ASBS education letter to every parcel within the ASBS and regularly gave public educational and school presentations on ASBS topics (e.g., OFGs, water conservation) that may be implemented by residents and are being implemented by the City. Additionally, the CPS attended public events to educate about protecting the ASBS. As the City's representative, the CPS interfaced with schools for environmental education programs with Pepperdine University, Point Dume Marine Science School, and Malibu High School. The CPS also developed new ASBS content and maintained pages on the City's web page, interfaced with the media, and expanded the City's outreach of ASBS topics using social media platforms including Facebook, Twitter, and Instagram. The *Keep It Clean, Malibu* website was enhance though this program and encourages residents to prevent pollution by providing guidance on the proper use of common products and best practices relating to other sources (e.g., pet waste).

In addition, ASBS 24 coastline and inland areas that could be tributary to it were regularly patrolled by the CPS, who looked for dry-weather runoff and other pollution threats in the coastal and inland areas. County staff routinely coordinated with the CPS by reported over irrigation. When individual properties were identified as non-compliant with ASBS regulations, such as due to over-irrigation, they were mailed educational materials and a cease-and-desist letter. The CPS personally engaged with these property owners and residents by providing education on the potential impacts to the ASBS and tailoring solutions to the property.

As part of the Proposition 84 State funding, the CPS was tasked with developing an outreach campaign to educate people about the issue and the result was *Keep it Clean, Malibu* – a multi-platform educational campaign designed to positively, proactively make people think about storm drains and what goes into them. The campaign contains five main elements:

1. A series of four Public Service Announcements starring a beautiful urban mermaid coming into contact with the pollutants we create on land.
2. A series of four storm drains painted by a local artist to draw attention to the drains and their connection to the ocean. A video highlighting the making of this artwork was also created.
3. An active social media campaign on Instagram primarily, but also Facebook and Twitter. Citizens are encouraged to get involved in celebrating the ASBS by posting pictures of the gorgeous marine life in the area.

4. Two special events designed to kick off the campaign and draw attention to the issue – a ribbon cutting ceremony for the storm drain art project and a red carpet premier for the video series, which was held on Earth Day.
5. Distribution of wearable collateral materials (bright blue hats and temporary tattoos) which prominently feature the "Keep it Clean, Malibu" slogan, in effect creating walking billboards of the message.

In addition to these five main elements, the City partnered with local organizations to promote the ASBS campaign messages at their special events and through their websites and social media. These partnerships range from water and energy utilities to schools to business and community groups. The special events included:

1. Pepperdine University Earth Day Fair
2. Earth Day Celebration hosted by Malibu Chamber of Commerce and Malibu Country Mart
3. Rhyming in the Universe Earth Day Celebration hosted by Team United and Malibu Ballet Performing Arts Society
4. Fiesta Malibu hosted by Juan Cabrillo Elementary School

The bright blue hats and temporary tattoos used to promote the *Keep It Clean, Malibu* message were received with enthusiasm. In order to receive a hat, citizens sign an ASBS Pledge to prevent polluted runoff and protect ocean water quality with their daily activities.

Even though the grant-funded outreach project that included the CPS is complete, the City added a new position in July 2014 which assumed the outreach and inspections duties of the CPS. The *Keep It Clean, Malibu* campaign and relevant videos may be found at www.keepitcleanmalibu.com and ASBS education in general at www.malibucity.org/ASBS.

3.2.2 Operations and Maintenance Programs

O&M programs are in place to maintain infrastructure within the area draining to ASBS 24. O&M programs, including street and parking lot sweeping, catch basin cleaning, and trash management and recycling programs, have been implemented by the LACDPW and the City and are described in the following sections. A map of the different programs and their implementation areas is presented in Figure 3-3.

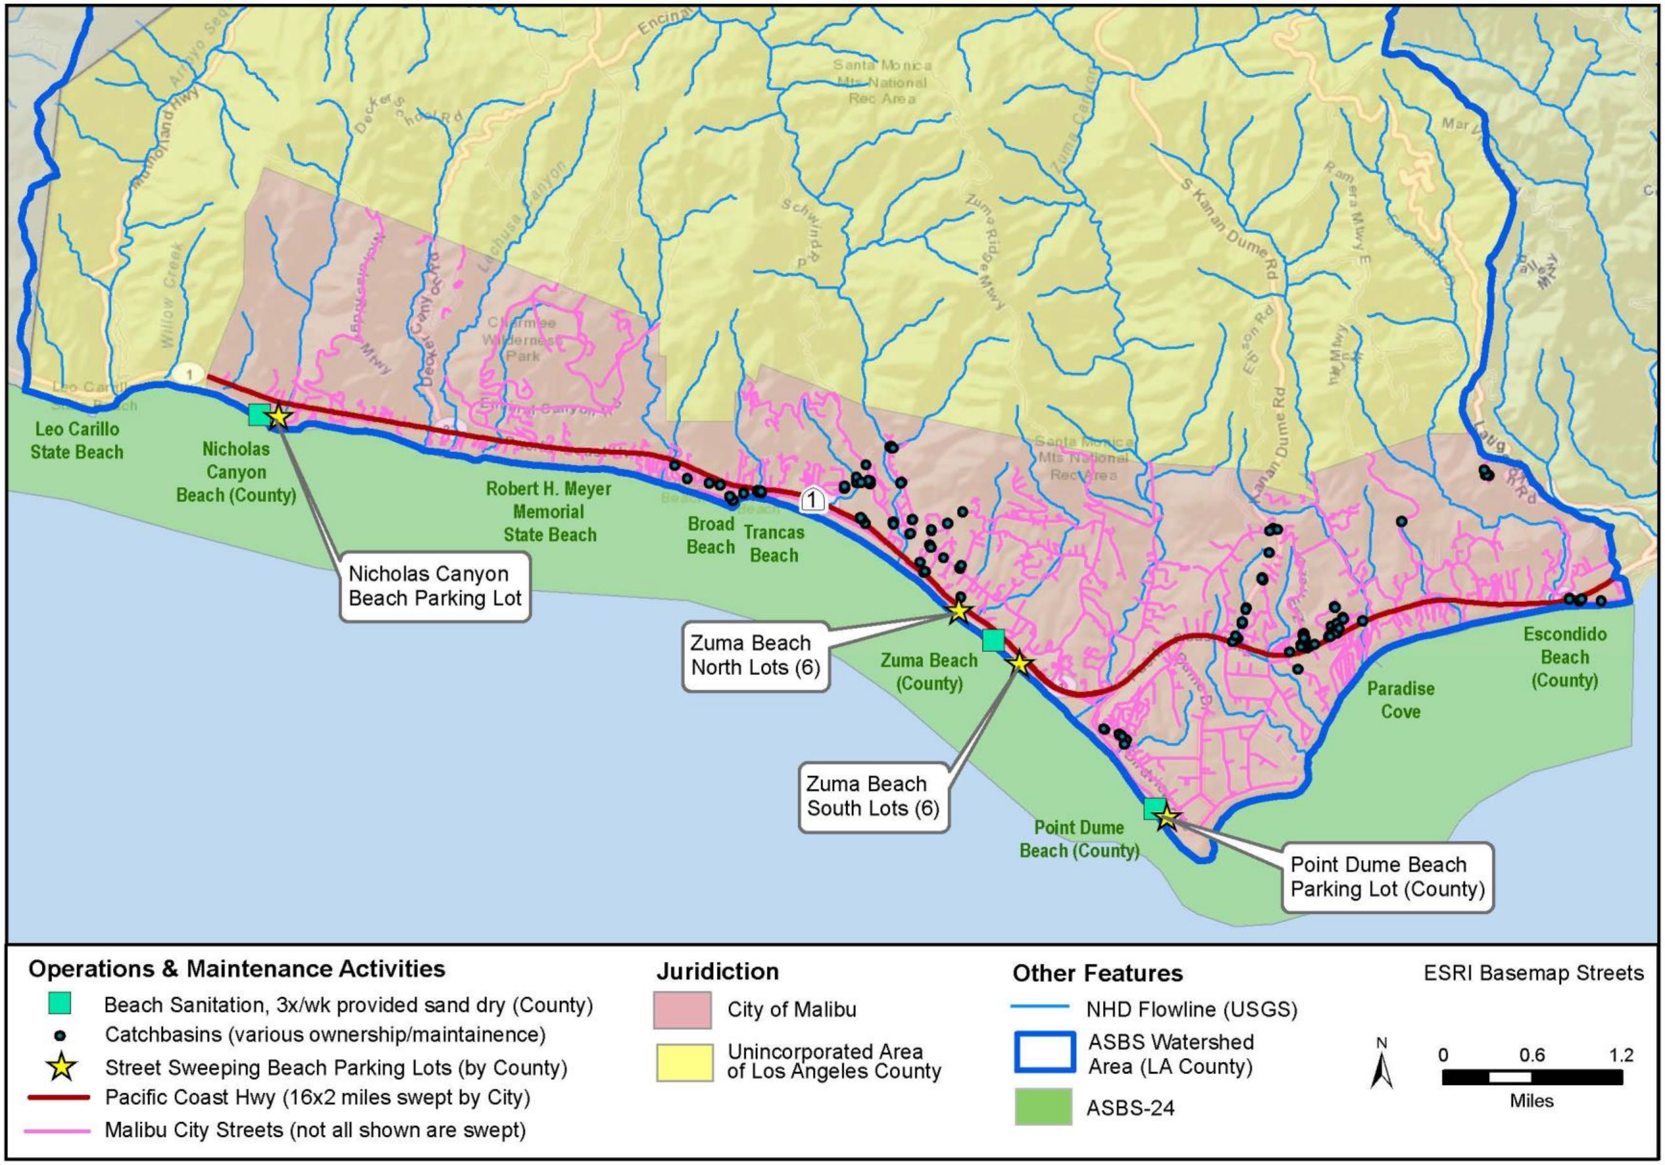

Figure 3-3. Locations of O&M Operations

3.2.2.1 Street and Parking Lot Sweeping

Studies have demonstrated that street sweeping is effective in reducing sediment, metals, and pesticide loading and, to a lesser extent, bacteria loading to the receiving water through physical removal of pollutants from paved surfaces (City of San Diego, 2010a, City of Portland, 2006). The County and City regularly maintain the roads, streets, and parking lots within the area draining to ASBS 24. The existing sweeping programs are presented on Table 3-1. Within the ASBS 24 drainage area, the County has jurisdiction over three beaches with County-maintained parking lots. All parking lots are swept on Saturday, Sunday, and Monday by a vacuum or regenerative air sweeper. The City shares a contract with California Department of Transportation (Caltrans) for sweeping PCH. The City's sweeping program was modified in 2013 to agree with Caltrans' statewide street sweeping policy, which requires use of mechanical sweeping equipment no more than once per week. The PCH is scheduled to be swept on Friday mornings (from 2:00 a.m. to 7:00 a.m.) to optimize sweeper access to the curb and gutter. City-maintained streets are swept monthly with a mechanical sweeper. The City maintains four regular sweeping schedules that are completed on the first, second, or third Monday or the third Wednesday of each month.

Table 3-1. Existing Street and Parking Lot Sweeping Programs within ASBS 24

<tr><td rowspan="2">City of Malibu</td><td>Pacific Coast Highway</td><td>Mechanical</td><td>Once/week</td></tr>
<tr><td>City-Maintained Streets</td><td>Mechanical</td><td>Once/month</td></tr>
</table>

3.2.2.2 Catch Basin Cleaning

The LACDPW and City implemented catch basin inspection and cleaning programs are designed to ensure that catch basins are: 1) properly marked with a "no dumping" message, most commonly applied with paint and stencil2) free of debris, and 3) in good condition. Catch basins are visually inspected by staff in the field and problem systems are flagged for maintenance. The routine inspection and cleaning/repair program is implemented in accordance with the priority assigned by each permittee to each system (i.e., catch basins consistently generating the highest volumes of trash and debris are Priority A; moderate volumes are Priority B; low volumes are Priority C). Priority A catch basins are cleaned four times a year, Priority B catch basins are cleaned twice a year, and Priority C catch basins are cleaned once a year. There are 152 catch basins within the ASBS 24 drainage area under the Parties' jurisdiction. As reported in the City of Malibu's 2011-2012 Annual Report, the material removed from the catch basins within the drainage areas to ASBS 24 mostly consists of "green waste that grows and thrives in the Southern California climate." There are 21 catch basins under the City's jurisdiction, which are classified as Priority B. There are 93 Priority B catch basins under the District's jurisdiction. The remaining 38 are under the County's jurisdiction (Road Maintenance Division) and are located in the upper portion of the watershed. These 38 catch basins are not part of the MS4 that drains to the ASBS and are classified as Priority C catch basins.

3.2.2.3 Waste Management & Recycling Programs

The County's and City's waste management programs include collection of waste and recyclables in public places such as bus stops, safe disposal of household hazardous waste; used oil collection/recycling events; waste management education; solid waste hauler permitting; Christmas tree recycling; brush clearance/green waste recycling events; bulky item collection; construction and demolition debris recycling; electronic and universal waste disposal; and an expanded polystyrene foam recycling program (i.e., Waste to Waves program). Education about recycling opportunities is provided through the PIPP discussed in Section 3.2.1.

The County's waste management program includes a regional beach sand "sanitation" program that is implemented at the three County Beaches located within ASBS 24. The beach sanitation program involves collecting beach debris in a screened hopper pulled by a tractor and properly disposing of the material. A rake system attached to the back of the tractor turns over the sand and allows solar radiation to "sanitize" the beach sand. Beach sand sanitation activities are implemented three times per week, provided that the beach sand is not wet. The implementation is scheduled during the morning hours to allow for maximal day-light exposure.

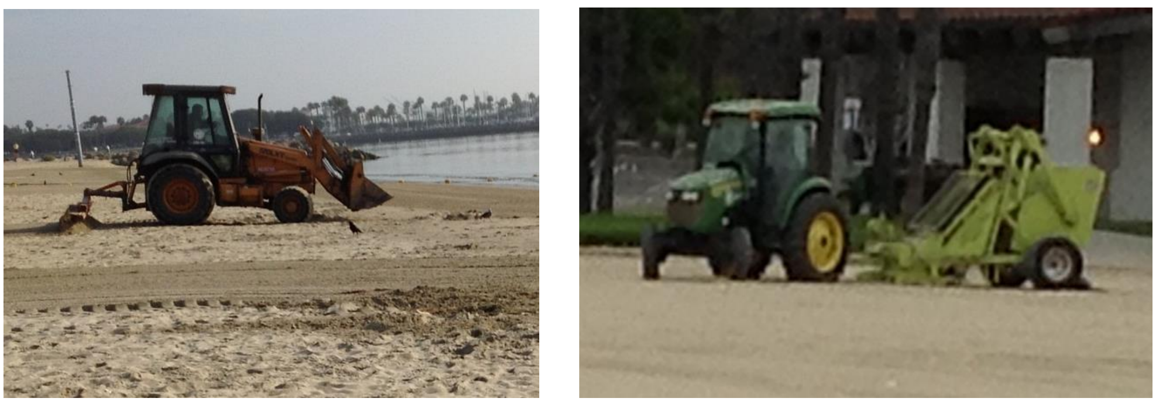

Figure 3-4. County Beach Sand Sanitation Program Equipment at Work

3.2.3 Enforcement Programs

Enforcement programs supporting environmental ordinances passed by the County and City are intended to eliminate non-authorized flows as defined in the General Exception; control illicit discharges; provide sediment and erosion control for construction sites'; verify National Pollutant Discharge Elimination System (NPDES) and ASBS compliance; and implement appropriate education and enforcement in response to urban runoff, trash, and other greening efforts. Existing enforcement programs within the area draining to ASBS 24 include the LACDPW and City illicit connection/illicit discharge (IC/ID) elimination programs, LACDPW and City construction programs, the City's commercial and industrial (should an industrial facility begin operating; there are currently no industrial facilities in the City) business inspection program, and City enforcement of violations observed while implementing the Clean Bay Restaurant certificate program (discussed in further detail later in this document). IC/ID elimination programs are discussed in the following section, and construction programs, commercial and industrial business inspection programs, and the Clean Bay Restaurant certificate program are discussed as part of the Inspection Program Assessment in Section 3.3.1.

3.2.3.1 Illicit Connection/Illicit Discharge Elimination Programs

The IC/ID Programs implemented by the Parties are designed to eliminate pollution by illicit connections and discharges to the MS4 and ultimately the ocean receiving waters. The regional IC/ID Programs start with detection. The LACDPW staffs a 24-hour Pollution Prevention Hotline, which is shared with the District and available in English and Spanish. A Chinese hotline is also offered, which is available in Mandarin. Any IC/IDs reported to the hotlines are routed to the appropriate personnel for response, which may include ceasing, cleaning up, or diverting IC/ID flows before they reach the ocean receiving water. The City utilized the LACDPW's hotlines for public reporting of IC/IDs through June 2012, and then the City launched its own 24-hour Pollution Prevention Hotline. IC/IDs may also be detected by the Parties during desktop screening of the MS4. Permitted and suspected IC/IDs are stored in the Maintenance Management System database for the LACDPW and District and in an Access database for the City. Regional IC/ID investigation data collected by the Parties and reported for the last 11 fiscal years, which run from July 1st of the previous calendar year through June 30th of the corresponding calendar year, are presented on Table 3-2.

The need for enforcement actions within the area draining to ASBS 24 is infrequent, with an overall decreasing pattern in the past 5 years. Recent dry weather monitoring of LACDPW outfalls has determined that no dry weather flows from these outfalls reach the ocean receiving water. Annually, there are relatively few IC/IDs within the City's jurisdiction and most of the IC/IDs tracked have been related to irrigation runoff. When individual properties are identified as non-compliant with ASBS regulations due to irrigation runoff, they are mailed a letter to "cease and desist" the observed discharge. The City staff (previously CPS) then works with the property owners to help correct the runoff problem. The property owner must submit a report within 1 month detailing how the problem was fixed. The City may conduct additional site visits and continue monitoring the site, or other additional actions depending on the specific case. General letters, including Notices to Comply, are sent to high-priority neighborhoods and individuals identified, based on the City's field reconnaissance and historic data. Areas where discharges, if they were to occur, are more likely to impact the ASBS are deemed a high priority. The purpose is to inform and educate the public about ASBS discharge restrictions. The City maintains a database with information on every case, including all communication and photos.

Note 1: IC/ID data covers the entire jurisdictional areas of the County, District, and City.
Note 2: Due to the ASBS restrictions on non-storm water discharges, the City considers any discharge inland of ASBS to not be conditionally exempt regardless of the nature of the discharge (with the exception of the exemptions in the Special Protections for seeps and other such natural flows including footing drains).

3.2.4 Dry Weather Monitoring

3.2.4.1 City of Malibu ASBS Focused Outreach Program

As part of the City of Malibu ASBS Focused Outreach Program the ASBS 24 was regularly patrolled by the CPS who looked for dry-weather runoff and other pollution threats in the coastal and inland areas. The CPS was funded by a Proposition 84 grant that continued through July 2014. Even though the grant-funded outreach project that included the CPS is complete, the City added a new position in July 2014 which assumed the outreach and inspections duties previously performed by the CPS. When individual properties are identified as being out of compliance with the Special Provisions and City policies, such as through over-irrigation, they are mailed educational materials and a cease-and-desist letter (see Section 3.2.3.1). City staff personally engages with these property owners by providing education on the potential impact to the ASBS and tailoring solutions (e.g., water conservation techniques, available rebate programs) to the property. There were eighty-three illicit discharge cases over the study period covered by the grant (November 2011 – March 2014) with a 96% success rate abating the runoff with “cease and desist discharge” letters followed by additional outreach, assistance, and sometimes site visits. Site visits were conducted at twenty-five properties to understand and mitigate runoff. Of the eighty-three cases over the project period, only three remain open. Two of the illicit discharge cases (2%) required assistance from code enforcement to gain compliance. Seventeen of the eighty-three properties were beachfront properties (20%), and only one illicit discharge from a low priority nonpoint source over the two and a half year project period actually reached the receiving water (1%). The patrol program coupled with outreach efforts to correct the observed issues is successful, but labor intensive.

3.2.4.2 County Dry Weather Outfall Inspections

County staff has been regularly performing inspections of outfalls along the ASBS to document the presence or absence of flow and where needed, take action to eliminate prohibited discharges. A summary of these outfall inspections for 2012 and 2013 is provided on Table 3-3 and Table 3-4, respectively. Of the inspected outfalls, only ASBS-002 had flows reaching the surf. Flow from this outfall was noted reaching the surf once out of the 13 times visited in 2012 and once out of the three times visited in 2013. In both cases these flows reaching the surf were observed in the first month that inspections occurred (January and February for 2012 and 2013, respectively). The suspected source of the flow was over-irrigation in 2012; outreach to residents has been performed as detailed Section 3.2.1. It is anticipated that this outreach effort has addressed the potential source of the non-storm water flows. In 2013 the suspected source of the flow was from a nearby construction site, and City staff visited that construction site to ensure that appropriated BMPs were in place to prevent future discharges. Inspections performed March and May of 2013 at ASBS-002 indicated that flow was not present. Several other outfalls were observed with flows or ponded water; however, due to the distance between the outfall and the surf zone, these minor flows did not reach the receiving water. Inspections will continue to ensure that discharges of non-storm, non-authorized runoff do not occur.

Table 3-3. 2012 Outfall Dry Weather Inspections Summary

Outfall	Beach	January, 2012			February, 2012			March, 2012			April, 2012			Source / Notes
		No. of Visits	No. of Flow	No. Flow to Surf	No. of Visits	No. of Flow	No. Flow to Surf	No. of Visits	No. of Flow	No. Flow to Surf	No. of Visits	No. of Flow	No. Flow to Surf

3.3 Inspection Program Assessment

Section I.A.2.c of the General Exception states that for MS4s, the ASBS Compliance Plan requires the following minimum inspection frequencies:

1. Weekly during the rainy season for construction sites.
2. Monthly during rainy season for industrial facilities.
3. Twice during the rainy season for commercial facilities.

In addition, the General Exception states that storm water drain outfalls equal to or greater than 18 inches in diameter or width will be inspected once prior to the beginning of the rainy season and once during the rainy season, and maintained to remove trash and other anthropogenic debris (SWRCB, 2012b).

Section 3.3.1 outlines the Parties' existing inspection programs and Section 3.3.2 outlines the recommended inspection program enhancements that would meet the requirements of the General Exception.

3.3.1 Existing Inspection Programs

The following sections outline the Parties' inspection programs that are currently in place. Discussions of specific LACDPW, District, and City inspections, where available, are limited to those areas draining to ASBS 24.

3.3.1.1 Commercial and Industrial Inspection Programs

Existing inspection programs for commercial and industrial facilities (e.g., restaurants, retail gasoline outlets (RGOs), automotive service facilities, United States Environmental Protection Agency (EPA) Phase I facilities, landfills) were conducted in accordance with the requirements of the 2001 NPDES permit (Order No. 01-182) (LARWQCB, 2001). The Permit included requirements for tracking, inspecting, and ensuring compliance for those facilities that are critical sources of storm water pollutants. The 2012 NPDES permit (Order No. R4-2012-0175) inspection frequencies are unchanged from the 2001 Permit requirements, although the minimum interval between inspections is reduced from 12 months to 6 months. The 2012 Permit also includes the requirement that commercial and industrial facility operators be notified of BMP requirements applicable to their site at least once during the 5-year permit cycle.

Commercial facility inspections are required by the NPDES Permit at a minimum of twice during the 5-year permit cycle. In 2008, the City began inspecting food-service related commercial businesses annually, exceeding the permit requirements. For industrial facilities, one industrial facility inspection is required within the first 2 years of the 2012 Permit and a second inspection is only required if an industrial facility has not filed a No Exposure Certification with the SWRCB. The City inspects RGOs and auto service facilities at least every other year, exceeding the permit requirement. The 2012 Permit requires follow-up inspections to be completed within 4 weeks of an infraction, and a minimum of two follow-up inspections and two enforcement letters must be issued to demonstrate a permittee's good faith effort to encourage a business to comply with the NPDES requirements.

Overall, the General Exception requires more frequent inspections than the NPDES permits. Commercial facility inspections are required at a minimum of twice per year during the rainy season. Industrial facility inspections are required a minimum of monthly, also during the rainy season. A summary of the seasonal minimum inspection frequencies required by the two NPDES permits and the General Exception for commercial and industrial facilities are presented on Table 3-5.

Table 3-5. Minimum Inspection Frequencies for Commercial and Industrial Facilities

Inspection Program	Inspection Frequency Required in ASBS 24	Historic Inspection Frequency, NPDES Permit Order R4-2012-0175	Historic Inspection Frequency, NPDES Permit Order No. 01-182
Commercial	Twice/year (rainy season)	Twice/5-year permit cycle, with at least 6 months between inspections	Twice/5-year Permit cycle, with at least one year between inspections[3]
Industrial[1]	Monthly (rainy season)	Twice/5-year permit cycle, with at least 6 months between inspections[2]	

[1]Industrial inspections frequencies will be implemented, if applicable to the ASBS 24 watershed.
[2] First inspection is required within 2 years of permit effective date. Second inspection (with at least 6 months between) is required before permit expiration if a No Exposure Certification has not been filed. Second inspections will also be performed at a minimum of 25% of facilities with No Exposure Certifications.
[3] No second inspection required at Phase I Tier II facilities determined to have no risk of exposure of industrial activities to storm water.

3.3.1.2 County Industrial and Commercial Inspection Program

The land use under the LACDPW's jurisdiction within the area draining to ASBS 24 is primarily undeveloped open space. There are no industrial facilities or commercial facilities within the area draining to ASBS 24 that must comply with the inspection frequencies outlined in the General Exception.

3.3.1.3 District Industrial and Commercial Inspection Program

Aside from its own properties and facilities, the District has no planning, zoning, development, permitting, or other land use authority over industrial or commercial facilities within its service area. As such, the District has no qualifying industrial or commercial facilities within the area draining to ASBS 24 that must comply with the inspection frequencies outlined in the General Exception.

3.3.1.4 City Industrial/Commercial Facilities Inspection Program

The goals of the City's commercial and industrial (should an industrial facility begin operating; there are currently no industrial facilities in the City) inspection program include compliance verification, enforcement as needed, and education regarding storm water and urban runoff issues, recycling, and City environmental quality ordinances.

The City's commercial and industrial inspection program is overseen by environmental programs staff. During an inspection, educational materials that may be provided include surface cleaning techniques, waste management, waste minimization, and recycling options; storm water pollution prevention tips; and potential BMPs tailored to the inspected business. Businesses may call City staff with any storm water- or inspection-related questions. City environmental programs staff also coordinates interdepartmentally with other City staff including the code enforcement officer,Public Works and the Building Safety inspectors, who have been trained to watch for storm water BMP infractions and are authorized to issue correction notices in the field. Code enforcement and the environmental programs staff work together to issue cease-and-desist letters if violations have not been corrected. Repeat offenses are subject to increased enforcement procedures and may be subject to Malibu's administrative citation ordinance, exposing the violator to civil penalties as well as traditional enforcement remedies.

The City conducts annual inspections of food-service commercial facilities and at least every other year on automotive related service facilities, going above and beyond the historic requirements of the NPDES Permit. There is not an extensive base of commercial businesses operating within the City. As reported in the 2011-2012 Annual Report (City, 2012), the City inspected 60 restaurants/food service-related businesses, three grocers,[1] six RGOs, and three automotive services[2] during the reporting year. Only a subset of these commercial businesses is located within the ASBS 24 watershed. Based on a review of available data, the area draining to ASBS 24 contains approximately 15 businesses that sell or serve food, three inns/motels/hotels, a couple of other stores, and one service station.

In conjunction with the annual commercial inspection program, the City implements the Clean Bay Restaurant Certification program of the Bay Foundation in partnership with several other agencies in the south Santa Monica Bay area specifically for food-service related businesses. Through the program, restaurants and other food management businesses are inspected and certified for proper handling of food waste, managing wash water, and implementing environmental policies that protect the storm drain system and ultimately the ocean receiving waters. The program certifies businesses as either 100% compliant with all program criteria or as non-compliant and therefore not certified under the Clean Bay Restaurant program. The program's primary success stems from brand recognition. It is a benefit to the partner agencies to work together in a larger regional and more recognized certification program so they may share resources such as promotional items and marketing materials, the advantage of Bay Foundation staff helping to promote the program at special events, and a standardized protocol; in essence, taking advantage of strength in numbers. As popularity and name recognition increases, there is a greater incentive to be certified in the program and more businesses will want to participate and take the extra steps to ensure they maintain certification. If a participant is found to not meet criteria or have a violation during the year that they are certified, they are subject to a strict rescinding policy and may have the certification revoked until the next period. The City's 2011-2012 Annual Report indicated that 93% of relevant businesses under the City's jurisdiction were currently certified under the program (City, 2012).

The City has complied with requirements to conduct inspections of industrial facilities when applicable. Industrial land use is very limited within the City's jurisdiction; in the 2011-2012 Annual Report, only one facility had active coverage under the State Industrial Activities Storm

[1] During the 2012-2013 annual reporting year, the Hughes Market grocery closed for business. The business will be replaced with a new organic grocer.
[2] All four RGOs that formerly housed automotive bays no longer offer these services. Two of the automotive service facilities are primarily RGOs.

Water General Permit and was in the process of terminating coverage. This business is under new ownership and is now a hardware store.

The City is exploring protocols to identify and track any new commercial and industrial facilities located within the area draining to ASBS 24 and ensure that inspections are implemented in accordance with the General Exception requirements. All current commercial facilities have been identified. Food service-related and RGO businesses in the area which may drain to the ASBS are being inspected at least twice in the wet season. There are no industrial facilities.

3.3.1.5 Construction Site Inspection Programs

In accordance with the Los Angeles County Municipal NPDES Permit, permittees are required to develop, implement, and enforce a construction program that prevents illicit construction-related discharges of pollutants into the MS4 and receiving waters; implements and maintains structural and nonstructural BMPs to reduce pollutants in storm water runoff from construction sites; reduces construction site discharges of pollutants to the MS4 to the maximum extent practicable; and prevents construction site discharges to the MS4 from causing or contributing to a violation of water quality standards.

Existing construction site inspection programs were implemented in accordance with the requirements of the 2001 NPDES permit. The Permit requires permittees to inspect all construction sites (1 acre and greater) a minimum of once during the wet season and requires implementation of BMPs such as inspection of graded areas during rain events to control erosion from slopes and channels. For all construction sites where a Storm Water Pollution Prevention Plan (SWPPP) is not adequately implemented, permittees are required to conduct a follow-up inspection within 2 weeks of the initial inspection. In addition, proof of a Waste Discharger Identification (WDID) number for filing a Notice of Intent (NOI) for coverage under the General Construction Storm Water Permit and certification that a SWPPP has been prepared is required prior to issuance of a grading permit. Permittees are also required to use a database or other effective system to track grading permits for construction sites totaling 5 acres or greater. In the case of violations, two follow-up inspections within 3 months and two enforcement letters must be issued to demonstrate a permittee’s good faith effort to encourage a business to comply with the NPDES requirements.

The 2012 NPDES Permit outlines the new, more stringent requirements for construction site frequency that became effective on December 28, 2012. According to the 2012 NPDES Permit, construction sites with a minimum of 1 acre of soil disturbance must be inspected by permittees a minimum of three times (e.g., prior to land disturbance, during active construction, and at the conclusion of the project) and at least monthly during the rainy season. Additionally, sites that discharge to a water body listed on the Section 303(d) List as impaired for sediment or turbidity, or determined to be a “significant threat to water quality,” will be inspected by permittees at least once every 2 weeks during the rainy season. All sites will be inspected prior to a forecasted storm event[3] and within 48 hours after a recorded storm event.[4] The 2012 NPDES Permit

[3] A forecast storm event is defined by the NPDES permit as two or more consecutive days with a greater than 50% chance of rainfall that has been predicted by the National Oceanic and Atmospheric Administration (NOAA). This definition is in agreement with the definition of a storm event in the Construction General Permit.

requires construction sites consisting of less than 1 acre of soil disturbance to be managed through the permittees' erosion and sediment control ordinances and building permit requirements. These smaller construction sites shall be inspected on an as-needed basis. The inspection requirements of the 2012 NPDES Permit are in addition to the visual inspection programs implemented by the construction contractor's Qualified SWPPP Practitioner in accordance with the requirements of the Construction General Permit.[5] Under the 2012 NPDES Permit, permittees are required to use an electronic system to inventory permits for all construction sites.

The General Exception requires more frequent inspections than the 2012 NPDES Permit in areas draining to ASBS 24. Construction sites, defined as sites with 1 acre or more of disturbance (SWRCB, 2010), must be inspected weekly during the rainy season. A summary of the seasonal minimum inspection frequencies required by the two NPDES permits and the General Exception are presented on Table 3-6.

Table 3-6. Minimum Inspection Frequencies for Construction Sites (1 Acre or Greater)

Inspection Program	Inspection Frequency Required in ASBS 24	Historic Inspection Frequency, NPDES Permit Order R4-2012-0175	Historic Inspection Frequency, NPDES Permit Order No. 01-182
Construction	Weekly (rainy season)	Three times (before, during, and following construction) and: Monthly (rainy season) or Once every two weeks (rainy season)*	Once/year, following rain event

*For construction sites tributary to a water body on the Section 303(d) List due to sediment or turbidity.

3.3.1.6 County Construction Site Inspection Program

The LACDPW Architectural Engineering, Construction, and Building and Safety Divisions, along with applicable County departments, are responsible for County construction inspections. The LACDPW's construction program requires all construction projects to develop and implement erosion and sediment control BMP plans prior to the start of construction (i.e., Wet Weather Erosion Control Plan [WWECP] for sites less than one acre of disturbed land, Local Storm Water Pollution Prevention Plan [LSWPPP] and a WWECP for sites greater than 1 acre of disturbed land). The LSWPPP must include year-round BMPs to control pollutants that originate from the construction site due to construction activities.

[4] A recorded storm event is defined in the NPDES permit as a ½-inch rain event. This definition is in agreement with the definition of a storm event in the Construction General Permit.

[5] In accordance with the Construction General Permit, non-storm water visual inspections are required weekly for Risk Level 1, 2, and 3 projects. These inspections are recorded quarterly and performed daily for LUP Type 1, 2, and 3 projects. Inspections are also required before forecasted storm events and within 48 hours of a recorded storm event.

In addition to filing an LSWPPP, for projects greater than 1 acre, the applicant must file a NOI per the State General Construction Storm Water Permit and obtain a WDID number from the State Water Resources Control Board (SWRCB, 2010). Prior to grading plan approvals, the LACDPW requires the applicant to submit copies of the NOI, WDID, and SWPPP. Projects are notified of any required changes to the SWPPP and BMPs prior to the start of the rainy season. Inspections occur thereafter, and also after each significant rainfall event. Post-construction structural BMPs are inspected annually as part of the permit renewal process. In the event that enforcement actions are taken, they occur in the order listed: warnings, stop-work notices, office meetings, notices of violation, referrals to the Regional Board, and fines or non-payment of general contractor's invoices until the violation is corrected.

The LACDPW has begun implementing new protocols to identify and track active construction sites located within the area draining to outfalls that discharge to the ASBS 24 in order to ensure that inspections are implemented in accordance with the General Exception schedule requirements, where applicable.

3.3.1.7 District Construction Site Inspection Program

Aside from its own properties and facilities, the District has no planning, zoning, development, permitting, or other land use authority over new developments or redevelopment projects, or development construction sites within its service area. Under the 2012 NPDES Permit, the District is subject to the minimum control measures of a Public Agency Activities Program, which differ from the minimum control measures imposed on other permittees. Only the Public Construction Activities Management Program, a component of the Public Agency Activities Program, could potentially be applicable to District facilities within the area draining to ASBS 24. When active construction sites under the jurisdiction of District are located within the area draining to ASBS 24, internal construction site inspections would be implemented in accordance with the existing inspection criteria defined by the LACDPW, as discussed in Section 3.3.1.6.

3.3.1.8 City Construction Site Inspection Program

Grading within the City is limited to single-lot development. The area of disturbance is restricted due to development constraints implemented by the Santa Monica Mountains Local Coastal Plan and the Municipal Code. The Development Construction Inspection Program is implemented by the Environmental Sustainability Department and the Public Works Department. Applicants are notified if an NOI for coverage under the State General Construction Storm Water Permit is required, and plans are not approved until proof of a WDID has been submitted.

The City's construction inspection program for all sediment-disturbing projects begins with a pre-grading meeting with the general contractor, deputy building official, and environmental & building safety inspector (occasionally the LACDPW inspector). At the pre-grading meeting, the SWPPP is reviewed and appropriate BMPs, including sediment and erosion controls, are discussed, and the implementation schedule is developed by construction phase. During the meeting, it is stressed to all contractors that the job site will be shut down until the required measures are in place if the contractor fails to comply. The SWPPP is discussed with the general contractor at commencement of building construction activities, with a reminder of the repercussions (i.e., tiered enforcement actions, up to and including site closure) of failing to comply. Project sites are visited regularly during the grading phase. During the construction phase, the building inspector routinely conducts on-site inspections. The implementation and maintenance of the appropriate BMPs are checked at each inspection.

Violations are addressed immediately. All issues receive an Initial Notice of Violation/Warning and corrective actions are required with strict compliance deadlines (24 hours during rainy weather and up to 72 hours during non-critical times). Sites are then re-inspected to verify compliance and a stop-work order may be issued until compliance is verified (City, 2012).

In accordance the General Construction Permit construction projects of 1 acre or greater are inspected at least twice during the rainy season The City currently inspects all construction sites monthly, and higher risk construction sites before/during rain events as of the 2013-2014 winter. The City is implementing new protocols to identify and track active single-lot construction sites located within the area draining to outfalls that discharge to the ASBS 24 to ensure that construction site inspections are implemented weekly during the rainy season, in accordance with the General Exception requirements (summarized on Table 3-6).

3.3.1.9 Storm Drain Outfall Inspection and Cleaning Programs

Existing storm drain inspection programs were implemented in accordance with the requirements of the 2001 NPDES Permit . Each permittee was required to implement a Public Agency Activities Program to minimize storm water pollution impacts and to identify opportunities to reduce these impacts from areas of existing development. One of the activities covered under the Public Agency Activities Program is storm drain operation and maintenance, which includes visual monitoring of open-channels and other drainage structures for trash and debris at least annually; removal of trash and debris from open channels at least once annually prior to the wet season; elimination of the discharge of contaminants during MS4 maintenance; and proper disposal of debris and trash removed during storm drain maintenance. The storm drain inspection frequency was not modified in the 2012 NPDES Permit .

In addition to the annual inspection required by the NPDES Permits, the General Exception requires an additional inspection during the rainy season. A summary of the minimum inspection frequencies required by the two NPDES Permits and the General Exception is presented on Table 3-7.

Table 3-7. Minimum Inspection Frequencies for Storm Drain Outfalls

Inspection Program	Inspection Frequency Required in ASBS 24	Historic Inspection Frequency, NPDES Permit Order R4-2012-0175	Historic Inspection Frequency, NPDES Permit Order No. 01-182
MS4 outfalls	Once prior to rainy season; once during rainy season	Once/year, before the rainy season	Once/year, before the rainy season

3.3.1.10 County MS4 Outfall Inspection Program

Systems within the area draining to ASBS 24 that are at least 18 inches in diameter are generally located in the parking lots along County beaches. Beach sand frequently piles up in the outlet of these systems. These outfalls are cleared by DBH prior to the rainy season and catch basin systems are cleaned out in late summer or early fall, prior to the rainy season and again during the rainy season, as part of the LACDPW's Road Maintenance Division annual drainage inspection program.

The LACDPW has begun implementing new protocols to identify applicable outfalls that discharge to ASBS 24 to ensure that inspections are implemented in accordance with the General Exception schedule requirements (i.e., in addition to prior to the rainy season, second inspection to be performed during the rainy season).

3.3.1.11 City MS4 Outfall Inspection and Cleaning Program

The City's Storm Drain/Culvert Facilities Maintenance program is in place for annual and post-storm inspection and cleaning of storm drain facilities. All storm drain inlets are cleaned annually, and priority storm drains are cleaned at a minimum of twice annually. This program ensures that litter, debris, and pollutants are removed to prevent them from getting into the local waterways and impacting beneficial uses. In collaboration with LACDPW, the City will be conducting similar protocols to identify outfalls that discharge to ASBS 24. In general, citywide outlets are inspected when accessible. No applicable ASBS outlets are owned by the City. A contract service provider conducts the culvert cleaning and maintenance work on behalf of the City.

3.3.2 Inspection Program Enhancements to Comply with ASBS Special Protection Requirements

As the Parties modify their inspection programs to comply with the requirements of the current 2012 NPDES Permit, the Parties will need to include enhanced protocols for inspection programs implemented for sites within the area draining to outfalls that discharge to the ASBS 24. The inspection program requirements of the 2012 NPDES Permit and the General Exception are presented in Section 3.3.1 and the details of the required program enhancements are discussed in the following sections.

3.3.2.1 County Inspection Program Enhancements

The recommended enhancements to the LACDPW's existing inspection program are presented on Table 3-8 and include:

- During the rainy season, increase the inspection frequency to once per week for construction sites (at least 1 acre) under the LACDPW's jurisdiction that are located within the applicable area draining to ASBS 24.
- Conduct inspection and cleaning of storm drain outfalls measuring at least 18 inches in diameter or width catch basins that are located within the area draining to ASBS 24 once prior to the rainy season and once during the rainy season, at a minimum.

Table 3-8. County Inspection Program Enhancements

Program	Enhancement	Frequency
Commercial	Not applicable	-
Industrial	Not applicable	-
Construction (at least 1 acre)	Increase inspection frequency	Once/week (rainy season)
Storm Drain Outfalls	Coordinate inspections with	Once/dry season (prior to rainy season)

	ASBS criteria	and once/rainy season/year

3.3.2.2 District Inspection Program Enhancements

The recommendations for the DPW's inspection program are presented on Table 3-9 and include the following:

- When the District's active construction sites (at least 1 acre) are located within the applicable area draining to ASBS 24, District will implement inspections once per week during the rainy season in accordance with Special Protections and during the dry season in accordance with the requirements of the 2012 NPDES Permit.
- Conduct inspection and cleaning of storm drain outfalls measuring at least 18 inches in diameter or width catch basins which are located within the area draining to ASBS 24 once prior to the rainy season and once during the rainy season, at a minimum.

Table 3-9. District Inspection Program Enhancements

Program	Enhancement	Frequency
Commercial	Not applicable	-
Industrial	Not applicable	-
Construction (at least 1 acre)	Increase inspection frequency	Once/week (rainy season)
Storm Drain Outfalls	Coordinate inspections with ASBS criteria	Once/dry season (prior to rainy season) and once/rainy season/year

3.3.2.3 City Inspection Program Enhancements

The recommended enhancements to the City's existing inspection program are presented on Table 3-10 and include the following:

- During the wet season, increase the inspection frequency for construction sites (at least 1 acre) within the City's jurisdiction that are located within the applicable area draining to ASBS 24 to once per week. Applicable construction sites are being inspected at this increased frequency.
- The outfalls associated with City maintained inlets are located on private properties and considered private. The City does not own or maintain outfalls that discharge to ASBS 24. As such, no enhancements are currently proposed for the City to inspect and clean outfalls.

Table 3-10. City Inspection Program Enhancements

Program	Enhancement	Frequency
Commercial	Increase inspection frequency	Twice/year (rainy season)
Industrial	Currently not applicable based on existing land uses	-
Construction (at least 1 acre)	Increase inspection frequency	Once/week (rainy season)

4.0 RECEIVING WATER ASSESSMENT

A determination of whether there is currently an exceedance of the natural water quality of the ASBS is the first step in the process of assessing the potential pollutant load reductions targets required to enhance the water quality of the ASBS. Wet weather receiving water quality monitoring data results were evaluated in comparison to data for reference monitoring sites, in accordance with the flowchart provided as Attachment 1 to the General Exception, to determine if an exceedance of the natural water quality currently exists.

4.1 Determination of Compliance with Natural Water Quality

In 2008, a study was conducted as part of Bight 2008 to assess water quality in southern California ASBS (Schiff et al., 2011). The study was designed to evaluate the range of natural water quality near reference drainage locations and to compare water quality near ASBS discharges to these natural water quality conditions. Additional reference monitoring was performed under the Regional Monitoring Program. During the development of the draft Compliance Plan, compliance with natural water quality was determined by comparing receiving water data from wet weather monitoring conducted for ASBS 24 to the 85th percentile threshold of reference sample concentrations measured during Bight 2008 and Bight 2013.

Concentrations of pollutants in post-storm receiving water were compared to those in pre-storm receiving water and to the 85th percentile threshold of reference sample concentrations. When post-storm receiving water concentrations are greater than the 85th percentile threshold and are greater than pre-storm concentrations for two or more storm events, results from the next storm are analyzed. If post-storm receiving water concentrations are again greater than the 85th percentile threshold and pre-storm concentrations, the constituent(s) are classified as exceedances of natural water quality. Concentrations of TSS, ammonia, nitrate, total orthophosphate, and total metals were compared to the 85th percentile thresholds.

Wet weather monitoring was performed by LACDPW at two receiving water locations: 1) S01, located off Zuma Beach directly out from ASBS-016, a 60-inch storm drain; and 2) S02, located off Escondido Beach, directly out from ASBS-028, a 36-inch storm drain. Monitoring was conducted during storm events occurring on February 19 and March 8, 2013, and February 28, 2014. Wet weather flows from ASBS-016 only reached the ocean receiving water at S01 during the February 28, 2014, monitored event. The City performed monitoring at receiving water Site 24-BB-03R. For safety reasons, this site was only sampled during the February 28, 2014, event. Therefore, the assessment of compliance with natural water quality was primarily performed for receiving water station S02, which had samples collected during three wet weather events. Receiving water station S02 is associated with ASBS-028, which is a 36-inch outfall that drains a mixture of developed and vacant land. There are additional identified point source clustered west and east of this site with three (ASBS-025, ASBS-026, and ASBS-027) located to the west (within 0.25 miles) and two (ASBS-029 and ASBS-030) located to the east (within 0.1 miles). Therefore, receiving water station S02 is considered to be representative of the typical to worst case scenario of the potential impact that storm water runoff may have on the water quality within the ASBS. **Error! Reference source not found.** shows the locations of the receiving ater stations monitored in support of the preparation of this Plan.

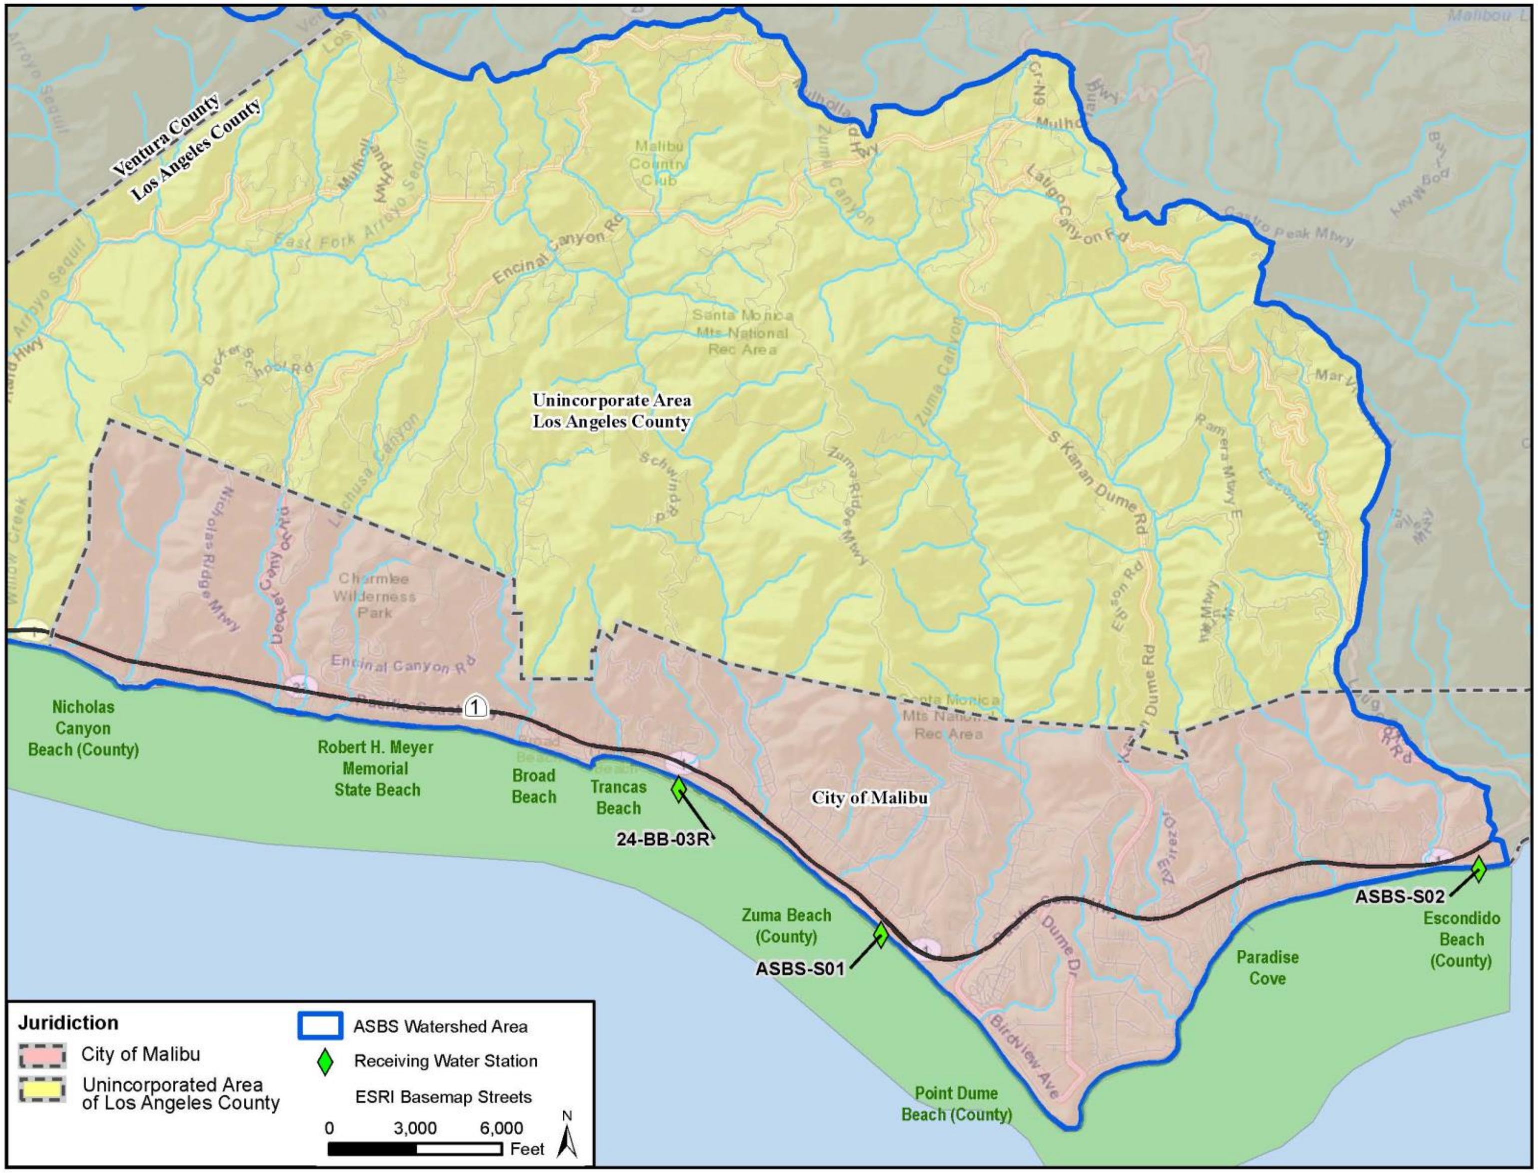

Figure 4-1. ASBS 24 Receiving Water Monitoring Location

RB-AR 7449

4.1.1 February 19, 2013, Storm Event Receiving Water Monitoring

The February 2013 storm event resulted in approximately 0.12 inches of rainfall based on rain gauge data obtained from County Fire Station 70 located at 3970 Carbon Canyon Road in Malibu, CA. Receiving water results were compared to the available list of constituents of reference site 85th percentile values. Post-storm concentrations of nitrate as nitrogen (N), selenium, total PAHs, and total pyrethroids were greater than the 85th percentile threshold (see Table 4-1). However, the nitrate as N post-storm concentration was less than the pre-storm concentration; therefore, the nitrate as N concentration is considered to be similar to background concentrations and is not classified as an exceedance. Since the selenium, total PAHs, and total pyrethroids concentrations were greater than the 85th percentile threshold and were greater than pre-storm concentrations, results from the proceeding storm event were analyzed to determine whether the natural water quality has been exceeded.

For constituents that are summed to get total values for comparison to 85th percentile total values (e.g., all OP pesticides, total PAHs, total pyrethroids), half of the method detection limits (MDL) were used for non-detect values. In the case of total pyrethroids for example, the reference sampling resulted in all non-detect values, and therefore the summation of the MDLs for the 10 selected pyrethroids is 6.75 µg/L. Following this process to determine total pyrethroids for the ASBS 24 receiving water stations results in an exceedance of 85th percentile threshold value anytime a pyrethroid included in the assessment has a measurable result (i.e., 85th percentile threshold in reality is zero). In actuality, the individual pyrethroid values may be less than half the MDL values (undetermined currently based on laboratory limitations) resulting in the possibility that the total pyrethroid value is less than the 85th percentile threshold. The same is true for both all OP pesticides and total PAHs assessments.

4.1.2 March 8, 2013, Storm Event Receiving Water Monitoring

The March 2013 storm event resulted in approximately 0.74 inches of rainfall based on rain gauge data obtained from County Fire Station 70. The selenium and total PAHs concentrations in the receiving water were again greater than both the 85th percentile threshold and pre-storm concentrations (see Table 4-2). As a result, the concentrations of both constituents are considered to be exceedances of natural water quality and may be contributing to alterations in natural ocean water quality within ASBS 24. In addition, concentrations of nitrate as N, copper, lead, mercury, zinc, and total PAHs were greater than both the 85th percentile threshold and pre-storm concentrations. Results from the subsequent monitored wet weather event (February 2014) were used to evaluate whether the listed constituents in storm water runoff were considered to be contributing to an exceedance of natural water quality.

The receiving water Site S02 results for the first monitored event (February 2013 event) included a concentration total pyrethroid that was greater than both the 85th percentile threshold and pre-storm concentrations (see Table 4-1). The February 2014 receiving water Site S02 concentration for total pyrethroid was not greater than both the 85th percentile threshold and pre-storm concentrations (see Table 4-2).

4.1.3 February 28, 2014, Storm Event Receiving Water Monitoring

The February 2014 storm event resulted in a total event rainfall of approximately 2.26 inches of rainfall based on rain gauge data obtained from County Fire Station 70. Pre- and post-storm samples were collected at Sites S01, S02, and 24-BB-03R.

The concentrations of total orthophosphate as P, TSS, mercury, selenium, silver, total PAHs, and total pyrethroids in receiving water at Site S02 were greater than both the 85th percentile threshold and pre-storm concentrations (see Table 4-3). Based on the results from the first and second monitored events in accordance with the General Exception, selenium and total PAHs are considered to be exceedances of natural water quality. The selenium and total PAHs results at Site S02 from the February 2014 event are consistent with those previous data. The mercury result being higher than both the 85th percentile threshold and pre-storm concentration for the second consecutive monitored event is considered to be exceedance of the natural water quality and may be contributing to alterations in natural ocean water quality within ASBS 24. Of the three storms monitored, the February 2014 events results for Site S02 are the only one where orthophosphate as P, TSS, or silver were above both the 85th percentile threshold and pre-storm concentrations. Therefore, the receiving water Site S02 measured concentrations of total orthophosphate as P, TSS, and silver being above both the 85th percentile threshold and pre-storm concentrations during one event are not considered to be exceedances of natural water quality.

The receiving water Site S02 results for the second monitored event (March 2013 event) included concentrations of nitrate as N, copper, lead and zinc that were greater than both the 85th percentile threshold and pre-storm concentrations (see Table 4-2). The February 2014 receiving water Site S02 concentrations for nitrate as N, copper, lead, and zinc were not greater than both the 85th percentile threshold and pre-storm concentrations (see Table 4-3), and therefore these constituents are not considered to be exceedances of the natural water quality.

Mercury, silver, zinc, and total PAHs concentrations in receiving water were greater than both the 85th percentile threshold and pre-storm concentrations for Site S01 (see Table 4-3). This monitored event was the only one of three in which flow from ASBS-016 reached the receiving water at Site S01, and thus, was the only time receiving water chemistry data were obtained at S01 as part of the General Exception monitoring. Based on first and second event results for Site S02, total PAHs is considered to be an exceedances of natural water quality. Based on second and third event results for Site S02, mercury is considered to be an exceedance of natural water quality. The receiving water Site S01 measured concentrations of silver and zinc being above both the 85th percentile threshold and pre-storm concentrations during one event is not considered to be an exceedance of natural water quality.

Pre-storm and post-storm samples were collected and analyzed at Site 24-BB-03R. For safety reasons, this site was not sampled previous to this event. The selenium concentration in the receiving water was greater than both the 85th percentile threshold and pre-storm concentrations for Site 24-BB-03R (see Table 4-3). The concentration of selenium being above the 85th percentile threshold and pre-storm concentrations is not considered an exceedance of natural water quality at Site 24-BB-03R. The selenium result at Site 24-BB-03R above the 85th percentile threshold and pre-storm concentrations are consist with the results for Site S02 where selenium is considered to be an exceedance of natural water quality based on the first and second event results.

4.1.4 December 2, 2014, Storm Event Receiving Water Monitoring

The December 2014 storm event resulted in a total event rainfall of approximately 1.14 inches based on rain gauge data obtained from County Fire Station 70. Pre- and post-storm samples were collected at Site 24-BB-03R.

The concentrations of total ammonia as N, silver, and total PAHs, in receiving water at Site 24-BB-03R were greater than both the 85th percentile threshold and pre-storm concentrations (see

Table 4-4. December 2014 Receiving Water Results). Based on the results from the third (see Table 4-3) and fourth monitored events, in accordance with the General Exception, there were no exceedances of natural water quality. Of the two storms monitored, the December 2014 event result for Site 24-BB-03R is the only one in which total ammonia as N, silver, or total PAHs were above both the 85th percentile threshold and pre-storm concentrations. Therefore, the receiving water Site 24-BB-03R measured concentrations of total ammonia as N, silver, and total PAHs being above both the 85th percentile threshold and pre-storm concentrations during one event are not considered to be exceedances of natural water quality.

4.1.5 Receiving Water Monitoring Conclusions

In post-storm samples collected in the receiving water (Site S02), selenium and total PAHs concentrations were above the 85^{th} percentile reference threshold and had post-storm concentrations that exceeded those of the pre-storm samples collected during three consecutive monitored storm events (February and March 2013 and February 2014). Mercury results at Site S02 were above 85^{th} percentile reference threshold and pre-storm concentrations for two consecutive events (March 2013 and February 2014). Based on the guidance found in Attachment 1 of the General Exception, this indicates an exceedance of natural water of the ASBS for these constituents.

Receiving water samples (Site S02) collected during the second monitored event had concentrations of nitrate as N, copper, lead, and zinc above the 85^{th} percentile reference thresholds and were above the pre-storm concentrations. Based on Attachment 1 of the General Exception, if these constituents are above the 85^{th} percentile reference thresholds in post-storm receiving water samples collected during the next monitoring event, then there would be an exceedance in the natural water quality of the ASBS for these additional constituents. February 2014 receiving water (Site S02) concentrations for nitrate as N, copper, lead, and nickel were not greater than both the 85^{th} percentile threshold and pre-storm concentrations, and these constituents are not considered an exceedance of natural water quality.

Of the three storms monitored, the only event in which flow from ASBS-016 reached the receiving water at Site S01 was during the February 28, 2014, storm (third monitored event), and thus, was the only time receiving water chemistry data were obtained at S01 as part of the General Exception monitoring. Mercury, silver, zinc and total PAHs concentrations in receiving water were greater than both the 85^{th} percentile threshold and pre-storm concentrations for Site S01. Based on the Site S02 results from the first and second events total PAHs is considered to be exceedance of natural water quality. Based on the Site S02 results from the second and third events mercury is considered to be exceedance of natural water quality. The receiving water Site S01 measured concentrations of silver and zinc being above both the 85^{th} percentile thresholds and pre-storm concentrations during one event is not considered to be exceedances of natural water quality.

Pre-storm and post-storm samples were collected and analyzed at Site 24-BB-03R during the February 2014 and December 2014 events. For safety reasons, this site was not sampled at other events. The ammonia as N, silver, and PAH concentrations in the receiving water were greater than both the 85^{th} percentile and the pre-storm concentration for site 24-BB-03R during the December event (see Table 4-4). However, during the February 2014 event only selenium concentration in the receiving water was greater than both the 85^{th} percentile threshold and pre-storm concentration for Site 24-BB-03R (see Table 4-3). Therefore, the concentration of ammonia, silver, PAH, and selenium being above the 85th percentile threshold and pre-storm concentrations are not considered exceedances of natural water quality at Site 24-BB-03R.

4.2 Bight 2008 Data for ASBS 24

A review of Bight 2008 ASBS 24 data was conducted, and a summary of the review is provided for reference and for comparison to the determination made in this Compliance Plan. Bight 2008 constituent concentrations values were obtained from a series of graphs provided as an appendix to the Bight 2008 report and are approximate (tabular data not currently available). The Bight 2008 effort included collecting and analyzing both reference and discharge receiving water samples. The Bight 2008 report showed the comparison between the reference 85th percentile threshold values and discharge samples (Schiff et al., 2011).

4.2.1 Metals

For total chromium, the Bight 2008 85th percentile threshold of reference conditions was 1.6 µg/L (revised by Bight 2013 data to 2.6 µg/L). Of the five ASBS 24 post-storm samples assessed for total chromium during Bight 2008, four had concentrations below the threshold (ranging from approximately 0.5 to 1.0 µg/L) and one was above the threshold (approximately 3.4 µg/L)(Schiff et al., 2011).

For total copper, the Bight 2008 85th percentile threshold was 2.2 µg/L (revised by Bight 2013 data to 1.9 µg/L). Of the three ASBS 24 post-storm samples assessed for total copper during Bight 2008, two had concentrations below the threshold (approximately 0.4 and 0.5 µg/L) and one was slightly above the threshold (approximately 2.3 µg/L)(Schiff et al., 2011).

For total nickel, the Bight 2008 85th percentile threshold was 1.5 µg/L (revised by Bight 2013 data to 2.2 µg/L). For the three ASBS 24 post-storm samples assessed during Bight 2008, two had concentrations below the threshold (approximately 0.5 and 0.7 µg/L) and one was above the threshold (approximately 4.2 µg/L)(Schiff et al., 2011).

For total zinc, the Bight 2008 85th percentile threshold was 8.6 µg/L (revised by Bight 2013 data to 19 µg/L). Of the five ASBS 24 post-storm samples assessed for total zinc during Bight 2008, three had concentrations below the threshold (ranging from 0 to approximately 2.1 µg/L) and two were above the threshold (approximately 10.5 and 11.0 µg/L)(Schiff et al., 2011).

Samples collected as part of the Bight 2008 efforts were not analyzed for mercury or selenium, and thus no Bight 85th percentile thresholds were established for these constituents.

4.2.2 Total Suspended Solids

For TSS, the Bight 2008 85th percentile threshold was 16.5 mg/L (revised by Bight 2013 data to 55.4 µg/). Of the five ASBS 24 post-storm samples assessed for TSS during the Bight 2008, two had concentrations below the threshold (approximately 8.0 and 10.0 µg/L) and three were above the threshold (ranging from approximately 50 to 130 µg/L)(Schiff et al., 2011).

4.2.3 Total PAHs

For total PAHs, the Bight 2008 85th percentile threshold was 19.6 ng/L (revised by Bight 2013 data to 12.5 ng/L). Of the four ASBS 24 post-storm samples assessed for total PAHs during the Bight 2008, all four samples had concentrations below the threshold (approximately 0, 5, 8, and 11 ng/L)(Schiff et al., 2011).

4.2.4 Organophosphorus Pesticides and Pyrethroids

Samples collected as part of the Bight 2008 efforts were not analyzed for organophosphorus pesticides or pyrethroids, and thus no Bight 85th percentile thresholds were established for these constituents.

5.0 OUTFALL ASSESSMENT OF POLLUTANT LOAD REDUCTION TARGETS

An assessment of the potential pollutant load reductions targets was performed to determine the magnitude of controls required to be implemented in order to enhance the water quality of the ASBS. The first step in the assessment process was to evaluate wet weather receiving water quality monitoring data in comparison to data for reference monitoring sites, in accordance with the flowchart provided as Attachment 1 to the General Exception, to determine if an exceedance of the natural water quality currently exists (see Section 4.0). This evaluation determined that an exceedance of natural water exists for three constituents at receiving water Site S02 and discussed in more detail in Section 4.0. Water quality results from outfall monitoring were evaluated for the applicable constituent to identify discharge locations that have a potential to be contributing to the exceedance of natural water quality. More specifically, the assessment evaluated where BMPs may be required to achieve outfall design storm discharge concentrations, on average, by either: 1) end-of-pipe concentrations below the Table B Instantaneous Maximum Water Quality Objectives (WQOs) in Chapter II of the Ocean Plan, or 2) achieving a 90% reduction in pollutant loading during storm events for the responsible applicant's total discharge. The Ocean Plan was updated subsequent to the General Exception adoption. The updated Ocean Plan now refers to Table B as Table 1 (formerly Table B), and this Plan utilized the updated table title.

5.1 Outfall Wet Weather Monitoring Results

The General Exception states that the ASBS Compliance Plan shall describe how the necessary pollutant reductions in storm water runoff will be achieved through prioritization of outfalls and implementation of BMPs to reduce end-of-pipe pollutant concentrations during a design storm to below either the Table 1 Instantaneous Maximum WQOs in Chapter II of the Ocean Plan or a 90% reduction in pollutant loading during storm events for the applicant's total discharge. For the constituents that are currently in exceedance of the natural water quality of the ASBS (mercury, selenium, and total PAHs), this draft ASBS Compliance Plan evaluates outfall discharges in comparison to the Table 1 Instantaneous Maximum WQOs as the pollutant load targets in order to be in compliance with the General Exception.

Chemistry results obtained from outfalls to ASBS 24 during the February 2013, March 2013, February 2014, and December 2014 storm events are presented on Table 5-1 through Table 5-4, respectively. Site ASBS-008 was not added to the monitoring list until after the February 19, 2013, storm event, so no data were collected during the first monitoring event. Site ASBS-008 was inadvertently not monitored during the third storm event. Sites ASBS-013, ASBS-016, and ASBS-031 did not flow during the February 19, 2013, storm event, and Sites ASBS-013 and ASBS-031 did not flow during the March 8, 2013, storm event. Site ASBS-031 did not flow during the February 2014 storm event. Outfalls that were less than 36 inches in diameter were evaluated for oil and grease and TSS only, while outfalls that were 36 inches or greater in diameter were evaluated for ammonia, nitrate, oil and grease, TSS, total orthophosphate, total metals, PAHs, organophosphorus pesticides, and pyrethroids. Table 5-1 through Table 5-3 include both PAHs (based on 13 constituents listed in the Ocean Plan) and total PAHs (based on the 25 constituents analyzed by the laboratory based on guidance from the Bight 2013

Committee). These tables also list the more commonly detected individual pyrethroids as well as the total pyrethroids.

Note 1 - Site associated with Receiving Water Station SO1
Note 2 - Site associated with Receiving Water Station SO2
Note 3 - PAHs based on constituents listed in Ocean Plan
Note 4 - Total PAHs based on constituents listed in Bight 2013 Work Plan.

The Ocean Plan Table 1 Instantaneous Maximum WQOs for mercury and selenium are 0.4 µg/L and 150 µg/L, respectively. Table 1 does not list Instantaneous Maximum WQOs for PAHs. This Plan focused on mercury and selenium in this assessment of pollutant load reduction targets. During the four monitored events the sampling results were all below these Ocean Plan Table 1 Instantaneous Maximum values. During the first storm monitored in 2013 (February 8, 2013), the highest measured values of mercury and selenium were 0.16 µg/L and 0.79 µg/L, respectively, at ASBS-003. Outfall ASBS-028 had measured mercury and selenium concentrations of 0.06 µg/L and 1.0 µg/L, respectively, during the second monitored storm, which occurred in March 2013. During the third monitored storm, which occurred in February 2014, the measured selenium concentration at Outfall ASBS-023 was the highest value measured at 5.1 µg/L. All outfall samples collected and analyzed for mercury had results of non-detect during the third event. The summary of the highest measured values in comparison with the Ocean Plan Table 1 Instantaneous Maximum values as well as other Ocean Plan Table 1 limiting concentrations is provided on Table 5-5.

Table 5-5. Ocean Plan Comparison to Summary of Maximum Outfall Results

	Ocean Plan Table 1 Values (Receiving Water Mixing Zone)			Maximum Measured Value (in Outfall Prior to Mixing Zone)		
Parameter	6-Month Median	Daily Maximum	Instantaneous Maximum	February 2013, Event 1	March 2013, Event 2	February 2014, Event 3
Mercury	0.04	0.16	0.4	0.16	0.06	<0.0012
Selenium	15	60	150	0.79	1.0	5.1

The summary table of maximum outfall results values for mercury and selenium indicate that the pollutant loading storm water discharges from outfalls for these constituents is far below the Ocean Plan Table 1 Instantaneous Maximum values. The highest mercury value measured is equal to the Ocean Plan Table 1 Daily Maximum values. The highest selenium value measured is below the Ocean Plan Table 1 Instantaneous Maximum with over an order of magnitude difference between the two. The highest selenium value measured is also below the most limiting concentration of the Ocean Plan Table 1, which the 6-Month Median value. The measured values of mercury and selenium, besides those presented in the summary table above, were significantly less than the maximum measured.

Common major sources of mercury include scrap metal piles, deteriorating metal and paint, and airborne emissions from burning coal, oil or municipal waste (UWE, 1997). Selenium is a naturally occurring element that persists in soils and aquatic sediments and may be leached from sediments as a result of modifications in the natural hydrologic regime (LARWQCB, 2002). Higher levels of selenium are also documented to be associated with the Monterey/Modelogeologic formation, which is prevalent in this area.

5.2 Outfall Assessment Conclusions

Following the guidance found in the Special Protections an assessment of outfalls was performed to determine where structural controls may be required to achieve the specified pollutant loading limitations on point source discharges into ASBS 24. Preceding the outfall assessment was the receiving water assessment that indicated, also based on the guidance found in the Special

Protections, that there are exceedances of natural water in the receiving water during wet weather events for mercury, selenium, and total PAHs where samples were available for this assessment. The outfall assessment included comparing the monitoring data for mercury and selenium to Ocean Plan Table 1 Instantaneous Maximum limitations. The Ocean Plan Table 1 does not list Instantaneous Maximum values for the protection of marine aquatic life for total PAHs, it only lists 30-day Average concentration limits for the protection of human health. The results of the comparison indicate the discharges to the ASBS from point sources (outfalls) are currently achieving, and significantly below, the target levels. Therefore, based on available data and guidance documents, the outfalls being evaluated in this Plan under the Regional Monitoring Program are currently not considered priority outfalls, and in accordance with the Special Protections of the General Exception, additional controls (e.g., BMPs) to achieve pollutant load reductions are not required in the tributary drainage areas to the Parties' outfalls.

Based on the guidance presented within the Special Protections, the assessments performed in the preparation of this Compliance Plan indicated that additional structural BMPs are not required. However, the Parties recognize that the ABSB 24 is one of most valued resources in the region and that wherever possible, and feasible, additional reductions in pollutant loading should be achieved. Accordingly, in July 2015, the City deemed construction complete for structural BMPs for the areas of Broad Beach Road and Wildlife Road where City inlets drain to private outlets in the ASBS area. Various existing nonstructural programs will continue to be implemented in order to maintain compliance with the requirements of the Special Protections and possibly achieve further reductions in pollutant loading. The Parties are considering implementing nonstructural controls and enhancements to existing controls for the purpose of further reducing pollutant loading to the ASBS.

6.0 CONTROL MEASURES

6.1 Enhanced Nonstructural Programs

Existing nonstructural PIPPs, O&M programs, and enforcement programs will continue to be implemented and maintained into the future to ensure ongoing protection of ASBS 24 and to meet the requirements of the ASBS Special Protections. This section describes enhancements to existing nonstructural programs intended to further promote load reductions and further improve and protect ASBS water quality. Proposed Potential program enhancements for feasibility consideration that will be evaluated and are presented in Appendix C and include the following:

- Infrastructure priority re-evaluation program.
- Enhanced, collaborative, environmentally friendly, alternative services program(s).
- ASBS education signage (County).
- Aggressive street sweeping (City).
- Street sweeping parking ordinances (City).
- Architectural copper and metal building material mitigation program(s) (City).
- Metal building material ordinances (City).

6.1.1.1 Infrastructure Priority Re-Evaluation Program

Currently, the County is in the design phase of retrofitting Unincorporated County areas catch basins in in North Santa Monica Bay from Arroyo Sequit on the northwest through Topanga Canyon on the southeast with full capture trash screens (this area includes the ASBS 24 drainage area). This activity includes a complete field inventory of all catch basins in the area. The Parties will enhance their existing annual cleaning programs for retrofitted catch basins.

If evaluation of future wet weather monitoring data indicates that additional nonstructural solutions are necessary to meet the Special Protection water quality criteria, the City and County will review and re-evaluate the existing inspection/cleaning priorities assigned to infrastructures located in the ASBS 24 drainage area. Agency-wide infrastructure inspection/cleaning programs (priorities and frequencies) are established using NPDES permit criteria and historic debris load data for each system. The receiving water or watershed of each system (e.g., catch basin, street, and parking lot) is not directly considered. Increased cleaning may be appropriate for ASBS 24 to enhance source control of gross pollutants (e.g., trash, debris, sediments) as well as associated pollutants, such as metals, organics, and nutrients. An infrastructure re-evaluation program may also provide benefits such as a streamlined, efficient, and effective implementation program for ASBS 24.

6.1.1.2 Enhanced Collaborative Environmentally Friendly Alternative Services Program(s)

When implementing this type of program, the County and City will look for opportunities to enhance existing environmentally friendly alternative services and PIPPs currently provided by the Parties. Types of existing PIPPs that may be enhanced include the Clean Bay Restaurant Certification Program, the *Keep It Clean, Malibu* campaign, City of Malibu's Environmentally

Preferable Purchases and Practices Policy (EPPP), Recycled Products Purchasing Policy (RCPP), Restaurant Certification Program, and Los Angeles County's Rethink LA Program. The LACoMAX platform has been presented as an example of types of enhancements and synergies, which may be implemented depending on water quality needs and available funding.

Users have identified LACoMAX as "easy, fast and rewarding" and a "great resource for L.A. County" to exchange goods. To reach a larger audience, this program could be cross-referenced with similar programs such as the Malibu Green Room webpage, Craigslist-Los Angeles, and other regional websites. The platform currently provides six management regions for exchange, and the platform could be expanded to include ASBS- and TMDL-specific regions, along with educational information related to the benefits of the program and reduced impacts to the ASBS and receiving waters that may be caused by improper disposal of unwanted items. Partner webpages could provide links to other exchange programs and up-cycling venues (e.g., Goodwill, consignment, thrift stores, and swap meets). Additional enhancements to the platform may be identified by analyzing user data from the existing platform and/or requesting users to complete questionnaires.

6.1.1.3 ASBS Educational Signage

This program would involve the design and installation of educational placards along boardwalks and at parking lot entrances to the beaches. These placards, translated in both English and Spanish, will describe the unique resources of ASBS 24 and highlight features of interest specific to each beach. Additional educational messages related to source controls and pollution prevention measures will be determined based on wet weather data and targeted sources. This program could provide a direct nonstructural intervention to potential pollutant sources at County beaches, as well as influence behavior for local beachgoers who live in residential areas that discharge to ASBS 24.

6.1.1.4 Aggressive Street Sweeping

This program would involve enhancing the City's existing street sweeping program. Aggressive street sweeping may include increased frequency of sweeping, use of enhanced sweeping technologies, or other sweeping solutions (USEPA, 2012a). The City may choose to implement a pilot study to determine the optimal sweeping program prior to full-scale implementation.

The City currently sweeps roads within its jurisdiction once each month and shares a contract with Caltrans to have PCH swept weekly. This program would involve increasing the frequency of sweeping on City streets located within the area draining to ASBS 24 to once per week. Increasing the sweeping frequency has been shown to increase the potential load reduction associated with metals, sediments, trash, and debris (City of San Diego, 2010a).

Vacuum and regenerative-air street sweeping technologies have been shown to be more effective than mechanical sweeping technologies at removing fine particulate matter, especially related to metals debris (City of San Diego, 2010a; City of Portland, 2006). As of 2013, the City uses motorized mechanical street sweeping equipment for all street sweeping activities. This proposed nonstructural program enhancement would apply to all City-maintained streets and would involve either: 1) replacing mechanical street sweepers with enhanced sweeping technologies during the standard end of the equipment life-cycle, or 2) requiring contractors responsible for local sweeping activities to only use enhanced sweeping technologies.

Because the City shares a street sweeping contract with Caltrans for sweeping the PCH it is subject to conditions of an agreement. At present, Caltrans' policy requires once-per-week sweeping using mechanical sweeping equipment. Historically, the City used enhanced sweeping technologies for streets within their jurisdiction, including the PCH. The City was requested by Caltrans to use mechanical sweepers due to their state-wide policy. Implementation of this recommended nonstructural program enhancement will require one of the following Caltrans policy changes: 1) a state-wide policy change, 2) local exemption to the state-wide policy, or 3) agreement to do additional sweeping beyond the state-wide policy requirement, using a vacuum or regenerative-air sweeper along the PCH in the ASBS 24 drainage area.

6.1.1.5 Street Sweeping Parking Ordinances

Mechanical sweeping technologies are most effective at removing trash, debris, and sediment from paved surfaces when the equipment travels along the curb and gutter (City of San Diego, 2010a; City of Portland, 2006). Under the existing City street sweeping program, residents and business owners have been requested to use off-street parking on scheduled street sweeping days whenever possible. Vehicles continue to park along the PCH and City streets during street sweeping days. The City currently does not have an ordinance restricting parking.

The City may consider implementing an ordinance prohibiting parking on City-maintained streets during regularly scheduled street sweeping activities. This programmatic enhancement would increase the potential load reduction associated with street sweeping activities independent of modifications to existing street sweeping equipment and sweeping frequency. Prior to implementation of a general parking ordinance, the City may need to conduct an education and outreach campaign and public opinion survey to identify the most effective street sweeping schedule and evaluate the public's appetite for program implementation. However, it is important to note that such an ordinance would be subject to scrutiny by the California Coastal Commission due to public beach access concerns, and is not likely to be feasible.

6.1.1.6 Architectural Copper and Metal Building Material Mitigation Program(s)

Metal building materials may appear to be a limited wet weather source, but in coastal areas buildings may be a year-round source of runoff and metals loading because the marine layer can create measurable runoff as water condenses on rooftops and buildings structures (City of San Diego, 2010b). Monitoring data of storm water wash-off from some metal building materials has been shown to be associated with elevated copper and zinc levels (Golding, 2008).

This program will investigate the feasibility of offering rebates for architectural copper and zinc mitigation measures applied to metal building structures. Potential mitigation measures may include: application of sacrificial paint (e.g., copper and zinc oxidation protection paints), downspout diversions, rain barrels, and cisterns. The rebate program could be modeled after the Cash for Grass and other water conservation incentive programs discussed in Section 3.2.1.2. Education materials could be incorporated into existing materials, such as the Surfrider OFG materials and ASBS materials, and online media, such as the Malibu Green Room and Clean LA websites.

6.1.1.7 Metal Building Material Ordinances

As discussed in Section 6.1.1.6, buildings with metal architectural features may be a year-round source of runoff and metals loading. Metal building material ordinances, including the architectural copper ban and zinc alternative building material ordinance, are proposed as a potential programs enhancement and are a true source control. It is generally recognized that implementation of any kind of metal building material ordinance will require significant education and outreach. Targeted audiences will include residents and businesses, and may also include architects and engineers who design and build structures within the ASBS 24 drainage area. A program such as this would first need to go through a feasibility review and also receive City Council approval.

Architectural Copper Ban
This City ordinance would prohibit use of architectural copper for all new developments and re-development projects for buildings and facilities located within the ASBS 24 watershed.

Zinc Alternative Building Material Ordinance
Galvanized zinc is frequently specified by agencies, including Caltrans, for outdoor installations due to material durability and lack of maintenance requirements. This City program would evaluate the feasibility of implementing a zinc building material policy that would eliminate, reduce, mitigate, or control the use of zinc building materials. Concurrent with the feasibility analysis, stakeholders would be engaged through public meetings. Based upon the findings of the feasibility analysis and stakeholder engagement process, a proposed zinc ordinance would be implemented.

6.2 Structural BMPs

The pollutant loading reduction assessment (Section 5.0) performed in preparation of this Plan indicated that structural BMPs are not required (pollutant loading is on average below the Ocean Plan Table B Instantaneous Maximum WQOs for the modeled design storm). However, in July 2015, the City deemed construction complete for structural BMPs for the areas of Broad Beach Road and Wildlife Road where City inlets drain to private outlets in the ASBS area.. These projects each installed biofiltration BMPs,and the Wildlife Road project only also included limited infiltration improvements to capture and treat wet weather flows entering the associated catch basins. Additional information on these projects, including conceptual design and drainage analysis, is included in Appendix C.

6.3 Pollutant Load Reduction Quantification For Nonstructural Controls

This section demonstrates how existing nonstructural programs have contributed to compliance with the zero dry weather discharge criteria of the Special Protections. This section also discusses the quantifiable percent reductions that have been achieved and that will be achieved using enhanced nonstructural controls. The quantification of the effectiveness of nonstructural controls is a developing science. Although the effectiveness of most nonstructural controls is not well documented in available literature, data on recent studies (e.g., street sweeping and source studies) provide a basis for developing quantification estimates. It has also been documented

(City of San Diego, 2010a; Brown et al., 2010; Pohl, 2010; Cac and Ogawa, 2010; Krieger et al., 2010) that nonstructural controls that target operational and true source controls can provide far more cost-effective, long-term solutions than end-of-pipe treatment BMPs.

Nonstructural BMPs are designed to reduce the concentrations of constituents at the source prior to the generation of surface storm water runoff and therefore prior to runoff entering storm drains, reaching BMPs, and reaching the receiving water. Typical load reductions associated with the quantification of nonstructural programs is on the order of 25% (LARWQCB, 2005) (County of Los Angeles, 2012).

6.3.1 Load Reductions Associated with Nonstructural Solutions

The scope of the nonstructural program load reduction quantification is limited. Many nonstructural programs currently implemented within ASBS 24, such as the Parties' IC/ID and spill response programs, cannot be quantified and entered into a load reduction model because they are designed to control constituents at their source for a sporadic event. However, these programs do offer a water quality benefit, and various types of data are available and may be used to demonstrate changes in public behavior.

When targeted at the actual pollutant source, nonstructural solutions (e.g., operational source controls) have been shown in studies to be very effective at removing the source and therefore reducing concentrations/loads to below regulatory requirements. For example, the *Mission Bay Clean Beaches Initiative Bacterial Source Identification Study* found birds and over-irrigation to be two major sources of bacterial contamination (Weston, 2004). Monitoring conducted following a redesign of the irrigation system and relocation of an in-water raft popularly used by birds indicated that bacterial concentrations in the receiving waters were very low. During the study, there was one exceedance, and follow-up studies showed that the source of the exceedance was not associated with irrigation runoff or birds (Weston, 2006).

Furthermore, true source controls that replace or modify the constituent content of products that have been determined to impact water quality should be part of the nonstructural program. True source controls have been proven to be highly cost effective as in the case of the banning of the pesticide Diazinon, which has resulted in a clear reduction from well above to now below the water quality objective in the Chollas Creek watershed, which is under a TMDL for this contaminant (SDRWQCB, 2007). Senate Bill 346 adopted in 2010 which requires reduction of copper in brake pads in California was achieved through the Brake Pad Partnership. The legislation was based on scientific data showing the impact of copper from brake pads on water quality in urban areas. This true source control approach will significantly reduce copper concentrations in most urbanized watersheds. In the urbanized Chollas Creek watershed (which is under a dissolved metals TMDL), it has been estimated that approximately 90% of the copper loading is from brake pad deposition (City of San Diego, 2009). It is anticipated that most of the copper load reduction necessary to meet the Chollas Creek TMDL will be achieved from the reduction of copper in brake pads, a true source control strategy.

As indicated in the Outfall Wet Weather Monitoring Results for 2013 and the Pollutant Load Reduction Targets, zinc and TSS are currently considered to be in exceedance of the natural water quality in ASBS 24. Nonstructural controls that include both operational and true source control measures to reduce zinc and TSS loading have therefore been emphasized.

6.3.2 Aggressive Street Sweeping

According to the EPA, street sweeping programs may reduce the need for other structural storm water BMPs and may prove more cost effective than structural BMPs, especially in more urbanized areas (USEPA, 2012a). Aggressive street sweeping can be highly effective in reducing wet weather metals loading (City of San Diego, 2010a; Seattle Public Utilities, 2009; City of Portland, 2006) and, to a lesser extent, bacteria (Skinner et al., 2010), while continuing to address trash, debris, and sediment pollution.

The County has implemented an aggressive street sweeping program at County Beach parking lots (i.e., sweeping three to four times per week with enhanced sweeping equipment). Given that these parking lots experience a reduced traffic load compared to the PCH and City streets, and have an aggressive sweeping schedule and program, the County's existing parking lot sweeping program is considered to be appropriate for protecting ASBS 24 water quality (i.e., program at a high level where adding enhancements may provide diminishing returns).

The City currently implements a two-part street sweeping program, including weekly mechanical sweeping along PCH and monthly mechanical sweeping along City-maintained streets. Sections 6.1.1.4 and 6.1.1.5 discuss potential enhancements to the City's existing sweeping program, including modifications to the sweeping schedule, sweeping equipment, and City parking policies. The pollutant load reductions associated with these enhanced sweeping program options are discussed in Appendix A. Program implementation may be limited by cost, especially once enhanced sweeping programs have reached a point of diminishing returns (USEPA, 2012a).

6.3.3 Commercial Programs

Commercial land use represents a very small portion of the ASBS 24 watershed, and the City's existing commercial inspection and outreach programs have been effective at preventing discharges from these facilities. Restaurants and grocers represent the predominant commercial business within this drainage area and existing programs have ensured compliance with the zero dry weather runoff criteria of the Special Protections by eliminating outdoor washing activities and promoting pollution prevention measures. As of February 2013, 51 of the 63 qualifying restaurants and food management businesses within the City's entire jurisdiction (e.g., 81% overall participation) were re-certified as being 100% compliant with all Clean Bay Restaurant Certificate Program criteria, which includes zero dry weather discharge off-site. It is important to note that the program also includes criteria that are not related to water quality. For instance, if a business is not implementing a recycling program, they would not be eligible for certification. Therefore, the percentage of businesses protecting water quality is likely to be higher than the overall participation rate. Ongoing implementation of this program will continue to ensure continue compliance with the zero dry weather runoff criteria of the Special Protections.

The City's existing commercial programs also provide wet weather water quality benefits. For example, waste management and spill prevention programs eliminate or control outdoor trash, metals, grease, and bacteria sources, which may be washed into the MS4 during storm events. Elimination of outdoor washing activities, especially near landscaped areas, can also control erosion and sediment disturbance. To date, the existing commercial inspection and outreach programs implemented by the City have potentially resulted in a 1% to 4% pollutant load reduction and have been incorporated into the initial assessment of wet weather load. Additional future load reductions may be achieved as participation in the Clean Bay Restaurant Certificate Program grows towards 100% participation and as synergies between PIPP programs are identified and incorporated into Enhanced Collaborative Environmentally Friendly Alternative Services Program(s).

6.3.4 Outreach, Water Conservation, and Irrigation Management Programs

Nationally, lawn care accounts for 32% of the total residential outdoor water use (USEPA, 2013) and over-irrigation is a common source of runoff. While irrigation runoff is a freshwater source and does not represent a pollutant unto itself, irrigation-related dry weather flows have the potential to erode landscaping and mobilize pollutants. Even when irrigation water does not reach the MS4, pollutant mobilization to impervious surfaces can create a non-point source of pollution during wet weather.

Use of water-saving devices (e.g., irrigation controllers, sprinkler heads) conserve water and prevent over-irrigation. The former Landscape Irrigation Efficiency Program (LIEP) and Water Saving Devices Rebates Programs' educational literature provide an estimated water savings of 13,500 gallons per location converted per year. Use of drought-tolerant plants and landscaping in place of grass provides additional water savings and further reduces the likelihood of over-irrigation. The water conservation and over-irrigation reduction programs that the County and the City administer and provide educational support for in the ASBS 24 drainage area have helped control over-irrigation runoff and achieve compliance with the zero dry weather discharge criteria of the Special Protections. These programs have also helped reduce pollutant mobilization and creation of non-point sources on impervious surfaces. As participation in the rebate program grows, there is potential for an additional 1% to 2% wet weather pollutant load reduction through this indirect source control program.

OFGs and CA Friendly Landscapes are structural BMPs that infiltrate runoff and bio-remediate pollutants, effectively disconnecting both dry weather and the first flush of storm water runoff from the receiving water. The City has two demonstration landscapes that can be used as examples to the community: one at Legacy Park and one at Bluffs Park. The City recognizes three residential OFGs, one of which is located within ASBS 24 at Point Dume. Promotion of local OFGs contributes to their implementation by residents, educational institutions, and businesses. Ongoing implementation of this program and the resulting net increase in OFG implementation will likely translate to an additional 1% to 2% wet weather pollutant load reduction.

The City provides education and outreach on water-saving incentive programs and OFGs, and responds to irrigation-related IC/IDs. The City's 24-hour Pollution Prevention Hotline received fewer than 10 calls during the first year, or on average less than one per month. (The Clean LA hotline, which is shared with the District, fielded 34,064 calls during the fiscal year covered under the 2011-2012 Annual Report [LACDPW, 2012].) Most of the IC/ID field investigations have been due to over-irrigation and were resolved within a month through collaboration between the City and the property owner. Additionally, as of September 5, 2014, the City launched a online water wasting report form in response to the historic drought conditions. This reporting form makes it more efficient for the community to notify and the City to respond to incidents of runoff due to over-irrigation among other water wasting activities. Ongoing implementation of the ASBS Focused Outreach Program will continue to increase participation in rebate programs and OFG and CA Friendly Landscape implementation, contributing to the wet weather load reductions previously discussed.

6.3.5 Metal Building Material Management Program

Recent studies have shown that architectural copper and galvanized steel building materials can elevate the metals concentrations measured in storm water runoff from 10 to 100 times greater than concentrations measured for non-metal building materials (City of San Diego, 2009; Chang et al., 2004; Davis et al., 2001). Zinc in storm water runoff measured directly from galvanized metal surfaces is typically very high, between 1,000 and 15,000 µg/L (Golding, 2008).

An aggressive outreach and incentive program may encourage targeted audiences to proactively modify infrastructure (e.g., install OFGs and rain barrels to capture runoff, replace with non-metal materials, diversion of air conditioning condensate away from metal infrastructure) and behaviors (e.g., proactive housekeeping, apply and maintain sacrificial coatings). In the ASBS, a phase-out and full ban of copper and zinc building materials represents a true source control measure that could significantly reduce metals loading to ASBS 24. In Palo Alto, a similar metal building material ordinance for copper plumbing fixtures was implemented in response to a copper TMDL (City of Palo Alto, 2011). Institutional controls and regulatory change also represent an important step toward laying the foundation for inspections, if determined to be appropriate.

A Simple Method model was prepared to estimate the load reductions from implementing this program. To complete the model, several assumptions related to a typical watershed were made and include the following:

- An urban watershed composed of 50% residential, 40% open space, and 10% transportation.
- Of runoff from these land uses, 25% have elevated concentrations of copper resulting from building materials (e.g., copper rain gutters).
- Incentive program would be utilized by 20% of the residential land use area.
- Where the incentive program is utilized, copper concentration reductions in storm water would be in the range of 40% to 80%.

Based on these assumptions, metal building material management programs could result in a 6% to 12% pollutant load reduction. For more information on the load reduction calculations, see Appendix D.

7.0 ASSESSMENT OF ANTHROPOGENIC SEDIMENTATION POTENTIAL

In accordance with the requirements of the General Exemption, the natural habitat conditions in the ASBS shall not be altered as a result of anthropogenic sedimentation (SWRCB, 2012b). An assessment of the potential areas prone to anthropogenic sedimentation was performed as part of this Compliance Plan for the purpose of identifying areas where sediment control BMPs may be required. The general assessment process included first performing a desktop analysis of geological conditions, topography, land use, and aerial imagery for the applicable area. Next, a reconnaissance of the area was performed to verify desktop findings and further analyze the drainage areas. Finally, the desktop and reconnaissance data collected were then compiled into this Plan, which details the assessment methodologies, results, and conclusions.

7.1 Sedimentation Definitions

Basic definitions relating to sedimentation and the coverage/applicability of the sedimentation identification assessment are provided below. These terms are relevant to the entire sedimentation assessment. Additional terms, applicable to specific subsections, are defined within the applicable subsection, as needed.

Erosion
"The process by which soil particles are detached and transported by the actions of wind, water, or gravity." (SWRCB, 2010).

Sediment
"Solid particulate matter, both mineral and organic, that is in suspension, is being transported, or has been moved from its site of origin by air, water, gravity, or ice and has come to rest on the earth's surface either above or below sea level." (SWRCB, 2010).

Sedimentation
"Process of deposition of suspended matter carried by water, wastewater, or other liquids, by gravity. It is usually accomplished by reducing the velocity of the liquid below the point at which it can transport the suspended material." (SWRCB, 2010).

Anthropogenic Sedimentation
For the purposes of this assessment, anthropogenic sedimentation is defined as sedimentation resulting from mankind activities in the past or present. Stated differently, anthropogenic sedimentation is any sedimentation that would not be present in nature in the absence of mankind and mankind improvements (i.e., past and present absence of mankind).

Compliance Plan Anthropogenic Sedimentation Assessment Area
In accordance with the General Exception, the Compliance Plan focuses on the assessment of point source discharges, including pollutants, and the potential controls to reduce pollutant loading from these point sources. Therefore, the Compliance Plan assessment of areas prone to anthropogenic sedimentation was limited to the tributary drainages areas associated with the point source outfalls detailed in Section 2.6 of the Compliance Plan. Figure 7-1 shows the Parties' identified outfalls and drainage areas (catchment areas).

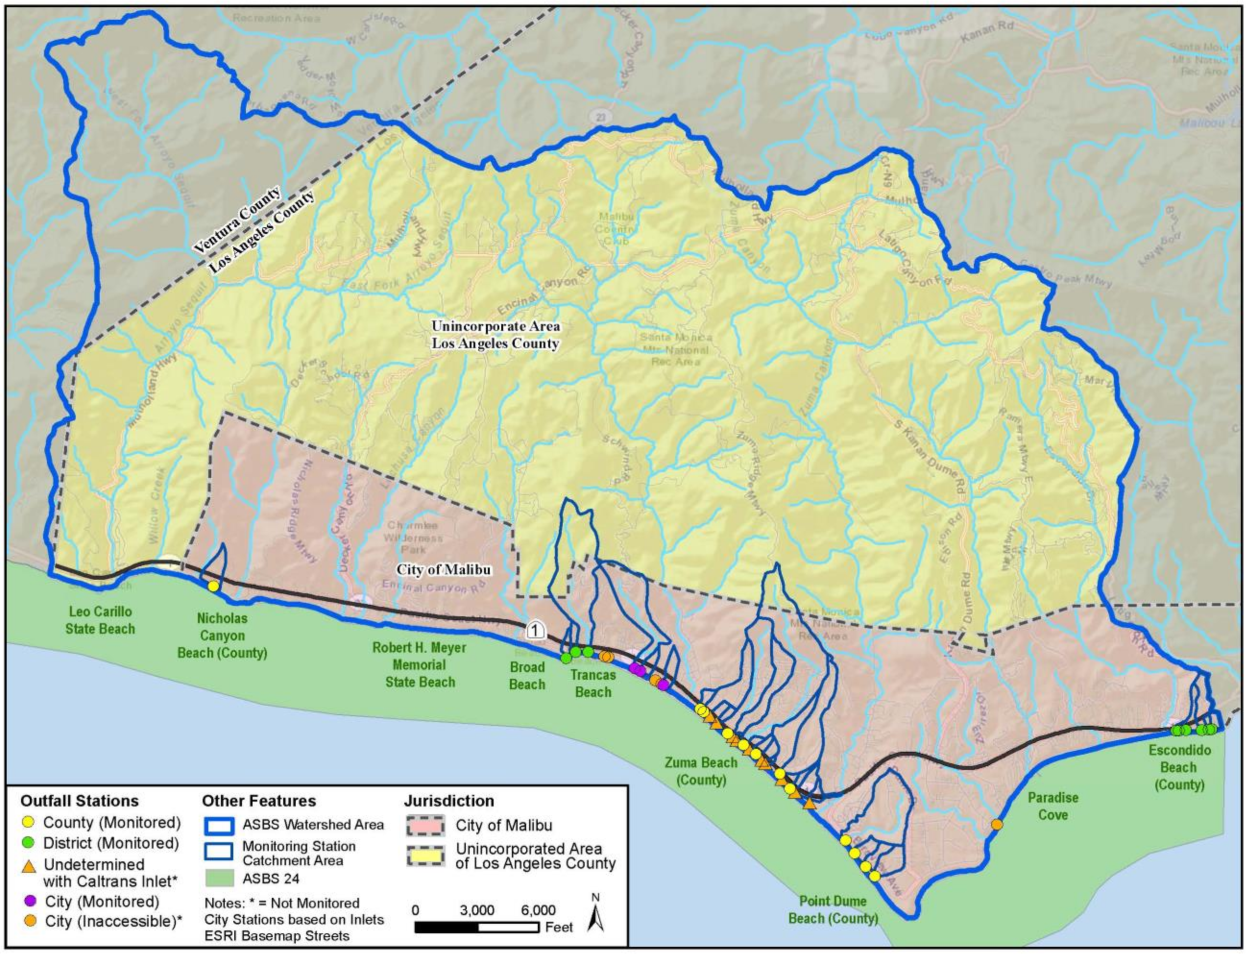

Figure 7-1. ASBS 24 Identified Outfall Catchment Areas

7.2 Desktop Analysis

A desktop analysis was performed evaluating the geology, topography, land use, and general surface condition (e.g., vegetation cover) in order to identify potential areas prone to erosion within the drainage areas tributary to the Parties' outfalls. The collection of area geological data included conducting literature reviews of five references applicable to the region ([City, 1995], [NPS, 1997], [Yerkes and Campbell, 1979],[SWRCB, 1979], and [SWRCB, 2012c]). County of Los Angeles Department of Transportation staff were interviewed regarding roadway maintenance activities and the frequency of sediment removal performed in the area. Sediment risk data for the area, obtained from the General Permit for Storm Water Discharges Associated with Construction and Land Disturbance Actives (Construction General Permit) (SWRCB, 2010), were evaluated to determine the general sediment risk for disturbed areas. GIS data relating to topography, land use, and aerial imagery were analyzed to evaluated surface gradients and vegetative coverage types in the area.

7.2.1 ASBS 24 Assessment Area Geology

As detailed in Section 2.6, the Compliance Plan identified 38 outfall point sources along the ASBS 24 coast within the Parties' jurisdiction. The drainage area for the northerly most outfall, located near Nicholas Canyon State Beach (ASBS-031), consists primarily of Santa Monica Mountain (Topanga Formations) with Trancas Formation along the shoreline. The drainage areas for the outfalls along the west half of Broad Beach (ASBS-001, -002, and -003) consist primarily of the Santa Monica Mountains (Topanga, Santa Susana/Coal Canyon, and Llajas Formations) with small areas of Trancas Formation along the coastline. The outfalls along the east half of Broad Beach and the northeast half of Zuma Beach (BB-001 through BB-003 and ASBS-004 through ASBS-016) have drainage areas that consist of varying percentages of Modelo Formation along the coast and Santa Monica Mountains (Topanga, Santa Susana/Coal Canyon, and Llajas Formations; Conejo Volcanics; and Diabase Intrusions). The outfalls located along the southeast half of Zuma Beach and Point Dume Beach (Westward Beach) (ASBS-017 through ASBS-024) have drainage areas within the Monterey/Modelo Formation. The drainage areas of the six outfalls located along Escondido consist of Santa Monica Mountain and small areas of Modelo Formation along the coast. Figure 7-2 and Figure 7-3 show the geological features and drainage areas of the Parties' outfalls identified in this Plan (NPS, 2007).

Map symbols used along the coastal area were defined using the National Geologic Map Database. Pleistocene marine terrace deposits along the shoreline include the Trancas and Monterey Formations. The symbols used to depict general costal geologic features in Figure 7-2 through Figure 7-3 included the following:

- Qa – Alluvial gravel, sand, and clay of flood plains.
- Qaf – Artificial cut and fill.
- Qao – Older dissected alluvial gravel, sand, and clay; on coastal area deposited in part on a wave-cut platform, forms several terraces.
- Qg – Gravel and sand of major stream channels.
- Qls – Landslide debris.
- Qos – Old dune sand at Point Dume.
- Qs – Beach Sand.
- Tr – Trancas Formation composed of marine sandstone, mudstone, silty shale, and claystone.
- Tmt – Monterey/Modelo Formation composed of marine clay shale and laminated to platy siltstone with sandstone.

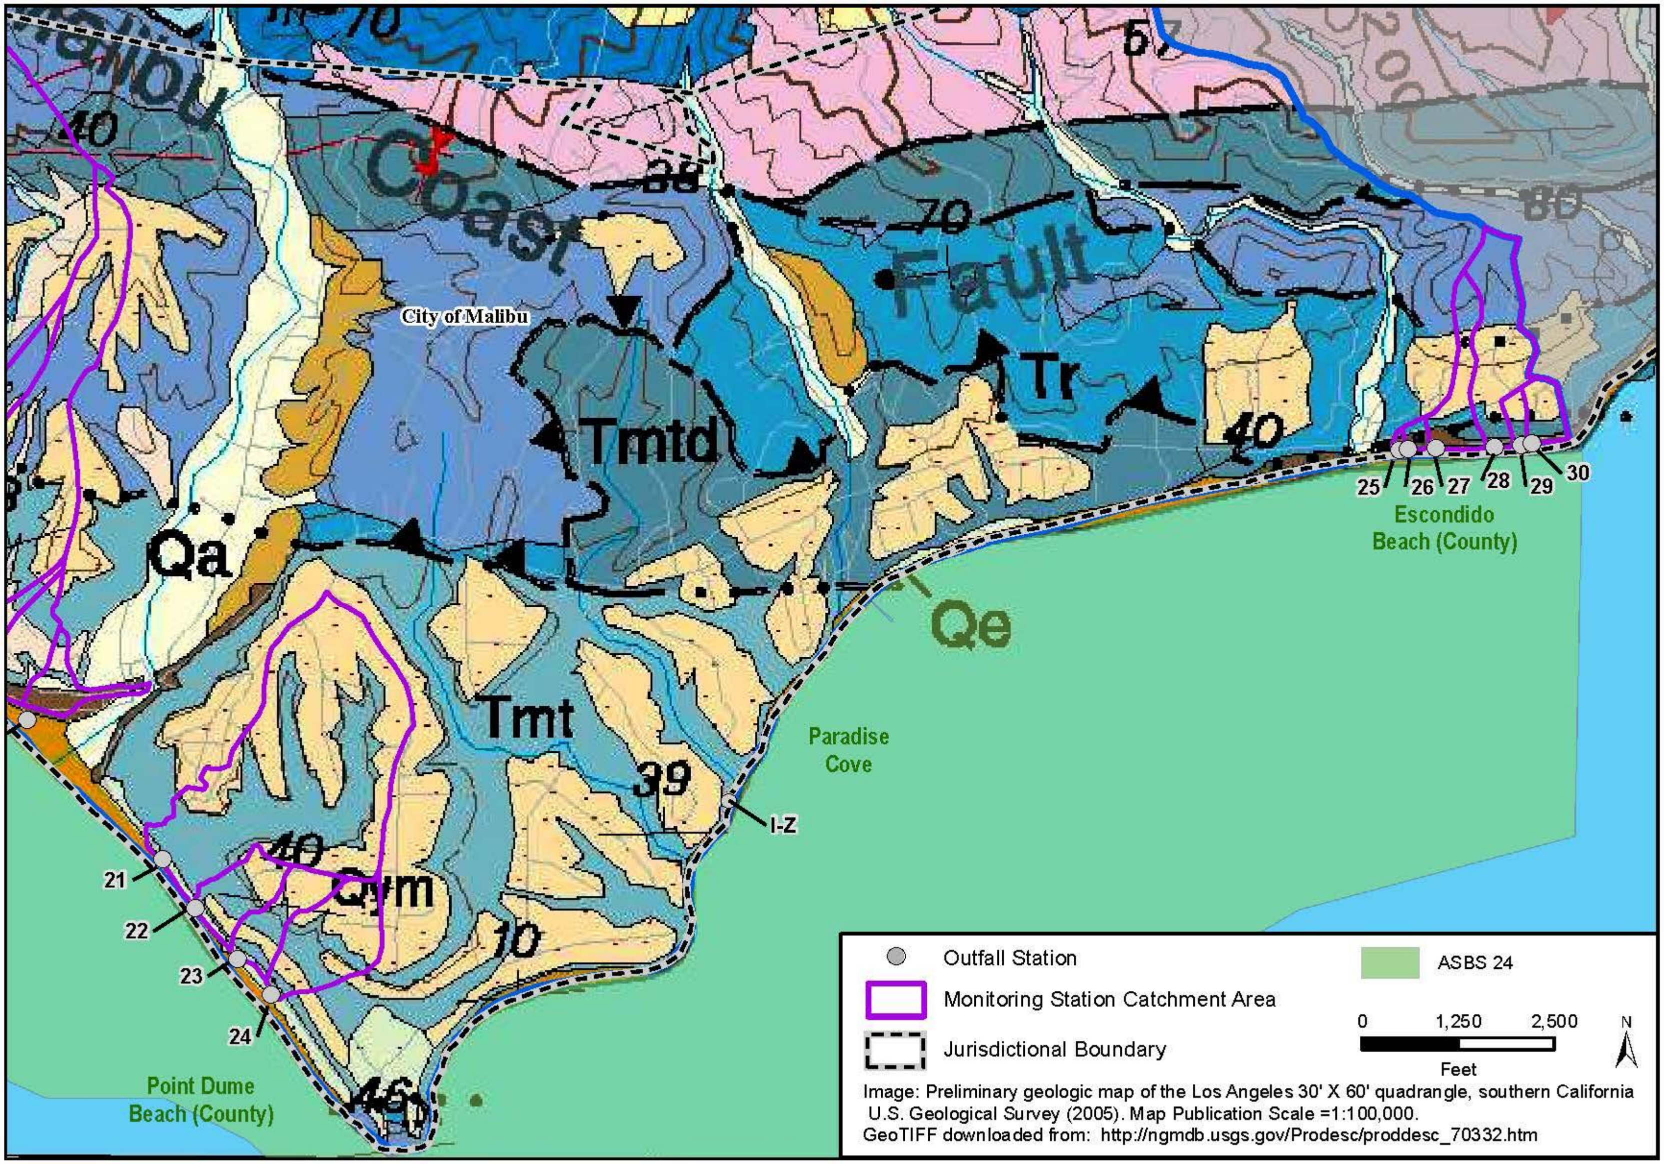

Figure 7-3. Geology of Outfall Drainage Areas, Point Dume Beach to Escondido Beach

7.2.2 Assessment Area Land Use

In general, land use within the drainage area tributary to the Parties' identified outfalls that discharge to ASBS 24 consists of various categories of residential and vacant land with relatively small amounts of commercial, transportation, and specialized (e.g., school, water storage) land uses. Table 7-1 summarizes the jurisdictional land uses for each catchment area.

Table 7-1. Outfall Drainage Area Land Use Summary

7.2.3 Imagery Review

Aerial and other photographic imagery data were reviewed using Google Earth® software and Environmental Systems Research Institute® (ESRI) GIS imagery sources to determine the types of land cover within the Parties' outfall drainage areas. The review showed that areas occupied by residential lots along the coast typically consisted of single-family dwellings, each surrounded by large areas of well-maintained landscaping that included grass, shrubs and brushes, and trees. Further inland, north of the PCH, residential lots were occupied by single-family dwellings and either well-maintained landscape and/or open space, natural type vegetation. The Google Earth® street view tool imageries were reviewed, which showed the residential lots and secondary roadways as having well-maintained vegetated areas with very little non-vegetated (bare) areas.

Caltrans' PCH right-of-way and highway traverses several of the Parties' outfall drainage areas. Although Caltrans is not a responsible applicant included under this Compliance Plan, the area within the Caltrans right-of-way drains to the Parties' outfall and thus, was evaluated to determine if the area has the potential to contribute anthropogenic sedimentation to ASBS 24. The desktop review showed that some cuts (excavations) were made into native soils along the roadway. The review did not reveal obvious areas of excessive erosion and sedimentation. However, due to the common historic erosion problems associated with similar roadways throughout the state, the areas where cuts were potentially made during roadway construction were flagged for further detailed evaluation during the field reconnaissance phase.

7.2.4 General Sedimentation Risk Assessment

In order to estimate the general sediment risk for the areas that drain to the Parties' outfalls, a sediment risk was determined for a hypothetical site based on the procedures detailed in the *NPDES General Permit for Storm Water Discharges Associated with Construction and Land Disturbance Activities* (Construction General Permit). The intent of this assessment is to determine the potential sediment for areas where minor improvements (e.g., landscaping) or other circumstances may result in bare soil that would not be considered construction activity. The assessment completed as part of this plan is not performed for the purpose of assessing construction activities, which are permitted and inspected through applicable County and City programs, and which require that risks be determined and mitigated through the proper implementation of BMPs.

7.2.4.1 Sedimentation Risk Assessment Methodology

The risk determination procedure detailed in the Construction General Permit includes determining both the "project sediment risk" and the "receiving water risk." The two risks are then used in combination to determine the overall project risk. However, for this plan (assessing potential sedimentation), only the sediment risk was evaluated.

The Construction General Permit describes two options for determining sediment risk: 1) GIS Map Method – EPA Rainfall Erosivity Calculator and GIS map, and 2) Individual Method – EPA Rainfall Erosivity Calculator and individual data. Both of these methods include using available EPA resources to estimate a rainfall-runoff erosivity factor. Depending on the method selected, the soil erodibility, project length, and slope parameters are estimated either from a map (Method 1) or from site-specific data applied to an erodibility factor nomograph and length-slope factor table (Method 2). For both methods, the data are applied to the Universal Soil Loss Equation (USLE) to estimate a sediment load for the applicable period (SWRCB, 2010). The USLE is detailed as follows:

$$A = R*K*LS*C*P$$

Where:

A = the computed soil loss (sheet and rill erosion) (tons/acre).
R = the rainfall erosive factor for the given period.
L = the slope length factor.
S = the slope gradient factor.
C = cover factor (1.0 for bare ground conditions).
P = management operations & support practice (1.0 for bare ground conditions).

Based on the computed soil loss (sediment load), the site is classified as having either a low-, medium-, or high-sediment risk (SWRCB, 2010). Table 7-2 summarizes the risk levels associated with the various soil loss quantities.

Table 7-2. Sediment Risk Levels

Soil Loss	Risk Level
<15 tons/acre	Low
15 – 75 tons/acre	Medium
>75 tons/acre	High

Source: SWRCB, 2010.

7.2.4.2 Sedimentation Assessment Calculations

To assess the general sediment risk for the area, a hypothetical site was evaluated using the methods described in the Construction General Permit. The time period was estimated to be 2 months in duration, from December 1st through January 31st.

The rainfall erositvity factor, or R factor, is calculated as a product of the Erosivity Index (EI) percentage and the average annual R value. These two parameters were obtained from the *Storm Water Phase II Final Rule Construction Rainfall Erosivity Wavier*. The R factors are used as surrogate measures of the impact that rainfall has on erosion and have been mapped using isoerodent contours (USEPA, 2012b). The R values are based on the analyses of data which indicated that when factors other than rainfall are held constant, soil loss is directly proportional to a rainfall factor composed of total storm kinetic energy (E) times the maximum 30-minute intensity (I). The numerical value of R is the average annual sum of EI for storm events during a rainfall record of at least 22 years, and the isoerodent maps were developed based on R values calculated for more than 1,000 locations in the western United States (SWRCB, 2010). The average annual R value, based on the referenced isoerodent contour maps for the area, was estimated to be between the values of 60 and 80 (80 selected), with units of hundreds ft.*tonf*in*(ac*h*yr)$^{-1}$.

Next, it was determined that the area is within EI distribution zone 25. Based on this zone, the percentages of the EI distributions throughout the year were determined and are summarized on Table 7-3.

Table 7-3. Erosivity Index, Annual Distribution for Zone 25

Month	Jan	Jan	Jan	Feb	Mar	Mar	Mar	Apr	Apr	May	May	Jun	Jun
Day	1	16	31	15	1	16	31	15	30	15	30	14	29
EI (%)	0	9.8	20.8	30.2	37.6	45.8	50.6	54.4	56.0	56.8	57.1	57.11	57.2
Month	Jul	Jul	Aug	Aug	Sept	Sept	Oct	Oct	Nov	Nov	Dec	Dec	
Day	14	29	13	28	12	27	12	27	11	26	11	31	
EI (%)	57.6	58.5	59.8	62.2	65.3	67.5	68.2	69.4	74.8	86.6	93	100	

Source: USEPA, 2012b.

The final R factor calculation is summarized on Table 7-4.

Table 7-4. R Factor Calculation Summary

Parameter	Value
EI % (Oct. 1 – Dec. 31)	11.7%
EI % (Jan. 1 – Mar. 30)	20.8%
Total EI %	32.5%
Average Annual R Factor	80 (100*ft.*tonf*in)*(ac*h*yr)$^{-1}$
Computed R Factor	26.0 (100*ft.*tonf*in)*(ac*h*yr)$^{-1}$

7.2.4.3 GIS Map Method for KLS Factor

The Construction General Permit details the use of the EPA Monitoring & Assessment Program (EPA EMAP) map to assist with determining the combined K, L, and S parameters for use in the USLE equation.

The soil erodibility factor K represents the susceptibility of soil or surface material to erosion, transportability of the sediment, and the amount and rate of runoff given a particular rainfall input (or lack of absorption and infiltration), as measured under a standard condition. Fine-textured soils that are high in clay have low K values (approximately 0.05 to 0.15) because the particles are resistant to detachment. Coarse-textured sandy soils also have low K values (approximately 0.05 to 0.2) because of high infiltration resulting in low runoff. Medium-textured soils (e.g., silt loam) have moderate K values (approximately 0.25 to 0.45) because they are moderately susceptible to particle detachment and produce runoff at moderate rates. Soils having a high silt content are especially susceptible to erosion and have high K values, which can exceed 0.45 and be as large as 0.65 (SWRCB, 2010).

The effect of topography on erosion is accounted for by the LS factor, which combines the effects of a slope length factor, L, and the slope gradient factor, S. Typically, as slope length and/or slope gradient increase, soil loss increases.

Figure 7-4 shows the EPA EMAP map. Based on this map, a KLS value of 1.6 was selected for the ASBS 24 drainage area.

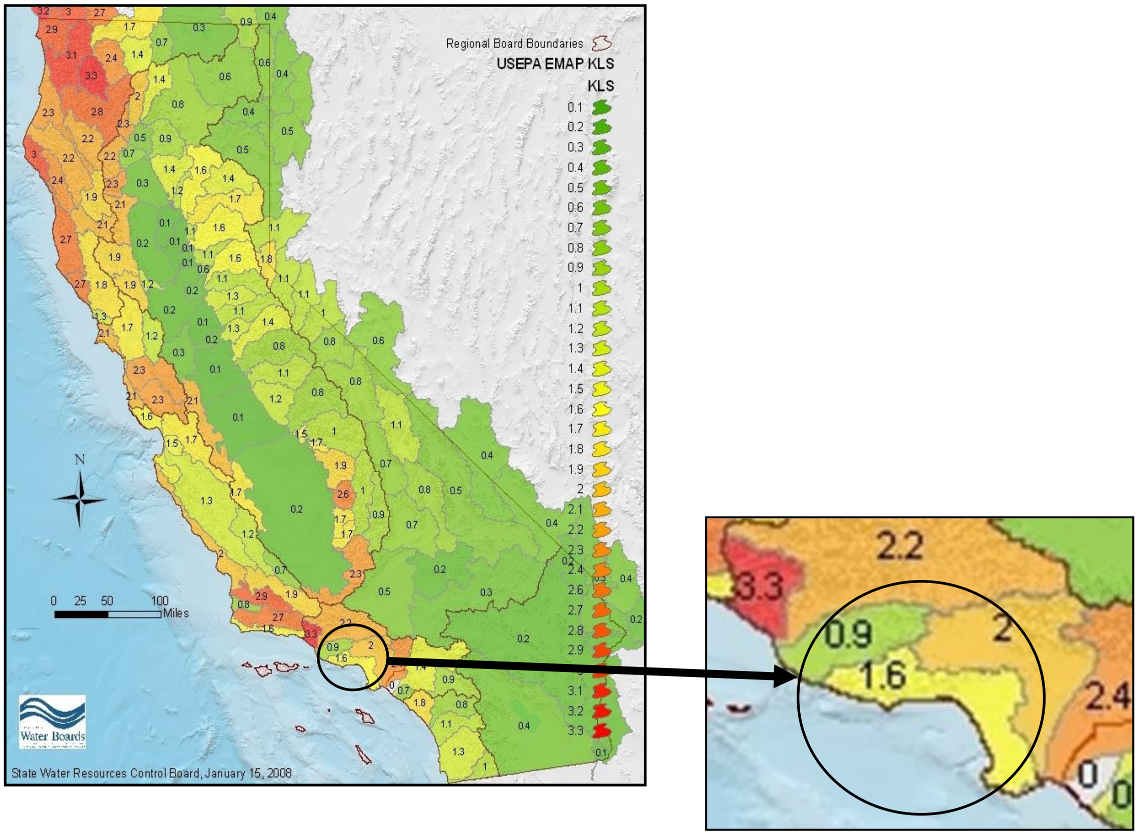

Figure 7-4. EPA EMAP (SWRCB, 2010)

The soil loss was calculated based on the assumptions made and values determined in this assessment. The soil loss for the hypothetical site was calculated to be 41.6 tons per acre. Based on the Construction General Permit sediment risk matrix (summarized on Table 7-2) and this value, disturbed areas (e.g., bare soil) draining to the ASBS would have, in general, a medium-level sediment risk.

7.2.4.4 Individual Method for KLS Factor

The Construction General Permit allows for site-specific data to be used in determining the KLS factor for the USLE equation. This includes performing soil analysis to determine the soil grain size distribution, site length, and average slope. This method was performed with the assumption that the soils consist of 60% sandy, 20% silty, and 20% clayey materials, which is reasonable for mountain formations and coastal bluffs. Based on an area of 0.25 acres (square), a length of 100 ft. was estimated. Based on the topography in the developed areas with slopes of approximately 2 to 10%, the higher end of the range was selected (10% slope).

Using the Soil Erodibility Factor Nomograph provided in the Construction General Permit, the K factor for the assumed soil composition was determined to be 0.19. Based on the LS Factors Table provided in the Construction General Permit and the stated assumptions, the LS factor was determined to be 1.46. Combining these parameters, it was determined that KLS is 0.277, the soil loss would be 7.2 tons per acre. Based on the Construction General Permit sediment risk matrix (summarized on Table 7-2), this value is considered a low-sediment risk for the applicable disturbed area.

7.2.4.5 Sediment Risk Assessment Summary

The assessment of the general sediment risk for disturbed areas with the ASBS 24 drainage area indicates that an area of disturbed soils without controls during the two relatively high rainfall months (December and January) during average conditions would have a potential sediment load of 7.2 tons per acre (per Method 2, individual site data calculations) or 41.6 tons per acre (per Method 1, GIS map data calculations). Smaller areas would have proportionally lower potential yields, as would disturbed areas with controls and/or disturbed areas that do not have a direct connection to the storm drain inlets (e.g., small area of disturbance above turf vegetation). Based on guidance found in the Construction General Permit, this equates to a low- (Method 1) to medium- (Method 2) sediment risk.

The difference between methods is based solely on the method used to calculate the KLS factor. The GIS map shows a large area with the same value, including the Santa Monica Mountains. Including the steep mountain terrain in the weighted average (by area), the slope calculation for the GIS map appears to have overestimated the KLS for the areas along the ASBS coast where developed areas are located. Additionally, the GIS map may overestimate the project slope length factor and slope gradient factor (LS factor). As such, the Method 2, site-specific data method seems much more accurate for the applicable area.

This assessment provides a general estimate of the sediment yield potential for disturbed (or bare) soil cover for the stated assumptions. The results of this assessment were used to aid in the evaluation of the drainage areas during field reconnaissance. Considering the soil loss calculations, the R factor is fixed for the area and the K factor may change slightly in the different geology across the drainage areas. However, the slope length (L) and slope gradient (S) vary greatly when areas with the potential to be prone to sedimentation are evaluated. The field reconnaissance was performed with a focus on the implications that the length and slope parameters have on the potential soil loss for areas of bare soil or spare vegetation. Table 7-5 provides annual soil loss calculations performed for various typical sloped small areas with bare soil or sparse vegetation cover throughout the year.

Table 7-5. Annual Soil Loss Calculations for Sloped Areas

Slope Length (ft.)	Slope Height (ft.)	Slope Gradient (%)	Width (ft.)	Area (acres)	KLS Factor	Annual Soil Loss (tons/year)
10	0.2	2	100	0.023	0.025	0.05
20	0.4	2	100	0.046	0.029	0.10
30	0.6	2	100	0.069	0.032	0.18
40	0.8	2	100	0.092	0.036	0.27
50	1	2	100	0.115	0.040	0.37
10	1	10	100	0.023	0.072	0.13
20	2	10	100	0.046	0.093	0.34
30	3	10	100	0.069	0.122	0.67
40	4	10	100	0.092	0.146	1.1
50	5	10	100	0.115	0.173	1.6
10	2.5	25	100	0.023	0.160	0.3
20	5	25	100	0.046	0.247	0.9
30	7.5	25	100	0.069	0.338	1.9
40	10	25	100	0.092	0.424	3.1
50	12.5	25	100	0.115	0.507	4.7
10	5	50	100	0.023	0.268	0.5
20	10	50	100	0.046	0.458	1.7
30	15	50	100	0.069	0.638	3.5
40	20	50	100	0.092	0.809	5.9
50	25	50	100	0.115	0.980	9.0

R = 80 (100*ft.*tonf*in)*(ac*h*yr)$^{-1}$.
K = 0.19.

Relative to the 50% (2:1 [horizontal: vertical]) gradient slope, the 2% slope gradient is estimated to lose only 4% as much soil for a 50-ft slope length, and the 10% slope gradient is estimated to lose approximately 18% as much. This relationship in non-linear, and as the slope gradient increases, the potential soil loss significantly increases. Similarly, as the slope length increases, the potential soil loss significantly increases. The 50-ft slope length calculation for the 2% slope gradient is estimated to have approximately seven times the soil loss of the 10-ft slope length for the same gradient. The 50-ft slope length calculation for the 50% slope gradient is estimated to have approximately 1,400% the soil loss of the 10-ft slope length for the same gradient. These typical calculations indicate that in areas where disturbance has created unnatural sloped areas, the potential for soil loss exponentially increases as the slope gradient and/or the slope length increase.

7.3 Sediment Assessment Field Reconnaissance

A field reconnaissance was conducted to confirm the desktop analysis and evaluate the ASBS 24 outfall drainage areas prone to erosion and sedimentation. All areas draining to outfalls that discharge to the ASBS 24 were observed for indications of existing or potential anthropogenic sedimentation. The field reconnaissance included driving the length of ASBS 24 as well as performing reconnaissance on foot within each outfall drainage area to perform a thorough evaluation. In general, the areas of developed land use evaluated were observed to be residences with associated hardscape (e.g., driveways, walkways) and well-maintained landscaping. Some areas were observed to have partially exposed (spare vegetation) natural bluff materials. Vegetation within the bluff areas consisted of a mixture of native scrubs and non-native species (e.g., ice plant). However, signs of erosion (e.g., rills, sloughing) were not observed on these exposed bluff materials, indicating that bluff material consisted of dense siltstone and/or sandstone formations consistent with a desktop geology evaluation performed as part of this plan. The field reconnaissance is presented, starting at the northerly most identified outfall located at Nicholas Canyon County Beach, moving south, and finishing at the southeast limits of ASBS 24 and the Escondido Beach area.

The photograph depicted in Figure 7-5 was taken looking west and downward towards the Nicholas Canyon County Beach parking lot. The up-gradient area between PCH and the parking lot is shown to have fairly good vegetation cover. A narrow foot/animal path leads down the sloped area. Signs of erosion were not observed in the area. Compared to natural cover, a parking lot with an impervious surface located on a mesa, such as the case here, increases storm water runoff quantity and velocity resulting in the potential to erode soils if not properly designed. The parking lot was observed to have several storm drain inlets with associated piping to convey collected storm water down to the ocean without the potential to increase erosion of the bluffs (i.e., outfall located at sea level along rocky shoreline).

Figure 7-5. Nicholas Canyon County Beach Parking Lot

Figure 7-6 shows the area east of the PCH up-gradient from Nicholas Canyon County Beach. PCH and a residence occupy the area, where it appears that the highway and residential access driveway were constructed by cutting away (excavating) some the native materials and creating 2:1 (horizontal: vertical) slopes. These slopes are shown with vegetation cover and without evidence of active erosion.

Figure 7-6. Nicholas Canyon Beach Upper Watershed Area

The photograph depicted in Figure 7-7 was taken above Broad Beach and shows the bluff area located between PCH and the residences that are situated along the shoreline. During the field reconnaissance, the majority of the bluff appeared to have vegetation cover. Some steep portions were exposed, resembling natural bluffs observed in the area where development has been restricted (e.g., the nearby El Matador State Beach). Signs of erosion from these bare areas were not observed in the bluff along Broad Beach Road.

Figure 7-7. Bluff Area Above Broad Beach

The photograph depicted in Figure 7-8 shows the area along PCH and directly above Broad Beach. Similar bluff materials, but having lower height, were observed at this location with similar vegetation cover as the bluffs located along Broad Beach. Thick vegetation was observed at the bottom of the bluff material adjacent to the roadway.

Figure 7-8. Directly Above Broad Beach Area

The east end of Broad Beach Road has thicker vegetation cover and a lower bluff height compared to the west area. Figure 7-9 shows the typical street composition of residences and associated improvements along the south (seaward) side and off-street parking area along the north side followed by a vegetated sloped area.

Figure 7-9. East Portion of Broad Beach

Further up the watershed to Broad Beach the geology changes to that of the Santa Monica Mountains with hills and valleys. Figure 7-10 shows the residential development and associated landscaping in this area.

Figure 7-10. Area Up-Gradient of Broad Beach

The photograph depicted in Figure 7-11 shows the area across from the southeast side of Zuma County Beach, north of PCH. Field reconnaissance observed a large vertical bluff. This bluff appears to be Miocene age Modelo Formation that may have been a naturally formed vertical wall or a result of grading associated with the construction of PCH. Evidence of erosion was not observed during the reconnaissance. The materials appeared to be very hard and resistant to erosive forces of nature.

Figure 7-11. Vertical Bluff Across from Zuma Beach

As with the other areas evaluated, away from the coast the geology was observed to be Santa Monica Mountains in the watersheds upstream of the Zuma County Beach shoreline. Good vegetation cover was observed in the sloped areas around the existing improvements, which included residences and a water tank (Figure 7-12). Thick native vegetation was observed above the developed areas.

Figure 7-12. Up-Gradient of Zuma Beach Area

Figure 7-13 shows a residential property located east of the intersection of Birdview Avenue and Bluewater Road. Typical of residences in the area, the landscaping included a mixture of brushes and trees on the sloped areas and turf in the flatter areas.

Figure 7-13. Residence Near Birdview Avenue & Bluewater Road

The photograph depicted in Figure 7-14 shows the area above Escondido Beach. This area was observed to have more gentle slopes of approximately 4:1 (horizontal: vertical) compared to the bluff areas observed near Zuma County Beach and Broad Beach. East of Escondido Creek and north of PCH, thick vegetation cover was observed, consisting primarily of ice plant, palm trees, and eucalyptus trees.

Figure 7-14. Pacific Coast Highway Near Escondido Beach

7.4 Anthropogenic Sedimentation Assessment Summary and Conclusion

The assessment included a review of the topography, geology, land use, and imagery to determine potential areas prone to anthropogenic sedimentation. This review indicated that the topography, geology, and land use are related. Geologic processes, beginning as far back as 80 million years, formed the sedimentary formations predominantly found along the coast shoreline and Point Dume upland mesa area, which include siltstone and sandstone. Approximately 16 million years ago, seismic actively began and continued for 3 million years to form the Santa Monica Mountains, which are composed of a combination of sedimentary and igneous rock formations (City, 1995). Land use zoning and development have occurred predominantly along the coast within the flatter areas at lower elevations. Some development has occurred inland within the Santa Monica Mountains, but for the most part, development in the mountainous areas of the ASBS 24 watershed has been restricted due to the conservation of the area at the federal, state, and local levels.

The desktop analysis included determining the general sediment risk for the area based on the procedures outlined in the Construction General Permit. These procedures included determining the rainfall erosivity (R factor), which is based on data collected over several years to determine the annual storm kinetic energy, on average, for the area. That factor, combined with properties of common soils and various slopes (up to 50%) and heights (up to 50 ft.), were used to determine the potential annual soils for disturbed loose soil areas within the watershed. Calculation results indicated that the potential for soil loss within disturbed areas increases rapidly for areas having slopes greater than 10% and heights of greater than a few feet. These results were used during the field reconnaissance to aid in determining if areas have the potential to contribute anthropogenic sedimentation to ASBS 24.

Field reconnaissance was performed in the areas with a focus on the areas that drain to the identified outfalls that discharge to the ASBS 24. In general, the drainage areas primarily consisted of larger lots (0.25 to approximately 1 acre) with existing residential structures, hardscape improvements, and landscaping. Landscape vegetation of sloped areas within developed areas, including residential properties and roadway rights-of-way, were observed to have fairly good cover. No signs of erosion (e.g., rills, gullies) were observed in sloped areas or alongside secondary roads or PCH.

The conclusion of this sediment identification assessment is that currently there are no areas prone to anthropogenic sedimentation within the drainage areas tributary to the identified outfalls that discharge to ASBS 24. Land use in the drainage areas consists predominantly of residential and vacant (open space) designations with associated roadway connections. The sloped areas associated with residential properties were observed to have good vegetation cover and appeared to be regularly maintained by landscaping professionals. Areas where cuts (excavation) were made during the construction of roadways were observed to have either good vegetation cover that has been maintained by responsible property owners or consist of hard coastal bluff materials resistant to erosive forces (e.g., large bluff along the southeast portion of Zuma County Beach, as shown in Figure 7-11). Therefore, at this time, no additional sediment BMPs are required by this plan.

8.0 IMPLEMENTATION SCHEDULES

8.1 General Exception Schedule

The General Exception (Resolution No. 2012-0012) was adopted and became effective on March 20, 2012. Resolution No. 2012-0031 amended the General Exception to revise some of the sections to be consistent with other sections. The two documents collectively are referenced to as the General Exception with Resolution No. 2012-0012, establishing the effective date and Resolution No. 2012-0031 providing referenced content. Table 8-1 provides a summary of the key milestones specified in the General Exception. The General Exception states that the Draft Compliance Plan shall be submitted to the State Board within 18 months of the effective date of the General Exception. However, due to the limited number of monitoring opportunities during the 2012-2013 wet season, the Parties requested and were granted an extension of 12 months in order to perform additional wet weather monitoring. This timeline extension is included in the summary table.

Table 8-1. General Exception Schedule of Milestones

Description	Duration	Date
Resolution No. 2012-012 (General Exception)		Adopted March 20, 2012
Resolution No. 2012-021 (Amended General Exception)		Adopted June 19, 2012
Non-authorized non-storm water discharges prohibited	Effective date of the General Exception	March 20, 2012
Nonstructural controls necessary to comply shall be implemented	18 months after the General Exception effective date	September 20, 2013
Draft Compliance Plan	*30 months after the General Exception effective date	September 20, 2014
Final Compliance Plan	*42 months after the General Exception effective date	September 20, 2015
Structural controls identified in Compliance Plan necessary to comply shall be operational	*7 years after the General Exception effective date	March 20, 2018
All discharges comply with the General Exception requirements	*7 years after the General Exception effective date	March 20, 2018

*Additional 12 months added to duration based on Draft Compliance Plan extension granted by State Board to allow for additional wet weather core monitoring.

8.2 Nonstructural Controls Implementation Schedule

The Compliance Plan uses adaptive management to plan (Figure 3-2. Adaptive Management Process), implement, assess, and refine nonstructural solutions implemented by the Parties in the ASBS 24 tributary drainage area. The initial assessment included special studies and existing PIPP, enforcement, and O&M nonstructural programs (see Appendix B); the Parties are currently meeting the compliance requirements detailed in the General Exception. The steps forward listed in this section include nonstructural programs that will allow the Parties to continue to be in compliance and may reduce wet weather pollutant loading. These steps forward include the following:

- Continue to implement, track, and refine effectiveness assessment protocols for nonstructural programs, as discussed in Section 3.0.

Table 8-2. Milestones and Schedule for Implementation of Enhanced Nonstructural Programs and Key Steps Forward

<table>
<tr><th>Timeline</th><th>Objective</th><th>Nonstructural Program(s) & Key Steps Forward</th></tr>
<tr><td><u>Initial Phase:</u>
2005–2012</td><td>1. Understand baseline conditions in ASBS.
2. Identify/address dry-weather and storm water runoff.
3. Progress towards zero dry weather runoff.</td><td>Progressed towards existing nonstructural programs identified in Section 3.2.</td></tr>
<tr><td>Before September 20, 2013</td><td>1. Zero discharge of non-authorized non-storm water to ASBS 24.
2. Inspection Policies in compliance with General Exception.</td><td>▪ Public Outreach (see Section 3.2).
▪ Outfall inspection program.
▪ Catch basin program re-evaluated.
▪ Amended Inspection Program (see Section 3.3).</td></tr>
<tr><td>09/20/2013</td><td colspan="2">Compliance with ASBS Special Protections for Dry Weather</td></tr>
<tr><td>09/20/2014</td><td colspan="2">Submit Draft ASBS Compliance Plan for ASBS 24</td></tr>
<tr><td><u>Wet Weather:</u>
2014–2015</td><td>1. Maintain zero dry weather runoff to ASBS 24.
2. Evaluate nonstructural BMPs that may provide wet weather load reductions.</td><td>▪ Evaluate aggressive street sweeping on City streets.
▪ Feasibility assessment and initial outreach for metal building materials ordinances.</td></tr>
<tr><td>09/20/2015</td><td colspan="2">Submit Final ASBS Compliance Plan for ASBS 24</td></tr>
<tr><td><u>Wet Weather:</u>
2015–2018</td><td>1. Maintain zero dry weather runoff to ASBS 24.
2. Evaluate nonstructural BMPs that may provide wet weather load reductions.</td><td>▪ Enhanced aggressive street sweeping on PCH, if feasible.
▪ Evaluate metal building materials ordinances and metal building material management incentive programs.
▪ Evaluate enhanced collaborative environmentally friendly alternative services program(s).</td></tr>
</table>

9.0 COST ESTIMATES

The Parties have implemented numerous nonstructural controls and related programs in order to eliminate non-authorized discharges to ASBS 24. The Parties continue to maintain these measures, and the annual estimated costs associated with the key programs, which are detailed in Section 3.0, are provided on Table 9-1. For more information on existing nonstructural measures, see Appendix B.

Table 9-1. Annual Nonstructural Program Costs

Program Type	Program Name	Approximate Cost ($/year)
Public Information & Participation Programs (PIPP)	Rethink L.A.	[1]$10,000
	Los Angeles County Materials Exchange (LACoMAX)	Costs in Rethink L.A.
	Water District #29 Tiered Water Rates Based on Increased Usage	N/A
	Water Conservation Program – Water Saving Devices Rebate Program	[1]$5,000
	Cash for Grass	[1]$5,000
	Landscape Irrigation Efficiency Program (LIEP)	[1]$5,000
	Ocean Friendly Garden (OFG) Program	Included in ASBS Focused Outreach Program
	Pepperdine Business School OFG Partnership	Included in ASBS Focused Outreach Program
	Solid Waste Management Program	$167,450
	Coastal Preservation Specialist (CPS)	[2]$35,957
PIPP Sub-total		**$228,407**
Operations & Maintenance (O&M)	City Curb & Gutter Cleaning & Repair Program	[3]$295,000
	City Storm Drain/Culvert Facilities Maintenance	[3]$25,000
	City Street Sweeping Contract	[3]$42,500
	Los Angeles County Street Sweeping	[1]$435,000
	City Trash Collection	[3]$25,000
	County Beaches Trash Collection	[1]$360,000
	County Beaches – Sanitation Program	Included in Trash Collect.
	Environmentally Preferable Purchases and Practices Policy (EPPP), Recycled Products Purchasing Policy (RCPP)	N/A
O&M Sub-total		**$1,182,500**
Enforcement	City IC/ID Elimination Program	$11,395
	County IC/ID Program	[1]$20,000
	City Pollution Prevention Hotline	$600
	Pollution Prevention Hotline, 1(888)Clean LA	[1]$3,000
	Coastal Preservation Specialist (CPS)	[2]$35,957
	Outfall Inspections	[4]$10,800
	City Commercial & Industrial Inspection Program	[4]$8,000
	Clean Bay Restaurant Certification Program	Included in Inspection
	Santa Monica Bay Regulations Review	N/A
	City Local Coastal Program	Included in Inspection
	City Construction Inspection Program	Included in Inspection
	Los Angeles County Construction Inspection Program	[4]$2,000
	Smoking at Beaches Ban	[1]$20,000
Enforcement Subtotal		**$111,752**
Total		**$1,522,659**

Note 1: Cost estimated based on fraction of regional program total cost (approximately 5%).
Note 2: Coastal Preservation Specialist cost divided evenly between PIPP and enforcement.
Note 3: Cost estimated based on fraction of City wide program total cost (approximately 50%).
Note 4: Cost estimated based on staff time to complete associated tasks.

APPENDIX B

Existing Nonstructural Programs Table

Existing Nonstructural Programs Within the ASBS 24 Area

Nonstructural Program	Program Subcategory	Name of Nonstructural Control	Project Descriptions for Existing Nonstructural Controls	Project Location	Target Source/ Target Audience	Targeted Water Quality Problem	Method of Measure	Program Start Date	Implementation Status/ Completion Date	Lead Agency	Approx. Cost ($/year)
Enforcement	IC/ID	City of Malibu Illicit Connection/ Illicit Discharge (IC/ID) Elimination Program	This program involves coordination of multiple City Departments to cease and eliminate pollution by illicit connections and discharges to the storm water system. The City has an active education, response, and enforcement program.	Regional	Residential, Commercial	Urban Runoff	# IC/IDs responses/year	November 1997	Ongoing implementation	City of Malibu	$11,395 (City Wide)
Enforcement	IC/ID	Los Angeles County (County) IC/ID Program	This program involves coordination of multiple County departments to cease and eliminate pollution by illicit connections and discharges to the storm water system. The County has an active education, response, and enforcement program. The data are tracked for the County region, as well as for the County's Road Maintenance Division (RMD), as part of its annual pre-storm season drainage inspection program.	Regional	Residential, Commercial, Industrial	Urban Runoff	# IC/IDs responses/year	November 1997	Ongoing implementation	Los Angeles County, District	$443,500 *(Regional)*
Enforcement	IC/ID	City of Malibu Pollution Prevention Hotline	A 24-hour hotline was launched to enhance the IC/ID program. The goal of this program is to offer a consistent reporting tool to citizens during non-business hours for spills or runoff that may pollute streams or coastal waters. Calls are received and dispatched to the appropriate personnel for investigation and resolution. The hotline is available in English and Spanish. The community may call 310-359-8003 to report incidents.	Regional	Residential, Commercial	Urban Runoff	# Hotline calls/year # IC/ID abated/year due to hotline	June 2012	Ongoing implementation	City of Malibu	$600 (FY 13-14, phone)
Enforcement	IC/ID	Pollution Prevention Hotline, 1(888)Clean LA	A 24-hour, bilingual hotline offers County staff, cities, and the public a means to report spills or runoff that may pollute coastal waters. Calls are received and dispatched to the appropriate personnel for investigation and resolution. The hotline is available in English and Spanish. A Chinese hotline is also available in Mandarin.	Regional	Residential, Commercial, Industrial	Urban Runoff	# Hotline calls/year # IC/ID abated/year due to hotline	November 1997	Ongoing implementation	Los Angeles County, District	-
Enforcement	Education, Inspections, Enforcement and ID	City of Malibu Water Waster Online Reporting Form	An online form to allow the community to report water waste has been introduced. All stakeholders are encouraged to make a collective effort to use water wisely, eliminate runoff, and reduce water waste, creating a culture of water conservation and water quality protection, and keep each other accountable by talking with those they see wasting water and using the reporting form. The form includes options to report issues included in the City's water conservation code. The City will provide notice, education and enforcement where needed to resolve issues. The online Water Waster Report form can be found at this link www.malibucity.org/WaterWaster	Regional	Residential, Commercial	Water Conservation, Urban Runoff	# Reports/year # Reports which included runoff abated/year	September 2014	Ongoing implementation	City of Malibu	Staff Time

Existing Nonstructural Programs Within the ASBS 24 Area

Nonstructural Program	Program Subcategory	Name of Nonstructural Control	Project Descriptions for Existing Nonstructural Controls	Project Location	Target Source/ Target Audience	Targeted Water Quality Problem	Method of Measure	Program Start Date	Implementation Status/ Completion Date	Lead Agency	Approx. Cost ($/year)
Enforcement	Education, Inspections, Enforcement	Commercial & Industrial Inspection Program	The County and City have implemented protocols to identify commercial and industrial facilities located within the applicable ASBS 24 drainage area and currently perform inspections at these sites in accordance with the Special Protections requirements (commercial facilities twice during the rainy season and industrial facilities monthly during the rainy season) The goals of these inspections include compliance verification, enforcement as needed, and education regarding storm water and urban runoff issues, recycling, and environmental quality ordinances. The County has not identified commercial or industrial sites within the applicable unincorporated County. City Environmental Programs staff, Code Enforcement Officers, Public Works staff, and Building Safety staff are regularly trained to watch for storm water best management practice (BMP) infractions. Staff are authorized and directed to issue correction notices. Repeat offenses are subject to increased enforcement procedures ranging from cease and desist orders to administrative fines and traditional enforcement remedies (City of Malibu Ordinance 325). If commercial or industrial sites apply for permits within the applicable unincorporated County, the sites will be inspected at the required frequencies listed in the Special Protections. Additionally, an annual voluntary training is conducted for all City staff to learn about protecting water quality.	Regional	Commercial, "Industrial"	Bacteria Organics Oil/Grease Trash Urban Runoff	<u>Changes in Inspection Results for Facilities:)</u>	November 1997	Ongoing implementation	City of Malibu	$8,000
Enforcement/ PIPP	Education, Incentives, Inspections	Clean Bay Restaurant Certification Program	The program is implemented in partnership with the Bay Foundation (also known as the Santa Monica Bay Restoration Commission & Foundation) and other bay cities. The goal is to recognize restaurants and food facilities that go above and beyond the minimum required by law to prevent pollution. Facilities are inspected annually. Only businesses with an inspection score of 100% receive certification. The City implements the rescinding policy for the Clean Bay Restaurant Certificate program, whereby a business that has been certified is subject to having its Clean Bay status rescinded for failing to maintain all of the criteria.	Regional, City of Malibu	Commercial	Bacteria Organics Oil/Grease Trash Urban Runoff	# Certified facilities *Rate of certification has increased 30% between 2009 & 2013.*	April 2009	Ongoing implementation	City of Malibu	See Commercial & Industrial Inspection Program
Enforcement	City Planning	City of Malibu Local Coastal Program	The City of Malibu Local Coastal Program, as certified by the California Coastal Commission, includes the Land Use Plan (LUP) and Local Implementation Plan (LIP) that details many environmental quality and protection standards, objectives, and implementation measures for new development and redevelopment projects. Additionally, conditions are placed prohibiting the installation of any new drains to the ASBS.	City of Malibu	Construction	Trash, Sediments, Urban Runoff, Storm Water Runoff	See Construction Inspection Program	September 1998	Ongoing implementation	City of Malibu	See Commercial & Industrial Inspection Program

Existing Nonstructural Programs Within the ASBS 24 Area

Nonstructural Program	Program Subcategory	Name of Nonstructural Control	Project Descriptions for Existing Nonstructural Controls	Project Location	Target Source/ Target Audience	Targeted Water Quality Problem	Method of Measure	Program Start Date	Implementation Status/ Completion Date	Lead Agency	Approx. Cost ($/year)
Enforcement	Education, Inspections, Enforcement	City of Malibu Construction Inspection Program	The City has implemented protocols to identify existing and future construction sites located within the applicable ASBS 24 drainage area. Identified sites will be inspected in accordance with the Special Protections requirements (weekly during the rainy season). Grading within the City is limited to single lot development (see Ordinance No. 51U). The City engages with construction contractors throughout the construction process. At a pre-grading meeting, the contractor, deputy building official, and inspector(s) review the Storm Water Pollution Prevention Plan (SWPPP) and identify appropriate BMPs. The SWPPP is again discussed at commencement of construction, with a reminder of the repercussions (i.e., job site shut-down) of failing to comply. Project sites are visited regularly during the grading phase and construction phase. BMP implementation and maintenance is checked at each inspection.	Regional	Construction	Trash, Sediments, Urban Runoff	# of Grading Inspections # of Building Inspections	November 1997	Ongoing implementation	City of Malibu	See Commercial & Industrial Inspection Program
Enforcement	Education, Inspections, Enforcement	Los Angeles County Construction Inspection Program	The County has implemented protocols to identify existing and future construction sites located within the applicable ASBS 24 drainage area. Identified sites will be inspected in accordance with the Special Protections requirements (weekly during the rainy season). All construction permit applicants are required to prepare a Wet Weather Erosion Control Plan or Local SWPPP based on the Construction BMP Handbook. The County conducts inspections, follow-ups, and enforcement. A computer database is used to track all single-lot (non-tract) projects that are categorized by the disturbed/graded area (acres).	Regional	Construction	Trash, Sediments, Urban Runoff	Winter 10-11: 3,383 sites underwent wet weather inspections	November-1997	Program Enhancement August 2013	Los Angeles County	$11,000 *(Regional)*
Enforcement	Code Enforcement	Expanded Polystyrene Packaging Ban Inspections & Enforcement	Approximately 65 food facilities are inspected each year for compliance with Ordinance No. 286, M.M.C. Chapter 9.24, Ban on Expanded Polystyrene Food Packaging.	Regional	Commercial	Trash, Urban Runoff	Approximately 80 food facilities inspected/year	October 2005	Ongoing implementation	City of Malibu	See Commercial & Industrial Inspection Program
Enforcement	Code Enforcement	Smoking at Beaches Ban	The Los Angeles County Sheriff engages Beach Patrol for enforcement of Ordinance No. 265, M.M.C. Chapter 12.05.035, Ban on Smoking at Malibu Beaches.	Regional	Residential, Commercial	Trash, Urban Runoff	21 miles of beaches patrolled	May 2000	Ongoing implementation	City of Malibu	$482,983 (total Beach Patrol cost)
O&M	Street Maintenance	City of Malibu Curb & Gutter Cleaning & Repair Program	Contract for annual curb and gutter cleaning and repair. This service ensures proper functioning of drainage facilities.	City of Malibu	City Facilities	Trash, Metals, Sediments, Urban Runoff	# Facilities cleaned/year Pounds material removed/year	February 1987	Ongoing implementation	City of Malibu	$590,000 (FY 13-14, City Wide)

Existing Nonstructural Programs Within the ASBS 24 Area

Nonstructural Program	Program Subcategory	Name of Nonstructural Control	Project Descriptions for Existing Nonstructural Controls	Project Location	Target Source/ Target Audience	Targeted Water Quality Problem	Method of Measure	Program Start Date	Implementation Status/ Completion Date	Lead Agency	Approx. Cost ($/year)
O&M	Street Maintenance	City of Malibu Storm Drain/Culvert Facilities Maintenance	Contract for annual and post-storm inspection and cleaning of storm drain facilities. All storm drains are cleaned annually. Priority storm drains are cleaned at a minimum of twice annually. This program ensures that litter, debris, and pollutants are removed to prevent them getting into the local waterways and impacting beneficial uses.	Regional	City Facilities	Trash, Metals, Sediments, Urban Runoff	# facilities cleaned/year, by priority Pounds material removed/year	February 1987	Ongoing implementation	City of Malibu	$50,000 (FY 13-14, City Wide)
O&M	Street Maintenance	City of Malibu Street Sweeping Contract	Contract for sweeping for public streets in City by means of a mechanical-type street sweeper. Street sweeping is a requirement of the NPDES permit and is intended to remove litter, debris, and pollutants from the roadways, thus preventing them from getting into local waterways. City streets are swept monthly (90 miles total, ~60 miles within the ASBS). The Pacific Coast Highway is swept weekly (54 miles total, 16 miles within the ASBS).	Regional	Streets/Parking	Trash, Metals, Sediments, Urban Runoff	Broom miles swept/year Pounds removed/year	March 2002	Ongoing implementation	City of Malibu	$85,000 (FY 13-14, City Wide)
O&M	Street Maintenance	Los Angeles County Street Sweeping	The County sweeps parking lots along the coastal ASBS to remove litter, debris, and pollutants from the roadways, thus preventing them from getting into local waterways. Parking lots are swept with vacuum or regenerative air sweepers three times per week, based upon seasonal use rates. Sweeping occurs at: Zuma Beach (12 lots), Point Dume (1 lot), and Nicholas Canyon (1 lot).	County Beaches - Parking Lots	Streets/Parking	Trash, Metals, Sediments, Urban Runoff	Broom miles swept/year Pounds removed/year	November 1997	Ongoing implementation	Los Angeles County	$8.7 Million *(Regional)*
O&M	Waste Management	City of Malibu Trash Collection	The City performed a needs study and subsequent implementation of placing trash receptacles at bus stops and high-use areas along the Pacific Coast Highway and City streets. Additional animal-proof containers were placed in the ASBS watershed including along PCH and in the Point Dume area. The refuse is collected weekly to prevent littering and any additional debris from getting into local water ways and drains.	Regional	Residential, Commercial	Trash, Urban Runoff	Frequency of removal	August 2003	Ongoing implementation	City of Malibu	$50,000 (FY 13-14, City Wide)
O&M	Waste Management	County Beaches Trash Collection	County staff empty beach trash cans 7 days a week, as needed, to prevent littering and any additional debris from getting into local water ways and drains. Trash cans are donated by Adopt-A-Beach and broken cans are replaced quarterly, as needed.	County Beaches	Streets/Parking	Trash, Urban Runoff	Frequency of removal	November 1997	Ongoing implementation	Los Angeles County	$7.2 Million *(Regional)*
O&M	Waste Management	County Beaches - Sanitation Program	County staff “sanitizes" the beach 3 days a week, provided the sand is not wet. A tractor with rake and screen system is used to collect trash and turn over the beach sand. This process removes solids and debris and allows the sun to "sanitize" the sand during the day. Operations are between 5 am and 13:30 pm daily.	County Beaches	Residential	Trash	Daily pickup	-	Ongoing implementation	Los Angeles County	See County's Trash Collection Program

O&M	Recycled Products Purchasing Policy	Environmentally Preferable Purchases and Practices Policy (EPPP), Recycled Products Purchasing Policy (RCP)	In accordance with Administrative Guideline No. 7.1.3 and M.M.C. 2.63.100, a policy was established to reduce waste by instituting new office practices that emphasize purchase of environmentally preferable products. The policy establishes the goal for all City employees to make waste diversion and reduction a routine part of the jobs, whenever feasible.	City of Malibu	City Facilities, City Staff	Trash, Urban Runoff	-	-	Ongoing implementation	City of Malibu	-
PIPP, O&M	Education, Waste Management	Solid Waste Management Program	Solid Waste Management Program was formed to comply with AB939 (California Integrated Waste Management Act of 1989) and implement source reduction of solid waste, including recycling, composting, environmentally safe transport, and land disposal. This includes City programs for safe disposal of household hazardous waste; used oil collection/recycling events; waste management education; solid waste hauler permitting; Christmas tree recycling; brush clearance/green waste recycling events; bulky item collection; construction and demolition debris recycling; electronic and universal waste disposal; and expanded polystyrene foam recycling program (i.e., Waste to Waves program). Program is in support of the CalRecycle goals to divert municipal waste from landfills.	Regional	Residential, Commercial	Trash, Urban Runoff	<u>Changes to Malibu's Annual Recycling Rate:</u> 57% (2000) to 68% (2012)	March 1997	Ongoing implementation	City of Malibu	$167,450
PIPP, O&M	Education, Waste Management	Rethink L.A.	Education and outreach program designed to encourage “rethinking” about waste management, including opportunities to implement reduction, recycling, and reuse. Program provides resources for buying recycled products and encourages carbon footprint BMPs, including a carbon footprint calculator, energy efficiency tips, and means of alternative transportation.	Regional	Residential, Commercial, Industrial	Trash, Urban Runoff	# Website visits # Workshops # Brochures # Attendees Regional Recycling Rate	-	Ongoing implementation	Los Angeles County	$200K *(Regional)*
PIPP, O&M	Education, Waste Management	Los Angeles County Materials Exchange (LACoMAX)	The goal of this program is to reduce waste transported to the landfill. The LACoMAX is an on-line service where the public may find, make available, or identify an entrepreneurial opportunity for discarding resource materials. The data platform includes 15 material classifications and six regions. It is also a location where garage sales may be advertised. The data platform provides information to other County waste management programs.	Regional	Residential, Commercial, Industrial, Construction	Trash, Urban Runoff	# Website visits # Workshops # Brochures # Attendees Regional Recycling Rate	-	Ongoing implementation	Los Angeles County	See Rethink L.A. program
PIPP	Education	Malibu Parks and Recreation Quarterly Newsletter	The Malibu Recreation Guide and Quarterly Newsletter is sent to residents and includes articles related to the Clean Water Program and Solid Waste Program. The City takes the opportunity to give reminders to the community about how to prevent pollution and reduce waste, as well as local event opportunities. The newsletters are also available at City Hall. ASBS articles have been regularly contributed since 2012.	City of Malibu	Residential	Urban Runoff	4 Issues/year # Newsletters mailed	December 1995	Ongoing implementation	City of Malibu	$33,000

PIPP	Education	*Living Lightly in Our Watersheds* Environmental Guide	The City and County collaborated with the Resource Conservation District of the Santa Monica Mountains in the revision and distribution of the *Living Lightly in Our Watersheds: A Guide for Residents of the Santa Monica Bay Watersheds* <www.malibuwatershed.org>. The guide was distributed to all Malibu residences and businesses. The City contributes to printing costs and distribution by mail and distributes materials at events. A new web-based and mobile platform is currently under development and is expected to launch by 2015. A new print edition of the guide is also expected in 2015.	Regional	Residential, Commercial	Urban Runoff	# Guides mailed # Visits to the website	July 2005	Ongoing implementation	Malibu Creek Watershed Council	$3,000 (City of Malibu) $20,000 (County of Los Angeles)
PIPP	Education	*Malibu Life* Environmental Newsletter	*Malibu Life* (formerly *Malibu Current*) Environmental Quarterly Newsletter is sent to all Malibu residences and businesses and distributed continuously to educate about ongoing environmental concerns and what the community can do to help, and provides updates on City environmental projects and programs. An ASBS article was published in Issue 2 Volume 1 in April 2007.	Regional	Residential	Urban Runoff, Water Conservation	# Articles # Newsletters mailed	April 2007	Implementation halted in 2010	City of Malibu	$2,000 (2010, printing & postage)
PIPP	Education	Wildlife and Marine Rescue Services	The City has had a contract with the California Wildlife Center since April 1996 to provide wildlife rescue services and was later amended to include marine mammal rescue services. In 2003, the City, in partnership with the California Wildlife Center, applied for and received a John H. Prescott Marine Mammal Rescue Assistance Grant. Wild Rescue is a secondary responder. Public outreach and education are also a part of the grant.	City of Malibu	Residential	Urban Runoff, Water Conservation	# Outreach events supported	March 1992	Ongoing implementation	City of Malibu, California Wildlife Center	$2,500 (FY 13-14) *($1,000-$2,500 historically)*

Existing Nonstructural Programs Within the ASBS 24 Area

Nonstructural Program	Program Subcategory	Name of Nonstructural Control	Project Descriptions for Existing Nonstructural Controls	Project Location	Target Source/ Target Audience	Targeted Water Quality Problem	Method of Measure	Program Start Date	Implementation Status/ Completion Date	Lead Agency	Approx. Cost ($/year)
PIPP	Education, Inspections, Incentives/ Enforcement	ASBS Focused Outreach Program Proposition 84 Project	This began as a Proposition 84 grant program, officially titled the Wildlife Road Treatment & ASBS Focused Outreach Program Proposition 84 Project. The temporary Coastal Preservation Specialist (CPS) position was created to perform outreach to the community. The CPS conducted field work throughout the ASBS area, including coastal and inland areas, to look for dry-weather runoff and other pollution threats. When individual properties were identified as being out of compliance with ASBS regulations, letters to "cease and desist" the discharge as well as educational materials were mailed. The City, via the CPS and/or other City staff worked with the property owners to help fix the problem. The property owner was required to submit a report detailing how the problem was fixed. The CPS and/or other City staff conducted site visits, continued monitoring the site, and performed other additional actions (case-specific). General letters, including Notices to Comply, were sent to neighborhoods and individuals of high priority that were considered more likely to impact the ASBS to inform them of ASBS discharge restrictions. A general ASBS letter was mailed to every parcel within the ASBS. A database with information on every case is maintained as issues arise in the ASBS watershed and includes all communications and photos. The project also included the installation of a structural BMP on Wildlife Road. The City plans to continue this program on a modified scale.	ASBS 24 (Area in Malibu city limits)	Residential, Commercial	Urban Runoff, Water Conservation	# ASBS letters mailed # Cease and Desist letters mailed # Follow-up 1-month reports submitted % Compliance with Orders to Cease and Desist Discharge # Notices to Comply letter mailed to high-priority addresses % Change in high-priority addresses. PIPP	Education	Community Meetings and ASBS Presentations	Outreach presentations to home owner associations, property owner associations, and other community groups about the City's Clean Water Program, including protecting water quality and conserving water have been conducted. Recent outreach by the CPS was about urban runoff and the ASBS.	ASBS 24 (Area in Malibu city limits)	Residential	Urban Runoff	# Presentations	October 2007	Ongoing implementation End of grant: July 2014	City of Malibu	See ASBS Focused Outreach Program
PIPP	Education	Point Dume Marine Science School Assembly and Science Projects	The City has collaborated with the Point Dume Marine Science School on various programs since 2005. An assembly to grades K-5 was conducted including a presentation on the water cycle, urban runoff, and how to prevent pollution from reaching the ASBS. Each grade level then completed a science project related to some component of the assembly at the appropriate grade level. A video of the science day was filmed and posted on the City's YouTube channel. The assembly and project was implemented by the CPS as part of the ASBS Focused Outreach Program. PIPP	Education, Incentives	Malibu Area Conservation Coalition	The Malibu Area Conservation Coalition (MACC) is a partnership of local government agencies, utilities, resource districts, and community stakeholders working within Malibu and the North Santa Monica Mountains that share the common goal of empowering local communities to conserve and protect natural and economic resources and habitat. Recognizing that watersheds, oceans, water, and power generation and delivery systems do not stop at jurisdictional boundaries, the coalition is dedicated to providing effective programs, environmental education, and outreach. MACC members work on joint projects and also cross-promote individual organizations' programs. Recent programs included Ocean Friendly Garden Program, Landscape Irrigation Efficiency Program, Cash for Grass, Earth Day festivals, and the Wild and Scenic Film Festival.	City of Malibu	Residential, Commercial	Trash, Urban Runoff, Water Conservation	# Participants # Events (certain programs will have more defined metrics)	August 2009	Ongoing implementation	City of Malibu	Staff Time
PIPP	Education, Incentives	Ocean Friendly Garden (OFG) Program	The OFG Program targets residences and businesses to promote water conservation and eliminate non-point source pollution from landscaping. It was implemented locally as a partnership of West Basin Municipal Water District and the Surfrider Foundation as part of a Proposition 50 Grant from the State. The program includes educational workshops, training events, irrigation controller rebates, and the design/build of demonstration gardens. The Bluffs Park OFG was redesigned and rebuilt (February-March 2013) into a demonstration garden. Outreach Events included: * Ribbon cutting ceremony (3/20/2013) * OFG Workshop (6/2013) * Urbanite Workshop * Chumash Day PowWow (4/13-14/2013) The overall OFG Program of the Surfrider Foundation offers additional resources. APPENDIX C

Potential Enhanced Nonstructural Programs Table

Potential Nonstructural Program Enhancements to Achieve Additional Wet Weather Load Reductions

Nonstructural Program	Program Sub-Category	Name of Nonstructural Control	Project Descriptions for Enhanced Nonstructural Controls	Target Source/ Target Audience	Targeted Water Quality Problem	Method of Measure	Lead Agency	Implementation Cost (Approx.)
O&M	Street Maintenance	Infrastructure Priority Re-Evaluation Program	This activity is a review and re-evaluation of existing inspection/cleaning priorities assigned to the catch basins, street, parking lot and other systems located in the ASBS 24 watershed. Prioritization criteria are based on the NPDES permit and are typically based upon historic trash and debris loading to a given system. This prioritization does not take into account the watershed or receiving water body that may be impacted by a given piece of infrastructure. Increased cleaning may be appropriate to meet the requirements of the ASBS Special Protections and General Exception or to provide a streamlined, efficient and effective implementation program for ASBS 24.	Residential, Commercial	Trash/Debris, Sediment	Existing Catch Basin Program Assessment, Other Program Assessments, Inspection Data, Pounds Removed / year	City of Malibu, County	$10K, +$25K/Year, maintenance per existing program
PIPP	Education, Incentives	Enhanced Collaborative Environmentally Friendly Alternative Services Program	This program would look for opportunities to enhance existing environmentally friendly services programs. For example, the LACoMAX could include an ASBS-specific region search and/or the City of Malibu could provide a link to via the Malibu Green Room webpage, with information related to local exchanges, a list of consignment facilities, etc. Programs that may also be enhanced in the future include the Clean Bay Restaurant Certification Program, City of Malibu's EPPP and RCP, and Los Angeles County's Rethink LA Program.	Residential, Commercial	Urban Runoff, Trash	Program-specific metrics will be developed	Los Angeles County, City of Malibu, Malibu Chamber of Commerce	$5K / Year
PIPP	Education	ASBS Signage at Beaches	Educational placards describing the ASBS would be developed and installed along the board walk and/or main public beach accesses along the ASBS. This signage would describe unique features of the ASBS, as well as highlight recommended BMPs for trash management, sediment management, irrigation control, etc.	Residential, Public	Urban Runoff, Trash	# placards installed, # beach visits/year	Los Angeles County, State of California	$20K
O&M	Street Sweeping	Increased Sweeping Frequency	This program would involve a pilot project to adjust the frequency of sweeping on City streets located within the ASBS drainage area from once per month to more frequently, paired with a runoff study to determine pollutant loading. Increasing the sweeping frequency has been shown to increase the potential load reduction associated with metals, sediments, trash, and debris.	Residential, Commercial	Metals, Sediments, Trash	Pounds of debris removed per year % reduction in pollutant loading vs. cost	City of Malibu	$360,000
O&M	Street Sweeping	Equipment Upgrade	As of 2013, the City of Malibu sweeps city streets using motorized mechanical street sweeping equipment. This proposed nonstructural program enhancement would involve either: 1) replacing mechanical street sweepers with enhanced sweeping technologies during the standard end of the equipment life-cycle, or 2) requiring contractors responsible for local sweeping activities to only use vacuum or regenerative air sweeping technologies.	Residential, Commercial	Metals, Sediments, Trash	Increased efficiency and pollutant load reduction for machine operation.	City of Malibu	Additional cost of ~$25K per machine.
PIPP	Education, Incentives	Architectural Copper and Metal Building Material Mitigation Program	This program would offer rebates for architectural copper and zinc mitigation measures. Rebates would be offered for existing structures and could be modeled after the Grass for Cash program. Potential mitigation measures may include: application of sacrificial paint (e.g., copper and zinc oxidation protection paints), downspout diversions, rain barrels and cisterns. Information could be incorporated into existing educational materials and through the ASBS Focused Outreach program, etc.	Residential, Commercial	Metals	# rebates offered, # facilities mitigated	City of Malibu, Los Angeles County	$150K / Year

Potential Nonstructural Program Enhancements to Achieve Additional Wet Weather Load Reductions

Nonstructural Program	Program Sub-Category	Name of Nonstructural Control	Project Descriptions for Enhanced Nonstructural Controls	Target Source/ Target Audience	Targeted Water Quality Problem	Method of Measure	Lead Agency	Implementation Cost (Approx.)
PIPP / Enforcement	City Ordinance, Education, Enforcement	Architectural Copper Ban	Monitoring data of storm water wash off collected from metal building materials have been shown to be associated with elevated copper levels (City of San Diego, 2009 and 2010a). This ordinance would prohibit use of architectural copper for all new developments and re-development projects, especially for buildings and facilities along the ASBS and PCH. This ordinance would likely require significant education and outreach to engineers and architects, as well as residents and general public.	Residential, Commercial	Copper	# brochures distributed, # workshops, Ordinance/Policy, # facilities enforced	City of Malibu	$5K
PIPP / Enforcement	City Ordinance, Education, Enforcement	Zinc Alternative Building Material Ordinance	It is recognized that for maintenance and durability, building materials are often specified as galvanized zinc. Monitoring data collected of storm water wash off from metal building materials have been shown to be associated with elevated zinc levels. This project would evaluate the feasibility and implement a zinc building material policy which would eliminate, reduce, mitigate or control the use of zinc building materials, based upon the findings of a feasibility analysis and stakeholder engagement process.	Residential, Commercial	Zinc	Feasibility analysis, Ordinance/Policy	City of Malibu	$10K + $5K/Year *(outreach)*

APPENDIX D

Enhanced Nonstructural Programs

Quantification Calculations

- Aggressive Street Sweeping
- Building Material Management Program

AGGRESSIVE STREET SWEEPING

Aggressive street sweeping can be highly effective in reducing metals loading (City of San Diego, 2010; Seattle Public Utilities, 2009; City of Portland, 2006) and, to a lesser extent, bacteria (Skinner et al., 2010), while continuing to address trash, debris, and sediment pollution. The County has implemented an aggressive street sweeping program at County Beach parking lots (i.e., sweeping three times per week with enhanced sweeping equipment). Given that these parking lots experience a reduced traffic load compared to the PCH and City streets and have an aggressive sweeping schedule and program, the County's existing parking lot sweeping program is considered to be appropriate for protecting water quality of the ASBS 24 (i.e., program at a high level where adding enhancements may provide diminishing returns). The City currently implements a two-part street sweeping program, including weekly mechanical sweeping along PCH and monthly mechanical sweeping along City-maintained streets. This assessment focuses on quantifying the potential additional water quality benefits that could be realized through enhancements to the sweeping programs associated with City street sweeping programs. Data from the *City of San Diego Targeted Aggressive Street Sweeping Pilot Study Effectiveness Assessment*, which evaluated the effectiveness of three types of street sweepers at two aggressive sweeping frequencies, are used in this section to evaluate the potential load reduction associated with sweeping the PCH and City-maintained streets.

The referenced 2010 City of San Diego report uses debris removal, or collection rate as a metric to assess the relative pollutant load reduction associated with the various aggressive street sweeping programs evaluated. The fine sediments collected in special study bins were weighed, sampled, and analyzed for grain size, metals, pesticides, and other constituents of concern. Daily sweeping data were translated into pounds of debris removed per linear broom mile swept, and pollutant-specific load reduction rates were estimated (City of San Diego, 2010). This method of measure was used to compare the effectiveness of different types of street sweepers at twice-per-week and once-per-week sweeping frequencies.

The 2010 City of San Diego study included detailed analysis of various routes through different types of watersheds (hilly, flat, rural, and urban), including the urban areas of Chollas Creek. The average pounds of debris removal per broom mile for mechanical and vacuum sweepers, at both once and twice a week frequencies for this particular urban route, are presented on Table D-1. The broom mileage data used to produce these sediment removal rates were extracted from the 2010 City of San Diego study (City of San Diego, 2010), which is available on the Think Blue San Diego website. Note that the frequency of sweeping implemented under a few of the existing sweeping programs implemented by the County (3 times/week) and City (once/month) do not perfectly correspond with the available data. Removal rates for these frequencies were extrapolated using the best-fit curves presented on Table D-1 and in Figure D-1.

Table D-1. Sediment Load Reductions Associated with Mechanical and Vacuum Sweeping (City of San Diego, 2010)

Sweeper Technology	Sweeping Frequency	Average Sediment Removal Rate (lb/broom mile)
Mechanical	Once/week[1]	49.4
	Twice/week[1]	30.9
	Once/month[2]	63.3
	Twice/month[2]	58.7
Vacuum	Once/week[1]	80.0
	Twice/week[1]	83.3
	Once/month[2]	77.5
	Twice/month[2]	78.4

[1] Calculated debris removal rate from referenced special study (City of San Diego, 2010).
[2] Calculated using interpolated values.

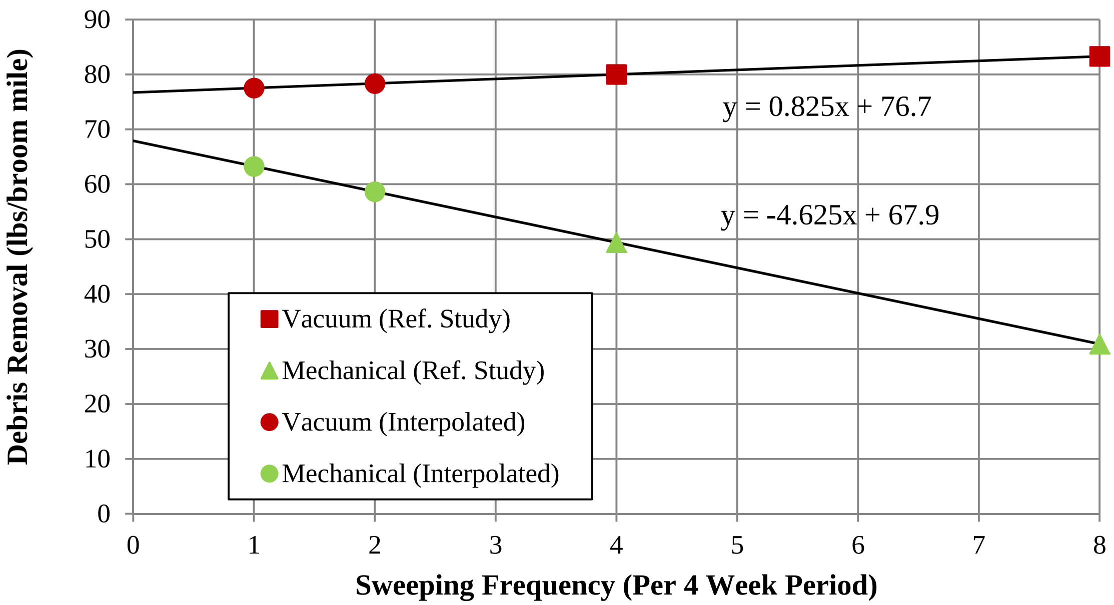

Figure D-1. Sediment Load Reductions Associated with Mechanical and Vacuum Sweeping (City of San Diego, 2010)

The potential debris reductions associated with street sweeping within ASBS 24 were calculated by determining the linear broom miles or path of travel and multiplying that length by the appropriate removal rate. The linear broom miles for each parking lot were determined using GIS information (aerial images, parcel layer, and land use data). Sweeping data for existing programs within the ASBS 24 are presented on Table D-2.

.

Table D-2. Existing Street Sweeping Programs Within ASBS 24

Authority	Beach Name	Acres (acres)	Single Trip Broom Miles (miles)	Yearly Broom Miles at Once/month frequency (miles/year)	Yearly Broom Miles at Twice/Month Frequency (miles/year)	Yearly Broom Miles at Once/Week Frequency (miles/year)
City of Malibu	PCH	-	16	192	384	832
	City Streets	-	59	702	1,404	3,042

The potential debris removal for each sweeping option considered was estimated by multiplying the yearly linear broom mileage by the applicable debris removal rate and results of these calculations are provided on Table D-3.

Table D-3. Potential Debris Removal Summary for Each Sweeping Method

Authority	Machine	Location	Frequency	Broom Miles (miles/ year)	Debris Removal Rate (lb/ miles)	Debris Removal Rate (lb/year)	Debris Removal Rate (kg/year)
City of Malibu	Mechanical	PCH	Once/month	192	63.3	12,149	5,503
			Twice/month	384	58.7	22,541	10,211
			Once/week	832	49.4	41,101	18,619
		City Streets	Once/month	702	63.3	44,419	20,122
			Twice/month	1,404	58.7	8,2415	37,334
			Once/week	3,042	49.4	150,275	68,074
	Vacuum	PCH	Once/month	192	77.5	14,885	6,743
			Twice/month	384	78.4	30,106	13,638
			Once/week	832	80.0	66,560	30,152
		City Streets	Once/month	702	77.5	54,423	24,653
			Twice/month	1,404	78.4	110,074	49,863
			Once/week	3,042	80.0	243,360	110,242

Debris removal includes sediment, organics, and trash. The 2010 San Diego study did not directly correlate debris removal to TSS removal. The potential debris removal calculations for the different street sweeping scenarios are provided to show the comparison between different types of sweepers and sweeping frequencies.

The 2010 San Diego study included monitoring the water quality for three storm events at sites located within the Chollas watershed (Route 3J). For each monitored event, three different street segments were sampled representing sites that had been swept by either a vacuum or mechanical sweeper, once per week and for the three continuous weeks prior to the storm event and an "unswept" site that had been swept once every two months prior to the event (City of San Diego, 2010). A summary of the TSS results and calculated load reductions are provided on Table D-4. .

Table D-4. Summary of Street Sweeping Water Quality Results (City of San Diego, 2010)

Storm Event	Type of Sweeping	TSS (mg/L)	TSS Percent Reduction
Mean of Three Storms	Un-swept (Once/2 months)	927.0	N/A
	Mechanical (Once/week)	243.8	73.7%
	Vacuum (Once/week)	135.8	85.3%

The TSS removal efficiencies shown on Table D-4 can be used in combination with watershed model output data to estimate the transportation land use TSS pollutant load reductions associated with enhancing programs to perform sweeping at a once-per-week frequency with these types of machinery. The estimated TSS load reduction can also be compared to the total TSS load from watershed model data to estimate the overall pollutant load reductions from the street sweeping program.

The load reductions summarized on Table D-4 are based on the 2010 San Diego study and removal efficiencies of mechanical and vacuum sweeping at a once-a-week frequency (City of San Diego, 2010). As part of this study, storm event monitoring samples (wet weather) were not collected for comparison of un-swept sites to sites that were swept at a frequency of once per month or twice per month. However, based on the debris removal data collected in the referenced study and applied to the ASBS 24 watershed (see Table D-3), sweeping less frequently (e.g., once per month or twice per month) would provide less of a load reduction, even though a specific percentage is not provided by this quantification analysis. There is a correlation between TSS and metals in urban storm water runoff (LARWQCB, 2005), and the reductions in TSS load shown on Table D-4 also represent load reductions of metals.

The Broad Beach Road Biofiltration Project (Project) is funded in part by the City of Malibu (City) and in part by the State Water Resources Control Board (SWRCB) through a Proposition 84 Grant Agreement between the two parties. The contents of this document do not necessarily reflect the views and policies of the State Water Resources Control Board, nor does mention of trade names or commercial products constitute endorsement or recommendation for use.

1. INTRODUCTION

The purpose of this report is to present the design basis and the evaluation of design alternatives for the Broad Beach Road Biofiltration Project (Project). This Preliminary Design Report will form the basis for the critical evaluation and selection of the Project design approach.

The Preliminary Design Report (PDR) is intended to document all the relevant studies, evaluations, and calculations for the Broad Beach Road Biofiltration Project and to produce two conceptual design alternatives for the Project. The Project scope of work requires that the PDR include the following:

- Hydrology studies and soils report;
- Groundwater mounding analyses;
- Utility maps and identification of utility interferences;
- Development of two conceptual design alternatives presented at the 10 percent design level;
- Site plans showing proposed improvements, landscaping, and best management practices (BMPs);
- Performance and maintenance for the proposed alternatives;
- Construction cost estimate; and
- Final design recommendations.

This report is presented in 10 sections. Section 1 is this report and Project introduction. Section 2 reviews the existing Project site conditions, including topographic maps and utility maps. Section 3 reviews various regulations and approvals considered in the development of the Project conceptual design. Section 4 presents the results of the soil and groundwater investigation, including the infiltration study and groundwater mounding analysis. Section 5 introduces the Project hydrology evaluation, including a review of site drainage and development of the Project site design capture volume. Section 6 reviews the Project objectives, introduces the proposed BMPs and site improvements, and develops two stormwater improvement alternatives. Section 7 presents construction cost estimates for the two alternatives. Section 8 includes a discussion of the two alternatives, with recommendations. Section 9 defines the limitations on use of this report. Section 10 presents pertinent references cited in this report.

1.1 Project Description and Background

The city of Malibu was awarded a Proposition 84 grant by the State Water Resources Control Board (SWRCB) for the Broad Beach Road Biofiltration Project. The stated purpose of this grant is for "diverting dry-weather and some stormwater runoff from a series of eight (8) storm drains onto permeable surfaces and into a biofiltration system along a one (1) mile stretch of Broad Beach Road to prevent discharges to Broad Beach." [SWRCB, 2011]. The City of Malibu has contracted with Geosyntec Consultants to prepare studies, develop design documents, provide community outreach, and support the City during construction of this Project.

The Project includes various stormwater BMPs, landscape, and other improvements to eliminate or greatly reduce dry-weather flows, improve stormwater quality through treatment, reduce erosion and sediment tracking, and possibly capture and use stormwater. Overall, the Project will improve runoff quality and reduce wet weather and dry weather flows to Broad Beach.

1.2 Project Objectives

The Project objectives are:

- Eliminate dry weather flows to the storm drain;
- Reduce wet weather flows to storm drain (as feasible);
- Improve water quality of wet weather flows to storm drain (i.e., storm water treatment, pollutant reduction) to the maximum extent practicable (MEP);
- Reduce potable water use for irrigation (as feasible);
- Restore habitat above Broad Beach Road (as feasible);
- Reduce slope erosion (as feasible); and
- Preserve street and visitor parking.

1.3 Terms of Reference

This report was prepared for the City of Malibu (City) by Geosyntec Consultant Team (Geosyntec) in support of the Broad Beach Road Biofiltration Project in the City of Malibu, California. This work was authorized under Agreement executed on October 27, 2011; this report satisfies Task 1.11 of the scope of services. This report was written by Jan Coward and Patrick Galvin, PE, with senior review conducted by Ken Susilo, PE, in accordance with Geosyntec's quality review procedures.

The City project manager for the Project is senior civil engineer Rob DuBoux, Esq., PE.

The Project is funded in part by the City of Malibu and in part by the State Water Resources Control Board through a Proposition 84 Grant Agreement between the two parties.

2. EXISTING SITE CHARACTERISTICS

2.1 General Site Condition and Location

Broad Beach Road, situated between Broad Beach and Pacific Coast Highway (PCH) in Malibu, California, runs parallel to the coastline with a general orientation within the Project area of southeast to northwest. Broad Beach Road is a paved two-lane residential street providing residents access to their homes along the south side of the road and providing parking and beach access for residents and visitors. A mostly unpaved strip along the northern edge of Broad Beach Road varying in width from 10 to 20 feet provides public parking on the north side of the road. This parking strip is separated from PCH by a vegetated hillside which varies in slope from slightly steep to nearly vertical bluffs where the elevation difference between the two roadways is at its greatest. The Project area is located in the western end of Malibu approximately three miles northwest of Point Dume (see Vicinity Map, Figure 2-1).

The Project drainage area encompasses approximately 4,500 linear feet of Broad Beach Road between PCH and Victoria Point Road and extends for the most part from the center line of Broad Beach Road to the top of the hillside between Broad Beach Road and PCH. The total Project drainage area is 12.3 acres.

The Project area is located at the mouth of Trancas Canyon (see Figure 2-2). Trancas Canyon Creek, which drains the 6,233 acre Trancas Canyon watershed, runs to the east of the Project area culminating in a small disturbed coastal lagoon adjacent to the commercial center at the intersection of Trancas Canyon Road and Pacific Coast Highway. The area north of the Project area and west of Trancas Canyon Road drains to Caltrans-owned catch basins along the northern edge of PCH. The Trancas Canyon watershed drainage is not addressed by this Project. With the exception of one area located on PCH, the drainage from PCH is not addressed by this Project.

2.2 Site Topography

The site topography is fairly consistent along the length of Broad Beach Road varying mainly in the elevation difference between Broad Beach Road and PCH and the steepness of the hillside. The Project area, corresponding to the drainage area, encompasses 12.3 acres, approximately 1.6 acres of which is asphalt and concrete paved roadway and parking area. A topographic survey was performed for the Project. The topographic maps are presented in Appendix A.

Broad Beach Road is paved with asphalt and has two lanes, each lane approximately 10 feet wide. The road is crowned at the center line with a lateral slope of roughly two percent. Thus, storm water runoff that lands on the south side of the road flows toward the private residence drains and storm water from the north side of the road flows to the city-owned catch basins. The roadway undulates but is relatively flat except for the western end which reaches a slope of up to five percent. The stretch of road within the Project area has four low points and the roadway elevation varies from 18 to 64 feet above mean sea level measured at roadway center line.

A shoulder area varying in width from roughly 10 to 20 feet lies on the north side of the road along the entire stretch, separating it from the hillside –this area is used for parking by visitors and residents. This area is mostly unpaved, covered by varying materials including gravel, decomposed granite, compacted dirt, sand, and patches of asphalt and concrete. The parking strip follows the same undulating gradient as the roadway in the longitudinal direction and slopes slightly from the toe of the hillside toward the edge of the roadway pavement.

The hillside that separates the parking area and the shoulder along the south side of PCH is relatively steep and in certain areas nearly vertical. The elevation difference from the top of the hillside to the bottom of the hillside varies between 20 and 60 feet. The vertical bluff sections coincide with where the shoulder along PCH is widened to allow for roadside parking.

The entrances to the properties along the south side of Broad Beach Road generally lie at the same elevation as the roadway, or lower.

Existing drainage patterns are described in *Section 5 Hydrology* .

2.3 Utilities

The major utilities within the Project area consist of storm drains, sanitary sewer, potable water, electricity, communication, and natural gas. In support of the development of this preliminary design, the Geosyntec team performed utility research and located existing utilities in the Project area. This work was done using available utility maps and by requesting utility owners to mark their utilities at the Project site. No independent field verification of utilities was conducted. The utility maps are presented in Appendix B.

2.4 Biology

In support of the development of this preliminary design, the Geosyntec team performed a preliminary Biological Assessment of the Project area. The intention of the Biological Assessment was to provide an objective preliminary evaluation of potential impacts of the Project on existing biological resources. The information presented below is a summary of the conclusions and recommendations from this assessment. The preliminary draft of the Biological Assessment report is presented in its entirety in Appendix C.

Based on review of historic vegetation maps, the site is significantly degraded from its historic condition prior to development of Broad Beach. Field surveys found that the vegetation was heavily invaded by naturalized and planted exotic species. The vegetation classifications described below were determined to best characterize the assessment area.

- *Coastal Bluff Scrub (3.1 acres)* - Coastal bluff scrub consists primarily of native plant species, although exotic invasives are present throughout. This vegetation occurs on the upper, steeper bluff slopes between Pacific Coast Highway and the lower landscaped zone along Broad Beach Road.

- *Ornamental Landscaping (4.2 acres)* - Ornamental landscaping consists primarily of exotic vegetation that has been planted and irrigated, including pines, junipers, eucalyptus, bamboo, bougainvilla, and invasive species such as pampas grass. This vegetation dominates the lower slope of the assessment area along Broad Beach Road.

- *Ornamental Landscaping/Coastal Bluff Scrub (1.1 acre)* - This classification represents an integration of native and planted vegetation, with invasive exotics such as iceplant also present throughout.

- *Ornamental Landscaping (Planted Sycamores) (0.2 acre)* - Planted and irrigated sycamores occupy a localized, small area between Broad Beach Road and artificial terraces upslope. These trees may fall under the protection of the City's Native Tree Protection Ordinance because they are native to California.

In general, the area has relatively few wildlife species present or expected to occur, due to its condition as fragmented habitat surrounded by high-traffic roads, frequent human disturbance, construction noise, and dominance of exotic vegetation. The exotic vegetation provides cover and limited nesting habitat for birds, but few food resources for native wildlife. Certain wildlife species, especially goldfinches and crows, were frequently observed moving between the assessment area and landscaping on residential properties to the south. After the Project design is further advanced, an additional biological assessment will be conducted to specifically address the proposed activities and their potential biological impact on the final Project areas.

2.5 Climate

The climate characteristics of the site reflect the general Mediterranean climate of central coastal regions of California. This climate regime is characterized by cool, wet winters and warm, dry summers with occasional periods of fog. Although infrequent, Malibu is periodically subjected to intense coastal storms.

The average daytime summer temperatures in the area are usually in the 70s to 80s (Fahrenheit). Nighttime low temperatures during the summer are typically in the high 50s to low 60s, while the winter high temperature tends to be in the 60s. Characteristic of Malibu’s marine microclimate, the winter low temperatures are in the low 50s. The annual average rainfall in Malibu is about 20 inches. Winter months tend to be wetter than summer months. The wettest month of the year is January with an average rainfall of about 5 inches.

2.6 Hardscape and Landscape

Many Broad Beach Road residents have created gardens across from their residences on city property. These gardens include many non-native invasive or ornamental plants and shrubs. On several parcels, numerous potted plants are also stored along the roadway. Although this property is owned by the city, many homeowners have installed private irrigation systems plumbed back to their residential water services. Irrigation piping runs under the road and was also observed within existing storm drain pipe. The private irrigation of gardens creates uncontrolled and unmanageable dry-weather flows which have been observed during recent site visits.

Residents have also constructed several garden and retaining walls along the hillside. These walls are constructed of a myriad of materials including cobbles, broken concrete, masonry brick, and cast-in-place concrete. Some walls appear to have served as a means of disposal of waste broken concrete from driveway replacements. The parcel-specific variable hardscape and landscape elements have created an inconsistent environmental theme for the neighborhood.

Examples of existing hardscape, landscape, and irrigation systems are presented in Figures 2-3 through 2-9.

3. REGULATORY REQUIREMENTS

3.1 Water Quality

The City storm drains within the Project area ultimately discharge through private drains to private beaches. After passing through a wave wash mixing zone in the Pacific Ocean, flows reach the Pacific Ocean and a designated Area of Special Biological Significance (ASBS 24). The California Ocean Plan [SWRCB, 2009] defines water quality objectives for ocean waters including all ASBS. Since compliance with Ocean Plan's stringent objectives is not always economically feasible nor in the public interest, the Ocean Plan allows the State Water Board to grant exceptions to its provisions as long as the public interest will be served and beneficial uses are protected.

As part of an application for a general exception to Ocean Plan requirements, Special Protections [SWRCB, 2012] have been proposed to fulfill the state mandate for protection of water quality in ASBS and to address the requirements identified in the Ocean Plan. On March 20, 2012 these Special Protections were recommended by the State Water Board as part of an Ocean Plan Exception. According to these Special Protections, the design storm for treatment control BMPs is defined as follows:

> "Design storm – For purposes of these Special Protections, a design storm is defined as the volume of runoff produced from one inch of precipitation per day or, if this definition is inconsistent with the discharger's applicable storm water permit, then the design storm shall be the definition included in the discharger's applicable storm water permit."

The applicable storm water permit in this case is the Los Angeles County National Pollutant Discharge Elimination System (NPDES) Municipal Storm Sewer Systems (MS4) Permit. Since under this permit the Broad Beach project is not considered a new development or a redevelopment, the permit requires that pollutants in stormwater discharge be reduced to the maximum extent practicable (MEP). In Los Angeles County the 0.75 inch design storm event is generally accepted as equivalent to MEP per the MS4 permit. This is also in compliance with the design storm requirements in the proposed revised MS4 Permit [LA RWQCB, 2012]. Since the one inch event is inconsistent with the applicable permit, the conclusion of this study is that the Broad Beach treatment control BMPs should be designed for the 0.75 inch design storm event.

3.2 Environmental Review

The Project is subject to the requirements of the California Environmental Quality Act (CEQA). CEQA requires that all projects be reviewed and that their environmental impacts be evaluated. The lead agency for the Project is the city of Malibu. On behalf of the city of Malibu, Geosyntec will prepare an Initial Study for the project.

This Project is an environmental improvement project (stormwater quality improvement) and the new constructed facilities will likely be hardscape and landscape improvements and natural water quality treatment facilities such as vegetated swales and biofilters. It is expected that the Initial Study will result in a finding of no impact or no significant impact with mitigation, qualifying the Project for a Negative Declaration or a Mitigated Negative Declaration.

As part of the CEQA process, a Frequently Asked Questions sheet will be published and distributed to the community to inform them of the Project. A public notice will be filed in the local newspaper and a public meeting will be conducted to provide the interested public with the opportunity to comment on the Project plans.

3.3 Coastal Development Permit

The California Coastal Act of 1976 (Div. 20 CA Public Resources Code Sections 30000 et. seq.) was adopted by the California Legislature in 1976 and became effective January 1, 1977. The Coastal Act provides a comprehensive regulatory framework for all new proposed non-exempt “development” (See PRC Sec. 30106 and 30610) within the Coastal Zone of the state of California. Pursuant to Sec. 30500 et. seq. of the Coastal Act each local government is responsible for preparing and adopting a Local Coastal Program (LCP) so as to implement the policies and provisions of the Act within its jurisdictional boundaries. Prior to Certification of an LCP the California Coastal Commission generally retains jurisdiction for the processing of Coastal Development Permits (CDPs) consistent with the Act; following certification of an LCP it becomes the primary responsibility of the Local government to review and approve all new proposed development within the Coastal Zone consistent with the provisions contained within its LCP.

In 2002 the City of Malibu’s Local Coastal Program was approved by the California Legislature and became law. Any new non-exempt development proposed within the City of Malibu must apply for and receive a Coastal Development Permit prior to commencement of development (See 13.3 of the Malibu Local Implementation Plan—“LIP”). The LIP and the Malibu Municipal Code provide the primary regulatory framework for review of new development.

The Project is located within the Coastal Zone in the City of Malibu and does propose new development therein; therefore the Project is governed by the City's Certified Local Coastal Program and is required to obtain a Coastal Development Permit prior to Project commencement in addition to other requisite Project entitlements.

3.4 Water Use Guidelines

The Los Angeles County Department of Public Health has established guidelines [Los Angeles County, 2011] for harvesting of rainwater, stormwater, and urban runoff for outdoor non-potable uses such as irrigation. The guidelines have categorized rainwater harvesting systems into four classes, Tier I – IV, depending on the potential water sources, and provide requirements for minimum water quality standard and treatment processes.

- Tier I – On-site collection of rainwater in rain barrels for on-site use in gravity flow systems.
- Tier II - On-site collection of rainwater in cisterns for on-site use.
- Tier III - On-site or off-site collection of rainwater, stormwater, and urban runoff in cisterns for on-site or off-site use. (Excludes water collected from locations zoned for high use transportation corridors, industrial, agricultural or manufacturing uses).
- Tier IV - On-site or off-site collection of rainwater, stormwater, and urban runoff in cisterns for on-site or off-site use. (Includes water collected from locations zoned for high use transportation corridors, industrial, agricultural or manufacturing uses).

Any rainwater harvesting systems based on storage of runoff from Broad Beach Road in underground cisterns would most likely be regulated under Tier III, due to the presence of urban (dry-weather) runoff generated from irrigation of the hillside.

For Tier III systems, if captured runoff is to be used for spray irrigation, irrigation water must be disinfected by chlorination or an equivalent technology. For drip or sub-surface irrigation, Tier III systems require only pre-screening (sediment filtration) of irrigation water. Project biofilters are anticipated to satisfy pre-screening requirements.

4. GEOTECHNICAL AND GROUNDWATER INVESTIGATIONS

4.1 General

To support the development of the preliminary design, Geosyntec performed geotechnical and groundwater investigations for the Project area. The information presented below is a summary of the investigations and the conclusions and recommendations from the Geotechnical and Groundwater Studies Report [Geosyntec, 2012]. The report in its entirety is included on a CD in Appendix D.

4.2 Purpose and Objectives

The Geotechnical and Groundwater investigations focused on the evaluation of subgrade soils along the Project alignment for the purpose of providing design input. This included assessment of groundwater conditions and infiltration potential. Geosyntec's scope of work consisted primarily of the following tasks:

- Gathering available geotechnical and geologic information;
- Performing a geotechnical field investigation consisting of six hollow-stem auger borings and six Geoprobe soundings;
- Performing a constant head infiltration test in the vadose zone and in saturated zones at the locations of the six Geoprobe soundings;
- Constructing temporary piezometers and monitoring groundwater elevations at select Geoprobe locations;
- Conducting laboratory testing of selected soil samples obtained from the borings and analytical testing of groundwater samples; and
- Conducting geotechnical engineering analysis.

4.3 Summary of Existing Conditions

4.3.1 Surface and Subsurface Conditions

To the north, the site is bounded by a predominantly vegetated bluff slope that extends up to the relict marine terraced platform on which Pacific Coast Highway is located. However, localized portions of the adjacent slope are devoid of vegetation and expose the rilled granular material of the marine terrace bluff. Exploratory borings encountered artificial fill, Quaternary Terrace deposits, and the Tertiary age Trancas Formation at depth.

Artificial fill deposits were encountered in five of the six explorations along Broad Beach Road. In general, the fill deposits consist of brown sands with varying amounts of gravel and clay. Within the limits of the explorations, artificial fills extended from the ground surface to maximum depths of four feet.

Quaternary-age terrace deposits were encountered within all of the 12 explorations performed for the investigation at the ground surface or underlying the artificial fill. The terrace deposits generally range in composition from brown to reddish brown, clayey to gravelly sand, to light brown to tan, silty sand. Within the older, upper terrace bluff (Qt), densities generally increase with depth from medium dense to very dense.

Along the terrace surface underlying Broad Beach Road, the densities generally ranged from medium dense to dense. A subset of these terrace deposits, identified as the “Beach Sands” or Qb is present at a number of the investigation locations along Broad Beach Road. This deposit identified separately from other terrace deposits due to its characteristic fine sand and relatively low fines content (20 percent).

At the location of Broad Beach Road, the beach sand is typically less than approximately 10 feet thick. Based on information from other investigations between Broad Beach Road and the ocean this thickness increases to 10-15 feet typically.

The Tertiary age Trancas Formation underlies the entire site at depth and was encountered in nine of the explorations –this formation generally consists of a hard, gray fat claystone. Along Broad Beach Road, the Trancas Formation was encountered beneath the terrace deposits at an elevation of +18 feet mean seal level (MSL) at the west end of the Project area and slopes down to an elevation of -5 feet MSL at the east end. It is anticipated that the erosional unconformity between the overlying terrace deposits and the Trancas Formation slopes up to the north beneath Pacific Coast Highway and slopes down towards the beach on the south.

Dozens of single family residences are present along the south side of Broad Beach Road along the Project alignment. Review of numerous foundation reports for these structures indicates that while some are founded on the Trancas formation using deep foundations other structures and appurtenances may be founded on the beach sands using shallow foundations.

4.3.2 Groundwater

The investigations performed by Geosyntec indicate that the groundwater gradient in the Beach Sands is typically from north to south (i.e., toward the ocean). It is expected that water that infiltrates at the surface along Broad Beach Road will flow within the Beach Sands toward the ocean along the sloping unconformity between the Trancas formation and Beach Sand. Additional flow infiltrated by this Project may raise groundwater elevations within the Beach Sand.

The measured static groundwater elevation varied along the alignment of Broad Beach Road from approximately 7.0 to approximately 20.5 ft above MSL. In general, the observed groundwater elevations are assumed to represent a dry-weather condition although "wet year" and "wet-weather" conditions are assumed to be within a few feet of these conditions as indicated by observations. The groundwater elevations recorded remained fairly constant over the monitoring period, suggesting that there is no significant tidal influence at these locations.

In conversations with Broad Beach residents, concerns were expressed regarding making changes that potentially increase infiltration and consequentially raise groundwater levels. Some homes have basements and at least one homeowner has observed water, presumably groundwater, leaking into the basement.

4.3.3 Onsite Wastewater Treatment Systems

Onsite wastewater treatment systems (OWTS), such as septic systems, for the residences along the south side of Broad Beach discharge to leach fields that are in some areas located in the backyards between the homes and the dunes, in the courtyard area between the garage and the house, or between the house and Broad Beach Road. Based on analysis of groundwater samples carried out for this Project, it appears that the locations sampled are generally unaffected by the operation of the OWTS's.

4.4 <u>Findings</u>

The California Department of Transportation (Caltrans) Stormwater Quality Handbook: Project Planning and Design Guide [Caltrans, 2007] and the Los Angeles County Department of Public Works Stormwater Best Management Practice Design and Maintenance Manual [LADPW, 2009] both present guidelines related to the siting of infiltration BMPs. The criterion for selection of an appropriate site for infiltration trenches contained in these documents were used as primary screening criteria for selection of appropriate locations for Project infiltration features.

Based on the results of the investigations and evaluations, from a geotechnical viewpoint, the proposed stormwater best management practices and streetscape improvements are feasible as long as direct infiltration is not included as a Project feature. While infiltration rates in some areas are within the acceptable ranges, the following design criteria restrict the use of infiltration:

- The shallow groundwater and a shallow confining layer will impose significant constraints on the geometry of infiltration facilities.

- Typically the invert of infiltration features would be approximately five feet below grade, which in areas of shallow groundwater would violate the criteria of a 10-foot separation from groundwater provided in Caltrans [2007] and CASQA [2003].

- Dozens of OWTS are potentially present within 50 feet of the proposed infiltration facilities. Operation of infiltration facilities within 100 feet of septic system or a leach field violates the Caltrans [2007] criteria.

- Structural foundations are present within 100 feet down gradient of the location of the proposed features. This violates the Caltrans [2007] criteria. Infiltration will produce an increase in groundwater elevations (however minor or temporary) in the beach sand unit where some unknown number of these foundations is located. Evaluations indicate that, for some areas, there is potential for liquefaction in the current groundwater configuration and an increased risk for liquefaction under mounded groundwater conditions. This is of particular concern for foundations within the beach sand. The impact on individual structures is difficult to assess given that they are so numerous and have such a variety of foundation systems and soil conditions.

The following proposed Project components are feasible from a geotechnical perspective:

- Biofiltration with underdrains and impermeable geo-membranes;

- Permeable pavements with no infiltration to subgrade; and

- Vegetated swales.

The following proposed Project components are not feasible from a geotechnical perspective:

- Biofiltration including infiltration; and
- Permeable pavements with infiltration to subgrade.

Limited equilibrium slope stability analyses indicate that existing slopes are stable under current conditions and are not a constraint on Project design in their current configuration.

With the stated limitations on infiltration and given the presence of only minimally liquefiable deposits along the alignment of the proposed BMPs, liquefaction of subgrade soils is not a constraint on the design of proposed drainage features and appurtenant structures.

4.5 Design and Construction Recommendations

The Geotechnical and Groundwater Studies Report includes geotechnical recommendations for proposed construction in the following areas:

(1) Drainage features, including biofiltration features and permeable pavements;
(2) Foundation design; and
(3) Earthwork.

A copy of the Geotechnical and Groundwater Studies Report is included as Appendix D.

5. HYDROLOGY

5.1 General

This section presents an analysis of the existing Project area hydrologic conditions and is intended to:

- Describe the existing hydrologic conditions including drainage infrastructure, catchment boundaries, soils, climate, and flow pattern; and

- Present the hydrologic basis for proposed stormwater BMPs.

5.2 Existing Hydrologic Conditions

5.2.1 General

The watershed associated with the Project site is roughly bounded on the north by the top of the hillside along the south side of PCH and on the south by the center line of Broad Beach Road, and has a total area of 12.3 acres. The watershed encompasses approximately 4,500 feet of Broad Beach Road. The total impervious area is estimated to be 1.5 acres consisting mainly of the asphalt pavement on Broad Beach Road area and PCH; however, there are also patches of concrete and asphalt along the roadside parking strip. There are eight catchment areas and ten City catch basins within the Project area. Drainage maps showing the catchment boundaries, drainage infrastructure, flow patterns, and pervious and impervious areas are presented in Appendix E.

5.2.2 Drainage Infrastructure and Flow Patterns

Broad Beach Road has local depressions and is crowned so that runoff from the northern half of the roadway flows toward the hillside, and runoff from the southern half flows toward the homes where it is typically collected in trench drains at the top or bottom of each resident's driveway. Hillside runoff (in which gullies and surface erosion were observed) and roadway runoff comingle on the mostly unpaved roadside parking strip to the north. The parking area is typically at its lowest elevation closest to the roadway. This directs the surface runoff along the road edge towards the catch basins.

The catch basins for Catchments 1 to 7 are located along the north side of Broad Beach Road are recessed into the hillside with a local depression in the area immediately in front of the inlet. Catchment 8 drains to a storm drain inlet, and although technically not a catch basin, it is referred to such in this report (see Appendix E).

As shown in Appendix E, within the vicinity of the low point of Catchment 5A there are three City catch basins; CB5A, CB5B, and CB5C. The outfalls from all three catch basins feed to the same storm drain. CB5A drains Catchment 5A. CB5B receives only flow from a non-City-owned storm drains that run down the hillside and no direct runoff from the Project area. CB5C drains only an area of a few hundred square feet of the southern half of Broad Beach Road.

The catch basin curb inlets typically have approximately 17 inch openings with varying widths. The distance from inlet invert to catch basin bottom varies from 2 to 4 feet.

Runoff from PCH and adjacent roadside areas flows toward slope drain inlets on both sides of PCH. With one exception, slope drains along the southern side of PCH drop directly into the catch basins along the northern side of Broad Beach Road. These flows are conveyed in Caltrans-owned buried pipes (slope drains) to the below-grade catch basins. As this is not part of the City MS4, it is not addressed by this Project. From the catch basins, water flows through storm drain pipes that cross under Broad Beach Road and tie into private storm drains at the residential property lines prior to discharge to the outfall points on the ocean side of the homes.

The exception to the description above is one slope drain in the western end of the Project area that drains 0.6 acres of PCH, including the road shoulder. This drain daylights at the bottom of the embankment slope; runoff from PCH comingles with surface runoff from Broad Beach Road prior to entering the catch basin.

Delineation of the eight catchment boundaries was carried out based on the following information:

- Topographic maps based on a survey performed for the Project;
- Topographic data (GIS) and aerial photos from Los Angeles County; and
- Field observations and measurements.

5.3 Stormwater Quality Design Volume

5.3.1 Technical Approach

The stormwater quality design volume per catchment was calculated using the methodology described in the Los Angeles County Department of Public Works' *Development Planning for Stormwater Management, A Manual for the Standard Urban Stormwater Mitigation Plan, Appendix A, Volume and Flow Rate Calculations*, issued on September 2002. The design storm event is the 0.75 inch 24-hour storm event which complies with the sizing requirements in the Los Angeles County NPDES MS4 Permit for structural and treatment control BMPs for new development and redevelopment projects. This is consistent with the recommendations in the *City of Malibu Local Coastal Program Local Implementation Plan* and in the Special Protections of the proposed General Exception to the Ocean Plan. Although the Project is a storm water quality improvement project and does not formally qualify as new development or redevelopment, this design criterion was selected for the Project.

The catchments correspond to the tributary areas for the catch basins.

The runoff coefficient curve for the pervious surfaces within the tributary area was selected based on soil maps from Los Angeles County Department of Public Works Water Resources Division. The soils in the Malibu area are identified as soil ID No. 038 [Los Angeles County GIS Data Portal, 2011].

5.3.2 Stormwater Quality Design Volume Calculation

Stormwater Quality Design Volume (SWQDv) was calculated using the following equation:

$$SWQDv\ (ft^3) = (2{,}722.5\ ft/acre) * [(A_I)(0.9) + (A_P + A_U)(C_U)]$$

Where:

A_C = Catchment Total Area (acres) = $A_I + A_P$

A_I = Impervious Area (acres)

A_P = Pervious Area (acres)

A_U = Contributing Undeveloped Upstream Area (acres)

C_U = Undeveloped Runoff Coefficient (-)

Values for A_I, and A_P were determined using the available topographic maps and aerial photos. A_I includes all paved area and A_P includes the remaining area. A_U was determined to be zero for all catchments. C_U was assigned the value of 0.1 based on the runoff coefficient curve for soil no. 038 [LADPW, 2006]. The calculated design volumes are presented in Table 5-1.

6. CONCEPTUAL DESIGN ALTERNATIVES

This section begins with a review of the Project objectives and a discussion of how those objectives are satisfied. Following this, each proposed stormwater BMP or improvement is presented. Finally, two stormwater alternatives are developed and described in detail.

6.1 Project Objectives and Stormwater Alternatives Development

As stated in Section 1, the goals for the Project are to:

1. Eliminate dry-weather flows to the storm drain;
2. Reduce wet weather flows to storm drain (as feasible);
3. Improve water quality of wet weather flows to storm drain (i.e., storm water treatment, pollutant reduction) to the maximum extent practicable (MEP);
4. Reduce potable water use for irrigation (as feasible);
5. Restore habitat above Broad Beach Road (as feasible);
6. Reduce slope erosion (as feasible); and
7. Preserve street and visitor parking.

In addition, feedback from the residents has indicated a preference that the constructed project should not create or perpetuate the existing condition of highly variable parking and landscape/hardscape elements. The Project should be consistent with the rustic natural environment that currently exists along portions of Broad Beach Road. Therefore, we have created an additional objective (new Objective 8) which is to ensure that proposed improvements are consistent with the neighborhood landscape theme of a rustic natural environment.

To address these objectives, Geosyntec developed two stormwater management alternatives. A discussion of each objective and how it is satisfied by the alternatives is provided below.

Objective 1: Eliminate dry-weather flows to the storm drain. It is assumed that the primary dry-weather flows that occur within the Project area are related to irrigation runoff. All the residences are located on the south side of Broad Beach Road and any residential runoff from irrigation, pavement cleaning, car washing, etc. is captured by private drains owned by each residence. Many residents have installed separate private irrigation systems on the north side of the street, on city of Malibu property and within the Project area. To eliminate dry-weather flows, these irrigation systems will be removed and city-operated water-efficient irrigation will be installed in place of these private systems. High-water-use ornamental and exotic plants will be removed and replaced with drought-tolerant native species, reducing the need for frequent irrigation during the dry season.

Objective 2: Reduce wet-weather flows to storm drain (as feasible). This objective is focused on water storage, use, and/or infiltration as a means of reducing discharge to the storm drains. Alternative 2 includes a water use option to reduce wet-weather flow. The soil and groundwater investigation specifically recommended <u>no</u> infiltration for this project, primarily due to the proximity to OWTS, low depth to groundwater, and concern for water intrusion in basements; therefore, infiltration is <u>not</u> considered an option for wet-weather flow reduction.

Objective 3: Improve water quality of wet-weather flows to storm drain (i.e., storm water treatment, pollutant reduction) to the MEP. This objective is met by several proposed Project elements. First, the roadway parking strip is proposed to be paved using concrete interlocking pavers. The construction of these pavers will not enhance stormwater infiltration (see Objective 2 above) but will reduce tracking of sediment from the currently soil/gravel parking strip to the proposed paved parking strip. Second, the parking strip area between the road and the toe of the embankment would be regraded to direct stormwater sheet flow away from the road and to vegetated swales located at the toe of the embankment. Vegetated swales will provide stormwater quality improvement. Third, garden walls (slough walls) and retaining walls are planned for various areas along the toe of the embankment, reducing erosion from the hillside and improving stormwater quality. Fourth, biofilters are proposed to treat wet-weather flows prior to discharge to the existing catch basins. Fifth, for Alternative 2, stormwater capture, storage, and use for irrigation are proposed. This provides a viable use option for a portion of the Project stormwater, if site conditions warrant use for irrigation. If site conditions do not support irrigation, the water will be discharged to and treated by the proposed biofilters, improving stormwater quality prior to discharge.

Objective 4: Reduce potable water use for irrigation (as feasible). This objective is satisfied by the removal of the numerous privately-owned irrigation systems on city property and installing a city-managed low water use irrigation system. The removal of non-native exotic plant species and replacement with native drought tolerant species also reduces potable water use for irrigation. Finally, for Alternative 2, captured stormwater is proposed to be used to replace potable water, for a portion of the Project area irrigation needs.

Objective 5: Restore habitat above Broad Beach Road (as feasible). The Project budget will support removal of invasive and non-native exotic species for portions of the Project area and planting of native species in areas disturbed by construction. These plantings will provide partial habitat restoration of the areas above Broad Beach Road, reducing water usage and reducing hillside erosion.

Objective 6: Reduce slope erosion (as feasible). As stated under Objective 5 above, the partial habitat restoration included in the Project will reduce slope erosion. The proposed garden walls and retaining walls will further reduce slope erosion.

Objective 7: Preserve street and visitor parking. Currently, the only visitor parking available for beach-goers or residential visitors is along the north side of Broad Beach Road. The proposed storm water improvements (i.e., swales and biofilters) have been set back from the road such that the parallel parking opportunities along the full stretch of Broad Beach Road are unchanged.

Objective 8: Proposed Project improvements should preserve and enhance the rustic landscape/hardscape theme for the neighborhood. This objective is met by the proposed landscape and hardscape elements. The landscape architect has developed a rural neighborhood theme which is carried through all the proposed stormwater improvements including pavers, garden and retaining walls, vegetated swales, biofilters, and plantings.

6.2 BMPs and Stormwater Improvements

6.2.1 General

This section provides descriptions of the proposed stormwater BMPs and stormwater improvements and identifies how they would function to meet the Project objectives. An overview of proposed BMPs and improvements to be included in each alternative is presented in Table 6-1.

6.2.2 Biofiltration

Biofiltration systems will be used as the primary treatment control BMP for treatment of stormwater and dry-weather runoff from the Project area. Biofiltration systems, sometimes referred to as bioretention systems, are landscaped shallow depressions that capture and filter stormwater and dry-weather runoff. These facilities function as soil-and plant-based filtration devices that remove pollutants through a variety of physical, biological, and chemical treatment processes. Biofilters typically consist of a surface ponding area, mulch layer, planting soils, and plantings. As water flows across the plantings and passes down through the organic-rich planting soil, pollutants are filtered, adsorbed, and biodegraded by the soil and plants. These systems provide a fairly high level of treatment. Because infiltration is unacceptable for this Project, biofilters will be designed with a lower impermeable membrane and a perforated underdrain to collect the treated water. The underdrain will connect to a collector pipe which will convey the treated water to a nearby catch basin. The outlet of the collector pipe in the catch basin will be located to facilitate sampling of biofilter effluent. Alternatively, an access point will be installed along the collector pipe to allow for effluent sampling. Typical cross-sections and details for the biofilters proposed for Broad Beach are shown in Figure 6-1.

Where sediment, trash and debris is expected in site runoff and a vegetated swale is not provided for water pretreatment, a pretreatment forebay will be included upstream of the biofilters. A forebay will reduce the rate of clogging of the biofilter and facilitate maintenance.

For this Project, the biofilters will not be designed to retain and infiltrate water - most water will flow through the filters and be discharged. However, low flows (i.e., dry-weather flows) may be partially or fully retained in the filter media. These relatively small water volumes are expected to be ultimately reduced by evapotranspiration.

The Project biofilters are designed to capture and treat the design capture volume during a storm event. A description of the biofilter sizing methodology for this Project is included in Appendix F. The calculated values for the required biofilter media surface area (A_{media}) for the two alternatives described later in this section are presented in Table 6-1.

6.2.3 Vegetated Swales

At present, stormwater flows off the embankment and towards a low elevation flow line between the street and the parking strip. The area between the edge of road pavement and the toe of the embankment will be graded to cause stormwater to flow off the road and off the parking strip to the embankment toe. A vegetated swale will be installed along the embankment toe, parallel to the road and will convey stormwater to storage or biofilter treatment facilities. Vegetated swales are an effective stormwater pretreatment BMP to filter out trash, debris, and coarse sediments - they also provide aesthetic enhancement for the area. The installation of vegetated swales will reduce pollutant loading and clogging on the downstream biofilters, extending the biofilter media life.

Vegetated swales are sloped and are not designed to pond water. Therefore, infiltration of water through vegetated swales is insignificant and it should not be necessary to install impermeable liners under the swales.

6.2.4 Water Collection, Storage, and Use or Treatment

Stormwater runoff can be collected in below-ground enclosed storage facilities (cisterns) and used for landscape irrigation, as required. Runoff would be conveyed in swales and gravity drain into systems of vaults, tanks, or pipes to store the water until needed. When needed, the water can be pumped from the underground storage and conveyed in pressurized pipes for use in drip irrigation. Drip irrigation is selected as the most viable use option. This site would be classified as a Tier III system under Los Angeles County requirements for rainwater and stormwater harvesting systems. Drip irrigation requires only sediment filtration prior to water use. Spray irrigation requires water disinfection, which adds an unattractive level of complexity to this stormwater use application.

If stored water cannot be used for landscape irrigation due to lack of irrigation water demand, the water would be pumped and discharged to biofilters after the storm peak had passed and the surface stormwater had been filtered and discharged. In this way, the biofilters can be used to filter stored water during times when the filters are otherwise not in use.

Local residents have expressed concern regarding underground storage of stormwater and the potential for leakage and infiltration of this water, possibly exacerbating a high groundwater condition in the neighborhood. Should stormwater storage be implemented, various technologies such as impermeable lining systems could be employed to provide additional assurance against leakage of stored water.

6.2.5 Concrete Pavers

The majority of the parking strip that runs parallel to Broad Beach Road is unpaved – the existing surface varies, including sand, soil, decomposed granite, and various types of gravel. This parking strip is commonly used for parking by residential visitors, workers, and beachgoers. Surface erosion of the unpaved parking surfaces can reduce stormwater quality. Sediment tracking from parking areas to the roadway mobilizes sediment and can reduce stormwater quality. This condition is exacerbated by muddy and wet conditions during storm events. The installation of pavers from the edge of road to form an approximately 10 foot wide parking strip is proposed. Pavers would provide a uniform surface for parking and greatly reduce erosion and sediment tracking. Paver selection and design will be made to reduce stormwater infiltration to the extent possible. In any event, the minor infiltration through paver system is expected to be significantly less than the existing condition where stormwater infiltrates through unpaved ground.

6.2.6 Retaining and Garden Walls

Retaining walls (structural walls) and garden walls (non-structural slough walls) are proposed for various locations along the hillside. The walls fulfill three purposes. First, installation of walls in designated locations will allow for the embankment to be cut back, opening up needed areas for biofilter installation. Second, the walls reduce soil erosion and sloughing from the hillside, which is a key contributor to sediment in stormwater. Third, the installation of walls creates a uniform hardscape theme across the neighborhood. Existing retaining walls are not engineered, are often ineffective for erosion reduction, and are constructed of a myriad of materials including cobbles, broken concrete, masonry brick, and cast-in-place concrete.

6.2.7 Irrigation System Removal/Replacement

A key element to reducing or eliminating dry-weather flows is the removal of privately-owned irrigation systems on the north side of the road. Although this property is owned by the city, homeowners have installed private irrigation systems plumbed back to their water services and have created private gardens and landscapes on city property. The private irrigation of gardens creates uncontrolled and unmanageable dry-weather flows which have been observed during recent site visits. Private systems would be removed and replaced with water-efficient low-volume irrigation controlled by city-controlled, automated evapotranspiration controllers. Water would be provided by the city and water use would be managed by the city. We recognize the communication efforts that will be required to implement the removal of these private irrigation systems. An estimate of annual water use for Broad Beach Road irrigation is provided in Appendix G.

6.2.8 Habitat Restoration

As mentioned above, many Broad Beach Road residents have created gardens across from their residences on city property. These gardens include many non-native invasive or ornamental plants and shrubs, most which require frequent irrigation. To reduce irrigation requirements and reduce the erosion potential, high water-demand ornamental plants and shrubs within 20 feet of the toe of embankment slope would be removed and replaced with more drought-tolerant, native species plants and shrubs. This will allow the city to manage irrigation (and reduce or eliminate dry-weather flows) and reduce potable water use on the hillside. Areas disturbed by construction will be revegetated with appropriate species. Other ornamental or exotic species will be removed, depending on proximity to the roadway and the plant-specific water consumption requirements. The creation of a more uniform native species plant/shrub environment furthers the objective of creating a more uniform landscape theme for the neighborhood. Again, we recognize the communication efforts that will be required to implement the removal of nonnative species that were planted by residents.

6.3 Stormwater Alternative 1

Stormwater Alternative 1 is comprised of a combination of BMPs and improvements including stormwater conveyance and treatment BMPs, retaining and garden walls, parking strip pavers, irrigation, and landscape improvements. Alternative 1 is differentiated from Alternative 2 in that Alternative 1 contains no stormwater storage or use options – in Alternative 1, all stormwater up to the design storm event is captured, treated, and discharged. A flow diagram illustrating the stormwater management principles for Alternative 1 is presented in Figure 6-2. In the subsections below, the specific application of these BMPs and improvements are addressed, as are issues related to parking, utilities, and operation and maintenance. The general layout and features of Alternative 1 are shown on Figures 6-4 through 6-14.

6.3.1 Stormwater Management Improvements

For Catchments 2 to 7 runoff will be collected from the road, parking strip and embankment and transported in vegetated swales that drain to biofilters located upstream of the catch basins. The swales will provide pretreatment while primary treatment will occur in the biofilters.

The swales will run along the toe of the hillside slope intercepting hillside runoff. The parking area will be regraded such that both the road and the parking area drain toward the swales. The swales will serve to channelize flow to the biofilters and will widen at the biofilters entrance to create sheet flow into the biofilter.

Biofilters will be located between the toe of the slope and the paved parking area. In some cases cuts will be made into the hillside to create more available filter area. Filtered water will be collected in underdrains that connect to collector pipes, discharging to the existing catch basins, or to the storm drains if more feasible. When the ponding capacity of the biofilters is exceeded, overflow will occur over a weir located at the end of the biofilter closest to the catch basin and then surface flow to the catch basin inlet. The top of weir elevation will be the same as the water surface elevation corresponding to the biofilter design ponding depth.

Locating adequately sized biofilters in Catchment 1 and the eastern part (east of CB8) of Catchment 8 was not deemed feasible due to lack of area and other logistical constraints such as utilities, parking, and steep slopes. For these two catchments, runoff is diverted to other areas where adequate area for treatment is available.

Runoff from Catchment 1 is diverted via gravity flow from catch basin CB1 to a biofilter in Catchment 2. The diversion structure will be designed to divert low flows while during high runoff events (in excess of design storm) water will overflow to catch basin CB1.

Runoff from Catchment 8 will be captured in a new wet sump adjacent to storm drain inlet CB8 and pumped to a biofilter in the western end of Catchment 8. The wet sump will be designed to receive and pump flows up to the design storm – events in excess of the design storm will overflow to CB8. A submersible pump can be used for this application. Noise levels outside of the sump are expected to be imperceptible to residents.

In general, the biofilters are sized for the design capture volume generated in their immediate tributary area. However, the biofilters in Catchment 2 and 8 are sized for both direct catchment runoff as well as the diverted runoff from other areas.

The proposed stormwater system improvements do not significantly alter the existing drainage patterns. Hillside and roadway runoff patterns are generally unchanged; however, regrading of the Broad Beach Road parking strip will concentrate flow along the toe of the slope instead of along the road pavement edge. Biofilters and swales are sited in order to maintain flood paths to existing catch basins.

6.3.2 Landscape, Hardscape, and Irrigation

Alternative 1 includes construction of garden and retaining walls and parking strip pavers, removal/modification of some of the existing garden and retaining walls, removal of all private irrigation systems and replacement with city-controlled, water-efficient irrigation systems, and replacement of exotic, ornamental, and invasive plant species. This alternative also includes replanting in areas disturbed by construction. The general plan indicating the Project areas where hardscape, irrigation, and planting improvements will be made is shown on Figures 6-4 through 6-14.

Selective plant material will be removed from the Project area to help create consistent landscape theme, reduce irrigation water use, and facilitate Coastal Bluff Scrub Habitat Restoration. The specific criteria applied to each area to determine which existing ornamental, exotic, or invasive plant species should be replaced are as follows:

- Invasive plant species will be removed from the first 20 feet of the Project slopes and parkway to the extent practical;

- Vegetation will be removed from existing utility setbacks;

- Vegetation will be removed from Project improvement areas including biofilter areas, vegetated swales, retaining walls, garden walls, parking areas, and concrete swales and gutters;

- Vegetation will be removed in locations where conflicts occur with the proposed slope irrigation improvements and proper system operations;

- Native vegetation that constitutes a high fire risk per Los Angeles County Fire Department Fuel Modification Plan will be removed;

- Trees with invasive roots will be removed that are located within 10 feet of proposed Project retaining walls, garden walls, and biofiltration areas; and

- Selective ornamental vegetation that is high water use will be removed.

The proposed irrigation system for the Project will be a low water use system featuring a smart weather based controller combined with low volume drip, bubbler and overhead rotary stream spray heads. The smart controller will allow for daily automatic adjustments to the watering schedule based on real time weather data. Flow sensing devices allow for system shut-down and delays in response to rain events and system failures. Low volume point to point irrigation using drip and bubbler systems provide for maximum water use efficiency. Rotary stream heads provide additional water savings with 30% increased efficiency over traditional spray heads. The estimated total water usage (ETWU) for the Project is approximately 740,000 gallons per year. This represents about 50% of the maximum applied water allowance (MAWA) for the proposed design.

Feedback from a conversation with one of the Broad Beach homeowners indicates that some of the existing irrigation systems may have been installed to serve as fire protection. This has not been confirmed but the need for fire protection will be evaluated during the design phase and more information will be solicited from the Broad Beach homeowners. The final design will comply with existing code and fuel modification requirements including the following:

- All proposed landscape and irrigation improvements will be implemented per the Los Angeles County Fire Department (LACFD) Fuel Modification Plan

Guidelines [LACFD, 2011] to create the desired defensible space around all combustible structures in a fire environment.

- All proposed landscape improvement plant species are subject to LACFD approval and will be inherently fire resistant and spaced appropriately.
- Existing native vegetation and ornamental plantings within the project fuel modification zones will be modified by thinning and removal of species constituting a high fire risk (refer to the LACFD Undesirable Plant List).
- Routine fuel modification maintenance will be regularly performed in all zones. Maintenance includes irrigation, pruning, thinning and annual removal of weeds, dead materials and other undesirable flammable vegetation required to keep the area in a fire safe condition. (Refer to the LACFD Fuel Modification Plan Maintenance and Long Term Maintenance sections)

The proposed planting for the Project will consist of native and drought tolerant grass species for the biofilter areas and vegetated swales. This vegetation provides water quality improvements for Project runoff and creates a distinct theme for the Project parkway. The slope planting will consist of a combination of drought-tolerant shrubs to enhance the existing plant material to create a more consistent landscape theme combined with Coastal Bluff Scrub species to facilitate native slope habitat restoration.

The proposed hardscape improvements for the project will include an interlocking concrete paver parking area, concrete veneer retaining walls and dry stacked boulder garden/slough walls. These elements will be installed throughout the project construction limits creating a consistent rural neighborhood theme and materials palette for the project. Miscellaneous existing garden/slough walls will be removed and either omitted or replaced with project theme walls as needed to construct the proposed biofiltration areas and vegetated swales. Existing retaining walls that are required due to existing grade and are structurally sound will remain and be enhanced with the project theme veneer so that all walls are consistent.

A plant palette exhibit and a materials exhibit for pavers and wall veneers are included in Appendix H. The exhibits present several different options.

6.3.3 Parking Considerations

The proposed improvements will allow for parallel parking along the entire stretch of roadway within the Project boundaries, similar to the current-day parking locations.

The installation of pavers will improve parking conditions in several areas where the surface is uneven due to ditches and erosion.

6.3.4 Utility Considerations

Existing utilities have been identified both by review of historical maps and by marking on Broad Beach Road by the utility owners. The preliminary design of BMPs and improvements has been developed in consideration of all known utilities and no significant utility conflicts are known. Prior to construction of the Project, the city of Malibu's contractor will be required to mark and locate all utilities within the Project area and to field verify locations of utilities that could be threatened by the work.

Los Angeles County owns a sewer line that runs along Broad Beach Road, between the road edge and the embankment. A sewage pumping station is located in Catchment 1. In some areas, this sewer line will be located under the proposed location of parking strip pavers. The depth of this utility will need to be verified to ensure it is protected during grading and subgrade improvement work.

The Gas Company owns a gas line that also runs parallel to the road between the sewer line and the road. Similar to the sewer line, this gas line will be under the parking strip where pavers are proposed. The depth of this utility will also need to be field verified to ensure it is protected during construction.

There are electrical transformers owned by Southern California Edison located along the north side of Broad Beach Road within the Project area. Electrical laterals traverse the parking area. We have not identified any significant conflicts between the electrical lines and the proposed construction. Locations and depths can be verified prior to construction. Vegetation will need to be removed around the existing transformers.

Charter Communications owns communications lines that primarily run along the south side of the road, outside of the Project area. We have identified several communications lines that cross the road to roadside amplifier boxes. These crossings are within the Project area but do not pose a conflict for the proposed work.

The Los Angeles County Waterworks owns a water main that is located near the road centerline and provides water to residents and to two hydrants located along the north side of the road within the Project area. These water supply lines are marked and do not pose a conflict for the proposed work. During design, coordination with the local fire department will be required to identify parking restrictions in front of fire hydrants. Currently, there are no posted parking restrictions in this area; however, we expect that the fire department may impose parking prohibitions in certain areas to ensure emergency hydrant access.

No telephone utilities were identified in the Project area.

6.3.5 Performance

The proposed configuration of treatment control BMPs and improvements will be designed to treat 100% of the runoff generated within the Project tributary area for storm events equal to or less than the design storm. Using vegetated swales and biofilters, pollutant removal treatment effectiveness is predicted to be medium to high. It is our expectation that, barring an unforeseen water line break, all dry-weather runoff will be treated by the biofilter system. Dry-weather runoff should be substantially reduced or even eliminated by the removal of private irrigation systems and the installation of new water efficient irrigation with smart controllers. Other than irrigation runoff, there are no other known sources of dry-weather runoff within the Project area.

Retaining walls, garden walls, and parking strip pavers will all reduce erosion and sediment transport in runoff. Pavers will also reduce sediment tracking from the parking strip to the roadway. New plantings of native species will also reduce erosion.

Potable water use will be reduced by elimination of the numerous private irrigation systems and installation of new water-efficient irrigation and smart irrigation controllers.

6.3.6 Operation and Maintenance

The following is a description of anticipated operation and maintenance requirements for the proposed BMPs and improvements.

Vegetated swales will require periodic removal of accumulated trash and debris. Removal of accumulated sediment and revegetation may also be required. Weed removal, trimming, and pruning are also necessary. Vegetated swales will require some minimal irrigation during dry months.

Biofilters will require periodic removal of accumulated trash and debris. If sediment removal is required, replacement of mulch and vegetation may also be necessary. Occasional pruning of shrubs and cleanup of leaves and organic waste may be required. Periodic replacement or addition of planting material and mulch will be needed to sustain the biofilter's treatment effectiveness. Minimal biofilter irrigation will be needed, especially during dry months. Irrigation needs will significantly diminish after plants become established.

Irrigation system maintenance will include periodic inspections of system performance and verification that dry weather flows are eliminated. Damaged sprinkler piping, sprinkler heads, and drip emitters will require replacement. Verification of proper operation of irrigation controllers will be required. The total water usage for the first year is estimated at 740,000 gallons. The yearly cost for this water usage is roughly $5,500 based on current water rates (see water usage and cost calculations in Appendix G). Water usage, and consequentially water costs, can be reduced after plants are established.

Areas that have been revegetated due to replacement of inappropriate species or in areas disturbed by construction will require inspection and landscape maintenance to ensure that plants are properly established and the plant health is sustained.

The wet sump in Catchment 8 and the pumping system will require periodic inspection and verification of proper operation. Pump maintenance will be minimal. Electricity to run this pump represents a trivial expense.

6.4 Stormwater Alternative 2

Stormwater Alternative 2 has many common elements to Alternative 1. The primary difference between the alternatives is that Alternative 2 includes collection and storage of runoff in underground cisterns. The collected water from the two proposed cisterns can be pumped for irrigation use or pumped to biofilters for treatment after the storm peak has passed. This storage and off-peak treatment permits more efficient use of the biofilters and results in a smaller Project biofilters footprint. In the subsections below, the proposed BMPs and improvements are presented. A flow diagram illustrating the stormwater management principles for Alternative 2 is presented in Figure 6-3. The general layout and features of Alternative 2 are shown on Figures 6-4 through 6-14.

6.4.1 Stormwater Management Improvements

As previously stated, stormwater management BMPs and improvements for Alternative 2 are similar to Alternative 1. However, Alternative 2 collects surface runoff from Catchment 1, part of Catchment 2, and Catchment 8 and stores this water in two underground stormwater cisterns. The cisterns are proposed to be constructed of a system of buried pipe that functions like a storage tank and is specifically manufactured for underground water storage. One cistern is located within Catchment 8 – all the runoff from Catchment 8 drains to swales, flows to a drain inlet, and is conveyed to the cistern. The total storage for the Catchment 8 cistern is 520 cubic feet. When storage capacity is exceeded, runoff will overflow to the existing storm drain inlet. Refer to Figure 6-5 for the proposed location of the storage system.

Stormwater in Catchment 1 and the western portion of Catchment 2 is captured in swales and gutters and flows to two drain inlets that are routed to a cistern located in Catchment 2, for storage. The total storage for this cistern is 2,080 cubic feet. Refer to Figures 6-11 and 6-12 for the proposed location of the storage system. When storage capacity is exceeded, runoff will overflow to the existing storm drain outfall from catch basins CB1 and CB2.

Residents have expressed concern that underground water storage facilities could leak, causing groundwater mounding and potentially exacerbating a high water table condition under their homes. If the manufactured cistern system is not determined to be sufficiently reliable for water storage, a system of synthetic liners can be considered to provide additional assurance that the water storage systems do not leak and infiltrate water to the subsurface.

Each of the two cisterns will be constructed with a wet sump to evacuate the stored water. Stored water can either be directed to biofilters located in Catchments 2 and 7 or water can be used for landscape irrigation. Each wet sump would be fitted with two pumps, one for landscape (a higher pressure, higher flow application) and one for water transfer to the biofilters (a lower pressure, lower flow application). Submersible pump noise is expected to be imperceptible to residents. Pumps would be controlled by a smart stormwater controller that assesses the volume of water in the cisterns, evaluates current climatic conditions and the forecast for future storms, assesses the need for irrigation based on evapotranspiration data, and controls each pump appropriately.

For portions of Catchment 2 and Catchments 3-7, the BMPs and improvements proposed are the same as Alternative 1. Refer to Figures 6-4 through 6-14 for details.

The Project benefits of stormwater storage are that there is approximately 2,600 cubic feet (approximately 19,500 gallons) of stored water available for irrigation. If irrigation is not needed, which is often the case in the winter, the water can be stored and discharged to the biofilters after the storm peak as passed, allowing the biofilters to be used more efficiently and resulting in a reduced area footprint for the biofilters. The reduced biofilter area for Alternative 2 is nearly 1,900 square feet (refer to Table 6-1) less than Alternative 1. The layout of Alternative 2 increases vegetated swale length by approximately 300 linear feet.

6.4.2 Landscape, Hardscape, and Irrigation

Landscape elements are similar between Alternatives 1 and 2. Hardscape elements are similar between the Alternatives with the exception that Alternative 2 has a smaller Catchment 2 retaining wall, due to the smaller biofilter area required. Alternative 2 has the same irrigation plan as Alternative 1 supplemented by an additional parallel drip irrigation system to support the use of stored stormwater. To avoid cross connection concerns, it is necessary to have completely independent irrigation systems supplied by potable water and supplied by stormwater.

6.4.3 Parking Considerations

There is no difference between Alternative 1 and Alternative 2 with regard to parking on Broad Beach Road.

6.4.4 Utility Considerations

The utility considerations unique to Alternative 2 are related to the underground storage of stormwater. Stormwater from Catchment 1 and a portion of Catchment 2 will be stored in a large diameter buried pipe located in Catchment 2. The pipe will require an excavation of up to approximately eight feet in depth. We have considered the need for shoring during this installation. The pipe location should not conflict with any existing utilities. For Catchment 8, the underground storage pipe installation will require an excavation to a depth of approximately six feet. This will likely require shoring, careful location of the adjacent sewer line, and ultimately replacement of the toe-of-slope swale.

6.4.5 Performance

Stored stormwater that is used for irrigation represents a net reduction in discharge to the ocean. That is consistent with the Project objectives. Furthermore, the stored water used for irrigation replaces potable water. The proposed storage systems have a capacity to store roughly one-third of the total design capture volume for the Project area. The performance of vegetated swales, biofilters, and landscape and hardscape elements is similar to Alternative 1.

6.4.6 Operation and Maintenance

The operation and maintenance items for Alternative 2 are similar to Alternative 1 with a few minor exceptions. The parallel drip irrigation system for stormwater irrigation use would require periodic maintenance. The submersible pumps found in the cisterns would require periodic inspection and occasional maintenance. The cost of electricity for pumping is considered trivial.

The total water usage for the first year is estimated at 715,000 gallons: 625,000 gallons for slope vegetation and 90,000 gallons for biofilter and swale vegetation.

Potable water use would be reduced for Alternative 2, due to use of stored water for irrigation. The cisterns will store approximately 2,600 cubic feet with equates to approximately 19,500 gallons. Water from the cisterns will be used to irrigate the biofilters and the vegetated swales. Although difficult to predict how much stormwater will substitute for potable water, we believe it is reasonable to expect that stormwater use for irrigation may replace between 5 and 10 percent of potable water use.

The yearly average cost for water usage is estimated to vary between $4,400 and $5,200 based on current water rates (see water usage and cost calculations in Appendix G). Assuming that 50% of the irrigation demand for the biofilters and vegetated swales is supplied by cistern water, the yearly average cost is estimated to be $4,800, roughly $700/yr less than Alternative 1. The amount of irrigation water for biofilters and vegetated swales supplied by cistern water can potentially reach 100%; however, this is unlikely since the demand will be greatest during dry periods when supply is low. These costs represent water usage for the first year. Water usage, and consequentially water costs, can be reduced after plants are established.

7. CONSTRUCTION COST ESTIMATE

Cost estimates were developed for the two proposed design alternatives for this 10 percent design level. The estimates represent solely contractor costs and do not include oversight, independent testing, construction management, or documentation. A 20 percent contingency was applied to each estimate. For this conceptual design, the costs were not escalated to spring of 2013, the predicted construction start date.

The following is a list of the various cost resources used in the development of the cost estimates:

- The Geosyntec team's experience on similar projects;
- Cost data for two recent, similar projects constructed in Malibu;
- Vendor quotes; and
- RS Means cost guide.

Through an iterative process the scope of construction was modified (reduced) in order to generally meet the Grant construction budget which is $1,675,836. Estimated construction costs correspond only to the improvements in the Project area that fall within the limits of construction on Figures 6-6 and 6-11, unless otherwise noted on the figures.

The estimate of construction costs for the two alternatives are:

Alternative 1 - $1,625,000

Alternative 2 - $1,688,000

A summary table of the primary cost items is presented in Table 7-1. Detailed cost estimates are presented in Appendix I.

8. DISCUSSION AND RECOMMENDATION

Alternatives 1 and 2 both generally satisfy the Project objectives. Each alternative eliminates or at least substantially reduces dry-weather flows. Both alternatives reduce erosion and sediment tracking through hardscape and landscape improvements. Both alternatives provide stormwater treatment and associated improvements in water quality for water discharged to Broad Beach. Both alternatives provide habitat restoration and reductions in potable water use related to planting of drought tolerant species. Both alternatives include consistent hardscape and landscape themes and carry these themes throughout the Project area.

The stormwater management elements that are different between the two alternatives are:

1. Reduction of potable water for irrigation; and

2. Volume of water discharged to Broad Beach.

Alternative 2 is a partial capture and treat alternative. Alternative 2 provides storage for approximately one-third of the design capture volume of runoff and either uses that water for irrigation or treats the stored water after the storm has passed, allowing for more efficient use of biofilters. This capture and use strategy reduces potable water needed for irrigation and reduces the volume of treated water discharged to Broad Beach. The capture and use strategy is progressive and demonstrates leadership and innovation by the city of Malibu.

The challenges related to Alternative 2 are that water storage and use adds additional cost, as compared to Alternative 1. The need for pumping systems increases the Project complexity and maintenance costs are also slightly higher (primarily related to maintaining a separate irrigation system). Finally, there may be a perception by the local residents that there is a risk of stormwater leakage from the cisterns, potentially causing undesirable infiltration.

Geosyntec believes both Alternatives are viable and attractive stormwater management approaches for Broad Beach Road. However, Geosyntec believes that Alternative 2 goes further to meet the goals of the grant by promoting a greater reduction of wet weather flow to the storm drain and by reducing potable water use for irrigation; Geosyntec therefore recommends Alternative 2.

9. LIMITATIONS

This Preliminary Design Report was developed in accordance with the scope of work, purpose, terms, and conditions described in the Terms of Reference, described in Section 1.

The conclusions contained in this investigation are based on the conditions as observed by Geosyntec personnel and as reported by relevant agencies and other named sources at the time the investigation was performed.

No warranty, expressed or implied, is made regarding the professional opinions expressed in this report or concerning the completeness of the data presented to us. If actual conditions are found to differ from those described in the report, or if new information regarding the site is obtained, Geosyntec should be notified and additional recommendations, if required, will be provided.

Geosyntec is not liable for any use of the information contained in this report by persons other than the City of Malibu as intended for the subject Project.

Executive Summary

ES.1. TMDL Summary

The North Santa Monica Bay Jurisdictional Groups 1 and 4 Wet-Weather Bacteria Total Maximum Daily Load (TMDL) Implementation Plan (Implementation Plan) has been prepared in response to Resolution No. 2002-022 of the California Regional Water Quality Control Board—Los Angeles Region (Regional Board) amending the Water Quality Control Plan for the Los Angeles Region to incorporate Implementation Provisions for the Region's Bacteria Objectives and to incorporate a Wet-Weather TMDL for Bacteria at Santa Monica Bay Beaches.

The TMDL features a reference system/anti-degradation approach, utilizing as its reference watershed the Arroyo Sequit subwatershed. The purpose of utilizing this approach is to ensure that bacteriological water quality is at least as good as that of a reference site and that no degradation of existing bacteriological water quality is permitted where existing bacteriological water quality is better than that of a reference site.

Jurisdictional Group 1 (J1) area is primarily comprised of the County of Los Angeles (the County), City of Malibu, and California Department of Transportation (Caltrans). Other agencies encompassed by the jurisdictional boundaries include the County of Ventura, the Cities of Calabasas and Los Angeles, and the State of California Department of Parks and Recreation. The County is the primary jurisdictional agency for J1. Jurisdictional Group 4 (J4) includes the City of Malibu (primary jurisdiction), County of Los Angeles, and Caltrans, and consists only of Nicholas subwatershed. Subwatersheds comprising Jurisdictional Groups 1 and 4 (J1/4) are shown in Figure ES.1.

Compliance measures include a number of activities that in combination would result in reducing the number of days in which water quality objectives are exceeded to less than or equal to that of the reference watershed. The TMDL stipulated a threshold number of exceedance days based on daily monitoring activities. In J1 the number of exceedance days is seventeen; in J4, the number of exceedance days is fifteen. It is recognized, however, that while the TMDL (and many of the related analyses) are based on daily criteria, because the Coordinated Shoreline Monitoring Plan (CSMP) describes many locations where weekly monitoring will occur, the number of exceedances will be pro-rated accordingly.

Non exceedance is defined as meeting water quality objectives. These objectives are, for rolling 30-day Geometric Mean Limits[1].

a. Total coliform density < 1,000/100 ml.
b. Fecal coliform density < 200/100 ml.
c. Enterococcus density < 35/100 ml.

1) The calculation of the 30-day geometric mean utilizing weekly sampling will require further discussion, should exceptions to the definitions described in section 1.1.4 be considered. It is assumed that this calculation will be reported as part of the Coordinated Shoreline Monitoring Plan Implementation.

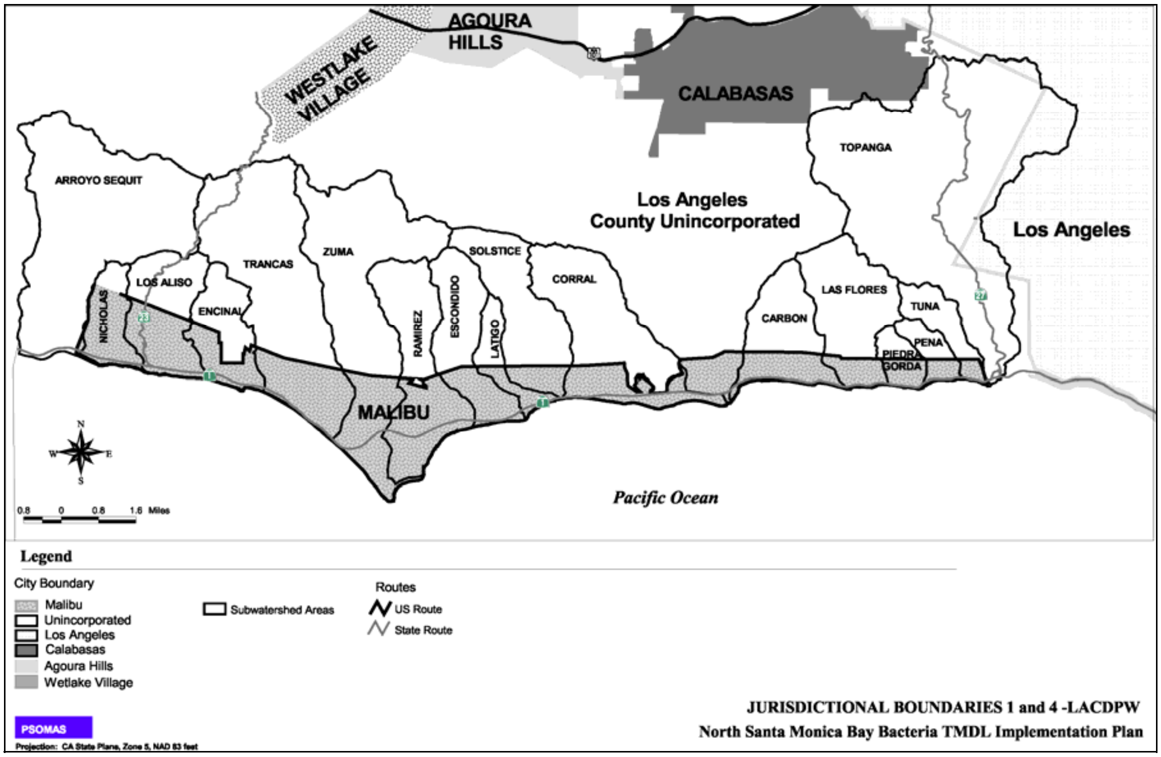

Figure ES.1 Jurisdictional Areas

For Single Sample Limits:

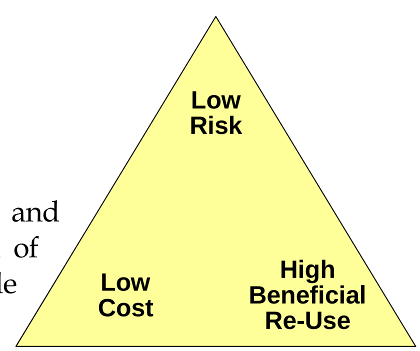
a. Total coliform density < 10,000/100 ml.
b. Fecal coliform density < 400/100 ml.
c. Enterococcus density < 104/100 ml.
d. Total coliform density < 1,000/100 ml, if the ratio of fecal-to-total coliform exceeds 0.1.

Given the proposed integrated approach presented in this plan, the schedule and target deadlines for meeting these compliance criteria are:

- Final Implementation Plan July 2005
- Re-evaluation: 2007
- 10% reduction (6 years): 2010
- 25% reduction (10 years): 2013
- 50% reduction (15 years): 2017
- Final targets (18 years): 2021

ES.2. Philosophical Approach

The Implementation Plan presents an iterative, adaptive, and integrated approach. This approach requires consideration of multiple beneficial uses and the targeting of multiple pollutants. Philosophically, an implementation compliance triangle was developed to illustrate the balance of low risk,



"Compliance Triangle"

low cost, and high beneficial reuse to determine site specific implementation.

The following activities were conducted during the development of the Implementation Plan:

- Estimating and Establishing Baseline Conditions
- Developing a Menu of Potential Activities
- Identifying Implementation Considerations
- Selecting and Prioritizing
- Planning and Implementation during the next 18 Years

ES.3. Baseline Conditions

Baseline conditions were established and estimated based on a number of evaluations, which included the following:

ES.3.1 Source Prioritization

This effort consisted of reviewing available monitoring data, land uses, soil conditions, slopes, studies and technical reports in order to target potential activities for this plan. Conclusions of this effort were that:

- There was no "smoking gun," and it is difficult to pinpoint specific sources;
- High loads/exceedances are linked to urbanization and proximity to shoreline, and
- Final subwatershed prioritization should consider beach use.

ES.3.2 Hydrogeology and Aquifers

The objective was to establish infiltration and groundwater recharge potential and the scale at which this was appropriate. Some key findings were:

- A review of geology and aquifers found no groundwater basins for recharge potential
- Soils were generally poorly draining and poorly suited for large scale infiltration
- Groundwater levels in those areas where soils were not poorly draining were high, and
- Opportunities tended to be local (on site) and less feasible on a large, regional scale.

ES.3.3 Surface Water Hydrology

A hydrologic analysis was conducted to support the potential incorporation of structural measures in TMDL implementation[2]. The purpose of the analyses was to estimate, on a macro-scale, preliminary potential volumes of water (within each subwatershed) that

2) The TMDL stipulated a threshold number of exceedance days based on daily monitoring activities. In Jurisdiction 1 the number of days is 17; in Jurisdiction 4, the number of days is 15. It is recognized however, that while the TMDL (and many of the related analyses) are based on daily criteria, because the Coordinated Shoreline Monitoring Plan describes many locations where weekly monitoring will occur, the number of exceedances will be pro-rated accordingly.

would theoretically need to be captured and treated to meet TMDL requirements. This planning-level analysis successfully resolved the discontinuity between exceedance-day TMDL criteria and conventional design-storm analytical techniques using a methodology that examined daily rainfall volumes over the historical period of record. This methodology involved 1) ranking daily rainfall volumes per year, 2) establishing the "critical" rainfall day each year, and 3) establishing a 90th percentile that corresponded to the TMDL criteria based on a review of the period of record. It should be noted that because daily precipitation values were used and because the TMDL stipulated a 17 -day exceedance criteria, the hydrologic analyses considered daily flow rates. For implementation purposes, the actual criteria will need to be adjusted to correspond to compliance monitoring frequencies.

Rainfall data sets were then converted to runoff volume estimates for each subwatershed using precipitation values, zoned land uses (and percentages of the subwatersheds that are impervious), soil types, and runoff coefficients developed by the County. To address the potential range of volumes, the analysis considered reduction factors (established in adjacent watersheds for similar conditions) in estimating ranges of target treatment volumes[3].

ES.3.4 Water Supply, Reuse, and Recreational Opportunities

Water supply and reuse was evaluated on a regional basis. Potential demand was based on land use and likely water consumption activities. Regional groundwater recharge potential was reevaluated, and potential recreational uses were identified. It was established that local measures such as on-site cisterns and on-site infiltration would be more appropriate. Reuse opportunities on recreational land were reviewed by examining open lands, trails, and municipal parks. Proximity to potential reuse sources and slope stability issues related to infiltration potential were also considered.

ES.4. Potential Activities

The suite of potential activities was categorized into non-structural (often called institutional or programmatic) measures and structural (often called treatment) measures.

ES.4.1 Non-Structural

Many of the nonstructural programs built upon existing Municipal Permit programs. In particular, bacteria-specific activities were identified for these efforts and included:

- Public Information and Participation
- Industrial/Commercial
- Development Planning

3) The proposed method is restricted to development of this Plan and reductions will be confirmed and developed further with future studies conducted as part of this Plan.

- Development Construction
- Public Agency Activities

ES.4.2 Structural

Structural measures included on-site and regional solutions. These solutions stipulated bacteria-specific treatment requirements, which often require pretreatment, as well as alternative wastewater treatment.

On-site structural solutions included:

- Residential cisterns
- On-site storage and reuse
- Small scale infiltration
- Porous pavements
- Grass/gravel pavers
- Retention grading
- Bioretention
- On-site wastewater alternatives

Regional (and subregional) solutions all require pre-treatment, and, as such, address multiple pollutants. Structural options included:

- Traditional wastewater treatment for stormwater
- Small packaged system
- Filtration
- Advanced oxidation
- Peracetic Acids
- Subsurface Flow Constructed Wetlands

ES.4.3 Other Implementation Considerations

Other considerations for implementation included site availability and permitting requirements associated with treatment. The ideal candidate sites were determined as publicly owned facilities, particularly given the cost of land in the J1/4 area. Regional solutions require more land for operational storage, especially where natural treatments are proposed.

Regulatory considerations include local regulations such as planning and zoning (including the City of Malibu Local Coastal Program (LCP)), Building Code, Plumbing Codes Fire Prevention, Urban Runoff/Stormwater Management. State and Federal regulations may also be important depending on the facility. These can be location specific (e.g., U.S. Army Corps of Engineers, California Department of Fish and Game, Regional Board permits and certifications), Coastal Zone Requirements (LCP), Resource Protection Agencies (U.S. Fish and Wildlife Service, National Marine Fisheries), National Pollutant Discharge Elimination System (NPDES) Waste Discharge Requirements, Department of Health Services (particularly for reuse activities) and Ocean Plan/Areas of Special Biological Significance(ASBS) considerations.

ES.5. Selecting and Prioritizing

The general methodology for development, evaluation, and prioritization of activities was developed in response to the following questions:

- Where do we have the most significant problems?
- What is our tolerance for uncertainty and does this tolerance depend on location?
- Where can we leverage solutions to achieve multiple benefits?
- Where do we have a higher probability of success?
- What do we want to do now versus waiting until better information and technologies become available?

In order to balance uncertainty, potential costs, and potential benefits in a manner consistent with an integrated approach, the "compliance triangle" model was developed. This philosophical model is an evaluation tool that helps balance costs, risks, and beneficial reuses. The following table delineates typical activities for non-structural, on-site, and regional options.

Table ES.1 Alternatives Comparison

Alternative	Non-Structural Options	On-Site Options	Regional Options
Low Cost	Implement existing and new programs (commit + pilot)	Pilot-scale implementation of the following: • Cisterns • On-site storage and reuse • Small-scale capture and infiltration	Not included
Low Risk	Implement existing and new programs (commit + pilot)	Not included	Capture, store, treat and discharge
Beneficial Reuse	Implement existing and new programs (commit + pilot)	Full-scale implementation of the following: • Cisterns • On-site storage and reuse • Small-scale capture and infiltration	Capture, store, treat, and beneficially reuse

In order to intelligently implement activities, different levels of commitment were established for this plan. These levels were:

- "commit"—the Agencies commit to this activity

- "pilot"—the Agencies are willing to commit to a pilot study to determine whether the proposed activity the preliminary design parameters are appropriate.

- "consider" – the Agencies will consider this effort, depending on the results of committed activities.

The following table describes the implementation levels of commitment based on ease of implementation and potential effectiveness.

Table ES.2 Commit-Pilot-Consider Model

		Implementation Requirements Rating		
		Difficult	**Moderate**	**Easy**
Potential Effectiveness Rating	**High**	Pilot	Commit	Commit
	Medium	Consider	Commit	Commit
	Low	Consider	Consider	Consider

In order to prioritize subwatersheds, results of the source prioritization effort were combined with monitoring data from the TMDL-defined "critical year".

- High Priority subwatersheds: Latigo, Corral, Las Flores, Piedra Gorda, and Ramirez
- Medium Priority subwatersheds: Carbon, Los Alisos, Topanga, and Escondido
- Low Priority subwatersheds: Nicholas, Encinal, Trancas, Zuma, Solstice, Pena, and Tuna

These priorities, in conjunction with subwatershed specific characteristics and the desired risk-cost-beneficial reuse relationship, contributed to the development of a unique suite of activities for each subwatershed. Watershed priorities are shown below in Figure ES.2.

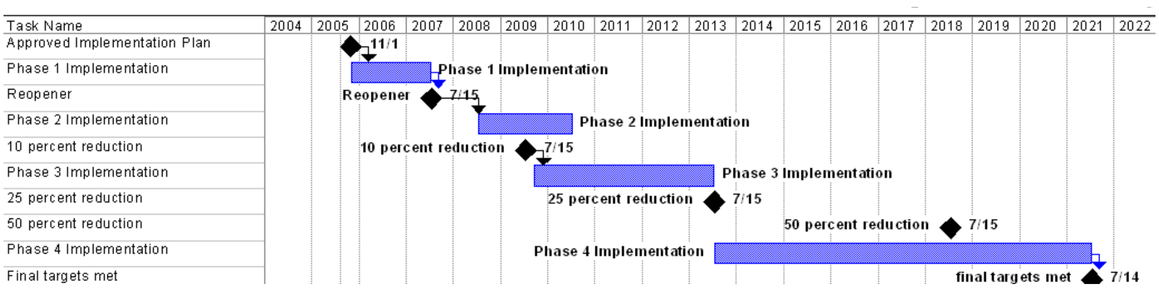
Figure ES.2 Subwatershed Priorities

ES.6. Planning and Implementation

ES.6.1 Schedule

The Implementation Plan was divided into four phases of activities. The activities consisted of implementation activities, as well as monitoring and additional studies that could be used to provide better information for future activities. To provide useful information, the additional studies will require extended development and implementation periods. Upon completion of these studies, it would be desirable to confirm, or adjust if necessary, the direction and requirements of the Implementation Plan. As such, the County and J1/4 Agencies proposed the addition of appropriately timed re-evaluation milestones. Implementation activities, suggested re-openers, and implementation milestones are illustrated below:

Santa Monica Bay Beaches Bacterial TMDL – J1/4
Implementation Plan Phasing



The general intent of what would be accomplished under each of the phases is as follows:

- Phase I – Conduct planning and initiate all committed non-structural activities and implement selected non--structural measures; initiate pre-feasibility studies for sub-regional pilot projects; develop inter-agency agreements for structural projects, initiate planning for on-site measures; initiate monitoring, additional studies, and source identification activities. The 2007 re-opener would follow Phase I. Note that Phase I is assumed to begin in November 2005, which is the basis of the proposed schedule. Should the initiation date change, the remaining implementation deadlines may change accordingly.

- Phase II – Continue implementation of committed non-structural activities; conduct non-structural pilot programs; continue planning for on-site measures; initiate planning and construction of pilot regional structural solutions; and continue and complete monitoring and source identification studies. A programmatic review is proposed to follow Phase II and is intended to leverage results not only from additional studies in these jurisdictional areas, but also advances in the technical, legal, and regulatory body of knowledge.

- Phase III – Refocus and reprioritize efforts as appropriate, and continue implementation of committed non-structural activities; implement successful piloted non-structural programs; begin implementation of on-site measures; and operate and evaluate pilot regional structural solutions.

- Phase IV – Refocus and reprioritize efforts as appropriate and continue implementation of non-structural solutions; continue or expand on-site measures; and continue, modify and/or initiate regional structural solutions.

ES.6.2 Subwatershed-Specific Activities

Activities were defined for each subwatershed. These activities included the appropriate level of non-structural, on-site structural, and regional structural activities based on subwatershed priorities and characteristics. In many cases, pilot scale implementation was proposed to establish the link of BMPs to water quality improvement, optimize design parameters, assess appropriate siting, and evaluate new technologies. These activities are summarized and presented on a subwatershed-specific basis in Section 5.

ES.6.3 Monitoring

Monitoring is a key element to both the re-evaluation of the Implementation Plan requirements and technologies after two years and for assessing the effectiveness of measures. Compliance monitoring is not, however, addressed in this plan. It is proposed that future monitoring take place during winter low flows, and winter storm flows (most critical). Six stations were proposed for future monitoring. The objective of these monitoring stations was to provide information to support future management decisions such as selection of structural and non-structural BMPs, and was not intended to be compliance-related. As such, proposed stations were not necessarily high priority watersheds, but represented watersheds where potentially useful information could be extracted. With the exception of Topanga Creek at the sandbar, all stations showed high bacteria counts (exceeding water quality standards) during the first storms of 2004-2005. The proposed stations are:

- Trancas Creek (discharges to Area of Special Biological Significance)
- Solstice Creek (potentially similar to Arroyo Sequit land usage and potential alternative reference subwatershed)
- Marie Canyon (high priority subwatershed)
- Sweetwater Creek (potential concentrated equestrian land uses)
- Topanga lagoon (sandbar and bridge)

In addition, effectiveness monitoring of structural measures per U.S. Environmental Protection Agency (EPA)/American Society of Civil Engineers (ASCE) protocols will also be incorporated in the long-term program.

ES.6.4 Additional Studies

Upon completion of the initial two years of monitoring, an evaluation will be made to determine whether microbial source tracking activities are required. Rationale for recommending such studies could include, but not be limited to, the need for further source identification; site specific, objective data development; and potential health risk assessments. This may include an evaluation of the appropriateness of the TMDL indicator constituents of concern.

Studies that would contribute to more cost-effective implementation of the bacteria TMDL, and which could be included in the J1/4 implementation effort include:

- Identification of the Most Relevant Human Health Indicators Study (2007-2009)
- Hydrology vs. Bacteria Loading Study (2005-2010)
- Bacterial Seasonal Variation Study (2005-2008)

ES.6.5 Integrated Plan Elements

The Implementation Plan was developed consistent with an Integrated Water Resources Approach (IWRA) on the basis of a) multiple pollutants removed and b) integrated water resources benefits. Table ES.3 below lists, for each recommended BMP, both the target pollutants and water resources benefits. For discussion purposes, target pollutants are grouped in the following families:

- Bacteria
- Nutrients
- Metals
- Organics
- Pathogens
- Trash

Integrated water resources benefits listed include:

- Conservation
- Reuse/Recycling
- Habitat
- Geomorphology (Hydromodification)
- Hydrology (Stream)
- Flood Control

ES.6.6 Performance Evaluation

Assessing the effectiveness of the management measures is critical to tracking progress toward meeting full TMDL compliance. Two basic approaches are presented in the Final Plan: 1) a Presumptive Compliance Approach and 2) a Targeted Monitoring-Based Approach.

The Presumptive Compliance Approach (PCA) assumes that the implementation of structural and non-structural BMPs will lead directly to reductions of exceedance days and attempts to quantify this relationship. It is recognized that there is significant uncertainty and it is expected that the iterative and adaptive management strategies are employed, both effectiveness will improve and the correlation of activities to water quality compliance will improve. The presumptive approach is confirmed in some cases by the use of information surveys toward targeted audiences.

The focused and targeted monitoring-based approach (TMBA) adopts some measures of presumptive compliance but incorporates monitoring data and attempts to normalize and extrapolate this monitoring data throughout the region. TMB results are presented in Interim Compliance Reports.

Other performance metrics include informational surveys, tracking of volumes of pollutants removed, and a comparison of expenditures relative to full implementation budgets.

Table ES.3 describes, for each recommended BMP, the performance evaluation measure and methods to be implemented to gage progress toward meeting TMDL targets.

ES.6.7 Reporting

An annual Implementation Plan progress report documenting compliance activities will be provided by the J1/4 Agencies. It is not anticipated that this report be exhaustive, but will include a summary of progress, successes and challenges, and requested modifications to the Implementation Plan. This report would reference activities conducted to date, compared to commitments made in this Implementation Plan.

ES.6.8 Program Budgets

Potential program budgets are not provided, but would eventually be considered for preliminary programmatic budgetary planning only. An initial budget analysis did not include those activities that are considered for implementation, but do include activities that are *committed* to or implemented on a *pilot* scale. In addition, specific allocation of costs between jurisdictional agencies was not addressed in this Plan.

Table ES.3
Summary of Best Management Practices, Integrated Water Resources Approach, and Performance Evaluation Measures

	BMPs and Activities	**Water Quality Benefits: Multiple Pollutants**	**Additional Integrated Water Resources Benefits**	**Performance Evaluation Measure and Method**

1. Introduction

1.1 TMDL Summary

The North Santa Monica Bay Jurisdictional Groups 1 and 4 Wet-Weather Bacterial Total Maximum Daily Load (TMDL) Implementation Plan (Implementation Plan) was prepared in response to Resolution No. 2002-022 of the California Regional Water Quality Control Board—Los Angeles Region (Regional Board) amending the Water Quality Control Plan for the Los Angeles Region (Basin Plan) to incorporate Implementation Provisions for the Region's Bacteria Objectives and to Incorporate a Wet-Weather TMDL for Bacteria at Santa Monica Bay Beaches (see Appendix A).

1.1.1 TMDL Development History

The Clean Water Act of 1972 (CWA), enacted into the U.S. Code, required States to develop a list, named the 303(d) List after the relevant section of the CWA, of impaired waters and name the pollutants for which they are impaired. States must then establish a watershed-based, pollutant-specific TMDL to bring impaired water bodies into compliance with the water quality standards necessary for achieving designated beneficial uses of the water body. The Santa Monica Bay beaches are designated as human body contact recreation, also known as REC-1, and are included on the State of California's 1998 303(d) List due to high indicator coliform bacteria exceedance.

The Regional Board released a first draft of the Santa Monica Bay Beaches Bacterial TMDL on November 9, 2001. As development of the TMDL progressed, the Regional Board staff decided to bifurcate the TMDL—one for dry weather and one for wet weather—to allow more time to consider the extensive public comments on the wet weather elements of the TMDL. Both the Dry- and Wet-weather TMDLs were approved by the U.S. Environmental Protection Agency (EPA) in June 2003 and became effective on July 15, 2003.

This Implementation Plan focuses on wet-weather TMDL implementation.

1.1.2 Jurisdictional Groups 1 and 4

The TMDL groups the subject area into seven jurisdictional groups and designates within each group a primary jurisdiction as the responsible agency. The jurisdiction that comprises greater than fifty percent of the land area in the group is selected as the primary jurisdiction. The responsible agency of each jurisdictional group is charged with submitting a TMDL implementation plan and a corresponding schedule to be used by the jurisdictional group.

Jurisdictional Group 1 (J1) area is primarily comprised of the County of Los Angeles (County), City of Malibu, and California Department of Transportation (Caltrans). Other agencies encompassed by the jurisdictional boundaries include the County of Ventura, the Cities of Calabasas and Los Angeles, and the State of California Department of Parks and Recreation. The County is the primary jurisdictional agency for J1, which is comprised of sixteen (16) subwatersheds (including the reference watershed, Arroyo Sequit watershed, which is excluded from the Implementation Plan). Jurisdictional Group 4 (J4) includes the

City of Malibu (primary jurisdiction), County of Los Angeles, and Caltrans, and consists only of Nicholas subwatershed.

Subwatersheds comprising Jurisdictional Groups 1 and 4 (J1/4) are shown in Figure 1.1. It should be noted that these subwatersheds do not include Malibu Creek Watershed.

1.1.3 Compliance Requirements

For this TMDL, the Regional Board implemented bacteria objectives using a reference system/anti-degradation approach. The purpose of utilizing this approach was to ensure that bacteriological water quality is at least as good as that of a reference site and that no degradation of existing bacteriological water quality is permitted where existing bacteriological water quality is better than that of a reference site. For the Wet-weather TMDL at Santa Monica Bay beaches, Leo Carrillo Beach and its associated drainage area, Arroyo Sequit Canyon, were selected as the local reference system. Leo Carrillo Beach was selected as the reference beach because it best met the three criteria for selection of a reference system. Specifically, its drainage is the most undeveloped subwatershed in the larger Santa Monica Bay watershed, it has a freshwater outlet (i.e., creek) to the beach, and it has adequate historical shoreline monitoring data.

Compliance Activities

Additional TMDL compliance activities included the following:

- Responsible agencies were required to submit a Coordinated Shoreline Monitoring Plan (CSMP) within 120 days of the effective date of the TMDLs to be used for compliance monitoring of the TMDLs. This plan was submitted in November 2003, and revised in April 2004.

- Responsible jurisdictions were required to develop an implementation plan for achieving compliance. After considering the Implementation Plan, the Regional Board will amend the TMDL and adopt an individual implementation schedule for each jurisdictional group that is as short as possible taking into account the implementation approach being undertaken.

1.1.4 Compliance Water Quality Objectives

The TMDLs are based on numeric targets for bacteriological water quality objectives for Water Contact Recreation (REC-1) revised by Regional Board Resolution 2001-018 amending its Basin Plan on October 25, 2001. This Basin Plan amendment received final approval from the EPA on September 25, 2002[1]. These water quality objectives are based on four bacterial indicators and include both geometric mean limits and single sample limits:

1) Resolution No. 2002-022, Finding 18.

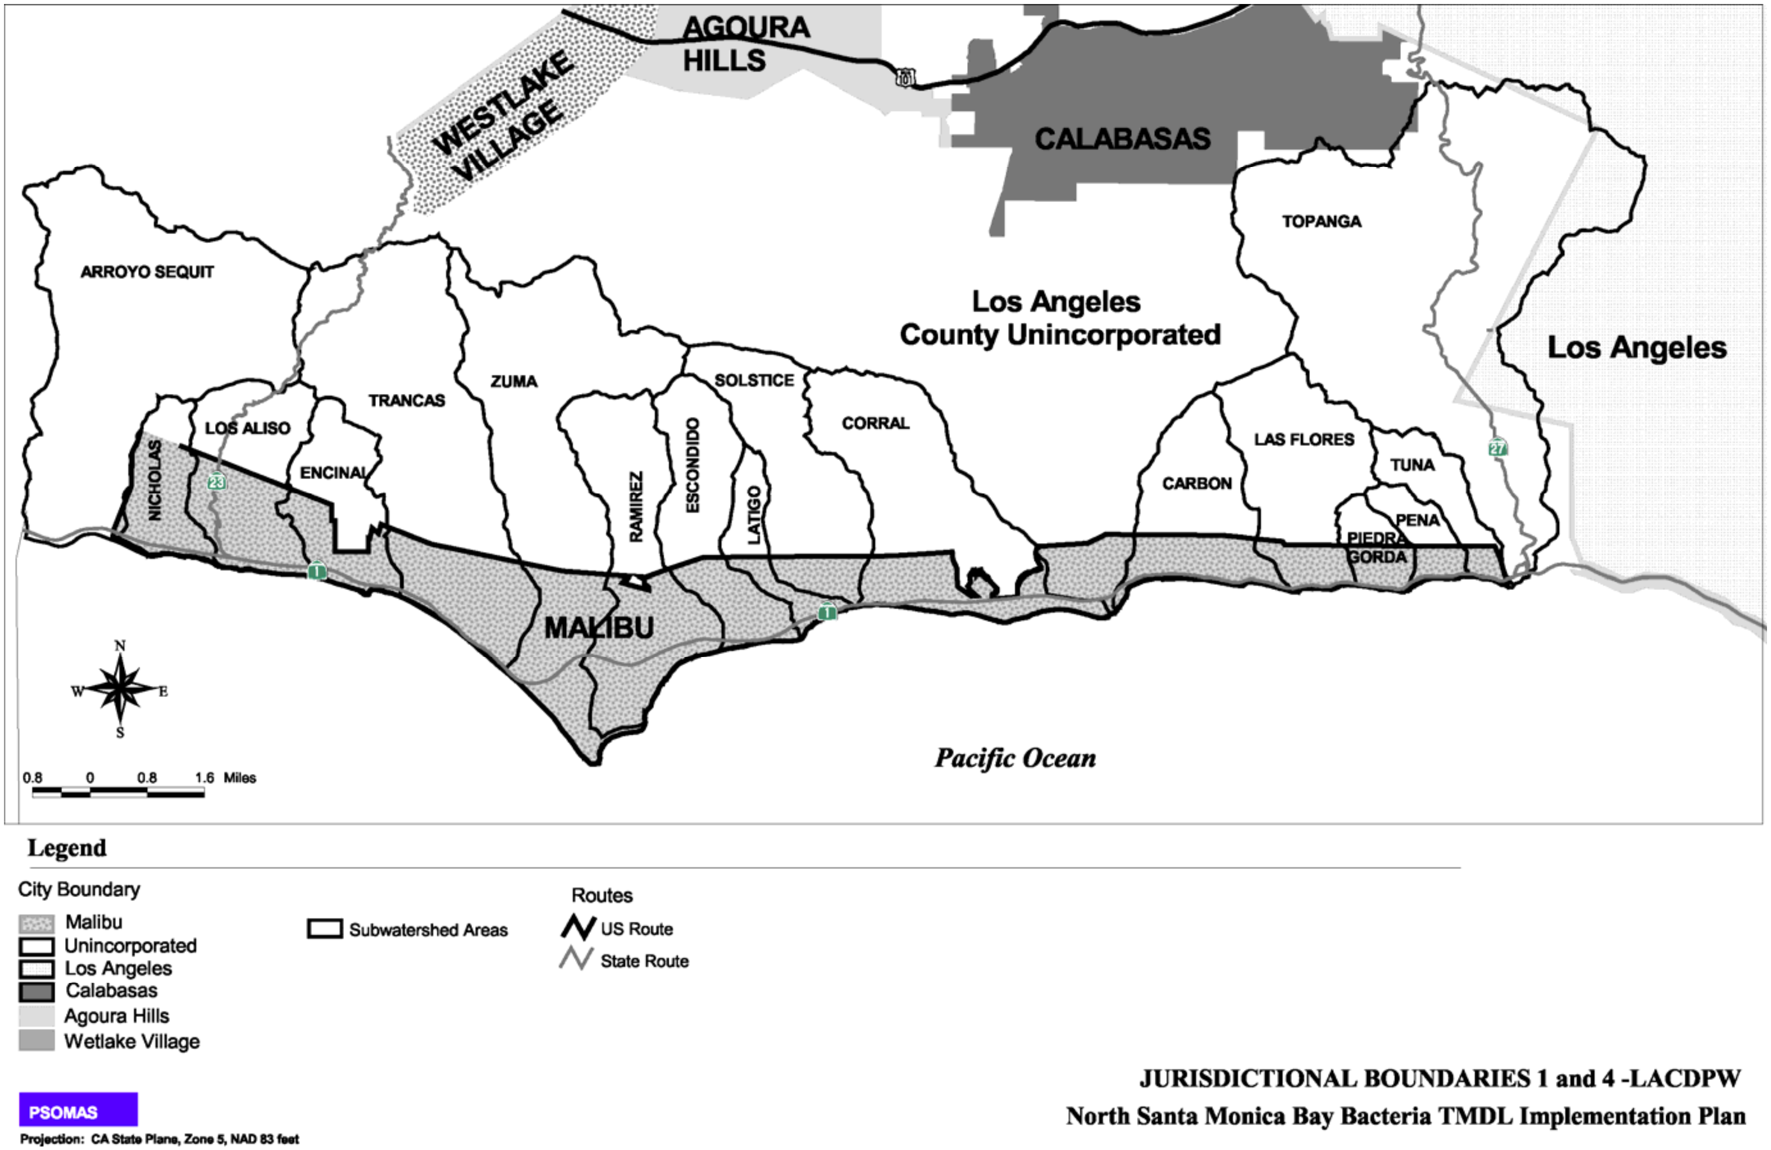

Figure 1.1 J1/4 Jurisdictional Agencies

RB-AR 7627

9-1513

1. **Rolling 30-day Geometric Mean Limits**
    a. Total coliform density shall not exceed 1,000/100 ml
    b. Fecal coliform density shall not exceed 200/100 ml
    c. Enterococcus density shall not exceed 35/100 ml.

The geometric mean is defined in Webster's Dictionary as "the nth root of the product of n numbers." Thus, the 30-day geometric mean calculation for the TMDL will be calculated as the 30th root of the product of 30 numbers (the most recent 30 day results). For weekly sampling, the 30 numbers are obtained by assigning the weekly test result to the remaining days of the week. If more samples are tested within the same week, each test result will supersede the previous result and be assigned to the remaining days of the week until the next sample is collected. This rolling 30-day geometric mean must be calculated for each day, regardless of whether a weekly or daily schedule is selected. Since zero cannot be used to calculate a geometric mean when bacteria is not detected in a sample, a value equal to half the detection limit will be used for calculation purposes. Development of alternative methods to calculate the 30-day geometric mean based on weekly data is outside the scope of this document.

2. **Single Sample Limits**
    a. Total coliform density shall not exceed 10,000/100 ml
    b. Fecal coliform density shall not exceed 400/100 ml
    c. Enterococcus density shall not exceed 104/100 ml
    d. Total coliform density shall not exceed 1,000/100 ml if the ratio of fecal-to-total coliform exceeds 0.1

The TMDL set allocations based on the maximum number of days within a storm year that sample results under the CSMP may exceed the water quality objectives (targets). Allocations for wet-weather are specific to each monitoring site and have been established based on historical monitoring data and/or comparison with historical monitoring data at the reference beach.

These site-specific allocations are listed below in Table 1.1. The maximum allowable number of exceedance days based on the reference system during year-round wet weather is seventeen (17) exceedance days per year under a daily sampling schedule. If a weekly sampling schedule is employed, the number of allowable exceedance days is scaled back accordingly to three (3) exceedance days per year for year-round wet weather.

Table 1.1 Final Allowable Wet-Weather Exceedance Days by Beach Location

	Estimated Number of Exceedance Days in Critical Year (1993)	Final Allowable Number of Exceedance Days
Leo Carrillo Beach, at 35000 PCH	17	17
Nicholas Beach- 100 feet west of lifeguard tower	14	14
Broad Beach	15	15
Trancas Beach ent., 50 yards east of Trancas Bridge	19	17
Westward Beach, east of Zuma Creek	17	17

	Estimated Number of Exceedance Days in Critical Year (1993)	Final Allowable Number of Exceedance Days
Paradise Cove, adjacent to west side of Pier	23	17
Latigo Canyon Creek entrance	33	17
Corral State Beach	17	17
Las Flores Beach	29	17
Big Rock Beach, at 19900 PCH	30	17
Topanga State Beach	26	17

1.1.5 Compliance Schedule

Based on the TMDLs as currently written, compliance schedules for TMDL compliance are listed below:

- Effective Date: July 15, 2003
- Project Kick-off: July 2004
- Draft Implementation Plan March 2005
- Final Implementation Plan July 2005
- Re-evaluation: 2007
- 10% reduction (6 years): 2009
- 25% reduction (10 years): 2013
- 50% reduction (15 years): 2018
- Final targets (18 years): 2021

Four years after the effective date, based in part on new data collected under the CSMP, the Regional Board will re-consider various provisions of the TMDLs, including:

- Allowable wet weather exceedance days
- Reevaluation of the reference system
- Reevaluation of the reference year
- Clarification or revision of the geometric mean implementation provision
- Reevaluation of proposed implementation plan elements

1.2 Coordinated Shoreline Monitoring Plan

While not part of this Implementation Plan, elements of the CSMP are discussed here. Compliance with the TMDL is to be based on monitoring conducted in accordance with the CSMP which has been submitted jointly by all jurisdictional groups and approved by the Regional Board. Monitoring under this plan began in November 2004. The CSMP was developed by a Technical Steering Committee consisting of representatives from each of the primary jurisdictions as well as additional responsible agencies. The plan was designed to comply with the monitoring requirements of both the dry- and wet-weather TMDLs and to provide data to support the re-evaluations that will be made when specific provisions of the

TMDLs are re-considered. CSMP monitoring sites located within J1/4 are listed Table 1.2 (from the Coordinated Shoreline Monitoring Plan, Revised April 7, 2004).

Table 1.2 J1/4 Coordinated Shoreline Monitoring Station Summary

Station Name	Type	Description (including historical site ID, if any)	Low Flow Diversion	Coordinates		Subwatershed	Sampling Agency

1.3 Implementation Plan Participants

1.3.1 Responsible Agencies

For the purposes of Implementation Plan development, the County has taken the lead for J1 while the City of Malibu has taken the lead for J4. Other affected agencies include Caltrans, and the County of Los Angeles Department of Beaches and Harbors. Other named agencies such as the City of Calabasas and City of Los Angeles have opted out of the Implementation Plan development as the extent of their impacted areas is limited.

It should be noted that Caltrans has reserved the right to proceed independently to address the TMDL goals depending on the specific costs and implementation measures identified during the implementation process.

1.3.2 Stakeholders

Stakeholder participation was primarily accomplished through the North Santa Monica Bay Watersheds Task Force, the members of which were solicited for input prior to the development of a draft plan, and who participated in an Implementation Plan workshop. Environmental groups actively engaged in the process included the Regional Board staff, Heal the Bay and the BayKeepers.

1.3.3 Other Implementation Plans

Concurrent with the development of this plan, Implementation Plans were being developed for the other Santa Monica Bay watershed Jurisdictional Groups, namely Groups 2 and 3 (combined plan) and Groups 5 and 6 (combined plan).

The City of Los Angeles is the lead agency for Jurisdictional Group 2 and is a significant participant in two other Jurisdictional Groups (3 and 7). The City of Santa Monica was designated the lead in Jurisdictional Group 3 and is a participant in Jurisdictional Group 2. Other responsible agencies within Jurisdictional Groups 2 and 3 include the City of El Segundo, the County of Los Angeles, and Caltrans.

Jurisdiction Group 5 is comprised of five responsible agencies: City of Manhattan Beach (primary jurisdiction), City of El Segundo, City of Hermosa Beach, County of Los Angeles and Caltrans. The limits of this area extend from the north boundary of the City of Manhattan Beach to just south of the Hermosa Beach Pier. Jurisdiction 6 is comprised of five responsible agencies: Cities of Hermosa Beach, Redondo Beach (primary jurisdiction) and Torrance, along with the County of Los Angeles and Caltrans. The limits of this area range from the boundary of Jurisdiction 5 just south of the Hermosa Beach Pier and just south of Artesia Boulevard in Redondo Beach, to the southern city limit of Torrance at the coast.

1.4 Objectives of Implementation Plan

There are numerous objectives for this Implementation Plan. First and foremost, the objective is to develop a plan that results in the improvement of water quality to a level such that shoreline waters meet or exceed the requirements of the TMDL and Resolution No. 2002-022. In addition, a significant objective of the Implementation Plan is to commit to strategic cost-effective solutions. It is recognized that cost-effective implementation of TMDL requirements in conjunction with other water resources demands and opportunities, will result in a greater overall benefit than solely focusing on treatment of bacteria in urban runoff. Therefore, this Implementation Plan represents an integrated water resources approach that takes a holistic view of regional water resources management by integrating planning for future wastewater, storm water, recycled water, and potable water needs and systems, and focuses on beneficial re-use of storm water, including groundwater infiltration at multiple points throughout a watershed. In addition, recognizing that bacteria are not the sole pollutant of concern, this Implementation Plan also addresses multiple pollutants for the Santa Monica Bay.

Because the Regional Board recognized that an integrated water resources approach not only provided water quality benefits to the people of the Los Angeles region, but also potentially served a variety of public purposes, it acknowledged that a longer timeframe is reasonable for an integrated water resources approach because it requires more complicated planning and implementation such as identifying markets for the water and efficiently siting storage and transmission infrastructure within the watershed(s) to realize the multiple benefits of such an approach.

Another objective of the Implementation Plan is, therefore, to include methods for identifying, developing, designing, implementing, purchasing, installing, monitoring, evaluating, and maintaining the most appropriate "source control" and "treatment control" solutions. Given the additional complexity of an integrated water resources approach, the Implementation Plan will be presented to the Regional Board to justify a timeframe of 18 years to comply with the TMDL requirements.

The last critical objective of the Implementation Plan is to provide an adaptive and iterative framework for implementation. Because source prioritization efforts have not yielded conclusive source tracking results, and because technologies, particularly for bacteria treatment are developing, it is recognized that both the objectives of the TMDL and mitigation strategies may require revision and reexamination. This recognition is incorporated in the scheduling and phasing of activities within the Implementation plan.

2. Summary of Technical Analyses

This section summarizes the results of technical analyses that were conducted as part of the development of the Implementation Plan. These analyses are listed in the reference section of this Implementation Plan.

2.1 Existing Conditions

The purpose of the Source Identification and Prioritization, Hydrogeology and Aquifers, and Hydrology analyses were to establish some baseline conditions to help understand the issues and conditions within the J1/4 area.

2.1.1 Source Identification and Prioritization

The purpose and objectives of the source identification and prioritization efforts were to, on a macro-scale, identify and evaluate potential sources of water quality impairment in the affected subwatersheds and to prioritize these sources. Numerous sources of data were evaluated in an attempt to establish some relation between the source loading and water quality impairment. The task involved: a literature search and assessment of historic water quality monitoring; a review of other resource management studies of the watershed areas, as well as personal communications with key stakeholders; resource mapping; and field reconnaissance.

Monitoring data for E. coli, fecal coliform, total fecal coliform and enterococcus have been collected over the past 5 years from the following entities: Heal the Bay, Resource Conservation District of Santa Monica Mountains, County of Los Angeles Department of Health Services, County of Los Angeles Department of Public Works, and the City of Los Angeles. Even though E. coli is not cited in the TMDL, it was included in the data collection since the presence of E. coli in water is a strong indication of recent sewage or animal waste contamination and is particularly relevant to fresh water.

Potential Sources as a Basis for Prioritization

While not directly relevant to the J1/4 study area, the results of a risk assessment prepared by Stone Environmental (2004) show that shallow groundwater in the Malibu Creek study area is significantly influenced by bacteria from sources other than On-Site Wastewater Treatment Systems (OWTS). Stormwater infiltration and direct percolation from the land surface in sandy soil areas are likely to be significant potential sources of contamination. These results provide insight into the potential sources of contamination within J1 and J4.

Given the indication that the OWTSs are probably not a widespread source of bacterial contamination at the beach, the source identification and prioritization effort focused instead on other potential sources including restaurants, horses, urban runoff, etc. An attempt was made to establish a correlation between subwatershed land uses, densities, soil properties, number of storm drains, and exceedance occurrences. Given the limited data, the task of source identification and prioritization was an exercise of deduction or a "process of elimination." The data did not support the identification of one conclusive source (e.g., restaurants, horse ranches, etc.) identified by the source identification and prioritization effort, but did identify the effects of urbanization, particularly urbanization in proximity to water bodies, as being linked to exceedance of water quality standards. As a result the focus of the prioritization effort shifted from source prioritization to targeted subwatershed prioritization to support an implementation strategy.

Therefore, potential sources or conditions associated with urban runoff, in conjunction with other factors such as proximity to a water body and recreational use of beaches, formed the basis for evaluating and prioritizing subwatersheds. Factors considered in the prioritization of subwatersheds included:

- Monitoring Data
  - Recent monitoring data, in particular, water quality exceedances associated with CSMP, was evaluated on a probability basis. Probabilities were determined by the proportion of single sample exceedance occurrences to total samples collected.
  - Exceedance-day monitoring data that formed the basis of the TMDL. The TMDL listed the number of exceedance days for a number of subwatersheds during the critical year (1993). Those subwatersheds with exceedance days exceeding 50% of the TMDL threshold were designated high priority, and those subwatershed with exceedances within 10% of the threshold were designated low priority.
- Land Use Based Criteria
  - Residential development near shoreline,
  - Commercial development near shoreline,
  - Horse ranch near shoreline,
  - Horse ranches in watershed,
  - Development near streams within watershed
  - Proportion of residential development in the watershed
  - Proportion of other development in the watershed

  Figures 2.1.1-2.1.16 graphically illustrates relative land uses for each subwatershed with the following subcategories: residential and educational; industrial and commercial; managed open space; and natural open space.
- Runoff potential: primarily a function of soil type, vegetation and land use.
- Physical criteria: number of storm drains at the shoreline, and
- Beach usage: relative potential exposure to humans as a function of beach usage assumed to be a function of parking lot spaces at beaches.

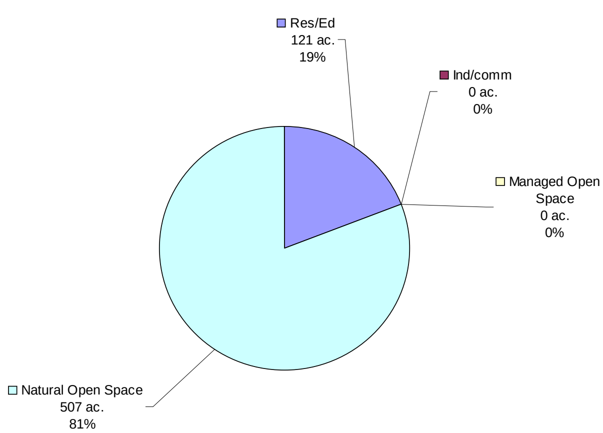

Figure 2.1.15 Piedra Gorda: Breakdown of Land Use

Ramirez

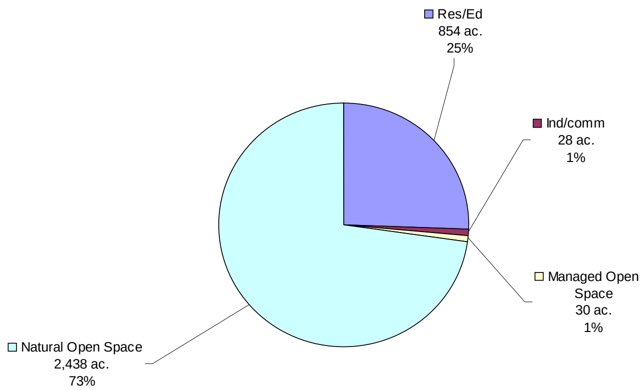

Figure 2.1.16 Ramirez: Breakdown of Land Use

The above factors were considered as a whole and priorities for subwatersheds were established on the basis of the above factors. In addition, those subwatersheds that were identified as high priority per the TMDL were also prioritized. The results of this analysis are illustrated in Figure 2.2. Based on the priority ranking and/or the TMDL exceedance days, it was established that the highest priority watersheds are Ramirez (Paradise Cove), Corral (including Marie Canyon), Latigo, Las Flores, and Piedra Gorda. Figures 2.3.1-2.3.3 present composite land uses for high, medium, and low priority subwatersheds.

2.1.2 Hydrogeology and Aquifers

Hydrogeologic and aquifer characteristics were evaluated on a macro-scale to establish the potential for infiltration as both a water conservation and water quality best management practice. Topography, basin slopes, and drainage patterns were evaluated as potential regional infiltration facilities. Geology of the project area was reviewed, and soils were evaluated based on Natural Resource Conservation Service (NRCS, formerly Soil Conservation Service) Soil Classification (ABCD) and the County soil types and runoff response characteristics.

These analyses concluded that the soils in the project area were, for the most part, poorly drained and not conducive to effective infiltration practices.

Because depths to groundwater are critical design parameters for both infiltration potential and septic system performance, the US Division of Mines and Geology was consulted to estimate general groundwater depths. A review of this data indicated that groundwater depths were generally:

- Less than 5 feet in beach areas
- 5 to 10 feet deep in coastal floodplain areas, and coastal stream canyons
- Approximately 10 feet in the upper reaches, and
- Significantly deeper along ridge lines and mountain peaks.

Figure 2.2 Subwatershed Priorities

High Priority

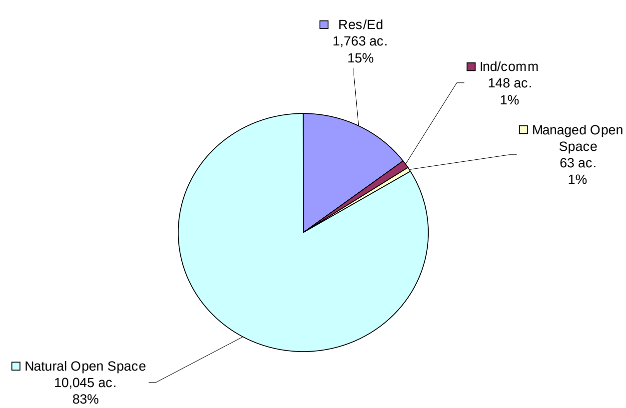

Figure 2.3.3 High Priority: Breakdown of Land Use
Latigo, Corral, Las Flores, Piedra Gorda, and Ramirez

Because most of the residences within J1/4 utilize onsite wastewater treatment systems (septic systems), seepage and impacts to groundwater are of importance, particularly since the level of risk of exposure is closely tied to the vertical separation between the infiltrating surface of the dispersal system and the water table.

Aquifer characteristics were characterized as being limited based on a review of DWR Bulletin 118 for the South Coast Hydrologic Region. The closest basins, Malibu, Thousand Oaks, and Russell Valley, are all outside the J1/4 area.

Therefore, given the local soils, geology, and groundwater conditions, and the need to avoid excessively raising groundwater levels in areas with onsite wastewater systems, the potential for regional groundwater injection and infiltration is limited, and localized infiltration practices are more feasible. It must also be recognized, however, that even local recharge can potentially increase the water table, thereby potentially impacting septic systems. As such, local recharge must be carefully evaluated for its potential to affect septic systems locally.

2.1.3 Surface Water Hydrology

A hydrologic analysis was conducted to support the potential incorporation of structural measures in the TMDL implementation[1]. The purpose of the analyses was to estimate, on a macro-scale, preliminary potential volumes of water (within each subwatershed) that would theoretically need to be captured and treated to meet TMDL requirements. This planning-level analysis successfully resolved the discontinuity between exceedance-day TMDL criteria and conventional design-storm analytical techniques using a methodology that examined daily rainfall volumes over the historical period of record. This methodology involved:

1) Ranking daily rainfall volumes per year. Precipitation analyses were conducted for four County of Los Angeles rain gages located at elevations ranging from 15 feet to 1620 feet, within and adjacent to the J1/4 areas.

2) Establishing the “critical” rainfall day each year—the 18th and 15th largest daily precipitation events each year.

3) Establishing a 90th percentile that corresponded to the TMDL criteria based on a review of the period of record. The volume corresponding to the top 10 percent of rainfall was selected as the critical storm volume. The average 90th percentile 18th largest storm volume was 0.68 inch; the 15th largest storm volume was 0.83 inch on average.

---

1) The TMDL stipulated a threshold number of exceedance days based on daily monitoring activities. In Jurisdiction 1 the number of exceedance days is seventeen; in Jurisdiction 4, the number of exceedance days is fifteen. It is recognized however, that while the TMDL (and many of the related analyses) are based on daily criteria, because the Coordinated Shoreline Monitoring Plan describes many locations where weekly monitoring will occur, the number of exceedances will be pro-rated accordingly.

It should be noted that out of necessity, the analysis needed to build upon the 17 exceedance-day criteria. For implementation purposes, the actual criteria will be adjusted to correspond to compliance monitoring frequencies.

Rainfall data sets were then converted to runoff volume estimates for each subwatershed using precipitation values, zoned land uses (and percentages of the subwatersheds that are impervious), soil types, and runoff coefficients developed by the County. To address the potential range of volumes, the analysis considered reduction factors established in adjacent watersheds for similar conditions in estimating ranges of target treatment volumes.

Table 2.1 shows the maximum target precipitation and runoff volume that would need to be managed (captured, treated, reused, diverted, etc.) for each subwatershed based on these rainfall depths.

Table 2.1 Target Precipitation and Storage Volumes

Subwatershed	Precipitation Volume (in.)	Runoff Coefficient	Maximum Target Volume (MG)[a]	Potential Reduced Volume (MG)[b]
Arroyo Sequit	0.68	0.24	34	13
Nicholas	0.83	0.28	8	3

Notes:
a. Based on target precipitation
b. Extrapolated from J2/3 analysis for reduced volume and 5 in 50 year exceedance, and should be considered preliminary and subject to change.

Studies on adjacent watersheds (TMDL Implementation Plans for Jurisdictional Groups 2 and 3) have involved further analyses based on a continuous simulation of 50-years of precipitation record in an attempt to provide further optimization of storage volumes. For a watershed in North Santa Monica Bay (Santa Ynez – runoff coefficient = 0.31), it was estimated that the target volumes could be reduced to 37% of the target volume, calculated in a similar method noted above, and still exceed TMDL requirements only 5 out of 50 years compared to 1 out of 50 years using the maximum target volume. Areas with lower runoff coefficients showed even greater percentage reductions (Susilo, 2004). In addition, the aforementioned analyses did not consider pollutant concentrations within storms or between a series of storms. Table 2.1 also lists target precipitation and storage volumes, and, assuming an effective percentage reduction similar to that calculated in an adjacent watershed, potential volumes that could be considered for implementation.

The proposed method is limited to the Implementation Plan and reductions will be confirmed and developed further with future studies. In Table 2.1, the "Potential Reduced Volume" column is an assumed volume based on adjustments and reductions developed at local watersheds. It is recognized that this volume is only a preliminary planning estimate, and will change upon the collection and analysis of both hydrologic streamflow and bacteria pollutograph data.

It must be noted that the hydrologic volumes are preliminary and presented for planning purposes. Furthermore, studies (for Jurisdictions 2 and 3) have shown that the target storage volumes in undeveloped subwatersheds may be overestimated by this approach; therefore, the values should be considered conservative. This will be addressed when pre-design parameters developed as part of future studies.

2.2 General Opportunities for Multiple Beneficial Uses

2.2.1 Water Supply and Reuse

This Implementation Plan utilizes an integrated water resources management approach that will identify beneficial use opportunities and treatment management options. The main purpose of this section is to summarize the current and future water supply beneficial uses, water use and reuse scenarios in the J1 and J4 study areas.

The approach used in evaluating beneficial use options involved identifying potential locations at both local and regional levels and estimating the amount of runoff that can be managed by the beneficial use options. The potential for beneficial use was assumed to be related to land uses since certain land uses offer more potential for reuse, such as landscape irrigation for golf courses and parks. Therefore, this analysis involved establishing a spatial distribution of potential areas and assessing the size and potential demand of these areas.

Potential efficiencies of various reuse options, local and regional, are discussed. Local reuse opportunities include on-site capture using cisterns. Regional reuse opportunities include groundwater recharge, reuse for recreation, regional capture and reuse for irrigation or other non-potable supply. In establishing reuse opportunities, a review of the practices of local water agencies was conducted. These agencies included: County of Los Angeles Water Works District 29, Las Virgenes Municipal Water District, West Basin Municipal Water District, and the City of Los Angeles. Estimates of potential demand indicated limited regional potential; the Trancas and Corral watersheds making up 75% of the approximately 1000 acre-feet of total potential demand. Within the Corral subwatershed, Pepperdine University already utilizes imported water from the Malibu Mesas Water Reclamation Plant which can provide 150 acre-feet of recycled water supply.

On this basis, the majority of reuse opportunities in J1/4 will likely be limited to localized on-site solutions. These solutions will be easier to implement.

2.2.2 Recreational Uses

Data sources for the evaluation of recreational water use opportunities included the Santa Monica Mountains Conservancy, the National Parks Service, and Southern California Association of Governments (SCAG). Figure 2.4 shows recreational areas and illustrates the placement of park areas relative to developed land (near the coast).

In addition, slopes and soil types were reviewed for potential applicability for regional and sub-regional water quality facilities. These evaluations indicated that many of the slopes and soil types were not readily suitable for larger scale (particularly land intensive) water quality best management practices.

2.2.3 BMP Location Evaluation

This effort was intended to evaluate potential sites for facilities that would be required to implement the TMDL implementation plan for various runoff management options. Both local (including sub-regional) and regional siting options were considered.

Local sites would allow for the storage and reuse of stormwater, reducing flow volumes and potentially improving water quality. Potential local sites include residential zoned facilities, parks and recreation centers (though state and federal facilities might require additional inter-jurisdiction coordination), government facilities (parking lots, service yards, etc.), schools (again requiring inter-jurisdictional coordination), and parking and urban vacant lots.

Regional treatment sites would require pre-treatment and storage, and possibly transmission pipelines, reuse locations, onsite storage and reuse. Operational storage was assumed to be equivalent to target runoff volumes described in Section 2.1.3. Regional methods of source control and regional treatment facilities could be required in order to maximize potential beneficial uses and reduce wet weather discharges to the beaches.

Criteria for regional sites included proximity to storage facilities, street access, public ownership (preferred), sufficient distance from development, flat terrain, avoidance of environmentally sensitive areas, and sites with public support. A detailed list of facilities is provided on a watershed-by-watershed basis in Section 5.

2.3 Description of Potential Non-Structural activities

This section describes existing non-structural (or institutional and programmatic) activities and recommends bacteria-specific programs to be considered for implementation. These activities build upon the NPDES Municipal Separate Storm Sewer System Permit for the County of Los Angeles, and are divided into five programs: 1) Public Information and Participation, 2) Industrial/Commercial (assumed to include illicit discharge and illicit connections), 3) Development Planning, 4) Development Construction, and 5) Public Agency Activities.

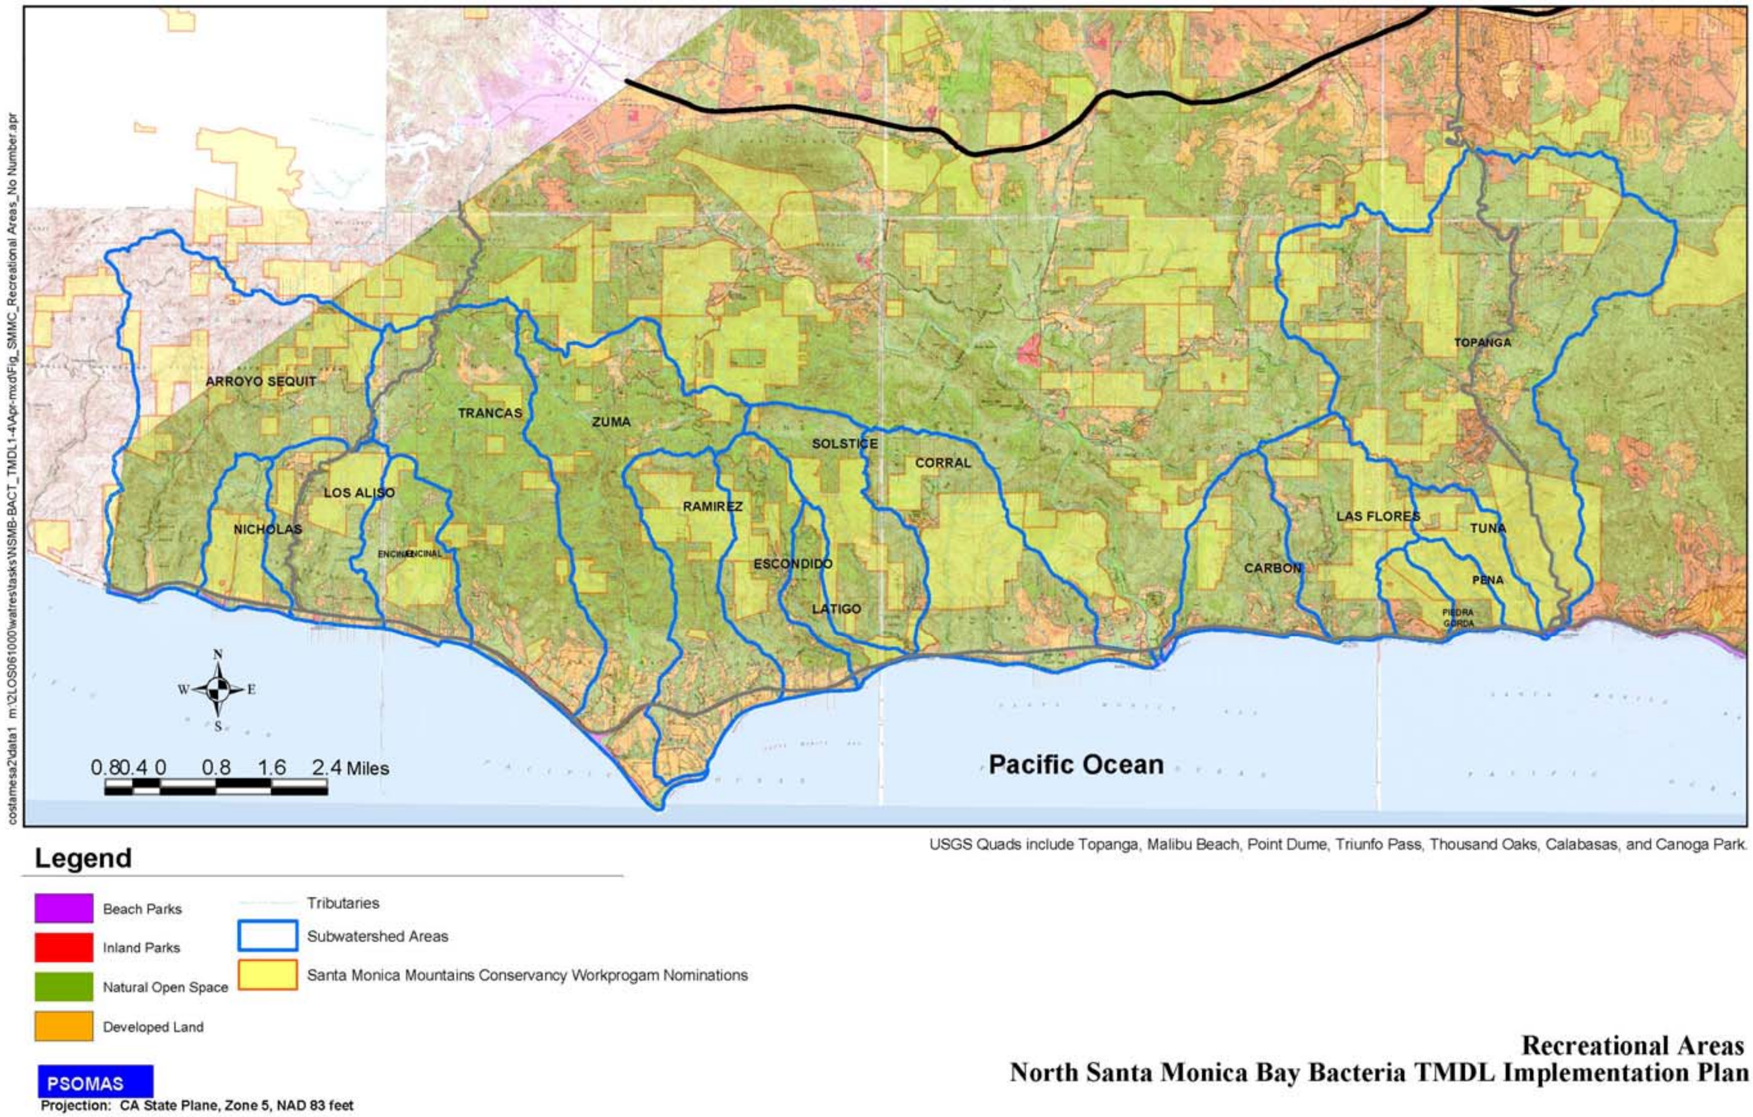

Figure 2.4 Recreational Areas

RB-AR 7647

9-1533

2.3.1 Public Information and Participation

The purpose of this public information and participation program is to implement nonstructural (source control/institutional) solutions as a critical and cost-effective element of an iterative and adaptive Bacteria TMDL program. This section reviews existing public information and participation programs as well as industrial/commercial facilities control programs and makes recommendations to incorporate bacteria TMDLs into these programs.

A number of Public Information/Public Participation programs were reviewed. Reviews consisted of phone interviews, online reviews, and document reviews. Multiple agencies operating within the jurisdictions were contacted along with environmental organizations and groups operating in the area. The programs described here are not an exhaustive list of all programs, but are rather an overall view of the most applicable and available programs. Not all environmental groups active in the area were contacted nor were all programs of agencies reviewed. Many agencies and environmental organizations co-sponsor programs. Thus, many of the materials are unified and redundant across agencies. Overall, current programs do not directly address bacteria, but rather seek to promote pollution prevention in general. Many current programs could be modified to discuss bacteria and other TMDLs and establish a link between certain activities and bacterial loading of stream and creeks.

Existing Programs included:

City of Malibu Clean Water Program

The Clean Water Program provides a brief introduction of the stormdrain system and BMPs that address water pollution prevention and targets three groups: residents, business team members, and contractors and developers. The Clean Water Team is represented by a dolphin mascot, Bu, that appeals to children and acts as a seal of approval for businesses participating in the Clean Water Program. As part of the program, local businesses and developers and contractors that implement the suggestions in the Clean Water Program receive a sign and a seal of approval sticker for display.

Numerous other handouts produced by the County of Los Angeles, Environmental Protection Agency, the Santa Monica Bay Restoration Project, and the Clean Water Program are also available at the Malibu Public Works counter. Items that are related to bacterial loading include picking up after pets, properly maintaining septic systems, and retaining storm water on site. A few of the brochures explain the link between bacterial loading and animal waste and improperly operating septic systems. The "Living Lightly" booklet – an informational handbook focused on watershed stewardship - is also available at the counter.

There is no municipal sewer system in the Malibu area. Therefore, most residents and business owners are entirely dependent on septic systems. For 2005, Malibu plans to release a septic system and leach field booklet and develop additional stormwater public information materials. The septic system and leach field booklet will be made available at the city, through the mail, and at real estate brokerages. These booklets are being developed to coincide with a septic system inspection program currently under development in a joint project with the Regional Board. For residential septic systems, the City recently launched a point-of-sale inspection program to identify and inventory septic systems in the area.

County of Los Angeles Stormwater Education Program

The County of Los Angeles Department of Public Works, implements a Stormwater Education Program (SEP) as part of its compliance with its NPDES Permit. The SEP uses a variety of mediums to educate the public and businesses about what people can do to prevent pollution from entering water bodies. A large portion of the area within J1/4 lies within the unincorporated area of the County of Los Angeles. SEP also provides assistance to incorporated cities to promote cohesive pollution prevention efforts throughout the region.

County brochures are directed at general stormwater pollutants except for the Dog Owner Tips which specifically focuses on cleaning up after your pets to reduce bacteria in stormwater. SEP provides online information targeted towards RV owners. This information is designed to educate RV owners regarding proper disposal practices for wastes. List of disposal sites are provided with contact information.

Caltrans' District 7 Programs

Caltrans is responsible for stormwater pollution controls along the State Highways in J1/4, including Pacific Coast Highway (LA-1), Decker Road (LA- 23), and Topanga Canyon Road (LA-27). As part of its storm water management activities, Caltrans uses a variety of methods to educate the public about the importance of managing storm water. The general approach of the Public Education Program is to:

- Inform the public regarding the storm water quality issues that pertain to Caltrans properties, facilities and activities; and

- Encourage public behavior changes regarding the release of potential pollutants (e.g., litter, spilled loads and oil leaks).

Caltrans' storm water outreach program consists of a variety of written materials, monthly and quarterly bulletins, a website, workshops, storm drain stenciling, anti-litter signs, a statewide Adopt-a-Highway Program, along with many local municipality partnerships. "Pathogens in Storm Drain Discharges Brochure" is an example of written materials that is most directly related to bacteria.

In District 7, "No Dumping" and "Litter Fee" signs were installed at selected locations on highways and freeways. Warnings were stenciled at the drain inlets to prohibit discharges into drainage systems in the park-and-ride lots, rest areas, vista points, and other areas with pedestrian traffic."

Other Public Information Programs

Many stakeholder groups have developed their own public information materials. Some of these groups include:

- Malibu Coastal Land Conservancy
- Septic Tank Service Providers' Programs
- Santa Monica Bay Restoration Commission
- Santa Monica Mountains Conservancy
- Santa Monica Mountain Trails Council
- Equestrian Trails, Inc.
- Resource Conservation District of the Santa Monica Mountains
- Pepperdine University

Bacteria-Specific Programs

Many programs are not currently addressing bacteria or informing the public about TMDLs. Most existing programs consist of general efforts to educate individuals, businesses, and industry about pollution prevention, impacts of pollution and good housekeeping. Bacteria-specific information can be incorporated into new and existing programs through the following programs:

- Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact

- Locate areas with corralled animals and educate property owners on bacteria TMDLs

- Identify horse stables in the region and implement pilot program

- Post signs at County and City-owned trailheads designated for equestrian users to not clean out horse trailers in parking lots and to clean up horse waste

- Outreach at trailheads encouraging hikers to use restroom facilities

- Provide septic system pumpers and customers with septic system guides

- Coordinate outreach activities with Pepperdine University

- Increase coordination between agencies and environmental organizations in preparing outreach materials

2.3.2 Industrial/Commercial

Agencies within the J1/J4 implement an industrial/commercial facilities control program. The goal of this program is to change behaviors through a combination of outreach and site visits. Most existing programs do not specifically target bacteria, but are designed to minimize general pollutants of concern that will tend to assist in reducing bacterial loading. A partial list of elements from existing programs follows:

City of Malibu

Malibu has implemented multiple programs to comply with the NPDES permit requirements for commercial/industrial facilities and to address local concerns. Some outreach programs target both residential and commercial/industrial facilities.

Inspections required under the permits for industrial and commercial facilities are conducted by the City's inspectors and restaurant inspections are contracted to the County of Los Angeles Department of Health Services (DHS) inspectors. Industrial and commercial facilities are given educational materials specific to the type of business during an inspection. These inspections are not specifically designed to target bacteria, but rather general pollutant BMPs. Additionally, all retail gasoline and automotive dealerships are required to meet the BMP requirements as specified by the Stormwater Quality Task Force Best Management Practice Guide for Retail Gasoline and Automotive Dealerships. To ensure that these commercial establishments are in compliance, the City has implemented a rigorous commercial business inspection program.

Enforcement actions include, but are not limited to, warnings, notices of violations, administrative civil liability actions, and monetary fines. Enforcement actions occur when continued violations are discovered. All inspection data is tracked in an inventory database of all commercial/industrial facilities. The City has indicated in its individual annual report to the Regional Board that commercial/industrial facilities generally do not follow up with training of their employees in BMPs without constant inquiries from inspectors and that most facilities do not keep up with all BMPs.

Representatives with the City of Malibu are concerned with bacteria loading from restaurant operations. Restaurant waste, in both solid form (packaging, paper products, cans, food products, etc..) and liquid form (i.e., cooking oil, grease, animal fats, food products, etc.), can collect in areas that come in contact with stormwater runoff and provide an ideal habitat for specific forms of bacteria that may enter stormwater drains. Prior to food service inspections, food service providers are mailed a BMP fact sheet for reducing pollution.

County of Los Angeles Department of Public Works

The Department of Public Works is responsible for ensuring compliance control programs for commercial and industrial businesses within unincorporated areas. The County of Los Angeles maintains an inventory of its commercial/industrial facilities along with inspection data. These inspections target pollutants of general concern and not specifically bacteria. Inspections are designed to be educational and informative for commercial/industrial facilities in conjunctions with confirming BMPs are properly implemented as required by law. BMPs can take the form of schedules of activities, prohibitions of actions, maintenance procedures, treatment requirements, and structural controls. When additional BMPs are needed, the inspector recommends non-structural BMPs. BMP handouts created for specific industries within Los Angeles the County include:

- General commercial/industrial facilities
- Equestrian and stable facilities
- Food and related products facilities
- Potential New Programs

As a means to reduce bacterial loading associated and/or linked to commercial/industrial facilities, modifications to existing programs and new programs are recommended. Effectiveness of these new programs can be measured via numerous methodologies including compliance, participation levels, and ultimately sampling. Existing commercial/industrial facility control programs are not directly addressing bacteria, other TMDLs, or informing commercial and industrial businesses about bacteria TMDLs. With regards to commercial horse stables and equestrian facilities, an anecdotal link has been established associating animal wastes with bacteria loading. Some of the bacteria-specific recommendations include:

- Provide an outreach program for all commercial facilities with corralled animals, including equestrian centers

- Provide for regular BMP inspections for restaurants

- Increase awareness of BMPs in restaurants by establishing a restaurant reward and recognition program

- Conduct industry specific workshops

- Investigate the possibility of increasing frequency of trash collection at restaurants

2.3.3 Development Planning

Two land use plans affect development in the subwatershed areas. One plan is the City of Malibu's Local Coastal Program (LCP), certified by the California Coastal Commission in September 2002. The second plan is the County of Los Angeles' Malibu Land Use Plan, which guides development in the unincorporated portions of the Santa Monica Mountains Coastal Zone and was certified by the California Coastal Commission in 1986. The subwatershed areas lie almost completely within the state-designated Coastal Zone. Any development within the Coastal Zone must be conducted in a manner that protects coastal resources.

As of this writing, the City's LCP is the subject of litigation and has not yet been implemented. If fully implemented as certified, the City's LCP will regulate both land uses and development standards within the City of Malibu. The County's Malibu Land Use Plan, a component of the County of Los Angeles General Plan, guides land uses but does not contain comprehensive development standards. Under the Land Use Plan, most development in the unincorporated Coastal Zone must undergo an additional level of environmental review prior to approval. The County is currently working on updating the Land Use Plan, which is primarily a policy document, and adding a local implementation program. The local implementation program will contain the standards that ensure coastal resources are protected from development. Together, the new Land Use Plan and the local implementation program—once certified by the California Coastal Commission—will constitute the County's LCP for the unincorporated portions of the Santa Monica Mountains Coastal Zone.

The City's LCP and the County's Malibu Land Use Plan are intended to be basic planning tools used by the local government, in partnership with the California Coastal Commission, to guide development in the coastal zone and contain the ground rules for future development and protection of coastal resources. The LCP and Land Use Plan specify appropriate location, type, and scale of new or changed uses of land and water. These programs govern decisions that determine the short- and long-term conservation and use of coastal resources. Chapter 17 of the City LCP's Local Implementation Plan details the Water Quality Protection Ordinance. This includes requiring development to evaluate potential adverse impacts to water quality and consider site design, source control and treatment control BMPs. This section also discusses designing to prevent the introduction of pollutants that may result in water quality impacts.

Many non-structural solutions that can be incorporated into an Implementation Plan for an effective bacteria control program can be implemented within the overall framework of the existing NPDES permit. The County of Los Angeles and the City of Malibu must implement a Development Planning Program, which identifies various controls to minimize water quality impacts of stormwater runoff generated from all Planning Priority Development and Redevelopment projects. Through the use of project planning and permit approval process and CEQA, Permittees are required to assure that appropriate post-construction BMPs are included in Priority Planning Development and Redevelopment Project plans and designs to:

- Minimize impacts from stormwater and urban runoff on the biological integrity of Natural Drainage Systems and water bodies

- Maximize the percentage of pervious surfaces to allow percolation of stormwater into the ground;

- Minimize the quantity of stormwater directed to impervious surfaces and the MS4;

- Properly designed and maintain Treatment Control BMPs in a manner that does not promote the breeding of vectors; and

- Provide appropriate permanent measures to reduce stormwater pollutant loads in stormwater from the development sites.

In addition to controlling peak flows, each Permittee is required to develop and implement a Standard Urban Storm Water Mitigation Plan (SUSMP). In terms of treating stormwater runoff from the development site, the SUSMP includes Numerical Design Criteria for Treatment Control BMPs. The two most common methods are a volumetric treatment control or a flow based treatment control. Bacteria-specific measures include further emphasizing applicable existing BMPs in development planning and construction programs

California Environmental Quality Act

The California Environmental Quality Act (CEQA), Public Resources Code, Section 21000 et seq., requires environmental assessments of projects in California. As a part of CEQA, a proposed project is evaluated to determine whether the project may have an adverse impact upon the environment. If an initial study indicates that significant adverse environmental impact may occur as a result of a proposed project then the environmental impact(s) must be mitigated. Either a Mitigated Negative Declaration, or for more substantial projects, an Environmental Impact Report comparing various project alternatives and identifying the impacts and mitigation measures must be prepared and adopted.

The Storm Water Quality Management Plan (SQMP) requires the assessment of a development project's impacts upon hydrology and water quality. Current guidance is contained within the Development Planning Model Program for the preparation and review of local CEQA documents. The guidance relies on a general approach to assessment. Revisions to these guidelines may be necessary to ensure that CEQA documents adequately address bacteria and other impairments for which TMDLs have been prepared when evaluating a project's water quality impacts.

The CEQA process can assist in the evaluation of appropriate BMPs to reduce pollutants. Addressing wet weather TMDLs during the CEQA process will require modification of existing hydrology and water quality evaluation criteria. Seven criteria designed to supplement the existing standard Initial Study checklist incorporated into the CEQA Guidelines along with any changes agencies may have made to incorporate stormwater quality issues into the CEQA review process are listed below

1. Potential impact of project construction on stormwater runoff

2. Potential impact of project post-construction activity on stormwater runoff

3. Potential for discharge of stormwater runoff

4. Potential for discharge of stormwater pollutants from material storage, vehicle or equipment fueling, vehicle or equipment maintenance (including washing), waste handling, hazardous materials handling or storage, delivery areas, loading docks or other outdoor work areas

5. Potential for discharge of stormwater to impair the beneficial uses of the receiving waters or areas that provide water quality benefit

6. Potential for the discharge of stormwater to cause significant harm on the biological integrity of waterways and water bodies

7. Potential for significant increases in erosion of the project site or surrounding areas.

When considering TMDL requirements in the CEQA process, the lead agency and project proponent should determine the potential for the project to increase bacterial loading based on the change in proposed land use and impervious surface, and evaluate the project characteristics that would minimize the impact of increased loading. These should be identified in the project SUSMP for permanent, post-construction BMPs. For larger projects (for example those in categories that require preparation of a SUSMP), a quantitative analysis may be required. The analysis would need to demonstrate that post-project bacteria loads, with application of BMPs, would be equal to or less than pre-project conditions. Alternatively, the analysis could demonstrate that through project BMP design, the project could manage a proportionately equivalent volume on-site to the target volume established in the TMDL for the watershed.

Any unique construction phase BMPs should be identified in the CEQA documentation and subsequently incorporated in the project Stormwater Pollution Prevention Plan (SWPPP) which would be prepared prior to construction. CEQA mitigation monitoring plans can identify these available mechanisms as the primary enforcement methods.

The criteria can be further refined to evaluate the project's ability to meet TMDL implementation requirements as an overall component of stormwater quality. The following plan of action is recommended for incorporating the review of TMDLs into the CEQA process:

1. Identify the TMDL required issues not currently addressed by CEQA
2. Address required TMDL issues within standard conditions of approval.
3. Modify CEQA review process.

2.3.4 Development Construction

As part of the existing NPDES Permit, requirements exist for construction activities that disturb equal to or greater than one acre of land or whose projects disturb less than 1 acre but are part of a larger common plan of development that in total disturbs one or more acres. As adopted by the State Board, the General Permit for Discharges of Storm Water Associated with Construction Activity (Construction General Permit, 99-08-DWQ), referred to as the General Permit, includes clearing, grading and disturbances to the ground such as stockpiling, or excavation, but does not include regular maintenance activities performed to restore the original line, grade, or capacity of the facility. The General Permit has the following provisions:

- Develop and implement a SWPPP which specifies BMPs that will prevent all construction pollutants from contacting stormwater and with the intent of keeping all products of erosion from moving off site into receiving waters.

- Eliminate or reduce non-stormwater discharges to storm sewer systems and other waters of the nation.

- Perform inspections of all BMPs.

Though many of the construction related BMPs are not specifically targeted at reducing or eliminating bacteria from runoff, implementation of the construction BMPs can effectively reduce bacteria in the receiving waters and storm drain systems. In general, there are two areas of focus for construction site BMPs that will assist in bacteria reduction: 1) enhanced sediment control, as sediment can contain bacteria, and 2) control/elimination of non-stormwater discharges from construction sites, as this becomes dry weather runoff which contributes to bacteria transport off-site. Therefore, by managing these two areas on construction sites, bacteria levels can be reduced in some cases. These categories already exist under SWPPPs, but additional emphasis could be given in contractor education and compliance inspection activities.

Examples of existing required BMPs that can be further emphasized include:

- Proper handling of temporary toilets (sanitary/septic waste management), and containment and cleanup of spills surrounding temporary toilets (sanitary/septic waste management)

- Proper management of lunch truck and food disposal (solid waste management), and

- Reduction of runoff from exiting site will result in less runoff to pick up bacteria from off site en route to the ocean (e.g. water conservation practices, illicit connection/discharge, potable water/irrigation, vehicle and equipment cleaning, liquid waste management)

2.3.5 Public Agency Activities

This task describes both current and recommended public agency activities for the three primary agencies: City of Malibu, County of Los Angeles, and Caltrans.

City of Malibu

In February 2002, the City of Malibu, along with the County, began implementing programs under a new NPDES permit cycle. City funds have also been allocated to record activity at all priority drains over the next few years. Drains that are suspected of contributing to degraded water quality will be a priority for video monitoring. Suspicious discharges will be sampled and tested, and the City will take enforcement actions if necessary.

Information on drainage system operation and maintenance (cleaning) activities was obtained from Melanie Irwin, former Public Education Coordinator for the City of Malibu.

Street sweeping reduces the amount of trash and debris in stormwater, which can potentially reduce bacteria levels. As part of the City's roadway operation and maintenance activities, all streets in the Malibu area are swept on a regular basis.

Raw sewage spills, leaks, and overflows from septic systems are a potential threat to both human health and the quality of receiving waters if the bacteria pollutants enter the storm drain system. Therefore, the City gives high priority to septic system complaints and reports of septic system failures, including overflows. To respond to septic overflows, the City has developed a spill response program that is implemented any time there is a septic spill.

The City does not maintain any corporate yards to support its maintenance activities, but City employees inspect the offsite yard to ensure that the pollution prevention plan is in place and that yard workers have a clear understanding of applicable BMPs including illicit discharge controls, good housekeeping practices, material storage controls, and vehicle leaks and spill controls.

County of Los Angeles

The County of Los Angeles has developed a Public Agency Activities Model Program for agencies to use in developing their own programs. The model provides specific guidance in the following areas:

- Sewage Systems Operations
- Public Construction Activities Management
- Vehicle Maintenance/Material Storage Facilities Management
- Landscape and Recreational Facilities Management
- Storm Drain Operation and Management
- Streets and Roads Maintenance
- Parking Facilities Management
- Public Industrial Activities Management
- Emergency Procedures
- Treatment Feasibility Study

Recent results of the Program, published in the 2004 annual program report, include a variety of measures to comply with the MS4 permit, including storm system maintenance and catch basin cleaning (trash and litter are potential carriers of bacteria).

The County also visually monitors open channel storm drains and other drainage structures for debris at least annually. Those sites experiencing frequent illicit discharges have been identified and prioritized for regular inspection by the County. The County has also designated stormwater coordinators to work with residents to prevent illegal dumping into storm drains, coordinate stormwater stenciling and facilitate work on clogged drains. Residents can call an environmental hotline (1-888-CLEANLA) to report illegal dumping into the County's storm drain system.

The County maintains a number of vehicle maintenance facilities, material storage facilities, and corporation yards which each have pollution prevention plans.

Caltrans District 7

Caltrans operates under a statewide NPDES permit which governs management of its storm water activities. As part of its storm water activities, Caltrans has developed an approved Storm Water Management Plan (SWMP) which addresses storm water pollution control related to planning, design, construction, maintenance and operation of all transportation facilities as an ongoing part of Caltrans normal business practices. An important component of the SWMP is the Project Planning and Design Guide (PPDG) which provides specific design guidance for incorporating BMPs into projects during the planning and design phases of a project. These include Treatment BMPs, Design Pollution Prevention BMPs, and critical Construction Site BMPs. Other components of the SWMP include research and development of BMPs, monitoring of storm water activity through regional work plans and annual reporting, and continual funding of storm water research and public education.

New Public Agency Activities

Through a combination of revising existing public agency activities and implementing new public agency activities, the agencies in Jurisdictions 1 and 4 can further focus activities to optimize reduction in bacteria and other TMDL constituents. Most existing agency activities do not specifically target bacteria TMDLs. Therefore, the following activity was offered for consideration.

- Establish guidelines for optimizing frequency of cleaning cycles for drainage facilities

2.4 Description of Structural BMPs

Structural Best Management Practices can be potentially implemented on a local, sub-regional, or regional scale. The watershed specific elements of the Implementation Plan will include specific recommended combinations of structural and non-structural measures to be implemented as appropriate within each jurisdiction or combination of jurisdictions that can quantitatively be predicted to have some success of achieving the reduction in exceedance days required by the TMDL. The purpose of this analysis is to identify these structural measures. This effort identified potential treatment requirements, technologies, and management options for specific areas of the watersheds that are to be treated for either discharge or reuse/recharge.

2.4.1 On-Site (structural source control) Options

These options include cisterns, on-site storage/reuse, onsite capture and infiltration, and septic-related BMPs; the stormwater BMPs are intended to reduce the total volume and flow rate of runoff leaving properties and entering the storm drain system, including any bacteria that might be picked up in the runoff on-site. Some limited pre-treatment might be required for a larger system to minimize operational problems. It should be recognized that on-site options, like non-structural options, may not fully mitigate the impacts of pollutant loading, but their implementation could contribute to integrated water quality solutions, and could contribute to the reduction of the magnitude and extent of downstream (regional) options.

Residential Cisterns

Cisterns are low-cost water conservation devices that could be used to reduce runoff volume and, for smaller storm events, delay and reduce the peak runoff flow rates. They store and divert runoff from impervious roof areas on residential properties. This stored runoff could provide a source of chemically untreated 'soft water' for gardens and compost, free of most sediment and dissolved salts.

On-Site Storage and Reuse Projects

This option involves capturing runoff from areas other than, or in addition to, rooftops and storing it for subsequent reuse on-site. These other areas include driveways, parking lots, and paved sports areas. This option could also include some treatment (such as chlorination) and would require careful management, and consideration of water distribution systems.

The potential sites for this type of system would be public parks, government facilities, or schools at which the runoff could be reused for irrigation without meeting full Title 22 treatment Standards (requiring filtration and disinfection). They would be installed underground since they would need to be big enough to storage large volumes of runoff. The landscape maintenance could involve a controlled subsurface distribution system (i.e., no sprinkler system) so that direct public contact is essentially eliminated. The opportunities for these types of projects would have to be identified and developed on a case-by-case basis.

Small Scale Infiltration Projects

Many on-site options have been identified that capture storm water and allow it to infiltrate into the ground at rates that would provide water quality treatment and reduce the downstream flow. The options include porous pavement, retention grading, infiltration pit, bioretention, and infiltration culverts are discussed. As with any infiltration option, the pre-design considerations include the following:

- Soil types and groundwater depths
- Presence of contaminated groundwater/subsurface soils, and the potential impacts of introducing pollutants into the subsurface system.
- Proximity to potentially impacted structures
- Maintenance to prevent long-term clogging

Porous Pavements

These on-site options include various pavement and paver options, including

- Porous Concrete:

- Grass Pavers:
- Gravel Pavers:
- Interlocking Paving Blocks:
- Pervious Crushed Stone:

Retention Grading

Residential landscape area retention grading is a concept whereby a site is graded to create a "sunken garden" that holds runoff and rainwater until it can be absorbed into the ground. This type of grading works best in highly permeable soils.

Infiltration Pits and Culverts

Infiltration pits are a common means of storm water management in many areas of the United States. They involve adding a grate with a rock pit below at the lowest end of paved areas such as driveways and parking lots.

Bioretention Areas

Bioretention areas are local landscape depressions that function as retention basins.

Analysis of Capture and Infiltration

Infiltrating runoff requires that the soils be permeable enough to allow percolation into the groundwater basin. Preliminary studies indicate that it is unlikely that there is opportunity for groundwater recharge through on-site infiltration projects on a large scale. There is the potential, however, for some runoff to infiltrate into the top layers of soil, where it will reduce the overall runoff volume leaving the site, recognizing potential risks due to slope stability. In addition to the need for permeable soils, an infiltration system requires that the soil be uncontaminated to avoid degradation of the underlying aquifer. One additional concern about the use of infiltration pits is that unmaintained or unmonitored installations could be a risk to groundwater quality (e.g. from illegal dumping). As with all the options maintenance of these installations is important to provide consistent treatment.

On-Site Wastewater Alternatives

While on-site wastewater alternatives are not typically a stormwater treatment option, given the potential for septic-related pollutant loads, and embracing an integrated, holistic approach to water resources management, potential alternative on-site wastewater options discussed here may be considered.

Reference is made here to a trademarked on-site wastewater treatment system called Living Machines™: integrated, multi-benefit, natural systems approaches to treating wastewater.

The Living Machines™ are site-specific biological solutions that re-route waste streams into resources. The technology is reportedly simple to operate, and more cost effective to build and run than conventional treatment.

2.4.2 Regional and Sub-Regional Structural Options

The following are potential regional (and sub-regional) options:

- Capture, store, treat and discharge
- Capture, store and beneficially reuse for irrigation or similar non-potable uses
- Capture, store, treat and inject

It should be recognized that the structural storm water BMPs presented here focus on bacteria-specific structural BMPs, and that in most cases, pre-treatment BMPs are required. These BMPs could include some combination of biofilters, extended detention basins, filters, and/or proprietary BMPs. These pre-treatment BMPs are not discussed in detail in this but the cumulative effect of pre-treatment as part of a treatment train is summarized in the table at the end of this section.

This section discusses traditional as well as candidate treatment technologies that could potentially be utilized for treatment of bacteria, where discharges are released. Traditional treatment methods would probably be most applicable with high wet weather runoff flowrates. The candidate treatments technologies have not been proved for this application but could possibly provide treatment on small-scale in localized drainage areas. The treatment technologies examined consist of the following:

- Traditional treatment
- Storm water Filtration Units
- Advanced Oxidation
- Peracetic Acid (PAA) and Other Bactericides
- Subsurface Constructed Wetlands

It should be noted that many of the information related to new and proprietary technologies were provided by vendors and manufacturers, and implementation should be carefully monitored and considered in the context of adaptive management practices.

Table 2.2 summarizes the BMP approaches described above. It should be noted that different BMPs have different pre-treatment options (which can provide removal of multiple pollutants) and different integrated uses. In general, pre-treatment will consist of a) gross-solids removal (e.g., utilizing screens or nets), and b) detention, which allows for deposition of sediments and particulate pollutants while providing transient storage for bacteria treatment.

Table 2.2 Structural BMP summary

Structural BMPs	Treatment Effectiveness							Integrated Resources		
	Bacteria	Nutrients	Metals	Organics	Trash	Sediment	Oil & Grease	Reuse	Conservation	Recharge
On-Site Options										
a) Cisterns	U	U	U	U	U	U	U	X	X	
b) Storage and Reuse	3	3	3	3	3	3	3	X	X	
c) Small Scale Infiltration	3	3	3	3	3	3	3	X	X	X
d) On-site Wastewater	3	U	U	U	U	U	U			
Regional Solutions										
Capture, Store, Treat, and Discharge	3	3*	3*	3*	3*	3*	3*			
Capture, Store, Treat, and Reuse	3	3*	3*	3*	3*	3*	3*	X	X	
Treatment options (subgroup)										
- Traditional Treatment/Small Package	3	U	U	U	1	1	1	N/A	N/A	N/A
- Storm Water Filtration	U/2 exp	2	3	3	3	3	3	N/A	N/A	N/A
- Advanced Oxidation	U/3 exp	U	U	U	1	1	1	N/A	N/A	N/A
- Peracetic Acid/bactericides	U/3exp	U	U	U	1	1	1	N/A	N/A	N/A
- SSF Wetlands	3	3	3	U	1	1	1	N/A	N/A	N/A

Notes: * required pretreatment is included in overall treatment train and will remove many of the other constituent pollutants
1 = low effectiveness, 2 = medium effectiveness, 3 = high effectiveness, U = unknown, exp = expected performance

Table 2.2 highlights the potential benefits of different structural options. These benefits include treatment effectiveness, and integrated water resources – both of which are critical to the integrated approach of this Implementation Plan.

2.5 Regulatory and Permitting Considerations

This section identifies specific local regulations including planning, public works and zoning codes, as well as state and federal regulations which cover the planning, siting and development of regional facilities which are under consideration.

In general, the regulatory issues associated with the options in Table 2.2 for the management of the urban wet weather runoff and attainment of the TMDL are related to:

- Permitting the construction and operation of regional facilities;
- Permitting effluent, whether for beneficial reuse or for discharge; and
- Permitting the construction of on-site treatment systems.

2.5.1 Local Considerations

Local permitting and regulatory considerations are summarized below, and require consultation should structural projects be considered for implementation.

County and City Code Citations

2.5.2 State and Federal Considerations

State and Federal considerations are tabulated and described below.

State/Federal Environmental Regulations that Govern Implementation Options for SMB Bacteria TMDL

	NPDES Permit	Coastal Zone	Dept. of Health Services	Fish and Game	Corps of Engineers	Fish and Wildlife	NFMS
On Site BMPs							
Cisterns	Already approved in Phase I MS4 permit	Already approved in LCP	N/A	N/A	N/A	N/A	N/A

	NPDES Permit	Coastal Zone	Dept. of Health Services	Fish and Game	Corps of Engineers	Fish and Wildlife	NFMS
Porous Pavement	Already approved in Phase I MS4 permit	Already approved in LCP	N/A	N/A	N/A	N/A	N/A
Infiltration Trenches	Already approved in Phase I MS4 permit	Already approved in LCP, but permit needed if landslide hazard	If considered groundwater replenishment	N/A	N/A	N/A	N/A
OSWT	N/A	Must meet LCP standards	N/A	N/A	N/A	N/A	N/A
Regional Solutions							
Treatment and Discharge Facility	Already approved in Phase I MS4—use of chemicals may require new permit; if new Ocean discharge, may need permit and antideg analysis	If in Coastal Zone – a Public Works Plan and Coastal Development Permit	N/A	Depends on location and discharge; if a new discharge would need approval	Depends on location of treatment and discharge	Depends on location of treatment / discharge; if new discharge would need approval	Depends on location of treatment/discharge; if new Ocean discharge would need approval
Treatment and Direct Reuse	New permit	If in Coastal Zone – a Public Works Plan and CDP	Permit Required and may meet Title 22	Depends on location	Depends on location	Depends on location	Depends on location

2.5.3 Permit Requirements for Direct Discharge to Waters

Treatment and Discharge Solutions

Capturing, treating and discharging stormwater flow could be considered consistent with the stormwater permit. This level of treatment could be considered a BMP and thus the existing permit would be sufficient.

Permitting for Discharge of Stormwater into Deeper Ocean Waters

The California Ocean Plan regulates discharges into the Pacific Ocean within three miles of territorial waters. Beyond three miles, the national Clean Water Act applies, mandating that the EPA to issue the permit. In most cases, the EPA has asked the state to jointly issue permits for US waters outside the three-mile zone.

The Ocean Plan has four specific requirements for point source discharges: 1) the same bacteria standards apply as those along the shore in waters less than 30 feet deep and bounded by a distance of 1,000 feet from the shoreline; 2) the discharge will not violate the physical characteristics of the ocean, such as discoloration, floatables and reduction of light; 3) the chemical characteristics of the ocean will not be violated; 4) the discharge must comply with water quality objectives of the Ocean Plan. When determining compliance, actual initial dilution and background concentration are considered. There are other aspects of the Ocean Plan that state that a discharge may not harm the biological characteristics of the Ocean. Table A of the Ocean Plan applies to effluent discharges only.

The Ocean Plan contains specific implementation requirements for permitting discharges. Stormwater can be discharged into the Ocean if, with dilution, it can meet the water quality standards as contained in Ocean Plan Table B and the implementation requirements contained in other parts of the Plan. In addition, if the stormwater discharge were located a distance from the shoreline, an anti-degration analysis may be necessary, as this would be considered a "new discharge." Because this would be an intermittent and occasional discharge that occurs only in wet weather, it may be possible to negotiate with the Regional Board to allow the existing stormwater permit to be applicable for ocean discharge.

The Ocean Plan also designates Areas of Special Biological Significance (ASBS). ASBS are "areas designated by the State Board as requiring protection of species or biological communities to the extent that alteration of natural water quality is undesirable." A portion of the J1/4 area north of Pt. Dume is located within the ASBS No.24 – Mugu Lagoon to Latigo Point (see Figure 2.5). It should be noted that the SWRCB is currently considering amendments to the Ocean Plan. The Ocean Plan prohibits discharges to ASBS and specifies that discharges shall be located a sufficient distance from ASBS-designated areas. However, the State Board does have the authority to grant exceptions to the prohibition on ASBS discharges, provided that the exception will not compromise protection of ocean waters for beneficial uses. The State Board has authorized four discharges under this exception authority. It is assumed that effective implementation of the Bacterial TMDL Implementation Plan will provide a basis for the State Board to allow for stormwater discharges to the Ocean.

One of the amendments that is moving forward on the Ocean Plan concerns bacterial standards. The State Board plans to a) add an enterococcus standard to the Ocean Plan; b) delete the single sample standards currently in the Ocean Plan and change to a trigger for additional monitoring; c) require monitoring for total coliform at offshore stations; d) require total and fecal coliform and enterococcus monitoring at all shoreline stations, and at all stations determined by the Regional Boards to be used for water-contact recreation; and e) amend the Bacterial Assessment and Remedial Action Requirements.

Figure 2.5 Areas of Special Biological Significance No. 24

In addition to the standards contained in the Ocean Plan, ocean discharges must comply with AB 411. AB 411 required the Department of Health Services to establish minimum standards for the sanitation of public beaches. DHS's implementing regulations were adopted in 1999 and require testing of waters adjacent to all public beaches for total coliform, fecal coliform, and enterococci; compliance with standards for total coliform, fecal coliform, and enterococci; use of DHS sampling protocols; and weekly bacterial testing between April 1 and October 31 for any beach visited annually by more than 50,000 people which also has a storm drain outlet that flows in the summer.

2.5.4 Treatment and Reuse Solutions

Beneficial reuse can take the form of irrigation as well as industrial use and other non-potable uses. To assure protection of public health where water reuse is involved, the California Department of Health Services (DHS) has been statutorily directed to establish statewide reclamation criteria for the various uses of reclaimed water (Water Code Section 13521). DHS has promulgated regulatory criteria which are currently set forth in the California Code of Regulations, Title 22, Division 4, Chapter 3, 60301 et seq. DHS's regulatory criteria include numerical limitations and requirements, treatment method requirements, and provisions and requirements related to sampling and analysis, engineering reports, design, operation, and maintenance.

The Regional Board must also approve the application for beneficial reuse of wastewater. No person may either reclaim water or use reclaimed water until the Regional Board has either issued reclamation requirements or waived the necessity for such requirements (Water Code Section 13524). In the process of issuing reclamation requirements, the Regional Board must consult with and consider recommendations of DHS (Water Code Section 13523). Title 22 officially only applies to recycled wastewater (of sewage origin). Formal application of Title 22 Regulations normally is triggered when a wastewater or water agency is proposing, often in conjunction with a water agency, or with direct users, to deliver treated wastewater. That type of reuse must be permitted by the Regional Board through WDR's, which might be added to an existing NPDES/WDR permit or as a stand-alone Water Reclamation WDR.

If an agency is contemplating stormwater reuse, the permitting process is not as clear. If the stormwater project is just treatment and discharge back to the channel or storm drain, it is assumed that the Regional Board would view that as a BMP, not a new discharge. If the reuse project is going to look like a traditional reuse project, where the producing agency (e.g. the MS4 agency) is delivering water to others for unrestricted irrigation use, it is a safe assumption that it would need to be free of potential pathogens that might have been in the source water (runoff). It is possible that this quality might be achieved with a slightly less stringent treatment train than typical Title 22 treatment.

2.5.5 Issues Regarding Implementation of Options Consistent With the State and Federal Regulations

On-site BMPs are already permitted under state and federal regulations. Only in an extreme situation in which the on-site solution would have the potential to damage a natural resource protected by a state or federal resource agency, (e.g. a wetland) would it be considered necessary to go beyond the existing permits.

However, for the regional solutions which involve treatment, discharge, or reuse, the state and federal regulations would be applicable if:

- The location of the regional facility impacts the natural aquatic, terrestrial or avian resources protected by the state and federal resource protection agencies.
- The location of the facility is in the Coastal Zone, thereby requiring a Coastal Development Permit, local planning and zoning approval, and a Public Works Plan for the Coastal Commission.
- The location of the facility requires construction in a wetland or Waters of the U.S., requiring dredging and filling of a wetland or Waters of the U.S., which would involve the Corps and the state and federal water quality and resource protection agencies.
- A new surface water discharge is developed for the product (effluent) of the regional facility requiring a new NPDES permit, and potentially an anti-degradation analysis.
- The product or effluent of the regional facility is reused as a non-potable water supply either directly or after storage in an aquifer where it is injected. This would require the Regional Board and DHS to permit the reuse and the groundwater replenishment.

2.6 Monitoring Considerations

The goal of the Implementation Plan monitoring program is to establish procedures to analyze and track water quality status and trends, assist in identifying pollutants of concern, point source tracking, and to evaluate reductions achieved by Best Management Practices (BMPs). It is intended to supplement the Coordinated Shoreline Monitoring Program by providing upstream tributary monitoring information, which would also assist in further identifying potential sources. It is also intended to provide information that could assist with the re-opener 2007, so that future generations of the Implementation Plan resources can be better focused.

A number of candidate monitoring stations have been identified to assist with further identifying potential sources and evaluating non-structural BMPs. Samples from the first storm of the wet season (in October 2004) were also taken at these stations.

The objective of these monitoring stations is to provide information to support future management decisions, such as selection of structural and non-structural BMPs, and is not intended to be compliance-related. As such, proposed stations were not necessarily high priority watersheds, but represented watersheds where potentially useful information could be extracted. With the exception of Topanga Creek at the sandbar, all stations showed high bacteria counts (exceeding water quality standards) during the first storms of 2004-2005. The proposed stations are:

- Trancas Creek (discharges to Area of Special Biological Significance)
- Marie Canyon (high priority subwatershed)
- Sweetwater Creek (potential concentrated equestrian land uses)
- Topanga lagoon (sandbar and bridge)
- Solstice Creek (potentially similar to Arroyo Sequit land usage and potential alternative reference subwatershed)

Sampling results indicated significant exceedances in the areas of interest. Of the sampling conducted, pre-event and storm event sampling indicated high levels of bacteria in most areas, and with the exception of some locations in Topanga Creek all samples exceeded water quality standards. October stormflow conditions showed significantly higher values than the August dry conditions. In August, only 1 of 6 Topanga Creek samples exceeded compliance limits while in October, 16 of 18 samples exceeded the limits (including all Enterococci results). These data indicate the importance of the winter high flow runoff in determining total bacterial loads from the watershed to the beaches.

These monitoring data are only used to indicate the potential for contributions to exceedances in the immediate vicinity of the watershed outflows to the bay. Shorezone dilution, dispersion, and degradation were not quantified as part of this study. It is not known if surfzone exceedances occurred in the immediate vicinity of the lower watershed at the time of the streamborne exceedances.

Another significant source of data was the Topanga Creek Watershed Water Quality Study, Final Report for the period October 2003 – 2004 was issued in December 2004 (Dagit, et al. 2004). The report summarizes water quality and exceedances for Topanga Creek and recommends BMPs for the watershed as part of ongoing work by the Resource Conservation District of the Santa Monica Mountains (RCDSMM). This study summarized percent exceedances for wet weather. In a reduced data set, Solstice showed no exceedances (only two samples). For other subwatersheds, exceedances were significantly higher. Arroyo Sequit, Nicholas, Zuma, and Topanga all showed exceedances between 24 and 30 percent. Los Alisos, Trancas, Ramirez, Latigo, and Piedra Gorda showed exceedances between 30 and 50 percent. Escondido and Corral had exceedances above 50 percent. Data were not available for the other subwatersheds.

3. Plan Development and Evaluation

3.1 Methodology

The general methodology for alternative development, evaluation, and prioritization of activities was developed in response to the following questions.

- Where do we have the most significant problems?
- What is our tolerance for uncertainty and does this tolerance depend on location?
- Where can we leverage solutions to achieve multiple benefits?
- Where do we have a higher probability of success?
- What do we want to do now versus waiting until better information and technologies become available?

In response to these questions, the methodology described below was developed. Each of these components and the implications therein are described in the following sections:

- To balance uncertainty between potential costs and potential benefits, consistent with an integrated approach, a "compliance triangle" model was applied to compare different broad approaches. This model balances costs, risks, and beneficial reuses.

- To address the allocation of resources, results of the watershed prioritization effort were used to tailor plan elements to watershed priorities.

- To systematically implement activities in a phased adaptive manner, a "commit-pilot-consider" approach was adopted.

3.2 The Compliance Triangle

Three different broad, thematic alternative approaches were developed and evaluated. The results of the evaluation formed the basis for the Implementation Plan. The result was the development of subwatershed-specific integrated solutions that would each meet the objectives of the TMDL while combining several runoff management options. The three over-arching concept alternatives are defined below:

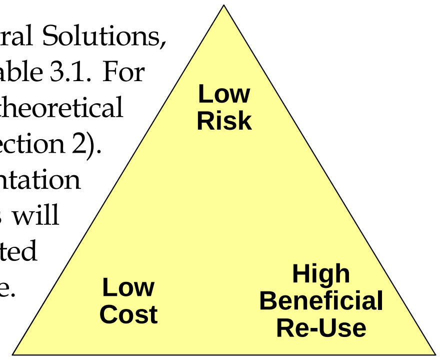
- **Low Cost** – includes options that meet the minimum regulatory requirements with the least capital and maintenance costs. This alternative would not include a high amount of beneficial use of runoff and may pose a higher risk of non-compliance with the TMDL.

- **Low Risk** – includes options that minimize the risk of non-compliance with the TMDL without regard to cost or optimizing the beneficial use of runoff.

- **Maximum Beneficial Reuse** – includes options that maximize the amount of runoff for beneficial use. This alternative assumes the same risk of non-compliance with the TMDL as the low risk alternative.

The "Compliance Triangle"

Each alternative includes components from Non-Structural Solutions, Local Solutions, and Regional Solutions, as shown in Table 3.1. For each structural alternative there is an upper limit, or theoretical goal, of runoff volume to be managed (as discussed in Section 2). For each thematic alternative, proposed implementation options are presented. The performance of these options will be evaluated and the implementation plan will be adjusted to address the findings at each re-evaluation phase. Regional solutions will be considered and may be included as part of the modification of the Implementation Plan.



"Compliance Triangle"

Table 3.1 Alternatives Comparison

Alternative	Non-Structural Options	On-Site Options	Regional Options
Low Cost	Implement existing and new programs (commit + pilot)	Pilot-scale implementation of the following: • Cisterns • On-site storage and reuse • Small-scale capture and infiltration	Not included
Low Risk	Implement existing and new programs (commit + pilot)	Not included	Capture, store, treat and discharge
Beneficial Reuse	Implement existing and new programs (commit + pilot)	Full-scale implementation of the following: • Cisterns • On-site storage and reuse • Small-scale capture and infiltration	Capture, store, treat, and beneficially reuse

3.2.1 Low Cost Alternative

The low-cost thematic, by definition, is the alternative configured to have the lowest capital and O&M costs. This alternative assumes a higher level of risk of compliance with the TMDL than the other alternatives by focusing on non-structural options and avoiding significant local or regional structural solutions. Thus, it has the lowest runoff management goal. The following runoff management options are included in the low cost alternative: 1) institutional (non-structural) options, 2) local options, and 3) regional options.

Non-Structural Options

Non-structural solutions are programmatic activities that provide source control measures intended to prevent or reduce the levels of bacteria, or bacteria sources (e.g., trash and pet waste) from initially being picked up by runoff whether onsite, in the street, or in the storm drain system. In general, institutional solutions do not substantially reduce the volume of wet weather runoff to be managed. Due to the ubiquitous nature of indicator bacteria, and limited correlation with human pathogen sources such as trash and fecal material, institutional solutions may have limited effectiveness in reducing indicator bacteria concentrations at the beaches. Human pathogen sources, however, such as human and animal fecal material, may be more significantly reduced by these measures and therefore reduce human health risk in beach waters.

On-Site Local Options

Local, or on-site, solutions provide an important step in managing wet weather runoff. Three options have been identified as potentially feasible for providing local source control for J1/4: 1) residential cisterns, 2) on-site storage and reuse, and 3) capture and infiltration. Pilot scale implementation of these local options will be included in the low cost option. With implementation of these options runoff is retained locally and discharge of runoff and associated bacteria is avoided.

Regional Options

The low cost solution will not include regional options because of the very high cost and major implementation requirements associated with management of runoff at the regional level.

3.2.2 Low Risk Alternative

The intent of the low risk thematic alternative is to manage the highest theoretical target runoff goal, and will include options that will minimize the compliance risk with the TMDL without regard to the cost or optimal beneficial use of runoff. The target runoff management goal for the low risk alternative is described in Section 2.1.4. The low risk alternative includes the same non-structural options as the low cost alternative. This alternative also includes regional storage and treatment options. However, the low risk alternative is designed to manage more runoff volume than the low cost alternative.

Non-Structural Options

The low risk alternative will include the same recommended institutional options as that of the low cost alternative.

On-Site Local Options

Local solutions are not included in the low risk alternative because, given the emphasis on Regional solutions, their implementation will not substantially reduce the need to manage runoff regionally to ensure the lowest level of risk.

Regional Options

For this option, runoff would be captured and initially stored in operational facilities. Treatment would depend on target constituents (in this case, primarily bacteria). Trash and suspended solids would be present in wet weather flow, and pretreatment of flows would, therefore, be required to remove these constituents before treatment to remove bacteria is implemented. Regional capture, storage, treatment, and discharge will require construction of storage and treatment facilities in each subwatershed designed to meet the AB411 beach standards. The effluent would then be discharged to the ocean, typically through storm drain outfalls. Preliminary target volumes by watershed could be as high as that described in Section 2.

3.2.3 Maximum Beneficial Reuse Alternative

The maximum beneficial reuse alternative includes options that maximize the amount of runoff that can be beneficially reused. The maximum beneficial reuse alternative shares the same non-structural options as the low cost and low risk alternatives, but includes additional options to beneficially reuse a portion of the runoff. Unlike the low cost alternative, this option recommends full scale implementation of cisterns, on-site storage and reuse, and small-scale capture and infiltration.

Non-Structural Options

The maximum beneficial reuse alternative will include the same recommended institutional options as that of the low cost alternative, which consist of new and expanded programs.

Local Options

The maximum beneficial reuse alternative incorporates all of the following local options: 1) residential cisterns, 2) public on-site storage and reuse projects, and 3) small-scale capture and infiltration projects. The maximum beneficial reuse option includes full scale implementation of each local option discussed in this section, whereas the low cost option only included pilot studies. It should be noted that full scale implementation implies implementation at publicly owned and proactive privately-owned facilities to the maximum extent practicable, and does not imply retrofitting of private residences or mandatory retrofitting programs.

Regional Options

Given the inventory of opportunities, this option does not appear to have significant immediate potential. The option is intended to divert wet-weather runoff to beneficial use with appropriate treatment for the intended use. It involves the capture, storage (operational storage facilities), diversion of runoff to facilities for treatment (to be determined but may be similar to Title 22 standards) for unrestricted outdoor water use, seasonal storage, and distribution to sites for reuse. Capturing and storing runoff eliminates discharge of the quantity of water downstream to the beach, thereby potentially reducing the number of exceedance days, especially at lower flows. This option involves use of some of the same capture, operational storage, and base treatment facilities as the treat and discharge option, but at a much smaller scale. In this case, a portion of the runoff that would have otherwise been discharged is beneficially reused as an irrigation supply to the extent that there is demand and it is economically feasible. To minimize capacity of treatment and/or off-stream diversion pumping to storage, short-term operational storage will likely be required to balance the hydrograph, and longer-term storage may be required to balance water availability with seasonal demand.

3.3 Alternatives Comparison for Area-Wide Implementation

Criteria for evaluation were developed to look at relative need (priority), costs, and benefits. The semi-quantitative comparison assumed full implementation throughout the jurisdictional areas. The subject criteria were:

- Volume of runoff managed
- Volume of runoff beneficially used
- Relative Cost
- Regulatory compliance
- Design complexity and constructability
- Facilities siting difficulty
- Reliability and Performance
- Compatibility with a phased approach

After evaluating each of the three alternatives, it appears that no one approach is clearly the single best watershed-wide solution for obtaining bacteria TMDL compliance. Instead, various options from the alternatives should be applied on a subwatershed by subwatershed basis. A summary of approaches selected for each subwatershed that takes into account the unique characteristics of that watershed is presented in the following section.

3.4 Subwatershed Focusing

As discussed in Section 2, watershed priorities were established. The results of this analysis are summarized in Figure 3.1. Using the results of the broad alternative evaluation the following general approach was used to develop implementation measures adapted to the watershed priorities:

- **Low priority watersheds** – generally low cost approach (non-structural measures)

- **Medium priority watersheds** – generally low cost and some beneficial use (generally on-site solutions)

- **High priority watersheds** – partial low risk and/or maximum beneficial use approach

3.5 Commit-Pilot-Consider Model

Prioritization of BMP options based on relevance to known contamination sources requires strong evidence relating water quality problems to specific sources of bacteria, such as septic systems, equestrian facilities, dog waste, restaurants, litter, or wildlife. Ideally, BMPs that address the most significant sources of bacteria should be given the highest priority. Based on analyses conducted as part of this Implementation Plan, the storm runoff from urban environments, in general, was identified as the highest priority contributor to bacterial contamination in Santa Monica Bay.

Figure 3.1 Subwatershed Priorities

RB-AR 7675

Thus, activities associated with urban development appear to be the most prevalent sources of bacteria. However, in the absence of more detailed source identification, the data was not sufficient to specifically pinpoint which sources were contributing most significantly to water quality impairment problems. Therefore, in the absence of conclusive evidence prioritizing specific sources of contamination within urban runoff, the logical approach is to implement a broad range of BMPs that target activities near the coast associated with urban land use.

3.5.1 Implementation Requirements and Potential Effectiveness

A commit-pilot-consider model was developed to evaluate the ***implementation requirements*** and ***potential effectiveness*** associated with each BMP. The approach was most directly applied to non-structural BMPs, but can be applied to structural approaches as well. BMPs are assigned a subjective rating of easy/moderate/difficult for implementation requirements and low/medium/high for potential effectiveness.

The implementation requirements rating is based on several factors including the relative cost, level of effort required to implement the BMP, permitting issues, regulatory constraints, and political issues.

The potential effectiveness rating is based on several factors including the potential to educate the public and/or business community, ability to change habits and behaviors, and geographic extent and coverage, and other factors that would presumably result in improved water quality.

3.5.2 Commit-Pilot-Consider

Three levels of implementation are proposed in this Implementation Plan.

- **Commit**: Agencies commit to engaging in the activities so designated within the indicated time frame

- **Pilot**: Agencies commit to limited scale implementation to establish the effectiveness of the measure (structural and non-structural) and to help identify the severity of the potentially targeted source (for non-structural solution)

- **Consider**: If the perceived need for this BMP, based on preliminary studies, is not apparent, or if the subject technology is potentially costly or unproven, these activities will be considered in future phases of implementation.

The basis for determining the appropriate level of implementation is illustrated in Table 3.2. BMPs at the "commit" level of the model are high priority BMPs, while BMPs at the "consider" level of the model are of lower priority. Pilot studies are recommended prior to full-scale implementation for BMPs at the "pilot" level of the model.

Table 3.2 Commit-Pilot-Consider Model

		Implementation Requirements Rating		
		Difficult	**Moderate**	**Easy**
Potential Effectiveness Rating	**High**	Pilot	Commit	Commit
	Medium	Consider	Commit	Commit
	Low	Consider	Consider	Consider

If the pilot study BMPs prove to be effective in reducing water quality impairment problems, in conjunction with continued evaluation of monitoring data to establish the relative bacteria contributions of various sources, consideration can then be given to widespread implementation.

3.6 Assessment of Effectiveness.

The Regional Board requests additional detail on specifics for assessing effectiveness. Two basic approaches are presented in the Final Plan: 1) a presumptive approach and 2) a targeted monitoring-based approach.

3.6.1 Presumptive Approach

The presumptive approach assumes that the implementation of structural and non-structural BMPs will lead directly to reductions of exceedance days and attempts to quantify this relationship. It is recognized that there is significant uncertainty, and it is expected that the iterative and adaptive management strategies are employed, both effectiveness will improve and the correlation of activities to water quality compliance will improve.

A presumptive approach is needed because of the high sensitivity of compliance to hydrology (exceedance days), and that as a result an ineffective could still yield short-term compliant results, while a plan that is beginning to show effectiveness could still show non-compliance. In addition, there is high sensitivity to other hydrologic factors such as the Malibu Creek drainage. There are potential contributions from other sources outside the sphere of influence of this plan (Onsite Wastewater Systems), and monitoring in the wave wash further could add additional variability which would make direct tracking of effectiveness difficult.

The California Association of Stormwater Quality Agencies (CASQA) has initiated efforts to quantify effectiveness, and the County of Los Angeles conducted (and will be updating) segmentation studies to establish behavioral changes tracked by public information efforts. None of these approaches, however, have presented definitive measures for quantifying water quality improvement due to the inherent difficult of this type of analysis.

Therefore, the first proposed measure of effectiveness is a presumptive approach tied to effort with presumed performance, which would be updated and revisited at the reopener phase in 2007.

Parameters assumed for this presumptive gage include:

- Population:
  - Permanent Residential Population: 18,000 (based on 2000 census values for Malibu and Topanga)
  - Assumed Non-Residential Population (workforce, visitors, students): 10,000
  - Total Target Population for all measures: 28,000
  - Approximate Population distribution (assumed based on total residential developed land use fraction)
    - High Priority Subwatersheds: 30%
    - Medium Priority Subwatersheds 40%
    - Low Priority Subwatersheds: 30%
  - Distribution/readership of local information outlets (Malibu Times): Circulation = 12,000, readership estimated 36,000. Malibu times Magazine circulation 25,000; readership estimated at 75,000 (source: personal communication with Malibu Times staff August 9, 2005)
- Commercial (from smartpages.com)
  - Equestrian-Related Businesses (stables, breeders, suppliers): 10
  - Pet Related Businesses (retail, suppliers, grooming): 50
  - Restaurants in J1/4 Areas: 50
  - Septic/Plumbing Services (not necessarily in Malibu Area): 30
  - Approximate distribution of commercial/industrial activity (assumed based on total land use areas)
    - High Priority Subwatershed: 40%
    - Medium Priority Subwatershed: 25%
    - Low Priority Subwatershed: 35%
- On Site Opportunities
  - Public Land Opportunities (within J1/4 agencies): 23 (see Attachment 1)
  - Public Land Opportunities (outside of J1/4 agencies)

    - Schools/Universities: 5
  - State/Federal Parklands (excluding Malibu Creek/Lagoon and Leo Carillo): 5 - El Pescador, La Piedra, El Matador, Point Dume, Robert H. Meyer.

- Behavioral change (change of activities contributing to pollutant loading and exceedances)*

  - Assumed average number of annual impressions required for 10% reduction in pollutant generating activities (reference segmentation study): 3/year (note that this could be 3 impressions for 100% of the population, or 7 impressions for 20% of the population and 2 impressions for 80% of the population)

  - Assumed number of annual impressions required for 25% reduction in pollutant generating activities: 4/year (potentially 7 impressions for 40% of the population, and 2 impressions for 60%)

  - Assumed number of impressions required for 50% reduction in pollutant generating activities: 6/year (potentially 8 impressions for 60% of the population and 3 impressions for 40%; or 7 impressions for 80% and 2 impressions for 20%)

- Assumed reductions based on incentive-based activities as a function of allocated budget*

  - 10% cost – 10% target reduction
  - 25% cost – 25% target reduction
  - 50% cost – 50% target reduction
  - 100% cost – 100% target reduction

  *Note: All parameters to be revisited upon additional information. Target reductions assumed to be composite number of allowable exceedances for all areas.

3.6.2 Targeted Monitoring-Based Approach

The Targeted Monitoring-Based Approach(TMBA) adopts some measures of presumptive compliance but incorporates monitoring data and attempts to normalize and extrapolate this monitoring data throughout the region.

The TMBA assumes the development of Annual Interim Compliance Reports that consider a number parameters, and present analyses and discussions of each parameter in order to estimate a reduction in pollutant loadings. These parameters consider:

- Coordinated in-stream monitoring. These data include water quality and flow data, with the first two years being primarily baseline information.

- Extrapolation of source control implementation effectiveness. This involves developing an algorithm, and applying it to extrapolate the effectiveness of activities within a targeted subwatershed that has isolated expected pollutant sources (typically not a high priority watershed), and applying these reductions to other subwatersheds that have similar expected sources.

- Extrapolation of small storm effectiveness. This involves developing and applying an algorithm that recognizes hydrologic variability and normalizes pollutant and hydrologic data for comparison with the benchmark (90th percentile) standard year.

- Hydrologic conditions and variable accountability. This involves better understanding hydrologic responses to better define targeted reductions in exceedances.

- Pilot projects. When on line, Pilot Projects will have raw data which can be analyzed and interpreted using the extrapolation algorithms described above.

- Assessment of progress toward full implementation

The TMBA, while also presumptive in many respects, will provide more results-oriented data by which to make more effective management decisions, to support progress toward compliance and potential adaptive and iterative modifications to the Plan. It is, however, anticipated that the TMB approach may not yield readily significant results until at least the 3rd year of implementation.

3.7 Implementation Plan Framework

Based on the focused approach for each subwatershed, and using the commit-pilot-consider model, an overall implementation plan framework was developed for the entire J1/4 watershed area. The plan summarizes the options and BMPs that would form the program within each subwatershed, the level of commitment, and potential phasing. This framework is presented and the plan described in detail in Section 4.

4. Implementation Plan Commitments

4.1 General Approach

This section presents an overview of the Implementation Plan commitments. It describes the general approach to implementation, the implementation phases and overall schedule, and the methods for plan assessment, monitoring and reporting. Detailed descriptions of specific activities, programs and projects and the specific plan commitments on a subwatershed basis are described in Section 5.

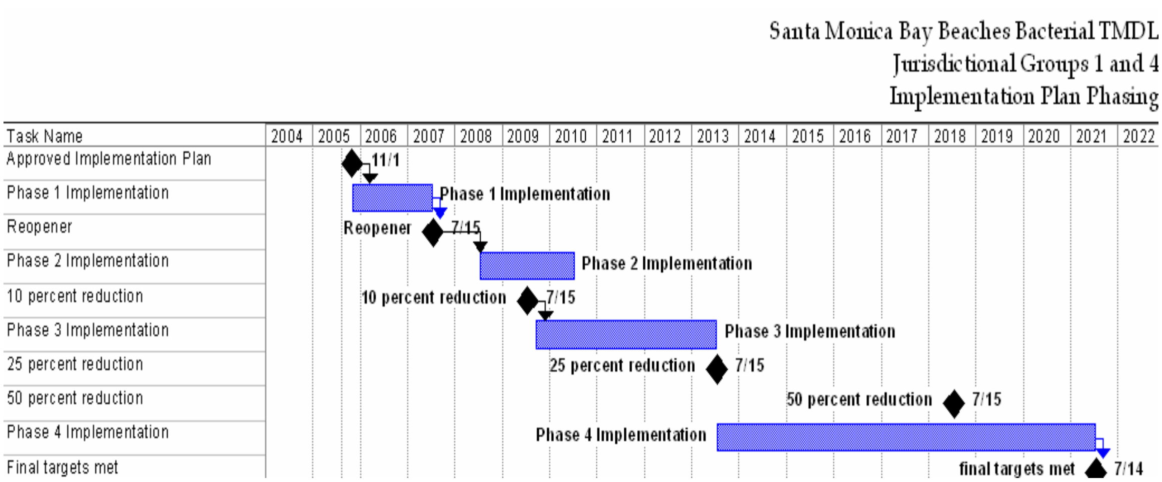
As outlined in Section 3, the Implementation Plan consists of combinations of non-structural activities, local on-site structural measures and regional structural solutions selected for each subwatershed. The elements contained in the plan for each watershed include those that are committed either for implementation or pilot programs/projects. Other measures may be considered at some point in the future depending upon the effectiveness of the committed and pilot programs or in response to specific opportunities that may be presented but are not part of the initial commitments. A summary of the plan is shown in Table 4.1.

Table 4.1 Summary of Watershed Activities

Sub watershed	Watershed Priority	Non-Structural Measures				Structural Measures	
		Public Information and Participation Programs	Industrial/ Commercial Facilities Control Programs	Development Planning and Construction Program	Public Agency Activity Control Program	On-Site Options	Regional Solutions
Nicholas	Low	Commit, Pilot & Consider	Consider only	Commit	Commit & Consider	Consider only	N/A
Los Alisos	Low (Low-Med)	Commit & Consider	N/A	Commit	Commit & Consider	Consider only	N/A
Encinal	Low	Commit & Consider	N/A	Commit	Commit & Consider	Consider only	N/A
Trancas	Low	Commit, Pilot & Consider	Commit, Pilot & Consider	Commit	Commit & Consider	Consider only	Consider only
Zuma	Low	Commit, Pilot & Consider	Commit, Pilot & Consider	Commit	Commit & Consider	Consider only	N/A
Ramirez	High	Commit, Pilot & Consider	Commit, Pilot & Consider	Commit	Commit & Consider	Commit & Consider	Pilot Project
Escondido	Med (Med-High)	Commit, Pilot & Consider	Consider only	Commit	Commit & Consider	Pilot & Consider	N/A
Latigo	High	Commit, Pilot & Consider	Consider only	Commit	Commit & Consider	Commit & Consider	Pilot Project
Solstice	Low	Commit, Pilot & Consider	Consider only	Commit	Consider only	Consider only	N/A
Corral	High	Commit & Consider	Commit & Pilot	Commit	Commit & Consider	Commit, Pilot & Consider	Pilot Project
Carbon	Low (Low-Med)	Commit & Consider	Commit & Pilot	Commit	Commit & Consider	Consider only	N/A

Sub watershed	Watershed Priority	Non-Structural Measures				Structural Measures	
		Public Information and Participation Programs	Industrial/ Commercial Facilities Control Programs	Development Planning and Construction Program	Public Agency Activity Control Program	On-Site Options	Regional Solutions
Las Flores	High	Commit, Pilot & Consider	Commit, Pilot & Consider	Commit	Commit & Consider	Commit & Consider	Pilot Project
Piedra Gorda	High	Commit & Consider	N/A	Commit	Commit & Consider	Commit & Consider	N/A
Pena	Low	Commit & Consider	N/A	Commit	Commit & Consider	Consider only	N/A
Tuna	Low	Commit & Consider	Commit & Pilot	Commit	Commit & Consider	Consider only	N/A
Topanga	Medium	Commit, Pilot & Consider	Commit, Pilot & Consider	Commit	Commit & Consider	Commit & Consider	Consider only

The Implementation Plan was divided into four phases of activities. The activities consisted of implementation activities, as well monitoring and additional studies that could be used to provide better information for future activities. To provide useful information, the additional studies will require extended development and implementation periods. Upon completion of these studies, it would be desirable to confirm, or adjust if necessary, the direction and requirements of the Implementation Plan. As such, the County and J1/4 Agencies proposed the addition of appropriately timed re-evaluation milestones (re-openers). Implementation activities, suggested re-openers, and implementation milestones are illustrated below:



The general intent of what would be accomplished under each of the phases is as follows:

- Phase I – Conduct planning and initiate all committed non-structural activities and implement selected non--structural measures; initiate pre-feasibility studies for sub-regional pilot projects; develop inter-agency agreements for structural projects, initiate planning for on-site measures; initiate monitoring, additional studies, and source identification activities. The 2007 re-opener would follow Phase I. Note that Phase I is assumed to begin in November 2005, which is the basis of the proposed schedule.

Should the initiation date change, the remaining implementation deadlines may change accordingly.

- Phase II – Continue implementation of committed non-structural activities; conduct non-structural pilot programs; continue planning for on-site measures; initiate planning and construction of pilot regional structural solutions; and continue and complete monitoring and source identification studies. A programmatic review is proposed to follow Phase II and is intended to leverage results not only from additional studies in these jurisdictional areas, but also from advances in the technical, legal, and regulatory body of knowledge.

- Phase III – Refocus and reprioritize efforts as appropriate, and continue implementation of committed non-structural activities; implement successful piloted non-structural programs; begin implementation of on-site measures; and operate and evaluate pilot regional structural solutions.

- Phase IV – Refocus and reprioritize efforts as appropriate and continue implementation of non-structural solutions; continue or expand on-site measures; and continue, modify and/or initiate regional structural solutions.

While these provide the general commitment to the timing and execution of activities, under the iterative approach the actual implementation of specific programs and projects will depend upon what is learned during each succeeding phase from the initial implementation of measures, the results of monitoring, and revisions that may be made to the TMDL at re-openers.

Tentative project schedules are presented in Appendix B to detail the general order and timing of committed activities within this Implementation Plan. The start and end dates of most projects have been approximated for budgetary and overall management purposes. These dates are not intended to be used as firm compliance dates, as several factors could cause projects to be expedited, delayed, or extended. It is the intention of the responsible agencies to programmatically follow this schedule; however, many factors, such as environmental permitting, land acquisitions, and ordinance change, are outside their direct control. Any significant changes to project schedules will be outlined within the annual progress reports.

4.2 Plan Execution

An analysis of wet weather runoff events and bacterial exceedances hypothesizes that if wet weather flow reaches the beach, then bacterial exceedance is highly likely. Therefore, the initial strategy for reducing exceedances is tied to a combination of reducing bacteria at the source through non-structural and on-site measures, and reducing the amount of runoff that reaches the receiving water, rather than focusing exclusively on treating the flow collected in the storm drain system for bacteria reduction. This strategy emphasizes the beneficial use of wet weather runoff and the installation of local solutions where possible to reduce downstream flows. It also focuses on local source control to reduce the level of bacteria and other pollutants discharged into the storm drains. Water quality improvements in the receiving waters would be realized from water quantity (flow) management practices, including local structural BMPs, as well as source control. Utilizing large-scale, end-of-pipe, regional solutions minimizes the risk of noncompliance, it also carries with it larger costs and potential impacts to the local, densely urbanized beach communities. Therefore, regional solutions are proposed to be limited to pilot scale implementation, and only after appropriate feasibility studies are conducted.

The Implementation Plan assumes an iterative, phased approach to implementation. Non-structural and on-site options will be implemented initially and the results of these efforts monitored to determine the subsequent course of action. In parallel, shoreline monitoring at the point of discharge from the storm drain to the surf zone ("zero point") as well as continued research on BMP effectiveness and pathogen indicators will be ongoing.

At the TMDL re-opener scheduled for July 2007, only very limited, short-term information and data will be available to assess the effectiveness of these measures for achieving water quality improvements in the Santa Monica Bay beaches. In addition, the numeric target, load allocation, and pathogen indicators for this TMDL may be revisited at this re-opener; however, the basis for compliance will likely not be fully reconsidered as sufficient research may not have been conducted and results [may not] have been evaluated for applicability to this TMDL by this time. Therefore, it is recommended that periodic re-evaluations, supported by annual reporting, be planned to more adequately incorporate the results of monitoring and special studies (see Section 4.3.2) as well as BMP performance in reviewing the TMDL approach. Potential time frames for additional re-openers are suggested in Section 4.1.

4.3 Monitoring

The monitoring proposed in this Implementation Plan is intended to support cost-effective implementation of control measures. It is not intended to replace reference beach study efforts (conducted by the Southern California Coastal Water Research Project), regulatory compliance monitoring (under the Coordinated Shoreline Monitoring Plan) or currently required Municipal Separate Storm Sewer monitoring efforts. In addition, monitoring is limited to wet-weather activities, as dry weather TMDLs are addressed in a separate implementation plan.

4.3.1 Water Quality Monitoring Recommendations

Sampling conducted to date provides a widespread snapshot of water quality conditions and that can be used as a record of baseline information on watershed contributions of bacteria to Santa Monica Bay beaches during wet weather periods. It is important to begin such programs recording status and trends as a basis for monitoring the effectiveness of storm water management BMPs. Multiple winter storm events should be collected from all lower watersheds as a means of assigning relative bacterial loading to the bay. Similarly, multiple stormflow samples of source areas and above and below BMPs will be needed to assess the design and effectiveness of watershed-based controls.

The variety of weekly, monthly, and storm-event based samples collected from SMB watersheds to date may be used as initial indicators of areas for BMP focus. They all are designed to measure point concentrations, and in some cases point loads. However, none of these sampling programs can be used to effectively gauge relative contributions from watersheds nor the relative value of various BMP designs without incorporating cumulative load, either monthly, seasonally, or storm event-based, as part of their results. Comparative loads will be needed to judge the cumulative effects on surfzone bacterial concentrations from individual watersheds. Similar to any TMDL, the challenge will be to back up from surfzone concentration limits to cumulative loads supporting compliance. Ocean and watershed flow and dilution modeling coupled with watershed flow measurements will be required to complete that link. Flow/stage height relationships may be available or can be created for lower watershed bridge crossings for the monitored watersheds. Upper watershed locations (such as Topanga Canyon locations) may be flow monitored using hand held meters or through the installation of gauged crossings or weirs.

Six stations were proposed for future monitoring. The objective of these monitoring stations was to provide information to support future management decisions such as selection of structural and non-structural BMPs, and was not intended to be compliance-related. As such, proposed stations were not necessarily high priority watersheds, but represented watersheds where potentially useful information could be extracted. With the exception of Topanga Creek at the sandbar, all stations showed high bacteria counts (exceeding water quality standards) during the first storms of 2004-2005. The proposed stations are:

- Trancas Creek (discharges to Area of Special Biological Significance)
- Solstice Creek (potentially similar to Arroyo Sequit land usage and potential alternative reference subwatershed)
- Marie Canyon (high priority subwatershed)
- Sweetwater Creek (potential concentrated equestrian land uses)
- Topanga lagoon (sandbar and bridge)

Winter Low Flow

As feasible, monthly monitoring at each of the 6 stations from periods between storms (at least a week after the last storm) to characterize the common, winter low flow periods (7 samples, November 2005 through April period of 2006 (and 2006- 2007)). This monitoring may reveal high concentration point sources suitable for BMPs and will help describe the pattern of seasonal loading by watersheds. This effort is not intended to be conducted throughout the entirety of the implementation period, rather, it will be initiated and ended as necessary.

Winter Storm Flows (most important)

As feasible, four storms from each of the 6 stations, at least 3 samples per storm per station for the same basic period as winter low-flow samples. Winter storm flows dominate the loading for all constituents and it is important to get a record of changing concentrations and flows during the course of individual storms in order to reconstruct total loads by storm and for the season-total estimate.

In addition to the stream site samples, opportunistic storm drain flows should be sampled from winter storms. Drains and potentially leaky sewer systems were documented in the Source Identification effort. Up to 3 drains per watershed per storm even could be sampled, as available, as part of the winter stormflow monitoring. All parameters, including flow, should be assessed from the drains as a means of pinpointing potential sources of load to the bay. The need for this additional effort would be established after the re-opener.

Simultaneous Surfzone Monitoring

Surfzone bacteria should be sampled at the same time as the stream sampling. Samples should be collected immediately up and downcoast from either the closed berm (which transmits water with some constituents, potentially including bacteria) or open stream channel. These results provide the final, important evidence documenting the relative contribution of the watershed to the surfzone contamination (the purpose of the TMDL). This effort will be completed as safety provisions will allow and as long as this data is deemed necessary for implementation purposes.

4.3.2 Hydrologic Loading Estimates

It is critical that the concentration data generated from the monitoring program be combined with simple hydrologic loading estimates from each watershed to produce estimates of seasonal and annual loads. Precipitation records and runoff models must be constructed for each watershed to relate to the point measurements of flow taken for each monitoring event. The modeling provides a cost-effective alternative to continuous flow records from gauging stations (the preferred alternative). Regardless, seasonal (monthly) and storm-event flow estimates from each subbasin will provide the information needed for source assessment and control. It is recommended that stream gages be provided in Topanga Canyon and in one of the smaller adjacent watersheds so that the Topanga precipitation gages can be utilized for calibration studies.

4.3.3 Structural BMP Monitoring

Because the integrated approach incorporates removal of multiple pollutants, structural BMPs will be monitored for effectiveness. One potential methodology for this effort is outlined in the *Urban Stormwater BMP Performance Monitoring A Guidance Manual for Meeting the National Stormwater BMP Database Requirements Prepared by GeoSyntec Consultants, Urban Drainage and Flood Control District and Urban Water Resources Research Council (UWRRC) of ASCE In cooperation with Office of Water (4303T) U.S. Environmental Protection Agency, Washington, DC 20460 April 2002 EPA-821-B-02-001* which includes provisions for sampling suites (recommended constituents) and detection limits. In addition, E. Coli should be incorporated as a constituent of concern to be added to the bacteria suite.

4.4 Additional Future Detailed Studies Needed

Due to the significant uncertainties associated with the initial development of the bacterial TMDL, there are a number of special studies that should be conducted either within J1/4 area or elsewhere in the Santa Monica Bay watersheds. In addition, a number of efforts and studies are continuing in other regions of California and the rest of the country on similar issues such as appropriate human health indicators. The following studies are suggested as highly relevant to both the J1/4 area and all of the Santa Monica Bay area. The results of such studies, as well as the experience gained during the early phases of implementation and monitoring, should support the need for additional permit re-openers as discussed in Section 4.1. The J1/4 agencies will partner with other jurisdictional groups (the Regional Board, SCCWRP and other parties) by conducting, contributing to, or tracking the results of such studies.

4.4.1 Identification of the Most Relevant Human Health Indicators Study

This study has potential implications throughout Santa Monica Bay and Southern California and is related to the previous proposed study. The purpose of this study would be to evaluate the effectiveness of existing bacteriological indicators as a gauge to evaluate potential risks to human health and, if appropriate, to recommend alternative indicators. This study would be of benefit during a first or potentially second, re-opener and as an implementation optimization tool.

The presence of three bacteria indicators (total coliform, fecal coliform, and enterococcus) in surface waters is used as an indirect measurement for human health risk. The scientific link between these indicators and actual risk is subject to debate, and it is generally agreed that additional scientifically defensible data would be beneficial. Because these indicators are used nationally and any effort to reassess their effectiveness must be scientifically sound and substantially founded, this effort is outside of the expertise of the J1/J4 agencies and should be completed with the help of the scientific, and potentially the regulatory community.

It is important to use indicators that would predict public health and beneficial uses of the Bay. It is also recognized that since the goal of this study is based on scientific discovery, the results nor its acceptance cannot be predicted or guaranteed, and the study would be costly.

The proposed time frame for this effort would be in Phase 2 of the Implementation Plan if work by other agencies cannot be leveraged.

4.4.2 Hydrology vs. Bacteria Loading

This study would potentially have applications throughout the Santa Monica Bay, but should be conducted in J1/4 areas because of the area's rural character. It is also recognized that this effort may have some overlap with current research (e.g., by the Southern California Coastal Water Research Project) and prior to initiation and development of a work plan, a more comprehensive investigation of this research is warranted. The study would monitor pollutant loads using a continuous sampler at runoff gage locations to determine pollutographs for several storm events. Monitoring data would be used to attempt to establish relationships between rainfall, runoff, and pollutant loading. Perhaps most critically, the effort would develop design hydrology for TMDL studies in the North Santa Monica Bay area and use the design hydrology and pollutant/runoff relationships. The County also would seek to use this study to determine if a peak flow exemption should be considered. This study would be of benefit during a re-opener and as an implementation tool.

Flow rate gaging stations are necessary to accurately measure storm flows, determine pollutant concentrations for grab samples, and calibrate rainfall-runoff models for design hydrology. Currently, there are no gaging stations located near drainage outlets in the North Santa Monica Bay watersheds. For this reason, calculating storm flows and subsequent pollutant loading cannot be performed with high levels of confidence. This makes the design of structural BMPs difficult. However, Topanga Creek (F34C-R), Malibu Creek (F130-R), and Ballona Creek (F38C-R) are existing runoff stations that can be modified for pollutant monitoring.

Determining the rainfall/runoff/pollutant load relationship should provide insight into costs associated with treatment of different runoff events. Exclusion of peak flow treatment may be possible if pollutants are diluted by large flow volumes.

The effort can be divided into two phases: monitoring bacteria levels/loading and development of design hydrology. For both phases, gaging stations must be constructed. The runoff data is necessary to determine pollutant loadings, determine runoff relationships, and calibrate a rainfall-runoff model.

For the monitoring portion, water quality samples from storm flows will be collected and combined with flow rate data generated from the gaging stations and/or model to determine pollutant loadings. This information will be analyzed to establish a link between storm intensity/duration and bacteria loading.

The design hydrology development will explore the relationships between rainfall, runoff, and pollutant loads. After establishing the relationships, a method of determining pollution loads will be established for ungaged watersheds in the North Santa Monica Bay area. A method for determining the amount of runoff that requires treatment will be established that is consistent with Public Works methodology.

The study could conclude that higher flows can be excluded from treatment processes without increasing a risk to human health. This could potentially reduce the cost to comply with the TMDL. New gaging stations and design hydrology could provide a more accurate account of storm flow rates making structural BMP design more efficient.

The processes to design and construct new gaging stations could be costly and lengthy, especially if right-of-way needs to be purchased or if construction is in a coastal zone – which is almost guaranteed. It may be possible to install gaging stations at existing bridge or channel facilities to reduce these costs and avoid construction in the coastal zones. The potential timeframe for this effort is July 2005-July 2010.

Assuming right-of-way will not need to be acquired, design and construction of stream gaging stations would take about two years with an additional year to develop and calibrate a model. Three to five years of monitoring data would be necessary to draw conclusions regarding bacteria loadings. Since a rainfall-runoff model can be applied retrospectively, these tasks can be performed concurrently. This study should be completed in three to five years of its starting date.

4.4.3 Bacteria Seasonal Variation Study

The results from this study can be applied to all of Santa Monica Bay, however due to the larger rural areas in NSMB, monitoring in J1/J4 is preferred. This effort could be conducted in concert with other monitoring efforts.

The purpose of the proposed study is to analyze how seasonal variations in tide, ocean currents, temperature, sunlight, red tide, aquatic life migration, and other natural phenomenon affect bacteria levels. This study would be of benefit during a re-opener and as an implementation tool.

The study would consist primarily of a literature review, and while it may assist in the understanding of bacteriological variances and spikes, it might be inconclusive or could result in additional uncertainty resulting in increased beach closures. This study could be completed within 3 years.

4.5 Reporting

Annual Implementation Plan progress reporting documenting compliance activities will be provided by the J1/4 Agencies. It is not anticipated that this report be exhaustive, but a summary of progress, successes and challenges, and requested modifications to the Implementation Plan. It is proposed that no additional reporting of monitoring results be required, but that monitoring results would be provided in an annual summary report of Implementation Plan Progress. This report would reference activities conducted to date, compared to commitments made in this Implementation Plan.

5. Subwatershed-Specific Implementation Plan

Section 5.1 describes in some detail, the proposed efforts and responsible agencies. Sections 5.2 through 5.18 describe activities specific to each subwatershed. These activities were based on priority and subwatershed-specific activities (based on land uses within subwatersheds).

5.1 Summary and Overview of Subwatershed-Specific Plans

This section describes specific activities for implementation. These activities are based on the previously-described source and watershed prioritization efforts, and include non-structural and structural measures. The subwatershed-specific matrices indicate a level of commitment for each activity ("commit-pilot-consider") and the time frame in which the activity would be implemented. The plans include non-structural, as well as on-site regional structural activities.

5.1.1 Non-Structural Activities

The following is a summary of non-structural measures that were identified for consideration, commitment to implement, or commitment to initiate pilot studies or programs.

Public Information and Participation Program

- ***Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact.*** The objective of this recommendation is to target pet owners with information about pet waste and its impact on the bay. Pet waste is typically associated with development as the concentration of pets is generally higher in higher density areas. Environmental literature currently does not draw the connection between pet waste and bacterial contamination in the bay. Animal feces can be washed into the bay through grass, landscaping, streets, and sidewalks which eventually lead to a storm drain. Even if the source is miles from the coast, pet owners would be more likely to pick up after their pets both at home and in public areas if they were aware that dog feces contains fecal Coliform and enterococci bacteria, which determine beach closures, and may contain pathogens such as Giardia and Salmonella that can make swimmers ill.

  This activity will be both planned and implemented during Phase 1 of TMDL implementation.

  Lead Agencies: County of Los Angeles and City of Malibu

- ***Locate areas with corralled animals and educate property owners on bacteria TMDLs.*** Horse stables and other animal corrals generate a preventable source of indicator bacteria. These studies identified 210 horse ranches within the J1/4 boundaries. It is assumed that there are higher incidences of corralled animals than horse ranches.

Properties with corralled animals could readily be determined by utilizing zoning maps and aerial photos thus narrowing down the zones that permit such uses. The impact of this effort would be dependent on the amount of land in the J1/4 area used for corralling animals, and it's potential to be improved by BMPs.

This program will educate the owners of corralled animals about bacteria TMDLs and steps they can take to decrease negative impacts on the environment. A network of volunteers from environmental organizations could be trained in this area. It should be also noted that all future development allowing corralled animals or horses within the City of Malibu will be regulated under the requirements of the Local Coastal Program Land Use Plan. Thus, these new developments will be required as a condition of approval to implement numerous BMPs that seek to reduce bacterial loading.

Lead Agencies: County of Los Angeles and City of Malibu

- ***Identify horse stables in the region and implement Pilot program.*** A pilot program can be established within a horse stable area to test and illustrate the effectiveness of BMPs in reducing bacteria. This program is designed for non-commercial stable owners and is applicable to corralled animals in general. Stable owners will be more likely to adopt a BMP they can see in action with real results. A potential site for this program is the City of Malibu owned Malibu Equestrian Center. Other potential areas for implementation of this program are those areas zoned for horse ranches that are within areas with little or no development such as Nicholas subwatersheds. Suitable BMPs are included in the City of LA's pamphlet on Stormwater Best Management Practices for Horse Owners & Equine Industry.

  Lead Agencies: County of Los Angeles and City of Malibu

- ***Post signs at City and County-owned trailheads designated for equestrian users to not clean out horse trailers in parking lots and to clean up horse waste.*** Parking areas at trailheads tend to be graded dirt lots that increase runoff at a greater rate in comparison with trails. On trails, horse waste is filtered by vegetation before entering waterways which may or may not be the case within trailhead parking lots. Posting signs in parking lots would reduce potential bacteria loading from horse manure.

  Lead Agencies: County of Los Angeles and City of Malibu

- ***Outreach at trailheads encouraging hikers to use restroom facilities.*** People may not realize the implications of urinating or defecating in natural areas such as local, state, and national parks. Posting signs at trailheads to remind hikers to use the restroom before a hike will both increase awareness and prevent improper waste disposal.

  Lead Agencies: County of Los Angeles and City of Malibu

- ***Provide septic system (OWTS) pumpers and customers with septic system guides.*** The goal of this suggestion is to provide septic system owners with information pertaining to their septic system and how to prevent pollution using proper maintenance procedures. The Stormwater Manager's Resource Center has compiled a pollution prevention fact sheet on septic system controls. This sheet indicates that resource system failures occur for a number of reasons, including improper siting, inadequate installation or system operation. A similar handout could be developed for homeowners and business owners who operate septic systems in Jurisdictions 1 and 4. The handout could be distributed to septic system pumping businesses throughout the Malibu area. Septic system pumpers would be motivated to distribute the handouts during pump out visits to generate new business from requests for additional services.

Lead Agencies: County of Los Angeles and City of Malibu

- ***Coordinate outreach activities with Pepperdine University.*** The goal of this program is to provide applicable outreach materials to Pepperdine University. Pepperdine University is located within the Corral Subwatershed. The campus consists of approximately 181 acres relatively in close proximity to the shore. It was established that the subwatershed where the University is located has had exceedances for total coliform, fecal coliform, and enterococcus. Activities would consist of distributing new materials to new dormitory residents at the beginning of each year, providing outreach materials for posting around campus and in dormitories; conducting workshops with Pepperdine staff (maintenance personnel, cafeteria staff) and presenting information to student organizations regarding the use of BMPs on campus. In addition, a communication link could be established with the university's science departments.

  Lead Agencies: County of Los Angeles and City of Malibu

- ***Increase coordination between agencies and environmental organizations in preparing outreach materials.*** Numerous efforts are continually put forth to produce outreach materials, but production is not always coordinated between organizations and agencies, resulting in similar duplicate materials being prepared, increasing overall costs or messages that are not consistent. Agencies and organizations within J1/4 should make it a high priority to coordinate activities between agencies and with various organizations operating in the area. The following list includes some ideas that may help to increase communication between agencies:

  Compile and distribute contact information from all the agencies and organizations in the J1/4 area.

  – Encourage organizations and agencies to post outreach materials on their websites so it can be easily reviewed.

  – Implement an email list or public listserv to discuss outreach materials and post new material before it is produced.

  – Fund a website that provides links to all agencies and organizations in the J1/4 area and their outreach materials.

– Provide additional funding and resources to augment and expand existing programs that specifically address bacterial pollution.

– This BMP could be adapted to provide an integrated approach. In order to do this, the agencies and organizations should work together to ensure that outreach materials address multiple, if not all the stormwater pollutants.

This activity will be both planned and implemented during Phase 1 of TMDL implementation.

Lead Agencies: County of Los Angeles, City of Malibu, and Caltrans.

Industrial/Commercial Facilities Control Programs
