- ***Provide an outreach program for all commercial facilities with corralled animals, including equestrian centers.*** Distribute previously produced pamphlets dealing with specific BMPs and educate owners regarding the bacteria TMDL and the need for BMPs. Develop this into a targeted industry sector-specific workshop, e.g. "Horse Lovers for the Environment Day." A locally-targeted sector workshop of this nature will draw from the local base of outdoor enthusiasts, and permit the equestrian commercial sector to respond to commonly-held suspicions that these activities are harmful to the environment. Businesses participating in these workshops and interested in implementing BMPs could use this as a selling point to prospective clients they may only want to keep their horses at facilities that are environmentally correct. These facilities in turn could pass on applicable knowledge from the workshops to clients such as that they should pick up after their horses while on trails. Participation by local businesses is expected to be high for a locally-oriented environmental protection program, and to generate sector-wide camaraderie in resisting the public image of these establishments as detrimental to the environment. It should be noted at the workshops that the Malibu Local Program Land Use Plan recently approved has stringent requirements for future confined animal facilities and existing facilities should implement those BMPs that will be required for future facilities.

  Lead Agencies: County of Los Angeles and City of Malibu

- ***Provide for regular BMP inspections for restaurants.*** Restaurants are potential sources of bacteria loading in urban runoff entering storm drains. Restaurants throughout Los Angeles County are inspected for food safety by the County of Los Angeles Department of Health Services (DHS). Health inspectors use their inspection results to award each restaurant a "grade" of A through C (or a numerical score for facilities receiving less than a C grade) which conveys to the public the performance of the restaurant in matters related to cleanliness and food safety. While it may not be possible to continue utilization of DHS staff for inspections, additional inspections either by trained water quality personnel or by DHS inspectors should be continued on a regular basis. Should DHS inspectors be utilized, they should be trained to assess compliance with storm water pollution control requirements for restaurants, and should report to the County each restaurant's performance regarding stormwater compliance and BMP implementation. If feasible, this would make use of an existing mechanism, thereby avoiding some of the additional cost and training requirements associated with implementing a new program. At this point it is not clear whether DHS-coordinated inspections can be continued and expensed.

This activity will be both planned and implemented during Phase 1 of TMDL implementation.

Lead Agency: County of Los Angeles, potentially the City of Malibu.

- ***Increase awareness of BMPs in restaurants by establishing a restaurant reward and recognition program.*** Restaurants are a potential source of urban bacteria loading. This pilot study would provide public recognition on a recurring basis for restaurants that qualify for a water quality protection award. Restaurants that implement stormwater quality measures including bacteria pollutant control measures can apply for the certification on a quarterly basis, and if they are found to have succeeded, are rewarded with recognition by the Malibu community. Recognition could include a framed certificate, recognition by the governing agency, and/or a newspaper advertisement for all qualifying restaurants. An additional qualification for the certification should be attendance by at least one current employee (in a decision-making capacity) to at least one of the annual "Malibu Restaurants for the Environment Day" BMP workshops.

  Once informed about restaurant BMPs, the restaurant-goers can report improper housekeeping practices such as the cleaning of mats outside and disposal of mop bucket water outside. With implementation of this program, improper housekeeping processes may be curtailed thus reducing a potential source of urban bacteria loading.

  Lead Agencies: County of Los Angeles and City of Malibu

- ***Conduct industry specific workshops.*** The agencies should conduct industry specific workshops for the bacteria TMDL in the Malibu area, particularly for those industries such as restaurants and equestrian facilities which may contribute to bacteria loading in runoff. These workshops should be locally-based and held on an annual or biannual basis. Repeating the workshops on a regular schedule would allow the TMDL agencies to provide new information to restaurant operators and equestrian facility owners as it becomes available (i.e. revised BMPs and updates on progress of the TMDL toward clean water) to keep the issue in the forefront of attention. In addition, outreach through scheduled workshops will help to address new restaurant operators and equestrian facility owners as they begin business within the region.

  This activity will be both planned and implemented during Phase 1 of TMDL implementation.

  Lead Agencies: County of Los Angeles and City of Malibu

- ***Investigate the possibility of increasing frequency of trash collection at restaurants.*** This pilot program would require restaurants to have refuse picked up more often with the cost borne by the restaurant. The recommendation should be initiated by inspecting a sample of restaurants and food processing facilities to identify existing practices, and evaluate the degree of accumulation of trash at the typical facility. Trash and associated food waste from restaurants is a potential urban source of bacteria and provides a medium for growth. During storm events trash not contained within covered receptacles has the potential to be washed into storm drains. This program may be incorporated into current inspection programs or into a revised program utilizing health inspectors as previously discussed. This recommendation might be assessed in conjunction with the enhanced implementation of BMPs, to determine whether trash management on-site is an effective substitute for increased frequency of trash collection, and which of the two is the lower-cost option for the agencies and for the businesses. A continuing discussion of this recommendation might be instituted at the annual or biennial sector-specific BMP workshops.

  Lead Agency: County of Los Angeles

Development Planning and Construction Program

- ***Further emphasize applicable existing BMPs in development planning and construction programs.*** Emphasizing existing BMPs for bacteria can be accomplished by providing information to construction site planners and site inspectors. If BMPs are not implemented, construction sites can contribute a substantial volume of runoff to storm drains since the sites are generally stripped of vegetation during construction. Construction sites can be potential sources of bacteria or at least provide runoff to serve as a medium to transport bacteria into storm drains. In handouts a link should be made between these BMPs and potential bacteria loading. During inspections inspectors should remind developers of the BMPs and ensure that they are properly implemented on a continuous basis.

  Lead Agencies: County of Los Angeles and City of Malibu

Public Agency Activity Program

- ***Establish guidelines for optimizing frequency of cleaning cycles for drainage facilities.*** Agencies within J1/4 should review cleaning cycles for drainage facilities relative to what is required by the NPDES permit and develop guidelines for an optimum program. Studies supporting this plan identified stormwater drains in urban areas as the sources of bacteria loading. This BMP could potentially require more equipment and labor to optimize current methods and timing of cleaning cycles. Optimized cleaning cycles could be implemented in coastal areas with higher densities. As a part of this BMP, pre and post-sampling of drains would be required to determine its effectiveness before it is implemented on a larger scale.

  This activity will be both planned and implemented during Phase 1 of TMDL implementation.

In Caltrans roadway facilities, recommendations with respect to increasing cleaning frequencies will be coordinated with the City of Malibu and implemented on a limited basis. These efforts are subject to approval through the normal processes with both agencies.

Lead Agencies: Caltrans, City of Malibu, and County of Los Angeles

Caltrans-Malibu Joint Agency Activities. City of Malibu and Caltrans will work together toward possible joint efforts to implement trash reduction measures on Pacific Coast Highway, State Route 1, that is heavily used by beach visitors. These measures could include increasing frequencies of street sweeping and trash pickup by entering into a delegated maintenance agreement, instituting Adopt-A-Highway Program for trash pickup by volunteers, and posting litter prohibition signs and special information signs at selected locations.

Lead Agencies: City of Malibu and Caltrans

5.1.2 On-Site Structural Activities

On-site solutions provide an important step in managing wet weather runoff. Three options have been identified as potentially feasible for providing local source control for J1/4: 1) residential cisterns, 2) on-site storage and reuse, and 3) capture and infiltration. With implementation of these options runoff is retained locally and discharge of runoff and associated bacteria is avoided.

It should be recognized that local solutions, like institutional solutions, may not fully mitigate the impacts of pollutant loading. For the low cost alternative, pilot studies will be conducted to evaluate effectiveness prior to implementation of the alternatives described below.

The lead agencies for local options will primarily be the County of Los Angeles and City of Malibu.

Residential Cisterns

Cisterns collect diverted runoff from impervious roof areas on-site, and are typically above-ground, storage reservoirs ranging from 60 to 10,000 gallons in volume. Cisterns can reduce the volume of runoff from a site, and for smaller storm events, delay and reduce the peak runoff flow rates. The runoff stored in the cistern provides a source of chemically untreated 'soft water' for gardens and compost, free of most sediment and dissolved salts. Individual cisterns could be located beneath each downspout, or the desired storage volume could be provided in one large, common cistern that collects rainwater from several sources.

For this alternative, cisterns will be implemented in a portion of the watershed to reduce runoff volume and, for smaller storm events, delay and reduce the peak runoff rates. In conjunction with other new and enhanced programmatic solutions, education and incentive programs will be implemented with the goal of achieving installation of cisterns at 5 to

10 percent of single-family and multi-family residences. It was assumed that 1,000 gallon cisterns would be installed at single-family residences and 10,000 gallon cisterns would be installed at multi-family residences.

It is estimated that a 5 to 10 percent level of installation would be able to manage approximately 36 to 72 acre-feet of wet weather runoff annually in the Jurisdiction 1 and 4 subwatersheds. One of the advantages of cisterns is that they may be proportionally more effective for managing runoff from small storms than from larger storms.

On-Site Storage and Reuse

On-site storage/reuse involves capturing runoff from rooftops and other hardscaped areas, performing limited treatment, and storing it for subsequent reuse on-site in a much larger (on the order of 100,000 gallons) underground-type of storage. Reuse would require careful management and consideration of water distribution systems.

Potential sites for this option are public parks, urban vacant lots, government facilities, commercial facilities, and schools; at which the runoff could be reused for irrigation under specific, controlled conditions without needing to meet full Title 22 treatment standards (requiring filtration and disinfection).

Small-Scale Capture and Infiltration

Small-scale capture and infiltration involves capturing runoff from hardscaped areas and infiltrating into the soil. Various methods for on-site infiltration include, but are not limited to, porous pavement, retention grading, dry wells, and bioretention. The majority of soils within Jurisdictions 1 and 4 are categorized as having very poor infiltration rates. Of the soils with high infiltration rates, much of this area is along the coastal sands or in the steep, mountainous terrains. The steep, mountainous terrain is not appropriate for on-site infiltration projects because there is no development or urban land use that generates runoff; and these areas are too far upstream of the desired runoff concentration points. Slope stability is also a significant concern. Smaller scale BMPs such as infiltration trenches, swales, French drains, and porous pavement should be considered on an individual parcel basis, particularly in rural residential areas.

Table 5.1 Potential Locations for On-Site Facilities

Site	Site Type	Subwatershed	Address	Jurisdiction	Approx. Area (acre)	Commitment
Malibu Lagoon County Beach (Surfrider)	Public Parking Lot	Carbon	23000 PCH, Malibu	LACDBH	0.68	Pilot
Las Flores Creek Park	Public Recreation Area	Las Flores	3755 Las Flores Canyon Road, Malibu	City of Malibu	4	Commit

Table 5.1 lists J1/4 Agency-owned candidate locations and levels of commitment for on-site measures within the J1/4 areas. These areas are somewhat limited and in some subwatersheds where on-site structural measures are committed, piloted, or considered, it may not be feasible to implement on-site structural measures within J1/4 Agency right of way. In this event other publicly-owned properties should be contemplated and

commercial development opportunities considered, before attempting to implement on private residential properties. It should be noted that while some of the listed facilities are sewer treatment plants, the functional use of these plants is not considered for storm water treatment. That is, the sewer treatment plants would not be used to treat runoff, but are facilities that are candidates for on-site treatment of local runoff.

5.1.3 Regional Pilot Projects

Regional structural solutions are recommended for evaluation as pilot projects for selected high-priority subwatersheds. These regional structural pilot projects should be considered candidate pilot projects that are subject to change and modification upon additional, more detailed study. Implementation of these pilot projects will be subject to confirmation of engineering feasibility and technologies that may change the treatment approach. These activities will initiate in Phase 1. The treatment volumes for pilot projects are generally below full target treatment volumes to better establish and understand the relationships between exceedances, storm volumes, and pollutant levels within storms, as well as to improve potential for optimal cost-effectiveness.

The following additional considerations should be made with respect to pilot projects:

- All projects require an administrative pre-feasibility evaluation.
- All projects require feasibility-study level analysis and conceptual designs.
- Proposed treatment concepts are subject to change.
- All parametric estimates (watershed area, treatment volume, etc.) are preliminary.
- Any budgetary estimates are preliminary and subject to change.
- All projects are subject to permitting and right-of-way resolution.
- Should a pilot project be found infeasible, replacement projects will be investigated.
- It is assumed that pilot projects will be operational throughout the implementation period, and that any decommissioning would occur after the implementation plan duration.
- All projects will require review of environmentally sensitive areas and establishment of jurisdictional delineations as appropriate. Project flow rates and treatment levels will depend on available right-of-way and project engineering, and are subject to modification.

5.1.4 Prioritizing and Phasing Philosophy

Activities stipulated for each subwatershed are determined by its priority rating. Priorities range from “low,” which would require primarily non-structural BMPs only, to “high” which would include more rigorous implementation of both non-structural and structural BMPs. The requirements for a “medium” priority watershed would fall between those of the low and high priority watersheds.

As previously stated, implementation categories for BMPs are “commit,” “pilot,” and “consider.” There are four phases in which these BMPs could be scheduled to begin planning and implementation. These phases are referenced in the summary tables in the following section. The summary tables include columns labeled “Initiate Planning” and “Initiate Implementation.”

“Commit” activities are the highest priority, and are generally scheduled to begin planning in Phase 1 with the following exceptions: a) “Further emphasize applicable existing BMPs in development planning and construction programs” though committed BMPS, are scheduled to initiate planning in Phase 2, and b) subwatersheds with committed structural BMP measures may not have a clearly defined initiated planning date, reflecting potential uncertainties, and instead may reference “Phase 1 or 2.” These watersheds include Ramirez, Latigo, Corral, Las Flores, Piedra Gorda, and Topanga.

BMPs that are to be piloted and considered would begin the planning phase no earlier than Phase 2 and implementation no later than phase 3. Items marked with an asterisk are those pilot or consider items that will be implemented only if necessary upon completion of the planning phase.

It should be noted that the medium priority subwatersheds of Los Alisos Canyon and Carbon do not include significantly different activities than their low priority counterparts. They, however, have accelerated schedules for the consideration of structural BMPs; with planning and implementation initiated in Phases of 2 and 3, respectively. It should also be noted that subwatersheds with potential for beneficial reuses (such as Trancas) would warrant consideration of additional BMP activities.

5.2 Arroyo Sequit

Because Arroyo Sequit is the reference subwatershed and basis for the Santa Monica Bay Beaches Bacterial TMDL, it is excluded from the Implementation Plan. Arroyo Sequit Subwatershed is virtually undeveloped (less than 2.5 percent is developed); therefore, anthropogenic sources of bacteria are sparse. It is for this reason that the CSMP (2004) identified the monitoring station at this subwatershed as a reference site for implementing the TMDL. Bacteria are still present in sampling, although at low levels and likely principally associated with wildlife, horses, and dogs. Much of the open space within the subwatershed is within parcels belonging to the Santa Monica Mountain Conservancy. Therefore, these lands have added protections.

5.3 Nicholas (J4)

5.3.1 Subwatershed-Specific Description

General Description

Nicholas Canyon is the sole Jurisdiction 4 area. It is a 1220-acre subwatershed that is bounded by Arroyo Sequit to the northwest and Los Alisos to the southeast. More than half of the Nicholas Subwatershed is within lands proposed for acquisition by the SMMC, and except for a small area of medium to high density and low density residential development along the shoreline, the subwatershed can generally be characterized as predominately natural open space. There is a 2-acre parcel in the subwatershed that is designated as a wildlife preserve or sanctuary. Just east of PCH is a horse ranch. Nicholas County Canyon Beach is a moderately popular beach that provides parking for 151 vehicles. The beach also provides fishing, picnicking, restrooms, showers, surfing, swimming, and in the summer months, there is a food truck.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 8 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds, this volume could be reduced to 3 million gallons.

Specific/Historical Concerns

Nicholas Canyon is considered a low priority subwatershed. Monitoring in the critical TMDL year did not show excessive exceedance days, and the source prioritization effort did not conclude that it was a high priority subwatershed.

5.3.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1. Specifics regarding potential implementation scheduling are provided in Appendix B.

Nicholas (J4) Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation
Non-Structural Measures					
Public Information and Participation Programs					
Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact or purchase	X			Phase 1	Phase 1
Locate areas with corralled animals and educate property owners on bacteria TMDLs		X		Phase 2	Phase 3
Identify horse stables in the region and implement pilot program		X		Phase 2	Phase 3
Post signs at County and City-owned trailheads designated for equestrian users to not clean out horse trailers in parking lots and to clean up horse waste			X	Phase 2	Phase 3*
Outreach at trailheads encouraging hikers to use restroom facilities			X	Phase 2	Phase 3*
Provide septic system (OWTS) pumpers and customers with septic system guides.	X			Phase 1	Phase 2
Increase coordination between agencies and environmental organizations in preparing outreach materials	X			Phase 1	Phase 1
Industrial/Commercial Facilities Control Programs					
Provide an outreach program for all commercial facilities with corralled animals, including equestrian centers			X	Phase 2	Phase 3*
Development Planning and Construction Program					
Further emphasize applicable existing BMPs in development planning and construction programs	X			Phase 2	Phase 2
Public Agency Activity Control Program					
Establish guidelines for optimizing frequency of cleaning cycles for drainage facilities	X			Phase 1	Phase 1

c) Small Scale Infiltration			X	Phase 3	Phase 4*
d) On-Site Wastewater			X	Phase 3	Phase 4*

*if necessary

5.4 Los Alisos

5.4.1 Watershed-Specific Description

General Description

Los Alisos Canyon is a 2380-acre subwatershed that is bounded by Nicholas Canyon to the northwest and Encinal to the southeast. Per SCAG (2000) land use data, it has 267 acres of residential development. In the upper region of the subwatershed around Decker Canyon there is a scattering of rural residential development and a small area designated as open space and recreation. In the area of La Vienta Creek and along the shoreline the area is mostly low density residential with a small area of medium to high density residential development (also along the shoreline). There are two inland parks west of PCH in the area of La Vienta Creek. Only 5 acres of non-pastoral or livestock agricultural land (nursery, vineyards) are found within the subwatershed. Most of the upper half of the subwatershed is protected by the Santa Monica Mountain Conservancy.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 10 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds, this volume could be reduced to 4 million gallons.

Specific/Historical Concerns

Los Alisos Canyon is considered a medium priority subwatershed based on the source prioritization effort described previously

5.4.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1. Specifics regarding potential implementation scheduling are provided in Appendix B.

Los Alisos Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures					
Public Information and Participation Programs					
Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact or purchase	X			Phase 1	Phase 1

*if necessary

5.5 Encinal

5.5.1 Watershed-specific description

General Description

Encinal Canyon is an 1830-acre subwatershed that is bounded by Los Alisos to the northwest and Trancas Canyon to the southeast. Per SCAG (2000) land use data, it has 179 acres of residential development. Scattered rural residential development is found beyond the incorporated boundaries of Malibu, and is located primarily along streams. Medium to high density development dominates the shoreline with some intermingling of low density development. Two small agricultural (non-pastoral or livestock) parcels comprising a total of about 14 acres are located relatively close to the shoreline. Approximately one-third of the land area within this subwatershed is proposed for acquisition by the SMMC.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 8 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds, this volume could be reduced to 3 million gallons.

Specific/Historical Concerns

Encinal Canyon is considered a low priority subwatershed based on the source prioritization effort described previously. Encinal has no zoned horse ranch or commercial land uses.

5.5.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1. Specifics regarding potential implementation scheduling are provided in Appendix B.

Encinal Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures					
Public Information and Participation Programs					
Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact or purchase	X			Phase 1	Phase 1
Post signs at County and City-owned trailheads designated for equestrian users to not clean out horse trailers in parking lots and to clean up horse waste			X	Phase 2	Phase 3*
Outreach at trailheads encouraging hikers to use restroom facilities			X	Phase 2	Phase 3*

*if necessary

5.6 Trancas

5.6.1 Watershed-Specific Description

General Description

Trancas Canyon is a 6580-acre subwatershed that is bounded by Encinal Canyon to the northwest and Zuma to the southeast. Per SCAG (2000) land use data, it has 635 acres of residential development. Nearly 15 percent of the Trancas subwatershed is comprised of developed land uses. A mixture of land uses, including medium to high and low density residential, mixed urban, educational, commercial, and rural residential, is found in the western portion of the subwatershed. The middle region of the subwatershed is virtually undeveloped, whereas the upper portion has a scattering of land uses, including rural residential, golf course, governmental, and agricultural. Approximately 26 acres of land within the northeastern section of the subwatershed is classified as cropland and pasture. There are 3 mapped horse ranches within the subwatershed, with one of the ranches located relatively close to the shoreline. Nearly half of the shoreline is comprised of a beach park. Relatively small-sized parcels owned by the proposed for ownership by the SMMC are scattered throughout the subwatershed. Trancas has some land uses indicating a potential reuse opportunity, but the location of these potential opportunities did not appear to be feasible for this activity.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 36 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds, this volume could be reduced to 13 million gallons. For a subwatershed of this size, additional hydrologic studies are recommended prior to feasibility-level designs.

Specific/Historical Concerns

Trancas Canyon is considered a low priority subwatershed. Monitoring in the critical TMDL year did not show excessive exceedance days, and the source prioritization effort did not conclude that it was a high priority subwatershed.

5.6.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1. Specifics regarding potential implementation scheduling are provided in Appendix B.

Trancas Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures					
Public Information and Participation Programs					
Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact or purchase	X			Phase 1	Phase 1

5.7 Zuma

5.7.1 Watershed-Specific Description

General Description

Zuma Canyon is a 6290-acre subwatershed that is bounded by Trancas Canyon to the northwest and Ramirez to the southeast. It has 796 acres of residential development (13 percent of the total subwatershed). Developed land (including commercial, and mixed urban) comprises about 18 percent of the Zuma subwatershed, making Zuma subwatershed the third most developed subwatershed within the project area. It has the second highest proportion of commercial development. Low density residential development scattered with commercial, agricultural, horse ranch, and medium to high density residential development comprises the western portion of the subwatershed. Development is also found in the far upper portion of the subwatershed and is mostly characterized by rural residential and agricultural land uses. There are seven mapped horse ranches in this subwatershed, with two of the ranches located relatively close to the shoreline. A few, small parcels proposed for ownership by the SMMC are found in the mid- to upper regions of the subwatershed. A large proportion of the shoreline is comprised of a beach park (Zuma Beach). Based on the October 2004 field reconnaissance of the CSMP monitoring site, there are a number of restaurants and food facilities adjacent to and directly on Zuma Beach. In addition, several public restrooms were identified on Zuma Beach.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 33 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds, this volume could be reduced to 12 million gallons. For a subwatershed of this size, additional hydrologic studies are recommended prior to feasibility-level designs.

Specific/Historical Concerns

Zuma Canyon is considered a low priority subwatershed. Monitoring in the critical TMDL year did not show excessive exceedance days, and the source prioritization effort did not conclude that it was a high priority subwatershed.

5.7.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1. Specifics regarding potential implementation scheduling are provided in Appendix B.

Zuma Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures					
Public Information and Participation Programs					
Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact or purchase	X			Phase 1	Phase 1
Locate areas with corralled animals and educate property owners on bacteria TMDLs		X		Phase 2	Phase 3
Identify horse stables in the region and implement pilot program		X		Phase 2	Phase 3
Post signs at County and City-owned trailheads designated for equestrian users to not clean out horse trailers in parking lots and to clean up horse waste			X	Phase 2	Phase 3*
Outreach at trailheads encouraging hikers to use restroom facilities			X	Phase 2	Phase 3*
Provide septic system (OWTS) pumpers and customers with septic system guides.	X			Phase 1	Phase 2
Increase coordination between agencies and environmental organizations in preparing outreach materials	X			Phase 1	Phase 1
Industrial/Commercial Facilities Control Programs					
Provide an outreach program for all commercial facilities with corralled animals, including equestrian centers			X	Phase 2	Phase 3*
Provide for regular BMP inspections for restaurants	X			Phase 1	Phase 1
Increase awareness of BMPs in restaurants by establishing a restaurant reward and recognition program		X		Phase 2	Phase 3
Conduct industry specific workshops	X			Phase 1	Phase 1
Investigate the possibility of increasing frequency of trash collection at restaurants	X			Phase 1	Phase 2
Development Planning and Construction Program					
Further emphasize applicable existing BMPs in development planning and construction programs	X			Phase 2	Phase 2
Public Agency Activity Control Program					
Establish guidelines for optimizing frequency of cleaning cycles for drainage facilities	X			Phase 1	Phase 1
Caltrans-Malibu Joint Agency Activities			X	Phase 1	Phases 1 & 2
Structural Measures					
On-Site Options					
a) Cisterns			X	Phase 3	Phase 4*
b) Storage and Reuse			X	Phase 3	Phase 4*
c) Small Scale Infiltration			X	Phase 3	Phase 4*
d) On-Site Wastewater			X	Phase 3	Phase 4*

*if necessary

5.8 Ramirez

5.8.1 Watershed-Specific Description

General Description

Ramirez Canyon is a 3350-acre subwatershed that is bounded by Zuma Canyon to the north and Escondido to the southeast. It has 318 acres of residential development, making Ramirez the most developed subwatershed within the project area, with about 27 percent of its land area characterized by non-open space uses. Nearly all of the development is within the lower portion of the subwatershed. Numerous land uses are represented in the developed portion of the subwatershed. Low density residential development comprises the greatest proportion of the developed land uses. Commercial land is located away from the shoreline. There is a 6-acre horse ranch located fairly close to the shoreline. The eastern portion of the subwatershed is planned for ownership by the SMMC.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 21 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds, this volume could be reduced to 8 million gallons. For a subwatershed of this size, additional hydrologic studies are recommended prior to feasibility-level designs.

Specific/Historical Concerns

Ramirez Canyon is considered a high priority subwatershed. Monitoring in the critical TMDL year showed excessive exceedance days, and the source prioritization effort confirmed that it was a high priority subwatershed.

5.8.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1. Specifics regarding potential implementation scheduling are provided in Appendix B.

Ramirez Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures

5.8.3 Description of Potential Pilot Project

The following table describes a potential pilot project for this subwatershed. It includes a project target location, treatment measure, and preliminary budget estimate. As previously stated it is expected that features related to this pilot project may change.

Project Name	Paradise Cove Pretreatment and System Upgrade
Jurisdictional Lead	City of Malibu/County of Los Angeles
Project Description/Benefit	Provide pre-treatment pollutant removal and storage capacity to increase the functional capacity of existing bacteria treatment system and evaluate the potential for system upgrade. Potential significant improvements in treatment performance
Regional, Sub-Regional, or On-Site	Sub-Regional
Subwatershed and basis for selection	Ramirez Subwatershed High Priority based on Source Prioritization and TMDL exceedance days in critical year
Integrated Project Element	Multiple Pollutants
Candidate Locations	Storage facilities adjacent to or upstream of existing Clear Creek System. Approximate land required (note storage can be covered at additional expense): 1 to 2 acres
Candidate Target Volume	Drainage is 60% of total watershed (estimated) and utilizing lower volume estimate, and Potential treatment of 50% of volume Required operational storage is 2.4 MG (approx 7.4 acre-feet).

Permitting/ Environmental Issues	Potential private land ownership issues. This stipulation makes the feasibility of the proposed pilot project somewhat in question. Therefore the pilot project should be considered "conditional" of resolution of right-of-way issues. Large operational storage required
Budgetary Estimates	To be determined

5.9 Escondido

5.9.1 Watershed-Specific Description

General Description

Escondido Canyon is a 2300-acre subwatershed that is bounded by Ramirez Canyon to the northwest and Latigo to the southeast. It has 318 acres of residential development. Rural residential development is found scattered throughout the subwatershed. Medium to high density residential development is found along the shoreline and low density residential development is found just east of the shoreline. About a third of the land area is within SMMC lands. About 43 acres of mapped horse ranches (representing about 2 percent of the subwatershed) are found fairly close to the shoreline. The proportion of horse ranches in this subwatershed is the highest within the project area. There is no coastal, public access from the Pacific Coast Highway (Route 1) to Escondido Beach; access is only via private properties and through two blocked gates.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 9 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds this volume could be reduced to 3 million gallons.

Specific/Historical Concerns

Escondido Canyon is considered a medium to high priority subwatershed. There was no monitoring in the critical TMDL year, but the source prioritization effort concluded that it was medium to high priority.

5.9.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1. Specifics regarding potential implementation scheduling are provided in Appendix B.

Escondido Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures					
Public Information and Participation Programs					
Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact or purchase	X			Phase 1	Phase 1

*if necessary

5.10 Latigo

5.10.1 Watershed-Specific Description

General Description

Latigo Canyon is the second smallest subwatershed in the J1/4 area, and is an 824-acre subwatershed that is bounded by Escondido Canyon to the northwest and Solstice to the southeast. Latigo has 80 acres of residential development, a substantial portion near the shoreline. Developed land within the Latigo subwatershed is characterized mostly by rural residential development in the central area of the subwatershed along the rim of Latigo Canyon and low and medium to high density residential development near the shoreline. Managed lands of the SMMC are found along the eastern border of the subwatershed.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 4 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds this volume could be reduced to 1 million gallons.

Specific/Historical Concerns

Latigo Canyon is considered a high priority subwatershed based on monitoring of exceedance days in the critical TMDL year.

5.10.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1. Specifics regarding potential implementation scheduling are provided in Appendix B.

Latigo Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures					
Public Information and Participation Programs					
Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact or purchase	X			Phase 1	Phase 1

*if necessary

5.10.3 Description of Potential Pilot Project

The following table describes a potential pilot project for this subwatershed. It includes a project target location, treatment measure, and preliminary budget estimate. As previously stated it is expected that features related to this pilot project may change.

Project Name	Latigo Shores Subsurface Flow Wetland
Jurisdictional Lead	County of Los Angeles
Project Description/Benefit	Utilize vacant County Beaches and Harbors land, east of Tivoli Condominiums and south of PCH, for treatment of creek flows through subsurface flow wetland system. Project requires pretreatment screens for gross solids removal. Diversion of flows and temporary storage. Assume wetland system can be fed during dry season with nuisance flows from creek or treated septic leach sources. System to be encase in concrete box to mitigate slope stability issues.
Regional, Sub-Regional, or On-Site	Subregional
Subwatershed and basis for selection	Latigo High Priority based on TMDL exceedance days in critical year
Integrated Project Element	Multiple Pollutants and potential integrated water resources (treated septic leach source)
Candidate Locations	Adjacent to outlet in vacant parcel. Alternative site may be privately owned land north of PCH and west of creek. Approximate land required (note storage can be covered at additional expense): 1 acre
Candidate Target Volume	90% of area (estimated) 50% of reduced volume assumed, or Operational storage = 0.45 MGD
Permitting/ Environmental Issues	Groundwater/septic leach water usage Potential private land ownership issues for access: This stipulation makes the feasibility of the proposed pilot project somewhat in question. Therefore the pilot project should be considered "conditional" of resolution of right-of-way issues. Engineering issue: Potential slope stability issues must be addressed and investigated as part of preliminary design process.

Budgetary Estimates	To be determined
Photo/Map: 	 Copyright © 2002-2004 Kenneth & Gabrielle Adelman, California Coastal Records Project, www.californiacoastline.org
Photo: Candidate Site	

5.11 Solstice

5.11.1 Watershed-Specific Description

General Description

Solstice Canyon is a 2840-acre subwatershed that is bounded by Latigo Canyon to the northwest and Corral Canyon to the southeast. Development within Solstice subwatershed is limited to rural residential and horse ranch uses and a small commercial area near the coastline. Much of this subwatershed is proposed for ownership by SMMC. A field reconnaissance conducted in October 2004 noted that the commercial area on the east side of Pacific Coast Highway at Solstice Canyon Road is comprised of restaurants and a gas station.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 35 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds this volume could be reduced to 13 million gallons.

Specific/Historical Concerns

Solstice Canyon is considered a low priority subwatershed based on the source prioritization effort described previously

5.11.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1. Specifics regarding potential implementation scheduling are provided in Appendix B.

Solstice Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures					
Public Information and Participation Programs					
Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact or purchase	X			Phase 1	Phase 1
Locate areas with corralled animals and educate property owners on bacteria TMDLs		X		Phase 2	Phase 3
Post signs at County and City-owned trailheads designated for equestrian users to not clean out horse trailers in parking lots and to clean up horse waste			X	Phase 2	Phase 3*
Outreach at trailheads encouraging hikers to use restroom facilities			X	Phase 2	Phase 3*
Provide septic system (OWTS) pumpers and customers with septic system guides.			X	Phase 2	Phase 3*
Increase coordination between agencies and environmental organizations in preparing outreach materials	X			Phase 1	Phase 1
Industrial/Commercial Facilities Control Programs

5.12 Corral

5.12.1 Watershed-Specific Description

General Description

Corral Canyon is a 4,300-acre subwatershed that is bounded by Solstice Canyon to the northwest and Malibu Creek to the southeast. It includes 244 acres of residential development. Corral subwatershed hosts the approximate 180-acre campus of Pepperdine University which is located in the southwestern area of the subwatershed fairly close to the shoreline. Except for a concentrated area of rural residential development in the east, most of the developed area in the subwatershed is near the shoreline and surrounding the university. Most of the residential development near the shoreline is medium to high density. This subwatershed has the third highest proportion of commercial development within the project area, and by far the highest proportion of land designated as mixed urban/construction. There is a golf course located just east of Malibu Colony near the shoreline.

A significant drain within Corral is Marie Creek, which is located in the eastern portion of the subwatershed. Within yards of Marie Creek is an accessible creek that opens directly to the ocean. In the vicinity of this creek is a residential area with homes along the beach.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 35 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds this volume could be reduced to 13 million gallons. For a subwatershed of this size, additional hydrologic studies are recommended prior to feasibility-level designs.

Specific/Historical Concerns

Corral Canyon is considered a high priority subwatershed based on the source prioritization effort. While it also has a theoretical demand for some water reuse, there appears to be sufficient supply.

5.12.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1.

Corral Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures

- Capture, Store, Treat, and Discharge			X	Phase 3	Phase 4*
- Capture, Store, Treat, and Reuse		X		Phase 1	Phase 3*
Treatment Options					
- Traditional Treatment/Small Package			X	Phase 3	Phase 4*
- Storm Water Filtration			X	Phase 3	Phase 4*
- Advanced Oxidation			X	Phase 3	Phase 4*
- Peracetic Acid/bactericides			X	Phase 3	Phase 4*

*if necessary

5.12.3 Description of Potential Pilot Project

The following table describes a potential pilot project for this subwatershed. It includes a project target location, treatment measure, and preliminary budget estimate. As previously stated it is expected that features related to this pilot project may change.

Project Name	Marie Canyon Drain Retrofit
Jurisdictional Lead	County of Los Angeles DPW
Project Description/Benefit	Provide upstream storage and diversion, with peracetic acid treatment and discharge back in to Marie Canyon Drain
Regional, Sub-Regional, or On-Site	Sub-Regional
Subwatershed and basis for selection	Corral High Priority based on Source Prioritization
Integrated Project Element	Multiple Pollutant removal
Candidate Locations	Potential reduced storage upstream of PCH
Candidate Target Volume	Assume Marie Canyon is 15% of Corral Drainage, Treat 50% of lowered target volume; Estimated required operational storage = 1 MG Approximate land required (note storage may be covered at additional expense): up to 1 acre
Permitting/ Environmental Issues	NPDES permitting with biocide addition Right of way Potential land acquisition upstream of PCH
Budgetary Estimates	To be determined

Photo: Upstream of Culvert	

Photo: Discharge Point	

5.13 Carbon

5.13.1 Watershed-Specific Description

General Description

Carbon Canyon is a 2310-acre subwatershed that is bounded by Malibu Creek to the northwest and Las Flores to the southeast. It has 315 acres of residential development (14 percent of the total area). This subwatershed has the highest proportion of commercial development (35 acres) of any of the J1/4 subwatersheds, and all of this development is near the shoreline along the east side of the Pacific Coast Highway. Rural residential development is found scattered within the eastern and western portions of the subwatershed. Medium to high density residential development is located on the west side of PCH, and low density residential development is found just east of PCH. A small beach park is found along the western shoreline. Carbon subwatershed is one of the most developed subwatersheds within the project area. Residential development is found near the CSMP monitoring station located in the Sweetwater Canyon area.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 16 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds this volume could be reduced to 6 million gallons.

Specific/Historical Concerns

Carbon Canyon is considered a medium priority subwatershed based on the source prioritization effort described previously

5.13.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1. Specifics regarding potential implementation scheduling are provided in Appendix B.

Carbon Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures					
Public Information and Participation Programs

5.14 Las Flores

5.14.1 Watershed-Specific Description

General Description

Las Flores Canyon is a 2921-acre subwatershed that is bounded by Carbon Canyon to the northwest and Piedra Gorda to the southeast. It has 282 acres of residential development. Within this subwatershed, medium to high density development flanks the shoreline along with commercial development. High density development is also found along the lower eastern and western boundaries of the subwatershed. Scattered low density development is found within the lower subwatershed; whereas, rural residential development is found scattered within the central and eastern areas of the subwatershed. A large proportion of the land is comprised of SMMC lands.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 17 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds this volume could be reduced to 6 million gallons.

Specific/Historical Concerns

The City of Malibu is currently engaged in restorations on the creek. These efforts have the potential to not only benefit riparian habitat and fluvial geomorphologic conditions, but also water quality.

Las Flores Canyon is considered a high priority subwatershed based on the critical year exceedances listed in the TMDL.

5.14.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1.

Las Flores Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures					
Public Information and Participation Programs					
Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact or purchase	X			Phase 1	Phase 1
Locate areas with corralled animals and educate property owners on bacteria TMDLs		X		Phase 2	Phase 3
Post signs at County and City-owned trailheads designated for equestrian users to not clean out horse trailers in parking lots and to clean up horse waste			X	Phase 2	Phase 3*
Outreach at trailheads encouraging hikers to use restroom facilities			X	Phase 2	Phase 3*
Provide septic system (OWTS) pumpers and customers with septic system guides.	X			Phase 1	Phase 2
Increase coordination between agencies and environmental organizations in preparing outreach materials	X			Phase 1	Phase 1
Industrial/Commercial Facilities Control Programs					
Provide an outreach program for all commercial facilities with corralled animals, including equestrian centers			X	Phase 2	Phase 3*
Provide for regular BMP inspections for restaurants	X			Phase 1	Phase 1

5.14.3 Description of Potential Pilot Project

The following table describes a potential pilot project for this subwatershed. It includes a project target location, treatment measure, and preliminary budget estimate. As previously stated it is expected that features related to this pilot project may change.

The potential creek restoration pilot project will improve riparian function and water quality through various instream habitat enhancement elements. Ancillary benefits include the reduction of flooding impacts, property damage or bank failure; improvement of creek form and function; and protection of fish and other wildlife. Public awareness, education and participation will be critical to the success of the pilot project and will help the water quality public education elements, as more people would be encouraged to value the restored natural environment. The physical attributes of Las Flores Creek will provide insight to potential solutions applicable to other sites. Hence, this potential pilot project can be used as a model for restoration and structural BMP projects.

Project Name	Las Flores Canyon Restoration and Water Quality Improvements
Jurisdictional Lead	City of Malibu
Project Description/Benefit	Restoration of Las Flores creek and acquisition of adjacent properties for biofiltration and infiltration prior to discharge to the creek.
Regional, Sub-Regional, or On-Site	Regional and sub-regional
Subwatershed and basis for selection	Las Flores High Priority based on TMDL exceedance days in critical year
Integrated Project Element	Multiple pollutants, biodiversity and habitat enhancement
Candidate Locations	Las Flores creek upstream of PCH
Candidate Target Volume	80-90% of watershed area 5 MGD total, smaller volumes in tributary drains
Permitting/ Environmental Issues	CDFG 1600 USACE 404 RWQCB 401
Budgetary Estimates	To be determined

5.15 Piedra Gorda

5.15.1 Watershed-Specific Description

General Description

Piedra Gorda is a 629-acre subwatershed that is bounded by Las Flores Canyon to the northwest and Pena to the southeast. About 80 percent of the land within this subwatershed is designated as open space, with the majority of that area proposed for ownership by SMMC. Even with this high percentage of undeveloped land, this subwatershed is threatened by contamination from development given that all remaining lands within the subwatershed are characterized by medium to high residential use, and these developed lands are located near the shoreline.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 3 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds this volume could be reduced to 1 million gallons.

Specific/Historical Concerns

Piedra Gorda Canyon is considered a high priority subwatershed based on the critical year exceedances listed in the TMDL.

5.15.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1.

Piedra Gorda Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures					
Public Information and Participation Programs					
Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact or purchase	X			Phase 1	Phase 1
Post signs at County and City-owned trailheads designated for equestrian users to not clean out horse trailers in parking lots and to clean up horse waste			X	Phase 2	Phase 3*
Outreach at trailheads encouraging hikers to use restroom facilities			X	Phase 2	Phase 3*
Provide septic system (OWTS) pumpers and customers with septic system guides.	X			Phase 1	Phase 2
Increase coordination between agencies and environmental organizations in preparing outreach materials	X			Phase 1	Phase 1
Development Planning and Construction Program					
Further emphasize applicable existing BMPs in development planning and construction programs	X			Phase 2	Phase 2
Public Agency Activity Control Program					
Establish guidelines for optimizing frequency of cleaning cycles for drainage facilities	X			Phase 1	Phase 1
Caltrans-Malibu Joint Agency Activities			X	Phase 1	Phases 1 & 2
Structural Measures

c) Small Scale Infiltration	X			Phase 1 or 2	Phase 3
d) On-site Wastewater			X	Phase 3	Phase 4*

*if necessary

5.16 Pena

5.16.1 Watershed-Specific Description

General Description

Pena Canyon is the smallest subwatershed area within the J1/4 jurisdictions, and is a 625-acre subwatershed that is bounded by Piedra Gorda to the northwest and Tuna to the southeast. About 96 percent of this subwatershed is represented by open space lands, and much of this area is proposed for acquisition by SMMC. Medium to high density residential development and beach park are the only other uses within the subwatershed and both of these uses are along the shoreline.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 3 million gallons, though based on detailed hydrologic studies in adjacent subwatershed, this volume could be reduced to 1 million gallons.

Specific/Historical Concerns

Pena is considered a low priority subwatershed based on the source prioritization effort described previously

5.16.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1. Specifics regarding potential implementation scheduling are provided in Appendix B.

Pena Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures					
Public Information and Participation Programs					
Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact or purchase	X			Phase 1	Phase 1

*if necessary

5.17 Tuna

5.17.1 Watershed-Specific Description

General Description

Tuna Canyon is a 1007-acre subwatershed that is bounded by Pena Canyon to the northwest and Topanga Canyon to the east. It has 39 acres of residential development. This subwatershed is virtually undeveloped with the exception of a few scattered areas of rural residential development in the east and medium to high density and commercial development along the shoreline. Nearly the entire subwatershed is proposed for acquisition by SMMC.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 4 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds this volume could be reduced to 1 million gallons.

Specific/Historical Concerns

Tuna Canyon is considered a low priority subwatershed based on the source prioritization effort described previously

5.17.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1. Specifics regarding potential implementation scheduling are provided in Appendix B.

5.18 Topanga

5.18.1 Watershed-Specific Description

General Description

Topanga Canyon is the largest subwatershed within the J1/4 area. It is a 12,611-acre subwatershed that is bounded by Tuna Canyon to the northwest and represents the eastern boundary of the J1/4 jurisdictional area. Nearly every category of land use is represented within its borders. There is little development near the shoreline other than a beach park, a small commercial area, and a small (2-acre) industrial site. The central and eastern areas of the subwatershed are marked by rural residential, commercial, public, horse ranch, educational, and mixed urban/construction land uses. This subwatershed has a relatively high concentration of horse ranches; however these ranches are all in the upper subwatershed. In the CSMP monitoring site vicinity, the Pacific Coast Highway, at the corner of Topanga Creek Boulevard, is flanked by a number of restaurants and shops. Within 2 miles up from the Pacific Coast Highway, Topanga Creek Boulevard is primarily surrounded by residential development.

Estimate of Potential Total Runoff to Be Managed

Hypothetical target 24-hour operational storage and treatment volumes were developed should structural measures be eventually required within the subwatershed. The upper limit of this volume is 65 million gallons, though based on detailed hydrologic studies in adjacent subwatersheds this volume could be reduced to less than 24 million gallons. For a subwatershed of this size, additional hydrologic studies are recommended prior to feasibility-level designs.

Specific/Historical Concerns

Topanga Canyon is the largest and most complex subwatershed in the study area. It is considered a medium priority subwatershed based on both the TMDL exceedance day monitoring for the critical year and the source prioritization effort described previously.

5.18.2 Watershed-Specific Plan of Activities

The following matrix summarizes the activities specifically designated for this subwatershed. The basis for activities selected in this matrix is primarily the subwatershed priority status. Descriptions of general activities described below were provided in Section 5.1.1. Specifics regarding potential implementation scheduling are provided in Appendix B.

Topanga Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*

5.19 Integrated Water Resources Plan Elements

The Implementation Plan was developed consistent with an Integrated Water Resources Approach (IWRA) on the basis of a) multiple pollutants removed and b) integrated water resources benefits. For each recommended BMP, both the target pollutants and water resources benefits are listed. For discussion purposes, target pollutants are grouped in the following families:

- Bacteria
- Nutrients
- Metals
- Organics
- Pathogens
- Trash

Integrated water resources benefits listed include:

- Conservation
- Reuse/Recycling
- Habitat
- Geomorphology (Hydromodification)
- Hydrology (Stream)
- Flood Control

5.20 Performance Evaluation

Assessing the effectiveness of the management measures is also critical to tracking progress toward meeting full TMDL compliance. Two basic approaches, discussed in Section 3.6 are presented in the Final Plan: 1) a Presumptive Compliance Approach and 2) a Targeted Monitoring-Based Approach.

The Presumptive Compliance Approach (PCA) assumes that the implementation of structural and non-structural BMPs will lead directly to reductions of exceedance days and attempts to quantify this relationship.

The focused and targeted monitoring-based approach (TMBA) adopts some measures of presumptive compliance but incorporates monitoring data and attempts to normalize and extrapolate this monitoring data throughout the region. TMB results are presented in Interim Compliance Reports.

Other performance metrics include informational surveys, tracking of volumes of pollutants removed, and a comparison of expenditures relative to full implementation budgets.

The table below describes, for each recommended BMP, the performance evaluation measure and methods to be implemented to gage progress toward meeting TMDL targets.

Summary of Best Management Practices, Integrated Water Resources Approach, and Performance Evaluation Measures

Activity Number	BMPs and Activities	Water Quality Benefits: Multiple Pollutants	Additional Integrated Water Resources Benefits	Performance Evaluation Measure and Method
	TMDL Monitoring and Studies	B = Bacteria N = Nutrients M = Metals O = Organics P = Pathogens T = Trash	CONS = water conserv RE = reuse/recycling HAB = habitat GEO = geomorphology HYD = hydrology (stream) FLD = flood & volume

5.21 Target Exceedance Day Reductions

It is desired to provide a basis from which measured data can be compared for the purposes of documenting compliance milestones. The following table presents target reductions by phase and subwatershed of exceedance days based on the 90th percentile condition. It should be emphasized that this is a prediction based on the implementation approach described previously and very limited available data. It is presented for the purposes of quantifying potential improvements on a subwatershed basis. As previously discussed, these reductions are provided assuming the daily sampling protocol, and should weekly sampling be conducted appropriate scaling should be applied.

Table of Target Exceedance Days Reductions

Station	Description	90th Percentile Conditions	Allowable Exceedance Days	Total Required Day Reduction	Implementation Schedule			
					10%	25%	50%	100%
DHS010	Leo Carillo	17	17	0	0	0	0	0
DHS009	Nicholas	14	14	0	0	0	1	1
DHS010a	Broad Bch	15	15	0	0	0	1	1

Minimum				**60**	**6**	**13**	**30**	**60**

6. Program Cost and Budget

6.1 Introduction

The following discussion on potential program budgets should be considered for preliminary programmatic budgetary planning only. The budget analysis does not consider those items that are to be considered, but not committed to or implemented on a pilot scale. In addition, specific allocation of budgets between jurisdictional agencies is not addressed in this Plan. Budgets are not being provided with the Draft Implementation Plan submittal, but the budgeting methodology is as follows.

Planning-level (order-of-magnitude) budget and staff resource (Full Time Equivalent, or FTE) estimates are estimated to the extent possible based on the preliminary concepts for projects and programs contained in Section 5. The estimates are intended to provide decision-makers with an order-of-magnitude sense of what expenditures and staff resources may be anticipated over the proposed 18-year implementation schedule. Given the iterative and adaptive nature of the implementation plan, and the many uncertainties associated with many of the programs and projects, the forecast for later phases are relatively speculative.

Budget estimates encompass in three broad categories:

- "Initial" budgets, for start up of non-structural programs, and planning, permitting, design and construction of structural measure;
- "Annual Operations and Maintenance (O&M)" budgets for ongoing expenditures of direct costs for conducting non-structural programs, or operating pilot or structural projects; and
- Annual full time equivalents (FTEs)" for potential staff resources for carrying out the program.

Some key assumptions made to develop the budget estimates for the committed and pilot projects are summarized below.

6.1.1 Non-Structural Programs (Commit and Pilot)

Budget estimates for committed non-structural programs include start-up or first year costs which may include a combination of staff and/or consultant labor, materials and other direct costs, workshops, etc. After the initial start-up year or period, a lower level of annual O&M budget, and an annual FTE level was estimated. It is assumed that all of the committed non-structural programs would continue at this level throughout the full implementation period.

Budget estimates for non-structural pilot programs include similar considerations as the committed programs during the pilot period. It is also assumed that all of the pilot programs with on exception as noted would prove sufficiently effective and be well enough defined to warrant continuing implementation, and annual O&M budgets and FTE's were estimated to continue at this level throughout the full implementation period. The one exception is with respect to increasing frequency of trash collection as restaurants. Initial budgets are shown to conduct the study, but the outcome cannot be predicted, and would not necessarily lead to increased costs to the local agencies, so no on-going budgets are shown.

6.1.2 On-Site Structural Solutions (Commit and Pilot)

Budgets for the implementation for on-site solutions assume that construction funding would be provided to assist those homeowners, commercial property owners willing to install and maintain accepted on-site measures including a potential mix of cisterns, on-site storage and reuse projects, and small scale infiltration projects. The budgets include planning and design, construction and long-term O&M plus a limited on-going staff effort (FTEs) to oversee, monitor and track the program implementation.

6.1.3 Regional and Sub-Regional Structural Solutions (Pilot)

The budget for implementing structural pilot projects was taken from the estimates developed and presented in Section 5. The initial budgets include the planning, engineering and construction, annual O&M are as shown in Section 5. For budgeting purposes, it is assumed that all four pilot projects will prove to be feasible and effective in helping reduce exceedances and will remain in place after the pilot program phase is over. Therefore, the annual O&M is carried forward throughout the remainder of the 18 year implementation period.

While it is possible that additional regional structural measures may be needed after assessing program results and progress after the first three phases, or, conversely, the one or more of the initial pilot projects may not be effective or necessary to continue. The budget estimate does not speculate on additional or expanded program elements beyond Phase 3.

6.1.4 Monitoring Budgets

Estimated costs to perform monitoring activities and special studies identified in Section 4 are also a key part of the cost estimate.

6.2 Total Budget by Year

Annual budgets will estimate capital, ongoing and FTE costs, beginning with the initial implementation period of FY 2005-06 and continuing through the end of the implementation period of 18 years. Initial budgets for various programs and projects will be spread over the implementation period, and annual O&M budgets and FTE's will be shown every year after the initial phase is complete. Total budgets (initial or O&M) and FTE's of each program/project will be totaled for each fiscal year throughout the implementation period, and depicted graphically.

7. Conclusions

The Implementation Plan discussed here presents an iterative, adaptive, and integrated approach to TMDL implementation for the North Santa Monica Bay Beaches J1/4 areas. This approach requires a review and emphasis on multiple beneficial uses and the targeting of multiple pollutants. Philosophically, the implementation approach balances of low risk (high cost), low cost (higher potential for exceedances), and high beneficial reuse to determine site specific implementation.

The following activities were conducted during the development of the Implementation Plan:

- Estimating and Establishing Baseline Conditions
- Developing a Menu of Potential Activities
- Identifying Implementation Considerations
- Selecting and Prioritizing
- Planning and Implementation during the next 18 Years

In order to most-effectively implement activities, different levels of commitment were established for this plan. These levels were:

- "commit"—the Agencies commit to this activity

- "pilot"—the Agencies are willing to commit to a pilot study to determine whether the proposed activity the preliminary design parameters are appropriate.

- "consider" – the Agencies will consider this effort, depending on the results of committed activities.

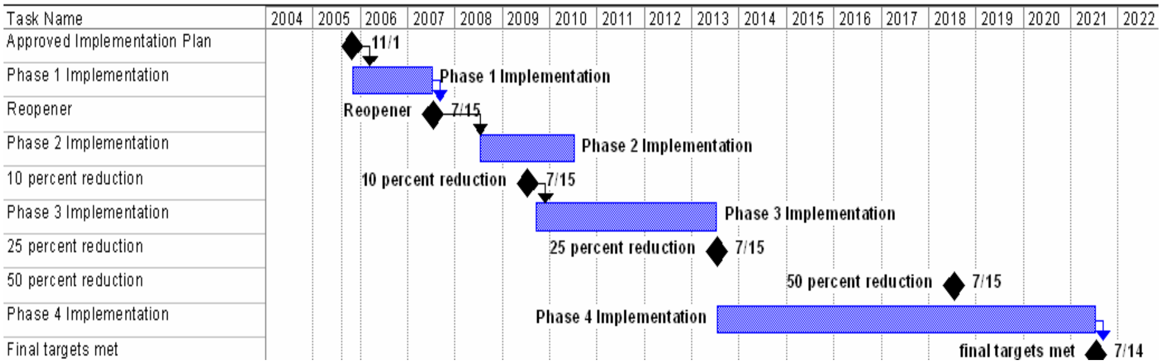
In order to prioritize subwatersheds, results of a source prioritization effort were combined with monitoring data from the TMDL-defined "critical year". This analysis resulted in the following categories:

- High Priority subwatersheds: Latigo, Corral, Las Flores, Piedra Gorda, and Ramirez
- Medium Priority subwatersheds: Carbon, Los Alisos, Topanga, and Escondido
- Low Priority subwatersheds: Nicholas, Encinal, Trancas, Zuma, Solstice, Pena, and Tuna

These priorities, in conjunction with subwatershed specific characteristics and the desired risk-cost-beneficial reuse relationship, contributed to the development of a unique suite of activities for each subwatershed.

The Implementation Plan was divided into four phases of activities. The activities consisted of implementation activities, as well as monitoring and additional studies that could be used to provide better information for future activities. To provide useful information, the additional studies will require extended development and implementation periods. Upon completion of these studies, it would be desirable to confirm, or adjust if necessary, the direction and requirements of the Implementation Plan. As such, the County of Los Angeles and J1/4 Agencies proposed the addition of appropriately timed re-evaluation milestones (re-openers). Implementation activities, suggested re-opener, and implementation milestones are illustrated below:

Santa Monica Bay Beaches Bacterial TMDL – J1/4



Implementation Plan Phasing

The general intent of what would be accomplished under each of the phases is as follows:

- Phase I – Conduct planning and initiate all committed non-structural activities and implement selected non--structural measures; initiate pre-feasibility studies for sub-regional pilot projects; develop inter-agency agreements for structural projects, initiate planning for on-site measures; initiate monitoring, additional studies, and source identification activities. The 2007 re-opener would follow Phase I. Note that Phase I is assumed to begin in November 2005, which is the basis of the proposed schedule. Should the initiation date change, the remaining implementation deadlines may change accordingly.

- Phase II – Continue implementation of committed non-structural activities; conduct non-structural pilot programs; continue planning for on-site measures; initiate planning and construction of pilot regional structural solutions; and continue and complete monitoring and source identification studies. A re-evaluation is proposed to follow Phase II and is intended to leverage results not only from additional studies in these jurisdictional areas, but also from advances in the technical, legal, and regulatory body of knowledge.

- Phase III – Refocus and reprioritize efforts as appropriate, and continue implementation of committed non-structural activities; implement successful piloted non-structural programs; begin implementation of on-site measures; and operate and evaluate pilot regional structural solutions.

- Phase IV – Refocus and reprioritize efforts as appropriate and continue implementation of non-structural solutions; continue or expand on-site measures; and continue, modify and/or initiate regional structural solutions.

Additional studies are proposed to support management and regulatory decision-making for the 2007 re-opener, as well as proposed additional re-openers. Upon completion of the initial two years of monitoring, an evaluation will be made to determine whether microbial source tracking activities are required. Rationale for recommending such studies could include, but not be limited to, the need for further source identification; site specific, objective data development; and potential health risk assessments. This may include an evaluation of the appropriateness of the TMDL indicator constituents of concern.

Studies that would contribute to more cost-effective implementation of the bacteria TMDL, and which could be included in the J1/4 implementation effort include:

- Identification of the Most Relevant Human Health Indicators Study (2007-2009)
- Hydrology vs. Bacteria Loading Study (2005-2010)
- Bacterial Seasonal Variation Study (2005-2008)

Potential program budgets are not provided, but would eventually be considered for preliminary programmatic budgetary planning only. An initial budget analysis did not include those activities that are *considered* for implementation, but do include activities that are committed to or implemented on a *pilot* scale. In addition, specific allocation of costs between jurisdictional agencies was not addressed in this Plan.

APPENDIX A

State of California
California Regional Water Quality Control Board, Los Angeles Region

RESOLUTION NO. 2002-022
December 12, 2002

Amendment to the Water Quality Control Plan (Basin Plan) for the Los Angeles Region to Incorporate Implementation Provisions for the Region's Bacteria Objectives and to Incorporate a Wet-Weather Total Maximum Daily Load for Bacteria at Santa Monica Bay Beaches

WHEREAS, the California Regional Water Quality Control Board, Los Angeles Region, finds that:

1. The federal Clean Water Act (CWA) requires the California Regional Water Quality Control Board, Los Angeles Region (Regional Board) to develop water quality standards which include beneficial use designations and criteria to protect beneficial uses for each water body found within its region.

2. The Regional Board carries out its CWA responsibilities through California's Porter-Cologne Water Quality Control Act and establishes water quality objectives designed to protect beneficial uses contained in the Water Quality Control Plan for the Los Angeles Region (Basin Plan).

3. Section 303(d) of the CWA requires states to identify and to prepare a list of water bodies that do not meet water quality standards and then to establish load and waste load allocations, or a total maximum daily load (TMDL), for each water body that will ensure attainment of water quality standards and then to incorporate those allocations into their water quality control plans.

4. Many of the beaches along Santa Monica Bay were listed on California's 1998 section 303(d) list, due to impairments for coliform or for beach closures associated with bacteria generally. The beaches appeared on the 303(d) list because the elevated bacteria and beach closures prevented full support of the beaches' designated use for water contact recreation (REC-1).

5. A consent decree between the U.S. Environmental Protection Agency (USEPA), Heal the Bay, Inc. and BayKeeper, Inc. was approved on March 22, 1999. This court order directs the USEPA to complete TMDLs for all the Los Angeles Region's impaired waters within 13 years. A schedule was established in the consent decree for the completion of 29 TMDLs within 7 years, including completion of a TMDL to reduce bacteria at Santa Monica Bay beaches by March 2002. The remaining TMDLs will be scheduled by Regional Board staff within the 13-year period.

6. The elements of a TMDL are described in 40 CFR 130.2 and 130.7 and section 303(d) of the CWA, as well as in USEPA guidance documents (e.g., USEPA, 1991). A TMDL is defined as "the sum of the individual waste load allocations for point sources and load allocations for nonpoint sources and natural background" (40 CFR 130.2). Regulations further stipulate that TMDLs must be set at "levels necessary to attain and maintain the applicable narrative and numeric water quality standards with seasonal variations and a margin of safety that takes into account any lack of knowledge concerning the relationship between effluent limitations

and water quality" (40 CFR 130.7(c)(1)). The provisions in 40 CFR 130.7 also state that TMDLs shall take into account critical conditions for stream flow, loading and water quality parameters.

7. Upon establishment of TMDLs by the State or USEPA, the State is required to incorporate the TMDLs along with appropriate implementation measures into the State Water Quality Management Plan (40 CFR 130.6(c)(1), 130.7). The Basin Plan and applicable statewide plans serve as the State Water Quality Management Plans governing the watersheds under the jurisdiction of the Regional Board.

8. Santa Monica Bay is located in Los Angeles County, California. The proposed TMDL addresses documented bacteriological water quality impairments at 44 beaches from the Los Angeles/Ventura County line, to the northwest, to Outer Cabrillo Beach, just south of the Palos Verdes Peninsula.

9. The Regional Board is establishing the above-mentioned TMDL to preserve and enhance the water quality at Santa Monica Bay beaches and for the benefit of the 55 million beachgoers, on average, that visit these beaches each year. At stake is the health of swimmers and surfers and associated health costs as well as sizeable revenues to the local and state economy. Estimates are that visitors to Santa Monica Bay beaches spend approximately $1.7 billion annually.

10. The Regional Board's goal in establishing the above-mentioned TMDL is to reduce the risk of illness associated with swimming in marine waters contaminated with bacteria. Local and national epidemiological studies compel the conclusion that there is a causal relationship between adverse health effects, such as gastroenteritis and upper respiratory illness, and recreational water quality, as measured by bacteria indicator densities. The water quality objectives on which the TMDL numeric targets are based will ensure that the risk of illness to the public from swimming at Santa Monica Bay beaches generally will be no greater than 19 illnesses per 1,000 swimmers, which is defined by the US EPA as an "acceptable health risk"in marine recreational waters.

11. Interested persons and the public have had reasonable opportunity to participate in review of the amendment to the Basin Plan. Efforts to solicit public review and comment include staff presentations to the Santa Monica Bay Restoration Project's Bay Watershed Council and Technical Advisory Committee between May 1999 and October 2001 and creation of a Steering Committee in July 1999 to provide input on scientific and technical components of the TMDL with participation by the Southern California Coastal Water Research Project, City of Los Angeles, County of Los Angeles Department of Public Works, County Sanitation Districts of Los Angeles County, Heal the Bay, and Santa Monica Bay Restoration Project.

12. A first draft of the TMDL for bacteria at Santa Monica Bay beaches was released for public comment on November 9, 2001; an interim draft TMDL covering wet weather only was released on June 21, 2002, for discussion at a public workshop; and a public workshop on the draft Wet-Weather TMDL was held on June 27, 2002 at a regularly scheduled Regional Board meeting.

13. A final draft of the Wet-Weather TMDL along with a Notice of Hearing and Notice of Filing were published and circulated 45 days preceding Board action; Regional Board staff responded to oral and written comments received from the public; and the Regional Board

held a public hearing on September 26, 2002 to consider adoption of the Wet-Weather TMDL.

14. The Regional Board continued the item from the September 26, 2002 Board meeting to the December 12, 2002 Board meeting to give staff time to make revisions based on public comments and Board discussion at the September 26, 2002 Board meeting. Specifically, the Board wanted an implementation program that was reasonable and as short as practicable given the testimony on impairments to the REC-1 beneficial use.

15. The Regional Board recognizes that there are two broad approaches to implementing the TMDL. One approach is an integrated water resources approach that takes a holistic view of regional water resources management by integrating planning for future wastewater, storm water, recycled water, and potable water needs and systems; focuses on beneficial re-use of storm water, including groundwater infiltration, at multiple points throughout a watershed; and addresses multiple pollutants for which Santa Monica Bay or its watershed are listed on the CWA section 303(d) List as impaired. The other approach is a non-integrated water resources approach.

    Some responsible jurisdictions and agencies have indicated a preference to take an integrated water resources approach to realize the benefits of re-using storm water to preserve local groundwater resources and to reduce reliance on imported water. The Regional Board recognizes that an integrated water resources approach not only provides water quality benefits to the people of the Los Angeles Region, but also recognizes that the responsible jurisdictions implementing this TMDL can serve a variety of public purposes by adopting an integrated water resources approach. An integrated water resources approach will address multiple pollutants, and as a result, responsible jurisdictions can recognize cost-savings because capital expenses for the integrated approach will implement several TMDLs that address pollutants in storm water. In addition, jurisdictions serve multiple roles for their citizenry, and an integrated approach allows for the incorporation and enhancement of other public goals such as water supply, recycling and storage; environmental justice; parks, greenways and open space; and active and passive recreational and environmental education opportunities.

    The Regional Board acknowledges that a longer timeframe is reasonable for an integrated water resources approach because it requires more complicated planning and implementation such as identifying markets for the water and efficiently siting storage and transmission infrastructure within the watershed(s) to realize the multiple benefits of such an approach.

16. Therefore, after considering testimony, the Regional Board directed staff to adjust the implementation provisions of the TMDL to allow for a longer implementation schedule (up to 18 years) only when the responsible jurisdictions and agencies clearly demonstrate their intention to undertake an integrated water resources approach and justify the need for a longer implementation schedule. In contrast, testimony indicated that a shorter implementation schedule (up to 10 years) is reasonable and practicable for non-integrated approaches because the level of planning is not as complicated.

17. A revised draft of the Basin Plan amendment and Tentative Resolution were circulated 45 days preceding Board action. Regional Board staff responded to oral and written comments received from the public on the revised draft. The Regional Board held a second public hearing on December 12, 2002 to consider adoption of the Wet-Weather TMDL.

18. On October 25, 2001, the Regional Board adopted Resolution 2001-018 establishing revised bacteriological water quality objectives for the Water Contact Recreation (REC-1) beneficial use, and the TMDL is intended to accompany and to implement the revised water quality objectives. The State Water Resources Control Board approved the Regional Board's Basin Plan amendment on July 18, 2002 in State Board Resolution 2002-0142, the Office of Administrative Law approved it on September 19, 2002 in OAL File No. 02-0807-01-S, and the US EPA approved it on September 25, 2002.

19. Under certain circumstances and through the TMDL development process, the Regional Board proposes to implement the aforementioned revised bacteria objectives using either a 'reference system/anti-degradation approach' or a 'natural sources exclusion approach.' As required by the CWA and Porter-Cologne Water Quality Control Act, the Basin Plan includes beneficial uses of waters, water quality objectives to protect those uses, an anti-degradation policy, collectively referred to as water quality standards, and other plans and policies necessary to implement water quality standards. This TMDL and its associated waste load allocations, which will be incorporated into relevant permits, are the vehicles for implementation of the bacteria standards as required under Water Code section 13242.

20. Both the 'reference system/anti-degradation approach' and the 'natural sources exclusion approach' recognize that there are natural sources of bacteria that may cause or contribute to exceedances of the single sample objectives.

21. The Regional Board's intent in implementing the bacteria objectives using a 'reference system/anti-degradation approach' is to ensure that bacteriological water quality is at least as good as that of a reference site and that no degradation of existing bacteriological water quality is permitted where existing bacteriological water quality is better than that of a reference site. The Regional Board's intent in implementing the bacteria objectives using a 'natural sources exclusion approach' is to ensure that all anthropogenic sources of bacteria are controlled such that they do not cause an exceedance of the single sample objectives. These approaches are consistent with state and federal anti-degradation policies (State Board Resolution No. 68-16 and 40 C.F.R. 131.12), while acknowledging that it is not the intent of the Regional Board to require treatment or diversion of natural coastal creeks or to require treatment of natural sources of bacteria from undeveloped areas. While treatment and diversion of natural sources may fully address the impairment of the water contact recreation beneficial use, such an approach may adversely affect valuable aquatic life and wildlife beneficial uses in the Region.

22. For the Wet-Weather and Dry-Weather Bacteria TMDLs at Santa Monica Bay beaches, Leo Carrillo Beach and its associated drainage area, Arroyo Sequit Canyon, were selected as the local reference system until other reference sites or approaches are evaluated and the necessary data collected to support the use of alternative reference sites or approaches when the TMDL is revised four years after the effective date. Leo Carrillo Beach was selected as the interim reference site because it best met the three criteria for selection of a reference system. Specifically, its drainage is the most undeveloped subwatershed in the larger Santa Monica Bay watershed, the subwatershed has a freshwater outlet (i.e., creek) to the beach, and adequate historical shoreline monitoring data were available. It is the intent of the Regional Board to re-evaluate the use of Leo Carrillo Beach due to potential problems arising from the heavy recreational use of the beach and the close proximity of two campgrounds.

23. Northern Bay beach monitoring sites are fewer in number and provide less comprehensive data than the extensive shoreline monitoring network elsewhere in Santa Monica Bay.

24. The numeric targets in this TMDL are not water quality objectives and do not create new bases for enforcement against dischargers apart from the water quality objectives they translate. The targets merely establish the bases through which load allocations and wasteload allocations (WLAs) are calculated. WLAs are only enforced for a dicharger's own discharges, and then only in the context of it National Pollutant Discharge Elimination System (NPDES) permit, which must be consistent with the assumptions and requirements of the WLA. The Regional Board will develop permit requirements through a subsequent permit action that will allow all interested persons, including but not limited to municipal storm water dischargers, to provide comments on how the waste load allocations will be translated into permit requirements.

25. The Regional Board has the authority to authorize compliance schedules through the basin planning process. In this Basin Plan amendment, the Regional Board establishes a schedule for implementation that affords the responsible jurisdictions and agencies up to ten or eighteen years, depending on the implementation approaches pursued, to implement this Wet-Weather Bacteria TMDL.

26. Previously, the Regional Board adopted a Dry-Weather Bacteria TMDL for the Santa Monica Bay Beaches. The Dry-Weather TMDL includes implementation provisions contained in Table 7-4.3 of the Basin Plan, including a provision to reconsider two years after the effective date the Dry-Weather TMDL and specifically the reference beach(es) used. Because that effort overlaps with reconsideration of the reference beach(es) anticipated by this Wet-Weather TMDL, the Regional Board proposes to coordinate the reconsiderations of the reference beach approach to assure efficiency and consistency in implementing the two Santa Monica Beaches TMDLs.

27. The basin planning process has been certified as functionally equivalent to the California Environmental Quality Act requirements for preparing environmental documents (Public Resources Code, Section 21000 et seq.) and as such, the required environmental documentation and CEQA environmental checklist have been prepared.

28. The proposed amendment results in no potential for adverse effect (de minimis finding), either individually or cumulatively, on wildlife.

29. The regulatory action meets the "Necessity" standard of the Administrative Procedures Act, Government Code, section 11353, subdivision (b).

30. The Basin Plan amendment incorporating a TMDL for bacteria at Santa Monica Bay beaches must be submitted for review and approval by the State Water Resources Control Board (State Board), the State Office of Administrative Law (OAL), and the USEPA. The Basin Plan amendment will become effective upon approval by OAL and USEPA. A Notice of Decision will be filed.

THEREFORE, be it resolved that pursuant to Section 13240 and 13242 of the Water Code, the Regional Board hereby amends the Basin Plan as follows:

1. Pursuant to sections 13240 and 13242 of the California Water Code, the Regional Board, after considering the entire record, including oral testimony at the hearing, hereby adopts the amendments to Chapters 3 and 7 of the Water Quality Control Plan for the Los Angeles Region, as set forth in Attachment A hereto, to incorporate the elements of the Santa Monica

Bay Beaches Bacteria TMDL for wet weather and to implement the water quality objectives for bacteria set to protect the water contact recreation beneficial use.

2. Pursuant to sections 13240 and 13242 of the California Water Code, the Regional Board, after considering the entire record, including oral testimony at the hearing, hereby adopts the amendments to Chapter 7 of the Water Quality Control Plan for the Los Angeles Region, as set forth in Attachment B hereto, to amend Table 7-4.3 of the Santa Monica Bay Beaches Bacteria TMDL for dry weather to change the date for revision of the TMDL from two years after the effective date to four years after the effective date [of the Wet-Weather TMDL] to achieve consistency in scheduling between the Dry-Weather and Wet-Weather TMDLs.

3. The Executive Officer is directed to exercise authority under Water Code section 13267, or other applicable law, to require additional monitoring data in the northern Bay beach regions to ensure that wet weather bacteria exposure is adequately quantified before the TMDL is reconsidered in four years.

4. The Executive Officer is directed to forward copies of the Basin Plan amendment to the State Board in accordance with the requirements of section 13245 of the California Water Code.

5. The Regional Board requests that the State Board approve the Basin Plan amendment in accordance with the requirements of sections 13245 and 13246 of the California Water Code and forward it to OAL and the USEPA.

6. If during its approval process the State Board or OAL determines that minor, non-substantive corrections to the language of the amendment are needed for clarity or consistency, the Executive Officer may make such changes, and shall inform the Board of any such changes.

7. The Executive Officer is authorized to sign a Certificate of Fee Exemption.

I, Dennis A. Dickerson, Executive Officer, do hereby certify that the foregoing is a full, true, and correct copy of a resolution adopted by the California Regional Water Quality Control Board, Los Angeles Region, on December 12, 2002.

ORIGINAL SIGNED BY
Dennis A. Dickerson
Executive Officer

Attachment A to Resolution No. 2002-022

Amendment to the Water Quality Control Plan – Los Angeles Region to incorporate Implementation Provisions for the Region's Bacteria Objectives and to incorporate the Santa Monica Bay Beaches Wet-Weather Bacteria TMDL

Adopted by the California Regional Water Quality Control Board, Los Angeles Region on December 12, 2002.

Amendments:

List of Figures, Tables and Inserts

Add under Chapter 7, Section 7-4 (Santa Monica Bay Beaches Bacteria TMDL):
Tables

Chapter 3. Water Quality Objectives, "Bacteria, Coliform"

Add under "Implementation Provisions for Water Contact Recreation Bacteria Objectives"

The single sample bacteriological objectives shall be strictly applied except when provided for in a Total Maximum Daily Load (TMDL). In all circumstances, including in the context of a TMDL, the geometric mean objectives shall be strictly applied. In the context of a TMDL, the Regional Board may implement the single sample objectives in fresh and marine waters by using a 'reference system/antidegradation ap□roach' or 'natural sources exclusion approach' as discussed below. A reference system is defined as an area and associated monitoring point that is not impacted by human activities that potentially affect bacteria densities in the receiving water body.

These approaches recognize that there are natural sources of bacteria, which may cause or contribute to exceedances of the single sample objectives for bacterial indicators. They also acknowledge that it is not the intent of the Regional Board to require treatment or diversion of natural water bodies or to require treatment of natural sources of bacteria from undeveloped areas. Such requirements, if imposed by the Regional Board, could adversely affect valuable aquatic life and wildlife beneficial uses supported by natural water bodies in the Region.

Under the reference system/antidegradation implementation procedure, a certain frequency of exceedance of the single sample objectives above shall be permitted on the basis of the observed exceedance frequency in the selected reference system or the targeted water body, whichever is less. The reference system/anti-degradation approach ensures that bacteriological water quality is at least as good as that of a reference system and that no degradation of existing bacteriological water quality is permitted where existing bacteriological water quality is better than that of the selected reference system.

Under the natural sources exclusion implementation procedure, after all anthropogenic sources of bacteria have been controlled such that they do not cause or contribute to an exceedance of the single sample objectives and natural sources have been identified and quantified, a certain frequency of exceedance of the single sample objectives shall be permitted based on the residual exceedance frequency in the specific water body. The residual exceedance frequency shall define the background level of exceedance due to natural sources. The 'natural sources exclusion' approach may be used if an appropriate reference system cannot be identified due to unique characteristics of the target water body. These approaches are consistent with the State Antidegradation Policy (State Board Resolution No. 68-16) and with federal antidegradation requirements (40 CFR 131.12).

The appropriateness of these approaches and the specific exceedance frequencies to be permitted under each will be evaluated within the context of TMDL development for a specific water body, at which time the Regional Board may select one of these approaches, if appropriate.

These implementation procedures may only be implemented within the context of a TMDL addressing municipal storm water, including the municipal storm water requirements of the Statewide Permit for Storm Water Discharges from the State of California Department of Transportation (Caltrans), and non-point sources discharges. These implementation provisions do not apply to NPDES discharges other than MS4 discharges.[1]

Chapter 7. Total Maximum Daily Loads (TMDLs) Summaries, Section 7-4 (Santa Monica Bay Beaches Bacteria TMDL)

Santa Monica Bay Beaches Bacteria TMDL (Wet Weather Only)*

This TMDL was adopted by the Regional Water Quality Control Board on December 12, 2002.

This TMDL was approved by:

The State Water Resources Control Board on [Insert Date].
The Office of Administrative Law on [Insert Date].
The U.S. Environmental Protection Agency on [Insert Date].

The following table summarizes the key elements of this TMDL.

[1] Municipal storm water discharges in the Los Angeles Region are those with permits under the Municipal Separate Storm Sewer System (MS4) NPDES Program. For example, the MS4 permits at the time of this amendment are the Los Angeles County Municipal Storm Water NPDES Permit, Ventura County Municipal Storm Water NPDES Permit, City of Long Beach Municipal Storm Water NPDES Permit, and elements of the statewide storm water permit for the California Department of Transportation (Caltrans).

Table 7-4.4. Santa Monica Bay Beaches Bacteria TMDL (Wet Weather Only): Elements

Element	Key Findings and Regulatory Provisions
Problem Statement	Elevated bacterial indicator densities are causing impairment of the water contact recreation (REC-1) beneficial use at many Santa Monica Bay (SMB) beaches. Swimming in waters with elevated bacterial indicator densities has long been associated with adverse health effects. Specifically, local and national epidemiological studies compel the conclusion that there is a causal relationship between adverse health effects and recreational water quality, as measured by bacterial indicator densities.
Numeric Target *(Interpretation of the numeric water quality objective, used to calculate the waste load allocations)*	The TMDL has a multi-part numeric target based on the bacteriological water quality objectives for marine water to protect the water contact recreation (REC-1) use. These targets are the most appropriate indicators of public health risk in recreational waters. These bacteriological objectives are set forth in Chapter 3 of the Basin Plan, as amended by the Regional Board on October 25, 2001. The objectives are based on four bacterial indicators and include both geometric mean limits and single sample limits. The Basin Plan objectives that serve as numeric targets for this TMDL are: 1. Rolling 30-day Geometric Mean Limits a. Total coliform density shall not exceed 1,000/100 ml. b. Fecal coliform density shall not exceed 200/100 ml. c. Enterococcus density shall not exceed 35/100 ml. 2. Single Sample Limits a. Total coliform density shall not exceed 10,000/100 ml. b. Fecal coliform density shall not exceed 400/100 ml. c. Enterococcus density shall not exceed 104/100 ml. d. Total coliform density shall not exceed 1,000/100 ml, if the ratio of fecal-to-total coliform exceeds 0.1. These objectives are generally based on an acceptable health risk for marine recreational waters of 19 illnesses per 1,000 exposed individuals as set by the US EPA (US EPA, 1986). The targets apply throughout the year. The final compliance point for the targets is the wave wash[2] where there is a freshwater outlet (i.e., publicly-owned storm drain or natural creek) to the beach, or at ankle depth at beaches without a freshwater outlet. Implementation of the above bacteria objectives and the associated TMDL numeric targets is achieved using a 'reference system/anti-degradation approach' rather than the alternative 'natural sources exclusion approach' or strict application of the single sample objectives. As required by the CWA and Porter-Cologne Water Quality Control Act, Basin Plans include beneficial uses of waters, water quality objectives to protect those uses, an anti-degradation policy, collectively referred to as water quality standards, and other plans and policies necessary to implement water quality standards. This TMDL and its associated waste load allocations, which shall be incorporated into relevant permits, are the vehicles for implementation of the Region's

[2] The wave wash is defined as the point at which the storm drain or creek empties and the effluent from the storm drain initially mixes with the receiving ocean water.

Element	Key Findings and Regulatory Provisions
	standards. The 'reference system/anti-degradation approach' means that on the basis of historical exceedance levels at existing shoreline monitoring locations, including a local reference beach within Santa Monica Bay, a certain number of daily exceedances of the single sample bacteria objectives are permitted. The allowable number of exceedance days is set such that (1) bacteriological water quality at any site is at least as good as at a designated reference site within the watershed and (2) there is no degradation of existing shoreline bacteriological water quality. This approach recognizes that there are natural sources of bacteria that may cause or contribute to exceedances of the single sample objectives and that it is not the intent of the Regional Board to require treatment or diversion of natural coastal creeks or to require treatment of natural sources of bacteria from undeveloped areas. The geometric mean targets may not be exceeded at any time. The rolling 30-day geometric means will be calculated on each day. If weekly sampling is conducted, the weekly sample result will be assigned to the remaining days of the week in order to calculate the daily rolling 30-day geometric mean. For the single sample targets, each existing shoreline monitoring site is assigned an allowable number of exceedance days during wet weather, defined as days with 0.1 inch of rain or greater and the three days following the rain event. (A separate amendment incorporating the Santa Monica Bay Beaches Dry-Weather Bacteria TMDL addressed the allowable number of summer and winter dry-weather exceedance days.)
Source Analysis	With the exception of isolated sewage spills, storm water runoff conveyed by storm drains and creeks is the primary source of elevated bacterial indicator densities to SMB beaches during wet weather. Because the bacterial indicators used as targets in the TMDL are not specific to human sewage, storm water runoff from undeveloped areas may also be a source of elevated bacterial indicator densities. For example, storm water runoff from natural areas may convey fecal matter from wildlife and birds or bacteria from soil. This is supported by the finding that, at the reference beach, the probability of exceedance of the single sample targets during wet weather is 0.22.
Loading Capacity	Studies show that bacterial degradation and dilution during transport from the watershed to the beach do not significantly affect bacterial indicator densities at SMB beaches. Therefore, the loading capacity is defined in terms of bacterial indicator densities, which is the most appropriate for addressing public health risk, and is equivalent to the numeric targets, listed above. As the numeric targets must be met in the wave wash and throughout the day, no degradation allowance is provided.
Waste Load Allocations *(for point sources)*	Waste load allocations are expressed as the number of sample days at a shoreline monitoring site that may exceed the single sample targets identified under "Numeric Target." Waste load allocations are expressed as allowable exceedance days because the bacterial density and frequency of single sample exceedances are the most relevant to public health protection.

Element	Key Findings and Regulatory Provisions
	For each shoreline monitoring site and corresponding subwatershed, an allowable number of exceedance days is set for wet weather. The allowable number of exceedance days for a shoreline monitoring site for each time period is based on the lesser of two criteria (1) exceedance days in the designated reference system and (2) exceedance days based on historical bacteriological data at the monitoring site. This ensures that shoreline bacteriological water quality is at least as good as that of a largely undeveloped system and that there is no degradation of existing shoreline bacteriological water quality. All responsible jurisdictions and responsible agencies[3] within a subwatershed are jointly responsible for complying with the allowable number of exceedance days for each associated shoreline monitoring site identified in Table 7-4.5 below. The three Publicly Owned Treatment Works (POTWs), the City of Los Angeles' Hyperion Wastewater Treatment Plant, Los Angeles County Sanitation Districts' Joint Water Pollution Control Plant, and the Las Virgenes Municipal Water Districts' Tapia Wastewater Reclamation Facility, discharging to Santa Monica Bay are each given individual WLAs of zero (0) days of exceedance during wet weather.

[3] For the purposes of this TMDL, "responsible jurisdictions and responsible agencies" are defined as: (1) local agencies that are responsible for discharges from a publicly owned treatment works to the Santa Monica Bay watershed or directly to the Bay, (2) local agencies that are permittees or co-permittees on a municipal storm water permit, (3) local or state agencies that have jurisdiction over a beach adjacent to Santa Monica Bay, and (4) the California Department of Transportation pursuant to its storm water permit.

Attachment A to Resolution No. 2002-022

Element	Key Findings and Regulatory Provisions
Load Allocations (for nonpoint sources)	Because all storm water runoff to SMB beaches is regulated as a point source, load allocations of zero days of exceedance are set in this TMDL. If a nonpoint source is directly impacting shoreline bacteriological quality and causing an exceedance of the numeric target(s), the permittee(s) under the Municipal Storm Water NPDES Permits are not responsible through these permits. However, the jurisdiction or agency adjacent to the shoreline monitoring location may have further obligations as described under "Compliance Monitoring" below.
Implementation	The regulatory mechanisms used to implement the TMDL will include primarily the Los Angeles County Municipal Storm Water NPDES Permit (MS4 Permit), the Caltrans Storm Water Permit, the three NPDES permits for the POTWs, the authority contained in sections 13267 and 13263 of the Water Code, and regulations to be adopted pursuant to section 13291 of the Water Code. Each NPDES permit assigned a waste load allocation shall be reopened or amended at reissuance, in accordance with applicable laws, to incorporate the applicable waste load allocation(s) as a permit requirement. The implementation schedule will be determined on the basis of the implementation plan(s), which must be submitted to the Regional Board by responsible jurisdictions and agencies within two years of the effective date of the TMDL (see Table 7-4.7). After considering the implementation plan(s), the Regional Board shall amend the TMDL at a public hearing and, in doing so, will adopt an individual implementation schedule for each jurisdictional group (described in paragraph 3 below) that is as short as possible taking into account the implementation approach being undertaken. Responsible jurisdictions and agencies must clearly demonstrate in the above-mentioned plan whether they intend to pursue an integrated water resources approach.[4] If an integrated water resources approach is pursued, responsible jurisdictions and agencies may be allotted up to an 18-year implementation timeframe, based on a clear demonstration of the need for a longer schedule in the implementation plan, in recognition of the additional planning and time needed to achieve the multiple benefits of this approach. Otherwise, at most a 10-year implementation timeframe will be allotted, depending upon a clear demonstration of the time needed in the implementation plan. The subwatersheds associated with each beach monitoring location may

[4] An integrated water resources approach is one that takes a holistic view of regional water resources management by integrating planning for future wastewater, storm water, recycled water, and potable water needs and systems; focuses on beneficial re-use of storm water, including groundwater infiltration, at multiple points throughout a watershed; and addresses multiple pollutants for which Santa Monica Bay or its watershed are listed on the CWA section 303(d) List as impaired. Because an integrated water resources approach will address multiple pollutants, responsible jurisdictions can recognize cost-savings because capital expenses for the integrated approach will implement several TMDLs that address pollutants in storm water. An integrated water resources approach shall not only provide water quality benefits to the people of the Los Angeles Region, but it is also anticipated that an integrated approach will incorporate and enhance other public goals. These may include, but are not limited to, water supply, recycling and storage; environmental justice; parks, greenways and open space; and active and passive recreational and environmental education opportunities.

Element	Key Findings and Regulatory Provisions
	include multiple responsible jurisdictions and responsible agencies. Therefore, a "primary jurisdiction," defined as the jurisdiction comprising greater than fifty percent of the subwatershed land area, is identified for each subwatershed (see Table 7-4.6).[5] Seven primary jurisdictions are identified within the Santa Monica Bay watershed, each with a group of associated subwatersheds and beach monitoring locations. These are identified as "jurisdictional groups" (see Table 7-4.6). The primary jurisdiction of each "jurisdictional group" shall be responsible for submitting the implementation plan described above, which will determine the implementation timeframe for the subwatershed. A jurisdictional group may change its primary jurisdiction by submitting a joint, written request, submitted by the current primary jurisdiction and the proposed primary jurisdiction, to the Executive Officer requesting a reassignment of primary responsibility. Two jurisdictional groups may also choose to change the assignment of monitoring locations between the two groups by submitting a joint, written request, submitted by the current primary jurisdiction and the proposed primary jurisdiction, to the Executive Officer requesting a reassignment of the monitoring location. If an integrated water resources approach is pursued, the jurisdictional group(s) must achieve a 10% cumulative percentage reduction from the total exceedance-day reduction required for the group of beach monitoring locations within 6 years, a 25% reduction within 10 years, and a 50% reduction within 15 years of the effective date of the TMDL. These interim milestones for the jurisdictional group(s) will be re-evaluated, considering planning, engineering and construction tasks, based on the written implementation plan submitted to the Regional Board two years after the effective date of the TMDL (see Table 7-4.7). If an integrated water resources approach is not pursued, the jurisdictional group(s) must achieve a 25% cumulative percentage reduction from the total exceedance-day reduction required for the group of beach monitoring locations within 6 years, and a 50% reduction within 8 years of the effective date of the TMDL (see Table 7-4.7). For those beach monitoring locations subject to the antidegradation provision, there shall be no increase in exceedance days during the implementation period above that estimated for the beach monitoring location in the critical year as identified in Table 7-4.5. The final implementation targets in terms of allowable wet-weather exceedance days must be achieved at each individual beach location no later than 18 years after the TMDL's effective date if an integrated water resources approach is pursued, or no later than 10 years after the TMDL's effective date if an integrated water resources approach is not pursued. In addition, the geometric mean targets must be achieved for each individual beach location no later than 18 years or 10 years after the effective date, respectively, depending on whether a integrated

[5] Primary jurisdictions are not defined for the Ballona Creek subwatershed or the Malibu Creek subwatershed, since separate bacteria TMDLs are being developed for these subwatersheds.

Element	Key Findings and Regulatory Provisions
	water resources approach is pursued or not.

Element	Key Findings and Regulatory Provisions
Margin of Safety	The TMDL is set at levels that are exactly equivalent to the applicable water quality standards along with the proposed reference system/antidegradation implementation procedure. An implicit margin of safety is included in the supporting water quality model by assuming no dilution between the storm drain and the wave wash, the point of compliance. This is a conservative assumption since studies have shown that there is a high degree of variability in the amount of dilution between the storm drain and wave wash temporally, spatially and among indicators, ranging from 100% to 0%.
Seasonal Variations and Critical Conditions	Seasonal variations are addressed by developing separate waste load allocations for three time periods (wet weather, summer dry weather and winter dry weather) based on public health concerns and observed natural background levels of exceedance of bacterial indicators. (The two dry-weather periods are addressed in the Santa Monica Bay Beaches Dry-Weather Bacteria TMDL.) The critical condition for this bacteria TMDL is wet weather generally, when historic shoreline monitoring data for the reference beach indicate that the single sample bacteria objectives are exceeded on 22% of the wet-weather days sampled. To more specifically identify a critical condition within wet weather in order to set the allowable exceedance days shown in Tables 7-4.5 and 7-4.6, the 90th percentile 'storm year'[6] in terms of wet days is used as the reference year. Selecting the 90th percentile year avoids a situation where the reference beach is frequently out of compliance. It is expected that because responsible jurisdictions and agencies will be planning for this 'worst-case' scenario, there will be fewer exceedance days than the maximum allowed in drier years. Conversely, in the 10% of wetter years, it is expected that there may be more than the allowable number of exceedance days.
Compliance Monitoring	Responsible jurisdictions and agencies as defined in Footnote 2 shall conduct daily or systematic weekly sampling in the wave wash at all major drains[7] and creeks or at existing monitoring stations at beaches without storm drains or freshwater outlets to determine compliance.[8] At all locations, samples shall be taken at ankle depth and on an incoming wave. At locations where there is a freshwater outlet, during wet weather, samples should be taken as close as possible to the wave wash, and no further away than 10 meters down current of the storm drain or outlet.[9] At locations where there is a freshwater outlet, samples shall be taken when the freshwater outlet is flowing into the surf zone. If the number of exceedance days is greater than the allowable number of exceedance days for any jurisdictional group at the interim implementation milestones the responsible jurisdictions and agencies

[6] For purposes of this TMDL, a 'storm year' means November 1 to October 31. The 90th percentile storm year was 1993 with 75 wet days at the LAX meteorological station.
[7] Major drains are those that are publicly owned and have measurable flow to the beach during dry weather.
[8] The frequency of sampling (i.e., daily versus weekly) will be at the discretion of the implementing agencies. However, the number of sample days that may exceed the objectives will be scaled accordingly.
[9] Safety considerations during wet weather may preclude taking a sample in the wave wash.

Element	Key Findings and Regulatory Provisions
	shall be considered out-of-compliance with the TMDL. If the number of exceedance days exceeds the allowable number of exceedance days for a target beach at the final implementation deadline, the responsible jurisdictions and agencies within the contributing subwatershed shall be considered out-of-compliance with the TMDL. Responsible jurisdictions or agencies shall not be deemed out of compliance with the TMDL if the investigation described in the paragraph below demonstrates that bacterial sources originating within the jurisdiction of the responsible agency have not caused or contributed to the exceedance. If a single sample shows the discharge or contributing area to be out of compliance, the Regional Board may require, through permit requirements or the authority contained in Water Code section 13267, daily sampling in the wave wash or at the existing open shoreline monitoring location (if it is not already) until all single sample events meet bacteria water quality objectives. Furthermore, if a beach location is out-of-compliance as determined in the previous paragraph, the Regional Board shall require responsible agencies to initiate an investigation, which at a minimum shall include daily sampling in the wave wash or at the existing open shoreline monitoring location until all single sample events meet bacteria water quality objectives. If bacteriological water quality objectives are exceeded in any three weeks of a four-week period when weekly sampling is performed, or, for areas where testing is done more than once a week, 75% of testing days produce an exceedence of bacteria water quality objectives, the responsible agencies shall conduct a source investigation of the subwatershed(s) pursuant to protocols established under Water Code 13178. If a beach location without a freshwater outlet is out-of-compliance or if the outlet is diverted or being treated, the adjacent municipality, County agency(s), or State or federal agency(s) shall be responsible for conducting the investigation and shall submit its findings to the Regional Board to facilitate the Regional Board exercising further authority to regulate the source of the exceedance in conformance with the Porter-Cologne Water Quality Control Act.

Note: The complete staff report for the TMDL is available for review upon request.

Attachment A to Resolution No. 2002-022

Table 7-4.5. Final Allowable Wet-Weather Exceedance Days by Beach Location

Beach Monitoring Location	Estimated no. of wet weather exceedance days in critical year (90th percentile)*	Final allowable no. of wet weather exceedance days (daily sampling)*

Notes: * The compliance targets are based on existing shoreline monitoring data and assume daily sampling. If systematic weekly sampling is conducted, the compliance targets will be scaled accordingly. These are the compliance targets until additional shoreline monitoring data are collected prior to revision of the TMDL. Once additional shoreline monitoring data are available, the following will be re-evaluated when the TMDL is revised 1) estimated number of wet-weather exceedance days in the critical year at all beach locations, including the reference system(s) and 2) final allowable wet-weather exceedance days for each beach location.

Notes: *Interim milestones will be re-calculated during the revision of the TMDL based on shoreline monitoring data collected from the wave wash and a re-evaluation of the most appropriate reference system and reference year. Furthermore, if an integrated water resources approach is pursued, as demonstrated by the implementation plans to be submitted to the Regional Board by the primary jurisdictions within two years of the effective date of the TMDL, the interim milestones will be re-evaluated on the basis of the implementation plan, considering planning, engineering and construction tasks. **Interim milestones for the Malibu and Ballona shoreline monitoring locations will be identified in subsequent bacteria TMDLs to be developed for these two watersheds. ***Monitoring sites are those shoreline locations currently monitored by the City of Los Angeles, County Sanitation Districts of Los Angeles County, and the Los Angeles County Department of Health Services at the time of adoption of this TMDL by the Regional Board. This list does not preclude the establishment of additional monitoring stations. For those subwatersheds without an existing shoreline monitoring site, responsible jurisdictions and agencies must establish a shoreline monitoring site if there is measurable flow from a creek or publicly owned storm drain to the beach during dry weather. # For those beach monitoring locations subject to the antidegradation provision, there shall be no increase in exceedance days during the implementation period above that estimated for the beach monitoring location in the critical year as identified in Table 7-4.5.

Attachment A to Resolution No. 2002-022

Table 7-4.7. Santa Monica Bay Beaches Bacteria TMDL (Wet Weather Only): Significant Dates

Date	Action
120 days after the effective date of the TMDL	Pursuant to a request from the Regional Board, responsible jurisdictions and responsible agencies must submit coordinated shoreline monitoring plan(s) to be approved by the Executive Officer, including a list of new sites* and/or sites relocated to the wave wash at which time responsible jurisdictions and responsible agencies shall select between daily or systematic weekly shoreline sampling.
20 months after the effective date of the TMDL	Responsible jurisdictions and agencies shall provide a draft written report to the Regional Board outlining how each intends to cooperatively (through Jurisdictional Groups) achieve compliance with the TMDL. The report shall include implementation methods, an implementation schedule, and proposed milestones.
Two years after effective date of TMDL	Responsible jurisdictions and agencies shall provide a written report to the Regional Board outlining how each intends to cooperatively (through Jurisdictional Groups) achieve compliance with the TMDL. The report shall include implementation methods, an implementation schedule, and proposed milestones. Under no circumstances shall final compliance dates exceed 10 years for non-integrated approaches or 18 years for integrated water resources approaches. Regional Board staff shall bring to the Regional Board the aforementioned plans as soon as possible for consideration.
4 years after effective date of TMDL	The Regional Board shall reconsider the TMDL to: (1) refine allowable wet weather exceedance days based on additional data on bacterial indicator densities in the wave wash and an evaluation of site-specific variability in exceedance levels, (2) re-evaluate the reference system selected to set allowable exceedance levels, including a reconsideration of whether the allowable number of exceedance days should be adjusted annually dependent on the rainfall conditions and an evaluation of natural variability in exceedance levels in the reference system(s), (3) re-evaluate the reference year used in the calculation of allowable exceedance days, and (4) re-evaluate whether there is a need for further clarification or revision of the geometric mean implementation provision.

Date	Action
Significant Dates for Responsible Jurisdictions and Agencies *Not* Pursuing an Integrated Water Resources Approach	
6 years after effective date of the TMDL	Each defined jurisdictional group must achieve a 25% cumulative percentage reduction from the total exceedance-day reductions required for that jurisdictional group as identified in Table 7-4.6.
8 years after effective date of the TMDL	Each defined jurisdictional group must achieve a 50% cumulative percentage reduction from the total exceedance-day reductions required for that jurisdictional group as identified in Table 7-4.6.
10 years after effective date of the TMDL	Final implementation targets in terms of allowable wet-weather exceedance days must be achieved at each individual beach as identified in Table 7-4.5. In addition, the geometric mean targets must be achieved for each individual beach location.
Significant Dates for Responsible Jurisdictions and Agencies Pursuing an Integrated Water Resources Approach to Implementation	
6 years after effective date of the TMDL	Each defined jurisdictional group must achieve a 10% cumulative percentage reduction from the total exceedance-day reductions required for that jurisdictional group as identified in Table 7-4.6.
10 years after effective date of the TMDL	Each defined jurisdictional group must achieve a 25% cumulative percentage reduction from the total exceedance-day reductions required for that jurisdictional group as identified in Table 7-4.6.
15 years after effective date of the TMDL	Each defined jurisdictional group must achieve a 50% cumulative percentage reduction from the total exceedance-day reductions required for that jurisdictional group as identified in Table 7-4.6.
18 years after effective date of the TMDL	Final implementation targets in terms of allowable wet-weather exceedance days must be achieved at each individual beach as identified in Table 7-4.5. In addition, the geometric mean targets must be achieved for each individual beach location.

Notes: *For those subwatersheds without an existing shoreline monitoring site, responsible jurisdictions and agencies must establish a shoreline monitoring site if there is measurable flow from a creek or publicly owned storm drain to the beach during dry weather.

TABLE OF CONTENTS

1 INTRODUCTION

1.1 Purpose and Scope

The purpose of this study is to develop a "quantification assessment" of the water quality benefits of the structural and non-structural BMPs recommended in the Santa Monica Bay Beaches Bacteria Total Maximum Daily Load (TMDL) Implementation Plan for wet weather in Jurisdictional Groups 1 and 4 in accordance with requirements described in California Regional Water Quality Control Board, Los Angeles Region, Resolution No. 2006-005.

1.2 Report Organization

This report is organized as follows:

Overview of Approach

Establishment of Water Quality Targets

Estimate of Water Quality Benefits, and

Estimate of Integrated Water Resources Benefits

1.3 Background

On August 30, 2005, the County of Los Angeles (Lead Agency for Jurisdiction 1), the City of Malibu (Lead Agency for Jurisdiction 4) and the California Department of Transportation submitted the *Santa Monica Bay Beaches Wet-Weather Bacteria Total Maximum Daily Load Implementation Plan: Jurisdictional Groups 1 and 4* (J1/4 IP). On April 6, 2006, the California Regional Water Quality Control Board, Los Angeles Region (LARWQCB) issued Resolution No. 2006-005 *Statement of support for the efforts of responsible jurisdictions and agencies in Jurisdictional Groups 1 and 4 to utilize an integrated water resources approach to achieve full compliance with the Santa Monica Bay Beaches Bacteria Wet Weather TMDL in the shortest possible timeframe and no later than July 2021.* This resolution is included in Appendix A.

Resolution No. 2006-005 required that the responsible jurisdiction submit quantifiable analyses to demonstrate that "(1) the proposed plan will meet the interim and final WLAs" [Waste Load Allocations] and "(2) the proposed implementation actions will achieve multiple water quality benefits and other public goals". This resolution also stipulated that this information be submitted within nine months, which ends in January 2007.

The purpose of this investigation is to provide quantifiable estimates of the integrated water resources benefits of the structural and non-structural BMPs recommended in the J1/4 IP, in terms of exceedance day reductions, based on an approach discussed with LARWQCB staff.

2 OVERVIEW OF APPROACH

2.1 Basin Plan Objectives

The TMDL is based on numeric targets for bacteriological water quality objectives for Water Contact Recreation (REC-1) as revised by Regional Board Resolution 2001-018 (amending its Basin Plan on October 25, 2001). This Basin Plan amendment received final approval from the EPA on September 25, 2002[1]. These water quality objectives are based on four bacterial indicators and include both geometric mean limits and single sample limits:

1. Geometric Mean (GM) Limits
   a. Total coliform density shall not exceed 1,000/100 ml.
   b. Fecal coliform density shall not exceed 200/100 ml.
   c. Enterococcus density shall not exceed 35/100 ml.
2. Single Sample (SS) Limits
   a. Total coliform density shall not exceed 10,000/100 ml.
   b. Fecal coliform density shall not exceed 400/100 ml.
   c. Enterococcus density shall not exceed 104/100 ml.
   d. Total coliform density shall not exceed 1,000/100 ml, if the ratio of fecal-to-total coliform exceeds 0.1.

Based on a reference watershed/antidegradation approach, the TMDL specifies wet weather Waste Load Allocations (WLAs), in the form of (single sample) exceedance days, for the various subwatersheds, as shown in Table 1. No exceedances of the geometric mean limits are allowed.

Because the TMDL 10% and 25% interim targets relate exclusively to SS exceedance days, GM exceedances are not evaluated as part of this Quantitative Assessment report.

[1]) Resolution No. 2002-022, Finding 18.

Table 1. Final Allowable Wet-Weather (Single Sample-based) Exceedance Days WLAs by Beach Location

Beach Location	Estimated No. of Exceedance Days Critical Year (1993)	Final Allowable Number of Exceedance Days
Leo Carrillo Beach, at 35000 PCH (Reference Watershed)	17	17
Nicholas Beach, 100 feet west of lifeguard tower (J4)	14	14
Broad Beach	15	15
Trancas Beach entrance, 50 yards east of Trancas Bridge	19	17
Westward Beach, east of Zuma Creek	17	17
Paradise Cove, adjacent to west side of pier	23	17
Latigo Canyon Creek entrance	33	17
Corral State Beach	17	17
Las Flores Beach	29	17
Big Rock Beach, at 19900 PCH	30	17
Topanga State Beach	26	17

Based on the J1/4 IP, which assumes consideration for integrated water resources approaches (as submitted), schedules for TMDL compliance are:

- Re-Open TMDL (re-evaluation): 2007
- 10% reduction: 2009
- 25% reduction: 2013
- 50% reduction: 2018
- Final targets: 2021

2.2 Exceedance day enumeration approach

The following steps were followed in order to compute the number of exceedance days within the J1/4 area based on monitoring data collected during the 2004/05 storm year (November 1 to October 31). The approach was developed in conjunction with representatives from other jurisdictional groups within the Santa Monica Bay Beaches area. For purposes of consistency, the same approach is presented here and is the basis for this analysis. Details of this analysis are provided in section 3.1:

- Compile monitoring data.
- Screen "wet" sampling data for single sample analyses.
- Compare with single sample limits (each single sample limit/parameter).
- Remove allowable single sample exceedance days from dataset.

2.3 Quantitative water quality assessment

The following steps were followed in order to estimate the water quality benefits associated with the J1/4 IP, based on the monitoring data collected during the 2004/05 Storm Year:

- Identify phase-specific non-structural and structural (on-site and regional) BMP activities for each subwatershed from the J1/4 IP.
- Estimate effectiveness for each BMP activity, in terms of percent bacteria concentration reduction. Percent (by area) implementation was assumed in some cases.
- For on-site and regional structural BMP activities, estimate BMP percent bacteria load removal by subwatershed, and assume equal to percent concentration reduction.
- For non-structural BMP activities, estimate percent concentration reductions from outreach program and relevant bacteria source tracking studies.
- Compute total percent reductions for all BMP activities for each subwatershed for Phases I/II (combined) and Phase III, which are scheduled to correspond with the 10% and 25% interim targets, respectively.
- Apply the total percent reductions for each subwatershed to the monitoring results, and re-compute exceedance days as described earlier.

- Determine reduction in exceedance days by comparing existing exceedance days with post-implementation exceedance days, and compare with the 10% and 25% interim targets, to assess anticipated effectiveness of the J1/4 IP.

2.4 Quantitative Integrated Water Resources Assessment Approach

Resolution No. 2006-005 states that "a longer implementation schedule… shall be granted if there is a clear demonstration that an integrated water resources approach will be pursued…. This demonstration shall provide numeric estimates of the benefits, including the reductions in other pollutants, groundwater recharged, acres of multi-use projects, and water (e.g., stormwater, runoff, wastewater) beneficially reused among other integrated water resources criteria…" The following thresholds were established to be the criteria related to quantifiable (numeric) estimates.

Threshold for reductions of pollutants. For interim target deadlines, each subwatershed will implement BMPs that address targeted pollutant groups. These pollutant groups (excluding bacteria) are nutrients, metals, total suspended sediment (TSS), and trash. Because target reductions have not been established in TMDL Implementation Plans, it is assumed that significant load reductions will constitute a clear demonstration of quantified benefits.

Groundwater recharged. Groundwater recharge opportunities are limited due to soil types and steep slope conditions, and groundwater is not a water supply resource locally. For onsite measures, the thresholds for demonstration of groundwater-related on-site BMPs are percentages of watersheds in which small-scale BMPs are implemented and the volume of potential water captured.

Water reused. Water reuse BMPs include residential cisterns and onsite storage and reuse projects. The thresholds for a clear demonstration of water reuse-related on-site BMPs are also the percentages of implementation in watersheds and the volume of potential water captured.

Other benefits. The implementation plan also described other beneficial uses, some of which are not described in the TMDL, but may still have significant value to the region: habitat development, geomorphology and hydrology considerations, and flood control

The thresholds for these measures are limited to an accounting of the number (and fraction) of the subwatersheds where these benefits are anticipated.

Acres of project. Managed and natural open spaces comprise 88% of the total jurisdictional areas. Acreage for project implementation will be limited to partial utilization on specific parcels, and selected regional facilities. In most cases, the regional facilities that provide any direct integrated benefits are already open space. Therefore, acres of project are not discussed in terms of a metric for quantifying integrated benefits.

Extent of integrated water resources activities within subwatersheds. The following table quantifies the extent of compliance of integrated water resources elements based on spatial distribution and subwatershed implementation.

Integrated Water Resources (IWR) Elements	Percentage of subwatersheds implementing	
	10 Percent Bacteria Target	*25 Percent Bacteria Target*
Multiple Pollutants Addressed	100%	*100%*
Groundwater Recharged	Planning only	*44% (7 of 16)*
Water reused	Planning only	*44% (7 of 16)*
Other benefits	*100%*	*100%*

Volumetric analysis. The following table summarizes percentages of volumes of water meeting multiple objectives.

Integrated Water Resources (IWR) Elements	Average percentages for subwatersheds	
	10 Percent Bacteria Target	*25 Percent Bacteria Target*
Multi-Pollutants Addressed	[Non-structural multi-pollutant and IWR benefits assessed qualitatively]	
Nutrients		*Onsite: 0-1% load reduction Regional: 30-81% load reduction*
Metals		*Onsite: 2% load reduction Regional: 30-81% load reduction*
TSS		*Onsite: 2% load reduction Regional: 50-81% load reduction*
Trash		*Onsite: 2% load reduction Regional: 24-90% load reduction*
Water Reused		*0.6% volume reduction*
Groundwater Recharged		*0.3% volume reduction*
Other benefits		*Habitat, Recreation, Education, Hydrology, Flood Control, Geomorphology/Hydromod*

3 ESTABLISH WATER QUALITY TARGETS

3.1 Exceedance Day Enumeration Approach

The first step in the quantitative assessment was to determine the number of exceedances from the J1/4 2004/05 storm year monitoring data. This exceedance day enumeration analysis was conducted as follows:

3.1.1 Compile monitoring data

Daily and weekly indicator bacteria monitoring results were compiled for the 2004/05 monitoring year. Indicators parameters here include: total coliform (TC), fecal coliform (FC), and enterococcus (EN). This monitoring data constitutes a blend of point zero and open beach sampling data.

3.1.2 Screen baseline data to conduct single sample (SS) analyses

For the subwatershed-specific analysis of SS exceedances (subwatersheds designated 1-18 in the Coordinated Shoreline Monitoring Plan), daily monitoring data were first synthesized to be representative of weekly data for consistency.[2] Then for all sites, weekly monitoring data were screened to only include "wet" days, defined as days having more than 0.1 inch of rain for the subject day, plus the subsequent 3 days. The Los Angeles County Department of Public Works (LACDPW) gage #482 (USC) was

[2] It should be noted that by screening daily monitoring data (available for subwatershed 1-18 only) to weekly (by selecting data from the predominant sampling weekdays only) in this step – which was done in order to render all the subwatershed datasets consistent – 1 SS weekly exceedance day was lost, as follows. Based on daily data, 45 exceedance days were identified, or 28 days beyond the allowable 17. 28 days translates to 4 weekly exceedance days, which is one more than was computed for site 1-18 (Topanga) based on weekly monitoring data analysis. This close result confirms that weekly monitoring data, as opposed to daily monitoring data, is adequate (in terms of temporal resolution) for estimating total number of exceedance days, and that daily/weekly-based exceedance days, and even allowable exceedance days (or WLAs), are translatable[0].[0]

used for this analysis as this was provided along with the monitoring data from LADPW, and for consistency with the November 1, 2004 LARWQCB monitoring clarification letter to the City of Los Angeles. Follow-up monitoring data (i.e., 48/96 hour tests which were collected following exceedances) for all sites were also removed from the weekly monitoring datasets for the identification of SS exceedances.

3.1.3 Compare data with SS limits

Wet weather results were compared with SS indicator bacteria limits (including the TC:FC ratio requirement), with all wet weather SS exceedances identified. Censored data (e.g., where results were greater or less than laboratory detection limits) were assumed to be equal to their detection limits. It is important therefore to recognize that percent reductions required to meet the TMDL may be larger than stated for some data points (i.e., those described as greater than the test limits). However, this assumption should not significantly affect the 2004/05 J1/4 water quality benefits analysis since all "greater than" results were for TC, and in most cases, events with TC exceedances also had exceedances for other indicators.

3.1.4 Remove allowable SS exceedance days from evaluated dataset.

Allowable SS exceedance days were removed from the dataset. Allowable exceedance day removal priority was given to dates with the highest number of exceedances among the three constituents. Among those dates, when ambiguity arose regarding which of two dates to remove or to retain, removal priority was given to the date with exceedances occurring for more than one constituent. (Wet-weather exceedances in total or fecal coliform concentration were usually accompanied by enterococcus exceedances.) An alternative removal priority approach being used for other jurisdictional groups was to remove dates with the highest percent reductions.

The number of allowable exceedance days was determined from the wet weather TMDL Waste Load Allocations (WLAs), translated from the 17 allowable exceedance days (based on TMDL modeling for the reference watershed, Arroyo Sequit), to a number that is comparable with weekly monitoring data. For most subwatersheds, this meant dividing the allowable 17 days by 7, and rounding the remainder week fraction up, resulting in 3 allowable weekly monitoring day exceedances. For subwatershed 4-1 (Nicholas), where 14 exceedance days are allowed, 2 allowable weekly exceedance days were assumed.

3.2 2004/05 Storm Year

The 2004/05 monitoring season (defined in the TMDL as November 1 to October 31 to be consistent with AB-411 implementing regulations) had 81 wet-weather days[3] at the USC rain gage, compared to 75 in 1993, or the 90th percentile year (in terms of wet-weather days) used in the TMDL. This USC rain gauge was used for this analysis to discriminate wet weather monitoring days consistent with LARWQCB recommendation from their November 1, 2004 letter to the City of Los Angeles.

3.3 Single Sample Exceedance Day Enumeration Results

Table 2 summarizes the wet weather exceedance days for each subwatershed, and for J1/4 total. Weekly exceedance days above allowable, computed by the method outlined above, are shown here. These weekly sampling results were multiplied by 7[4] to summarize the total number of estimated exceedance days for 2004/05, as shown in the 3rd column. After accounting for weekly monitoring frequency, these results were compared with estimated final wet weather exceedance day reductions from the TMDL.[5] Based on this comparison, significantly more exceedances were observed in

[3] Wet-weather days are defined in the TMDL as days having >=0.1 inches of rain plus the 3 days following.

[4] This is based on the assumption that each weekly grab sample concentration is actually representative of 7 days. Note that this may be a conservative assumption for the estimation of total exceedance days as 48 and 96 hour follow up sampling often demonstrates that the sample locations have returned to compliance.

[5] Note that there is little correlation observed between estimated/predicted exceedance day reductions from the TMDL and those based on 2004/05 monitoring results.

2004/05 than were estimated in the TMDL (which is based on modeling predictions for the 90th percentile wet year).

Table 2. 2004/2005 Single Sample Wet Weather Exceedance Days Summary

Subwatershed	Weekly Exceedance Days Above Allowable	Total Est. Exceedance Days Above Allowable	Est. Final Exceedance Day Reduction from TMDL[6]
Arroyo Sequit (ref. watershed)	1	7	0
Los Alisos	0	0	NA
Encinal	0	0	NA
Trancas	2	14	2
Zuma	4	28	0
Ramirez (2 monitoring sites)	4	28	6
Escondido	2	14	NA
Latigo	1	7	16
Solstice	2	14	NA
Corral (2 monitoring sites)	6	42	0
Carbon	3	21	NA
Las Flores	4	28	NA
Piedra Gorda	0	0	13
Pena	0	0	NA
Tuna	0	0	NA
Topanga	3	21	9
Nicholas	0	0	0
Total (excluding ref. watershed)	31	217	46+

Figure 1 below summarizes the number of exceedances days (beyond allowable) by subwatershed, with comparison to the priority categories established in the J1/4 IP. It

[6] *Existing* monitoring sites are shown with numbers of predicted exceedance day reductions for comparison with 2004-05 monitoring results. All existing monitoring sites have been moved to "point zero" with the exception of Piedra Gorda, which remains an open beach monitoring site. *New* monitoring sites (all located at point zero, with the exception of Los Alisos and Encinal) are shown with NA (not applicable) since they were not modeled in the TMDL.

should be noted that the number of exceedance days does not necessarily track priority as well as might be expected. Combined with the results of the comparison with estimated exceedance day reductions from the TMDL shown in Table 2, this chart demonstrates the unpredictable nature of indicator bacteria exceedances.

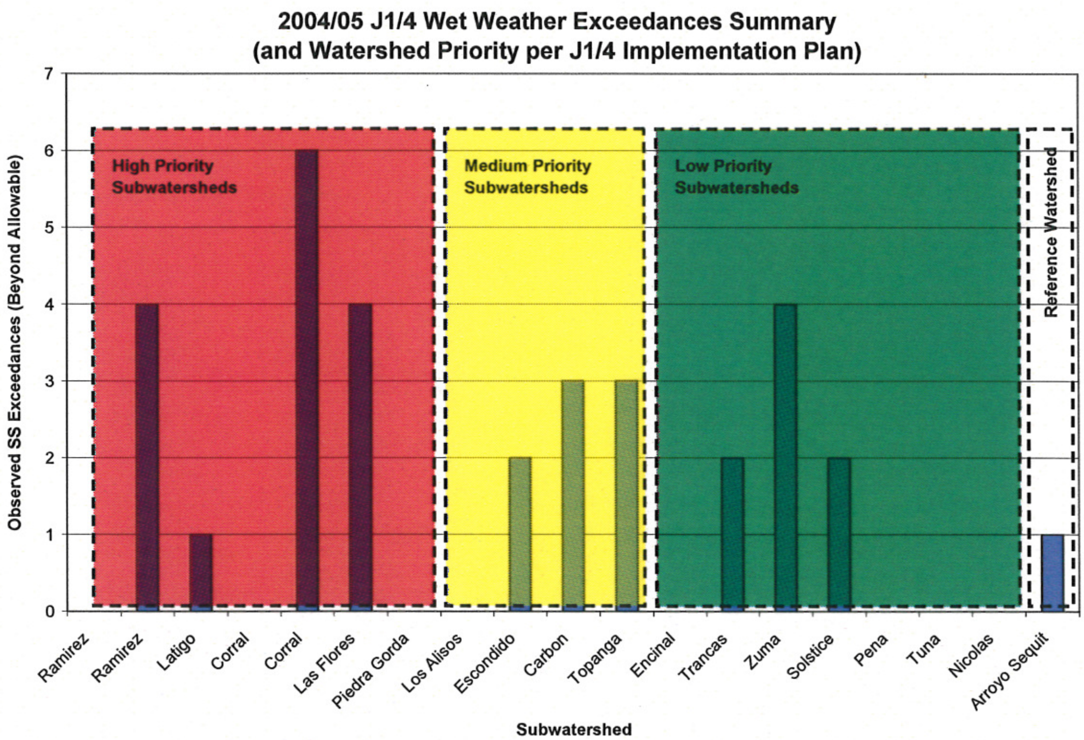

Figure 1. 2004/05 single sample exceedance days summary, compared with IP subwatershed priority categories.

Charts are provided in Appendix B summarizing the measured indicator bacteria concentrations, with allowable exceedances removed, for example subwatersheds 1-1 (Arroyo Sequit; reference watershed), 1-5 (Zuma), and 1-9 (Latigo). Total exceedance days at each site are as follows: Arroyo Sequit – 1, Zuma – 4, Latigo – 1. All of these exceedance days are due, at least in part, to enterococcus.

3.4 Concentration Reduction Results

Estimated concentration reductions required to attain final compliance with the TMDL exceedance day WLAs were computed. Table 3 summarizes the results relative to the single sample limits for each site. Concentration reductions were generally greatest for enterococcus; required reductions were also most frequent for this indicator.

Table 3. Summary of single sample maximum exceedance concentrations (beyond allowable) and final percent reduction targets, for each indicator for each site.

			Total Coliform SS Std: 10,000		Fecal Coliform SS Std: 400		Enterococcus SS Std: 104	
Location	Subwatershed	Type	Max.	% Red.	Max	% Red.	Max	% Red.
SMB-1-1	Arroyo Sequit	Point Zero	2359	---	189	---	175	41%

SMB-4-1	Nicolas	Point Zero	738	---	226	---	97	---

3.5 Interim Compliance

31 total non-allowable exceedance days (TED) were identified for all J1/4 sites in 2004/05, based on the single sample limits and the TMDL WLAs (or allowable SS exceedance days).

Therefore, the interim targets[7], in terms of TED reductions, are as follows:

- 10% target – 3 TED reduction by 2009
- 25% target – 8 TED reduction by 2013

An analysis of the SS limit-based exceedance days demonstrated that the minimum percent concentration reductions required to achieve compliance with the 10% and 25% TED reduction targets are 23% and 69%, respectively. Therefore, these concentration reductions will be a minimum goal for the J1/4 IP activities.

3.6 Additional Observations

The following observations further emphasize the unpredictability of exceedance days (which may have implications regarding the potentially uncontrollable nature of exceedance days), the uncertain nature of the reference watershed condition, and the conservatism of the analysis (since even the reference watershed's exceedance days were beyond the WLA). One possible solution to this for the LARWQCB would be to make the reference watershed-based limits a moving target (i.e., defined by each year's data).

- Exceedance frequencies did not correlate well with either subwatershed priority (from the J1/4 IP) or predicted exceedance day reductions (from the TMDL).

- Enterococcus (most common indicator exceedance) concentrations were not correlated to rain depth (either 1 day or 4 day totals).

---

[7] The scope of this quantitative assessment only includes an analysis relative to the 10% and 25% interim targets.

- Wet-weather day exceedance probabilities were not statistically different than dry-weather day exceedance probabilities.

- Arroyo Sequit, the reference watershed, exceeded the SS limits on 4 days (based on weekly monitoring data), or 1 more than estimated in the TMDL. Stated differently, SS limits were exceeded 28 days (4 weeks x 7 days/week), or 11 beyond the allowable 17 from the TMDL.

4 ESTIMATE WATER QUALITY BENEFITS

The J1/4 IP categorizes activities as "commit", "pilot", and "consider". The purpose of this task is to quantify benefits of "committed" and "piloted" activities, in terms of total exceedance day (TED) reductions for the entire J1/4 area, for comparison with 10% and 25% interim targets. This analysis is referred to as the "quantitative assessment" portion of the report.

To accomplish this, J1/4 IP activities for Phases I-III (corresponding to the 10% and 25% interim target deadlines, respectively) were identified, conservatively translated into anticipated bacteria concentration reductions, and converted into TEDs as described in the approach outlined earlier in this report.

4.1 Approach

The basic rationale for the quantitative assessment is that BMP activities have predictable percent bacteria concentration reductions associated with them. It is further assumed that the reductions can be calculated based on outreach program effectiveness and bacteria source loads, in the case of non-structural activities, or based on BMP percent removal and area treated, in the case of structural activities. This approach is based in part on the quantitative assessment approaches implemented for other Santa Monica Bay Jurisdictions.

The quantitative assessment analysis was conducted as follows:

1. Non-structural and structural (on-site and regional) BMP activities for each subwatershed were determined from the J1/4 IP. Table 4 is an example subwatershed-specific BMP planning summary from the J1/4 IP.
2. Effectiveness was estimated for each BMP activity, in terms of percent bacteria concentration reduction. Percent (by area) implementation was assumed in some cases. Low and high effectiveness scenarios were simulated for comparison.
    a. For regional structural BMP activities: Percent concentration reductions were calculated based on estimated BMP percent removal and treated area (as percent of total watershed area). Estimated BMP percent

removal values are as follows: 99% for capture/reuse and disinfection/discharge BMPs, 90% for subsurface wetland, and 25% for creek restoration/biofiltration projects. These estimates assume that BMPs will be sized to the appropriate capture volume, so bypass discharges will only contribute to *allowable* exceedances (i.e., bypass frequencies will correspond to the allowable probability of exceedance).

   b. For on-site structural BMP activities: For areas that are not treated by regional structural BMPs, percent concentration reductions were assumed equal to BMP percent load reductions, which were calculated based on percent volume removal (80% based on SUSMP sizing), treated area (2.5% of total residential area), and reported residential runoff coefficients and fecal coliform event mean concentration values.

   c. For non-structural BMP activities: For areas that are not treated by structural BMPs, percent concentration reductions were calculated based on estimated program effectiveness (based on surveys for the Los Angeles County focused study) and targeted source percent contributions (based on relevant bacteria source tracking studies).

3. Total percent reductions (or reduction ranges) were computed for all BMP activities for each subwatershed. These percents were compiled for Phases I/II (combined) and Phase 3, since these were scheduled to correspond with the 10% and 25% interim targets, respectively, in the J1/4 IP. This quantitative assessment scope is for these two initial interim targets only.

4. The total percent reductions for each subwatershed were applied to the monitoring results, and single sample exceedance days were recomputed as described earlier.

5. The reduction in exceedance days were determined by comparing existing exceedance days with post-implementation exceedance days, and compared with the 10% and 25% interim targets, to assess anticipated effectiveness of the J1/4 IP.

Table 4. Example subwatershed-specific implementation plan

Latigo Best Management Practices	Commit	Pilot	Consider	Initiate Planning	Initiate Implementation*
Non-Structural Measures					
Public Information and Participation Programs					
Outreach to pet owners establishing a link between animal wastes and health issues and focus on point of contact or purchase	X			Phase 1	Phase 1
Locate areas with corralled animals and educate property owners on bacteria TMDLs		X		Phase 2	Phase 3
Post signs at County and City-owned trailheads designated for equestrian users to not clean out horse trailers in parking lots and to clean up horse waste			X	Phase 2	Phase 3*
Outreach at trailheads encouraging hikers to use restroom facilities			X	Phase 2	Phase 3*
Provide septic system (OWTS) pumpers and customers with septic system guides.	X			Phase 1	Phase 2

4.2 Assumptions

The assumptions inherent to this quantitative assessment approach are as follows:

- BMP percent concentration reductions are the same for each indicator group.
- Bacteria concentrations in stormwater are not a function of rainfall or runoff volume or intensity. Based on a regression analysis between rainfall depths (both 1 day and 4 day totals) and enterococcus concentrations (the most common cause of exceedance days at J1/4 sites in 2004/05), no correlation could be found, thus supporting this assumption.
- Bacteria source contributions (in terms of percent of total load) are not a function of rainfall or runoff volume or intensity (e.g., humans contribute x% of the total bacteria load regardless of whether there is a small or large storm).
- For regional structural BMP effectiveness estimates:
    - BMP designs will adhere to sizing criteria which are based on discharge frequencies equal to the reference watershed number of allowable yearly exceedances, therefore bypass or overflow conditions are assumed to correspond to allowable discharges.
    - BMP treatment area (in terms of percent of total developed area) and BMP effectiveness (in terms of anticipated influent vs effluent concentration reduction) can be multiplied to estimate percent bacteria concentration reductions at the subwatershed outlet.
- For regional and on-site structural BMP effectiveness estimates:
    - BMP percent concentration reduction is constant, is not a function of raw influent concentration, and is a sufficiently robust and predictable statistic for estimating BMP performance.
- For non-structural BMP effectiveness estimates:
    - Surveys for the Los Angeles County focused study on willingness to change pollutant-causing behaviors, which demonstrated approximately 50% implementation in response to outreach activities, are applicable for various outreach types (e.g., targeting pet, equestrian, or human sources) and for various demographics and coastal areas within the LA region.

- Source load percentages reported in relevant bacteria source tracking studies can be used to estimate maximum concentration reductions achievable.

4.3 J1/4 IP Activities

Subwatershed-specific BMPs that were modeled for this quantitative assessment analysis are summarized in Tables 5 and 6. Table 5 summarizes those activities planned for implementation in Phases I and II (which corresponds to the 10% interim target deadline), and Table 6 summarizes those activities planned for implementation in Phase III (which corresponds to the 25% interim target deadline.

Table 5. J1/4 IP Phase I/II BMP activities summary (for 10% interim target)

* A *piloted* BMP according to the J1/4 IP's subwatershed specific BMP summary matrices.

** A *considered* and "if necessary" BMP according to the J1/4 IP's subwatershed specific BMP summary matrices. These BMPs were not modeled for the quantitative assessment.

4.3.1 Regional structural BMPs

For the J1/4 quantitative assessment analysis, only "commit" and "pilot" BMP activities were included. To conservatively assess water quality benefits of the J1/4 IP, "consider" activities were not assumed to be implemented. Regional structural BMPs here include capture, store, treat, and discharge or reuse projects. These BMPs are planned for 4 of the 5 high priority subwatersheds only, according to the J1/4 IP.

No regional structural BMPs are planned for Phase I/II, therefore no regional BMP effectiveness is assumed for Phase I/II. Regional structural BMP effectiveness, in terms of bacteria concentration reduction for Phase III, is summarized in Table 7 for those subwatersheds with plans for implementing regional pilot projects.

Table 7. Summary of Regional BMP Pilot Projects and Estimated Effectiveness Values

Subwatershed	Regional BMP Pilot Project Type	Est. BMP Effectiveness (in terms of percent removal)	Area Treated (as percent of total drainage area) per J1/4 IP	Total Conc. Reduction Assumed for Quantitative Assessment
Ramirez (SMB-1-7)	Storage/ Disinfection	99%	100%	99%
Latigo	Subsurface Wetlands	90%	90%	81%
Corral (SMB-1-12)	Storage/ Disinfection	99%	100%	99%
Las Flores	Creek restoration and biofiltration	25%	80%	20%

No regional structural BMP effectiveness is assumed for Phase III at other subwatersheds, which do not have plans for regional BMPs.

4.3.2 On-site structural BMPs

For the J1/4 quantitative assessment analysis, only "commit" and "pilot" BMP activities were included. To conservatively assess water quality benefits of the J1/4 IP, "consider" activities were not assumed to be implemented. On-site structural BMPs here include cisterns, storage/reuse, small scale infiltration, and on-site wastewater treatment systems. These BMPs are planned for the medium and high priority subwatersheds only, according to the J1/4 IP.

All on-site BMPs were assumed to have 100% effectiveness (since there would not be discharge below the design volume) and treated area coverages equal to 2.5% of the residential areas. 2.5% is based on an assumption that half of the cistern implementation target reported in the J1/4 IP (5-10% of total residential areas) will be achieved by the end of Phase III. Based on percent of total developed areas (i.e., dividing 2.5% of the residential area by total residential and commercial area), this rounds to 2% for all subwatersheds with plans for implementing on-site measures in Phase III.

Table 8 summarizes the land use profiles for each subwatershed, with those subwatersheds with plans for implementing on-site measures highlighted in bold. Residential/educational land use ranges from 10-25% for these subwatersheds. This table also summarizes the treated residential land use area as a percent of the total developed area for each subwatershed.

No on-site structural BMPs are planned for Phase I/II, therefore no on-site BMP effectiveness is assumed for Phase I/II. On-site structural BMP effectiveness, in terms of bacteria concentration reduction, for Phase III is estimated based on fecal coliform load reduction (approach described below) for those subwatersheds with plans for implementing on-site measures. No on-site structural BMP effectiveness is assumed for Phase III at the non-highlighted subwatersheds.

Table 8. Subwatershed land use summary for on-site BMP effectiveness analysis (Subwatersheds in bold are those with residential on-site BMPs planned for Phase III)

Sub-watershed	J1/4 IP Priority	Land Uses				Total Area (acres)

Using the modified rational method, land use areas from Table 8, and runoff coefficients from Ackerman & Schiff (2003) – also reported in the Los Angeles County-wide BMP Prioritization Methodology (Geosyntec, 2006) – total runoff volumes, normalized for precipitation (i.e., volumes per unit rainfall), were computed for each subwatershed. BMP capture volumes (again normalized) were then estimated for on-site structural BMPs based on assumptions for percent residential implementation (2.5%) and percent volume reduction per site (80% average annual volume capture assumed, consistent with SUSMP-based design criteria).

The percent volume capture formula is as follows:

$$V_B = PA_R * A_R * C_R * PV_R$$

RB-AR 7819

9-1705

Where:

V_B = BMP Volume Capture (sum for on-site BMPs), per unit rain depth
PA_R = BMP Implementation as Percent of Total Residential Area
A_R = Total Residential Area
C_R = Residential Runoff Coefficient
PV_R = BMP Percent Volume Capture

Table 9 summarizes the land use runoff coefficients used. Table 10 summarizes the estimated volume capture values for all on-site BMPs.

Table 9. Land Use Runoff Coefficients (Ackerman & Schiff, 2003)

Land Use	**Runoff Coefficient**
Commercial	0.61
Open	0.06
Residential	0.39

Table 10. On-site Volume Capture Summary

Subwatershed	Total BMP Treatment Area (ac)	Residential Runoff Coefficient	Total BMP Volume Capture
Ramirez	21.4	0.39	6.7
Escondido	8.0	0.39	2.5
Latigo	2.0	0.39	0.6
Corral	10.6	0.39	3.3
Las Flores	7.1	0.39	2.2
Piedra Gorda	3.0	0.39	0.9
Topanga	35.2	0.39	11.0

Using the BMP volume capture estimates from above, plus average stormwater pollutant event mean concentration (EMC) values reported in the BMP Methodology (Geosyntec, 2006), percent fecal coliform load removal estimates were made for on-site structural BMPs is as follows:

$$PLC = \frac{V_B * EMC_R}{\sum_i A_i * C_i * EMC_i}$$

Where:

PLC = Cumulative On-site BMP Percent Pollutant Load Capture
V_B = BMP Volume Capture (sum for on-site BMPs), per unit rain depth
EMC_R = Average Event Mean Concentration (EMC) for Residential
i = Land Use Category
A_i = Total Area for Land Use i
C_i = Runoff Coefficient for Land Use i
EMC_i = Average EMC for Land Use i

Table 11 summarizes the land use average fecal coliform EMC values used. Table 12 summarizes the percent fecal coliform load capture estimates for on-site BMPs, by subwatershed. These load percents were then assumed to directly translate to percent bacteria concentration reductions based on the simplifying assumption that total subwatershed runoff volume reductions were negligible (otherwise this translation would require adjustment for total reduced volume); this approach is consistent with the method employed for other jurisdictions. Therefore Table 12 reports the final on-site BMP effectiveness estimates used for this Quantitative Assessment analysis.

Table 11. Average Fecal Coliform EMCs by Land Use (Geosyntec, 2006)

Land Use	Fecal Coliform, MPN/100ml
Commercial/ Educational	72,035
Open	255
HDSF Residential	98,272

Table 12. On-site Fecal Coliform Load Capture Summary (as percent of total load)

Subwatershed	Bacteria (Fecal Coliform)
Ramirez	1.9%
Escondido	1.9%
Latigo	2.0%
Corral	1.6%
Las Flores	1.9%
Piedra Gorda	2.0%
Topanga	1.9%

4.3.3 Non-structural BMPs

For the J1/4 quantitative assessment analysis, only "commit" and "pilot" BMP activities were included. To conservatively assess water quality benefits of the J1/4 IP, "consider" activities were not assumed to be implemented. Non-structural BMPs here include outreach activities to pet owners, corralled animal owners, equestrian hobbyists, and septic system owners. These BMPs are planned for all priority subwatersheds, according to the J1/4 IP.

Non-structural BMPs were assumed to be 50% effective (in terms of behavior change) based on Los Angeles County surveys on willingness to change pollutant-causing behavior.

Humans and pets (addressed in all subwatersheds in Phase I/II) were assumed to contribute 22% of the total source load, based on minimum values reported by relevant bacteria source tracking studies conducted in similar watersheds, in terms of land uses (i.e., low urbanization) and region (i.e., central/southern California). Corralled animals (addressed in all subwatersheds in Phase III) were assumed to contribute a negligible portion of the total source. Horses (addressed only in the Topanga subwatershed, during Phase III) were assumed to contribute 2% of the total source load. Table 13 summarizes the source contributions reported in the referenced studies.

Non-structural BMP effectiveness for Phase I/II is estimated at 11%, in terms of bacteria concentration reduction. This is based on 50% implementation effectiveness multiplied by 22% human and pet source contributions. No addition non-structural BMP effectiveness is assumed for all subwatersheds other than Topanga for Phase III due to negligible source contributions reported for corralled animals in analogous watersheds. Phase III non-structural reduction at Topanga is estimated at 12% since horse control measures are also proposed here for pilot implementation. Reductions associated with equestrian BMPs are not included in the reduction estimates for other subwatersheds since their equestrian-related non-structural activities are included as "to be considered" or "if necessary" BMPs in the J1/4 IP.

Table 13. Bacteria source tracking studies used for the J1/4 quantitative assessment.

Watershed:	Rincon Watershed*	Morro Bay**	San Lorenzo River	Value Used for Quant. Assessment
Year of Report:	1999	2002	2006	NA
CA County:	Ventura	San Louis Obispo	Santa Cruz	NA

** Results shown for Los Osos and Chorro Creeks.

4.4 Estimated Water Quality Benefits

Estimated bacteria percent concentration reductions, by subwatershed, are summarized in Table 14 for Phase I/II (corresponding to the 10% interim target deadline), and in Table 15 for Phase III (corresponding to the 25% interim target deadline). To avoid double counting, for Phase III subwatersheds where multiple BMPs are planned, total concentration reductions were estimated by the following steps:

1. For Latigo and Las Flores subwatersheds: On-site structural BMP effectiveness estimates were summed with the regional BMP effectiveness estimates based on the assumption that on-site BMPs can be located upstream of these subsurface wetland and creek restoration/biofiltration projects, and their benefits still be realized. It was also assumed that estimated on-site BMP effectiveness values were small enough, and estimation methods conservative enough, that double-counting impacts would be negligible. Non-structural BMP effectiveness estimates were multiplied by the area not treated by these regional projects (10% and 20% for Latigo and Las Flores, respectively), and this scaled-down effectiveness was added to the on-site/regional effectiveness total.

2. For Ramirez (SMB-1-7) and Corral (SMB-1-12) subwatersheds: On-site structural and non-structural BMP effectiveness estimates were not included due to the significant effectiveness (99%) already estimated for these disinfection regional BMP projects.

3. For Ramirez (SMB-1-6), Corral (SMB-1-11), Escondido, Piedra Gorda, and Topanga subwatersheds: No regional BMPs proposed for these subwatersheds. On-site BMP effectiveness estimates were simply summed with non-structural BMP effectiveness estimates. It was assumed that estimated on-site BMP effectiveness values were small enough, and estimation methods conservative enough, that double-counting impacts would be negligible.

4. For all other subwatersheds: Only non-structural BMPs apply here.

Table 14. J1/4 IP Phase I/II Estimated Percent Concentration Reduction Benefits (for 10% interim target)

4.5 Comparison to Interim Targets

Computed SS exceedance day reductions, based on estimated bacteria percent concentration reductions and 2004/05 monitoring data, are summarized in Table 12.

These results demonstrate that total estimated exceedance day reductions for Phase I/II of the J1/4 IP do not meet the 10% interim target, although the total estimated exceedance day reductions for Phase III of the J1/4 IP do meet the 25% interim target.

5 ESTIMATE INTEGRATED WATER RESOURCES BENEFITS

5.1 Thresholds for Quantified Benefits

Resolution No. 2006-005, item 6 states that "a longer implementation schedule… shall be granted if there is a clear demonstration that an integrated water resources approach will be pursued…. The types of approaches coupled with quantifiable estimates of the integrated water resources benefits of the proposed structural and non-structural BMPs included in the Implementation Plan would provide the obligatory demonstration that an integrated water resources approach is being pursued. This demonstration shall provide numeric estimates of the benefits, including the reductions in other pollutants, groundwater recharged, acres of multi-use projects, and water (e.g., stormwater, runoff, wastewater) beneficially reused among other integrated water resources criteria…"

In order to provide a clear demonstration of integrated water resources, the following thresholds were established to be the criteria related to quantifiable (numeric) estimates.

5.1.1 Threshold for reductions of pollutants

For the first (10 percent) interim target deadline, each subwatershed will implement BMPs that address targeted pollutant groups. These pollutant groups are consistent with the Los Angeles County-Wide BMP Prioritization Methodology (Geosyntec, 2006) jointly established by the County of Los Angeles, City of Los Angeles and Heal the Bay, funded by the State Water Resources Control Board, and administered by the Regional Water Quality Control Board. These pollutant groups (excluding bacteria) are nutrients, metals, total suspended sediment (TSS), and trash.

For the second (25 percent) interim target deadline, numeric reductions in pollutant loads and concentrations will, on a limited basis, mimic the spatial patterns of the anticipated bacteria load reductions. Because target reductions have not been established in TMDL Implementation Plans, it is assumed that significant load reductions will constitute a clear demonstration of quantified benefits.

5.1.2 Groundwater recharged

As discussed in the Implementation Plan, groundwater recharge opportunities are limited due to soil types and steep slope conditions. Furthermore, groundwater is not a water supply resource locally, and infiltration near onsite wastewater systems may cause undesired impacts to water quality. Therefore, regional groundwater recharge (exclusive of limited onsite site-design measures) was not considered an integrated water resource benefit that should be implemented or quantified.

Implementation of groundwater-related on-site measures will be implemented as part of the 25 percent interim target deadline and coordinated with water reuse measures. The thresholds for a clear demonstration of groundwater-related on-site BMPs are twofold: 1) the percentages of watersheds in which small-scale BMPs are implemented (with a target equal to the 25% interim exceedance day reduction target), and 2) the volume of potential water captured.

5.1.3 Water reused

Water reuse BMPs include residential cisterns and onsite storage and reuse projects. The thresholds for a clear demonstration of water reuse-related on-site BMPs are twofold: 1) the percentages of watersheds in which cisterns and onsite project BMPs are implemented (with a target equal to the 25% interim exceedance day reduction target), and 2) the volume of potential water captured.

5.1.4 Other benefits

The implementation plan also described other beneficial uses, some of which are not described in the TMDL, but may still have significant value to the region. These additional benefits are habitat development, geomorphology and hydrology considerations, and flood control The thresholds for these measures are limited to an accounting of the number (and fraction) of the subwatersheds where these benefits are anticipated.

5.1.5 Acres of project

As described in the Implementation Plan the following describes current land use in the J1/4 jurisdictional areas. Managed and natural open spaces comprise 88% of the total jurisdictional areas. Acreage for project implementation will be limited to partial utilization on specific parcels, and selected regional facilities. In most cases, the regional facilities that provide any direct integrated benefits (such as the subsurface wetlands in Latigo and stream restoration in Las Flores) are already open space. Therefore, because any changes in land use acreage would not change the land use distribution, acres of project are not discussed in terms of a metric for quantifying integrated benefits.

Land Use	Acres	Percentage
Residential/Educational	5,983	11%
Industrial/Commercial	398	1%
Managed Open Space	609	1%
Natural Open Space	47,650	87%
Total	54,640	100 %

5.2 Potential for compliance with interim thresholds based on watershed implementation

The following table quantifies the extent of compliance of integrated water resources elements based on spatial distribution and subwatershed implementation.

Integrated Water Resources (IWR) Elements	Percentage of subwatersheds implementing	
	10 Percent Bacteria Target	*25 Percent Bacteria Target*
Multiple Pollutants Addressed	100%	*100%*
Groundwater Recharged	Planning only	*44% (7 of 16)*
Water reused	Planning only	*44% (7 of 16)*
Other benefits	*100%*	*100%*

Tables 17-20 summarize, for each recommended BMP and for each subwatershed, both the target pollutants and the water resources benefits.

Table 17. Multi-Pollutant Benefits Summary Matrix

5.3 Quantified IWR Benefits – Water Conservation

Using the modified rational method, land use information from the Implementation Plan, and runoff coefficients from Ackerman & Schiff (2003) – also reported in the Los Angeles County-wide BMP Prioritization Methodology (Geosyntec, 2006) – total runoff volumes, normalized for precipitation (i.e., volumes per unit rainfall), were computed for each subwatershed. BMP capture volumes (again normalized) were then estimated for on-site structural BMPs based on assumptions for percent residential implementation (2.5%, from Section 3) and percent volume reduction per site (80% average annual volume capture assumed, consistent with SUSMP-based design criteria). To estimate reuse volumes, cisterns and storage/reuse BMP capture volumes were used (assumed 2/3 of total on-site BMP application). To estimate groundwater recharge volumes, infiltration BMP capture volumes were used (assumed 1/3 of total on-site BMP application). Percent of total subwatershed runoff volume was used to characterize these benefits. No regional structural or non-structural water conservation benefits were quantified.

The percent volume capture formula is as follows:

$$PVC = \frac{PA_R * A_R * C_R * PV_R}{A_S * C_S}$$

Where:

PVC = Cumulative BMP Percent Volume Capture
PA_R = BMP Implementation as Percent of Total Residential Area
A_R = Total Residential Area
C_R = Residential Runoff Coefficient
PV_R = BMP Percent Volume Capture
A_S = Total Subwatershed Area
C_S = Subwatershed Net Runoff Coefficient

Table 21 summarizes the land use runoff coefficients used. Tables 22 and 23 summarize the percent volume capture estimates for reuse and infiltration BMPs, respectively.

Table 21. Land Use Runoff Coefficients (Ackerman & Schiff, 2003)

Land Use	Runoff Coefficient
Commercial	0.61
Open	0.06
Residential	0.39

Table 22. On-site Reuse Volume Summary (Cisterns and Storage/Reuse BMPs)

Subwatershed	Total BMP Treatment Area (ac)	Residential Runoff Coefficient	Total BMP Volume Capture (ac-ft)	Sub-watershed Area (ac)	Sub-watershed Net Runoff Coefficient	Sub-watershed Total Volume (ac-ft)	Percent Volume Reuse
Ramirez	14.2	0.39	4.4	3,350	0.149	498	0.9%
Escondido	5.3	0.39	1.7	2,300	0.108	250	0.7%
Latigo	1.3	0.39	0.4	824	0.093	76	0.5%
Corral	7.1	0.39	2.2	4,297	0.106	454	0.5%
Las Flores	4.7	0.39	1.5	2,920	0.095	278	0.5%
Piedra Gorda	2.0	0.39	0.6	628	0.124	78	0.8%
Topanga	23.5	0.39	7.3	12,586	0.098	1,238	0.6%

Table 23. On-site Groundwater Recharge Volume Summary (infiltration BMPs)

Sub-watershed	Total BMP Treatment Area (ac)	Residential Runoff Coeff.	Total BMP Volume Capture (ac-ft)	Sub-watershed Area (ac)	Sub-watershed Net Runoff Coefficient	Sub-watershed Total Volume (ac-ft)	Percent Volume Infiltr.
Ramirez	7.1	0.39	2.2	3,350	0.149	498	0.4%
Escondido	2.7	0.39	0.8	2,300	0.108	250	0.3%
Latigo	0.7	0.39	0.2	824	0.093	76	0.3%
Corral	3.5	0.39	1.1	4,297	0.106	454	0.2%
Las Flores	2.4	0.39	0.7	2,920	0.095	278	0.3%
Piedra Gorda	1.0	0.39	0.3	628	0.124	78	0.4%
Topanga	11.7	0.39	3.7	12,586	0.098	1,238	0.3%

5.4 Quantified Multi-Pollutant Benefits

Using the BMP volume capture estimates from above, plus average stormwater pollutant event mean concentration (EMC) values reported in the BMP Methodology (Geosyntec, 2006), percent load removal estimates were made for total suspended solids (TSS; sediment metric), trash, nitrate (nutrient metric), and total lead (metal metric).

The percent load capture formula for on-site structural BMPs is as follows:

$$PLC = \frac{V_B * EMC_R}{\sum_i A_i * C_i * EMC_i}$$

Where:

PLC = Cumulative On-site BMP Percent Pollutant Load Capture
V_B = BMP Volume Capture (sum for on-site BMPs)
EMC_R = Average Event Mean Concentration (EMC) for Residential
i = Land Use Category
A_i = Total Area for Land Use i
C_i = Runoff Coefficient for Land Use i
EMC_i = Average EMC for Land Use i

Table 24 summarizes the land use average EMC values used. Table 25 summarizes the percent pollutant load capture estimates for on-site BMPs, by subwatershed.

Multi-pollutant benefits were also evaluated for the four regional structural BMP projects proposed. A simple load reduction estimation approach was employed. Percent volume capture was multiplied by percent concentration reduction, as shown in the formula below. Average percent volume capture is assumed equal to percent area treated, as reported in section 4.3.1, therefore this approach is only appropriate for flows below the water quality volume. Unlike the on-site BMP load reduction estimation approach, a percent concentration reduction term was required for each regional BMP for each pollutant because these are flow-through BMP types (i.e., removal is less than 100%). These assumed percent concentration reduction values are summarized in Table 26, and are approximations based on best professional judgment.

The estimated load reductions for each regional BMP project are summarized in Table 27.

The percent load reduction formula for regional structural BMPs is as follows:

$$PLR = PV_B * PCR_V$$

Where:

PLR = Regional BMP Percent Pollutant Load Reduction
PV_B = BMP Percent Volume Treatment (of total subwatershed runoff volume)
PCR_B = BMP Percent Concentration Reduction

Non-structural BMP multi-pollutant benefits were evaluated qualitatively and are summarized in Table 28. These results are based on reported estimates from the Malibu Creek Quantitative Assessment, Task QA.3 (CDM, 2006) as well as an understanding of the source and transport mechanisms associated with each pollutant and targeted by each non-structural activity.

Table 24. Average EMCs by Land Use for Indicator Pollutants (Geosyntec, 2006)

Land Use	Trash, cf/ac	Nitrate, mg/L-N	Total Lead, ug/L	TSS, mg/L
Commercial/ Educational	1.0	0.46	2.1	58
Open	0.0	1.0	0.01	28
HDSF Residential	1.0	0.30	5.0	65

Table 25. On-site Pollutant Load Capture Summary (as percent of total load)

Subwatershed	Trash	Nutrients (Nitrate)	Metals (Total Lead)	Sediment (TSS)
Ramirez	1.9%	0.8%	2.0%	1.6%
Escondido	1.9%	0.5%	1.9%	1.4%
Latigo	2.0%	0.3%	2.0%	1.2%
Corral	1.5%	0.3%	1.7%	1.0%
Las Flores	1.8%	0.3%	1.9%	1.2%
Piedra Gorda	2.0%	0.6%	2.0%	1.6%
Topanga	1.9%	0.4%	2.0%	1.3%

Table 26. Estimated Average Percent Concentration Reductions by Regional BMP Type

Regional BMP Type	Trash, cf/ac	Nitrate, mg/L-N	Total Lead, ug/L	TSS, mg/L
Storage/Treatment	90%	30%	30%	50%
Subsurface Flow Wetlands	90%	90%	90%	90%
Creek Restoration/ Biofiltratoin	30%	90%	70%	70%

Table 27. Regional BMP Pollutant Load Capture Summary (as percent of total load)

Subwatershed (proposed regional BMP project type)	Trash	Nutrients (Nitrate)	Metals (Total Lead)	Sediment (TSS)
Ramirez (SMB-1-7) (storage/ treatment)	90%	30%	30%	50%
Latigo (subsurface flow wetland)	81%	81%	81%	81%
Corral (storage/ treatment)	90%	30%	30%	50%
Las Flores (SMB-1-2) (restoration/ biofiltration)	24%	72%	56%	56%

Table 28. Reduction in Non-Bacteria Related Pollutant Loads that Could be Achieved by Non-Structural BMPs Proposed in the J1/4 IP

BMP	Trash	Nutrients (Nitrate)	Metals (Total Copper)	Sediment (TSS)
Septic Guidance	Low	High	Low	Low
Pet Owner Outreach	Low	High	Low	Medium
Horse & Corralled Animal Owner Outreach	Low	Medium	Low	Medium

6 LIMITATIONS

The following limitations are provided to clarify and constraint potential future applications of this analysis:

- The purpose of analysis was solely to meet submittal requirements established by the LARWQCB that were stipulated in order to establish an integrated water resources approach (and commensurate implementation schedule). No other use or application is intended.

- The analyses should be revisited should any other application be considered.

- The analyses presented herein were based on previously submitted methodologies and assumptions that were previously approved in concept by the LARWQCB.

- The analyses presented herein do not provide an evaluation of uncertainty or probability and represent the best estimate of the Santa Monica Bay Beaches jurisdictional agencies.

APPENDIX A

LARWQCB RESOLUTION NO. 2006-005

State of California
California Regional Water Quality Control Board, Los Angeles Region

RESOLUTION NO. 2006-005
April 6, 2006

Statement of support for the efforts of responsible jurisdictions and agencies in Jurisdictional Groups 1 and 4 to utilize an integrated water resources approach to achieve full compliance with the Santa Monica Bay Beaches Bacteria Wet Weather TMDL in the shortest possible timeframe and no later than 2021

WHEREAS, the California Regional Water Quality Control Board, Los Angeles Region, finds that:

1. The federal Clean Water Act (CWA) requires the California Regional Water Quality Control Board, Los Angeles Region (Regional Board) to develop water quality standards which include beneficial use designations and criteria to protect beneficial uses for each water body found within its region.

2. The Regional Board carries out its CWA responsibilities through California's Porter-Cologne Water Quality Control Act and establishes water quality objectives designed to protect beneficial uses contained in the Water Quality Control Plan for the Los Angeles Region (Basin Plan).

3. Section 303(d) of the CWA requires states to identify and to prepare a list of water bodies that do not meet water quality standards and then to establish load and waste load allocations, or a total maximum daily load (TMDL), for each water body that will ensure attainment of water quality standards and then to incorporate those allocations into their water quality control plans.

4. Many of the beaches along Santa Monica Bay were listed on California's 1998 section 303(d) List, due to impairments for coliform or for beach closures associated with bacteria generally. The beaches appeared on the 303(d) List because the elevated bacteria and beach closures prevented full support of the beaches' designated use for water contact recreation (REC-1).

5. A consent decree between the U.S. Environmental Protection Agency (USEPA), Heal the Bay, Inc. and Santa Monica BayKeeper, Inc. was approved on March 22, 1999. This court order required completion of a TMDL to reduce bacteria at Santa Monica Bay beaches by March 2002.

6. The Regional Board adopted two TMDLs to address bacteriological water quality impairments for 44 beaches along Santa Monica Bay located in Los Angeles County, California. The Regional Board adopted a TMDL to address water quality impairments during dry weather on January 24, 2002 and a TMDL to address wet weather impairments on December 12, 2002 (Resolutions 2002-004 and 2002-022, respectively).

7. The Regional Board incorporated the dry weather and wet weather TMDLs along with appropriate implementation measures into its Basin Plan as required (40 CFR 130.6(c)(1),

130.7). The Basin Plan and applicable statewide plans serve as the State Water Quality Management Plans governing the watersheds under the jurisdiction of the Regional Board.

8. The Regional Board established the above-mentioned TMDLs to preserve and enhance the water quality at Santa Monica Bay beaches and for the benefit of the 55 million beachgoers, on average, that visit these beaches each year. At stake is the health of swimmers and surfers and associated health costs as well as sizeable revenues to the local and state economy. Estimates are that visitors to Santa Monica Bay beaches spend approximately $1.7 billion annually.

9. The Regional Board's goal in establishing the above-mentioned TMDLs is to reduce the risk of illness associated with swimming in marine waters contaminated with bacteria. Local and national epidemiological studies compel the conclusion that there is a causal relationship between adverse health effects, such as gastroenteritis and upper respiratory illness, and recreational water quality, as measured by bacteria indicator densities. The water quality objectives on which the TMDL numeric targets are based will ensure that the risk of illness to the public from swimming at Santa Monica Bay beaches generally will be no greater than 19 illnesses per 1,000 swimmers, which is defined by the USEPA as an "acceptable health risk" in marine recreational waters.

10. The Dry Weather and Wet Weather Santa Monica Bay Beaches Bacteria TMDLs cover 44 beaches and 29 subwatersheds, with multiple jurisdictions and agencies that are responsible for compliance. Therefore, in the Wet Weather TMDL for implementation planning the Regional Board grouped the subwatersheds into Jurisdictional Groups. Each Jurisdictional Group is comprised of one or more subwatersheds, the beach(es) associated with these subwatersheds, and all responsible jurisdictions and agencies within the subwatershed(s). Each Jurisdictional Group is assigned a primary jurisdiction. A primary jurisdiction is that jurisdiction comprising greater than fifty percent of the subwatershed land area. The primary jurisdiction is responsible for submitting an implementation plan for the Jurisdictional Group per the requirements of the Wet Weather TMDL.

11. Jurisdictional Group 1 is responsible for sixteen subwatersheds, including Arroyo Sequit, Los Alisos, Encinal, Trancas, Zuma, Ramirez, Escondido, Latigo, Solstice, Corral, Carbon, Las Flores, Piedra Gorda, Pena, Tuna, and Topanga. The primary jurisdiction is the County of Los Angeles. Other participating responsible jurisdictions and agencies in Jurisdictional Group 1 include the City of Malibu and California Department of Transportation (Caltrans).

12. Jurisdictional Group 4 is responsible for one subwatershed, referred to as the Nicholas Canyon subwatershed. The primary jurisdiction is the City of Malibu. Other participating responsible jurisdictions and agencies in Jurisdictional Group 4 include the County of Los Angeles and Caltrans.

13. During the adoption of the wet weather TMDL, the Regional Board recognized two broad approaches to implementing the TMDL. One possible approach is an integrated water resources approach that takes a holistic view of regional water resources management by integrating planning for future wastewater, storm water, recycled water, and potable water needs and systems; focuses on beneficial re-use of storm water, including groundwater infiltration, at multiple points throughout a watershed; and addresses multiple pollutants for which Santa Monica Bay or its watershed are listed on the CWA section 303(d) List as impaired. The other possible approach is a non-integrated water resources approach in which

implementation is achieved by focusing on narrowly tailored, end-of-the-pipe solutions to improve bacteriological water quality without incorporating other environmental and public goals.

14. The Regional Board recognized that an integrated water resources approach not only provides water quality benefits to the people of the Los Angeles Region, but also that the responsible jurisdictions implementing this TMDL can serve a variety of public purposes by adopting an integrated water resources approach. An integrated water resources approach will address multiple pollutants, and as a result, responsible jurisdictions can recognize cost-savings because capital expenses for the integrated approach will implement several TMDLs that address pollutants in storm water. In addition, jurisdictions serve multiple roles for their citizenry, and an integrated approach allows for the incorporation and enhancement of other public goals such as water supply, recycling and storage; environmental justice; parks, greenways and open space; and active and passive recreational and environmental education opportunities.

15. The Regional Board acknowledged that a longer timeframe is reasonable for an integrated water resources approach because it requires more complicated planning and implementation such as identifying markets for the water and efficiently siting storage and transmission infrastructure within the watershed(s) to realize the multiple benefits of such an approach. Therefore, after considering testimony, the Regional Board revised the implementation provisions of the TMDL to allow for a longer implementation schedule (*up to* 18 years) if the responsible jurisdictions and agencies clearly demonstrate their intention to undertake an integrated water resources approach and justify the need for a longer implementation schedule. In contrast, the Regional Board required a shorter implementation schedule (*up to* 10 years) for non-integrated approaches because the level of planning is not as complicated.

16. The Regional Board has the authority to provide compliance schedules through the basin planning process. In the wet weather TMDL, adopted by the Regional Board, the Regional Board established dual schedules for implementation that afford the responsible jurisdictions and agencies up to ten or eighteen years, depending on the implementation approaches pursued, to implement the wet weather TMDL.

17. The implementation provisions in Table 7-4.4 of the wet weather TMDL state that, "the implementation schedule will be determined on the basis of the implementation plan(s), which must be submitted to the Regional Board by responsible jurisdictions and agencies within two years of the effective date of the TMDL" (Resolution 2002-022, Attachment A).

18. The implementation provisions in Table 7-4.4 further state that, "responsible jurisdictions and agencies must clearly demonstrate in the above-mentioned plan whether they intend to pursue an integrated water resources approach." If the responsible jurisdictions and agencies prefer an integrated approach, there must be a clear demonstration of need for the longer implementation schedule in the implementation plan. Otherwise, at most a 10-year implementation timeframe will be allotted by the Regional Board, depending upon a clear demonstration of the time needed in the implementation plan.

19. Per the requirements set forth in the wet weather TMDL, responsible jurisdictions and agencies in Jurisdictional Groups 1 and 4 jointly submitted a draft Implementation Plan to the Regional Board on March 15, 2005. Regional Board staff met with the responsible jurisdictions and agencies in Jurisdictional Groups 1 and 4 to review and provide comments on the draft Implementation Plan. Regional Board staff also provided written comments to

the responsible jurisdictions and agencies in a letter dated July 8, 2005. The responsible jurisdictions and agencies submitted a final Implementation Plan to the Regional Board on August 30, 2005.

20. The Implementation Plan submitted by Jurisdictional Groups 1 and 4 lays out a four phase, iterative-adaptive program that combines unique non-structural activities, local on-site structural measures and regional structural solutions for each subwatershed based on subwatershed characteristics and priorities.

21. The Implementation Plan for Jurisdictional Groups 1 and 4 incorporates the principles of an integrated water resources approach by taking a holistic view of regional water resources management by integrating planning for future wastewater, storm water, recycled water, and potable water needs and systems; focusing on beneficial re-use of storm water, including groundwater infiltration at multiple points throughout a watershed; and addressing multiple pollutants.

22. The implementation schedule is phased over 16 years with a final compliance date of 2021 (18 years after the effective date of the TMDL). The Implementation Plan for Jurisdictional Groups 1 and 4 is divided into four phases. The first phase begins with the submittal of the final Implementation Plan (July 2005) and extends until July 2007, the date for reconsideration of the TMDL. In the first phase, Jurisdictional Groups 1 and 4 will initiate all committed non-structural activities; pre-feasibility studies for four (4) sub-regional pilot projects; planning for on-site BMPs; and monitoring, additional studies and source identification activities. Phase II extends until July 2010. In the second phase, Jurisdictional Groups 1 and 4 will continue to implement committed non-structural activities; conduct non-structural pilot programs; continue planning for on-site BMPs; initiate planning and construction of sub-regional pilot projects; and continue monitoring and source identification studies. Phase III extends until July 2013. In the third phase, Jurisdictional Groups 1 and 4 will refocus and reprioritize efforts as appropriate and continue to implement committed non-structural activities; implement successful piloted non-structural programs; begin to implement on-site BMPs; and operate and evaluate pilot sub-regional projects. The final phase extends until final compliance in 2021. In the final phase, Jurisdictional Groups 1 and 4 will again refocus and reprioritize efforts as appropriate and continue to implement non-structural solutions; continue or expand on-site BMPs; and continue, modify or initiate regional structural solutions.

23. The responsible jurisdictions and agencies in Jurisdictional Groups 1 and 4 have committed to 14 targeted non-structural measures; 4 local on-site structural measures; and 4 subregional pilot projects in high priority subwatersheds pending the results of the feasibility studies. These commitments are expected to achieve the early interim milestones of 10% and 25% reductions in exceedance days beyond the allowable exceedance days set forth in the wet weather TMDL.

24. Regional solutions are a secondary resort in managing runoff and reducing bacteria loading at the beaches. However, due to scientific uncertainties it is not possible to guarantee that the implementation actions outlined in the Implementation Plan for Jurisdictional Groups 1 and 4 will achieve the necessary reductions in exceedance days as required by the TMDL. Therefore, it is essential to start the feasibility and conceptual analyses for regional solutions early in the implementation schedule (prior to 2013) in order to identify potential land requirements, physical limitations, and implementation issues. Because these regional solutions require a significant amount of time to plan and implement, beginning the

feasibility analyses early will provide the responsible jurisdictions and agencies sufficient time to make changes and other arrangements and still keep to the implementation schedule.

25. Interested persons and the public have had reasonable opportunity to participate in the development and review of the Implementation Plan for Jurisdictional Groups 1 and 4. The responsible jurisdictions and agencies in Jurisdictional Groups 1 and 4 held two stakeholder workshops on December 1, 2004 and February 1, 2005 during the development of the Implementation Plan.

26. The final Implementation Plan for Jurisdictional Groups 1 and 4 submitted by the responsible jurisdictions and agencies to the Regional Board was posted on the Regional Board's website in advance of the April 6, 2006 Board hearing. A Notice of Hearing was published and circulated 30 days preceding Board action; Regional Board staff responded to oral and written comments received from the public; and the Regional Board held a public hearing on April 6, 2006 to consider the Implementation Plan for Jurisdictional Groups 1 and 4.

THEREFORE, be it resolved that pursuant to Regional Board Resolution 2002-022, Attachment A, Amendment to the Water Quality Control Plan – Los Angeles Region to incorporate Implementation Provisions for the Region's Bacteria Objectives and to incorporate the Santa Monica Bay Beaches Wet Weather Bacteria TMDL, Table 7-4.4, "Implementation", adopted by the Regional Board on December 12, 2002 and effective on July 15, 2003:

1. The Regional Board hereby acknowledges the submission of a draft Implementation Plan and final Implementation Plan dated August 30, 2005 by responsible jurisdictions and agencies in Jurisdictional Groups 1 and 4, including the City of Malibu, County of Los Angeles and California Department of Transportation, per requirements of the Santa Monica Bay Beaches Bacteria Wet Weather TMDL as set forth in Resolution 2002-022, Attachment A, Table 7-4.7.

2. The Regional Board hereby determines that the responsible jurisdictions and agencies in Jurisdictional Groups 1 and 4 as identified in (1) have demonstrated at a conceptual level in the Implementation Plan that they intend to pursue an integrated water resources approach as defined in the Santa Monica Bay Beaches Bacteria Wet Weather TMDL, Table 7-4.4.

3. The Regional Board hereby determines that assuming the responsible jurisdictions and agencies in Jurisdictional Groups 1 and 4 as identified in (1) adequately comply with the terms of this resolution, they will have demonstrated based on their conceptual plan the need for the longer implementation schedule as outlined in the final Implementation Plan dated August 30, 2005, which commits to a final compliance date of July 2021.

4. Given the conceptual commitment to an integrated water resources approach and to achieving final compliance by July 2021 outlined in the Implementation Plan for Jurisdictional Groups 1 and 4, the Regional Board strongly supports and encourages the efforts of the responsible jurisdictions and agencies to (1) aggressively implement early actions as outlined in the Implementation Plan and (2) make timely adjustments and refinements to the Implementation Plan to ensure that bacteriological water quality impairments at Santa Monica Bay beaches are resolved in the shortest possible timeframe.

5. The Regional Board encourages an integrated water resources approach and recognizes that additional time may be necessary to pursue such an approach to TMDL implementation. In order to clearly justify an extended implementation schedule beyond 10 years and up to 18 years from the effective date of the TMDL, the responsible jurisdictions and agencies are required to submit additional quantifiable analyses as described below to demonstrate (1) the proposed plans will meet the interim and final WLAs and (2) the proposed implementation actions will achieve multiple water quality benefits and other public goals.

   The Regional Board strongly encourages responsible jurisdictions and agencies pursuing an integrated water resources approach to employ natural methods as opposed to end-of-pipe, whenever it would be effective and feasible.

6. Per the provisions of the TMDL, the Regional Board will determine, when the TMDL is reconsidered in 2007, if a longer implementation schedule (up to 18 years from the TMDL effective date) shall be granted if there is a clear demonstration that an integrated water resources approach will be pursued.

   The types of approaches proposed coupled with quantifiable estimates of the integrated water resources benefits of the proposed structural and non-structural BMPs included in the Implementation Plan would provide the obligatory demonstration that an integrated water resources approach is being pursued. This demonstration shall provide numeric estimates of the benefits, including reductions in other pollutants, groundwater recharged, acres of multi-use projects and water (e.g. stormwater, runoff, wastewater) beneficially reused among other integrated water resources criteria outlined in the Santa Monica Bay Beaches Wet Weather Bacteria TMDL. Responsible jurisdictions and agencies should submit to the Regional Board technically defensible quantifiable estimates of integrated benefits for actions to meet the first and second interim compliance deadlines (6 and 10 years after the effective date of the TMDL, respectively). This information must be submitted within 9 months to allow sufficient time for staff analyses prior to the Board's reassessment of the TMDL, scheduled for July 2007.

7. The Regional Board recognizes that it is critical to establish a technically defensible quantitative linkage to the interim and final waste load allocations (WLAs) to measure progress toward achieving the WLAs. The linkage should include target reductions in stormwater runoff and/or total coliform, fecal coliform and enterococcus using the 90th percentile year for the jurisdictional group and each individual subwatershed.

   The Regional Board also recognizes that it is essential to establish quantitative estimates of the water quality benefits provided by the proposed structural and non-structural BMPs to meet the first interim compliance deadline (6 years after the effective date of the TMDL), and preliminary estimates of the benefits provided by the proposed BMPs to meet the second interim compliance deadline (10 years after the effective date of the TMDL). These estimates, including a quantitative analysis of their linkage to the interim WLAs, are necessary to provide assurance that interim compliance deadlines will be achieved given the uncertainties involved in an integrated water resources approach. Estimates should address reductions in exceedance days, bacteria concentration and loading, and flow in the drain and at each beach compliance monitoring location. Responsible jurisdictions and agencies should submit such information to the Regional Board within nine months so that the Regional Board staff will have time to assess the information in time for the reconsideration of the TMDL.

8. The Regional Board directs staff to develop draft language for Board consideration that incorporates into the Los Angeles County Municipal Separate Storm Sewer System (MS4) NPDES permit at reissuance explicit requirements for responsible jurisdictions and agencies in Jurisdictional Groups 1 and 4 to submit single coordinated regular reports to the Board on progress toward achieving the required reductions set forth in the TMDLs. These single coordinated regular reports may be submitted as part of the Los Angeles County MS4 Annual Program and Annual Monitoring reports. Reports on progress toward compliance with the TMDL shall include data and information on (1) water quality improvements in the receiving water; (2) the effectiveness of BMPs implemented as part of the Implementation Plan for Jurisdictional Groups 1 and 4 measured in terms of water quality improvement and quantity of wet weather runoff reduced, captured, treated, or infiltrated; and (3) the performance of other programmatic solutions, source identification activities and source control measures. Data on water quality improvements may include for example reductions in exceedance days compared to historical data and interim milestones, where appropriate; the proportion of wet weather days that exceed the water quality objectives by storm year as defined in the TMDLs; and corresponding rainfall data as set forth in the Santa Monica Bay Beaches Bacterial TMDLs Coordinated Shoreline Monitoring Plan submitted by responsible jurisdictions and agencies.

   Given the iterative approach outlined in the Implementation Plan for Jurisdictional Groups 1 and 4, reports shall also include documentation on changes and refinements to the Implementation Plan based on the results of shoreline monitoring data, data on BMP effectiveness, and evaluations of pilot projects and other implementation actions under consideration. Such updates to the Implementation Plan shall include revised quantitative estimates of the water quality benefits of the proposed BMPs and the linkage to the waste load allocations identified pursuant to (7) above.

9. The Regional Board further directs staff to develop draft language for Board consideration that incorporates into the Los Angeles County MS4 NPDES permit at reissuance specific provisions to reopen the TMDL section of the permit and incorporate, after providing the opportunity for public comment, TMDL-related provisions as well as additional implementation actions, including but not limited to institutional controls, source identification and control, and structural and treatment controls if adequate progress is not being made to achieve compliance with Santa Monica Bay Beaches Bacteria TMDLs.

10. The Regional Board anticipates the California Department of Transportation (Caltrans) as a responsible agency to work cooperatively with the responsible jurisdictions and agencies under the Los Angeles County MS4 NPDES permit to achieve compliance with the Santa Monica Bay Beaches Bacteria TMDL, including requirements as set forth pursuant to (8) and (9) above. In the event that Caltrans decides to proceed independently to address compliance with the TMDL, Caltrans will be required to meet the applicable significant dates for responsible jurisdictions and agencies as contained in Attachment A to Resolution No. 2002-022, Table 7-4.7.

11. The Regional Board encourages responsible jurisdictions and agencies to begin feasibility studies and planning for regional solutions to managing wet weather runoff and bacteria loading early in the implementation schedule (prior to 2013) to ensure sufficient time to redirect implementation activities if necessary to include regional solutions and still achieve the final compliance deadline.

I, Jonathan Bishop, Executive Officer, do hereby certify that the foregoing is a full, true, and correct copy of a resolution adopted by the California Regional Water Quality Control Board, Los Angeles Region, on April 6, 2006.

Jonathan S. Bishop
Executive Officer

APPENDIX B: WET WEATHER MONITORING RESULTS

The following figures summarize the indicator bacteria measured single sample concentrations, with allowable exceedances removed, for example subwatersheds 1-1 (Arroyo Sequit; reference watershed), 1-5 (Zuma), and 1-9 (Latigo). Total exceedance days at each site are as follows: Arroyo Sequit – 1, Zuma – 4, Latigo – 1. All of these exceedance days are due, at least in part, to enterococcus.

Figures 2 through 4 illustrate 2004/05 wet weather single sample monitoring results, by indicator, for example site 1-1 (Arroyo Sequit; reference watershed).

Figures 5 through 7 present 2004/05 wet weather single sample monitoring results, by indicator, for example site 1-5 (Zuma).

Figures 8 through 10 present 2004/05 wet weather single sample monitoring results, by indicator, for a TMDL-designated High Priority site SMB 1-9 (Latigo).

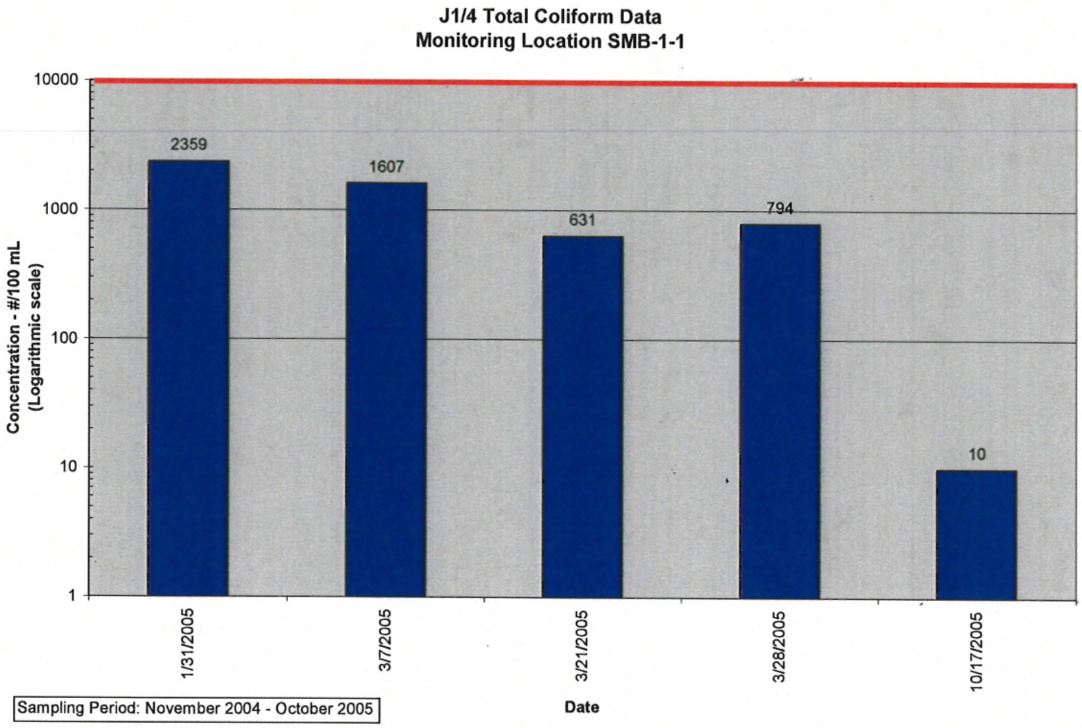

Figure 2 Total Coliform results for Arroyo Sequit (SMB 1-1)

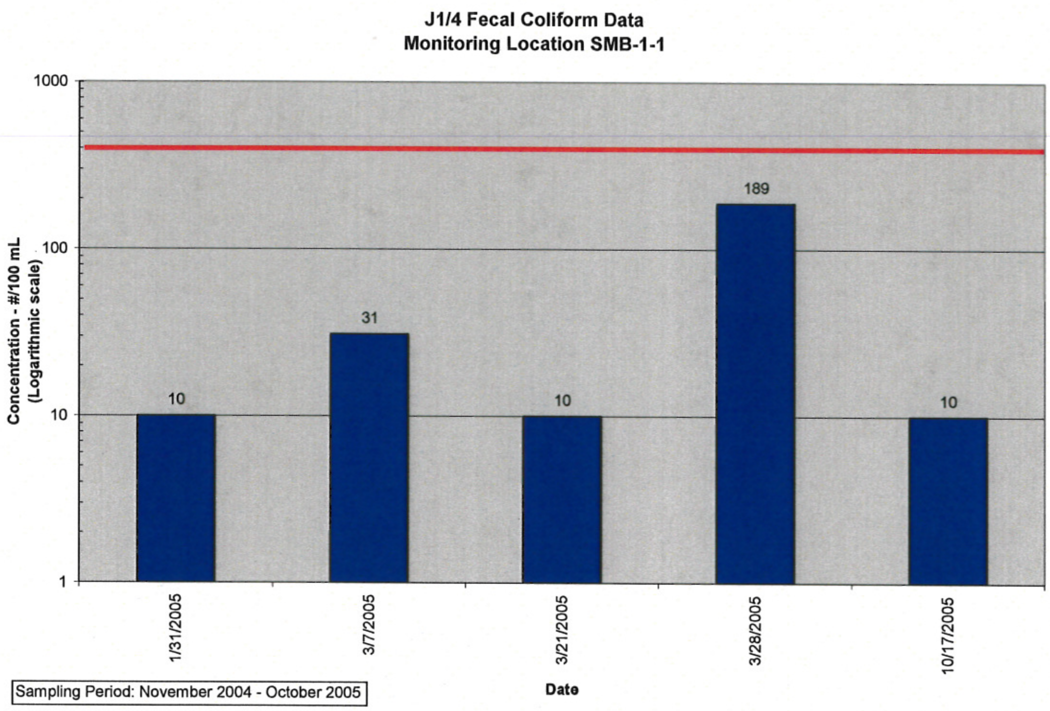

Figure 3. Fecal Coliform results for Arroyo Sequit (SMB 1-1)

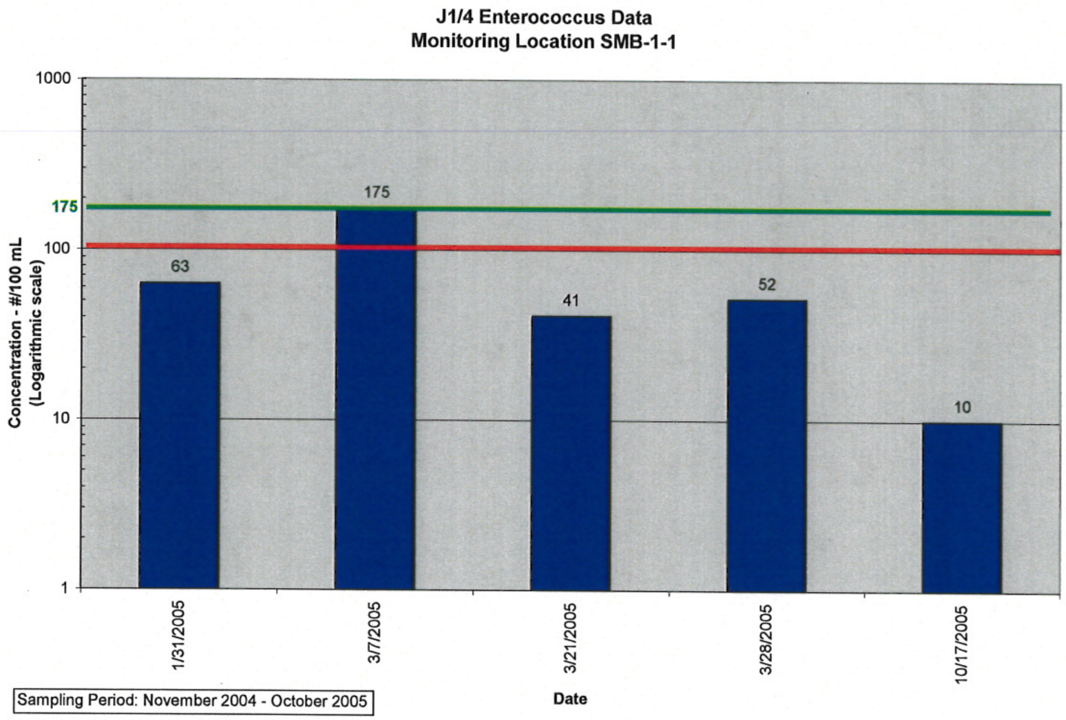

Figure 4 Enterococcus for Arroyo Sequit (SMB 1-1) showing violations of standards

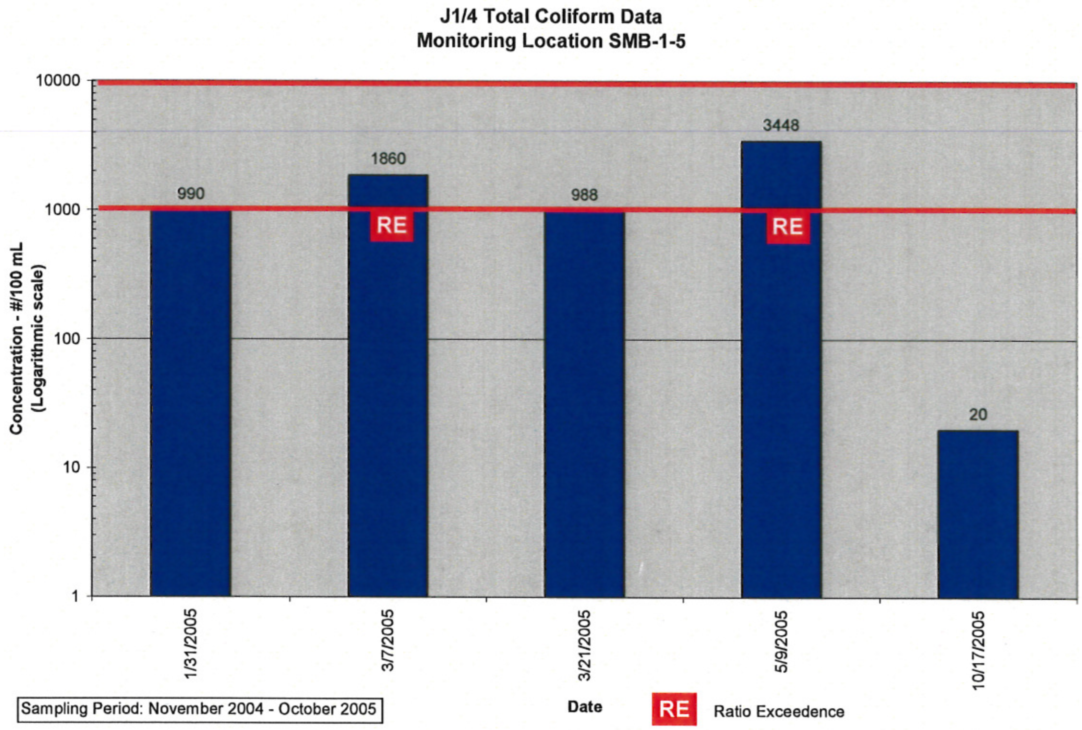

Figure 5. Total Coliform results for Zuma (SMB 1-5)

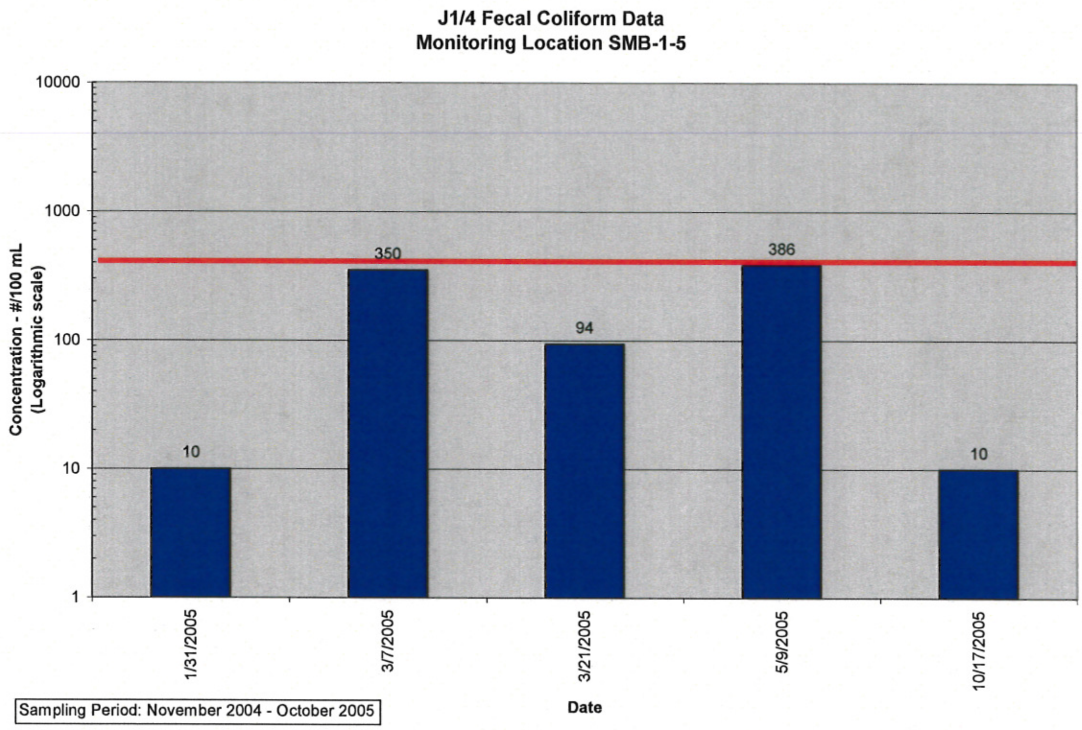

Figure 6. Fecal Coliform results for Zuma (SMB 1-5)

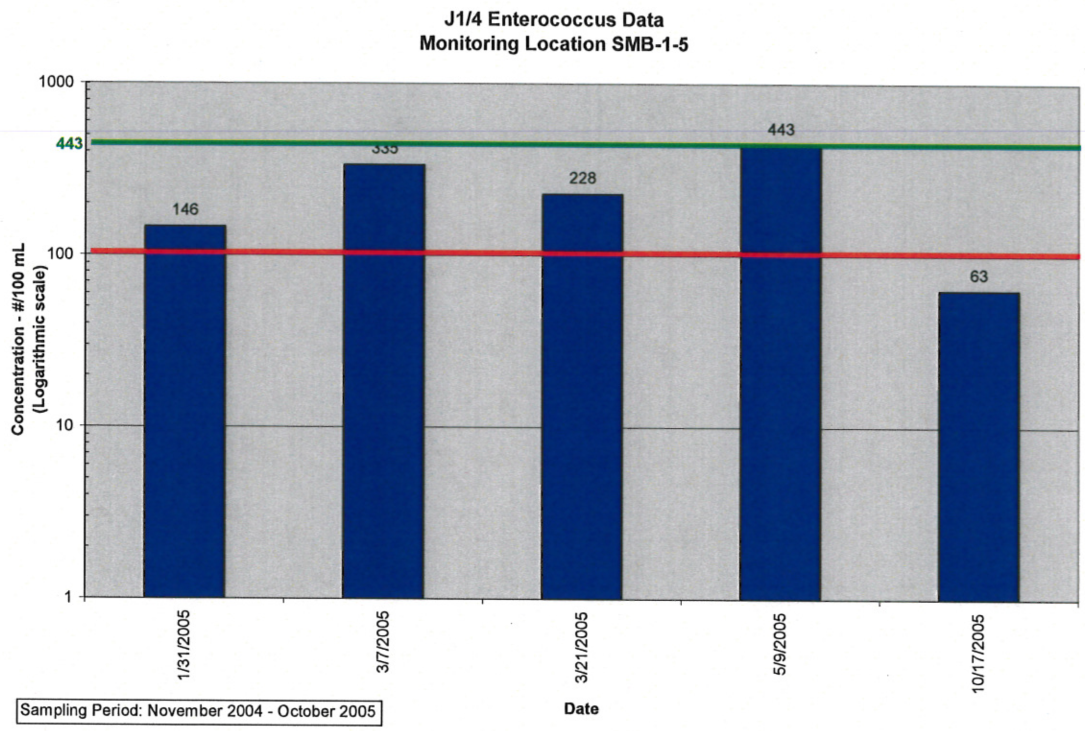

Figure 7. Enterococcus Results for Zuma (SMB 1-5)

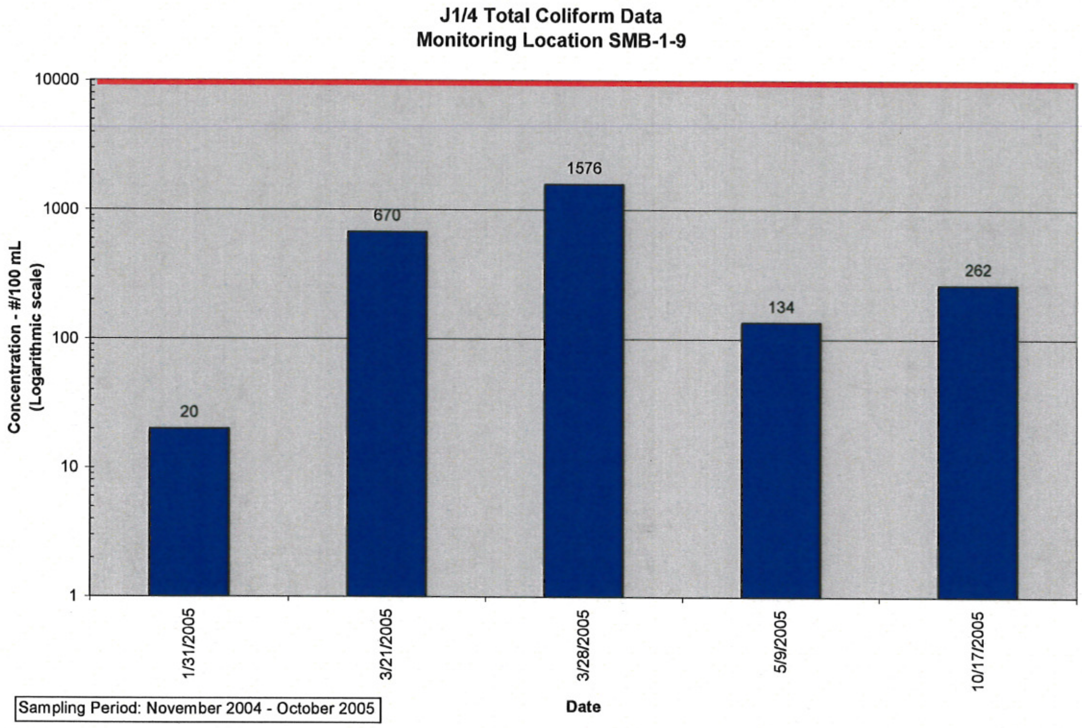

Figure 8. Total Coliform results for Latigo (SMB 1-9)

September 2010

PREFACE

The Committee's Definition of Natural Water Quality

Natural ocean water quality: That water quality (based on selected physical chemical and biological characteristics) that is required to sustain marine ecosystems, and which is without apparent human influence, *i.e.*, an absence of significant amounts of:

a) man-made constituents (e.g., DDT),
b) other chemical (e.g., trace metals), physical (temperature/thermal pollution, sediment burial) and biological (e.g., bacteria) constituents at levels that have been elevated due to man's activities above those resulting from the naturally occurring processes that affect the area in question, and
c) non-indigenous biota (e.g., invasive algal bloom species) that have been introduced either deliberately or accidentally by man.

Natural ocean water would be expected to vary noticeably both from place to place, and from time to time. For example, there are significant variations in the composition of minor constituents of seawater (e.g., nutrients, oxygen, trace metals) with depth in the ocean, as well as with distance from land and even between ocean basins. Furthermore, significant ocean properties such as salinity, temperature, and pH vary appreciably with location, season, and year to year due to natural oceanographic processes.

Even within California's coastal ocean, spatial differences exist as a result of regional differences in solar radiation, precipitation, and naturally occurring fresh water. Coastal seawater will differ measurably in trace element composition as a consequence of local watershed geology. Various places on the California shelf have naturally occurring hydrocarbon and groundwater seepage. In near-shore seawater, temporal and seasonal differences in suspended sediments result from variations in wave action. Naturally occurring marine life itself also alters water quality by various processes. For example, seawater near a sea lion haul-out may be high in fecal bacteria levels.

In addition, there are naturally occurring large-scale ocean cycles that dramatically influence the physical, chemical and biological components that support marine life along the California coast. For example, El Niño and La Niña oceanographic events can significantly alter the surface water temperature along the California coast thus extending or diminishing the range and abundance of cold versus warm water species. Rainfall during such El Niño events can also exert large influences on coastal water quality due to significant flood events that deliver (natural) sediments from undeveloped watersheds. Turbidity events associated with California river systems during large flood events have been observed from space.

However, the reality is that vast areas of the ocean are no longer pristine. Truly natural water quality probably does not now exist in California's coastal ocean, and may be rare throughout the world. For example, plastic debris can be found in remote areas of the ocean thousands of miles from continents, and persistent organic pollutants may be found in marine life inhabiting equally remote regions. Even if anthropogenic land-based waste discharges were to be completely eliminated from a section of coastline, there is no guarantee that natural water quality would be reestablished there. Aerial deposition, pollutants carried by oceanic currents from distant sources, and vessel discharges may influence water quality conditions.

As a result, it is not practical to identify a unique seawater composition as exhibiting *natural water quality*. Nevertheless, the committee believes that it is practical to define an *operational natural water quality for an ASBS*, and that such a definition must satisfy the following criteria:

- it should be possible to define a *reference* area or areas for each ASBS that currently approximate *natural water quality* and that are expected to exhibit the likely natural variability that would be found in that ASBS,
- any detectable human influence on the water quality must not hinder the ability of marine life to respond to natural cycles and processes.

Such criteria will ensure that the beneficial uses identified by the Ocean Plan are protected for future generations.

TABLE OF CONTENTS

EXECUTIVE SUMMARY

In response to the regulatory concerns about Areas of Special Biological Significance (ASBS), the California State Water Resources Control Board (State Water Board) empanelled eight experts from different scientific disciplines to develop a functional definition of "natural water quality." It is the work of this Natural Water Quality Committee (NWQC) that is the focus of this report.

The NWQC had a three-year mission to advise State Water Board staff regarding impacts of Scripps Institution of Oceanography's (SIO) discharges into an adjoining ASBS. While the committee focused on SIO and other relevant data in the SIO vicinity, they also recognized the importance of their work in the context of the greater ASBS, Ocean Plan, and stormwater issues. In response, the NWQC agreed that their recommendations may provide guidance for assessing impacts to water quality in any ASBS in the State. To that end, the NWQC addressed three primary questions:

1) Are water quality objectives and permit limits being met?
2) What are impacts of waste discharges to marine species and communities?
3) What would ambient marine water quality be like without waste discharges?

With regard to question 1, SIO has performed extensive monitoring of its waste seawater discharges, stormwater discharges, and marine receiving water. On the whole, the NWQC agreed that SIO was meeting the water quality objectives and permit limits in their permit. In fact, reasonable potential analysis indicated that many constituents were not a threat to ASBS water quality. The NWQC identified three issues of concern in SIO discharges: a) when constituent concentrations did exceed permit concentration limits, this occurred more frequently in stormwater than seawater discharges; b) ubiquitous constituents, such as dioxin, are not introduced at SIO, but were recorded in SIO seawater intake and discharge waters indicating inputs from external sources; and c) methodological issues raised concerns about potential false positive results for measurements including total residual chlorine and toxicity. Of particular concern was chronic stormwater toxicity as recorded in giant kelp (germination and fertilization) and purple sea urchin (fertilization) bioassays.

With regard to question 2, groundbreaking work has been performed in terms of biological monitoring at southern California ASBS, focusing on the rocky intertidal and subtidal communities. The NWQC felt it was too soon to identify the impacts of waste discharges on biological communities, but preliminary data show promise and warrant further assessment as well as continued monitoring for biological status and impacts.

With regard to question 3, the NWQC felt that it was practical to approximate what ambient marine water quality would be like in the absence of (or minimally influenced by) waste discharges by comparing water quality parameters in ASBS to water quality parameters at reference sites. In fact, based on recent studies at targeted reference sites in southern California, average water quality in ASBS was very similar to reference sites. Poor water quality in southern California ASBS was observed, but typically limited to a small number of discharges and/or constituents. The NWQC observed that, at times, concentrations of certain constituents at reference sites were higher than concentrations in Table B water quality objectives listed in the California Ocean Plan.

The NWQC identified four recommendations that regulatory agencies should consider. First, further work needs to occur for quantifying natural variability. While the reference site approach was successfully applied in southern California, insufficient information was collected to have certainty in assigning natural water quality ranges throughout the State (i.e., reference sites need to be sampled in central and northern California). Second, effort should be spent identifying the most appropriate monitoring indicators. Not all indicators need to be measured at all times and adaptive strategies that trigger more (or less) monitoring are a practical and cost-efficient mechanism for ASBS stakeholders. The NWQC emphasized that biological monitoring is considered to be an important addition to monitoring of individual chemical constituents, in order to assess impacts on receiving biological populations and communities. Third, the NWQC recommended that regulators revise Table C of the California Ocean Plan to reflect nearshore, near-surface post-storm reference site water quality. The existing Table C was developed over 30 years ago from open ocean sites, using now out-of-date laboratory methods, for use with plume modeling data to calculate effluent limits at offshore submarine outfalls. Fourth, the NWQC urged regulatory agencies to identify strategies to account for shifting baselines. One flaw of the reference site approach is that, as a practical matter, natural water quality is defined as "the best of what's left." As future development occurs, this may lead to a steady decline in overall water quality.

BACKGROUND

The coastal environment of California is an important ecological and economic resource. It is home to diverse and abundant marine life and has some of the richest habitats on earth including forests of the giant kelp, *Macrocystis pyrifera.* The State Water Resources Control Board (State Water Board) has created 34 Areas of Biological Significance (ASBS) in order to preserve and protect these especially valuable biological communities.

California's coasts are also a repository for waste discharges from the State's ever-increasing population. Treated municipal and industrial wastewaters, urban runoff, and power generating station discharges all represent a number of threats to marine life from human activities. As a result, the State Water Board, in the California Ocean Plan, has prohibited the discharge of waste to ASBS, with certain exceptions. All ASBS are State Water Quality Protection Areas that require special protection under state law.

Despite the prohibition against waste discharges to ASBS, a recent survey has observed approximately 1,658 outfalls to these marine water quality protected areas (SCCWRP 2003). As a result, the State Water Board has initiated regulatory actions, establishing special protections through the Ocean Plan's exception process. The intent of these regulatory actions is to achieve natural water quality of the ocean receiving water in the ASBS. One of the first regulatory actions was taken in San Diego at the ASBS adjacent to the Scripps Institution of Oceanography (SIO). The SIO, which owns and maintains the discharge outfalls to the La Jolla ASBS, was issued an Ocean Plan exception and a National Pollutant Discharge Elimination System (NPDES) Permit. As part of this regulatory action, State Water Board staff was asked to create a panel of experts from different scientific disciplines to help develop a functional definition of "natural water quality." It is the work of the Natural Water Quality Committee (NWQC) that is the focus of this report.

The NWQC includes eight members (Table 1). The NWQC has the mission to evaluate the SIO monitoring data and to advise the San Diego Regional Water Quality Control Board (RWQCB) regarding impacts of SIO's discharges to ASBS. While the committee focused on SIO and other relevant La Jolla data, they also recognized the importance of their work in the context of the greater ASBS, Ocean Plan, and stormwater issues. In response, the NWQC agreed that their work may provide guidance for assessing impacts to water quality in any ASBS in the State. To that end, the NWQC is addressing three primary questions:

1) Are water quality objectives and permit limits being met?
2) What are impacts of waste discharges to marine species and communities?
3) What would ambient marine water quality be like without waste discharges?

The NWQC created a three-year timeline to achieve milestones that help to answer these three questions. The first question, which is focused almost entirely on the SIO permit and site specific issues, was addressed in the first year. The second question, which has both site specific and regional spatial scale issues, was addressed in the second year. The increase in spatial scale is necessary because biological impacts at the SIO ASBS can only be interpreted in response to species and communities outside of the SIO ASBS. The third question, which is almost entirely exclusive of the SIO ASBS, was addressed in the third year. The increase in spatial scale for question three is a reflection of the need to select appropriate regional or statewide reference conditions, which by definition excludes areas with discharges.

DEFINITION OF NATURAL WATER QUALITY

Natural ocean water quality: That water quality (based on selected physical chemical and biological characteristics) that is required to sustain marine ecosystems, and which is without apparent human influence, *i.e.*, an absence of significant amounts of:

a) man-made constituents (e.g., DDT),
b) other chemical (e.g., trace metals), physical (temperature/thermal pollution, sediment burial) and biological (e.g., bacteria) constituents at levels that have been elevated due to man's activities above those resulting from the naturally occurring processes that affect the area in question, and
c) non-indigenous biota (e.g., invasive algal bloom species) that have been introduced either deliberately or accidentally by man.

Natural ocean water would be expected to vary noticeably both from place to place, and from time to time. For example, there are significant variations in the composition of minor constituents of seawater (e.g., nutrients, oxygen, trace metals) with depth in the ocean, as well as with distance from land and even between ocean basins. Furthermore, significant ocean properties such as salinity, temperature, and pH vary appreciably with location, season, and year to year due to natural oceanographic processes.

Even within California's coastal ocean, spatial differences exist as a result of regional differences in solar radiation, precipitation, and naturally occurring fresh water. Coastal seawater will differ measurably in trace element composition as a consequence of local watershed geology. Various places on the California shelf have naturally occurring hydrocarbon and groundwater seepage. In near-shore seawater, temporal and seasonal differences in suspended sediments result from variations in wave action. Naturally occurring marine life itself also alters water quality by various processes. For example, seawater near a sea lion haul-out may be high in fecal bacteria levels.

In addition, there are naturally occurring large-scale ocean cycles that dramatically influence the physical, chemical and biological components that support marine life along the California coast. For example, El Niño and La Niña oceanographic events can significantly alter the surface water temperature along the California coast thus extending or diminishing the range and abundance of cold versus warm water species. Rainfall during such El Niño events can also exert large influences on coastal water quality due to significant flood events that deliver (natural) sediments from undeveloped watersheds. Turbidity events associated with California river systems during large flood events have been observed from space.

However, the reality is that vast areas of the ocean are no longer pristine. Truly natural water quality probably does not now exist in California's coastal ocean, and may be rare throughout the world. For example, plastic debris can be found in remote areas of the ocean thousands of miles from continents, and persistent organic pollutants may be found in marine life inhabiting equally remote regions. Even if anthropogenic land-based waste discharges were to be completely eliminated from a section of coastline, there is no guarantee that natural water quality would be reestablished there. Aerial deposition, pollutants carried by oceanic currents from distant sources, and vessel discharges may influence water quality conditions.

As a result, it is not practical to identify a unique seawater composition as exhibiting *natural water quality*. Nevertheless, the committee believes that it is practical to define an *operational natural water quality for an ASBS,* and that such a definition must satisfy the following criteria:

- it should be possible to define a *reference* area or areas for each ASBS that currently approximate *natural water quality* and that are expected to exhibit the likely natural variability that would be found in that ASBS,
- any detectable human influence on the water quality must not hinder the ability of marine life to respond to natural cycles and processes.

Such criteria will ensure that the beneficial uses identified by the Ocean Plan are protected for future generations.

SPECIFIC FINIDINGS

Q1: Are water quality objectives and permit limits being met?

The NWQC met 20 times between October 2005 and August 2010. At several of those meetings the monitoring and conditions specific to the SIO NPDES permit were considered. Both effluent and receiving waters had been sampled by SIO since 2005 and the following general conclusions were drawn:

1) waste seawater system effluent measurements had identified some constituents of concern such as copper, suspended solids, settleable solids, acute toxicity (topsmelt), chronic toxicity (kelp) and dioxins. Notably, copper concentrations in waste seawater have generally declined over the permit period;
2) runoff generally had more constituents with concentrations greater than those specified in Ocean Plan Tables A and B compared with the waste seawater system. These constituents included copper, turbidity, oil and grease, settleable solids, PAHs, indicator bacteria, chronic toxicity (urchins, topsmelt and kelp) and dioxins;
3) chromium, lead, and zinc in the runoff were also elevated above the Ocean Plan Table B six month median levels on more than one occasion during wet weather;
4) receiving water in the ASBS was elevated above water quality objectives on at least one occasion for chronic toxicity (kelp) and/or dioxin during wet and dry weather sampling;
5) dioxins appear to be ubiquitous in the environment and are likely not a direct result of SIO activities (see Attachment B);
6) one sampling period coincided with a red tide event (June 2005) that may have had a confounding or synergistic effect with regard to the toxicity tests;

7) water quality measurements also revealed some technical shortcomings of EPA and State approved test methods, such as elevated total residual chlorine measurements in seawater matrix (see Attachment C), and acute toxicity interpretations; and
8) most other Table B constituents were not detected, or were present in small amounts that represented no reasonable potential (RP) to cause impacts based on RP analysis using State Water Board developed software.

A receiving water study for bacterial contamination was conducted by SIO examining more than 10 sites plus outfall discharges at multiple time intervals during dry weather. The results indicated that bacterial concentrations were routinely low and below water quality standards. In general, the NWQC determined that bacterial monitoring was an inappropriate indicator for assessing potential impacts to aquatic life for this ASBS than other water quality measures. Given that SIO and the County Health Department routinely monitors this beach for the protection of human health, the NWQC recommended against future non-routine bacterial monitoring and that efforts should be reinvested into other monitoring elements.

Finally, SIO had developed a dilution and dispersion computer model for their discharges into the nearshore coastal zone of the ASBS. The model had been previously calibrated and validated at the mouth of the Santa Margarita River that discharges into the littoral zone near Oceanside. Based on model runs at La Jolla conducted by SIO, results indicated that dilution of SIO discharges could be very large due to turbulent mixing and advection by wave action and longshore currents. Model output illustrated dilution factors ranging three orders of magnitude. The NWQC agreed that a 7:1 dilution factor was appropriate. While the model input parameters (i.e., tide, wave height and direction, etc.) were some of the best available, there was some concern that little model validation at the La Jolla ASBS had been conducted.

Q2: What are impacts of waste discharges to marine species and communities?

Quantifying the chemical components of an effluent only partially assesses the potential of waste discharge to ASBS. Ultimately, the biological integrity of marine communities residing in ASBS also need to be assessed to determine if the human influence on water quality is hindering the ability of marine life to respond to natural cycles and processes. To this end, several ASBS stakeholders and the State Water Board utilized scientists at the University of California Santa Cruz to compile data from existing intertidal biological monitoring programs from ASBS statewide. The goal was to assess if historical data were sufficient to make statements about the integrity of ASBS intertidal marine communities (Raimondi 2009).

Raimondi (2009) evaluated the historical data from 12 ASBS intertidal monitoring programs and summarized five features that hindered an independent, integrated assessment of biological impacts in ASBS. First, the methods used in the monitoring programs differed dramatically, ranging from careful designs developed from specific questions to almost naturalist perspectives of sites. Second, all of the monitoring programs were done either by the dischargers or their consultants. Third, the basis for determining if a discharge is causing an impact differed dramatically among monitoring programs. Fourth, and most important, most monitoring programs were not clear about the basis for determining impacts. One strong recommendation for an integrated assessment was that there should be a general basis for determining impact that is consistently applied. There should also be a general assessment design that would yield information sufficient to produce a rigorous determination of impact. Finally, the reporting requirements for assessments should be standardized including data and metadata reporting, transfer, and storage.

In part to overcome the limitations addressed by Raimondi (2009), a regional ASBS biological monitoring program was implemented in southern California. Twenty one rocky intertidal sites were quantitatively sampled for habitat quality, invertebrate and algal abundance, and composition by Raimondi's UC Santa Cruz Coastal Biodiversity research team. The monitoring question focused on differences between reference and ASBS discharge sites. Preliminary results indicated that: 1) there were no significant differences in macro-invertebrate or algal species richness based on geographic grouping or type of site (discharge vs. reference); 2) there were large geographic differences in algal and sessile invertebrate species composition, likely reflecting natural biogeography, but no statistically significant differences between reference sites and ASBS discharge sites; and 3) there were large geographic differences in mobile invertebrate species composition, once again reflecting natural biogeography, but no statistically significant differences between reference sites and ASBS discharge sites. However, the answers differed when sessile and mobile species were jointly considered. Not only were geographic differences observed, but differences were also observed at two discharge sites relative to reference condition (one of which was in La Jolla). While more work is needed to investigate the relationship of these differences to water quality impacts, it demonstrates that biological data can be used, and the NWQC suggested that there is sufficient data to warrant further investigation.

Because of the value of biological information, ASBS stakeholders in southern California supported monitoring of 70 subtidal rocky reef sites. Quantitative sampling for habitat quality, vertebrate, invertebrate and algal abundance, and composition was coordinated by Dr. Dan Pondella at Occidental College with collaborators at UC Santa Barbara and San Diego State University. Similar to the intertidal monitoring, the monitoring question focused on differences between reference and ASBS discharge sites. Data analysis for the subtidal rocky reefs has not progressed as far as the intertidal monitoring. Initial data examination has identified clear differences in community composition based on habitat characteristics (i.e., rock relief), but large differences in biological community characteristics between ASBS and reference sites have yet to be determined.

One last piece of biological monitoring was conducted by SIO, who performed a bioaccumulation study in receiving waters. This monitoring, which used both mussels and sand crabs, occurred in the vicinity of localized reference and ASBS discharge sites. The results indicated that:

1) most organic constituents were present at statistically nonsignificant levels relative to a reference site during the study period;
2) certain pollutants were elevated in transplanted mussels near the SIO pier (Cr, Ni, Fe, and Mn) and at the south end of the adjoining La Jolla ASBS (As) where the City of San Diego storm outfalls are located relative to other sites within the study area;
3) certain pollutants were elevated in transplanted mussels near the SIO pier (Cr and Ni) relative to historical statewide Mussel Watch results; and
4) large relative variability in tissue concentrations from sand crabs due to age/reproductive status precluded an assessment of spatial scale gradients and an evaluation of potential effects.

Q3: What would ambient marine water quality be like without waste discharges?

The State Water Board funded a pilot project during the winter of 2007-08 to evaluate selection of, and sampling methods in, potential reference sites. Proposed reference sampling was determined in collaboration with stakeholders and included surf zone samples at the mouth of a watershed with limited anthropogenic influences, defined as a minimum of 95% open space. The pilot project included a minimal number of sample sites in southern, central and northern California. The pilot project found no detectable levels of the synthetic pollutants DDT and PCB in the samples, and mean values for ammonia and metals were below Ocean Plan six-month medians objectives. The only trace metals with maximum values slightly above the six-month medians were chromium and lead. Notably, mean concentrations of PAHs were approximately an order of magnitude greater than the Table B 30-day average objective.

The State Water Board funded a statewide monitoring program during the winter of 2008-09 specifically to assess the water quality in ASBS near and far from regulated discharge sites. More than 100 chemical constituents and toxicity were measured from 62 sites using a probabilistic study design; roughly half of sites were sampled in the ocean directly in front of a regulated discharge and the other half were located in the ocean >500 m from a regulated discharge. It is important to point out that the sample sites >500 m from direct discharges may have been influenced by other watershed drainages into or adjacent to the ASBS, and therefore may represent background, but not necessarily natural, conditions. Samples at each site were collected <24 hr prior to rainfall and again <24 hr following rainfall. At least one ocean receiving water site was sampled within most mainland ASBS in California.

The statewide survey illustrated generally good chemical water quality in mainland ASBS sites (Table 2). None of the constituents measured exceeded the instantaneous maximum objective listed in the California Ocean Plan (SWRCB 2003). Seven out of 15 constituents did not exceed the Ocean Plan's most stringent objectives (six-month median or 30-day average, depending on the specific constituent) including strictly anthropogenic chemicals such as DDTs or PCBs. Of the eight parameters that did exceed the most stringent Ocean Plan objectives, six (arsenic, cadmium, copper, lead, nickel and zinc) exceeded the objective for relatively small (<15%) portions of ASBS shoreline. Many of these constituents are common in urban stormwater, but have natural sources as well.

Two constituents exceeded Ocean Plan objectives over relatively large proportions of ASBS shoreline including chromium (50%) and polycyclic aromatic hydrocarbons (PAH; 87%) (Table 2). Sources of chromium and PAH can be either natural or anthropogenic. The extent of Ocean Plan exceedence for chromium and PAH was similar near and far from discharge sites following storm events. Similarly, the extent to which chromium and PAH exceeded Ocean Plan standards was similar between pre-storm and post-storm conditions near discharges. It is important to note that the chromium standard is based on the more toxic form, hexavalent chromium, but that total chromium was analyzed for this study. The lack of excessive chemical contamination in ASBS receiving waters was supported by infrequent (<5% of ASBS shoreline) chronic toxicity to a California endemic species (the purple sea urchin, *Strongylocentrotus purpuratus*).

Table 2. Percent of ASBS shoreline with constituent concentrations that exceeded State Water Board Ocean Plan objectives following storm events.

	Ocean Plan Objective	% Shoreline Greater Than OP Objective		
		All ASBS	<500 m from Discharge	>500 m from Discharge
Ammonia-N[1]	0.6 mg/L	--	--	--
Arsenic[1]	8 ug/L	1.6	2.7	--
Cadmium[1]	1 ug/L	2.1	3.6	--
Chromium[1]	2 ug/L	50	61	35
Copper[1]	3 ug/L	6.9	4.8	9.8
Lead[1]	2 ug/L	4.8	--	11.5

DDTs[2]	0.17 ng/L	--	--	--
Dieldrin[2]	0.04 ng/L	--	--	--
PAHs[2]	8.8 ng/L	87	85	89
PCBs[2]	0.019 ng/L	--	--	--

[1] 6-month median

[2] 30-day average

While the statewide survey provided valuable estimates of overall chemical condition in ASBS, it lacked an assessment of natural water quality. To address this data gap, the regulated dischargers and Regional Water Quality Control Boards (RWQCBs) initiated a collaborative ASBS regional monitoring program in the Southern California Bight (Bight'08). One goal of Bight'08 was to identify and sample reference sites to determine natural water quality. The dischargers and regulators agreed on reference site criteria that tried to simulate ASBS discharge sites with respect to most factors except one; lack of anthropogenic sources (e.g., <10% watershed development in the contributing catchment). A second goal was to compare these reference site concentrations to concentrations measured near ASBS discharges. Similar to the statewide survey, Bight'08 focused on wet weather conditions.

Regional reference condition was typified by low concentrations and lack of toxicity (Table 3). However, the range of reference site concentrations exceeded Ocean Plan objectives for 8 out of 10 parameters, including chromium and PAH. Intriguingly, the ASBS discharge sites behaved very similarly to reference sites. In fact, average chromium and PAH concentrations at ASBS discharge sites following storm events were not significantly different from average reference site concentrations for all constituents. While there were individual discharges and constituents that were dissimilar from reference concentrations, these appeared to be isolated events rather than the typical condition at southern California ASBS.

For comparing discharge sites to a measure of natural water quality, a threshold level equivalent to the 85th percentile of the reference site post-storm concentrations was used. This 85th percentile level was chosen to represent natural water quality to eliminate uncertainty associated with outliers, thereby being protective of water quality. Exceedence of natural water quality conditions was relatively infrequent at ASBS discharge sites; general constituents, nutrients, and trace metals were the most frequent groups of constituents to exceed natural water quality conditions identified in this study.

Table 3. Minimum, maximum, median, and mean (±95% confidence interval; CI) of post-storm constituent concentrations at reference sites in the Southern California Bight during 2009.

Constituent	Reference Site Concentrations							Ocean Plan Objective
	Units	%ND	Min	Median	Max	Mean	(±)95% CI	
TSS	mg/L	8	Nd	7.7	1692	140	171	-

THE NEED FOR ADDITIONAL GUIDANCE

Consistent with the NWQC's desire to provide guidance to the State Water Board not only for SIO, but for all ASBS, the Committee delved into several issues in more detail. These included:

1) Interactions with the Coastal Ocean Observing System,
2) ASBS grant monitoring,
3) Suggested goals and approaches for protection of ASBS,
4) TCDD measurement, and
5) Total residual chlorine measurements.

The findings and recommendations for each of these issues are summarized below. Further details are captured in a series of white papers presented in Attachments A through C of this report.

Interactions with the Coastal Ocean Observing System

One concern related to the management and regulation of a specific ASBS is that the conditions of the ambient receiving waters may be influenced as much, or more, by discharges outside of the ASBS. These external ASBS discharges, if large enough, may overwhelm discharges inside the ASBS.

For the southern California region, the Southern California Coastal Ocean Observing System (SCCOOS) maintains an active set of ocean observing and modeling resources. One of SCCOOS comprehensive resources is the surface current mapping network that spans the entire California coastline (in collaboration with the Central California Coastal Ocean Observing System [CENCOOS]). Surface current mapping provides the capability of producing connectivity matrices and probability maps illustrating the likely regions of influence from discharges outside of the ASBS boundaries. A demonstration project was conducted to evaluate the probability of Los Penasquitos Lagoon discharge interacting with the San Diego-Scripps ASBS.

Los Penasquitos Lagoon is located approximately 7 km north of the San Diego-Scripps ASBS. Depending on the direction, speed and duration of coastal currents, it is possible that outflow from the Los Penasquitos Lagoon enters the region of that the San Diego-Scripps ASBS and its neighboring La Jolla ASBS. A statistical analysis using hourly data from surface currents measured by SCCOOS was used to estimate the percentage of time the Los Penasquitos outflow would enter the ASBS. Based on a complete year of data, it appeared that water from the lagoon entered the ASBS 10 to 25% of the time. Two years of precipitation data (62 days with measurable rainfall) were examined for wet weather contributions to the ASBS from Los Penasquitos Lagoon and its watershed. Within three days following each rain event, SCCOOS scientists predicted the wet weather plume would enter the ASBS 5 to 10% of the time.

This preliminary analysis indicated that it is possible for distant, non-ASBS regulated discharges to be transported into ASBS jurisdiction. While significant additional work needs to be completed to assess the extent of this problem, SCCOOS and CeNCOOS desire to continue their relationship with the state and regulated parties. Additional work could include: a) dilution and degradation of discharge constituents in addition to transport; b) targeted time scales to evaluate critical conditions; c) producing probability maps for other ASBS of concern; and d) interaction with other water quality issues such as harmful algal blooms.

ASBS Grant Monitoring

The voters of California have approved bond measures for Proposition 84 that provides funding to assist responsible parties to comply with the discharges prohibition into ASBS. The State Water Board is planning on distributing approximately $32,000,000 from Proposition 84 specifically to remove waste from discharges that drain directly to ASBS. Approximately $1,000,000 from Proposition 84 may be set aside to provide for coordinated effectiveness monitoring for the suite of projects recommended for funding. As a result, the NWQC was encouraged by State Water Board staff to address monitoring issues related to Proposition 84 grant funded projects. The NWQC addressed this issue in three steps: 1) determine the success (or failure) of monitoring programs associated with other grant programs; 2) assess what factors would be important for grant funded monitoring for ASBS; and 3) provide recommendations to the Proposition 84 Task Force, the body that evaluates Proposition 84 grant proposals, including monitoring.

Ultimately, the NWQC made three recommendations to the Proposition 84 Task Force to enhance the grant program monitoring components (*see NWQC White Paper*, Attachment A). These recommendations included: 1) a cohesive, question-driven monitoring program; 2) a unified monitoring design that ensures comparability in sampling, data analysis, and information management; and 3) a single person or group responsible for coordinating, collating, assessing and reporting on the Proposition 84 monitoring effort.

Suggested Goals and Approaches for Protection of ASBS

Recommendation

The State Water Board should consider a broader goal for protection of Areas of Special Biological Significance (ASBS) and different approaches for achieving that goal.

Background

The Ocean Plan establishes requirements that apply to discharges of waste to California ocean waters in general, with the intent of protecting the beneficial uses of those waters. The Ocean Plan also establishes a higher level of protection for ASBS by prohibiting discharges of waste to ASBS (with certain exceptions). The Ocean Plan specifies that

RB-AR 7884

waste discharges are to be located a sufficient distance from ASBS "to assure maintenance of natural water quality conditions" in ASBS.

Although "maintenance of natural water quality conditions" in ASBS would be desirable, such a goal may not always be realistic. Considering the definition of "natural water quality" (see *NWQC Definition* above), and considering the nature, extent, and magnitude of anthropogenic influences on California coastal waters (and their ecosystems) and on the watersheds and stream systems that drain to the coast, it seems unlikely that "natural water quality conditions" (or, for that matter, natural biological conditions) are or can be consistently achieved and maintained in all ASBS at all times. For example, substances such as mercury or dioxins are ubiquitous in the ocean at low levels and are not always from natural sources.

Although "maintenance of natural water quality conditions" in ASBS is probably not always an achievable goal, a goal to "minimize anthropogenic influence on water quality" in ASBS is realistic and provides a direction forward for continuing improvement.

Existing and Suggested Approaches

Completely stopping all existing waste discharges directly into ASBS would result in improved, more nearly natural, less anthropogenically influenced water quality conditions in ASBS. In some cases (e.g., certain smaller storm drainages and nonpoint runoff sources), such improvements may be insignificant yet the cost of terminating such discharges may be substantial. In fact, stopping and re-routing storm runoff potentially harms the ecosystem by altering the hydrologic cycle.

The State Water Board approach to regulating direct discharges to ASBS has been the inclusion of prohibitions and special conditions in Ocean Plan exceptions, referred to as "Special Protections," with permits implementing those conditions. Those conditions generally require the elimination of dry weather runoff, ensure that wet weather runoff and marine laboratory waste seawater does not alter natural water quality in the ASBS, and that adequate monitoring be conducted to determine if natural water quality and the marine life beneficial use is protected. Compliance for storm water runoff has generally been determined or proposed to be determined in receiving water.

However, stopping discharges directly into ASBS cannot ensure absolute protection of water quality in ASBS, if only because other discharges (including distant sources and aerial deposition) can influence water quality conditions in ASBS. The degree to which a discharge might influence an ASBS is a function of a number of factors, including but not limited to the proximity of the discharge to the ASBS and the characteristics of the discharge. Consequently, larger, "more polluted" discharges outside of or further away from an ASBS could have a greater influence on that ASBS than smaller, "less polluted" discharges directly into or closer to the same ASBS. Although the Ocean Plan calls for discharge locations to be kept away from ASBS, in many cases the locations where anthropogenically influenced land runoff (e.g., via streams and rivers) enters the ocean cannot readily be changed. Even if such locations could be changed, doing so could have significant adverse effects on beneficial uses of waters outside of ASBS (e.g., in estuaries).

In order to avoid significant expenditures that do little to protect ASBS, an assessment of existing and potential anthropogenic influences on each ASBS should be conducted. Those influences should be ranked as posing a high, medium, or low threat to the ASBS. Priority should be given to reducing and minimizing the anthropogenic influences that pose greater threats, regardless of their proximity to the ASBS.

In order to provide a higher level of protection to ASBS, a higher level of protection should be provided to California coastal waters as a whole. ASBS exist within the larger context of California coastal waters as a whole. ASBS are not separate from or isolated from those waters. Water, biota, and substances move between ASBS and surrounding coastal waters. Therefore, providing a higher level of protection to California coastal waters as a whole would also provide a higher level of protection to ASBS. This might be accomplished using various combinations of requirements, including requirements that would limit the total mass of specified pollutants that can be discharged into California coastal waters or segments thereof.

Dioxins

Dioxins (also known as TCDD) are toxic compounds that have both anthropogenic (e.g., combustion byproducts) and natural (e.g., forest fires) sources. Atmospheric deposition is a major source of dioxin in soil and water and national background soil levels are 1 to 6 ng/kg TEQ (TCDD Equivalents) in rural areas and 7 to 20 ng/kg TEQ in urban areas. In the California Ocean Plan, the objective for TCDD Equivalents addresses the human health beneficial use via consumption of seafood. The objective for TCDD Equivalents is 0.0039 picograms per liter, the lowest objective for any of the constituents in the Ocean Plan.

The Scripps Institute of Oceanography (SIO) ASBS Monitoring Program measures dioxins in their effluent and receiving water during dry weather and wet weather conditions. SIO Dioxin TEQ results were consistently above permit limits, but all of the sample concentrations (with one exception) were below the range detected in stormwater from the San Francisco Bay and the Santa Monica Bay areas. Since Scripps has no source of dioxin in their seawater system, the NWQC assumes that the TCDD in SIO discharges is most likely from regional sources such as stormwater runoff and/or aerial fallout (*See Attachment B*). This is supported by the results of their monitoring data where seawater discharge concentrations and congener profiles were similar to the concentrations measured in ambient seawater samples. Stormwater discharge samples routinely had greater TCDD concentrations than seawater discharge results. In particular, stormwater discharge (Outfall 002) sampled on 11/30/2007 had noticeably greater concentrations and a different congener profile than previous samples. This sample was collected just after a major forest fire in the San Diego area upland from SIO.

Total Residual Chlorine

Many NDPES Permit holders discharging estuarine or marine water into the coastal waters of California are required to monitor their effluent and/or receiving water for Total Residual Chlorine (TRC), even if they are not chlorinating their effluent. Chlorine is toxic to marine aquatic life and therefore Table B of the California Ocean Plan (SWRCB, 2005) lists 6-month median, daily maximum, and instantaneous maximum of 2, 8, and 60 µg/L, respectively. SIO does not add chlorine to its seawater or stormwater discharges.

At present, it is difficult to accurately quantify the amounts of residual or free chlorine in marine systems due to matrix interference introduced by naturally occurring salts of iodide and bromide. Two matrix-associated interferences were noted by the NWQC (*See Attachment C*). First, free chlorine reacts almost instantaneously with salt in seawater, so that any free chlorine has essentially reacted before the sampler can cap the sample bottle. Second, interferences by other oxidizing compounds such as bromide and iodide will cross-react with method reagents leading to a potential false negative. In the case of SIO, nearly every sample of seawater discharge exceeded permit limits. Since SIO does not chlorinate its discharge, the NWQC assumes that the permit limit exceedences for TRC are false positives. In addition, the NWQC recommends that the State Water Board either change the required method for TRC and/or allow for altering the interpretation of results (i.e., total residual oxidants).

CONCLUSIONS

- **On the whole, the Scripps Institution of Oceanography is meeting effluent limitations and water quality objectives in their permit.**

  The SIO consistently meets effluent limitations listed in their NPDES permit for the vast majority of monitored constituents and concentrations of constituents in excess of Ocean Plan objectives in receiving water was rare. In fact, the discharge monitoring requirements were eased in 2008 when reasonable potential analysis indicated that many constituents were unlikely to be a threat to ASBS receiving waters. However, not all constituents were within regulatory limits at all times. The NWQC identified three issues that regulators should be aware of. The first issue was the difference between seawater discharges (from once through use in aquaria and holding tanks) and stormwater discharges (from surface runoff generated both on- and off-campus). Stormwater discharges from SIO exceeded permit limits more frequently than seawater discharges, and often for known stormwater constituents such as copper and chronic toxicity (kelp, urchins). The second issue was ubiquitous constituents. Perhaps the best example of this issue was the frequent exceedence of permit limits for dioxins, which SIO does not add to its process stream, but is found routinely in receiving waters and stormwater discharges from southern California. The third issue was methodology. Two examples of methodology arose in our survey of SIO results including total residual chlorine (TRC) and toxicity testing. The NWQC observed many examples of permit limit exceedences for TRC, but after further investigation, identified that the method currently approved by the NPDES permit is prone to false positives in a seawater matrix. The NWQ prepared a white paper in this report that provides regulators and other ASBS stakeholders potential options for resolving this issue. The NWQC also observed several examples of acute toxicity, particularly for fish. While certain toxicity results were statistically significant, other toxicity exceedences did not have a significantly different response relative to controls (i.e., <5% effect). This is a known issue to regulators, but makes it difficult to identify when true toxic events occur that regulators should care about.

- **It is too soon to tell if there are impacts of waste discharge to marine species and communities**

  Examining biological impacts in ASBS is a worthwhile endeavor and SIO, as well as the other ASBS stakeholders in southern California, should be commended for undertaking biological monitoring. Collaboratively, these 14 entities have partnered with universities to conduct intensive biological surveys of communities in rocky intertidal and rocky subtidal habitats. While the final data analysis has not been completed, it is clear from preliminary results that a regional reference condition approach is necessary to define “natural” in ASBS. The NWQC agreed that comparing an ASBS to a minimal number of isolated reference sites is inadequate to describe these complex and dynamic habitats. The NWQC also recognizes that, while the current surveys are focused on spatial comparisons (many sites), examining temporal trends (individual sites over time) is necessary to assess how sites respond to both natural and anthropogenic stresses. Attributing causes and sources of impact to biological systems is not an easy task, particularly in intertidal and rocky subtidal reef systems where natural perturbations (waves, tidal exposure, etc.) and human-induced (fishing, trampling, kelp harvesting, etc.) stressors can be significant influences in addition to water quality. Yet, these are areas of special *biological* significance and minimum monitoring requirements could be used to trigger more detailed exploration when impacts are observed. One avenue currently being explored, and one that the NWQC endorses, is investing effort into identifying key indicator species, species groups, or assessment indices that can provide simple and effective answers to questions about water quality (and perhaps other) impacts.

- **It is practical to quantitatively define ambient water quality without (or with minimal) waste discharges.**

The definition of natural water quality supplied by the NWQC is an achievable goal. The collaborative southern California monitoring program (Bight'08) is currently the best illustration of this success. Bight'08 proxied natural water quality by examining the chemical and toxicological properties of ambient ocean water at reference sites. Results indicated no detectable trace synthetic organic compounds (i.e., DDT, PCB) or toxicity, and generally low concentrations of naturally occurring constituents (trace metals, PAH). With one minor exception, all of the constituents had median values below the strictest Ocean Plan objectives. However, there were times at reference stations when maximum concentrations of several naturally occurring constituents exceeded current Ocean Plan Table B thresholds. More importantly, values for many constituents in the reference data set exceeded Table C ("Background Seawater Concentrations") in the Ocean Plan. One positive outcome, and with few exceptions, most southern California ASBS discharge sites and monitored parameters behaved similarly to reference site conditions. While the reference site criteria used in Bight'08 could be altered, or alternative criteria could be developed, the fact that regulated parties and regulatory agencies could come together and agree on currently existing reference sites is a powerful statement.

It is important to note that the NWQC did discuss other approaches that could work, including tracers of waste discharge or reference condition normalizers, which could also be further explored. In addition, the reference area approach may have its limitations as in the case of widespread anthropogenic influences (i.e., PAHs, TCDDs) or the situation where distant sources impinge on reference site water quality. (i.e., transport of large stormwater plumes)

RECOMMENDATIONS

- **Further work needs to occur for quantitatively defining natural water quality.**

  While the definition of natural water quality supplied by the NWQC is an achievable goal, quantifying natural water quality is not concluded. It is important that the true range of natural variability be encompassed. Having too broad a reference site characterization will provide insufficient protection for ASBS. Having too narrow a reference site characterization will promote unrealistic or unachievable goals for regulated entities. The work initiated by Bight'08 represents the first such attempt in California to determine natural water quality characteristics in the nearshore following storm events. The NWQC felt that although the Bight'08 program provided sufficient information for the SWRCB to move forward, prudent management would also seek additional information. For example, Bight'08 quantified intra-annual (storm-to-storm) variability, but lacked inter-annual or even decadal scale variability known to produce natural alterations in ocean water composition and biological communities. Similarly, additional reference sites in central and northern California would be a sensible next step. Finally, the NWQC recognized that, for some instances, the reference site approach can be problematic. For example, the reference site approach may be limited in the case of widespread anthropogenic influence (i.e., PAHs, TCDDs) or the situation where distant sources impinge on reference site water quality. (i.e., transport of large stormwater plumes from outside the ASBS). All of these causes of natural variability, and impacts from unanticipated anthropogenic contributions, should be investigated before final natural water quality ranges can be ascertained. In addition, further collaboration between the ocean observing systems, regulators, and responsible parties can assist with identifying contributions from distant sources.

- **Effort should be spent identifying the most appropriate monitoring indicators**

  The NWQC strongly recommends that biological monitoring occur in addition to the required chemical or toxicological monitoring. Biological monitoring provides an integrative measure over time that chemical and toxicological measures do not. Biological monitoring also measures the effects of unmeasured constituents and/or cumulative effects of constituents. Regardless of chemical, toxicological or biological measures, the most informative indicators within each class should be selected. Minimizing the indicator list to the most informative measures will reduce per-event costs, enabling more locations or time periods to be monitored. If this approach is taken, the NWQC strongly urges that adaptive monitoring triggers be established *apriori* that can be used to increase (or decrease) monitoring effort should problems (or lack of problems) be identified. If the chemical constituent list is reduced, the utility of integrative measures such as toxicity also become more valuable. The NWQC suggests that multiple species and endpoints be considered for toxicity testing and, if sufficient toxicity is observed, dischargers be required to conduct toxicity identification evaluations (TIEs) to determine the problematic constituents.

- **Improvements should be made to the Ocean Plan**

  Table C in the California Ocean Plan (Seawater Background Concentrations) was first adopted in 1983 and based on relatively sparse data over 30 years old collected far from shore. Perhaps this was appropriate since the information was intended to be used with plume modeling data to calculate effluent limits for relatively consistent discharges of effluents from publicly owned treatment works (POTW) through offshore submarine outfalls. The current emphasis on stormwater runoff is incongruous with this application. Stormwater is highly unpredictable, where flows and concentrations can change by orders of magnitude over short time scales (sometimes within minutes) and is discharged at the surface. Table C values should be altered to reflect current needs, including values for nearshore, post-storm water quality.

  Other changes to the Ocean Plan that should be considered include addressing: a) new or revised methods for measuring total residual chlorine , b) improving trace metal sample extraction to eliminate interferences with seawater (such as using EPA Method 1640), and revise the acute toxicity equation in cases when survival in undiluted effluent is greater than control survival.

- **Regulatory agencies need to identify strategies to account for shifting baselines**

  Based largely on verbal accounts, it is suspected that increases in human population and development since the mid-1970's have resulted in degradation of water quality and biological communities. This may or may not be true, but scant little data is available to inform us. If true, then the water quality conditions at reference sites we identify today may be significantly different than they were 35 years ago when the ASBS were first designated. The NWQC is concerned that operational definitions of natural water quality years from now might be significantly different from today's conditions. In order to account for the potential shifting baseline where natural water quality is, as a practical matter, defined as the best of what's left, the NWQC recommends that the State Water Board identify how they plan to deal with future increases in human population and development and the potential for water quality degradation in and near ASBS and present day reference sites.

Natural Water Quality Committee
Initial Recommendations for Monitoring ASBS Implementation Projects

The Natural Water Quality Committee (NWQC) was formed at the direction of the State Water Resources Control Board (SWRCB, resolution 2004-052, Section 3.a.). The charge of the NWQC was to define natural water quality based on a review of monitoring data and to advise the Water Boards regarding the attainment of natural water quality relative to waste discharges in Areas of Special Biological Significance (ASBS). Some of these recommendations have focused on monitoring as one approach to assessing the attainment of natural water quality.

The voters of California have approved Bond measures for Proposition 84 that provides funding to assist responsible parties to comply with the discharge prohibition into ASBS. The SWRCB is planning on distributing approximately $32,000,000 from Proposition 84 specifically to remove waste from discharges to ASBS. Approximately $1,000,000 from Proposition 84 may be set aside to provide for coordinated effectiveness monitoring for the suite of projects recommended for funding. As a result, the NWQC was encouraged by State Water Board staff to address monitoring issues related to Proposition 84 funded projects. The NWQC addressed this issue in three steps: 1) determine the success (or failure) of monitoring programs associated with other grant programs; 2) assess what factors would be important for grant funded monitoring for ASBS; and 3) provide recommendations to the Proposition 84 Task Force, the body that evaluates Proposition 84 Grant proposals, including monitoring.

After discussions with RWQCB and SWRCB staff, task force members from other grant programs (i.e., Proposition 50), and the grantees themselves, the NWQC came to three conclusions regarding the successes and failures of previous grant programs. Frequently in the past, grant programs were incapable of assessing the success/failure of their program for either removal of pollutants or improvements to receiving waters. Inadequate guidance was provided to the grantees on the specific goals of the monitoring programs employed, especially to those grantees that lacked capabilities and experience with monitoring. Specifically, grantees rarely had a vision of the State's monitoring objectives such as cumulative pollutant removal. Even for those grantees with experience and capability, the timeline of the grant programs (typically two to three years) were inconsistent with adequately quantifying the goal of measuring pollutant reductions.

The NWQC discussed several important elements to enhance the Proposition 84 grant program monitoring components. These elements included: 1) a cohesive, question-driven monitoring program; 2) a unified monitoring design that ensures comparability in sampling, data analysis, and information management; and 3) a person or group responsible for coordinating, collating, assessing and reporting on the Proposition 84 monitoring effort. A clear statement of objectives needs to be composed so as to provide a vision for the Proposition 84 monitoring program. Monitoring experts universally agree that this is best achieved through the use of a well-formed and unambiguous monitoring question, much akin to a hypothesis for testing. This question should be crafted with care and agreed to by the Proposition 84 Task Force or other governing body.

A centralized monitoring design should be created with sufficient scientific rigor that the monitoring question can be answered with a specified level of confidence. It is impossible to describe what this design may look like until the monitoring question is created, but there are certain elements that must be included. The first element should be some level of standardized sampling. Standardized sampling approaches ensure representativeness and reduce bias in data collection. For example, flow weighted composite sampling during wet weather runoff can produce very different results than grab sampling, even during the same storm event at the same site. Comparing data from different sampling approaches is inappropriate and could lead to faulty conclusions. Similarly, standardized quality assurance should be achieved through the laboratory analysis portion of a large-scale monitoring program. Comparability is paramount and several large-scale monitoring programs use performance-based quality assurance guidelines to ensure comparability for laboratory analysis. Finally, a centralized data management system is necessary for collating the reams of information generated by multiple monitoring programs. Grantees will focus on the monitoring data associated with the management actions specific to their project and these individual data sets will be, for the most part, relatively small and easy to manage. Combining data sets from numerous individual grant projects *post hoc*, however, would be daunting to impossible and could cost hundreds of thousands of dollars unless a well-conceived information management system is implemented before data collection. Thankfully, several systems exist within the state that could be used as a vehicle for data management.

Finally, a person or group must be tasked from the beginning with the responsibility for coordinating the Proposition 84 ASBS monitoring program. Deriving monitoring questions, ensuring comparability and quality assurance/training cannot be done as a sideline to one’s daily activities. It is a full-time job. The larger the program, the more likely it will require additional personnel to accomplish all of the integration necessary to address the monitoring question. It will be this entity that shall be responsible for communicating with grantees on monitoring and eventually for writing a summary report of the program’s success at reducing pollutant loads and/or concentrations.

The NWQC had four recommendations to the ASBS Task Force on a structure for the statewide grant monitoring program to achieve the three goals of monitoring question(s), comparability, and organization. The first recommendation stated the singular monitoring question of utmost importance, “How much pollutant (i.e., in kg) was removed as a result of the grant-funded BMP?” Several additional questions are feasible and perhaps warranted, but this single question must be answered. The second recommendation addressed who should coordinate the Proposition 84 monitoring. The NWQC felt that the SWRCB should coordinate this monitoring, perhaps through one of their statewide programs such as the Surface Water Ambient Monitoring Program (SWAMP). Third, the NWQC felt that at least 10% of each grant should be allocated to monitoring activities. Each grantee can conduct this coordinated monitoring themselves or, if they prefer, return 10% of the grant back to the SWRCB to arrange for the coordinator to conduct this monitoring. Regardless of who implements the monitoring, the SWRCB must use the $1 million set aside from Proposition 84 to conduct the coordination, quality assurance, and data management to ensure comparability. Finally, the NWQC recommended that grantees be allowed a 1-year, no-cost extension to conduct post-construction monitoring. The extra time will provide invaluable monitoring information, particularly in the drier parts of the state where rainfall is limited to a short window of time during the year.

ATTACHMENT B

Dioxin White Paper
State Water Resource Control Board- Natural Water Quality Committee
August 2010

Dioxin is a general term for a group of chemicals that are highly persistent in the environment. Dioxins and a related group, the furans, are among the most toxic pollutants known to science. The US Environmental Protection Agency, in a draft report in September 1994, describes dioxin as a serious public health threat. According to their report, there does not appear to be a "safe" level of exposure to dioxin, and dioxins have been found in the general US population "at or near levels associated with adverse health effects." The most toxic dioxin compound is 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD).[1]

TCDD is the prototype for a class of halogenated aromatic hydrocarbons, which appear to have a common mechanism of action and to produce similar effects, although they differ in potency. TCDD achieved notoriety in the 1970's when it was discovered to be a contaminant in the herbicide Agent Orange and was shown to produce birth defects in rodents. It continues to generate concern because of its widespread distribution as an environmental contaminant, its persistence within the food chain, and its toxic potency.[2] TCDD is the most toxic polychlorinated dibenzo-p-dioxin (PCDD) to fish.[3]

Dioxins originate as combustion byproducts, from impurities during the manufacture of wood preservatives and herbicides, and as a byproduct of wood pulp bleaching. New research suggests that forest fires are also a major source of dioxins.[4] The estimated distribution of Dioxin sources for 2004 were; backyard trash burning (25%), societal, e.g. residential wood combustion, gasoline and diesel use, etc (5%), industrial (15%), and natural forest fires (54%).[4] Atmospheric deposition is a major source of dioxin in soil and water and US background soil levels are 1-6 ng/kg TEQ (TCDD Equivalents) in rural areas and 7-20 ng/kg TEQ in urban areas. San Francisco Bay Area stormwater contains 0.2 – 65 pg/L and Santa Monica Bay Watershed concentrations range from 1 – 53 pg/L.

<u>TCDD Equivalents</u>
In the California Ocean Plan TCDD Equivalents are defined as “the sum of the concentrations of chlorinated dibenzodioxins (2,3,7,8-CDDs) and chlorinated dibenzofurans (2,3,7,8-CDFs) multiplied by their respective toxicity factors…” The objective for TCDD Equivalents is for the human health beneficial use, through consumption of seafood, based on the fact that it is a carcinogen. The objective for TCDD Equivalents is 0.0039 picograms per liter, the lowest objective for any of the constituents in the Ocean Plan.

The California Toxics Rule has an objective for TCDD (but not equivalents), set at 0.0013 picograms per liter.

Recently the San Francisco Regional Board used a different definition for TCDD Equivalents based on new information: TCDD Equivalents means the sum of the concentrations of chlorinated dibenzodioxins and chlorinated dibenzofurans multiplied by their Toxicity Equivalency Factor (TEF) and their Bioaccumulation Equivalency Factor (BEF).[5]

$(TEC)_{TCDD}$ = The sum of $(C)_x(TEF)_x(BEF)_x$

Where $(TEC)_{TCDD}$ = TCDD Equivalents concentration in effluent

$(C)_x$ = concentration of total congener x in effluent

$(TEF)_x$ =TCDD toxicity equivalency factor for congener x

$(BEF)_x$ = TCDD bioaccumulation equivalency factor for congener x

Toxicity Equivalency Factor and Bioaccumulative Equivalency Factors are listed in the table below.

The Scripps Institute of Oceanography (SIO) ASBS Monitoring Program measures dioxins in their effluent and receiving water during dry weather and wet weather conditions. A synopsis of the TEQ (pg/L) results are presented in the following table.

Outfall 001- Seawater Discharge		Outfall 002- Stormwater Discharge Wet Weather		Receiving Water- Dry Weather	
Sample Date	**TEQ (pg/L)**	**Sample Date**	**TEQ (pg/L)**	**Sample Date**	**TEQ (pg/L)**
9/30/2005	0.00587	2/27/2006	0.105		
10/13/2005	0.00876	11/30/2007	2.12		
11/16/2005	0.00930	1/5/2008	0.663		
8/21/2006	0.00222	2/6/2009	0.524	8/21/2006	0.00134
5/14/2007	0.00172	3/7/2010	0.601	5/14/2007	0.00227
10/14/2008	0.00703			10/14/2008	0.00251
7/28/2009	0.00355			7/28/2009	0.00331

SIO Dioxin TEQ results were almost all (with one exception) below the range detected in both the San Francisco Bay Area Stormwater and the Santa Monica Watershed. Since Scripps has no likely source of dioxin in their water system, the source of these compounds is most likely from particles present in the local coastal zone from runoff and/or aerial fallout which is supported by the following points:

- The results for the stormwater discharge (Outfall 002) are 2 orders of magnitude higher than the seawater
- The results for the seawater discharge (Outfall 001) are similar to the receiving water

- The result for the stormwater discharge (Outfall 002) sampled on 11/30/2007 are higher than the other sample dates. This sample was collected following a large forest fire upland from SIO. Moreover, the dioxin composition (not shown here) of this sample is also significantly different from all the other samples collected.

Toxicity Equivalent Factors by dioxin congener. OCDD was the primary congener found in SIO discharge.

Congener	Toxicity Equivalency Factor (TEF)	Bioaccumulation Equivalency Factors (BEF)

Issues Related To Measuring Residual Chlorine
In Non-chlorinated Estuarine and Marine Water
October 2009

Background

Many NDPES Permit holders discharging estuarine or marine water into the coastal waters of California are required to monitor their effluent and/or receiving water for Residual Chlorine, even if they are not chlorinating their effluent. Chlorine is toxic to marine aquatic life and therefore Table B of the California Ocean Plan (SWRCB, 2005) lists 6-month median, daily maximum, and instantaneous maximum of 2, 8, and 60 µg/L, respectively. The USEPA 304(a) water quality criteria for chlorine are in terms of Total Residual Chlorine (TRC) in fresh water, which includes free chlorine and chloramines, and in seawater are for chlorine-produced oxidants (CPO), which includes the oxidative products of chlorine (hypobromous acid (HOBr), hypobromous ion (OBr-), and bromamines). The one hour average criteria is 19 µg/L for TRC and 13 µg/L for CPO, and the four day average criteria is 11 µg/L for TRC and 7.5 µg/L for CPO. However, the analytical methods typically used for Residual Chlorine (Standard Methods for the Examination of Water and Wastewater- 19th Edition, 1995) have detection limits around 10 µg/L or higher which exceeds the 6-month median and daily maximum values.

Sources of Chlorine

There are many potential sources of chlorine. Chlorine is used as a disinfectant in sewage wastewater treatment and in marine laboratories. Chlorination is also performed at power generating facilities using once-through cooling, and may be present in power plant discharges. Chlorine and other oxidants are being considered for treatment of ballast water in oceangoing vessels prior to discharge. There are various technologies for dechlorination, including the application of sulfite or sulfite compounds. Other discharges of free chlorine include may be due to the drainage of swimming pools, illicit laundry discharges, the use of chlorine bleach as a cleaning agent in waterfront activities, and industrial spills.

Chlorine and Chlorination Byproducts in Seawater

The issue of monitoring the release of chlorine into the marine environment is of great importance. While chloride ions are the most abundant ions in seawater, free chlorine is highly reactive and not a natural component in marine water. The formation of potentially dangerous byproducts as a result of chlorination can lead to negative consequences for ecologically important areas along our coast. Once introduced into a solution, whether seawater or freshwater, chlorine is generally present as either hypochlorous acid or hypochlorite which are both regarded as free chlorine. These compounds quickly react with the surrounding constituents, such as bromide, iodide, ammonia, and manganese through oxidation reactions to form a variety of products. Exposure to sunlight or any agitation of the solution increases the rates of these reactions. Any free chlorine that is left over is labeled as residual chlorine and quantified.

However, at present it is difficult to accurately quantify the amounts of residual chlorine in marine waters due to the complex nature of seawater. Unfortunately, the higher salt content makes the methodologies currently being used to quantify residual chlorine in fresh water unreliable for use with seawater samples (Johnson, 1977).

Seawater naturally contains approximately 67ppm of bromide and 64ppb of iodide, which are both quickly oxidized to bromine and iodine when they come into contact with chlorine. Seawater also contains variable amounts of ammonia, which in the presence of chlorine can lead to the formation of haloamines (e.g., chloramines and bromamine). As a result of these reactions, the free chlorine is reduced to chloride, while the bromine and iodine form hypobromous and hypoiodic acids, both potent oxidants, and the ammonia is oxidized to bromamine or chloramine, which are toxic to aquatic life. The rates of these reactions are quite rapid, to the point that they are almost instantaneous. For example, the oxidation of bromide by chlorine can use up one-half of the free chlorine in less than one second. These newly formed oxidants will continue to react with nearby compounds and eventually be reduced back to bromide, iodide, and ammonia.

Trihalomethanes (THM) are also formed as a result of chlorination in the presence of organic matter. The formation of these compounds is a function of precursor concentration, contact time, chlorine dose and pH. Typically, only four THM compounds are normally found and analyzed in the lab. They include chloroform (CHCl3), bromodichloromethane (CHBrCl2), dibromochloromethane (CHBr2Cl), and bromoform (CHBr3). Polyhalomethanes are naturally found in low concentrations in marine waters. Some species of marine algae are sources of polyhalomethanes including but not limited to bromoform (CHBr3), brodichlormethane (dichlorobromomethane, CHBrCl2), chloroform (trichloromethane, CHCl3), and dibromochloromethane (CHBr2Cl). Rock pool and shallow subtidal seaweeds in the genera *Laminaria, Fucus, Pelvetia, Gigartina, Polysiphonia, Enteromorpha, Chaetomorpha, Ulva, and Cladophora,* have been specifically identified as trihalomethane producers (Nightingale et al. 1995; Moore, 2003). Productive coastal waters are enriched with bromoform due in part to their production by marine macroalgae and possibly by marine microbes (Manley, Goodwin and North 1992). Seaweeds appear to be the dominant natural oceanic source of bromoform and methylene bromide. The marine coastal zone is a major source of bromoform produced by cyanobacteria (blue green algae), and other microalgae including phytoplankton and benthic forms. A major environmental source of chloromethane is also the decomposition of seaweeds. Salt marsh flowering plants also produce methyl halides (Murray et al. 2002). Toxicological studies suggest that chloroform is a potential human carcinogen (Standard Methods 19th Ed. 2005). The Ocean Plan defines halomethanes as the sum of bromoform, bromomethane (methyl bromide) and chloromethane (methyl chloride). The Ocean Plan's 30-day average water quality objective is 130 µg /l for total trihalomethanes (TTHM) and is based on protection of human health; the 2005 Ocean Plan does not provide an objective for the protection of marine aquatic life.

Measuring Chlorine in Seawater

It is because chloride, bromide and iodide are present in such high amounts that the determination of residual chlorine in seawater is so problematic (Johnson, 1977). By the time the analysis of seawater is initiated, the majority of the free chlorine will have reacted with something and been reduced to harmless chloride ions. Unfortunately, the methods used to measure the concentration of residual chlorine are not specific to that element. Rather, they measure the total concentration of oxidizing agents in the solution. Consequently, the oxidized bromine, iodine, and bromamine compounds would register as residual chlorine, even though they are something completely different (Eaton, 1995), and a more appropriate measurement may be for chlorine-produced oxidants. For this reason, it is important to be cautious when reviewing residual chlorine data for seawater samples. According to the 19th Edition of Standard Methods for the Examination of Water and Wastewater, as well as a paper published in the journal Chesapeake Science by Dr. J. Donald Johnson, iodide based residual chlorine methods, including colorimetric, amperometric monitors, and amperometric titrations, are inappropriate for the quantification of residual chlorine in estuarine and marine samples. Amperometric and continuous monitoring systems have been used successfully for chlorine-produced oxidants but do require additional expertise and care when making these measurements.

ACKNOWLEDGEMENTS

The authors are deeply indebted to the members of the SWRCB's Natural Water Quality Committee for guidance and review: Andrew Dickson (Scripps Institution of Oceanography), Burt Jones (University of Southern California), Steve Murray (California State University Fullerton), Rich Gossett (California State University Long Beach), and Bruce Posthumus (California Regional Water Quality Control Board, San Diego).

ABSTRACT

California has designated 34 different marine water quality protected areas, termed Areas of Special Biological Significance (ASBS), which extend across roughly 500 miles (32%) of state shoreline. Recent surveys observed over 1,600 outfalls into ASBS, most of which are storm drains potentially discharging nonpoint sources of pollutants. The goal of this study was to assess the extent and magnitude of water quality impacts in California's ASBS following storm events. A stratified probabilistic design was used for sampling receiving water shorelines near (discharge) and far (non-discharge) from storm drain outfalls. In all, more than 98 target analytes were measured from 33 sites immediately prior to (pre-storm) and immediately following (post-storm) wet weather. In general, reasonably good water quality exists in California's ASBS following storm events. Many of the target analytes measured did not exceed the State of California's Ocean Plan water quality standards (WQS) and toxicity, using an endemic test species, was rare. The post-storm concentrations of most constituents in discharge and non-discharge strata of ASBS were similar. Likewise, the average concentration increase across all target analytes from pre- to post-storm was less than 3-fold in the discharge stratum. The three potentially problematic parameters identified were total PAH, chromium, and copper. Total chromium did not exceed state WQS such as the instantaneous maximum and daily maximum, but did exceed the six-month median WQS in an estimated 50% of the state's ASBS shoreline-miles. Total PAH exceeded the 30-day average WQS in an estimated 87% of the state's ASBS shoreline-miles. Copper exceeded WQS less extensively (7% of ASBS shoreline-miles), but exclusively in the discharge stratum and for dissolved as well as total copper concentrations. The relatively good water quality on a statewide basis was not evenly distributed. In southern California, whose shoreline is under much more intense development than elsewhere in the state, almost twice as many target analytes exceeded WQS as in central or northern California.

INTRODUCTION

By their proximity, oceans adjacent to coastal land development are continually subjected to pollutant inputs. In the United States, approximately 53% of the population lives in counties bordering the coast, but comprises only 17% of the land area (Culliton *et al*. 1998). This has led to habitat alteration (Boesch *et al*.2001), eutrophication (Bricker *et al*.1999), contaminated sediments (USEPA 2005), and accumulation of toxics in tissues of marine organisms (O'Connor 1998).

One conservation strategy used to safeguard the marine environment is the establishment of protected areas where portions of the coast are set aside for limited use. Marine protected areas exist for some of the most ecologically sensitive areas around the world including Australia's Great Barrier Reef, Fiji, the Galapagos Islands, and others. Many marine protected areas also exist within the United States including California, Hawaii, and Florida (NOAA 2008). Virtually all of these marine protected areas, however, were established based upon natural resource needs and not exclusively water quality issues. Almost in unanimity, the aforementioned marine protected areas initially have fisheries-based goals that limit recreational and/or commercial fishing. Water quality goals, if addressed, were not the primary motivation for the establishment of the marine protected area.

Unlike most other coastal conservation strategies, the State of California established 34 marine protected areas in 1974-75 specifically for the protection of water quality (SWRCB 2005). Although they are called areas of special biological significance (ASBS), not all of these marine water quality protected areas also limit harvesting (i.e., fishing). Twenty-five of the ASBS occur on the mainland of California comprising 499 shoreline miles and 32% of the state coastline (Figure 1). The primacy of water quality protection is indicated within state policy whereby all "discharge of waste is prohibited" and "natural water quality must be maintained" in these ASBS (SWRCB 2005).

The State of California has done a remarkable job limiting point source discharges in ASBS. Less than 10 point source discharges exist statewide, and these are almost entirely discharges from marine aquaria and/or flow through seawater systems associated with research academic institutions. However, little attention has been placed on non-point source discharges, which are much more numerous. Over 1,600 outfalls have been identified along ASBS shoreline (SCCWRP 2003). The vast majority of these outfalls were storm drains that could potentially discharge urban and agricultural runoff from upstream development. Large portions of this upstream development did not exist when the ASBS were originally established in the mid-1970's.

The objective of this study was to assess the extent and magnitude of water quality impacts in ASBS following storm events. Further, the magnitude and extent of impact in ASBS was compared between areas near stormwater discharges and areas distant from discharges to determine the potential of storm drain outfalls to cause the observed impacts in water quality. Ultimately, the goal was to determine if significant water quality impacts existed within ASBS, with the results guiding managers on the need and direction of potential future intervention.

METHODS

This study utilized a probabilistic-based design to estimate the shoreline-miles or percent of total shoreline-miles with observed impacts to water quality. Probabilistic designs, wherein sample sites are selected randomly, enable unbiased estimates of extent (Stevens 1997). For the current study design, the sampling frame consisted of all mainland ASBS shoreline, divided into two groups: 1) areas near direct discharges defined as less than 500m from a pipe, drain, or other surface discharge greater than 18 inches diameter; and 2) non-discharge areas defined as more than 500 m distant from direct discharges. The 500 m cutoff was selected based on nearshore modeling studies by Jenkins and Wasyl (2007). All sites were collected from shoreline receiving water. No effluent samples were collected as part of this study. All sites were sampled for only a single storm event between February and April 2009.

A total of 33 sites were selected for sampling. Twenty-one sites were from the discharge stratum and 12 sites were from the non-discharge stratum (Table 1). At each site, samples were collected immediately prior to (<48 hours), then immediately following (<24 hours), significant storm events. Sampling criteria included: 1) all post-storm samples must be collected as soon after the storm event as possible (nearly all were collected less than six hours following cessation of rainfall); 2) at discharge sites, stormwater flows must reach the ocean; and 3) all ocean receiving water samples must be collected by hand from the shore (no boats). These criteria helped ensure that the focus was on receiving waters, that recent stormwater inputs had occurred, and examining the area closest to shore where potentially the least mixing occurs.

All water samples were analyzed for 98 parameters: 1) general constituents including total suspended solids (TSS), dissolved organic carbon (DOC), and salinity; 2) nutrients including nitrate (NO3-N), nitrite (NO2-N), ammonia (NH3-N), total nitrogen (TN), total phosphorus (TP), and ortho-phophate (PO4-P); 3) dissolved and total trace metals (As, Cd, Cr, Cu, Ni, Pb, Ag, Se, Zn); 3) chlorinated hydrocarbons including total PCB (sum of congeners 18, 28, 37, 44, 49, 52, 66, 70, 74, 77, 81, 87, 99, 101, 105, 110, 114, 118, 119, 123, 126, 128, 138, 149, 151, 153, 156, 157, 158, 167, 168, 169, 170, 177, 180, 183, 187, 189, 194, 201, 206) and total DDT (sum of o,p'- and p,p'-DDT, DDE, and DDD); 4) total polycyclic aromatic hydrocarbons (28 PAH); and 5) short-term chronic toxicity using an early life stage of an endemic species. All sample analysis followed standard methods and/or EPA approved procedures (APHA 2006). Trace metals were prepared for analysis using ammonium pyrrolidine dithiocarbamate (APDC), a chelation method that concentrates trace metals and removes matrix interferences (USEPA 1996). Fertilization success of the purple sea urchin, *Strongylocentrotus purpuratus*, was used for toxicity testing (USEPA 1995).

The project focused on performance-based measures of quality assurance. In general, laboratory data quality was quite good: no laboratory blank samples greater than the method detection limit; 96% success meeting data quality objectives (DQOs) for precision using laboratory duplicates; 91 % success meeting DQOs for accuracy using spiked samples. The lowest accuracy success rate was for cadmium (12 of 15 batches) and zinc (8 of 16 batches) where the requirement of 75-125% recovery from seawater was not met. This was due, in part, to the APDC chelation method that has lower affinities for extracting cadmium and zinc.

Data Analysis

Based on the study design, two data analysis approaches were utilized to compare spatial (discharge vs. non-discharge strata) and temporal (pre-storm vs. post-storm) relationships. The first approach examined the magnitude of changes in space and time. To do this, area-weighted geometric means were calculated for total ASBS shoreline and for each stratum and time period using a ratio estimator approach following Thompson (1992):

$$m = \frac{\sum_{i=1}^{n} (p_i * w_i)}{\sum_{i=1}^{n} w_i},$$

Where:
m = Log_{10} of the area-weighted mean concentration for population j.
p_i = Log_{10} of the parameter value (e.g., concentration) at station i.
w_i = Area weight for station i.
n = Number of stations in population j.

The standard error of the mean is calculated using the following equation where the 95% confidence intervals about the mean were calculated as 1.96 times the standard error.

$$\text{Standard error (SE)} = \sqrt{\frac{\sum_{i=1}^{n} ((p_i - m) * w_i)^2}{\left(\sum_{i=1}^{n} w_i\right)^2}},$$

where:
m = Log_{10} of the area-weighted mean concentration for population j.
p_i = Log_{10} of the parameter value (e.g., concentration) at station i.
w_i = Area weight for station i.
n = Number of stations in population j.

All concentrations below detection limits were treated as zero. Area-weighted geometric means and confidence interval were back-transformed for tables and graphs.

The second data analysis approach focused on estimating the areal extent of impact. To accomplish this, area weights for each sample that exceeded State of California water quality standards (WQS) were summed and divided by the total area-weight for the stratum and time period of interest. The WQS are defined in Table B of the California Ocean Plan (SWRCB 2005). Four WQS exist including six-month median, 30-day average, daily maximum, and instantaneous maximum thresholds.

RESULTS

The post-storm concentrations of most constituents in discharge and non-discharge strata of ASBS were similar (Table 2). Except for DOC and dissolved copper, there was no statistical difference in area-weighted geomean concentrations between post-storm discharge and non-discharge strata. In the case of post-storm copper geomean concentrations, the discharge stratum was greater than the non-discharge stratum. The case was reversed for DOC; the non-discharge was greater than the discharge stratum. Although not statistically different, the area-weighted geometric mean concentration in the discharge stratum was greater for 14 of the remaining 24 parameters compared to the post-storm non-discharge stratum. Post-storm concentrations of chlorinated hydrocarbons, such as total DDT and total PCB, were uniformly non-detectable in both strata.

On average, the increase in concentration across all target analytes from pre- to post-storm samples was less than 3-fold in the discharge stratum (Table 2; Figure 2). In fact, none of the target analyte concentrations were significantly greater post-storm compared to pre-storm. Average concentrations for 12 of the 25 target analyte actually decreased from pre- to post-storm in the discharge stratum. Of the remaining 13 target analytes, the most substantial concentration increases were for dissolved iron (26-fold) and DOC (15-fold).

In general, exceedence of WQS such as instantaneous maxima, daily maxima, and six-month medians, were infrequent for ammonia and trace metals following storm events (Table 3). None of the target analytes collected post-storm exceeded WQS based on instantaneous maxima. Only a single target analyte collected post-storm exceeded the WQS based on the daily maximum. This analyte, total chromium, exceeded 2% of the post-storm shoreline-miles across all ASBS. Ten of 18 parameters collected post-storm exceeded the WQS based on six-month median objectives. Three parameters were dissolved metals (cadmium, copper, and nickel); none of these dissolved metals exceeded the six-month median in more than 2% of the ASBS shoreline-miles. Seven of the parameters exceeding the six-month median were for total metals. The parameter that exceeded the six-month median WQS most frequently (50% of ASBS shoreline-miles) was total chromium. Total nickel exceeded the six-month median WQS second most frequently (15% of ASBS shoreline-miles). Total arsenic, cadmium, copper, lead and zinc exceeded six-month median WQS between 2 and 7% of the ASBS shoreline-miles.

In contrast to ammonia and trace metals, exceedence of state WQS for trace organic parameters was much more frequent (Table 4). Of the six target organic analytes collected post-storm, only total PAH exceeded the 30-day average WQS. However, total PAH exceeded the 30-day average WQS an estimated 87% of the ASBS shoreline-miles. Other trace organic parameters including total DDTs, total PCBs, chlordane, and dieldrin did not exceed the 30-day average WQS.

Except for total chromium and total nickel, there was no dramatic difference in the extent of post-storm WQS exceedences between discharge and non-discharge strata (Tables 3 and 4). The difference in exceedence of the six-month median WQS following storm events was nearly two-fold for total chromium (35% of shoreline-miles for the non-discharge stratum compared to 61% of shoreline-miles for the discharge stratum) and a factor of eight for total nickel (3% of shoreline-miles for the non-discharge stratum compared to 24% of shoreline-miles for the discharge stratum).

Contrary to expectations, there was little change in the extent of WQS exceedences from pre- to post-storm in the discharge stratum (Tables 3 and 4). For example, the percent of shoreline-miles that exceeded WQS for chromium and total PAH changed by less than 10% (Figure 3). On the other hand, there were substantial changes in the extent of WQS exceedence from pre- to post-storm in the non-discharge stratum, particularly for these same two target analytes. The extent of shoreline-miles approximately doubled pre- to post-storm for total chromium and total PAH. In fact, the extent of post-storm WQS exceedences of total PAH in the non-discharge stratum looked very much like the extent in the discharge stratum (89% vs. 86% of shoreline-miles, respectively).

Exceedences of the WQS occurred most frequently in southern California compared to northern or central California (Figure 4). The Irvine Coast ASBS in southern California had the greatest number of target analytes (six) sampled post-storm that exceeded WQS and had concentrations that increased from pre- to post-storm. The Robert Badham ASBS followed with four target analytes sampled post-storm that exceeded WQS. No ASBS in Central and Northern California exceeded these same criteria by more than three target analytes. Only a single ASBS in southern California (San Diego-Scripps ASBS) had no exceedences of the WQS for any analyte. There were six ASBS in Central and Northern California that had no analytes exceeding the WQS.

The occurrence of toxicity in post-discharge samples from ASBS was rare. Roughly 3% of the shoreline miles observed post-storm toxicity. This was relatively evenly split between non-discharge and discharge strata.

DISCUSSION

Based on the results from this study, generally good water quality exists in California's ASBS following storm events. Most target analytes measured did not exceed the State of California's WQS and, for the majority of analytes that did exceed the WQS, the relative extent of impact was small (< 7% of ASBS shoreline-miles). All of the target analytes that exceeded WQS have natural as well as anthropogenic sources (e.g., trace metals), but synthetic pesticides (e.g., total DDTs, total PCBs, chlordane and dieldrin) never exceeded WQS and were rarely detected. Additionally, toxicity using an endemic species (sea urchin fertilization test) was infrequent indicating unmeasured analytes were likely not problematic. Finally, average receiving water concentrations of most common stormwater constituents (i.e., lead, zinc, etc.) were statistically similar between the discharge and non-discharge stratum, and average concentrations measured pre-storm were statistically similar to post-storm concentrations in discharge stratum. The lack of demonstrative impact following storm events is an important finding because the greatest perceived risk to ASBS water quality is from stormwater runoff generated by urban, agricultural, and other nonpoint source activities.

While the summary of post-storm water quality in ASBS can be described as good, there were three parameters that stand out as potentially problematic. These include total PAH, chromium, and copper. Total PAH is a known stormwater contaminant from studies not only in California (Stein *et al*.2006), but around the United States (Hoffman *et al*.1984). Total PAH concentrations in ASBS were generally low, never exceeding 186 ng/L. Unlike all the other analytes that indicated impairment, the WQS for PAH is based on risk to human health through bioaccumulation in seafood. Hence, the total PAH WQS may be marginally applicable for the protection of marine aquatic life. Interestingly, the frequency of WQS exceedence for total PAH was similar between pre- and post-storm in the discharge stratum so non-storm sources may be at play. Other potential sources could be numerous including dry weather runoff (Stein *et al*. 2006), atmospheric deposition (Sabin *et al*.2009), or natural seeps (Leifer *et al*.2006). Clearly, future work on source attribution of total PAH and its potential for biological effects, should be evaluated.

Unlike total PAH, the WQS for chromium is based on the predicted marine life toxicity of its most harmful state, hexavalent chromium. While total chromium is the accepted surrogate for hexavalent chromium in most regulatory applications, no analysis was done in this study to evaluate the relative contribution of hexavalent chromium. Since toxicity was infrequently observed, one can hypothesize that hexavalent chromium was often below the WQS. However, the disparity in the extent of total chromium exceeding WQS between the discharge stratum and non-discharge stratum was sizeable (61% vs. 35% of ASBS shoreline-miles, respectively). Therefore, total chromium in stormwater discharges likely has some influence on ASBS receiving water concentrations. Adding to the concern, total chromium is a commonly found analyte in urban stormwater discharges, with industrial land uses having amongst the greatest concentrations in southern California (Tiefenthaler *et al*.2008). Chromium is also a naturally occurring component of serpentine rock in many coastal California locations (Caillaud *et al*. 2009). Because of the issues associated with natural versus anthropogenic sources of chromium, surveys focused on chromium and the relationship between total and hexavalent chromium at problematic ASBS may be warranted.

Copper was the final target analyte of concern. The concern was generated by four factors that individually aren't alarming, but collectively may indicate stormwater influences. First, total copper exceeded WQS, although not extensively (7% of ASBS shoreline-miles). However, the extent of impact occurred exclusively in the discharge stratum while the non-discharge stratum was free of copper WQS exceedences. Second, the copper WQS exceedence in the discharge stratum occurred post-storm, but was absent in pre-storm samples. Third, the WQS exceedence occurred not just for total copper, but also for dissolved copper. Fourth, the average dissolved copper concentration was significantly greater post-storm than pre-storm. The third and fourth factors are relevant to stormwater inputs because dissolved copper is more bio-available, and an inherently greater toxicological risk to marine life, compared to total copper (Arnold *et al*.2005). Moreover, copper is consistently observed in stormwater discharges (Tiefenthaler 2008). Further, copper has been identified as the primary toxicant of concern for failed toxicity tests using the sea urchin fertilization test in near coastal water influenced by stormwater runoff (Bay *et al*.2003)

The larger concern for total PAH and total chromium may actually be in the non-discharge stratum. It was in the non-discharge stratum that WQS exceedences rose dramatically from pre- to post-storm. While average concentrations did not dramatically increase, they were very near the state's WQS and the extent of ASBS shoreline-miles exceeding WQS doubled or tripled. In fact, the extent of WQS exceedence in non-discharge areas post-storm looked very similar to the extent observed in the discharge stratum. This study design element was intentional; we wanted to see if discharges either inside or outside of ASBS may impact non-discharge shoreline. The influence of distant sources, at least for these two target analytes, was obvious.

An alternative hypothesis is that applying long-term WQS to short-term events, like storm events, are not appropriate in the nearshore zone. California has several short-term thresholds including instantaneous maximum, daily maximum, and additional long-term thresholds such as the 30-day average (for trace organics) or six-month median (for ammonia and trace metals). However, it is standard regulatory practice to use even single samples to evaluate the long-term thresholds when additional data are not available. In the case of this study, even the most problematic target analytes (total PAH and total chromium, both of which have both natural and anthropogenic sources) did not exceed the short-term thresholds. It was application of the long-term thresholds, whose benchmark concentrations are much lower, when WQS exceedences became problematic. For this reason, a more appropriate measure might be "natural water quality" as designated in state policy. Natural water quality, while attractive, has its own set of technical and political challenges. Since no statewide data exists from natural (e.g., reference) sites, additional data collection would be necessary.

Finally, the notably good water quality on a statewide basis was not evenly distributed throughout the state. Some ASBS exceeded WQS standards at a much greater frequency and these regions should likely receive further attention. For example, sites in southern California fared worse than their northern or central California counterparts. This may be due, in part, to the intense urbanization of the southern region. More than 20 million people live in southern California and coastal development pressure is intense (Ackerman and Schiff 2003). In the survey of storm drain discharges to ASBS, over 46% occurred in southern California. In fact, so much development occurs in southern California coastal watersheds, that the non-discharge stratum (defined as >500m from drain discharges 18 inches and greater), did not exist in southern California.

Overview

The purpose of this document is to detail a Trash Monitoring and Reporting Plan (TMRP) and Minimum Frequency of Assessment and Collection/ Best Management Practice (MFAC/BMP) program to implement the Santa Monica Bay Nearshore and Offshore Debris Total Maximum Daily Load (TMDL), effective March 20, 2012. The implementation of the TMDL covers the entire Santa Monica Bay Watershed Management Area (WMA).

The TMRP encompasses a description of an MFAC program, procedures to assess compliance with the MFAC program, current BMPs, a monitoring program to quantify trash from source areas, and information on sources to prioritize BMP implementation. The TMRP includes monitoring and assessment procedures that allow for determination of compliance for both point and nonpoint sources.

The TMRP and MFAC/BMP program described herein are being submitted on behalf of the County of Los Angeles (County), the Los Angeles County Department of Beaches and Harbors (DBH), and the City of Hermosa Beach, three of the responsible parties identified in the TMDL, to address point and non-point source trash in the Unincorporated County Areas, on beaches and harbors owned and operated by the County, and non-point source trash within the Hermosa Beach owned by the City of Hermosa Beach within the Santa Monica Bay Watershed Management Area. Future implementation efforts may warrant changes based upon outcomes of subsequent studies and findings. Significant deviations from the County TMRP and MFAC/BMP program will initiate notification to the Los Angeles Regional Water Quality Control Board (Regional Board).

TRASH DEFINITION

For purposes of the TMRP and MFAC/BMP program, trash is any persistent solid material that is manufactured or processed and directly or indirectly, intentionally or unintentionally, disposed of or abandoned into the environment. Materials properly placed within trash collection bins (e.g., cans or dumpsters) are not considered trash with regards to MFAC assessment or trash generation rate evaluations. Naturally occurring vegetation waste is also not considered trash.

TMRP REQUIREMENTS

TMRP requirements apply to both point sources (e.g., catch basins within the municipal separate storm sewer system) and nonpoint sources (i.e., beaches, harbors, non-beach open space and parks.) As outlined in the TMDL, assessment metrics for point source waste load allocations (WLAs) and nonpoint source load allocations (LAs) are as follows:

Point sources:

- The installation of full capture devices on all conveyances discharging to waterbodies within the Santa Monica Bay WMA[1].

Nonpoint sources:

[1] Where full capture devices are not feasible (e.g., due to size limitations), the County will elect to use partial capture devices or other controls to remove trash from the subdrainage area at the commensurate trash generation rate.

- No trash on Beaches or in Harbors immediately after a cleanup event.
- Trash is not accumulating in deleterious amounts.
- Trash generation rate of sources areas does not exceed the benchmark of 113,150 pounds per mile per year (310 lbs/mi/day) for Beaches and Harbors, or 162,468 pounds per square mile per year (640 gal/mi^2/yr) for Non-Beach Open Space and Harbors, and displays a decreasing trend over time.

In the event the assessment metrics are not met, the County may evaluate the BMPs currently being employed and determine if additional BMPs may result in attaining the metrics. If changes to existing BMPs or implementation of additional BMPs are determined to likely result in attaining the assessment metrics, the County will describe the proposed modifications and the schedule for effecting the modifications as part of the Annual Monitoring Report. Where assessment metrics are not met, the County will be in compliance with the TMDL by completing the BMP evaluation, reporting the results and schedule for changes as appropriate in the Annual Monitoring Report, and, as appropriate, implementing the identified changes.

The TMRP is designed to address the following requirements:

- Assessment and Monitoring
    - Establish nonpoint source monitoring requirements
    - Develop initial monitoring protocols, locations, and frequencies
        - MFAC assessment program for Beaches and Harbors (nonpoint sources)
        - MFAC assessment program for Non-Beach Open Space and Parks (nonpoint sources)
        - Evaluation of trash generation rates from nonpoint source areas
    - Establish reporting requirements
- BMP Implementation
    - Prioritize High Trash Generation Areas (point and nonpoint sources)
    - Evaluate and identify most appropriate Full Capture Systems (FCS) or Partial Capture Systems (PCS)/BMPs to install or implement (point and nonpoint sources)
    - Evaluate MFAC/BMP program effectiveness (nonpoint sources)
- Point source implementation
    - Outline FCS sizing.
    - Propose definitions for “major rain event” and “proper operation and maintenance”

Trash receptacles placed for proposer disposal of unwanted items, and cleanup events to collect trash, are the major BMPs of the MFAC program. The following are the proposed collection and monitoring procedures that will be used for the TMRP:

MFAC Collection Program:

- Maintain existing daily cleanup events for Beaches, Harbors, and Burton Chace Park.
- Implement daily cleanup events for trash source areas of Beaches, Harbors, and Burton Chace Park.
- Continue conducting as-needed cleanup events for Non-Beach Open Space and Parks.

Assessment program for MFAC:

- Define MFAC Assessment Sites.
- Visually survey and collect any trash within 100 foot long site reach at defined locations immediately after a cleanup event. If any trash is found, it will likely necessitate additional field staff training or evaluation of modified collection procedures to capture all trash.

Evaluation program and definition of trash generation rate for nonpoint source areas:

- Define Source Area Evaluation Sites.
- Collect all trash within evaluation area at defined locations in the late afternoon before dusk, and weigh the trash collected.
- Extrapolate the collected trash data from evaluation sites to the whole location (e.g., a beach) for comparison with the benchmark.
- Demonstrate a decreasing trend in trash generation rates over time.

Trash Monitoring Program

- Conduct monitoring as per the MS4 permit, if so required.

The proposed components of the monitoring program and the purposes they serve in the TMRP for meeting the TMDL requirements are listed in Table 1, in addition to the frequency at which the components of the program will be conducted.

Table 1. Proposed Components of the MFAC Program and the Frequency of Implementation.

Component	Purpose	Frequency
MFAC Collection Program (Cleanup Events)	Zero-trash requirement to be met immediately after cleanup events	Daily for Beaches and Harbors Daily for source areas of Beaches and Harbors Daily for Non-Beach Open Space and Parks near shorelines
MFAC Assessment Sites	MFAC assessment that zero-trash metric has been met immediately after cleanup events	Annually for Beaches and Harbors Annually for Non-Beach Open Space and Parks
Source Area Evaluation Sites	Collection of trash to determine trash generation rate for specific areas	Semi-annually for Beaches and Harbors Semi-annually for Non-Beach Open Space and Parks
Point Sources	Determination of attaining the specified point source WLAs and progressive reduction	None. Assumes all County point sources will be implementing full capture Assumes monitoring of MS4 system and drainage channels will be addressed through the MS4 permit

In addition, the County TMRP will serve as the monitoring guidelines and procedures that will be used for the MFAC/BMP program effort. Any changes and revisions to the described procedures will be included with annual monitoring reports. The MFAC/BMP program as defined in the BPA is “Established at an interval that prevents trash from accumulating in deleterious amounts that cause nuisance or adversely affect beneficial use between collections”.

MFAC/BMP Program Requirements

The MFAC/BMP program applies to nonpoint sources only. Requirements for the MFAC/BMP program are associated with TMRP requirements and are as follows:

- Develop initial minimum frequency of monitoring and collection, as well as protocol and locations (nonpoint sources)
    - Collection and monitoring program for Beaches and Harbors
        - Routine trash generation rate evaluation
    - Collection and monitoring program for Non-Beach Open Space and Parks
        - Routine trash generation rate evaluation
- Implement an initial suite of structural and/or nonstructural BMPs
- Develop Health and Safety Plan

Data and results gathered from the MFAC/BMP program will assist in determining TMRP required BMP Implementation actions and may additionally affect monitoring protocols, locations, and frequencies.

GENERAL APPROACH

The County will initially use the default baseline load allocations (LAs) for nonpoint sources and the default WLA for point sources, as given in the BPA (see **Comparison with Established Baselines** section). The County TMRP proposes the following procedures for meeting the TMDL requirements as listed in the BPA:

1. Conduct initial TMRP actions to meet the following goals:
    a. Cleanup events (no monitoring), conducted daily to remove trash from Beach and Harbor shorelines, Beach and Harbor source areas, and Harbor waters.
    b. MFAC assessments, conducted annually immediately after a cleanup event to ensure all trash is collected.
    c. Evaluation of source areas, conducted semi-annually with collection conducted in late afternoon before dusk to determine if the trash generation rate is decreasing and whether the trash is accumulating at a rate deleterious to beneficial uses.
2. Prepare a monitoring report one year from the start of the required monitoring[2] and each year thereafter that provides the following information:
    a. Results of all nonpoint source monitoring efforts
        i. MFAC assessment results
        ii. Source area evaluation results
        iii. Number of cleanup, MFAC assessment, and source area evaluations conducted
    b. Summary of all efforts implemented at point sources
        i. Number of installed FCSs and percent of coverage
        ii. Summary of any point sources not addressed with FCSs
        iii. Description of point sources to be addressed the following year
    c. Determine if the County is within with TMDL assessment metrics
        i. Zero trash after MFAC assessment events
        ii. Trash generation rates below baseline
        iii. Reduction in trash generation rates
    d. Discussion of effectiveness of the MFAC/BMP program
    e. If necessary, proposed revisions to the MFAC/BMP program and TMRP, including:
        i. Assessment site revisions
        ii. Evaluation site revisions
        iii. Monitoring frequency revisions

---

[2] The start of the required monitoring program will be based upon receipt of the Regional Board Executive Officer's approval letter

iv. BMP implementation revisions.

These proposed procedures comprise a tentative list that may be modified after the monitoring efforts begin. Any major deviations will warrant Regional Board notification. The annual reports will incorporate TMRP results and description of components and/or elements added or modified by the County.

PROGRAM COVERAGE

The Basin Plan Amendment (BPA) lists numerous responsible parties who are not participating in the County TMRP effort and are not covered by any component of the County TMRP. The County is assuming that non-participating responsible parties will implement their own plan/s and the Regional Board will enforce all requirements associated with BPA milestones and requirements in an equitable manner to ensure that the trash impairments are addressed in all listed areas.

The TMRP is developed to assess and evaluate the trash collection and generation rate in areas under the County jurisdiction. Specifically, the beaches may receive trash from areas outside the County jurisdiction, including from Caltrans (Pacific Coast Highway) and storm drain discharges from upstream non-County urban areas. The site selection and monitoring presented herein are designed to exclude to the extent possible trash emanating from areas outside of County control.

As subsequent implementation efforts take place, other parties within the watershed may agree to join this implementation effort, whereupon modified procedures (e.g., notification to the Regional Board of party joining the effort, increased sampling and/or MFAC/BMP program requirements, and reporting requirements covered under the joint effort) will be followed.

TRASH COLLECTION PROCEDURES

Trash collection will occur primarily through cleanup events, which occur generally on a daily basis at Beaches and Harbors. Secondary trash collection may occur through source area evaluation events. Ideally, there will be no trash remaining during MFAC assessment events, which are scheduled to occur immediately after the primary cleanup events, however, remaining trash collection will be collected and weighed. A schedule of monitoring events including cleanup, MFAC assessment, and source area evaluation events is provided in Table 2.

Cleanup Events

Cleanup events will include collection of trash from sandy beach areas and harbor waters. A specific protocol is not required for collection procedures occurring at cleanup events. As long as the frequency of cleanup events meets the frequencies specified herein, the County may use any methods or techniques desired for trash collection at cleanup events.

Monitoring, Assessment, and Evaluation Approach

For the TMRP, MFAC monitoring sites are identified for locations that fall under County jurisdiction. Depending on existing monitoring and assessment activities at each of these sites, changes in monitoring may be proposed in the future to refine the evaluation and assessment of the MFAC/BMP program. The intent of the monitoring and assessment approach is to ensure that the MFAC program requirements are being met, and to utilize available resources to the extent possible to meet other TMRP requirements so that duplicative efforts are minimized.

MONITORING SITE LOCATION APPROACH

The impaired locations listed in the BPA consist of broadly defined areas, including the waterbodies within the Santa Monica Bay WMA, the Santa Monica Bay, and the shoreline/beaches of the Santa Monica Bay. Adjacent land areas which may contribute trash to these areas (e.g., beaches, marinas, open spaces, and parks in the WMA) are also included. It is important to note that there are various leased or privately owned Beach and Harbor areas scattered along the Santa Monica Bay shoreline. Leased and privately owned areas are not addressed in the TMRP and are to be avoided when conducting TMRP and MFAC/BMP activities. Only areas owned by the County and maintained by DBH will be covered by the County TMRP. In addition, the unique topography in certain areas of the WMA contains dangerous and inaccessible areas, such as cliffs and bluffs, which cannot be safely cleaned of trash or monitored, as described in the Health and Safety Plan (see **Attachment B**).

The proposed approach for meeting both the MFAC and TMRP requirements includes the use of two types of monitoring sites:

- MFAC Assessment Sites (Assessment Sites)
- Source Area Evaluation Sites (Evaluation Sites)

The Assessment Sites are specific sites located adjacent to impaired waterbodies within the WMA, which are representative of the critical areas defined in the BPA. These sites are also considered a component of the MFAC/BMP program, and are used to monitor the assessment metric of no trash remaining after a cleanup event.

The Evaluation Sites will primarily be used to determine the trash generation rates for the nonpoint source areas. Data from Evaluation Sites will be used to help identify High Trash Generating Areas adjacent to selected Assessment Sites, evaluate the effectiveness of the MFAC/BMP program, and determine the assessment metrics to compare with TMDL baseline and trending reduction requirements.

Specific assessment and evaluation sites are listed in **Attachment A**. The following is a discussion of the site selections.

MFAC ASSESSMENT SITES

MFAC Assessment Sites (Assessment Sites) serve the following purpose under the TMRP:

- Allow for repeatable monitoring efforts and comparable data analysis to evaluate assessment metrics and the TMDL load allocation.

The Assessment Sites were selected for their representation of impaired areas as well as their safety and accessibility. Each Assessment Site is intended to provide a representative assessment of the County jurisdiction as listed in the BPA and locations for long-term assessment. For each Beach and Harbor location, generally one Assessment Site has been proposed.

Detailed monitoring of 100 foot sections of a shoreline will be conducted at each Assessment Site. Procedures for conducting monitoring are described in the **Monitoring Procedures** section of the TMRP report. Specific details pertaining to each site sampled will be included in subsequent annual monitoring reports.

SOURCE AREA EVALUATION SITES

The Source Area Evaluation Sites (Evaluation Sites) meet the following TMRP requirements:

- Evaluation of the trash generation rate for nonpoint sources.
- Measure over time for to determine trend.
- Evaluate the effectiveness of the MFAC/BMP program.

Evaluation Sites are focused in or around locations likely to be trash hotspots (e.g., parking lots, pay stations, recreation areas, and restaurants). Evaluation sites are generally areas that are cleaned on a daily basis. Monitoring procedures conducted at the Evaluation Sites will include weighing and photographing all trash that is collected. Monitoring procedures are described in the **Monitoring Procedures** section. No specific source identification data will be collected and the specific amount of information collected per Evaluation Site may vary based on feasibility, necessity of information, and accessibility of the site. Similar to the Assessment Sites, Evaluation Sites will not be located in areas deemed unsafe, inaccessible or on leased/private property where access has not been granted.

TMRP COVERAGE

The County will not be held accountable for other responsible parties not participating in the County TMRP effort (as listed in the **Overview**). The County will not be held responsible for any monitoring not conducted in the areas defined as being outside the Watershed or County boundaries characterized in Figure 1. Additionally, Trash TMDLs are effective for both the Malibu Creek and Ballona Creek Watersheds (both of which being part of the Santa Monica Bay WMA). The Malibu Creek and Ballona Creek Trash TMDL each specify the requirements for their respective areas, and are not readdressed here.

More specifically, the TMRP will cover locations deemed to be “source areas” within the WMA. Source areas[3] may be defined as locations that are in immediate proximity of the Santa Monica Bay, and thus have a strong likelihood of contributing trash directly to the waters of the Santa Monica Bay (i.e., all locations situated on a coastline waterfront, such as Beaches and Harbors). Though the TMRP will also address other locations that are likely to indirectly contribute trash to the waters of the Santa Monica Bay (e.g., Open Space and Parks not along a coastline waterfront), the only requirement for these sites will be to ensure trash is not discharged to Santa

[3] Distinct from “point source” and “nonpoint source” categorizations, which primarily serve to indicate the pattern of trash dispersion, can be used broadly to refer to any locations where trash may potentially be released, and may or may not also qualify as source areas

Monica Bay by conducting trash assessments as needed. Appropriate BMPs, which may or may not include a MFAC program, will be implemented to ensure trash is not discharged from these areas. More intensive monitoring procedures are applied at Beach and Harbor source areas, where the County plans to focus its resources. Monitoring efforts at Beaches and Harbor source areas are intended to capture all trash that would otherwise come in contact with the waters of the Santa Monica Bay.

The City of Hermosa Beach has elected to use the County TMRP and associated documents for Hermosa Beach. City of Hermosa Beach, not the County, will be solely responsible for implementation of the actions proposed in the TMRP for Hermosa Beach. Will Rogers, Venice, Dockweiler, and Point Fermin beaches will not be covered in the LA County Santa Monica WMA TMRP as the individual cities which have jurisdiction over these beaches plan to prepare separate TMRPs that will cover these locations. White Point/Royal Palms Beach will not be covered in the Santa Monica Bay WMA TMRP because shoreline conditions preclude MFAC Assessments and there are no suitable source areas under County jurisdiction. If such constraints change, the beach will be added to the TMRP and MFAC/BMP program requirements.

There is some likelihood that trash sources within the WMA that are not under County jurisdiction discharge trash to the selected monitoring locations in the TMRP, potentially causing an exceedance of the baseline WLA and/or LA. Such exceedances may likely occur with point and nonpoint sources or infrastructure maintained by Caltrans or other Municipal Separate Storm Sewer System (MS4) Permittees, especially under storm conditions. Since it is not currently feasible to differentiate County trash from non-County trash once it has been discharged and dispersed, the County will monitor all trash that is found in its source areas. For the TMRP, however, the evaluation sites are selected to exclude areas dominated by trash from non-County sources. The County will utilize all the strategies within its authority to achieve its allocations, pursuing any actions necessary to prevent or resolve such issues (e.g., obtaining necessary permits to install FCS or PCS in the infrastructure of the County flood control district). For the purposes of the TMRP, the County will assume that any further actions that are required[4] will be covered by the MS4 permits and addressed through requirements outlined within the respective permits. Documentation and discussion of these issues will be included in subsequent annual monitoring reports.

[4] Including visual monitoring and removal of trash, addressing fugitive trash deposited either illegally or through wind transport, and identifying and prioritizing areas of illicit discharge in all open channels and other MS4 drainage structures

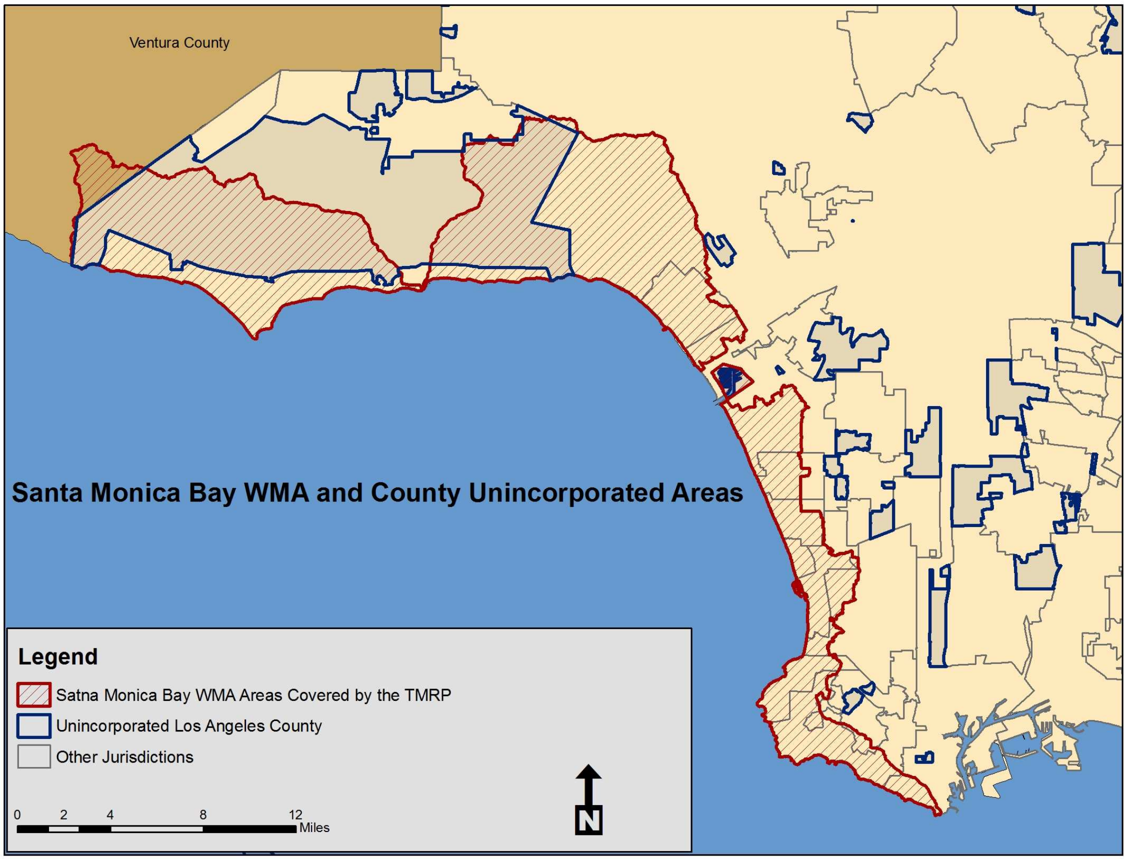

Figure 1. Santa Monica Bay WMA and County Unincorporated Areas

INACCESSIBLE AREAS

Areas of the WMA that are deemed inaccessible due to safety concerns or limited access will not receive cleanings and will not be assessed by the TMRP effort. Specifics on areas deemed inaccessible will be included in the annual monitoring reports.

MONITORING PROCEDURE APPROACH

Trash monitoring for the TMRP requires the collection of trash in a specified manner that allows for the generation of reproducible results that can be compared over time. Additionally, the monitoring procedure needs to define the metric that will be used to measure the trash collected. The standard procedures for each type of site (Assessment Site vs. Evaluation Site) also vary, with a more detailed approach used at the Assessment Sites. The procedures for monitoring can be found in the **Monitoring Procedures** section of the TMRP, and the Standard Operating Procedures for monitoring can be found in the **Standard Operating Procedures** section of the Health and Safety Plan.

The monitoring procedure approach that has been selected for the TMRP is to record the weight of trash collected.

Monitoring Locations and Frequencies

MONITORING SITE LOCATIONS

Assessment and Evaluation Sites are proposed for nonpoint sources owned by the County or maintained by DBH and are presented in **Attachment A**. Generally, each beach maintained by the DBH contains one Assessment Site and one Evaluation Site. Assessment and Evaluation Sites are summarized in Table 2.

Assessment Sites will be selected at locations where cleanup event assessment metrics will be measured. The level of monitoring effort for Assessment Sites should be minimal. These sites will be approximately 100 feet in length and follow the detailed procedures for identification and assessment given in the TMRP. The number of Assessment Sites will be based on the County's selected approach.

Evaluation Sites will be used to provide additional coverage requirements for the impaired areas listed in the BPA. These sites will be utilized for source area evaluation, assessment for Areas of High Trash Generation, and/or BMP effectiveness requirements. The level of effort for Evaluation Site monitoring will be greater than that required for Assessment Sites.

MONITORING FREQUENCY

The frequency of required monitoring for impaired locations listed in the BPA may vary from one to two times per year. The overview of the proposed frequency of cleanup, MFAC assessment, and source area evaluation events is presented in Table 2.

A summary of the event frequencies is as follows:

1. Total Assessment Sites = 13 (one per nonpoint source where site conditions permit)
    a. 11 sites monitored once per year (Beaches)
    b. 1 site monitored once per year (Harbors)
    c. 1 site monitored once per year (Non-Beach Open Space and Parks)
2. Total Evaluation Sites = 12 (one per Beach, Harbor, Open Space and Park)
    a. 10 sites monitored twice per year (Beaches)
    b. 1 site monitored twice per year (Harbors)
    c. 1 site monitored twice per year (Non-Beach Open Space and Parks)

Table 2. Proposed Monitoring Events in the Santa Monica WMA

Location	Event Frequency		
	Cleanup	Morning MFAC Assessment(1)	Afternoon Source Area Evaluation(2)
Beaches			
Nicholas Canyon Beach	Once per day	Annually	Semi-annually
Zuma Beach	Once per day	Annually	Semi-annually
Point Dume Beach	Once per day	Annually	Semi-annually
Latigo Shores Beach	Once per day	None(3)	Semi-annually
Dan Blocker Beach	Once per day	Annually	None(4)
Malibu/Surfrider Beach	Once per day	Annually	None(4)
Las Tunas Beach	Once per day	None(3)	Semi-annually
Topanga Beach	Once per day	Annually	Semi-annually
Marina Beach	Once per day	Annually	Semi-annually
Manhattan Beach	Once per day	Annually	None(4)
Hermosa Beach	Once per day	Annually	Semi-annually
Redondo Beach	Once per day	Annually	Semi-annually
Torrance Beach	Once per day	Annually	Semi-annually
White Point/ Royal Palms Beach	Once per day	None(3)	None(4)
Harbors			
Marina Del Rey	Once per day	Annually	Semi-annually
Non-Beach Open Space and Parks			
Burton Chace Park	Once per day	Annually	Semi-annually

(1) MFAC assessments performed immediately after cleanup events, generally at one site per location
(2) Source Area evaluations performed generally at one site per location
(3) Shoreline conditions preclude MFAC Assessments
(4) No suitable source areas under County jurisdiction

MFAC Assessment Sites

MFAC assessments at Beaches and Harbors will be performed on an annual basis, immediately following a cleanup event. Cleanup events at Harbor shorelines and sandy areas of Beaches are performed on a daily basis year round.

Burton Chace Park in Marina del Ray is the only park within the County jurisdiction identified as potentially contributing trash to beach shorelines or harbor waters. DBH performs daily cleanups at Burton Chace Park. Annual MFAC assessments will be conducted at Burton Chace Park. If other Non-Beach Open Spaces and Parks are found to be source areas of trash to the Santa Monica Bay shoreline or Harbor waters, then appropriate BMPs will be defined and applied to these areas. Instead of conducting MFAC assessment at other Non-Beach Open Spaces and Parks, however, the County may opt to focus its resources on monitoring efforts at Beaches and Harbors where trash has the highest likelihood of making contact with the waters of the Santa Monica Bay.

No point source monitoring is proposed because it is anticipated that all County point sources will be addressed through full capture. FCSs are designed to capture any particles measuring 5 millimeters or more in any direction, and will be sized for the peak flow rate of a "major rain event", defined as a one-year, one-hour storm in the subdrainage area. For full capture, the County will use connector pipe screen (CPS) devices.[5]

A CPS device is a vertical screen with 5 mm openings, installed inside a catch basin directly upstream of the connector pipe in such a manner that all water entering the basin must pass through the device. A vertical opening is provided around the perimeter of the screen to allow storm water to bypass in the event of a large storm or if the screen becomes clogged. CPS devices are currently manufactured and installed by Advanced Solutions (Stormtek) and American Storm Water (Debris Dam). CPS screens and bypass openings will be sized according to the recommendations and procedures given in the County CPS design manual.[6]

The purpose of a Connector Pipe Screen (CPS) is to contain trash within a catch basin and exclude it from the storm drain system. As such, routine maintenance will likely be necessary to remove trash from the catch basin to prevent it from accumulating to a point that would affect the performance of the CPS or the catch basin itself. Per the County CPS design manual, "proper operation and maintenance" will be defined as inspecting and cleaning each catch basin each year (e.g., at least once between May 1 and September 30), as well as inspecting and providing additional cleaning of any catch basin that is at least 40% full of trash and/or debris.

The County will perform phased implementation of FCSs at point sources over an eight year period. See Table 4 for a schedule of planned FCS implementation. If FCSs cannot be or are otherwise not implemented at point sources, trash generation rate monitoring procedures will need to be implemented. Monitoring at these locations will use the weight of trash collected from the catch basins not draining to a FCS.

For MFAC assessment sites, the proposed schedule of monitoring frequency is given in Table 2.

Source Area Evaluation Sites

Source area evaluation will be performed at Beaches and Harbors source areas on a semi-annual basis. For both Beaches and Harbors, source area evaluation will be conducted in the afternoon. To optimize usage of County resources, the frequency and locations of subsequent (e.g., year two) Evaluation Site monitoring may be modified upon review of the data gathered. As listed in the BPA, after the first year effort, monitoring frequencies may be revised pending review of the data collected through the MFAC/BMP program. A proposed monitoring schedule for Evaluation Sites is given in Table 2.

The County will initiate the given monitoring program within six months from the receipt of a letter of approval from the Regional Board Executive Officer (E.O.).

---

[5] CPS devices were certified by the Regional Board as an approved full-capture device on August 1, 2007

[6] Connector Pipe Screen Design: Full Capture TMDL Compliance, Screen and Bypass Sizing Requirements, Technical Report (April 2007), available at: http://www.waterboards.ca.gov/rwqcb4/water_issues/programs/tmdl/fcc/la%20county%20full%20capture%20request%20package.pdf

Monitoring Event Preparation

Monitoring events should only be conducted during daylight hours under safe weather conditions. The weather forecast should be checked immediately prior to each monitoring event. Monitoring events will not occur during or immediately after storm events. Precipitation events within the WMA can cause elevated water levels and unsafe conditions. If at any time during a monitoring event, field personnel feel that site conditions are unsafe for any reason, the event should be abandoned and the project manager notified of the situation.

Prior to mobilization for each monitoring event, field personnel should prepare the equipment necessary to conduct the trash assessment monitoring event. Required equipment is listed in Table 3.

Table 3. Equipment Checklist

Required Trash Assessment Items	
☐ First Aid Kit ☐ Cellular Telephone ☐ Copy of TMRP document	☐ Large Trash Bags (e.g., Green 'N' Pack Eco Friendly Lawn & Leaf Bags [30" x 33" x 1.1 mil, 30 gallon] or Glad ForceFlex Lawn Drawstring Bags [32.5" x 38" x 1.1 mil, 39 gallon])
☐ Trash Monitoring Worksheets	☐ Work Gloves/Medical Gloves
☐ Hazardous Material/Intractable Trash Logs	☐ Sharps Container
☐ Clipboard	☐ Digital Camera
☐ Notebook	☐ Garbage Bag Tags
☐ Pens/Pencils and Permanent Marker	☐ Scale (e.g., Hand-Held Scale)
☐ Side Pack/Messenger Bag	☐ Hiking Boots
☐ GPS Unit	☐ Wader Boots
☐ Measuring Wheel/Tape Measure	☐ Maps and Aerial Photos
☐ Cones/Flagging Stakes	☐ Sunscreen Lotion
☐ Timepiece	☐ Hat/Sunglasses
☐ Trash Grabber (e.g., Ettore 49036 Grip 'n Grab)	☐ Coins and small bills for parking

Additionally, any necessary permits required for access to restricted areas and/or trash removal will be obtained prior to the monitoring event.

SITE DEFINITION

For all monitoring locations, site locations have been identified as listed in the **Monitoring Site Locations** section. At each of the selected monitoring locations (see **Attachment A**), monitoring will take place at a defined 100 foot section of the impaired area that is identified as the monitoring site. All subsequent monitoring events will take place within the same identified 100 foot area. If for any reason the location of a site is modified during an assessment event, the field crews will need to note the change and contact the project manager of the deviation.

Site Length

When the site is first established the 100 foot section will be accurately measured that includes sinuosity of the location. The length should be measured as the actual shoreline, channel/drain, open space, or park length (including curves), not necessarily in a straight line. Where possible, the upper and lower boundaries of each site should be identified by clearly visible and fixed landmarks, such as structures or natural formations that are notable. If possible, the boundaries may be flagged or physically marked to save time during subsequent assessment events. In addition, GPS coordinates should be recorded for the boundaries of each site during the first event. Again, if a section of the length is blocked or deemed inaccessible, the site can be moved to a more accessible location but any move will need to be noted and the project manager notified upon completion of the event.

Site Width

During the first site visit, the field team will document the transverse boundaries of the lengths to be monitored. For trash assessment events at Beaches, the site boundaries will be defined by the area between the current visible high-water line or beach crest[7] and the lowest level to which the water recedes. For trash assessment events at Non-Beach Open Space and Parks as well as trash evaluation events at all nonpoint sources, site boundaries will be five to ten feet wide and will represent the areas within which trash can be carried to the waterbody by wind or water. For trash assessment events at Harbors, the site boundaries will be confined to the water. As appropriate, the boundaries may be defined by a physical structure, such as a fence or roadway, and will be documented in field notes and/or with digital photographs. Subsequent monitoring events will follow similar procedures within the same specified boundaries. If unable to resample previous areas, field crews will note the change and reason for the change in the monitoring worksheets.

---

[7] The approximate line along and closest to a shoreline where the slope of the beach changes in steepness due to wave action. No sand or rocks wetted by waves will be found above the current visible high-water line or beach crest.

Monitoring Procedures

For the required monitoring events, trash will be collected following standard operation procedures as outlined in the TMRP. The amount of effort per event will vary based on the types of sites being monitored for that specific event. In particular, the BPA specifies that assessment shall focus on the shorelines or interface along Santa Monica Bay. However, procedures as outlined in TMRP are still required to be followed. During each monitoring event the weight of trash will be recorded. As such, the amount of trash will be determined using weight of trash as the standard metric.

MFAC Assessment and Source Area Evaluation Events

During each MFAC assessment and source area evaluation event at each site, a crew comprised of a minimum one or two-person monitoring crew will move through the entire Assessment Site or Evaluation Site. Though there should be no trash present at Assessment Sites during an assessment event, the monitoring crew will note and collect any trash not captured by the prior collection event. Trash collected during an assessment event will be weighed and recorded. At Evaluation Sites and Assessment Sites, the monitoring crew will collect and weigh every piece of trash[8] found. Collecting all trash items will allow the site to be revisited and re-assessed for impairment and usage patterns. No waste receptacles will be covered by MFAC assessment and source area evaluation efforts.

A trash grabber or similar tool (e.g., metal kitchen tongs) should be used to help pick up trash. It is important to look under vegetative cover to see if trash has accumulated beneath. The ground and substrate should be inspected to ensure that small items are picked up and collected.

*****To avoid injury while picking up trash, team members should always wear gloves and avoid touching trash with unprotected hands*****

All collected trash shall be placed in trash bags and weighed to determine the weight of trash collected at each site. The amount of time needed for the trash monitoring should also be recorded.

To account for items which are too heavy to be lifted or are embedded in the area (e.g., boats that wash up during storms), referred to as intractable or “legacy trash”, specific notes will be written on the trash monitoring worksheet (along with GPS coordinates and/or digital photographs) as to avoid noting the same item/s during the next monitoring event. Legacy trash items will need to be removed by qualified individuals with appropriate equipment, therefore the monitoring crew will not attempt to remove these items themselves.[9]

Prior to deployment, the monitoring crew shall be informed or trained as to what hazardous materials are and may potentially be, and how to safely remove these items. If a potentially hazardous item is found during the assessment, the crew will not touch or move the item but shall inform the lead field technician. If the lead field technician determines that the item cannot

[8] Trash as defined in the TMRP

[9] Intractable or legacy trash is usually heavy and will interfere with assessment and evaluation efforts, which use weight as the single metric for measuring amounts of trash

be safely removed, the location of the item will be documented (along with photographs and/or GPS coordinates). Hazardous material identification and removal is further defined in the Health and Safety Plan along with a detailed list of items that are considered “Hazardous” and banned from disposal in the trash. More information can be found on the California Integrated Waste Management Board Website: www.ciwmb.ca.gov/hhw/info/. The appropriate authorities will be contacted immediately for removal of the hazardous item(s), if proper training or collection materials are not available to the monitoring crew.

MFAC ASSESSMENT SITE PROCEDURES

MFAC assessment will occur at Beaches and Harbors as well as Non-Beach Open Space and Parks. While monitoring Assessment Sites, the field crew will fill out a trash Monitoring Worksheet (**Attachment D**). Trash MFAC assessment will be conducted using the following procedures:

At Beaches

Before the first event at each site, set the specific shoreline location for the reference endpoints. Provide the coordinates for the two reference endpoints of each site, as located along the current visible high-water line or beach crest. Each site reach must be approximately 100 feet in length. Also provide a description for the general location.

1. Immediately after a cleanup event at each designated site, at least one field crew member will be deployed for the follow-up assessment event.

2. A Monitoring Worksheet will be used to record observations and notes. If available, multiple individuals can participate in an assessment event, but only one individual is to be recording information on the Monitoring Worksheet in order to minimize the potential for errors.

3. Using the description and coordinates of the reference endpoints, find the approximate location at which to begin the assessment.

    a. If for some reason it is not possible to access an endpoint or entire site, note the reason/s and contact the project manager for further directions.

    b. If project manager is unavailable, note the time of the visit and continue on to the next site.

4. Record the coordinates for each of the two corners of the starting location.[10] The distance between these points should encompass the site width to be monitored, with the higher point situated on the current visible high-water line or beach crest and the other point on the lowest level to which the water recedes.

5. Before beginning the assessment, record the starting time.

[10] If a line were drawn between the two corner points, the line would lie roughly perpendicular to the adjacent shoreline.

6. Proceed to walk along and visually sweep the shoreline area between the current visible high-water line or beach crest and the lowest level to which the water recedes. Look carefully for any articles of trash. Head towards the far end of the 100 foot reach, noting and collecting any trash that may be found within the site. Make additional notes as appropriate, and check the GPS device every so often to ensure that assessment efforts are confined to the approximate designated location.

7. If large items are identified or hazardous materials are found, follow the procedures in the **Identified Hazardous Materials and Intractable Trash** section of the Health and Safety Plan.

8. Upon arriving at the approximate end location, record the stop time and then record the coordinates of each of the two corners of the end location.

9. Take a digital photograph to document the cleanliness of the site.

10. Complete any remaining relevant portions of the Monitoring Worksheet.

If the monitoring group identifies a more efficient and/or modified method to record monitoring information, the method will be noted in the subsequent annual report.

At Harbors

Before the first event at each site, set the specific shoreline location for the reference endpoints. Provide the coordinates for the two reference endpoints of each site, as located along land-water interface. Each site reach must be approximately 100 feet in length. Also provide a description for the general location.

1. Immediately after a cleanup event at each designated site, at least one field crew member will be deployed for the follow-up assessment event.

2. A Monitoring Worksheet will be used to record observations and notes. If available, multiple individuals can participate in an assessment event, but only one individual is to be recording information on the Monitoring Worksheet in order to minimize the potential for errors.

3. Using the description and coordinates of the reference endpoints, find the approximate location at which to begin the assessment.

    a. If for some reason it is not possible to access an endpoint or entire site, note the reason/s and contact the project manager for further directions.

    b. If project manager is unavailable, note the time of the visit and continue on to the next site.

4. Record the coordinates for each of the two corners of the starting location.[11] The distance between these points should encompass the site width to be monitored.

5. Before beginning the assessment, record the starting time.

6. Proceed to move along and visually sweep the general area. Look carefully for any articles of trash. Head towards the far end of the 100 foot reach, noting and collecting any trash that may be found within the site. Make additional notes as appropriate, and check the GPS device every so often to ensure that assessment efforts are confined to the approximate designated location.

7. If large items are identified or hazardous materials are found, follow the procedures in the **Identified Hazardous Materials and Intractable Trash** section of the Health and Safety Plan.

8. Upon arriving at the approximate end location, record the stop time and then record the coordinates of each of the two corners of the end location.

9. Take a digital photograph to document the cleanliness of the site.

10. Complete any remaining relevant portions of the Monitoring Worksheet.

At Non-Beach Open Space and Parks

Before the first event at each site, set the specific endpoints by providing coordinates for each of the four corners of the site. Each site reach must be 100 feet in length and at least 5 to 10 feet in width. Also provide a description for the general location.

1. Immediately after a cleanup event at each designated site, at least one field crew member will be deployed for the follow-up assessment event.
2. A Monitoring Worksheet will be used to record observations and notes. If available, multiple individuals can participate in an assessment event, but only one individual is to be recording information on the Monitoring Worksheet in order to minimize the potential for errors.

3. Using the description and coordinates of the endpoints, find the approximate location at which to begin the assessment.

    a. If for some reason it is not possible to access an endpoint or entire site, note the reason/s and contact the project manager for further directions.

    b. If project manager is unavailable, note the time of the visit and continue on to the next site.

[11] If a line were drawn between the two corner points, the line would lie roughly perpendicular to the adjacent shoreline.

4. Record the coordinates for each of the two corners of the starting location. The distance between these points should encompass the site width to be monitored.

5. Before beginning the assessment, record the starting time.

6. Proceed to walk along the length of the reach, visually sweeping across the width. Look carefully for any articles of trash. Head towards the far end of the 100 foot reach, removing any trash that may be found within the site for subsequent weighing. Make additional notes as appropriate, and check the GPS device every so often to ensure that assessment efforts are confined to the approximate designated location.

7. If large items are identified or hazardous materials are found, follow the procedures in the **Identified Hazardous Materials and Intractable Trash** section of the Health and Safety Plan.

8. Upon arriving at the approximate end location, record the stop time and then record the coordinates of each of the two corners of the end location.

9. Take a digital photograph to document the cleanliness of the site.

10. Complete any remaining relevant portions of the Monitoring Worksheet.

MFAC Assessement Site Completion

Following the completion of the site assessment, the team should check the Monitoring Worksheet for completion. The total time for the assessment event, including start time and end time, should also be noted on the worksheet. It is important to complete the worksheets before leaving the site while the memory is still fresh.

Observations about the condition of the site, locations of any possible trash found, potential contributing sources, and other observations should be recorded in the appropriate spaces on the trash monitoring worksheet.

SOURCE AREA EVALUATION SITE PROCEDURES

The effort for the Evaluation Site monitoring will include trash collection and take place at a later time of day. Trash collection may include items on the ground or items caught within structures or vegetation, but will exclude all items contained within waste receptacles. Source area evaluation will occur at Beaches and Harbors as well as Non-Beach Open Space and Parks. Evaluation procedures are as follows:

At Beaches, Harbors, Non-Beach Open Spaces and Parks

Before the first event at each site, set the specific endpoints by providing coordinates for each of the four corners of the site. Each site reach must be 100 feet in length and at least 5 to 10 feet in width. Also provide a description for the general location.

1. In the late afternoon before dusk, at least two field crew members will be deployed for an evaluation event. A Monitoring Worksheet will be used to record observations and notes, but only one individual is to be recording information on the worksheet to minimize the potential for errors.

2. Using the description and coordinates of the endpoints, find the approximate location at which to begin the assessment.
    a. If for some reason it is not possible to access an endpoint or entire site, note the reason/s and contact the project manager for further directions.
    b. If project manager is unavailable, note the time of the visit and continue on to the next site.
3. Before beginning the evaluation, record the start time.
4. Proceed to walk along the length of the reach, visually sweeping across the width.
5. Collect any articles of trash found, heading towards the far end of the 100 foot reach. Make additional notes as appropriate, and check the GPS device periodically to ensure that evaluation efforts are confined to the approximate designated location.
    a. In areas where large amounts of trash are accumulating, note any observations on the Monitoring Worksheet.
    b. If large items are identified or hazardous materials are found, follow the procedures in the **Identified Hazardous Materials and Intractable Trash** section of the Health and Safety Plan.
6. Upon arriving at the approximate end location, record the stop time and then record the coordinates of each of the two corners of the end location.
7. Take a digital photograph to document the cleanliness of the site.
8. If trash was found and a trash bag used to contain items found within the site, secure the bag opening and label the bag with the site name and date.
9. Use a hand-held scale to weigh the bag. Record the weight on the Monitoring Worksheet.
10. Complete any remaining relevant portions of the Monitoring Worksheet.

Source Area Evaluation Site Completion

Following completion of the site, the team should check the Monitoring Worksheet for completion. The total time for the collection event, including start time and end time, should also be noted on the worksheet. General site observations should be recorded on the trash monitoring worksheet as well. It is important to complete the worksheets before leaving the site while the memory is still fresh.

POST-EVENT ACTIVITIES

At the completion of source area evaluation events, all collected trash will be taken to a County facility. At the County facility, all trash will be placed in a dumpster and subsequently be sent to a landfill or recycling facility for appropriate disposal.

The contracted agency should make all reasonable attempts to recycle the materials collected during the event, with time permitting. The recycling of materials is not a requirement of the TMDL or the TMRP/MFAC and is at the discretion of the contractor. If items are too large to remove or are deemed hazardous or “Legacy Trash”, the contractor shall immediately contact the program manger to initiate removal of the items.

In addition, the trash generation rate will be calculated at the completion of source area evaluation events. Dividing the weight of trash collected by the site length (Beaches and Harbors) or area (Non-Beach Open Space and Parks) will yield an approximated site-specific trash generation rate, which may be used to estimate the trash generation rate for the entire location. For trash generation rate calculations, site length will be 100 feet and site width may be calculated using the coordinates of the monitored area, as recorded on a Monitoring Worksheet. The collected data will be used to inform the annual report in assessment of the comparison to baseline and, over time, evaluation of reducing trend in the rate.

Special Circumstances for Safety Consideration

Within the Santa Monica WMA there are several potentially hazardous factors that exist. One of these is the potential to encounter homeless individuals that are known to occupy the area. The other factors include steep cliffs and access trails, ocean currents, confined spaces, and invasive species. The potential for these special circumstances are discussed in more detail below and in the Health and Safety Plan (**Attachment B**). The Health and Safety Plan provides a more comprehensive review of special circumstances for safety consideration, including additional special circumstances not covered in the TMRP. Cleanup, assessments, and evaluations will not occur in areas with safety concerns.

HOMELESS INDIVIDUALS AND PROPERTY

There is the potential for encounters and/or interactions with homeless individuals during trash collection activities. The possibility of unknowingly collecting items which may be deemed property of a homeless individual may create the potential for a serious altercation. During any cleanup or monitoring event, field staff are required to use discretion in all interactions with individuals in the field (standard for any encounter, homeless or not) and should handle themselves in a professional and courteous manner. If at any time field staff feel uncomfortable or in danger, activities must immediately cease and all staff must return to a safe location. Field staff will record the amount of monitoring that took place prior to the work interruption, and note on the field sheets the end point location and time. If any situation escalates to a perceived dangerous level, field staff must immediately leave the area and contact the appropriate authorities. In the event that trash items appear to be property of a homeless individual, field staff should thus consider the items “Legacy Trash” and follow procedures outlined in the **Hazardous Materials and Legacy Trash** section of the Health and Safety Plan. Care must be taken when collecting pertinent data, and as previously stated, if at any time during monitoring or cleanup field staff feel threatened or in danger, cease all activities and move to a more secure location.

STEEP CLIFFS AND ACCESS TRAILS

Some of the assessment sites are located near or at the base of steep cliff sides and access trails. Commonly paired with crumbling earth, sharp rocks, and uneven terrain, the potential to slip and fall causing serious injury is possible at these locations, even during the driest of weather. Steep cliffs may also present the danger of landslides. Field crews will need to ensure that all precautions are taken when sampling adjacent to environments exhibiting these conditions. Field crews should avoid cliff sides and precarious trails, and identify safe routes to the designated sites. During assessment efforts, field crews should take caution when using dirt access trails and ensure that all procedures as outlined in the Health and Safety Plan are followed. Dangerous environments are deemed off limits during all assessment events.

OCEAN TIDES AND CURRENTS

The combination of ocean tides and rocky terrain often produce slippery surfaces. Especially when working in close proximity to the water, strong waves and/or rip currents may present additional dangers. Field crews should be aware of their surroundings at all times, take precaution when walking on wet surfaces, and consider wearing a pack to keep their hands as free as possible.

RB-AR 7954

Collection, assessment, and evaluation events may be curtailed during periods of high surf.

CONFINED SPACES

At no time are field crews to enter any confined spaces, including storm drain outlets, freeway underpass tunnels, or any confined area located at or near a monitoring location. These confined spaces can include areas of dangerous gas buildup and other potential hazards that field crews will not be trained properly in addressing. If trash is accumulating in a confined space, notification will be given the project manager which will include a specific site location, a brief narrative of the observations, and the time and date of the observation.

Reporting Requirements

ANNUAL MONITORING REPORT

Each year, an annual monitoring report will be submitted to the Regional Board. The annual report will address Point Sources, Beaches, Harbors, and Non-Beach Open Space and Parks. Any instances of not attaining TMDL WLAs or LAs, TMRP, or MFAC/BMP Program provisions; and any BMPs proposed to address assessment metrics not meeting desired levels will also be described in the annual report.

Point Sources

For point sources, the County will:

- Include a report of the number and percent coverage of installed FCSs.
- State whether the County is attaining the TMDL schedule for installation.
- Provide an estimate of the number of point sources to be included in County efforts for the following year.
- Identify any point sources that cannot be fitted with a FCS (e.g., at a catch basin due to size constraints).

In the case that a point source is not suitable for or cannot be fitted with a FCS, the County will default to using a PCS or performing institutional controls to demonstrate the removal of trash at the daily generation rate (DGR). Institutional controls that are used at point sources without FCSs will be noted in the annual report.

Beaches

For Beaches, the County will:

- Provide a tabulation of the number of cleanup, assessment, and evaluation events conducted at shorelines and source areas.
- Include results from MFAC assessments.
- Include results from source area evaluations.
- State whether the County is attaining the following:
  - Zero trash after assessments
  - Trash generation rate below baseline
  - Trash generation rate at a reducing trend (evaluated beginning with the third annual report)

In the event any of the above are not achieved, the County will evaluate current BMPs and propose changes to existing BMPs or institute additional BMPs to ensure future assessment metrics are met in the future. Possible BMPs that may be implemented include providing additional training for field crew members, providing additional trash receptacles, or increasing legal enforcement for littering. If determined necessary, proposed modifications will be included in the Annual Report.

Harbors

For Harbors, the County will:

- Provide a tabulation of the number of cleanup, assessment, and evaluation events conducted at shorelines and source areas.
- Include results from source area evaluations.
- State whether the County is attaining the following:
    - Zero trash after assessments
    - Trash generation rate below baseline
    - Trash generation rate at a reducing trend (evaluated beginning with the third annual report)

In the event any of the above are not achieved, the County will evaluate existing BMPs and propose changes to existing BMPs or institute additional BMPs to ensure future assessment metrics are met in the future (e.g., additional training for field crew members, additional trash receptacles, and increasing legal enforcement for littering). If determined necessary, proposed modifications will be included in the Annual Report.

Non-Beach Open Space and Parks

For Non-Beach Open Space and Parks, the County will:

- Provide a tabulation of the number of cleanup assessment, and evaluation events conducted.
- Include results from MFAC assessments.
- Include results from source area evaluations.
- State whether the County is attaining the following:
    - Zero trash after assessments
    - Trash generation rate below baseline
    - Trash generation rate at a reducing trend (evaluated beginning with the third annual report)

In the event any of the above are not achieved, the County will evaluate existing BMPs and propose changes to existing BMPs or institute additional BMPs to ensure future assessment metrics are met in the future and include a description of any program modifications in the annual report.

TMRP/MFAC REVISION

All proposed revisions the County determines to be necessary to the TMRP and/or MFAC/BMP program will be proposed in the annual monitoring report. Revisions may include procedural modifications, increasing or reducing the frequency of MFAC assessment and collection, redefining "critical conditions" as given in the BPA, and changing the location or number of MFAC assessment and source area evaluation sites.

COMPARISON WITH ESTABLISHED BASELINES

To perform source area evaluation, the County will be using the baseline LAs and WLA as established in the BPA, for nonpoint sources and point sources, respectively.

Nonpoint Sources

For Beaches and Harbors, the data collected at Evaluation Sites will be used to compare trash generation rates to the TMDL default baselines. Additionally, monitoring sites are to show a decreasing trend of accumulation.[12] As mentioned in the BPA, compliance with the nonpoint source LAs may be achieved through the implementation of the MFAC/BMP program.

Point Sources

Point sources will be addressed using FCSs. A FCS "is any single device or series of devices that traps all particles retained by a 5 mm mesh screen and has a design treatment capacity of not less than the peak flow rate Q resulting from a one-year, one-hour, storm in the subdrainage area".[13,14] If there are physical constraints that prevent the usage of a FCS, alternative methods of compliance will be proposed on a case-by-case basis. As such, a small percentage of catch basins may require some combination of PCS/BMPs.

For the annual monitoring report, the County will prepare and include a plan outlining the proposed FCS installation schedule and/or PCS installation and BMPs to be implemented. Point sources will not be prioritized for FCS installation. For the TMRP, the County has identified 62 catch basins for inclusion as shown in Figure 2 of **Attachment A**. The projected general timeline for FCS installation at the identified point sources is given in Table 4.

Table 4. General Timeline for FCS Installation.

Final Date	Number of FCSs Installed[(1)]
March 20, 2016	13
March 20, 2017	25
March 20, 2018	38
March 20, 2019	50
March 20, 2020	62

(1) Based on 62 catch basins covered by the TMRP

CURRENT BMP EFFORTS

The County actively engages in a three-pronged approach for pollution prevention: 1) Education; 2) Incentives; and 3) Enforcement. Listed below are current trash management procedures or

---

[12] A decreasing trend constitutes a negative slope when the data is graphed on a time series plot

[13] Per Resolution No. 04-023, adopted by the Regional Board on March 4, 2004

[14] "Rational equation is used to compute the peak flow rate: Q = C x I x A, where Q = design flow rate (cubic feet per second, cfs); C = runoff coefficient (dimensionless); I = design rainfall intensity (inches per hour, as determined per the rainfall isohyetal map), and A = subdrainage area (acres)."

BMPs that have been put in place by the County. The given BMPs, combined with the monitoring described in the TMRP, represent the initial MFAC/BMP program for the County. As new BMPs are implemented in the Watershed, this list will be updated to account for increased efforts. Each Annual Report will include the suite of BMPs employed for the corresponding year. Current BMPs include:

- Daily cleaning of all County-owned or operated beaches.
- Daily cleaning of all harbor waters.
- *Ordinances*
    - Title 12 Chapter 12.85 - Ban on plastic carryout bags
    - Title 17 Chapter 12.365 - Smoking prohibited on County beaches
    - Title 17 Chapter 4.645 - Smoking prohibited at County parks
    - Low Impact Development Ordinance - Reduce impacts from stormwater runoff
- *FCSs*
    - Ballona Creek Watershed - There are 368 catch basins that collect runoff from County-unincorporated communities located within the Ballona Creek Watershed. To date, the County has achieved a total 88.5 percent reduction to date with the installation of 333 full-capture devices and a 81.1 percent reduction based on a 3-year average for all of the County unincorporated areas within the Ballona Creek Watershed.
    - Malibu Creek Watershed - The County has installed 192 FCSs in catch basins within the Malibu Creek Watershed in unincorporated County areas.
- *Trash and Recycling Receptacles* - Wedded clamshell-lid trash and recycling cans have been installed at areas owned, operated, or otherwise maintained by the County. These receptacles are also marked with messages and images that encourage their usage.
- *Industrial and Commercial Inspections* - Annual inspections targeting facilities lacking minimum stormwater BMPs and housekeeping practices to reduce sources of trash.
- *Maintenance and Cleanup Activities* – Parking lot and street sweeping program with most streets swept on a weekly basis in unincorporated County areas.
- *Public Information and Participation Programs* - CleanLA public outreach program and website (www.888CleanLA.org) educates residents about stormwater pollution prevention. The CleanLA campaign teaches residents about proper disposal of waste and the importance of watershed protection. Information provided through these programs includes how to report illegal dumping, why it is important to prevent animal waste and general pollution from entering the storm drain system, and locations for proper RV sewage waste disposal. The creative multimedia campaign includes broadcast of stormwater pollution prevention messages through radio, television, billboards, newspapers, video aired on Metro buses, and the Internet.
- *Storm Drain Markers* - All storm drains in the unincorporated County are appropriately marked with a “no dumping” message.

- *Development Planning Program* - The County requires post-construction BMPs to reduce the impact of development on water quality including reducing the transport of trash via stormwater runoff.

RECEIVING WATER LIMITATIONS STATUS REPORT

[This page has been left blank intentionally]

RECEIVING WATER LIMITATIONS STATUS REPORT

I. Introduction

The 2012 Los Angeles County Municipal Separate Storm Sewer System NPDES Permit (MS4 Permit) provides that Permittees electing to develop a Watershed Management Program (WMP) or Enhanced Watershed Management Program (EWMP) shall submit an Integrated Monitoring Program (IMP) or Coordinated Integrated Monitoring Program (CIMP). The County of Los Angeles (County) submitted draft WMPs, EWMP Work Plans, and draft CIMPs in June 2014.

Under the 2012 MS4 Permit, it is unclear as to whether Receiving Water Limitation (RWL) status reports should be submitted pending the approval of the CIMPs. The permit no longer requires the submittal of RWL Compliance reports or subsequent status reports with respect to those compliance reports. Instead, the permit now calls for an Integrated Monitoring Compliance report where there is a determination by either the Permittee or the Regional Water Board that discharges from the MS4 are causing or contributing to an exceedance of an applicable receiving water limitation. As set forth in the RWL Compliance Reports submitted under the old permit, there has been no such determination. In addition, the current permit's Integrated Monitoring Compliance report requires different information than the RWL Compliance and Status Reports submitted under the old permit.

Although it appears that submittal of an RWL Status Report is no longer required, because of the uncertainty that surrounds this issue, the County is submitting this RWL Status Report for the information of Regional Water Board staff during this transition period between the termination of the old permit and its monitoring program, and the executive officer's approval of the IMPs and CIMPs under the new permit.

The RWL Status Report in Sections II and III below provides the status of the County's RWL Compliance Reports from 2010, 2008, and 2006, respectively.

II. Status for 2010 RWL Compliance Report

The 2010 RWL Compliance Report was submitted voluntarily as a result of a March 2, 2010, United States District Court order in which the court concluded that the California Ocean Plan's prohibition against discharges of "waste" into an Area of Special Biological Significance (ASBS) is a water quality standard that is incorporated into the 2001 Permit and discharges from the MS4 into ASBS No. 24 violate this Permit requirement.

In June 2009, the State Water Board accepted the County's application for a general exception to discharge into the ASBS. The State Water Board adopted the general exception and the associated conditions (special protections) on March 20, 2012. Dischargers are required to submit a wet-weather compliance plan and implement any nonstructural Best Management Practices by September 20, 2013, and implement any structural Best Management Practices by March 20, 2016. (The date to submit a wet-weather compliance plan was thereafter extended to September 20, 2014.) Furthermore, dischargers are required to commence monitoring during the 2012-13 storm season. As such, observational monitoring of County and Los Angeles County Flood Control District (LACFCD) outlets for dry-weather direct discharges was performed, during which 39 storm drains were surveyed from February to April of 2012 along the following beaches: Broad, Zuma, Westward, and Escondido. Of these, the County is monitoring 12 storm drains.

On May 30, 2012, the State Water Board sent a letter requesting information regarding our plan to initiate monitoring in the next storm season. We responded to the State Water Board indicating that the County plans to participate in the Southern California ASBS Regional Integrated Monitoring Program. On September 6, 2012, we received written authorization to conduct regional and core monitoring within the ASBS for the upcoming storm season. The County's ASBS monitoring work plan was submitted in November 2012 as requested by the State Water Board.

As stated earlier, the ASBS General Exception required the submittal of a compliance plan and a pollution prevention plan by September 20, 2013, to the State Water Board. During the preparation of plans, the County determined that additional monitoring would be needed to produce accurate plans and subsequently requested a deadline extension from the State Water Board. In a letter dated February 20, 2014, the State Water Board granted an extension of the submittal deadline to September 20, 2014. The Draft ASBS Compliance and Pollution Prevention Plans were submitted to the State Water Board and courtesy copies were sent to the Regional Board on September 18, 2014.

III. Status for 2006 and 2008 RWL Compliance Reports

As stated in the 2006 and 2008 RWL Compliance Reports, there was no evidence showing that County discharges caused or contributed to an exceedance of an applicable water quality standard and the reports were submitted voluntarily to assist the Regional Board in identifying the sources of exceedances at various shoreline monitoring locations along Santa Monica Bay. As such, the submission of this status report should not be construed to mean that the County was the source of any exceedance of any applicable water quality standard, and no such inference should be drawn.

SMB-1-07, 1-08, and 1-09

The North Santa Monica Bay Source Identification Study was suspended in 2010 due to a lack of bacteria water quality exceedances at sites 1-07, 1-08, and 1-09, and based on study results to date. Results from summers of 2007 to 2009 in Ramirez Canyon Creek and Escondido Creek ruled out the upper watershed as a source of bacteria to the beach. Testing for bacteroides provided little evidence of human sources at Ramirez and Escondido Creeks. In spring 2010, beach samples rarely exceeded bacteria standards; as a result, the source identification study was suspended. Site SMB-1-09 at Latigo saw zero exceedances of bacteria WQS during summer dry-weather months in 2009 and 2010. In summer 2011, sites SMB 1-07, SMB 1-08, and SMB 1-09 saw an increase in exceedances of bacteria WQS. In summer 2012, there was a reduction in exceedances at SMB 1-08 and site SMB 1-09 had zero exceedances. In summer 2013, sites SMB 1-07 and SMB 1-08 had zero exceedances, whereas site SMB 1-09 had one exceedance. Lastly, in summer 2014, sites SMB 1-07 and SMB 1-09 had zero exceedances, while site SMB 1-08 had one exceedance.

SMB 2-07

Design plans were completed for construction of a rubber dam in Santa Monica Canyon Channel to increase capacity of a new City of Los Angeles low-flow diversion. Construction will be overseen by the LACFCD. Construction of Phase 1 began in March 2012, which included fence replacement and concrete work. Phase 2, which involves the installation of the rubber dam, began construction in July 2012. Due to delays associated with right-of-way/easement issues, we expect completion by the end of December 2014. The County is funding the design and construction of this project that provides a service to the City of Los Angeles. The City of Los Angeles will own and operate the rubber dam while the LACFCD will maintain it for a period of two years following construction, as part of an agreement with the City of Los Angeles.

<u>SMB BC-01</u>
The revised Santa Monica Bay Bacteria TMDL (effective 7/2/2014) removed site SMB BC-01 because it reflects conditions in Ballona Creek and there are sufficient monitoring sites in the Ballona Creek estuary as part of the Ballona Creek Bacteria TMDL.

<u>MdRH-5, 6, 7</u>
The County and LACFCD are currently preparing the Enhanced Watershed Management Program for the Marina del Rey watershed to address water quality improvements for bacteria, metals, and toxics. The plan will be submitted to the Regional Board in June 2015. The County and LACFCD were also issued a Time Schedule Order (TSO) for the dry-weather bacteria TMDL and are complying with the measures laid out in the TSO which includes construction of the Parking Lot BMP projects and the Oxford Basin Retention Project.

Topanga Source ID Study
FINAL Report Dec 2012- August 2014

TABLE OF CONTENTS

LIST OF FIGURES

LIST OF TABLES

LIST OF APPENDICES
(Attached Separately)

LIST OF ABBREVIATIONS

AB411 – Assembly Bill 411: Ocean water standards
AB885 – Assembly Bill 885: OWTS policy
ATP – Microbiological alternate test procedure
BC – Ballona Freshwater Marsh
BH – BacHum Taqman human-associated assay
BMI – Benthic macroinvertebrates
BMP – Best management practices
BO – Beach outlet (located directly in front of lagoon, City sampling site)
BR – Brookside Drive (1700 m from ocean)
BSA – Bovine Serum Albumin
BT – Bacillus thuringiensis
BU – Beach Upcoast (located 175 m west of the beach outlet at the lagoon)
CFS – Cubic feet per second
CFU – Colony-forming unit
COC – Chain of custody
CPOM – Course particulate organic matter
D18 – Diatoms only
DO – Dissolved oxygen
EC – Escherichia coli
ENT – Enterococci
EPT – Ephemeroptera, Plecoptera, Trichoptera
FF – First flush = Rain events where greater than 0.75” of rain falls during a single storm.
FFG – Functional feeding group
FIB – Fecal indicator bacteria
H20 – Soft bodied algae and diatoms combined
HF- HF183 Taqman human-associated assay
IMS – Immunomagnetic separation method
LACDBH – Los Angeles County Department of Beaches and Harbors
LACDPH – Los Angeles County Department of Public Health
LACENVR – Los Angeles County Environmental Health
LARWQCB- Los Angeles Regional Water Quality Control Board
LG – Lifeguard station (located on Topanga Beach)
LOD – Limit of detection
LT – Lower Topanga (annual stream survey site beginning at 3200 m)
MC – Malibu Creek
MM – Mile marker
MPN – Most probable number
MST – Microbial source tracking
Narrows – The section of Topanga Creek between Owl Falls (6500 m) and Scratchy Trail (4800 m).
ND – Not detected
NRR – Non-removal reach for crayfish project (3700 -3900 m)
NTU - Nephelometric Turbidity Unit

OF – Owl Falls (located 6500 m upsstream of the ocean)
OWTS – On-site wastewater treatment system
PBS – Phosphate buffering saline
PCH – Pacific Coast Highway
PHAB – Physical Habitat Data collected with SWAMP protocol
PPM – Parts per million
QA/QC – Quality assurance / quality control
qPCR – polymerase chain reaction quantification
RA – Relative abundance (%)
RCDSMM – Resource Conservation District of the Santa Monica Mountains
RKM – River kilometer
RLU – Relative light units
ROQ – Range of quantification
RR – Removal reach for crayfish project (3500-3700 m)
RV – Recreational vehicle
S2 – Soft bodied algae only
SC-IBI Southern California Index of Biotic Integrity
SCC-IBI – Southern California Coastal Index of Biotic Integrity
SCCWRP – Southern California Costal Water Research Project
SIPP – Source Identification Protocol Project
SP – Snake Pit (located 300 m upstream of the ocean)
ST – Scratchy Trail (located 4800 m upstream of the ocean)
SWAMP – Surface Water Ambient Monitoring Program
SWRCB – State Water Resources Control Board
TAC – Technical Advisory Committee
TB – Topanga Bridge (located 3600 m upstream of the ocean)
TC – Total coliform
TKN – Ammonia and organic nitrogen
TL – Topanga Lagoon
TMDL – Total maximum daily load
TV – Tolerance value
UCLA – University of California, Los Angeles
UCSB – University of California, Santa Barbara
USC – University of Southern California
UT – Upper Topanga (annual stream survey sampling site beginning at 4500 m)
UTM – Universal Transverse Mercator
WQO – Water Quality Objectives
WY – Water year

EXECUTIVE SUMMARY

The purpose of the Topanga Source Identification Study was to examine the various locations where bacterial exceedances of fecal indicator bacteria (FIB) are occurring and to use state-of-the-art methods to identify the possible sources of fecal contamination (human, gull, dog, horse) in lower Topanga Creek and at Topanga Beach. Based on the information gathered, we have identified and suggest some Best Management Practices that could potentially reduce, mitigate or eliminate these inputs and thus improve water quality at Topanga Beach.

Topanga Beach received poor wet weather water quality ratings between 2006 and 2014. The beach exceeded the water quality objectives set for Fecal Indicator Bacteria (FIB) from the Ocean Standards (AB411) based on weekly samples collected by the City of Los Angeles Environmental Monitoring Division. This happened frequently enough for Topanga Beach to be identified by Heal the Bay as the 4th most polluted beach in the state for the 2010-2011 season and as the 10th most polluted in 2011-2012. From 2012-2014, overall precipitation levels were very low, and water quality throughout the Santa Monica Bay was excellent. However, Topanga Beach was listed as “B” for summer dry (April – October 2012), “C” for winter dry (Nov 2012– Mar 2013), and “F” for wet weather year-round (Heal the Bay 2013). In 2014, summer dry was "A", winter dry "B", and "C" for wet weather year-round (Heal the Bay 2014). One of the goals of the Ocean Standards water quality objectives was to reduce the number of exceedances during the recreational season (April 1- October 31). In 2013 there were 17 exceedances and thus far in 2014 there have been four confirmed exceedances.

The information provided in this report includes all data collected from December 2012 through August 2014. Input from the Technical Advisory Committee throughout the study (2012-2014) helped identify data gaps, as well as refined and focused the sampling efforts.

Hypotheses and Results

At the start of the study, we identified the following hypotheses to test.

HYPOTHESIS 1. ***Upper watershed sources of FIB are not conveyed to the beach via the creek.***

Result: The upper watershed is not contributing to the exceedances observed at Topanga Beach. Based on the data collected thus far, FIB levels in the creek upstream of the lagoon do not appear to correlate with exceedances observed at Topanga Beach.

Data indicated that except for a few occasions, mainly associated with either rain events or observed transient activity, fecal indicator bacteria levels were unlikely to affect surfzone and lagoon water quality. Samples collected from the Pacific Coast Highway (PCH) Bridge, within the lagoon and along the beach in the ocean had clearly different patterns than those observed upstream within Topanga Creek.

HYPOTHESIS 2. ***Concentrations of FIB and/or markers and nutrients decrease as the creek flows downstream from town through the Narrows. Benthic macro-invertebrate community species diversity, sensitivity, and abundance increases as the creek flows downstream.***

Result: Concentrations of FIB and nutrients decrease as the creek flows downstream from town through the Narrows.

Conditions of FIB in the creek in the Narrows section, located between Owl Falls (6500 m) and Scratchy Trail (4800 m) appear conducive to a decrease in EC and ENT levels and observed levels of human- and dog-associated marker.

Nutrient levels in Topanga Creek and Lagoon are low overall, and despite the very low flow conditions in 2012-2014, the pattern of decreasing levels of nutrients as the creek flows downstream are consistent with those observed in previous studies (Dagit et al. 2004). Exceptions to this pattern were observed during rain events and associated with transient activities.

Result: From Owl Falls to Scratchy Trail and Topanga Bridge, benthic macroinvertebrate species diversity increases as the creek flows downstream. However, overall SCC-IBI scores are low throughout Topanga Creek.

The biotic integrity of benthic macroinvertebrate communities in Topanga Creek, as measured by Simpson's Diversity Index and SCC-IBI, was highest at Scratchy Trail and Topanga Bridge. Lower downstream, Brookside Drive showed significant disturbance, as this site ran dry twice throughout the course of the study. Throughout the watershed, both low and high flow conditions resulted in decreased IBI scores. Average total coliform in 2014 was also significantly correlated to low SCC-IBI total and EPT taxa scores. Only 16 of a total of 35 samples analyzed (2003-2014) had 500 or more individuals, which limited the ability to apply the SCC-IBI metric. A regional comparison of Topanga Creek to other Santa Monica Mountain sites (Malibu, Cold Creek, Arroyo Sequit, Solstice) revealed that since 2003 Topanga has had very low scores, second only to Malibu. The onset of drought in 2002 has had significant impacts on Topanga Creek, in terms of both SCC-IBI scores and species composition. In spite of low SCC-IBI scores, Topanga remains an important reference creek for the region, as it continues to flow throughout most of the reaches where others run dry.

HYPOTHESIS 3. ***FIB and/or pathogens are not leaking from faulty septic systems in the lower watershed, from septic systems along Pacific Coast Highway in Topanga State Park or from the County Lifeguard facility.***

Result: Testing of the septic systems along PCH indicated that the system at the Ranger residence at the Topanga Ranch Motel was possibly leaking, so repairs were completed in summer 2013. It is no longer leaking. The system at the Feed Bin was also a potential source of leachate and requires repair and further testing to evaluate the input potential into Topanga Creek. The other systems within Topanga State Park do not appear to be leaking, nor does the County Lifeguard facility.

Although testing in Summer 2013 indicated that the majority of septic systems in the area adjacent to Topanga Lagoon are not likely to be actively contributing any leachate at this time, there are several studies that suggest that there can be a long lag time between input into the ground water table and emergence in either the ocean or a lagoon (Stone Environmental 2004). Since most of these systems have only been capped since 2008, additional testing in the future may be required in order to conclusively document any potential inputs.

HYPOTHESIS 4. ***Lower watershed and/or lagoon sources of FIB (human and non-human inputs such as gull, dog, etc.) are correlated with exceedances at Topanga Beach.***

Result: Contributions from Topanga Lagoon are correlated with FIB levels in the ocean during rain events and when the lagoon is connected to the ocean directly.

FIB levels are significantly increased when the lagoon is breached and connected to the ocean regardless of winter or recreational season.

Result: Dogs and gulls are a significant source of fecal contamination to the lagoon and ocean and likely contribute to exceedances of ENT state water quality standards at the ocean and lagoon sites.

Gull levels were detected 94% of the time in lagoon samples and 80% of the time in ocean samples, indicating that gulls are an important and chronic source of fecal contamination to Topanga Lagoon and ocean sites. Dog marker levels in Topanga waters were similar to those measured at Rosie's Dog Beach in Long Beach, CA and were detected on average 71% of the time at ocean sites and 64% of the time at lagoon sites. This confirms that dog waste is also a significant source of fecal contamination to Topanga Lagoon and ocean.

Result: Human marker was detected infrequently in the creek, lagoon and ocean.

In Topanga, continued sampling for human-associated marker is recommended. During Year 1 (July 2012 to June 2013), human-associated marker was detected in the ocean on five sampling dates, including first flush, and also on four dates in the lagoon, one of which was first flush. There was a total of seven dates with either ocean or lagoon detection. Results from Year 2 (July 2013 – June 2014) are encouraging, as human marker was detected in the ocean on just two days, one of which was first flush. For the lagoon, human hits were observed only during the first flush event of Year 2. Further sampling is needed to determine if this trend continues and if it will continue to occur under non-drought conditions.

Summary of Results

This DRAFT FINAL report (9.23.14) for the Topanga Source Identification Study includes extensive discussion of the following specific efforts in accordance with the deliverables required by the grant, however a summary of the most important results is included here for ease of use.

1. **Present physical and chemical water quality conditions in the main stem of the creek, and along Topanga Beach and Lagoon.** (See Chapters 6-7)

   - Rainfall was below normal for both years the study took place, and significant rain events were few and far between. Therefore, flow was consistently low throughout the study period as well.
   - The average wetted width of the creek remained fairly constant throughout the study but average depths decreased in some locations in 2014.
   - Water temperature, pH, and specific conductivity were relatively stable and consistent with previous data collected (Dagit et al 2004, 2000-2012 RCDSMM unpublished data).
   - Habitat types remained consistent during the course of the study with riffles, runs and glides dominant in the lower reach of the creek (below 3600 m) and a more complex mix of flow habitats (cascade/fall, riffle, run, glide and pool) found upstream. None of the flow habitats in study reaches were dry during either year.
   - Geomorphology and gradient affect the types of flow habitats present, with the lower gradient reach below 3600 m (<3%) being dominated by run-riffle complexes and the upper gradient (3-6%) being pool dominated.
   - Smaller substrates such as fines and gravel were more frequent in the lower reach, whereas larger substrate such as cobbles, boulder, and bedrock were more frequent in the upper reach, which has a higher gradient (> 3%).
   - Instream habitat complexity includes abundance levels of filamentous algae, aquatic macrophytes, boulders, woody debris, undercut banks, overhanging vegetation, living tree roots and artificial structures. In 2014, both the lower and upper reaches had greater habitat complexities than in 2013 despite the low flows.
   - The proportions of cover values for several riparian vegetation types were also estimated for the lower and upper reaches. Trees and saplings > 5m had the highest proportion of sparse cover in both the lower and upper reaches.
   - Overall, both reaches of Topanga Creek have relatively stable banks that can support a complex assemblage of aquatic organisms. The higher level of fines and gravel in the lower reach are highly mobile. Snorkel survey and habitat typing focused on habitat for endangered steelhead trout documented the pulses of sediment moving downstream with storm events over time (Dagit and Krug 2011). While the specific

location of the sediment slugs varies over time, and results in decreased pool habitat in certain reaches, the overall amount of pool habitat and refugia for fish remained fairly constant, despite a very wet year in 2005. Overall, channel morphology has also remained fairly constant over time (Dagit and Krug 2011).

- In-situ parameters (water temperature, dissolved oxygen, pH, conductivity, salinity) were, in general, within the standard tolerance ranges for wildlife.
- Nutrient and algae levels were, in general, low throughout the study period, with only occasional exceedances.
- On average, nitrate and orthophosphate levels decrease from Owl Falls (OF, 6500 m; the site closest to town) downstream to the lagoon but this decline is more pronounced between OF and Scratchy Trail (4800 m)
- On average, Brookside Drive (BR, 1700 m) had the highest levels of Ammonia.
- Owl Falls had the highest nutrient levels and Scratchy Trail has the lowest nutrient levels on average.

2. **Microbial source tracking results.** (See Chapter 3)

- The lagoon is a source of FIB to the ocean. FIB levels are significantly increased when the lagoon is breached.
- Levels of FIB and all markers increase from the most downstream creek site (SP) to the lagoon. The lagoon may serve either as a location where microbial levels may be increasing due to growth (FIB) or to the presence of new inputs (FIB and markers).
- FIB in the surfzone do not appear to originate from an upstream creek source, except on days when both flow and FIB levels in the upper watershed are elevated. Days where creek input had potential to significantly impact downstream levels occurred on two sampling dates during this study, including the first flush event during year two of the study.
- Winter samples were four to eight times higher than samples for the recreational season for the dog and gull marker, indicating that these markers follow a seasonal trend and may have more of an impact to water quality during the winter.
- Dog and gull marker levels indicate a significant source of fecal contamination to the lagoon and ocean, and both dog and gull sources are likely contributing to exceedances of ENT and EC state water quality standards at the ocean sites. When ENT levels were in exceedance, gull marker levels were higher than when ENT levels were in compliance at BO, and TL. When dog marker levels in Topanga water samples were compared to levels at two reference beaches and one dog beach, dog marker levels at Topanga were similar to levels at the dog beach. No dog marker was detected at the two reference beaches sampled (Dockweiler and Malibu).
- Human marker was detected infrequently in the lagoon and ocean (13%). Average human marker values were higher at ocean sites when ENT levels were in exceedance vs. in compliance of state water quality standards. During Year 1 (July 2012 to June 2013), human-associated marker was detected in the ocean on five sampling dates,

including first flush, and also on four dates in the lagoon, one of which was first flush. There was a total of seven dates with either ocean or lagoon detection. Results from Year 2 (July 2013 – June 2014) are encouraging, as human marker was detected in the ocean on just two days, one of which was first flush. For the lagoon, human hits were observed only during the first flush event of Year 2.

3. **Description of human health risk associated with human and non-human sources of fecal contamination. (**See Chapter 4)

- Previous studies have well established that there is a correlation between the levels of FIB in recreational waters and incidence of illness when the likely source of fecal contamination is human.
- The risks associated with exposure to non-human sources of fecal matter in recreational water are still not well characterized, as epidemiological data on this topic are insufficient. However, there is some evidence in the literature for greatly reduced risk in water polluted by nonhuman fecal matter.
- Interest is growing in quantitative microbial risk assessment (QMRA) as a framework for understanding risk of illness in recreational water exposure.
- Ongoing research is required to fill data gaps before QMRA can be applied as an effective approach for predicting risk in recreational coastal waters. While US EPA has opened a door, site-specific water quality criteria (as would be derived from QMRA) are still not accepted under California regulations.
- For Topanga to be a candidate for QMRA in the future, testing for host-specific markers and pathogens (viruses) must be continued to assess the downward trend observed in human-associated marker and to monitor reductions in dog and gull pollution as sources. These measurements must continue as the drought ends so the role of the creek can be fully assessed. Depending on those results, it may be possible to conduct a thorough risk assessment and move towards site specific objectives.

4. **Examination of changes in macro-invertebrates, aquatic species of special concern and endangered fishes in relation to water quality conditions.** (See Chapters 8-11)

- Benthic macroinvertebrate Southern California Coastal Index of Biotic Integrity (SCC-IBI) scores increase from upstream to downstream. The lower scores in the downstream sites appears related to lack of flow.
- Both the high and low flow conditions resulted in decreased SCC-IBI scores.
- Although the SCC-IBI score for Topanga Creek was initially documented as Good (46) in 2001, analysis of the samples collected between 2003 -2014 range from Fair to Very Poor, and in fact 19 of 35 samples had too few individuals to apply the metrics.
- Average Total Coliform per site in 2014 (excluding first flush) was significantly and negatively correlated to EPT taxa, and also to total SCC-IBI scores ($F<0.05$, $R2=0.88$, $R2=0.64$). Average nutrient levels did not seem to be correlated with SCC-IBI scores.

- Drought conditions have reduced IBI scores throughout the region
- Crayfish removal had no effect on water quality or nutrient levels.
- Crayfish removal improved BMI community compositions while on-going but the effect was not observed two months after removal ceased.
- Crayfish removal could be beneficial in improving ecosystem health and nutrient cycling within the creek.
- Examination of diatom and soft-bodied algae communities can provide secondary indicators and multiple lines of evidence to better characterize the responses of southern California creeks to both natural (floods, wildfire) and anthropogenic inputs will allow for better understanding of the dynamics of aquatic systems.
- Diatom data from Topanga 2013-2014 provides a baseline snapshot of low flow conditions.
- A total of 125 diatom species were observed in Topanga Creek in 2013-2014. 46 species, many of them of cosmopolitan distribution, were common to both years, with 40 different species found only in 2013 and 39 species found only in 2014.
- Cladophora glomorata is the most common taxa found throughout southern California, appears to be a reliable indicator of high total Nitrogen (3.5 mg l-1) (Stancheva et al. 2012) and was also the dominant species observed in both Topanga and Malibu Creeks despite their different nutrient levels. This could possibly be a result of inability to differentiate between species in the same genus that appear taxonomically similar, but in fact represent different species with different tolerance preferences. It could also mean that further refinement of the tolerance limits and preferences is needed.
- Applications of three different indices of biologic integrity showed a consistent picture between sites and creeks for the soft body algae only (S2), diatoms only (D18) and combination of both (H20). These metrics from the Southern California Index of Biotic Integrity (Fetscher et al. 2014) are only recently available, so it is not yet possible to compare the snapshot of conditions in Topanga and Malibu Creeks in 2013 to other sites regionally.

Identification of potential remedial actions and BMP's. (See Chapter 12 and 13)

We recommend that the following potential actions are considered for implementation in order to reduce exceedances at Topanga Beach and improve the water quality and habitat in the upper watershed. Additional recommendations for further studies to continue the investigation of sources of bacteria and other pollutants are detailed in Chapter 13.

Recommended BMP's for Topanga Beach:

1) Restore Topanga Lagoon and Lower Topanga Creek State Park. This is a longer-term project, but by restoring natural function to Topanga Lagoon, it would be possible to not only reduce the bacterial sources but also improve habitat for a variety of endangered species, especially tidewater gobies and southern steelhead trout.
2) Continued enforcement of the County code and additional signage may reduce impact and presence of dog feces. The marker data documents a rise in dog associated markers in the winter months when lifeguard supervision and peer-pressure from beach visitors are reduced. During the study, dogs and dog feces, were routinely observed on the beach. The winning student posters have been affixed to the lifeguard station to assist with public outreach.
3) Continue coordinated enforcement to reduce the number of homeless and transients camping in and around the beach and under the PCH underpass. A mass balance calculation of input of one direct deposit to the lagoon (~200g of human feces) was calculated to result in an exceedance of ENT (Riedel et al. 2014 submitted). Direct deposits were observed at both the lagoon and beach on multiple occasions during the study. Direct deposits associated with the transient population is again an enforcement issue but one that could potentially reduce exceedances.
4) Continued maintenance and monitoring of the Lifeguard Station shower and restrooms. Some drainage from the showers directly to the beach was observed on several occasions. When tides are high or storm events shift the lagoon mouth downcoast in front of the building, there is potential for this to become a source.
5) Investigate possible installation and maintenance of culvert filters along Pacific Coast Highway at Topanga Beach to prevent direct road surface run-off spills into Topanga Lagoon.
6) Upgrade the septic systems at the Topanga State Park along PCH as conditions change and opportunities arise. As the lagoon park plan evolves, incorporating state of the art septic systems into any visitor serving facilities is recommended.
7) Increase outreach to commercial facilities that are on septic systems along the beach. The Feed Bin has the last remaining septic system that is connected to a seepage pit. Upgrading that system should be a priority.
8) Additional patrolling of the state park for transient and RV dumping activity could help with any exceedances in the creek, similarly, further enforcement of the no-dogs-allowed-on-beach rule would probably help with the FIB issues at the beach/lagoon.
9) Increase public outreach concerning the problem with dog feces pollution. While changing behaviors is difficult, peer pressure to pick up after your dog, as well as to reduce the number of dogs visiting the beaches could help.
10) Participate in future monitoring and develop funding to initiate a quantitative microbial source identification study to evaluate the potential for developing appropriate site specific objectives.

Recommended BMP's for the Topanga Creek Watershed:

Although it does not appear that inputs into the upper watershed are associated with the exceedances at Topanga Beach, there are indications that they negatively impact the creek's ecosystem. A number of BMP's could be implemented throughout the watershed in order to reduce inputs to the creek and possibly improve overall conditions in Topanga Creek.

1) Establish a community outreach program to inform residents of potential septic system impacts to the creek and encourage them to upgrade their existing septic systems by installation of effluent-filters in septic tank outlets to reduce particulates into leach fields or seepage pits, thus reducing bacterial and nutrient contamination potential. The community outreach program should include identifying funding sources to assist property owners in upgrading their septic systems.
2) Establish a community outreach program to inform residents of potential impacts to the creek from sub-surface and surface graywater discharges.
3) Through community outreach, encourage the installation of additional trash receptacles behind Topanga Market and Abuelita's.
4) Through community outreach, encourage the availability of public restrooms in Topanga Center.
5) Continue coordinated efforts to remove transient encampments and illegal marijuana farms located adjacent to the creek.
6) Implement the Santa Monica Mountains Local Coastal Program policy for existing equestrian facilities to encourage such facilities to come into compliance with all of the LCP policies and regulations as soon as possible.

Additional recommendations for future research are included in Chapter 13.

Documentation of community participation:

One important element of this study was to educate the local community and engage elementary through undergraduate students in the investigation of bacterial sources and pollutants in Topanga Creek. To that end, the RCDSMM, Watershed Stewards Program Members and Dr. Jenny Jay's team at UCLA provided a series of in-class and field programs reaching over 400 students.

Community outreach documented in Appendix E included:

1) Yearly community meetings (May 2013 and 2014) to highlight care and maintenance of septic systems and graywater systems, share the preliminary results of the study, and discuss potential BMP's.
2) Yearly watershed field class and UCLA mentoring for 5th graders at Topanga Elementary School and 6-8th graders at Topanga Mountain School.
3) In 2014, students participated in an experiment at Topanga Beach to examine decay rates and levels of FIB contained in the sand along the beach. Students worked with their UCLA undergraduate mentors to collect and analyze data and then prepare posters to share results. These posters were presented at UCLA and to the community.
4) Students also participated in a poster contest to explain why dogs on the beach are a problem. The three winning posters are being made into signs that will be posted at Topanga Beach.
5) Yearly neighborhood meeting to discuss "hot spots" and brainstorm solutions. This action was not completed.
6) Two articles per year in the local newspaper and relevant web sites updating results of the study to the community. Copies of the articles are included in Appendix E.
7) Twice yearly training of Stream Team volunteers. Trainings took place on Saturday 1 December 2013, 5 June 2013, and again on 23 October 2013 to train new Watershed Steward and UCLA student interns.

Acknowledgements

First and foremost, we wish to thank Supervisor Zev Yaroslavsky for the financial support for this effort. Chief of Staff Alisa Katz and Deputy Susan Nissman were key to developing a coordinated effort that will not only assist the County in learning more about the water quality issues at Topanga Beach, but will hopefully also provide innovative, cost-effective solutions for making sure the waters of LA County are safe for swimmers, as well as support a viable ecosystem.

Numerous Resource Conservation District of the Santa Monica Mountains (RCDSMM) and University of California at Los Angeles (UCLA) staff, students and volunteers cheerfully got up in the dark for many months to help collect data. We could not have collected and processed the samples without the assistance of: Uriel Cobian, Ian Davies, Steve Harrison, Raven Logiuroto, Sofi Peterson, Gabriel Sloggy, Ken Wheeland, and Steve Williams.

A variety of interns and Watershed Steward members assisted in the benthic macroinvertebrate analysis under the guidance of Jenna Krug, Crystal Garcia and Lizzy Montgomery. We could not have completed the work without your help.

2013: Uriel Cobian, Carrie Fong, Ariane Jong, Matt Kirby, Diana LaRiva, Gabby Njm, Katherine Pease, Tessa Reeder, Vanessa Thulsiraj, Karen Vu, Amy Zimmer-Faust, Mark Ziman.

2014: Kayti Christianson, David Gottesman, Allie Irwin, Monica Jarquin, Robert Ruzicka and Sylvia Zamudo.

We are grateful to Bill Howell for allowing us to use his driveway for access to the creek!

We also wish to acknowledge the assistance and support of the rangers and staff at Topanga State Park, as well as the lifeguards at Topanga Beach, and the staff of LA County Department of Beaches and Harbors. Your stewardship of the beach is much appreciated.

Funding to Dr. Jay's lab at UCLA for the Source Identification Protocol Project was provided by the California State Water Resources Control Board.

BioSolutions and Topanga Underground provided technical assistance with the septic system monitoring and examination.

Dr. Jed Fuhrman provided virus analysis.

The staff at Southern California Coastal Water Research Project, including Dr. S. Betty Fetscher, Raphael Mazor, and Steven Weisberg provided important expertise and advice.

We would also like to recognize the UCLA student mentors and students and teachers from Topanga Elementary School and Topanga Mountain School who participated in the spring educational program.

Dr. Katherine Pease from Heal the Bay graciously answered many questions, provided important data and loaned us a great microscope used to examine the macroinvertebrates.

Dr. Richard Ambrose at UCLA also loaned us equipment to facilitate BMI analysis.

The members of the Technical Advisory Committee provided invaluable information that helped us refine our study plan and examine our results. Members included:

Purpose (as Proposed in 2012)

How does Topanga Creek decline from an "A" grade creek into an "F" grade beach?

1) Identify the likely sources (both physical location and source, i.e., human, bird, dog, horse, etc.) of elevated fecal indicator bacteria (FIB) at Topanga Beach by testing the creek from MM 2.02 to the beach. Test the hypothesis that the creek is grade "A," and sample in and around the lagoon to fine tune our understanding of when and investigate when and why the beach gets grade "F."
2) Identify best practices or remedial actions that could reduce or eliminate fecal contamination from human or animal sources.
3) Implement K-12 and community education and outreach to engage stakeholders in water quality problems and best management practices to solve them.

This report provides background information, documents methods used, summarizes data gathered and suggests recommended Best Management Practices for moving forward. This report is organized according to standards used in scientific publications, which results in some repetition of methods and results that interconnect between chapters. Our intention is to submit these chapters for peer-reviewed publication, in addition to completing the final report required by this grant.

The intended audience for this report includes County and agency staff, as well as interested citizens, Stream Team volunteers, and our student participants.

Community Outreach and Technical Oversight

Topanga is a small community with many active and concerned stakeholders. The proposed testing meets the needs identified in the Topanga Creek Watershed Management Plan (2002). Input from local experts and agency staff was solicited through the formation of a Technical Advisory Committee, which met in December 2012 to help guide sampling strategy, and again in April and October 2013, April, May and October 2014 to review preliminary results and suggest refinements. In May 2013, a community meeting held at the Topanga Public Library provided a wonderful opportunity to engage property owners in a collaborative effort to understand the preliminary results, and examine acceptable procedures for maintenance, monitoring and implementation of Best management Practices (BMP's) for septic and graywater systems that meet the regulatory standards of AB885. Building on the long-standing effectiveness of the RCDSMM Stream Team, volunteers and local students were solicited and trained to assist in data collection. Another community meeting was held in May 2014 to discuss the results regarding the inputs from dogs at the beach, and included a poster contest which resulted in student posters being deployed at Topanga Beach to educate the community.

Even though this study did not sample in the developed upper watershed, we recognize that inputs from the private inholding areas within the predominately public open space of the watershed could have negative impacts. Reaching out at the neighborhood level to property owners adjacent to previously identified "hot spots" is a difficult and sensitive endeavor. Due to the focused attention on the beach and lagoon, we did not conduct these meetings, however, we did provide detailed information to the whole watershed through articles in the Topanga Messenger, on Zev's blog and through community meetings.

In order to be successful in reducing pollutants entering Topanga Creek, Lagoon and Beach, an on-going education program was identified as critical. In-class watershed classes were provided to the Topanga Elementary School (TES) kindergarteners. In both spring 2013 and 2014, 5th grade students from TES, along with 6-8th graders from the Topanga Mountain School (TMS) participated in a collaborative project with UCLA undergraduate students to develop and test hypotheses about water quality that included both in-class and field studies. This culminated with the students working with their UCLA mentors to produce scientific posters explaining their hypothesis, results and conclusion that they presented on campus at UCLA and to the community. This was a great way for students to make the connections between what goes down the kitchen sink/tub and pollution in the creek. Getting the students into the ocean to collect and analyze samples was not only great fun, but gave them a real sense of how research works. The posters summarizing the student projects are found in Appendix E.

Need for Project

In spite of the removal of houses and their accompanying septic systems within the Rodeo Grounds area of the lower watershed (and other coastal engineering solutions described below), Topanga Beach received poor wet weather water quality ratings between 2006 and 2014. The beach has exceeded the water quality objectives set for Fecal Indicator Bacteria (FIB) based on the Ocean Standards (AB411) obtained from weekly samples collected by the City of Los Angeles Environmental Monitoring Division. This happened frequently enough for Topanga Beach to be identified by Heal the Bay as the 4th most polluted beach in the state for the 2010-2011 season and as the 10th most polluted in 2011-2012. No systematic sampling of the creek or adjacent up and downcoast reaches of the beach had been done since 2004.

Over the past few years, a number of actions have been implemented to reduce possible bacterial contamination of Topanga Beach. In 2008, Los Angeles County Department of Beaches and Harbors upgraded their septic system associated with the restrooms and lifeguard station. Since 2008, the septic systems located within the former Rodeo Grounds Road and Snake Pit area have been removed. The septic systems associated with the Topanga Ranch Motel (ranger house only), Reel Inn, Cholada's, Rosenthal Winery, and the Topanga Feed Bin have been sealed and are now being pumped weekly or as needed in compliance with California Department of Parks and Recreation requirements.

Topanga Creek was listed by the Regional Water Quality Control Board 303(d) list for lead in the upper watershed and bacteria at Topanga Beach. No other pollutants of concern have been listed for the watershed. Topanga Creek has no stormwater conveyance systems per se, but in actuality stormwater is "conveyed" and enters the creek in a variety of ways via surface flow, private and public culverts and natural drainages.

A variety of analytical methods now allow for identification of specific source-associated molecular markers, including human, dog, horse, and gull. In collaboration with the State of California Source Identification Project (SIPP), this MST study was completed in order to provide insight concerning sources of elevated FIB in the Topanga watershed.

The funding contributed by the County has:

1) enabled comprehensive sampling for FIB and molecular markers within the Topanga Creek watershed that has complemented and expanded on hypotheses and results generated during extensive SIPP MST study of the Topanga watershed;
2) allowed for analysis of the benthic macroinvertebrate Southern California Coastal Index of Biotic Integrity in Topanga Creek, which has provided a greater understanding of the biological health of the Topanga watershed;
3) provided sufficient information to develop/recommend possible remedies to the problems identified; and provided substantial outreach and education to local K-12 students and the general public.

1 Background Information (Previous Studies prior to 2012)

Functional bacterial communities are essential to both human and ecosystem health. The focused sampling and monitoring provides the County and the Regional Water Quality Control Board with information that will assist in identifying potential FIB sources and reducing contributions from these sources that lead to exceedances of state bacterial water quality standards.

This study provided an interesting opportunity to examine the biology of the Topanga Creek watershed as well as mechanisms that allows assimilation of fecal and nutrient pollution, processing upper watershed inputs in such a way that these inputs do not extend downstream to the extent that they influence the patterns observed on the beach.

1.1 2003-2004 Sampling Summary

The last comprehensive sampling and monitoring in the Topanga Creek Watershed took place in 2003-2004. At that time, several "hot spots" in the upper watershed were identified. Total and fecal coliform bacterial exceedances were associated with storm events when tested at the Bridge on Topanga Canyon Blvd. (3600m), which is located approximately halfway between the town and the ocean (Figure 2-1). Enterococcus limits were exceeded for 50% of total storm sampling events, and the Bridge was one of the few locations where enterovirus RNA tests were positive (two events of 24) (Dagit et al 2004). Tests for *Bacteroides* were negative in all sampling events (n=12). These results need to be examined in light of known transient encampments, but one of the conclusions from the 2003-2004 study was that due to the small sample size, insufficient data was collected and additional sampling was needed in order to fully understand the patterns of pollutants in Topanga Creek as they move towards the beach.

In addition to examining the FIB conditions, other variables such as nutrients (nitrate-N, nitrite-N, orthophosphates, ammonia-N and turbidity) were also documented. Again, the pattern indicated that nutrient levels decreased as the creek flowed downstream, and hot spots identified within the upper watershed remained on the low end of typical urban conditions.

1.2 2011-2012 SIPP Sampling Summary

In a review of historical data (January 2005 – November 2011) taken by the City of Los Angeles Environmental Monitoring Division and compiled by the Los Angeles County Department of Public Works an unusual pattern of bacterial exceedances occurring at Topanga Beach well into the dry season (as late as mid July) was noted. When these data were compared to creek flow data collected by the County at the same time as the bacterial data, it was apparent that bacterial exceedances correlated strongly with breaches in the Topanga Creek Lagoon (Figure 1-1). The Topanga Lagoon discharges episodically into the ocean as late as July. This correlation between Lagoon discharges and high FIB values in ocean water samples strongly suggested that Topanga Lagoon was the primary source of high FIB levels in the surf zone.

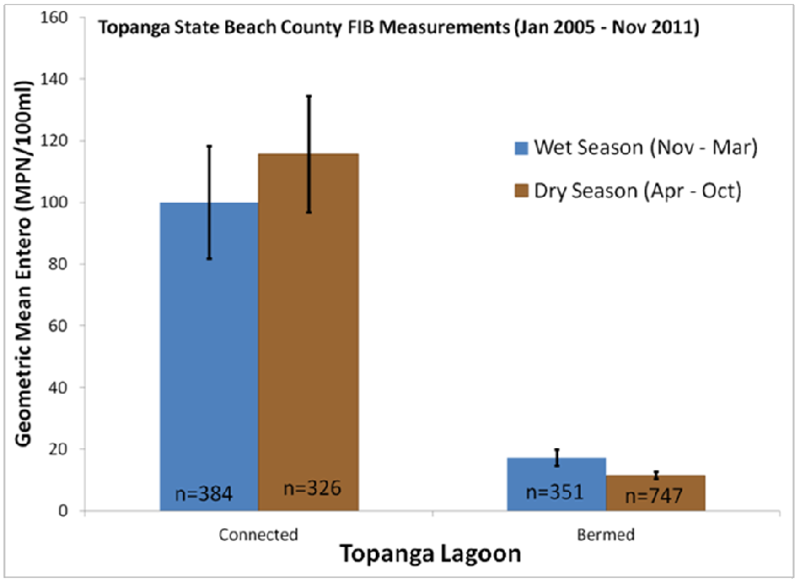

Figure 1-1 Geometric mean of Enterococcus (MPN/100mL) connected and bermed conditions for wet and dry seasons between January 2005 – November 2011.

Based on this historical analysis and the identification of the lagoon as an important source of FIB to the ocean, the UCLA SIPP team began a microbial source tracking study of those areas in October 2011. This effort began with a full watershed snapshot in October 2011 and continued through the summer of 2014. "Hot spots" identified with this snapshot were further analyzed with additional sampling and source associated markers were used to identify potential sources of fecal contamination to the watershed.

A "first flush" storm event occurred on 5 October 2011. Volunteers from the RCDSMM and UCLA collected representative water samples throughout the upper watershed downstream to the ocean at locations previously sampled in 2003-2004. Preliminary results reflected a pattern similar to that observed in the earlier study.

Results from the 2011 first flush sampling event indicated high bacterial levels throughout the watershed and, in most cases, samples were positive for the human-associated marker. Subsequent sampling events identified at least four "hot spots". These were Entrado/Highvale Road (not re-verified in 2012 due to lack of flow), Behind Abuelita's in town, Mile Marker 2.02 Bridge, and the Lagoon. The sampling effort of 2012 identified a hot spot of high ENT levels and related human-associated marker in the town region of the Topanga watershed. To better understand the nature and extent of this hot spot, samples were taken three times over two weeks in an attempt to bracket in the source (Figure 1-2 and Figure 1-3).

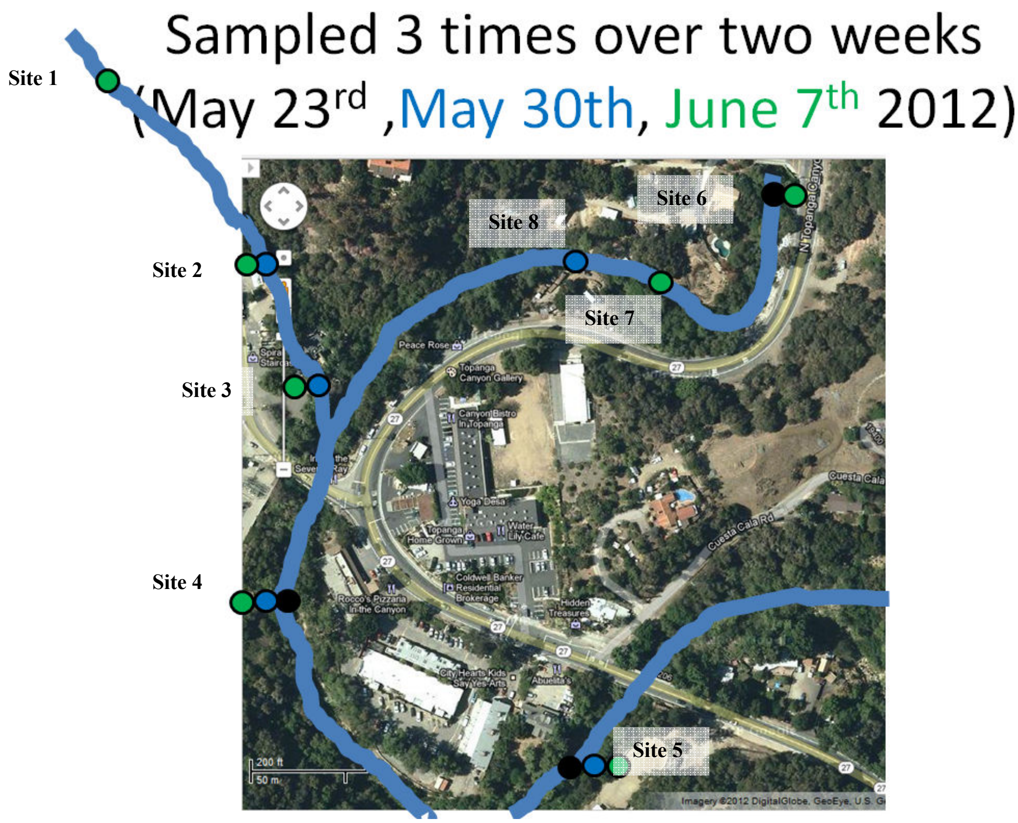

Figure 1-2 Locations of hot spot sampling taken three times over two weeks trying to locate source of large ENT levels originally detected at site 5 (Behind Abuelita's; BA).

The intensive sampling indicated that there was a source of FIB in both the main stem of the creek and the Old Topanga tributary. The main stem source did not extend above the School Road crossing, while the Old Topanga source was not definitively bracketed as exceedance levels were found at the northernmost site sampled (Backbone Trail Crossing). These sample were further analyzed for human, dog, and horse-associated markers (Table 1.1). Horse-associated marker was not detected at any of the sites sampled. High levels of human marker were detected along the Old Topanga Creek stem near the large power transformer box in addition to high levels of dog marker detected at the Inn of the Seventh Ray site. These sources may explain the concurrent hits of human and dog markers at the Post Office site. However, samples were not positive for either the human or dog marker at the Behind Abuelita's site (Figure 1-3).

The watershed sampling efforts in 2012 also expanded our understanding of the reduction in FIB levels within the Narrows, occurring between the confluence of Dix Creek with Topanga Creek at Owl Falls (6500 meters upstream from the ocean across from Jalan Jalan) and the Scratchy Trail access point (4800 meters upstream from the ocean and located near mile marker 3.75), in an area with little human development,

Sites along the main stem did not show markers except for one hit for BacHum at a level too low to quantify at the School Road site (Table 1-1). High levels of human marker were detected along the Old Topanga Creek stem near the large power transformer box in addition to high levels of dog marker detected at the Inn of the Seventh Ray site. These sources may explain the concurrent hits of human and dog markers at the Post Office site but either these sources were too diffuse to detect at Behind Abuelita's (BA) or another animal is the source of FIB seen at Behind Abuelita's (Figure 1-3).

Table 1-1 Results of hot spot sampling three times over two weeks in the summer of 2012. Map numbers correspond with sites labeled in Figure 1-2. ND indicates maker not detected, D indicates marker detected but at a level too low to quantify.

Site	Map #	ENT 5/23	ENT 5/30	ENT 6/7	HF183 5/23	HF183 5/30	HF183 6/7	BacHum 5/23	BacHum 5/30	BacHum 6/7	Dog 5/23	Dog 5/30	Dog 6/7

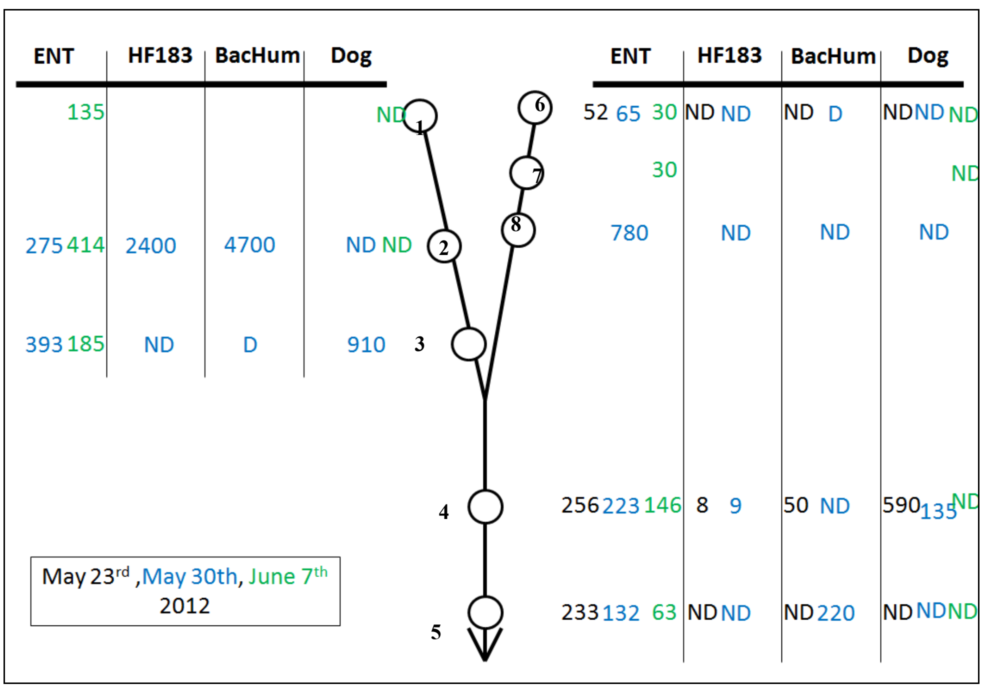

Figure 1-3 Results of hot spot sampling three times over two weeks.
Abstracted site map is shown in the middle of the figure with corresponding ENT or marker values shown (horse marker not shown because all results returned not detected (ND)). Color indicates date of sample with black 5/23/12, blue 5/30/2012, and green 6/7/2012.

1.3 Additional On-going Studies in Topanga Creek

Good water quality is essential to supporting populations of endangered species in the region, including the southern steelhead trout (*Oncorhynchus mykiss*). Topanga and Malibu Creeks are the only places where southern steelhead trout are still consistently present in the Santa Monica Bay. In 2006, there was a die-off of trout in Malibu, while those in Topanga remained healthy. The reason for this die-of remains unclear. Since 2009, the RCDSMM has deployed water quality monitoring sondes in Malibu, and in 2010, were able to compare the conditions in Malibu with those in Topanga. Those results are presented in a report on the status of steelhead in the Santa Monica Bay (Dagit and Krug 2011).

1.4 Sampling Plan 2012-2014

In December 2012, a two year tiered effort providing comprehensive sampling of the Topanga watershed was initiated. The Topanga study is a cooperative endeavor between the RCDSMM, the Jay Lab at UCLA (this lab was one of five core labs that participated in the state-funded Source Identification Protocol Project (SIPP) run by SCCWRP), the Fuhrman lab at USC, and the trained volunteers of the Topanga Creek Stream Team. Topanga Underground and BioSolutions, Inc. provided the septic tank tracing and testing information.

Building on the data collected by the SIPP MST study, this work provides the County with a better understanding of how and why exceedances occur at Topanga Beach.

A Technical Advisory Committee (TAC) was convened in December 2012 to provide oversight and assist in fine-tuning the sampling design and analysis. The TAC is comprised of stakeholder representatives including Los Angeles County Departments of Beaches and Harbors, Public Health, Public Works and the Third District Supervisorial representatives, as well as scientists from the Southern California Coastal Water Research Project (SCCWRP), California Department of Parks and Recreation, Caltrans, Regional Water Quality Control Board, University of California, Los Angeles (UCLA), BioSolutions, Topanga Underground, and RCDSMM. In addition, the proposed SIPP-related microbial source tracking (MST) efforts were evaluated and approved by the other three core labs involved in the project: the Southern California Coastal Water Research Project (SCCWRP), Alexandria Boehm's lab at Stanford, and Patricia Holden's lab at UCSB. A complete list of TAC members is found in the acknowledgements. Additional TAC meetings took place in April and October 2013, April and October 2014.

1.5 Sources of Bacteria to the Beach

Sources can be divided into two categories, lower watershed sources and upper watershed sources that travel to the beach via the main stem of the creek.

1.5.1 *Potential Lower Watershed Sources Examined*

Septic systems along Pacific Coast Highway in Topanga State Park. The systems at Cholada's, Ranch Motel Ranger residence, Reel Inn, Malibu Feed Bin, and Rosenthal Winery are being pumped weekly or more as needed in compliance with the contracts administered by the California Department of Parks and Recreation. They are all older systems and are disconnected from leach fields or seepage pits, these tanks were tested during summer 2013 to examined the conditions of outlet T's to ensure that they have been sealed to prevent any discharge into abandoned drainfields. The holding capacity and pumping protocol of these tanks was also examined. Results are included in Chapter 6 and Appendix H.

Beaches and Harbors restrooms and lifeguard station. While a stand-alone treatment facility exists at this site, it was evaluated and listed as a potential source in the event of a malfunction and/or maintenance issues.

Wildlife, including gulls and other seabirds, deer, coyotes. Although it is only 1.8 acres, the remnant lagoon at the mouth of Topanga Creek is consistently used by roosting and foraging waterfowl. Bacterial contributions from bird feces have been identified as the source of FIB in other coastal lagoons, such as Cowell Beach in Santa Cruz (Russell et al. 2013) and a beach in Racine, WA (Converse et al. 2012).

1.5.2 *Potential Upper Watershed Sources Moving Downstream Through the Creek to the Lagoon Examined*

Homes on septic systems throughout watershed. While many homes in Topanga were built in the 1920's and 1930's resulting in old septic systems, the County Public Health Department has a program in place to monitor existing systems. Approximately 200 of the 3,000 homes in the watershed are located directly adjacent to the creek.

Transient encampments. Several locations throughout the watershed are known to house transient populations. While encampments are dispersed whenever identified, it is possible that new encampments exist.

Horses. There are several establishments housing large numbers of horses, and many residents throughout the watershed have one or two horses on fairly small parcels. Horses are ridden in open land throughout the watershed, resulting in a potentially diffuse bacterial source. Horse feces at barns are sometimes composted and these piles could also serve as a bacterial source.

Dogs. Fecal matter from the many household dogs would be a potential diffuse source of bacteria in the watershed.

Wildlife including coyotes, deer and birds. 70% of the watershed is undeveloped; thus, the watershed is home to coyotes, deer, native pond turtles, mountain lions, and other species.

1.6 Hypotheses Tested

1) Upper watershed sources of FIB are not conveyed to the beach via the creek.
2) Concentrations of FIB and/or pathogens and nutrients decrease as the creek flows downstream as measured between the MM 2.02 bridge and the lagoon. Benthic macroinvertebrate community species diversity, sensitivity, and abundance increase as the creek flows downstream from the town.
3) FIB and/or pathogens are not leaking from faulty septic systems in the lower watershed along Pacific Coast Highway in Topanga State Park or from the County Lifeguard facility.
4) Lower watershed and/or lagoon sources of FIB (human and non-human inputs such as gull, dog, etc.) are correlated with exceedances at Topanga Beach.

2 Study Sites 2012-2014

The location of sampling sites (Table 2-1) includes County funded sites in the ocean and Topanga Lagoon, moving upstream as far as the Topanga Bridge (3600 m), which is located halfway between the ocean and the town of Topanga. Locations in Topanga Creek have been mapped and are identified by both pool name and meters upstream from starting place at the Pacific Coast Highway Bridge (Table 2-1). In addition, UCLA is also sampling further upstream using SIPP funding. Detailed information on the standard operating procedures and Quality Assurance/Quality Control protocols are found in Appendix G. Using the approaches described below, we have endeavored to test each hypothesis and identify both the locations of sources of FIB and/or pathogens, as well as identify the host species.

2.1 Sampling Locations

Sample sites were chosen in order to gain a comprehensive understanding of water quality within the Topanga watershed. Sites with high levels of FIB were retained, while additional sites were occasionally added in order to more effectively identify source of elevated FIB, or removed if patterns of FIB levels at that site varied little with sites directly above and below. A few locations above Owl Falls were sampled on several occasions as part of the SIPP study in 2013. However, due to a lack of flow in the upper watershed, the primary focus of the effort was downstream of the total upper watershed inputs (Table 2-1). All sites were sampled at the first flush rain events (17 Nov. 2012, 24 January and 8 March 2013, and 27 February 2014).

Photos were taken at each site to document specific conditions for that sampling event. These photodocumentation summaries are found in Appendix B.

3 Microbial Source Identification Study

3.1 Background

Topanga Beach, California is frequently listed as one of the most impacted beaches in the state of California (Heal the Bay 2013) based on fecal indicator bacteria (FIB) levels, despite numerous projects within the lower watershed intended to improve water quality. Ranked 9th most polluted California beach in 2006, 4th in 2010-11, and 10th in 2011-12, Topanga Beach has FIB exceedances well into the summer season, but the sources of FIB to the ocean have been unknown. Potential sources of fecal contamination to the watershed include malfunctioning septic systems, transient populations, horses, dogs, gulls and other wildlife specific to the region. Topanga Creek and lagoon may also be potential sources of FIB to the surfzone; microbial contamination may be transported from the upper watershed via the creek to the lagoon and beach. Studies have also shown beach sand and sediments can harbor bacteria and serve as a source of FIB to the water column (Ishii et al. 2007, Yamahara et al. 2009).

A two-year microbial source tracking (MST) study was initiated in the Topanga Creek watershed that measured FIB levels and also utilized culture-independent molecular markers for detection of host-associated fecal contamination. Unlike FIB, which can originate from multiple hosts, MST methods can help identify unique sources of fecal pollution through use of host-associated markers that allow for identification of the likely original host of fecal pollution to environmental waters (Harwood et al. 2013, Boehm et al. 2013).

Hypotheses and Objectives

This study investigated sources of FIB to the Topanga Creek watershed and reports on the applicability of using MST technology. A combination of approaches including snapshot surveys, long-term monitoring during wet (winter) and dry (recreational) seasons, and the use of a suite of markers at all sites was utilized to identify likely sources of FIB. We hypothesized that:

1) Lagoon discharge negatively impacts water quality at Topanga Beach
2) Concentrations of FIB and/or host-associated markers decrease as the creek flows downstream towards the lagoon; therefore, creek inputs do not affect surfzone FIB during both normal and drought conditions.
3) Spatial and temporal patterns of FIB and host-associated markers exist between sites in the lower watershed
4) Lower watershed and/or lagoon sources of FIB (human and non-human inputs such as gull, dog, etc.) are correlated with exceedances at Topanga Beach.

A fifth hypothesis concerning the use of a rapid viability-based method (IMS/ATP) and a sixth hypothesis concerning differential decay rates for FIB and markers in sediment were also explored and results are included in Appendix J.

3.2 Methods

Field Site- Topanga Creek Watershed

Topanga Beach receives over 750,000 annual visitors and suffers from poor water quality. Due to the Mediterranean climate, this region experiences a dry recreation season (April – October) and wet season (November – March), with typical rainfall averaging 20 inches a year. However, rainfall during the course of this study was below average levels. Topanga Creek watershed (approximately 47 km^2) is 70% undeveloped (GeoPentech, 2006) and includes a creek and lagoon system. Topanga Creek drains the upper watershed and cumulates in Topanga Lagoon, a dynamic lagoon system that breaches and berms throughout the year, contributing variable flow to Topanga Beach. This site is critically important to several sensitive and endangered species including the steelhead trout, California newts and multiple species of frogs (Western toads, California tree frogs and Pacific frogs) (Dagit et al. 2007, Dagit et al. 2003). For additional information regarding site details including location and site descriptions please see Section 2 of this report.

Fecal Indicator Bacteria (FIB) Analysis

Water samples collected from Topanga watershed were analyzed for fecal indication bacteria (FIB) levels and host-associated molecular markers for human, dog, horse, and gull. To obtain FIB concentrations, Total Coliform (TC), *Escherichia coli* (EC), and enterococci (ENT) were measured with Colilert-18™ and Enterolert™ (IDEXX, Westbrook ME) reagents and protocols to determine the most probable number (MPN) of cells per 100 ml sample. Samples were analyzed at a 1:10 dilution as recommended by the manufacturer, or a 1:100 dilution on an as needed basis. The limit of detection (LOD) for these assays is 10 MPN/100ml and any sample below the limit of detection was assigned a value of 5 MPN/100ml for analysis. Samples above the range of quantification (ROQ) were assigned the maximum value depending on the dilution used. For example, samples with observed concentrations of >24196 MPN/100ml were set to 24196 MPN/100ml.

Host-associated Marker Analysis

Two human-associated markers were measured using the HF183 Taqman (HF) (Haugland et al. 2010) and the BacHum Taqman (BH) assays (Kildare et al. 2007). Results from year one showed strong correlation between HF and BH markers. Therefore, BH was used only to confirm a human signal in samples positive for the HF183 marker (n=42) during the second year of the study. Samples were also analyzed for animal sources with three additional markers. The Gull2 Taqman assay (Gull) (Lu et al. 2008) was used to measure gull-associated marker and the DogBac Taqman assay (Dog) (Dick et al. 2005) was used to measure dog-associated marker. A conventional endpoint PCR assay, HoF597 (Horse), was used to detect fecal inputs associated with horse waste. Marker selection was based on a previous multi-laboratory comparison study (Boehm et al. 2013). Primers and conditions used for each qPCR assay are listed in Table 3-1.

For the measurement of HF183, BH, Dog and Gull gene copies per 100 ml, sample water was filtered through 47 mm, 0.4 µm pore size, HTTP polycarbonate filters (EMD Millipore, Billerica, MA) in triplicate. Each filter was placed in an individual two ml polypropylene screw cap tube, containing 0.3 g, 212 – 300 µm (50 – 70 U.S. sieve) acid washed glass beads (Sigma-Aldrich, St. Louis, MO) and stored at -80°C until DNA extraction. DNA extraction was conducted with the DNA-EZ ST1 Extraction Kit (GeneRite, North Brunswick NJ) following the manufacturer's protocol. Eluted DNA samples were stored at -20°C until analysis of molecular host-associated markers with qPCR.

FIB and Marker Analysis

Geometric means and standard deviation of the geometric mean were calculated for FIB and host-associated markers and are shown in Tables 3-3 and 3-4 and Figures 3-1, 3-2, 3-4 to 3-7 for creek, lagoon, and ocean sites. The number of samples analyzed for each site is listed below (Table 3-2).

Table 3-2. Number of samples used to calculate geometric mean for FIB and markers at creek, lagoon, and ocean sites: OF (Owl Falls), ST (Scratchy Trail), TB (Topanga Bridge), BR (Brookside Drive), SP (Snake Pit), BU (Beach Upcoast), BO (Beach Outlet), LG (Lifeguard Station), HB (Hwy 1 Bridge), TL (Topanga Lagoon), and LO (Lagoon Outlet). Data are entered for each site and indicator as follows: n for total site/ n for winter season/ n for recreational season for each site.

	Site	TC	EC	ENT	HF	BH	Gull	Dog

Host-associated Marker and FIB QA/QC

The qPCR reaction mixture consisted of 2 µL of DNA template combined with the appropriate primer probe sets and thermal cycling conditions, depending on the assay used. Samples and calibration standards were run in triplicate. A five-point standard calibration curve was run alongside samples on each well plate. Standard curves had efficiencies between 90 - 110% and $R^2 > 0.99$. Filter blanks, consisting of 50 mL of PBS passed through the polycarbonate filter, were also generated with each set of processed samples. Negative controls (no template controls) and filter blanks and extraction blanks were included to ensure contamination of samples did not occur during either the filtration or extraction processes, or while plating samples in the 96 well plate during the qPCR procedure. In addition, FIB values recorded in this study were compared with FIB values measured during regular water quality monitoring conducted by the county Public Health department. A strong linear relationship between both data sets were observed for measured TC and EC values ($R^2 = 0.7$).

Dog-associated marker survey

A survey of FIB and dog marker concentrations in water and sand was conducted at four beaches in May 2014, with the goal of comparing dog marker levels from Topanga to both references beaches and a dog beach. Water and sediment samples were collected during morning hours (6 AM – 11:30 AM) on May 2, 2014 from Topanga (n=24), Malibu (n=4) and Dockweiler (n=4), both of which served as controls as they have minimal dog activity, and Rosie's Dog Beach in Long Beach (n=16).

Marine sites were sampled using autoclaved 125 mL Nalgene bottles that were submerged ankle deep in ocean waters on an incoming wave. The top one cm of sediment was collected with sterile 50 ml Falcon tubes by sliding the tube across the surface; 10 composite scrapes collected within a one square meter made up the sediment surface samples for both wet and dry sediment. Wet sediment was collected within the tidal wash zone. Approximately 4 m inland of that location, a dry surface sediment sample and a depth sample was also collected. Trowels cleaned with ethanol were used to dig six inches below the surface of the sand; a clean falcon tube was then used to collect sand at this depth. Samples were processed on-site for TC, EC and ENT, with the help of Topanga Elementary School and Topanga Mountain School as part of the community involvement and outreach effort. Extra sediment and water samples were then transported on ice, to the lab, within six hours of collection and filtered/preserved for DNA extraction at UCLA. Samples were stored at -80^{o}C until further processing for qPCR.

Analysis of isolates with 16S rRNA Sequencing

Enterococcus (ENT) isolates were characterized in order to help determine whether ENT originating from water samples collected at Topanga Lagoon and ocean sites are predominately fecal or environmental-associated species . *E. faecalis* and *E. faecium* are the most prevalent ENT species in human feces and can be distinguished from other species (e.g. *E.casseliflavus* and *E.mundtii*) that are more often associated with plants and soil (Byappanahalli et al. 2012). Bacterial isolates were selected and isolated from lagoon and ocean sites after three consecutive sampling trips on July 2, 2014, July 15, 2014, and August 11, 2014 as well as from a subset of samples collected during summer 2013. Bacterial isolates were cultured with mEI media following the membrane filtration USEPA Method 1600 and with the Enterolert^{TM} defined substrate test (IDEXX, Westbrook ME). For USEPA Method 1600, presumptive enterococci isolates (identified with a blue halo) were selected from each plate and subcultured onto Todd Hewitt plates. For Enterolert, 70% ethanol was used to disinfect the back of the Quanti-Tray and media was removed from fluorescing wells with a sterile 1 ml syringe following methods used for isolation in Ferguson et al. 2013. Bacterial isolates were purified from both Enterolert and mEI because these two culture-based methods can differ due to substrate differences and/or differences in selectivity of the two methods (Ferguson et al. 2013).

Following purification of bacterial isolates, DNA was extracted according to Shanks et al. (2011). Universal primers were used to amplify partial 16S rRNA genes by PCR. The MoBio 12500-50 UltraClean PCR Clean-Up kit was used according to manufacturer's guidelines for DNA purification. Further processing and sequencing of the 16S gene was performed at UCLA Genotyping and Sequencing Core (GenoSeq, Los Angeles, CA) with the Biosystems 3730 Capillary DNA Analyzer, using capillary technology. Sequences were realigned with CLUSTALW (SDSC WorkBench 3.2) and blasted against the NCBI nucleotide database (NCBI-BLAST).

Horse PCR Sensitivity Analysis

To investigate whether negative samples analyzed from Topanga were a factor of poor LOD, an experiment was conducted to ascertain if the horse LOD varies depending on water matrix. HoF597 (horse marker) LOD was determined at our field site in creek (CW), lagoon (LW) and marine (MW) waters.

Fresh fecal matter from 12 individual horses was collected in the summer of 2013. Samples were collected into falcon tubes using sterile spatulas from fresh deposits, stored on ice and transported back to the lab for analysis. Approximately one gram of feces per horse was combined to make a composite sample of 12g, which was then diluted in 50mL of artificial freshwater (AW) (for AW recipe see Riedel et al., 2014) to create a final horse feces slurry concentration of 0.24g/mL. This procedure was repeated and new slurries created by spiking composite samples into the different water types: creek, lagoon or marine. A 1:100 dilution was then made from the initial slurry type (AW, CW, LW and MW) and used as the starting concentration for analysis (.00024g/mL).

3.3 <u>Results</u>

Comparison of geomeans for winter and recreational seasons for FIB and host-associated markers

Seasonal and weather effects on FIB/marker concentrations were examined by grouping data collected in the winter (November - March) versus recreational (April - October) season, or during active rainfall (raining) versus dry event (not-raining) samples.

For the overall study, when geometric means of the watershed FIB and marker values from winter season were compared to the geometric means of the recreational season, the winter season samples were four to eight times higher than recreational season samples for the Gull and Dog markers (Table 3-3). However, the geomeans of the winter and recreational season values for FIB (EC, ENT, and TC) as well as the human marker were within a factor of two of each other.

Table 3-3. Winter (Nov. 1 to Mar. 31) and Recreational Season (April 1 to Oct. 31) geometric means of FIB and marker values from Oct. 5th, 2011 to Aug. 11th, 2014. Values in parentheses indicate number of data points (N). Rain data not used in this analysis.

	TC MPN/100ml	**EC** MPN/100ml	**ENT** MPN/100ml	**HF** gene copies/100ml	**BH** gene copies/100ml	**Gull** gene copies/100ml	**Dog** gene copies/100ml
Winter	613.4 (180)	47.0 (180)	46.4 (188)	18.7 (176)	58.8 (121)	1855 (176)	1229.0 (174)
Recreation	1060 (184)	35.2 (184)	69.1 (207)	21.3 (200)	56.3 (119)	488.3 (201)	171.6 (199)

Comparison of geomeans for FIB and host-associated markers during active rain and not-raining events

Several sampling events occurred during active rainfall with largest rain events occurring on 10/5/11, 11/17/12, 1/24/13, 3/8/13, 2/27/14. When geometric means of the watershed FIB and marker values of samples taken during rain were compared to the geometric means of non-rain samples, the rain samples were three to nine times higher than non-rain samples with the exception of Gull marker (Table 3-4). Geometric means for all markers and FIB were higher in samples collected during active rainfall, which is typical of other studies throughout southern California (Noble et al. 2003, Boehm et al. 2002, Surbeck et al. 2006).

Table 3-4. Geometric means of FIB and marker values for all samples collected during active rainfall versus all samples collected when not actively raining from Oct. 5th, 2011 to Aug. 11th, 2014. Values in parentheses indicate number of data points (N).

	TC MPN/100ml	**EC** MPN/100ml	**ENT** MPN/100ml	**HF** gene copies/100ml	**BH** gene copies/100ml	**Gull** gene copies/100ml	**Dog** gene copies/100ml
Raining	3340.4 (50)	361.5 (51)	278.4 (59)	69.6 (51)	324.2 (42)	1082.0 (50)	4007.1 (49)
Not Raining	808.8 (364)	40.6 (364)	61.8 (379)	20.1 (376)	57.1 (242)	910.5 (377)	430.0 (373)

Relationship between FIB levels and environmental variables

The relationship between the following physical and chemical variables (conductivity, temperature, dissolved oxygen, pH, turbidity, and nutrients) and FIB levels was compared. Temperature, conductivity, and pH levels were not correlated with FIB levels. Turbidity levels were highly correlated with ENT and EC measurement at several of the creek sites: BR (ENT R=0.76, EC R=0.96), ST (ENT R=0.99, EC R=0.99), and OF (ENT R=0.90, EC R=0.91). Nutrient levels (nitrate and phosphate) were also correlated with ENT and EC levels at the upper watershed sites: ST (R>0.75) and OF (R>0.90). Fecal sources may contain increased levels of nutrients and turbidity, which could result in the correlations seen here. At the lower watershed sites (TB, BR, and SP), nutrients and FIB levels were not correlated.

Spatial analysis along the creek of geometric means of FIB and host-associated markers

Five sites along the creek (OF, ST, TB, BR and SP) were analyzed for FIB and host-associated markers. Geometeric means of TC remained high at all sites sampled, suggesting a natural background signal of total coliform bacteria in the creek. Highest levels of all three FIB were observed just downstream of the developed portion of the watershed near the town of Topanga at Owl Falls site (6500 m). A decrease was seen immediately downstream of this site at Scratchy Trail (4800 m) for geometric means of EC and ENT. Values increased somewhat by SP (300 m), the site just upstream of Topanga Lagoon for EC (Figure 3-1).

In addition, a selection of samples from creek sites was analyzed for the horse marker. All samples analyzed, including samples from the first flush rain event during year two of the study, were negative for the horse marker (n=34). Further, the limit of detection was calculated for the horse marker assay. Using a slurry of fecal matter collected from twelve horses from the Hansen Dam Equestrian Center on September, 17th, 2013, endpoint PCR was performed on a series of ten-fold dilutions. In all waters tested, the LOD was between 0.01 and 0.1 CFUs/µL of DNA extract.

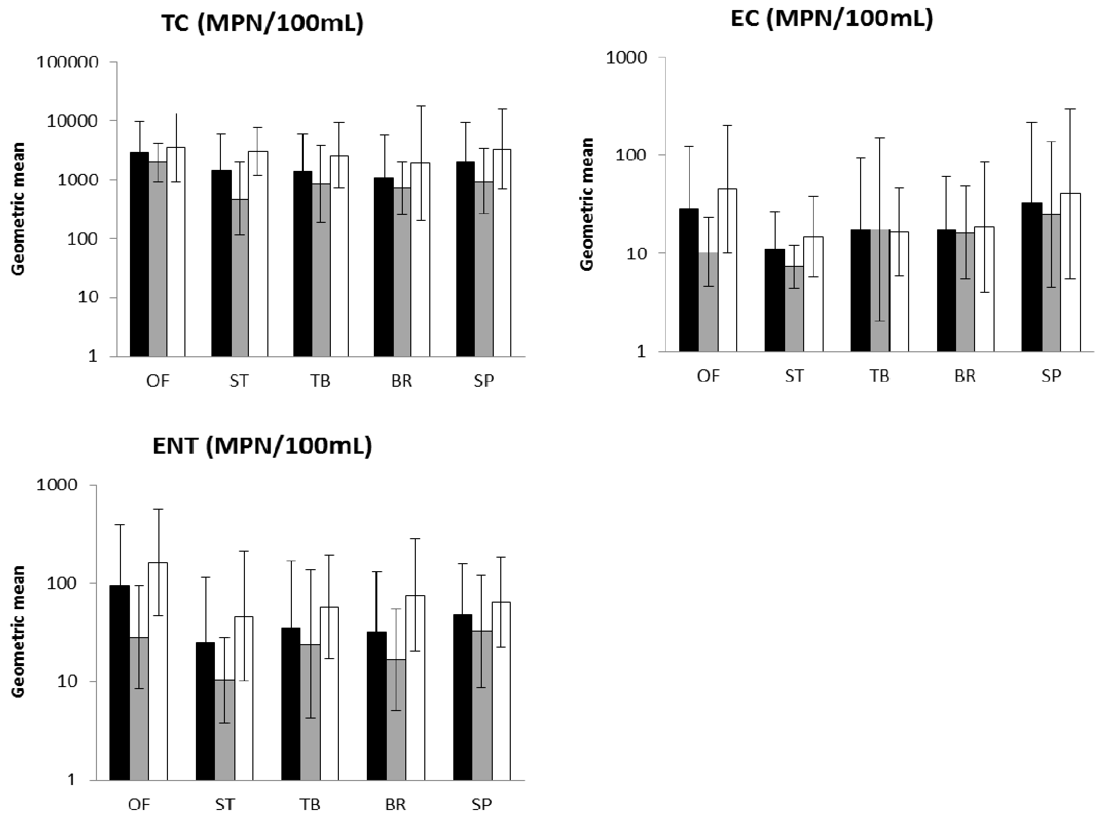

Figure 3-1. FIB values for Topanga Creek sites: Owl Falls (6500m OF), Scratchy Trail (4800m ST) Topanga Bridge (3600m TB), Brookside Dr. (1700m BR) and Snake Pit (300m SP) from 5 Oct 2011 to 11 August 2014. Note the log scale vertical axis to accommodate the large range of values and the scale range changes. The sites are ordered from north (left) to south (right). The overall geomean for each site is shown in black while gray indicates the winter season geomean and white indicates the recreational season geomean.

As with EC and ENT, the geomeans of the human- and dog-associated markers were highest at OF and decreased at the next downstream site, ST. For most of the creek, dog marker had a geomean of 100 copies/100 mL. Levels of the gull-associated marker were low throughout the creek with a geomean of approximately 100 copies/100 mL (Figure 3-2).

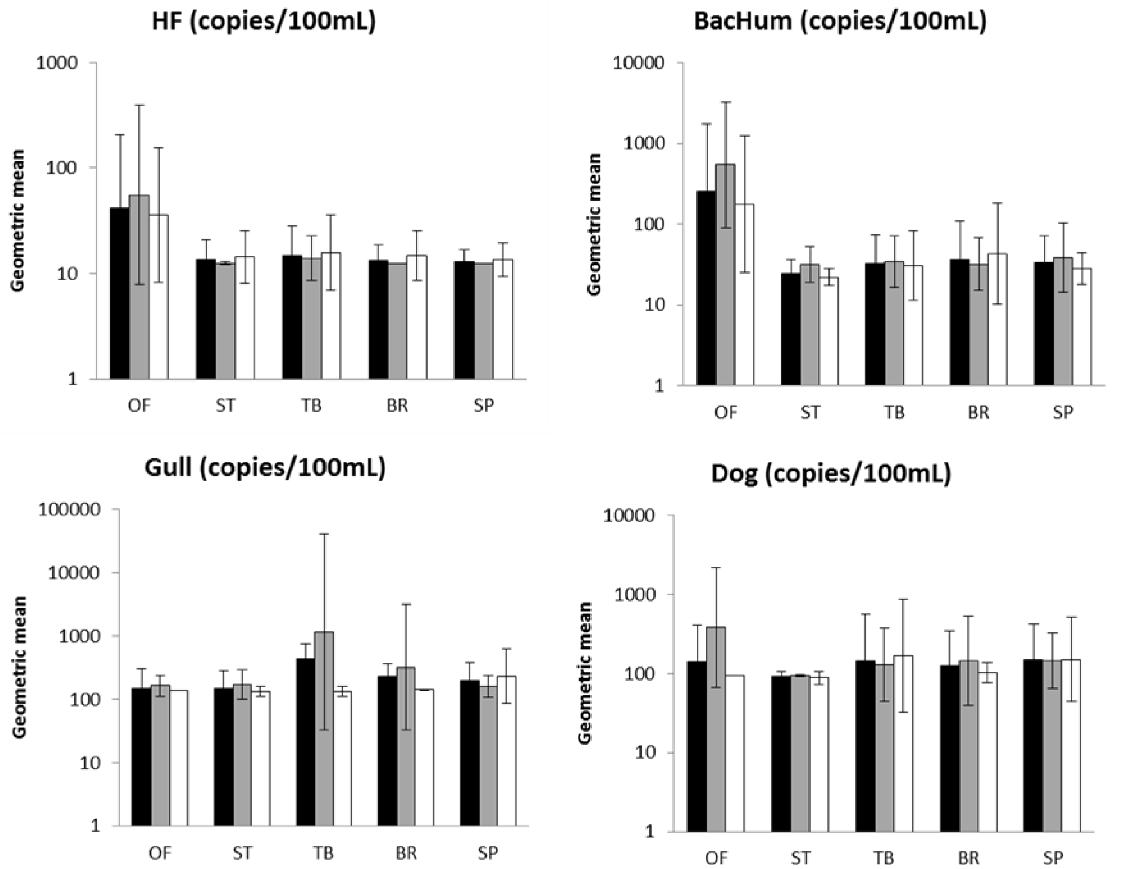

Figure 3-2. Marker values for Topanga Creek sites: Owl Falls (6500m OF), Scratchy Trail (4800m ST) Topanga Bridge (3600m TB), Brookside Dr. (1700m BR) and Snake Pit (300m SP) from 5 Oct 2011 to 11 August 2014. Note the log scale vertical axis to accommodate the large range of values and the scale range changes. The sites are ordered from north (left) to south (right). The overall geomean for each site is shown in black while gray indicates the winter season geomean and white indicates the recreational season geomean.

Analysis of Predicted Surfzone FIB From Creek Input During Drought and Normal Rainfall Conditions

In order to gauge relative impact of creek fecal inputs on surfzone water quality, predicted surfzone FIB was calculated based on creek flow and creek FIB concentrations from the current study period (2012-2014) and from historical data taken between 2003-2004. During the 2003-2004 study period Topanga received 18.71 inches of cumulative rainfall compared to 9.99 in 2013 and 6.85 so far in 2014.

In the period that was studied for this report, Topanga Lagoon and Creek acted as primarily disconnected systems, with inputs to the upper watershed decreasing prior to reaching the lower watershed. In order to speculate about potential impacts from the upper watershed on surfzone FIB during different flow regimes, dilution factors were calculated for creek inputs to the ocean. The contribution of freshwater discharge to surfzone FIB was approximated using a two end-member conductivity model, modeled after McLaughlin et al. (2007).

Conductivity at the Beach Outlet site was used as a conservative tracer to predict fraction of creek input to surfzone on days when the lagoon was connected. 100% creek was estimated based on average conductivity of all creek sites and 0% creek conductivity was estimated based on maximum conductivity at Beach Upcoast when the lagoon was not discharging. Using the end-member model, contribution of creek water to beach outlet on days when the lagoon was connected was calculated. This was then converted to a range of dilution factors for creek to ocean and related to creek flow at each time point. The relationship between dilution factor at Beach Outlet and creek flow rate was not linear, due to various mixing mechanisms, and had a logarithmic relationship ($y = -6.193\ln(x) + 11.207$, $R^2=0.85$). This relationship was then used to predict a conservative dilution factor for each sampling date based on creek flow. Creek flow data available for the 2003-2004 analysis were qualitative and ranked 1-4. These values were converted to an estimated quantitative flow measurement.

Once dilution factors had been calculated, as described above, these were applied to actual creek FIB values in order to speculate on predicted contribution of creek FIB to surfzone FIB levels, for a connected system. This analysis was speculative and assumed an open lagoon to the ocean, which would be the conservative approach. For the 2003-2004 season, when FIB and flow data from Topanga Bridge were used, creek FIB could have potentially led to exceedances in the surfzone on two out of 14 dates sampled. One of these dates was first flush (10/19/2004) and the other date (9/14/2004) had extremely elevated ENT (ENT>1500MPN/100 mls). When FIB and flow levels were applied from Falls Drive, predicted surfzone ENT levels were in exceedance only during the first flush event.

For the 2012-2014 season, when FIB and flow data from Topanga Bridge were used, this analysis predicted that creek FIB could have led to one exceedance of surfzone FIB levels, this date corresponded to the 2014 first flush event, and two exceedance events if Owl Falls flow and FIB data were applied, with one of these two events corresponding to the 2014 first flush event. Based on this analysis, it does not appear that creek FIB contribute significantly to elevated surfzone FIB, except during events of elevated flow and elevated FIB, such as a first flush event (Figure 3-3). Further, analysis of FIB data from 2003-2004 confirms that this trend may carry over to rainier years, which experience increased flow and connectivity between upper and lower watershed sites.

Spatial analysis in the lagoon of geometric means of FIB and host-associated markers

Levels of FIB in Topanga Lagoon did not vary with location or season (Figure 3-4). For the human-associated marker, a higher geomean was observed during recreational season at the lagoon outlet. However, data plots included for lagoon outlet are from year one of sampling only, though May 28, 2013. Also, there was a marked difference in the observed levels of dog-associated markers by season. Levels of the dog-associated marker in recreational season were lower than those observed in the winter for all three lagoon sites. This marker increased by ten to 100 times from the creek to the lagoon. Geomean for the gull-associated marker was 100 to 1000 times greater than levels seen in the creek. FIB levels were comparable between the three sites for wet and recreational season, indicating that FIB is fairly homogenous throughout the lagoon.

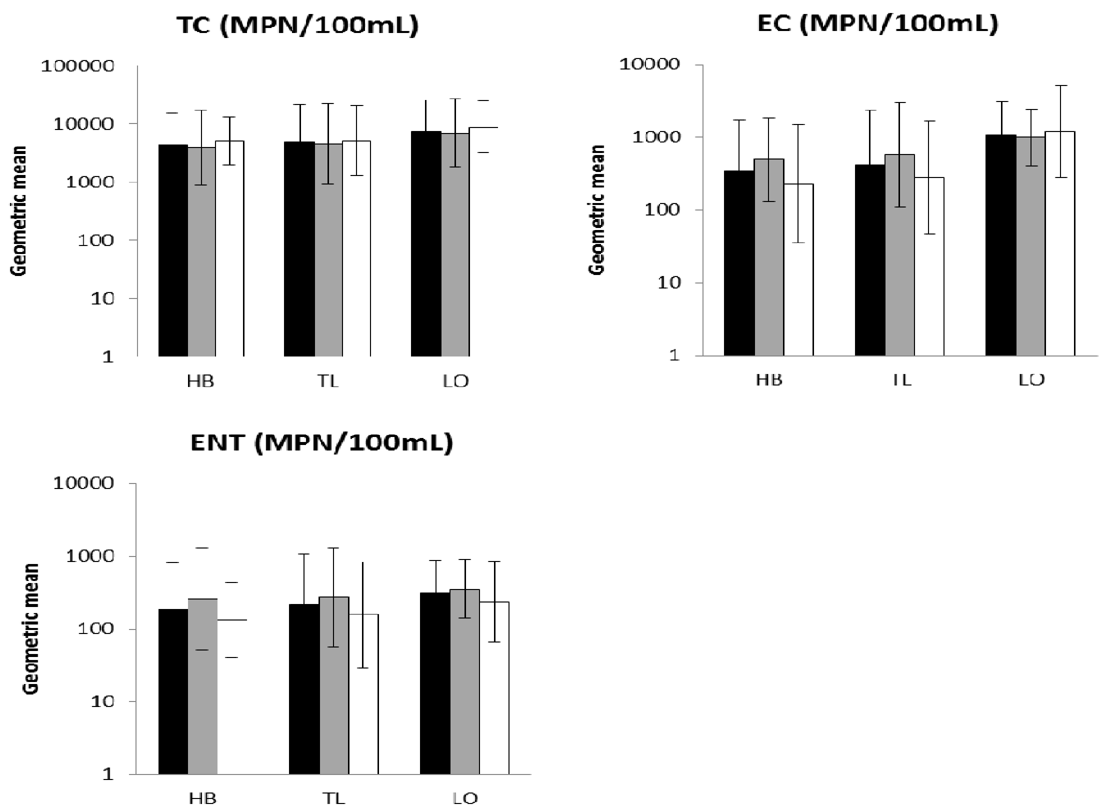

Figure 3-4. FIB values for lagoon sites (PCH Bridge over upper end of the lagoon-HB), Topanga Lagoon east wall-TL, Lagoon Outlet-LO) from 5 Oct 2011 to 11 August 2014. Note the log scale vertical axis to accommodate the large range of values and the scale range changes. The sites are ordered from north (left) to south (right). The overall geomean for each site is shown in black while grey indicates the winter season geomean and white indicates the recreational season geomean. ND indicates the limit of detection. Numbers under the x-axis indicate quantity of observations for each geomean.

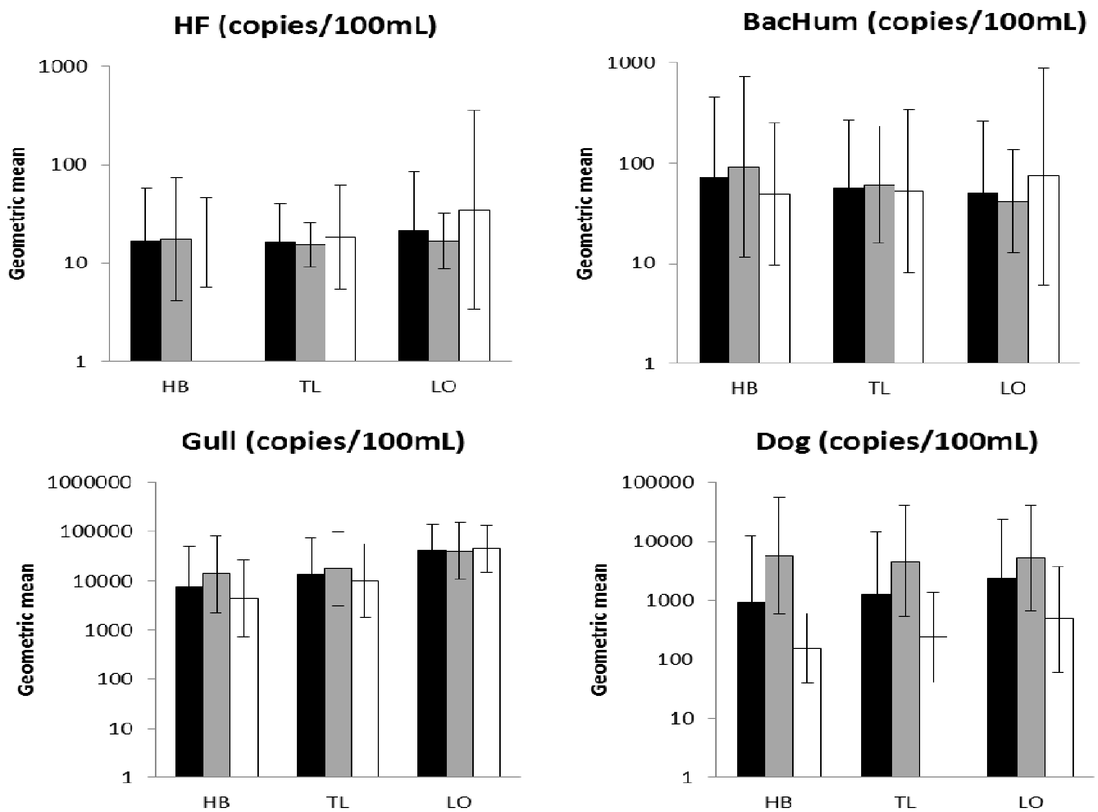

Figure 3-5. Geometric means for host-associated marker values for lagoon sites (PCH Bridge over upper end of the lagoon-HB, Topanga Lagoon east wall-TL, Lagoon Outlet-LO) from 5 Oct 2011 to 11 August 2014. Note the log scale vertical axis to accommodate the large range of values and the scale range changes. The sites are ordered from north (left) to south (right). The overall geomean for each site is shown in black while grey indicates the winter season geomean and white indicates the recreational season geomean. ND indicates the limit of detection. Numbers under the x-axis indicate quantity of observations for each geomean.

Spatial analysis in the ocean of geometric means of FIB and host-associated markers

The most striking trend for FIB levels in the ocean was the marked increase in the geomean for ENT observed from Beach Upcoast (BU), to Beach Outlet (BO), to Lifeguard (LG). The prevailing current is eastward at Topanga Beach; thus, these results suggest that the lagoon serves as a source of FIB to the ocean. Further, FIB levels at the ocean sites were higher at BO and LG (especially for ENT), indicating that upcoast sources are not likely contributing to FIB levels at BO and LG.

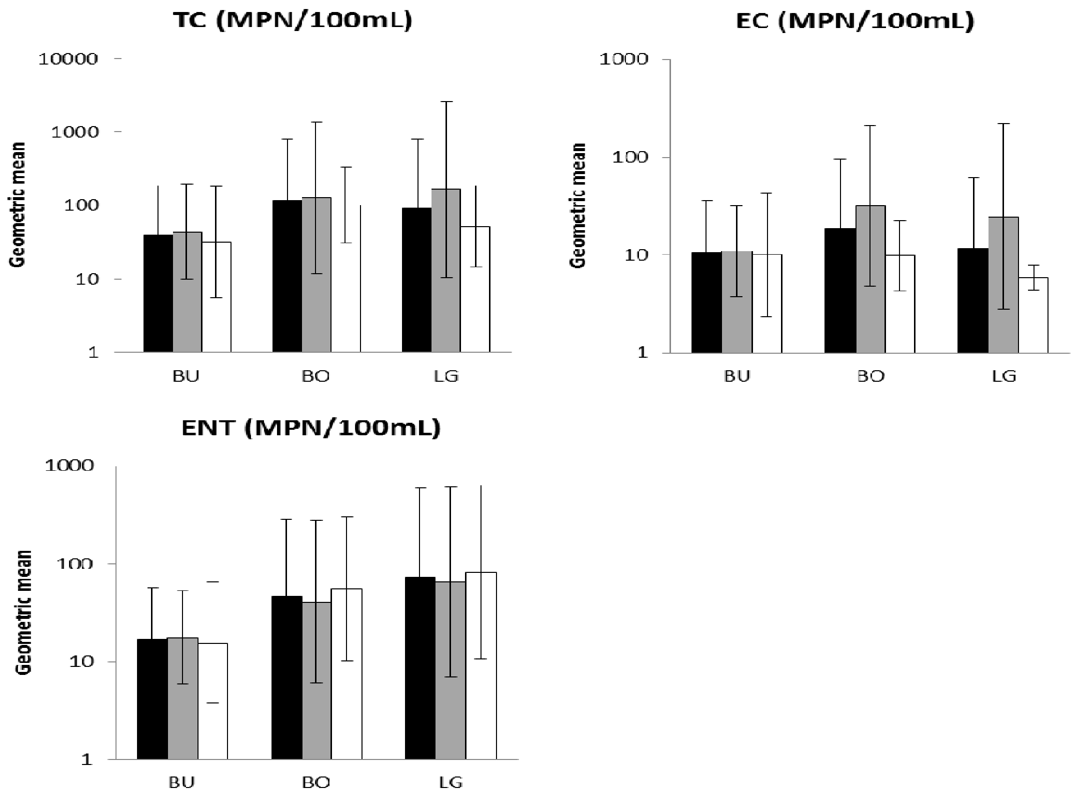

Figure 3-6. FIB values for ocean sites (Beach Upcoast-BU, Beach Outlet-BO) from 5 Oct 2011 to 11 August 2014. Note the log scale vertical axis to accommodate the large range of values and the scale range changes. The sites are ordered from west (left) to east (right). The overall geomean for each site is shown in black while grey indicates the winter season geomean and white indicates the recreational season geomean. ND indicates the limit of detection. Numbers under the x-axis indicate quantity of observations for each geomean.

In the recreational season, the human-associated marker tends to decrease in the west to east direction. This may correlate with the transient population frequenting this section of beach. Levels of dog-associated marker were also highest at BU. As seen in the lagoon, levels of dog-associated marker were higher in the winter season.

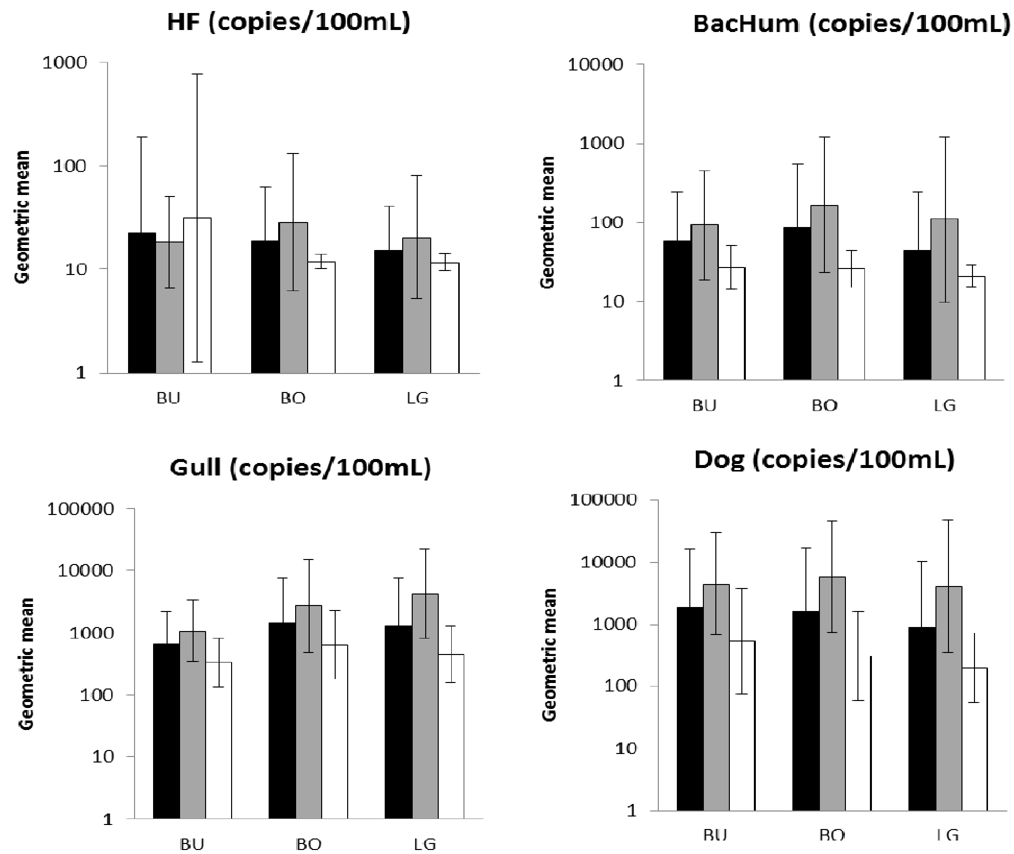

Figure 3-7. Geometric means of host-associated marker values for ocean sites (Beach Upcoast BU, Beach Outlet BO) from 5 Oct 2011 to 11 August 2014. Note the log scale vertical axis to accommodate the large range of values and the scale range changes. The sites are ordered from west (left) to east (right). The overall geomean for each site is shown in black while grey indicates the winter season geomean and white indicates the recreational season geomean. ND indicates the limit of detection. Numbers under the x-axis indicate quantity of observations for each geomean.

Analysis of Frequency of Exceedances of Bacteria Standards at Lagoon and Ocean Sites

Frequency of samples that exceeded the single sample standards of: 104 MPN/100 ml for ENT, 400 MPN/100 ml for EC, and 10,000 MPN/100 ml for TC were analyzed for BU, BO, LG, and TL. Tables 3-5 and 3-6 show the percentage of sampling dates when either TC, EC, or ENT was in exceedance.

Table 3-5. Frequency of exceedance of state bacteria standards for TC, EC, ENT at BU, BO, LG, and TL during winter and recreational seasons (April1 –Oct 31). Sampling events occurring during active rain were excluded from analysis.

	BU		BO		LG		TL	
	Winter	Recreation	Winter	Recreation	Winter	Recreation	Winter	Recreation
TC	0%	0%	10%	0%	8%	0%	33%	31%
EC	0%	0%	5%	0%	8%	0%	52%	44%
ENT	15%	14%	19%	33%	25%	31%	81%	69%

Table 3-6. Frequency of exceedance of state bacteria standards for TC, EC, ENT at BU, BO, LG, and TL for all sampling dates. Sampling events occurring during active rain were excluded from analysis.

	BU	BO	LG	TL
TC	0%	5%	4%	32%
EC	0%	3%	4%	49%
ENT	15%	26%	28%	76%

TC and EC exceedances were infrequent for the ocean sites, with BU in compliance of TC for all sampling dates included in analysis (all dates sampled except active rain events). However, TL exceeded 32% of the time for TC and 49% of the time for EC. For ENT, BO, BU, and LG exceeded more often, exceeding the state bacterial standard between 15 and 28% of the time. Overall, the frequency of exceedances for FIB was higher at LG and BO than at BU. TL was in exceedance for ENT and EC on more than half of sampled dates.

Analysis of ENT isolates with 16S rRNA Sequencing

Speciation of a selection of ENT isolates was completed in order to provide complementary information regarding ENT measured at the lagoon and ocean sites. Twenty isolates were isolated from mEI agar at Topanga State Beach and Topanga Lagoon, during summer 2013, and 100% of these isolates were identified as *E. faecalis*. *E.faecalis* is thought to be more fecal-associated than other species of enterococci such as *E.gallinarum* or *E.casseliflavus* (Ferguson et al., 2013).

Analysis of Frequency of Marker Detection at Lagoon and Ocean Sites

Human marker detections were infrequent at the ocean and lagoon sites, with three detections during Year one and two detections during Year two. For both years, one of these detections (and the highest level of human marker detections) corresponded with the first flush event. Presence of transients and human feces were recorded for each sampling event. Human feces were observed on seven different sampling days, while transients at Topanga Beach were recorded on 14 different sampling days. Only on February 24, 2013 did a positive human signal at BU (82 copies/100 ml) coincide with recorded observations of both transients and human feces. For the remaining 13 dates when transient activity was recorded, all samples collected at marine and lagoon sites (BO, BU, LG, HB and TL) were negative for the human marker. For human feces, the human marker was positive when the presence of human direct deposits was observed on two separate dates (Feb 24 2013 and July 2 2014). In addition, a second ocean site, LG, was also positive for the human marker on the February 24, 2013 sampling date.

Overall, the human-associated marker was detected in 13% of ocean water samples and in 14% of lagoon water samples collected during the course of the study. The human-associated HF183 marker was detected six times throughout the study at the Beach Outlet (BO), four times in the first period of the study (Oct 11 2011 – July 1 2013) and twice during the second period of the study (July 31 2013 – August 11 2014). Other marine sites were also positive for the human marker on two (LG) and four (BU) occasions (Figure 3-8).

A.

Marker	Site			Total
	BU	**BO**	**LG**	**Ocean**
HF183	12%	16%	8%	13%
Gull	76%	84%	80%	80%
Dog	76%	74%	58%	71%

B.

Marker	Site			Total
	HB	**TL**	**LO**	**Lagoon**
HF183	8%	17%	20%	14%
Gull	91%	95%	100%	94%
Dog	58%	64%	80%	64%

Figure 3-8. Frequency of detection of gull, dog, and human marker at lagoon and ocean sites for all sampling dates. A) Frequency of marker detection at ocean sites. B) Frequency of marker detection at lagoon sites.

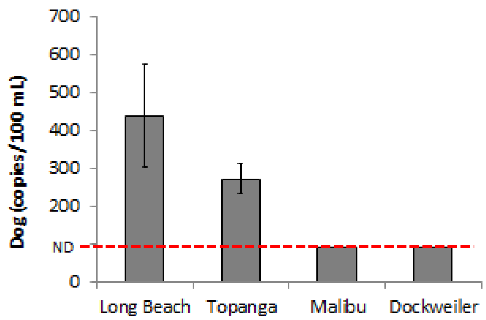
Dog and gull marker were both detected in high frequency at lagoon and ocean sites. Gull levels were detected 94% of the time in lagoon samples and 80% of the time in ocean samples. Dog marker levels were detected on average 71% of the time at ocean sites and 64% of the time at lagoon sites.

In order to better understand levels of dog marker seen in Topanga, a dog survey study was conducted to determine the impact of dog fecal waste on Topanga water quality. Sediment and water samples were collected from four beaches and analyzed for FIB and the dog marker. Levels measured at Topanga were compared to reference sites that are free of dogs and to a dog beach where dogs are permitted and regularly frequent the designated beach area. Reference beaches (Malibu and Dockweiler) were negative for the dog marker in all sediment and water samples collected. Sediment samples collected from Rosie’s Dog Beach in Long Beach, CA were also negative for the dog marker. However, all water samples from Rosie’s Dog Beach had detectable levels (219 – 823 copies/100 ml) of the dog-associated marker. Highest average ENT concentrations (91 MPN/100 ml) from all four sites sampled was measured from Rosie’s Dog beach (Figure 3-9).

Although dogs are prohibited at Topanga, levels measured from Topanga Beach were similar to those seen at the Rosie’s Dog Beach. All sediment samples were negative for the marker, except one (Site 6 – 159,303 copies/100 ml). Three of seven water samples (43%) collected on May 2, 2014 were positive for the dog marker at Topanga Beach. Water samples had dog marker concentrations ranging from 193 – 334 copies/100 ml (Figure X). FIB measured from sediment were typically low (0.5 – 7.1 MPN/g) for ocean sites. Average FIB concentrations for water samples were 51MPN/100 ml and 29 MPN/100 ml for EC and ENT, respectively.

In this single day dog survey, fecal waste did not appear to impact the sand at beaches sampled, however, there was a measureable impact on water quality.

A.



B.

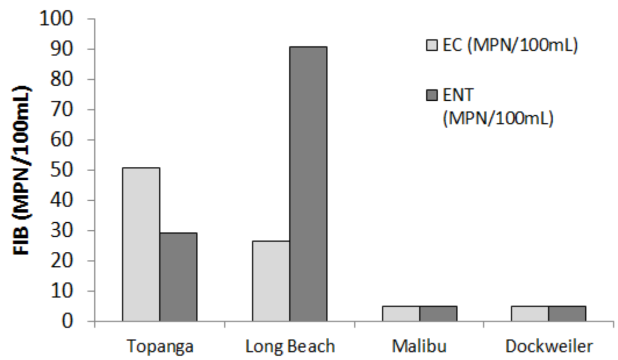


Figure 3-9. A) Average dog marker levels in water sampled during dog survey at the dog beach (Long Beach), Topanga, and the two reference beaches (Malibu and Dockweiler). B) Average FIB levels in water sampled during dog survey at the dog beach (Long Beach), Topanga, and the two reference beaches (Malibu and Dockweiler).

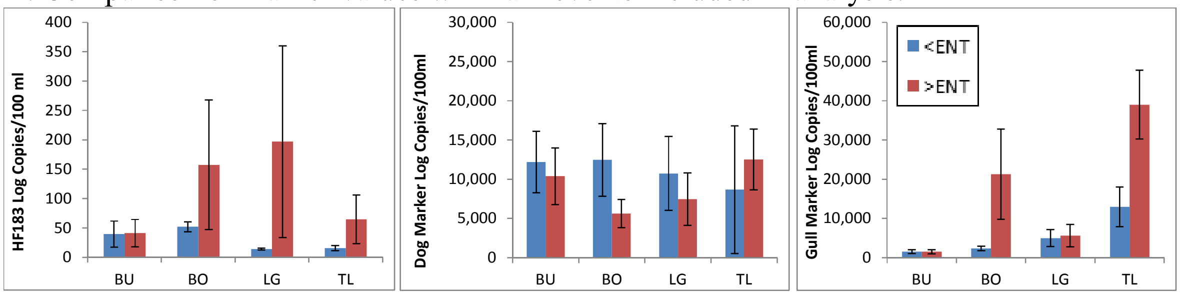
Relationship between FIB and DNA-marker levels at the lagoon and ocean

To determine whether exceedances in ENT or EC are indicative of a higher magnitude of host-associated fecal markers, data were combined for each of the three ocean sites and for the TL (Topanga Lagoon) site according to whether the water quality standard for enterococci of 104 MPN/100mL was exceeded or in compliance.

For the BO (Beach Outlet), LG (lifeguard Station), and TL (Topanga Lagoon) sites, there was a clear trend for increased human marker levels when ENT was in exceedance versus in compliance both when rain events were included and excluded from analysis. At BO (Beach Outlet) and TL (Topanga Lagoon) there was also a trend for increased gull marker levels when ENT was in exceedance versus in compliance.

A. Comparison of marker values with rain events included in analysis.



B. Comparison of marker values with rain events excluded from analysis.

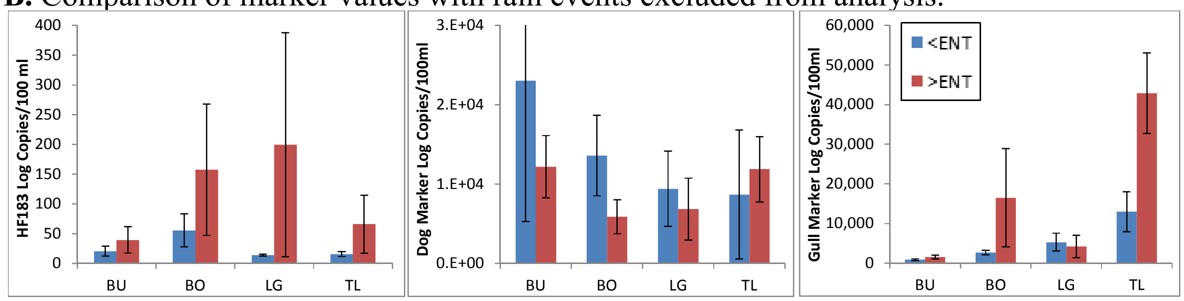


Figure 3-10. Average marker data were grouped and compared by whether ENT exceeded state water quality standards at the three ocean sites and one lagoon site: BO (Beach Outlet), BU (Beach Upcoast), LG (Lifeguard Station), and TL(Topanga Lagoon), Figure depicts average marker concentrations when ENT was in compliance (blue bars) versus in exceedance (red bars) and standard error of the mean.

Due to potential differences in environmental decay rates of these markers, it is difficult to directly compare contribution of different sources to FIB concentrations. Analysis below is solely an approximation of potential FIB concentration resulting from dog and gull sources. The geomean for the dog and gull marker for ocean and lagoon sites, on days when gull and dog marker were detected, is listed below in Table 3-7. The concentration of dog and gull marker detected was converted to gram feces per 100 ml based on 10*10^10copies per gram wet dog feces and 8.15 *10^6 copies per gram wet gull feces from prior studies (Ervin et al. 2014, Riedel et al. 2013). This was then converted to approximate CFU/100 ml *Enterococcus* based on an estimated 2.38*10^4 MPN/gram gull feces (from this study) and 8.8*10^7 CFU/gram dog feces (from Ervin et al. 2014). The relationship between grams of wet gull feces and ENT concentration was based on measurement of ENT from gull feces collected from 15 gulls at Topanga Beach on October 30, 2013.

Average input to Topanga Lagoon and ocean, based on best estimates from the literature, shows that both dog and gull are likely contributing to elevated FIB in the lagoon and surfzone. In particular, gulls appear to contribute to impaired water quality at the lagoon.

Table 3-7. Estimated enterococci concentration resulting from average dog and gull marker concentration at lagoon and ocean sites.

Marker	Site	Geomean copies/100 mls	Estimated gram feces/100 ml	Estimated ENT cfu/100 ml
DOG	BO	5705	6.E-07	50
	BU	4083	4.E-07	36
	LG	3518	4.E-07	31
	TL	4425	4.E-07	39
Gull	BO	2206	3.E-04	89
	BU	1057	1.E-04	43
	LG	2655	3.E-04	107
	TL	17542	2.E-03	710

3.4 Discussion

Within the MST portion of this study, the following hypotheses were tested and results are as follows:

1. *Lagoon discharge negatively impacts water quality at Topanga Beach.*

Based on the historical analysis, the lagoon is a source of FIB to the ocean. FIB levels are significantly increased when the lagoon is breached and connected to the ocean regardless of winter or recreational season.

2. *Concentrations of FIB and/or host-associated markers decrease as the creek flows downstream towards the lagoon.*

FIB in the surfzone do not primarily originate from an upstream creek source, except under extremely elevated FIB levels and high flow events (during first flush events). Conditions in the creek along the Narrows section, located between Owl Falls (6500 m) and Scratchy Trail (4800 m) appear conducive to a decrease in EC and ENT levels and observed levels of human- and dog-associated marker. This observed sink is also confirmed in the laboratory microcosms conducted to explore decay of FIB and markers (see Appendix J for more detail). Inactivation rates of FIB and the human marker were highest in ST and OF sediment, likely due to sediment characteristics.

Further, our predictive analysis confirms that creek FIB do not contribute significantly to surfzone FIB, except under extremely elevated FIB levels and high flow events (such as first flush events). This pattern is likely to hold during years that have increased rainfall.

3. *Spatial and temporal patterns of FIB and host-associated markers exist between sites in the lower watershed.*

Levels of FIB and all markers increase from the lower watershed creek site (SP), located 300m upstream of the lagoon, to lagoon sites. For TC, an increase of a factor of five is seen, while for EC a factor of 10-20 increase is observed. For ENT, a factor increase of 3-30 is observed. Thus, the lagoon may serve either as a location where microbial levels may be increasing due to growth or to the presence of new inputs. The host-specific markers do not multiply in the environment, thus their increase in the lagoon indicates lower watershed sources. FIB, on the other hand, may result from those fecal inputs or from environmental growth. Regardless, the lagoon appears to be a source of both FIB and host-associated markers.

4. *Lower watershed and/or lagoon sources of FIB (human and non-human inputs such as gull, dog, etc.) are correlated with exceedances at Topanga Beach.*

Dog and gull marker appear to be a significant source to the lagoon and ocean and likely contribute to exceedances seen in FIB data. Based on best estimates from the literature, when gull and dog marker concentration was converted to an estimated ENT concentration, both gull and dog marker levels were high enough to elevate surfzone and lagoon FIB. Gull levels were detected 94% of the time in lagoon samples and 80% of the time in ocean samples, indicating that gulls are an important and chronic source of fecal contamination to Topanga Lagoon and ocean sites. Further, dog marker levels in Topanga waters were similar to those measured at Rosie's Dog Beach in Long Beach, CA and were detected on average 71% of the time at ocean sites and 64% of the time at lagoon sites. This confirms that dog waste is also a significant source of fecal contamination to Topanga Lagoon and ocean.

Human marker was detected infrequently in the lagoon and ocean. There was a clear trend for increased average human marker level when ENT was in exceedance at BO, LG, and at TL. During Year 1 (July 2012 to June 2013), human-associated marker was detected in the ocean on five sampling dates, including first flush, and also on four dates in the lagoon, one of which was first flush. There was a total of seven dates with either ocean or lagoon detection. Results from Year 2 (July 2013 – June 2014) are encouraging, as human marker was detected in the ocean on just two days, one of which was first flush. For the lagoon, human hits were observed only during the first flush event of Year 2. Further sampling for the human-associated marker is recommended to determine if this trend continues and if it will continue to occur under non-drought conditions.

Summary

- The lagoon is a source of FIB to the ocean. FIB levels are significantly increased when the lagoon is breached.

- Levels of FIB and all markers increase from the most downstream creek site (SP) to the lagoon. The lagoon may serve either as a location where microbial levels may be increasing due to growth (FIB) or to the presence of new inputs (FIB and markers).

- Upstream creek sources do not appear to be a primary contributor to FIB in the surfzone, except on days when both flow and FIB levels in the upper watershed are elevated. Days where creek input had potential to significantly impact downstream levels occurred on two sampling dates during this study, including the first flush event during year two of the study.

- Winter samples were four to eight times higher than samples for the recreational season for the dog and gull marker, indicating that these markers follow a seasonal trend and may have more of an impact to water quality during the winter.

- Dog and gull marker appear to be a significant source to the lagoon and ocean and are likely contributing to exceedances of ENT and EC state water quality standards at the ocean sites. When ENT levels were in exceedance, gull marker levels were higher than when ENT was in compliance at BO, and TL. When dog marker levels in Topanga water samples were compared to levels at two reference beaches and one dog beach, dog marker levels at Topanga were similar to levels at the dog beach. No dog marker was detected at the two reference beaches sampled (Dockweiler and Malibu).

- Human marker was detected infrequently in the lagoon and ocean. Average human marker values were higher at ocean sites when ENT was in exceedance vs. in compliance of state water quality standards. During Year 1 (July 2012 to June 2013), human-associated marker was detected in the ocean on five sampling dates, including first flush, and also on four dates in the lagoon, one of which was first flush. There was a total of seven dates with either ocean or lagoon detection. Results from Year 2 (July 2013 – June 2014) are encouraging, as human marker was detected in the ocean on just two days, one of which was first flush. For the lagoon, human hits were observed only during the first flush event of Year 2.

4 Description of human health risk associated with human and non-human sources of fecal contamination

In Topanga, continued sampling for human-associated marker is recommended. Detailed description of human marker results are provided in the MST chapter of this report. Briefly, during Year 1 (July 2012 to June 2013), human-associated marker was detected in the ocean on five sampling dates, including first flush, and also on four dates in the lagoon, one of which was first flush. There were a total of seven dates with either ocean or lagoon detection. Results from Year 2 (July 2013 – June 2014) are encouraging, as only human hits were detected in the ocean on just two days, one of which was first flush. For the lagoon, human hits were observed only during first flush of Year 2. Further sampling is needed to determine if this trend continues and what occurs under non-drought conditions.

This study showed attenuation of upper watershed FIB sources through the creek, including the human marker. Notably, however, this study occurred under drought conditions, and extension of findings to typical conditions should be done with care. As described in detail in the MST chapter, using flow and FIB levels from both this work and a previous study conducted in 2003 - 2004 taken together, the extent to which upper watershed sources have the capacity to affect beach water quality under higher flow conditions was estimated. Conductivity measured at the beach outlet was used with flow measurements to estimate a relationship between flow and the dilution factor, which is a non-linear function of flow due to various mixing mechanisms. Using FIB data along with qualitative flow estimates from the previous study, and assuming steady flow at the lagoon, creek FIB had the capacity to cause exceedances on the beach when both flow and FIB levels are high. Specifically, ENT present at greater than approximately 1500 MPN/100 mL, which occurred twice from the 2003 – 2004 sampling effort and twice during the two-year period of this work, were projected to impact beach water quality.

Previous studies have well established that there is a correlation between the levels of FIB in recreational waters and incidence of illness when the likely source of fecal contamination is human. Landmark studies (Cabelli et al. 1982, Kay et al. 1994) provide dose-response curves between levels of FIB and observed ailments in swimmers. The risks associated with exposure to non-human sources of fecal matter in recreational water are still not well characterized, as epidemiological data on this topic are still insufficient.

Studies of the relevance of these relationships to beaches with nonhuman sources of FIB show various outcomes. There is some evidence in the literature for greatly reduced risk in water polluted by nonhuman fecal matter. Cheung et al. (1991) studied nine beaches in Hong Kong and mentioned that one beach with primarily livestock sources did not show increase risk of illness in accord with what would be predicted by the traditional models. However, differentiating between pathogenicity of sources was not a focus of the study and sources at the other beaches are not discussed.

Other studies conducted at beaches without a direct human source show increased risk of ailments in swimming populations, but not in a dose-response relationship with indicators. For example, at a marine beach without a known source of sewage, Fleisher et al. (2010) did not observe increased illness at higher levels of ENT. However, for the group of participants randomly assigned to swim, the risk of gastrointestinal, acute febrile respiratory, and skin illness increased by factors of 1.76, 4.46, and 5.91, respectively.

Similarly, in Mission Bay, CA, where FIB are primarily from nonhuman sources, a large epidemiology study showed that the incidence of illness was not associated with FIB levels (Colford et al. 2007). However, with swimming defined as any water contact at all, swimmers had significantly higher rates of diarrhea and skin rash than non-swimmers. With swimming defined as having swallowed water, the risk for diarrhea increased, and the risks for skin rash, cramps, and eye irritation were all significantly higher than for non-swimmers.

A third group of epidemiological studies do show relationships between illness and FIB levels that are comparable to those observed at beaches impacted with human waste. For example, a local epidemiological study was conducted at Doheny Beach in Orange County in 2007 and 2008 (Colford et al. 2012). Urban runoff via San Juan Creek is the largest source of FIB to this beach. In this study, 9,525 individuals were studied to determine the relative illness rates at various levels of exposure (non-swimming, body immersion, head immersion, and swallowed water.) Water quality parameters were measured traditionally; in addition, enterococci were measured by three rapid methods. Some notable findings from this study include: 1) The risk of diarrhea was significantly increased among all swimming groups compared to non-swimmers; 2) Eye infections and earaches occurred at higher rates for swimmers; and 3) FIB levels were strongly positively associated with diarrhea. The strongest association was observed for those swallowing water on days San Juan Creek was flowing into the ocean.

At beaches in Santa Monica Bay, Haile et al. (1999) studied health effects due to swimming in coastal water impacted by storm drain runoff (which had tested for presence of human associated viruses). While most epidemiological studies compare swimmers with non-swimmers, this study compared only swimmers, and took into account the distance from a storm drain and the water quality at that time and location. The three major findings: 1) The risk of many ailments was higher among subjects swimming near the storm drain; 2) There was a positive association between adverse health outcome and the levels of bacterial indicators; and 3) The relative risk was in general higher for swimming in water containing observable levels of enteric viruses.

McBride et al. (1998) studied the risk of illness at seven beaches in New Zealand. The study included two control beaches with minimally impacted water quality, two beaches impacted by animal fecal matter, and three beaches with elevated human fecal waste. The results showed risks at beaches impacted with human and non-human fecal matter to be similar, and much higher than risks at control beaches.

Thus, while the World Health Organization assumes that non-human fecal sources pose less of a risk compared to human fecal sources (WHO, 2003), data are still needed to fully understand this issue.

Interest is growing in quantitative microbial risk assessment (QMRA) as a framework for understanding risk of illness in recreational water exposure. It is based on hazard assessment (understanding which pathogens pose a risk), an exposure assessment (based on known information regarding many factors including ecology of the microorganisms), and knowledge of the dose-response relationships. A drawback to this approach is that the etiological agents in many epidemiological studies are still unknown,

Soller et al. (2010) conducted a QMRA to investigate risks following recreational water exposure to gull, chicken, pig, and cattle fecal pollution. The major findings include: 1) risks of gastrointestinal illness were found from exposure to water contaminated with both cattle and human fecal matter may be similar. While a number of human pathogens are known to be present in cattle feces, some of which are capable of causing more serious harm than a self-limiting gastrointestinal illness, the prevalence of these pathogens is unknown; and 2) risks of illness after exposure to fecal matter from gulls, chickens, and pigs seems to be much lower than those estimated after exposure to human waste in a recreational water setting. One exception could be human illness resulting from pig hepatitis E virus genogroup C (Rutjes et al. 2009).

Thus, it appears that the risk of exposure to avian sources of fecal pollution poses less of a risk than exposure to human waste. Based on a QMRA approach applied to known pathogens, Soller et al. (2014) present ENT levels that represent equivalent risk to water quality standards for waters containing mixtures of fecal sources. The authors calculate that for waters with 30% of the ENT from human sources, risk of illness is predicted to be lower; thus, higher standards could be allowed.

There is much ongoing research to fill in the data gaps required for QMRA to be an effective approach for predicting risk in recreational coastal waters. While US EPA has opened a door, site-specific water quality criteria (as would be derived from QMRA) are still not accepted in California. Increased information on etiological agents and their ecology is needed. Also, there is a dire need for QMRA predictions to be anchored with epidemiological studies.

For Topanga Beach to be a candidate for QMRA in the future, testing for host-specific markers must be continued to assess the downward trend observed in human-associated marker and to monitor reductions in dog and gull pollution as sources. These measurements must continue as the drought ends so the role of the creek can be fully assessed.

5 Septic System Testing Results

5.1 Introduction

Topanga Beach received poor wet weather water quality ratings between 2006-2014. The beach has exceeded the water quality objectives set for Fecal Indicator Bacteria (FIB) based on the Ocean Standards (AB411) based on weekly samples collected by the City of Los Angeles Environmental Monitoring Division. This happened frequently enough for Topanga Beach to be identified by Heal the Bay as the 4th most polluted beach in the state for the 2010-2011 season and as the 10th most polluted in 2011-2012. Overall precipitation levels were very low in 2012-2013, and very low in 2013-2014 and water quality throughout the Santa Monica Bay was excellent. However, Topanga Beach was listed as “B” for summer dry (April – October 2012), “C” for winter dry (Nov 2012– Mar 2013), and “F” for wet weather year round. This pattern was repeated in 2014 however the lack of rain resulted in a wet weather grade of “C” (Heal the Bay 2014).

Los Angeles County is responsible for maintaining water quality levels at Topanga Beach that meets receiving water standards not only for FIB, but also for nutrients, trash, and several other identified beneficial uses (Table 6-21). The Regional Water Quality Control Board set TMDL’s for the Santa Monica Bay overall, but not specifically for Topanga Beach, lagoon or creek. In 2012, Topanga Beach had a total of 35 exceedances of FIB levels, which was reduced to 19 exceedances in 2013 (Heal the Bay Beach Report Card 2014). One of the goals of this study is to identify potential sources of FIB so that appropriate actions can be taken to reduce the number of exceedances per year, and meet the 25% reduction goal in 2013 required by AB 411.

The septic systems located along Pacific Coast Highway (PCH) were identified as potential sources of FIB to Topanga Lagoon and beach (Hypothesis 3). Although it was not feasible to test the privately owned systems on the south side of PCH, west of Topanga Lagoon, it was possible to test the systems managed by California Department of Parks and Recreation in Topanga State Park on the north side of PCH, as well as the lifeguard station restrooms managed by Los Angeles County Department of Beaches and Harbors. These systems are physically closest to the lagoon and examining their condition and function to confirm that they are not contributing FIB was a high priority.

Aerial and ground surveys to map locations of the septic systems and their potential connectivity were completed in summer 2013. The topographic survey was conducted by Chris Nelson and Associates. Details of the system plans and locations are provided in Appendix H.

All of the septic systems located in the former Rodeo Grounds Road area were removed in 2008. The septic systems associated with the houses along Malibu Lane and in the Snake Pit area behind the Reel Inn were also removed as of 2011. In most cases, the tanks were either physically removed or backfilled. The leach fields were also backfilled and disconnected from the old tanks. Although these old systems are no longer functional, it is possible that leachate from these systems could still be trickling in through the water table to the lagoon. Modeling of the movement of septage through the water table surrounding Malibu Lagoon and Creek suggested that the time lag for movement could be years (Stone Environmental 2004). However, examination of these sites and testing with florescent dyes did not support contributions from these systems to the lagoon at this time.

Additionally, the Los Angeles County Lifeguard Station restroom facility at Topanga Beach was upgraded in 2008 with a state of the art Advantex treatment system. The renovated system incorporates state of the art chlorination, de-chlorination, and UV treatment to eliminate bacterial contamination.

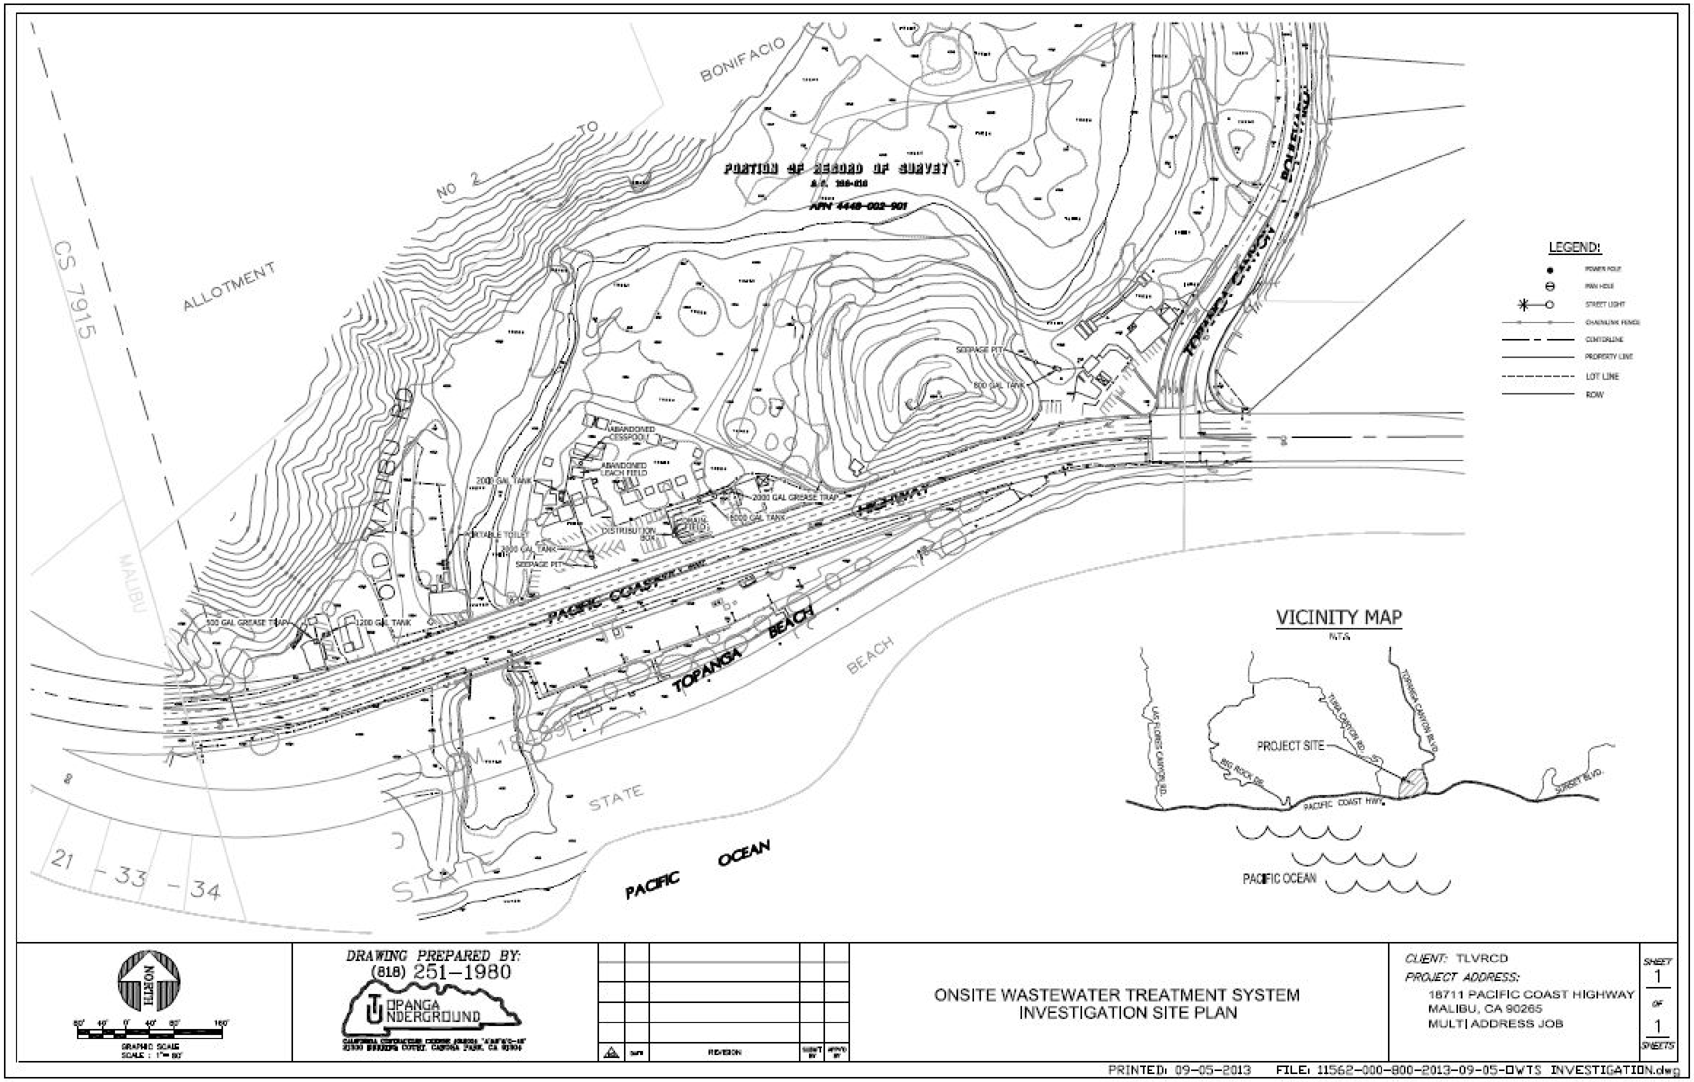

Figure 5-1 Map of Public Septic Systems adjacent to Topanga Lagoon.

5.2 Methods

Topanga State Park

Existing tanks within Topanga State Park were pumped out, then tested by backfilling to a minimum depth of 2" above the riser seam to prevent damage from hydrostatic uplift. They were then monitored for two hours. No tank was accepted if there was any leakage over the two hour period. Topanga Underground conducted testing in spring and summer 2013.

Los Angeles County Department of Beaches and Harbors Restrooms and Lifeguard Station

Water samples were pulled from the system at a sampling port where fluids pass between the UV disinfection system and the distribution box, which connects to a subsurface leach field. Samples were collected monthly from January 2013 through July 2013 by technicians from BioSolutions. Each 2 liter sample was collected and processed according to the sampling protocol, within the normal holding time by the Jay Lab at UCLA. A 500 mL sample was collected and tested for nutrients by the RCDSMM. BioSolutions also collected samples tested by Pat-Chem Inc, Moorpark, CA for: biological oxygen demand (BOD), dissolved oxygen, total suspended solids (TSS), pH, turbidity, total alkalinity, carbonate alkalinity, bicarbonate alkalinity, and hydroxide alkalinity.

Samples were held in a cooler with the Chain of Custody forms and placed within the gated area. In February 2013, we were unable to coordinate sample collection. In May and June 2013, the cooler with the empty bottles was stolen but by coordinating with the BioSolutions technician we were able to obtain samples in any case. Subsequently, we have set it up to coordinate via phone and take bottles to the technicians when they arrive on site.

5.3 Results

5.3.1 Topanga State Park

The septic systems along Pacific Coast Highway within Topanga State Park were evaluated as described above. These septic systems are being pumped weekly or more as needed, in compliance with the contracts administered by the California Department of Parks and Recreation. They are all older systems and even though no longer connected to leach fields or seepage pits, the potential for leakage is present.

SITE-3931 S. Topanga Canyon Blvd- Malibu Feed Bin- **NOT FUNCTIONAL AND POTENTIAL CONTRIBUTOR TO CREEK**

The On-site wastewater treatment system (OWTS) was located in the area to the west side of the site, on the west side of the west driveway. The system is between 40 and 50 feet from the stream bank, depending on how the top of bank is defined. The tank had a single 4" cast iron pump riser. The tank was excavated and inspected. The tank is a poured-in-place concrete septic tank, (5' x 10' x 3') with a capacity of 800+/- gallons. A radio locator, inserted into the tank outlet pipe, found a 4' x 26' seepage pit located N/W of and 15' from the tank.

The system is not functional at this time. The seepage pit was 100% full and backed up into the tank during the inspection. We notified the Feed Bin manager that the tank and the pit needed to be pumped. Two 8" pumping risers were installed on the tank and the pit has an existing 4" pumping riser. There was no evidence of sewage or effluent surfacing over the tank or the pit. The seepage pit servicing this system could be a contributor to bacteria in the creek, if there is a below-grade path, which permits the effluent seeping out of the pit to travel to the creek. This connection was not documented at this time and would require use of dyes to test connectivity. As pointed out, the distance is probably less than 50 feet from the pit to the creek.

Recommendation: The tank outlet line should be capped so that the seepage pit is no longer in use. The septic tank will then have to be pumped as required. If the total use causes the tank to fill up weekly, a 6,000 gallon holding tank can be rented, and a float operated pump placed in the septic tank, discharging to the tank. A larger truck can then be used to dispose of the sewage. Pumping cost will have to be determined and the cost of tank rental and installing the pump looked at to determine the least expensive option.

SITE-18661 Pacific Coast Highway-Reel Inn – **Not expected to be a contributor**

The system is located at the parking lot west of the restaurant. The system consists of a 2000 gallon grease trap, a 6000 gallon septic tank, a D-Box and a 3900 sq. ft. leach field. The leach field is at least 200 feet from the creek both to the west and the north. It does not appear that this system is a contributing factor to the problems in Topanga Lagoon and beach.

Both the tanks are being pumped on a regular basis. We believe that the timing of the pumping and the rate at which the tanks fill up do not coincide and that occasionally the system discharges effluent to the leach field.

Recommendation: Develop and implement a more effective pumping plan to avoid discharges.

SITE-19711 Pacific Coast Highway-Ranger Station – **May be a contributor**

This system has several components. There is a 4" clean out on the sewer line behind the partially occupied Ranger cabin. There is an abandoned 14 foot cesspool located between a palm tree & the nearby small tree adjacent to the ranger house. This is apparently not connected to anything & was dry. By water testing and some pipe cleaning, we determined that the Ranger Cabin was draining to the tank west of the main driveway (#1), between the first row of cabins and the ranger cabin. This tank (#1) was checked and it was basically empty. We believe that the bottom of the tank is cracked and effluent is seeping out and that is the reason the tank is empty. This tank is closer to the top of bank north of the bridge that any other tank on all the sites. Tank (#1) was pumped empty and 6" of concrete placed over the existing floor. This should prevent any future leakage.

By water testing the Tank #1 outlet we believe that if full, it would overflow into the larger tank (#2) located in the front parking lot adjacent to PCH, which served the former market (removed in 2002). Tank #2 had some water in it, but there is nothing flowing into it at this time. Tank #2 is connected to seepage pits in the front PCH parking lot. This system is close to the creek and could be a contributor to bacteria levels.

Recommendation: Repair the leak in Tank #1 (completed in September 2013). Plug both the inlet and outlet to test the tank following the repair. Repair the cracked manhole covers located in the PCH parking lot. Conduct dye tests to determine if any leaching is making it to the creek/lagoon.

SITE-19741 Pacific Coast Highway-Rosenthal Wine- **Not contributing from an OWTS.**

This site was inspected and there does not appear to be any OWTS in use on the site. The bathroom in the building had no fixtures and there are several Portable Toilets outside the building. This site is actually the closest building to the creek, however as there is no system in use, this location does not contribute to the bacteria levels via an OWTS. However, there is regular surface run-off from the site associated with irrigating the lawn.

Recommendation: Reduce irrigation and prevent run-off directly from the surface to the lagoon.

SITE-19753 Pacific Coast Highway-Something Fishy – **Not contributing**

The OWTS for this site is still in place, however the building was removed some years ago and the system is not in use. We believe that when this system was in use it was located behind the building and was over 100 feet from the creek.

This system is not contributing to the problem.

SITE-18757 Pacific Coast Highway-Wiley's Bait Shop – **Not contributing**

The building has no bathroom facilities. There is a single sink discharging into a 3' X 3' gravel packed pit. The shop uses the toilet facilities at Cholada's. This site is over 200 feet from the creek.

This system is not contributing to the problem.

SITE-19763 Pacific Coast Highway-Cholada Restaurant – **Not contributing**

The OWTS consists of an 800± gallon Grease Trap and a 1500± gallon septic tank. The grease trap is located under the kitchen floor and the septic tank is in the parking lot east of the building. This system is over 250 feet from the creek.

The system is not connected to the original leach field. Both tanks are being used as holding tanks and they are being pumped as needed.

This system is not contributing to the problem.

5.3.2 Los Angeles County Department of Beaches and Harbors Restrooms and Lifeguard Station

FIB and Marker results are summarized in Table 5-1 through Table 5-7. It was interesting to note that even after advanced septic processing that kept FIB levels quite low, DNA from dead cells was detected by both human marker tests and are present in almost every sample (Table 5.4-5-5). The detection of Dog DNA in April 2013 (Table 5-6) is consistent with additional information from 2014 (see Figure 3-7). Based on the FIB results summarized in Tables 5-1 to 5-3, it does not appear that the lifeguard septic system is contributing FIB to either the lagoon or ocean.

In May 2013, surface runoff was observed from the concrete apron of the showers at the Lifeguard station to the ocean. Between May and July 2013, samples were collected in the swash zone of the ocean near the location drainage was observed. Based on high enterococcus readings documented in May 2013 during a rain event, the Los Angeles County Department of Beaches and Harbors examined the plumbing to make sure that all shower water is being captured by the septic system as per design, and conducted the maintenance required to keep the connections functioning (Figure 5-2). Subsequent testing suggests that this may be a wet weather problem only. The high enterococcus numbers could also be related to the detection of both dog and gull markers. It was interesting that no human markers were detected.

Figure 5-2 Photograph of the collection system at the Topanga Beach Restroom showers

Nutrient levels in the lifeguard septage samples tested by the RCDSMM were consistently extremely high and most required a 1/100 dilution in order to even test given the limitations of the colorimeter. Nitrate-N, ammonia–N, orthophosphates were in exceedance (Tables 5-8 to 5-12) in all samples. On 5 June 2013, the samples were not diluted and thus were completely over-range.

5.4 Discussion

The function of septic systems located adjacent to the beaches, wetlands, and lagoons, are a concern throughout the country. The combination of high water tables, limited filtration distance through sandy soils, and close proximity to inundation by high tides can cause unintended connectivity between septic leach fields and the ocean (Izbecki 2011). The proximity of septic systems located at Topanga Beach, and adjacent to the beach and lagoon were identified as possible contributors to the exceedances recorded at Topanga Beach.

There is always a remote possibility that there is some historical sewage effluent that is leaking into the creek from old systems. Note that presently and in the past all the sewage effluent was discharged to either seepage pits or leach fields and this eventually ended up in the water table below the area. If the geology at the below-grade elevation of the upper part of the water table was such that there is or was geologic features that eventually permitted the water table to migrate to the creek, there could be contamination.

A study in the Malibu Civic Center concluded that the septic systems, in the shopping centers along Cross Creek Road ended up in the Malibu Lagoon rather quickly and that there were some systems around the perimeter, of the Civic Center that may take 75 years to migrate to the Lagoon (Izbicki 2011, Stone Environmental 2004). The siting of the leach field for the Lifeguard treatment system suggests that effluent would have to travel through the fill material into groundwater at least 393 feet before it would discharge into Topanga Lagoon. It would have to travel at least 285 feet before discharging into the ocean.

With the 2008 upgrade of the Topanga Beach Lifeguard Station Restrooms, waterless urinals were installed to reduce water consumption along with the installation of an Advanced Treatment System to meet the California Ocean Plan. The goal for the treatment plant is to nitrify the existing TKN (ammonia and organic nitrogen) to the California Ocean Plan standard of <2.4 mg/L ammonia (SWRCB 2009). With the addition of the waterless urinals and water reduction faucets and showerheads, water dilution for the incoming ammonia was reduced and TKN before treatment increased.

The nitrification process consists of a recirculation of water over a textile media utilizing ambient air for oxygen. An alkalinity of 7.14 ppm is required to convert 1 ppm ammonia to nitrate. The available alkalinity provided in the incoming potable water from LA County Water District 29's 2012 report was an average of 79 ppm. Any additional demand for alkalinity would start coming from the pH in the wastewater until this was consumed. As the pH falls, the treatment process loses efficiency and recirculation has to be reduced to prevent die-off of beneficial bacteria. The necessary alkalinity needed to convert the ammonia is as follows:

> 132 ppm TKN x 7.14 ppm alkalinity = 942.48 ppm alkalinity.
>
> 942.48 ppm needed alkalinity – 79 ppm available alkalinity = 863.48 ppm supplemental alkalinity needed to convert TKN and maintain neutral pH.

The function of the Lifeguard treatment system could be improved with the addition of a chemical feed alkalinity system, similar to that installed at all the new Zuma, Point Dume, and Surfrider Beach systems. By installing an automatic injection system of soda ash to supplement the alkalinity needed for proper nitrification and TKN (ammonia) conversion, the system could knock down the ammonia content to below 2.4mg/L and bring the pH up to an acceptable level between 6.5 and 9. The monitoring results from the Surfrider Beach Treatment system illustrate the reductions possible (Table 5-14). This would also help with other treatment factors, as the beneficial bacteria in this system are being significantly affected and possibly killed by the acidic pH.

Table 5-14 Los Angeles County Sampling Results for Surfrider Beach Treatment System

LA County –Malibu Monitoring Project					
Parameter	2/24/12	4/20/12	10/26/12	2/8/2013	5/10/13
Biological Oxygen Demand (mg/l)	5.81	15.4	4.85	5.95	ND*
ammonia-N(mg/l)	0.160	0.180	0.411	0.570	1.67
pH	8.34	6.88	6.08	8.09	7.88
Total coliform (MPN/100mL)	ND	ND	130	ND	2400
Fecal coliform (MPN/100mL)	ND	ND	ND	ND	20
Enterococcus (MPN/100mL)	ND	ND	ND	ND	ND
Turbidity (NTU)	2.95	1.05	2.13	11.7	0.560

*ND= Non Detect

Nitrates and nitrites are expected to be high as they are part of the chemical breakdown of ammonia in the nitrification process. If necessary, Total Nitrogen could also be lowered by adding additional equipment to de-nitrify the effluent. Currently that is not required at beach areas under the California Ocean Plan (SWRCB 2009). This upgrade has been discussed with Los Angeles County Public Works and a quote was provided to then a year or so ago. They seemed open to the idea of retrofitting these older beach treatment systems. Funding for such upgrades may be available through the State Water Resources Control Board, as recommended in SWRCB resolution 2012-0032.

6 Nutrient and In-situ Testing Results

6.1 Introduction

Although bacteria levels are a main focus of this investigation, the aquatic health of Topanga Lagoon and creek is influenced by numerous other factors. In 2003-2004, we identified total suspended solids and nutrients as potential problems in the upper watershed above the town of Topanga. Eutrophication describes the excessive growth of algae and plant matter due to the increased input of factors needed to photosynthesize, such as nutrients. Eutrophication occurs naturally in freshwater ecosystems over time with sedimentation; however, the process has been accelerated in many places due to nearby human activity. Input of nutrients can be from point (e.g., wastewater treatment plants, culverts) or non-point (e.g., fertilizer runoff) sources.

Aquatic species typically tolerate levels of nutrient loading that are lower than drinking water standards used to evaluate water quality. For instance, the drinking water standard used by the Regional Water Quality Control Board to regulate discharge from sewage treatment facilities for nitrogen–N is 10 mg/L. The EPA limit for freshwater aquatic systems for nitrogen-N is 1 mg/L (EPA 2012). In Malibu Creek that is also the target proposed.

Additionally, excessive nutrients typically lead to algae blooms, which can affect in-situ water quality parameters, such as pH and dissolved oxygen. For instance, when algae and plants are photosynthesizing during the day, dissolved oxygen levels will be high, however, when they respire at night, or die, oxygen is depleted. Aquatic organisms typically require a consistent level of 5 mg/L or above of dissolved oxygen to survive, and when levels drop below this, it can be detrimental to the aquatic wildlife (LARWQCB 1994 with 2011 updates).

The goal of this part of the study was to determine if nutrient loading was an issue in Topanga Creek and if so, if nutrient levels, along with bacteria levels, decreased from upstream sites to downstream sites as water moves through the natural section of the Narrows and the lower watershed below town.

6.2 Methods

Samples were collected just below town at Owl Falls (OF; 6500 m), further downstream at Scratchy Trail (ST; 4800 m), Topanga Bridge (TB; 3600 m), Brookside Drive (BR; 1700 m), Snake Pit (SP; 300 m), and in Topanga Lagoon (TL; 0 m) from 2012 to 2014. Samples collected from OF and ST were done so with funding from SIPP (Source

Identification Project). All other samples were collected thanks to funding from LA County Supervisor Zev Yaroslovsky's office. Standard Citizen Water Quality Monitoring parameters were incorporated into the sampling effort, which provided an outreach opportunity for RCDSMM Stream Team volunteers, local students, and during the 2013-2014 year, members of the Watershed Stewards Project.

Water samples were collected in the field in 500 mL bottles. Bottles were rinsed three times and filled and capped underwater. Samples were collected monthly during the dry season (April – October) and bi-weekly during the wet season (November – March), and at the first flush rain event (> 0.75") at the same time and locations as FIB samples. Nutrient testing (nitrate-N, nitrite-N, orthophosphates, ammonia-N) of grab samples was done within six hours of collection using a LaMotte SMART3 Colorimeter. Turbidity was tested using a LaMotte Turbidimeter 2020we.

In-situ parameters included water temperature, pH, salinity, conductivity, and dissolved oxygen. Water temperature (ºC) and dissolved oxygen (mg/L and % saturated) were tested using a handheld YSI 55 DO meter. Conductivity (µS/cm) and pH were tested using handheld Oakton probes (waterproof ECTestr11 and waterproof pHTestr 30, respectively). Salinity (ppm) was tested using a handheld refractometer (ATC 300011 SPER SCIENTIFIC salt refractometer). Air temperature was measured using a mercury thermometer.

Algae cover was measured and recorded in two ways: 1) visual estimate of percent cover, and 2) random point contact (RPC) where a random point is generated on a transect stretching across the creek where flow is taken and the substrate below that point is recorded. Substrate was recorded as: terrestrial plant, aquatic plant, algae unknown, *Cladophora, Enteromorpha,* diatoms, bare bedrock, bare boulder, bare cobble, bare gravel, or sand. A complete description of the methodology is found in Appendix G.

6.3 Results

6.3.1 Physical Conditions

6.3.1.1 Lagoon-Ocean Connection

The connection between Topanga Lagoon and the ocean was monitored at every rain event and sampling event by the project team as well as daily by the Los Angeles County Lifeguards until June 2013. When possible, breaches were noted as manual or natural as well. We also relied upon daily monitoring using the web camera located on top of the lifeguard station. Although images were blurry, they did allow us to detect lagoon connections.

Substantial rainfall events were minimal and total rainfall was below normal for 2012-2013 and 2013-2014 water years (WY; Table 6-1). Similarly, breach events that connected the lagoon to the ocean were quite limited in both years (Table 6-2). Connection lasted for less than ten days in 2012-2013, and fewer than seven days in 2013-2014. The breach in April 2013 was manually done by a local shovel brigade and recorded by the lifeguards.

*First flush events (>0.75”) 17 Nov 2012, 24 Jan 2013, 27 Feb 2014

Between Dec 2012 and Aug 2014, there were several “king” tide events, where unusually high tides (generally over 6.5’) caused overwash from the ocean to the lagoon, although they did not always results in a full breach (Table 6-2).

Table 6-2 Topanga Lagoon high tides, overwash, and breach events, November 2012 – August 2014.

Date	High Tide Time	Tide Height (ft)	Breach Events and Rain event Date, inches	Sand Berm Condition

*LA County Lifeguard data was available until June 2013. Data since June comes from observations during water quality sampling events.

**Sand berm connection was open at the time of water quality sampling (5:58 am), but closed when the Lifeguard data was recorded. High tide was at 4:17 am, height was 5.1 ft

6.3.1.2 Site Conditions

At each sampling event, qualitative information concerning site conditions was noted. These included water clarity, color and odor, surface conditions, and presence of foam, debris and trash. Compliance was indicated by an ability to clearly see the bottom, lack of discernable odor, and lack of surface oil or foam (Table 6-3). Table 6-7 summarizes the observations of site conditions and compliance. The two sites in Upper Topanga, Owl Falls (6500 m) and Scratchy Trail (4800 m) had the highest percentage of sample dates where water conditions were not compliant, whereas two Lower Topanga sites, Topanga Bridge (3600 m) and Brookside Drive (1700 m) had the lowest percentage. The percentage of dates when not compliant increased again further downstream at the two sites closest to the PCH and nearby development. Lack of compliance was typically due to poor water clarity or unclear water, and only occasionally due to the presence of an odor, surface oil or foam/bubbles.

Table 6-3 Summary of qualitative water conditions data, Dec 2012- Aug 2014.

Site	Total Dates Sampled	Number Dates not Compliant*	% Not Compliant	Number of dates not compliant				
				Water Clarity (not clear)	Water Color (not clear)	Water Odor Present	Surface Oil Present**	Foam/ Bubble Present**
Topanga Lagoon 0 m (TL)	28	10	36	3	7	5	0	3
Snake Pit – 300 m (SP)	22	10	45	4	3	3	5	0
Brookside Drive- 1700 m (BR)	26	3	12	1	1	0	1	1
Topanga Bridge – 3600 m (TB)	29	4	14	1	1	1	2	0
Scratchy Trail- 4800 m (ST)	21	15	71	9	11	0	1	1
Owl Falls – 6500 m (OF)	19	11	58	3	10	0	0	1

*Each sampling date that was not compliant may be associated with multiple water condition values that are not compliant or compliant. To calculate the percentage of dates not compliant, the number of sampling dates not compliant was used (not the number of water conditions not compliant).
**Surface oil and foam/bubbles could be from biological or non-biological sources.

Impacts from transients, careless visitors, or dumping from RV's were observed throughout the study period. Human, dog and bird feces were observed at various sites and times, but fairly consistently at Topanga Lagoon (Table 6-4). The presence of bird feces at the lagoon, which was mainly gull, was not surprising. Topanga Beach does not permit dogs on the beach. However dogs were observed frequently and their feces were observed occasionally. Human feces were observed on several occasions in the pedestrian underpass below PCH, as well as along the creek (Figure 6-1). Observations of human feces in the underpass often coincided with observations of transient activity. We also documented RV discharge along the shoulder of Topanga Canyon Blvd. (Figure 6-2) that was associated with a strong urine smell, and suspected discharge into the culvert from the shoulder of PCH that connects directly to Topanga Lagoon (Figure 6-3).

Table 6-4 Summary of feces observations by sampling date and location, where H=Human, D=Dog, and B=Bird. (gray boxes indicate transient activity observed).

Trash was observed in light abundance (1-10 pieces) fairly regularly at Topanga Lagoon and Topanga Bridge, the two most easily accessible sites, and episodically at the other sites along Topanga Creek (Figure 6-4). Moderate (11-50) and heavy (>50) amounts of trash were observed fairly often at Topanga Lagoon, however, rarely observed in the creek. The majority of the trash observed consisted of discarded plastic, bottles and cans (Figure 6-5). Spray paint cans were routinely picked up and removed from under the Topanga Bridge and Lagoon, two places where tagging is typically observed.

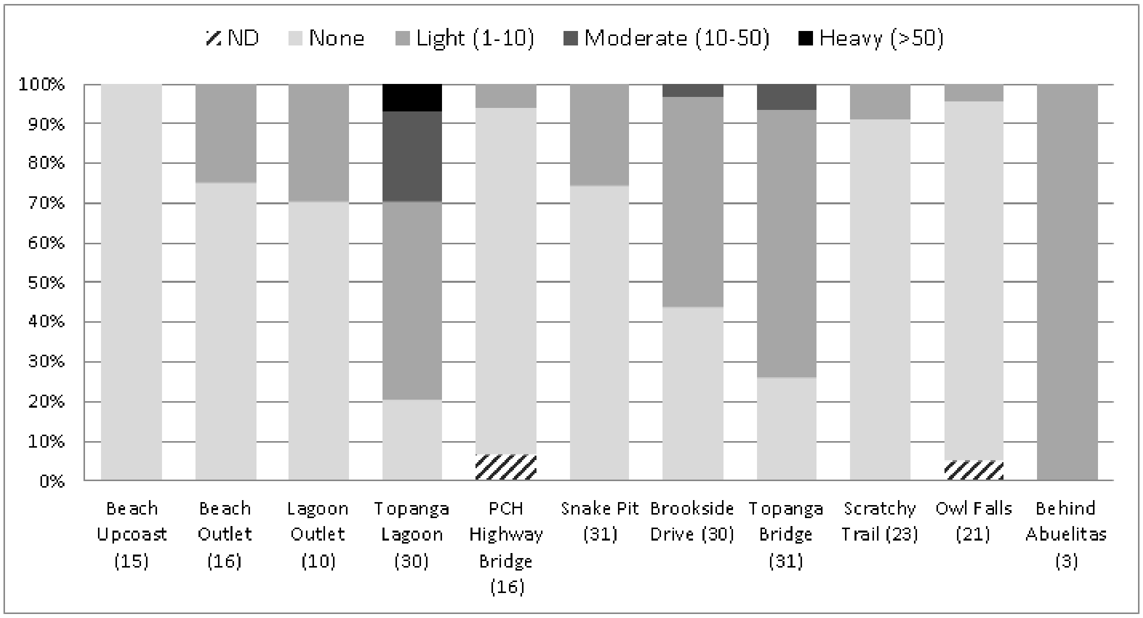

Figure 6-4 Percentage of sampling events when trash was observed and in what abundance at sampling sites along Topanga Creek, Lagoon and Beach between Dec 2012-Aug 2014. Number of dates each site was sampled is in parentheses below site name.

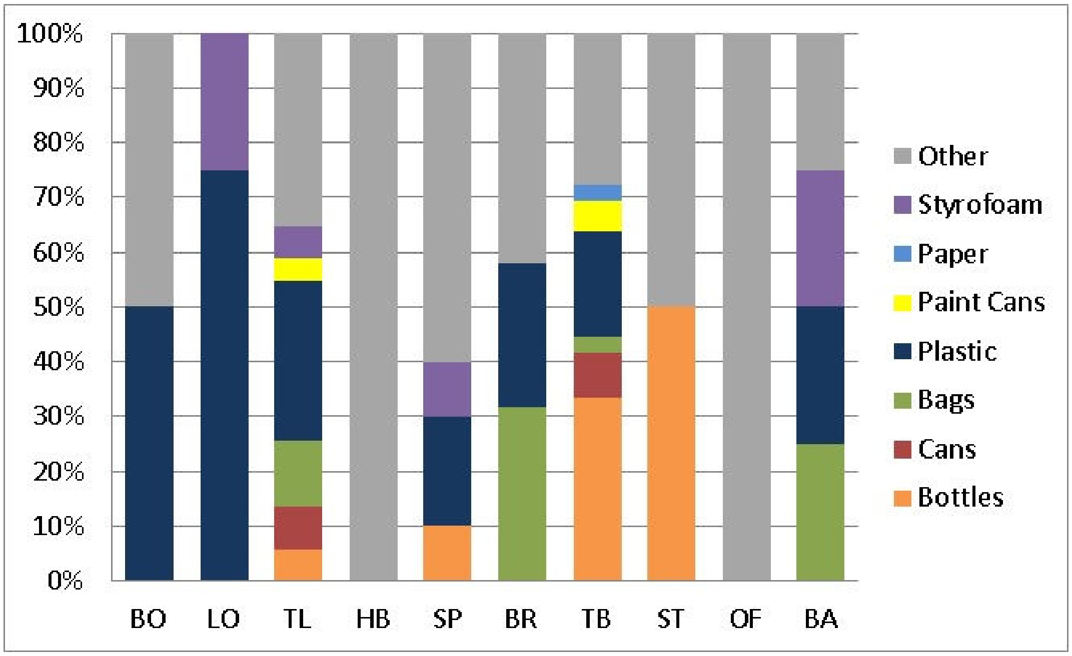

Figure 6-5 Percentage of sampling events where various types of trash were observed. Occurrences and types of trash observed during 31 sampling events from Dec 2012-August 2014.

6.3.1.3 First Flush, Flow and Depth

First flush sampling events occurred on January 24, 2013 and February 27, 2014. These were events where greater than 0.75” of rain fell during a single storm. January 24 was considered first flush for water year 2012-2013 because it had been almost two months since a considerable rainfall event. Data for these two events is presented separately from non-first flush events in the tables below.

There was very little rainfall between Dec 2012 and Aug 2014, which resulted in very low flow conditions, even during rain events (Table 6-5). In fact, the creek never recharged sufficiently to reach continuous base flow. The reach between 400-1650 m connected during a short rain event in January 2013 and late-February to early-March 2014, but otherwise flowed sub-surface with a few pools during rain events. Depth is one of the most variable parameters measured, even though we attempted to measure at the same location each time. Depth is directly related to rainfall, except in Topanga Lagoon, where depth increases when the sand berm is closed, causing a pooling effect. Compared with the flow and depth recorded in 2003-2004, levels were generally much lower (Dagit et al. 2004). For instance in 2003-2004, the lagoon had an average depth of 50 inches versus 17 during this study, and the Topanga Bridge averaged 40 inches versus 8 during this study. Additionally, a slug of sandy sediment continues to accumulate in the lagoon since 2011, and reduce overall depth (Table 6-6).

Table 6-5 Summary of flow (cfs) in Topanga Creek, Dec 2012- Aug 2014.

		First Flush (FF) Events		Non-FF Events		
Site	**Total # Dates Sampled**	**01/24/13**	**02/27/14**	**Max Flow (cfs)**	**Min Flow (cfs)**	**Mean Flow (cfs)**

6.3.2 *Chemical Conditions*

6.3.2.1 Water Temperature

Snapshot water temperatures taken in the early mornings using the YSI Model 55 dissolved oxygen meter varied seasonally, but average temperatures were highest in the Lagoon and Snake Pit (300 m). Although Snake Pit (300 m) is fairly well shaded, it is consistently shallow and, throughout the study period, often disconnected from the 1700 m site by an approximate 1000 m stretch through lower Topanga that ran subsurface. Average temperatures throughout the rest of the creek up to town did not vary much, but did increase slightly from lower to upper sites (Table 6-9).

Table 6-7 Summary of water temperature (ºC) in Topanga Lagoon and Creek, Dec 2012- Aug 2014.

		First Flush (FF) Events		Non-FF Events

*Two sets of data were taken at Snake Pit (300 m) during the first flush event on 24 Jan 2013. The first set was taken at 13:30, followed by a surge in flow and resampling at 14:45. Both data points are presented respectively.

Water temperature was also monitored in several locations throughout Topanga Creek at 30-minute intervals using Tidbit v2 temperature data loggers (Onset Hobo; Figure 6-6). Data from Ski Pole Pool, a site located at 2000 m, is shown here as it is representative of the creek and has both air and water temperature data associated with it. The endangered southern steelhead (*Oncorhynchus mykiss*) is also typically observed in this location, and monitored consistently. Despite relatively warm air temperatures, especially in Spring 2014, water temperatures in Ski Pole Pool remained below 25ºC throughout the study period. On the low end, water temperatures rarely dropped below 10ºC.

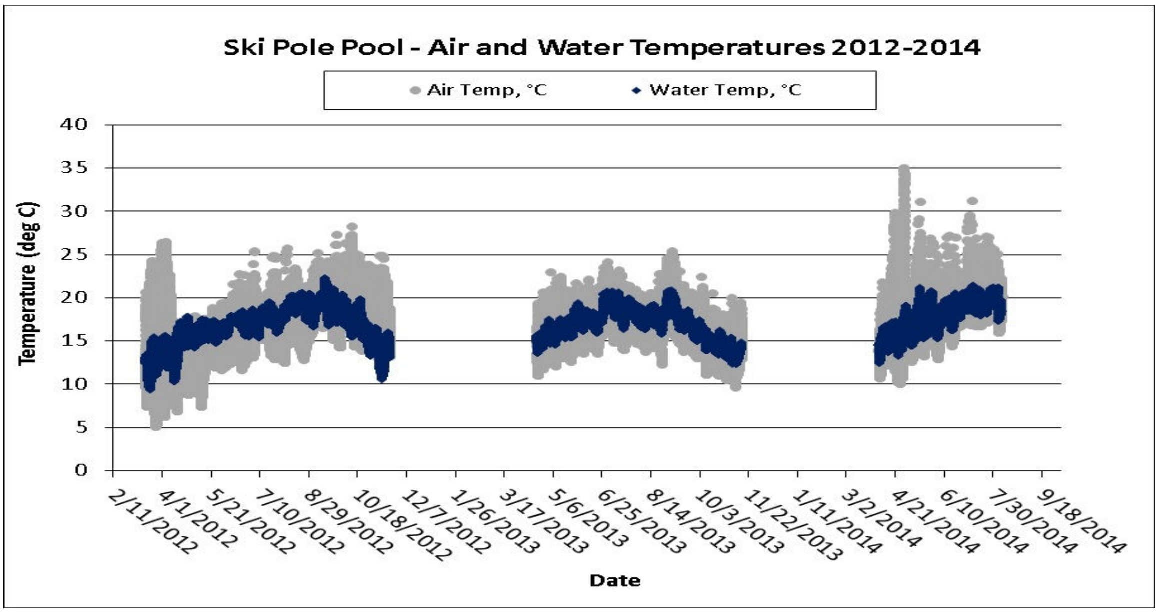

Figure 6-6 Air and water temperatures (ºC) from Onset Hobo Tidbit v2 loggers at Ski Pole Pool (2000 m). Gaps in data are from when hobos were removed during the wet season.

To date, *O. mykiss* have been observed only rarely in Topanga Lagoon and only for short periods of time when they are present. The lagoon, however, is an important habitat for endangered tidewater gobies (*Eucyclogobius newberyii*). *E. newberyii* have a wider temperature and dissolved oxygen tolerance than *O. mykiss,* and, despite the higher average temperatures in the lagoon, thrive there and approximately 200 meters upstream (RCDSMM, *unpublished data*). Water temperature was monitored in upper Topanga Lagoon (50 m above PCH bridge) at 30-minute intervals using a Tidbit v2 logger between Dec 2013 and Aug 2014. Additionally, water temperature and dissolved oxygen levels were monitored continuously using a YSI 6600 water quality probe in lower Topanga Lagoon (below PCH bridge) by Southern California Coastal Water Research Project (SCCWRP) between November 2013 and June 2014 (Figure 6-7).

Water temperatures were mostly comparable in the lower and upper lagoon except for during a period of time from April to June 2014 when temperatures were considerably higher in the lower lagoon. This could be a result of reduced water depth in the lagoon following the late-February storm and associated sedimentation accompanied by high air temperatures during that time. Dissolved oxygen levels in the lower lagoon were consistently over 6 mg/L from Nov 2013 to early Mar 2014 prior to that storm. The resulting sedimentation following the storm and perhaps a glitch in the probe caused a lapse in data from early March to April 2014. The probe appeared to start working properly again in late-April and showed variable, and generally low DO levels until the end of May. Readings then became more consistent, however remained lower than before the Feb storm. DO readings were taken throughout the creek as well during regular sampling events and are discussed further in Chapter 6, section 6.3.2.2.

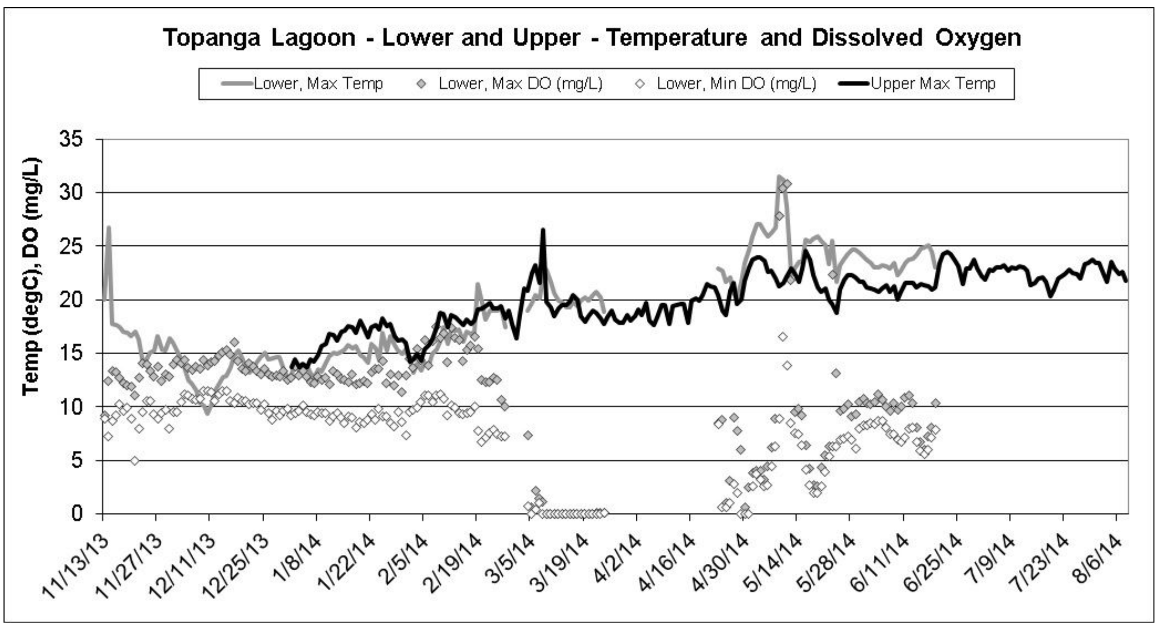

Figure 6-7 Daily maximum water temperatures (ºC), maximum and minimum dissolved oxygen (mg/L) levels of the lower (below PCH bridge) Topanga Lagoon, as well maximum temperatures in the upper (50 m above PCH bridge) Topanga Lagoon, Nov 2013 to Aug 2014. (Temperature and DO data for lower lagoon courtesy of the Southern California Coastal Water Resources Project)

6.3.2.2 <u>Dissolved Oxygen</u>

Dissolved oxygen (DO) levels naturally vary during the day, and are typically highest in the middle to late in the day when plants and algae are photosynthesizing, and lowest in the early morning, after plants and algae have been respiring throughout the night.

Samples should be representative of lowest DO levels as they are collected just before, at, or just after dawn. Every attempt was made to collect samples within the same time frame at each sampling event, thus reducing the variability related to normal diurnal fluctuations. The Los Angeles Regional Water Quality Control Plan (LARWQCB 1994 with 2011 updates) has a water quality objective of greater than 5 mg/l for any single determination in cold water, and greater than 7 mg/l for all waters, except where natural conditions cause lesser concentrations.

Snake Pit (300 m) had by far the lowest DO levels overall (Table 6-7). This site is fairly well shaded and the least variable over time (Figure 6-8), but was disconnected from the upper creek, or stagnant for much of the study period. The other site with lower levels of DO was Owl Falls (6500 m), located at the upper end of the study reach and although the minimum DO recorded was under 5 mg/L, the average was above 5 mg/L. Brookside Drive (1700 m) had the highest average DO, followed by Topanga Lagoon.

6.3.2.3 pH

pH levels throughout the creek and lagoon remained fairly consistent and did not fluctuate significantly. Most aquatic species prefer a pH range between 6.5-9 in freshwater systems. Although average pH (7.6-8.2) was slightly on the alkaline side, even maximum recorded levels (7.9-8.5) remained within the tolerance limit range for most aquatic species (Table 6-8). Snake Pit (300 m) again stands out with the lowest average pH.

Table 6-8 Summary of pH in Topanga Lagoon and Creek, Dec 2012- Aug 2014.
(Water Quality Objective 6.5-9.0)

*Two sets of data were taken at Snake Pit (300 m) during the first flush event on 24 January 2013. The first set was taken at 13:30, followed by a surge in flow and resampling at 14:45. Both data points are presented respectively.

6.3.2.4 Water Temperature, pH, and Dissolved Oxygen

Figure 6-8 shows water temperature, pH and dissolved oxygen for each site for the duration of study. See Appendix A for graphs with more detail. Snake Pit was dry from November through February 2014 (first flush) and started to dry up in early August again. Brookside Drive was dry for the months of September and October 2013, and August 2014.

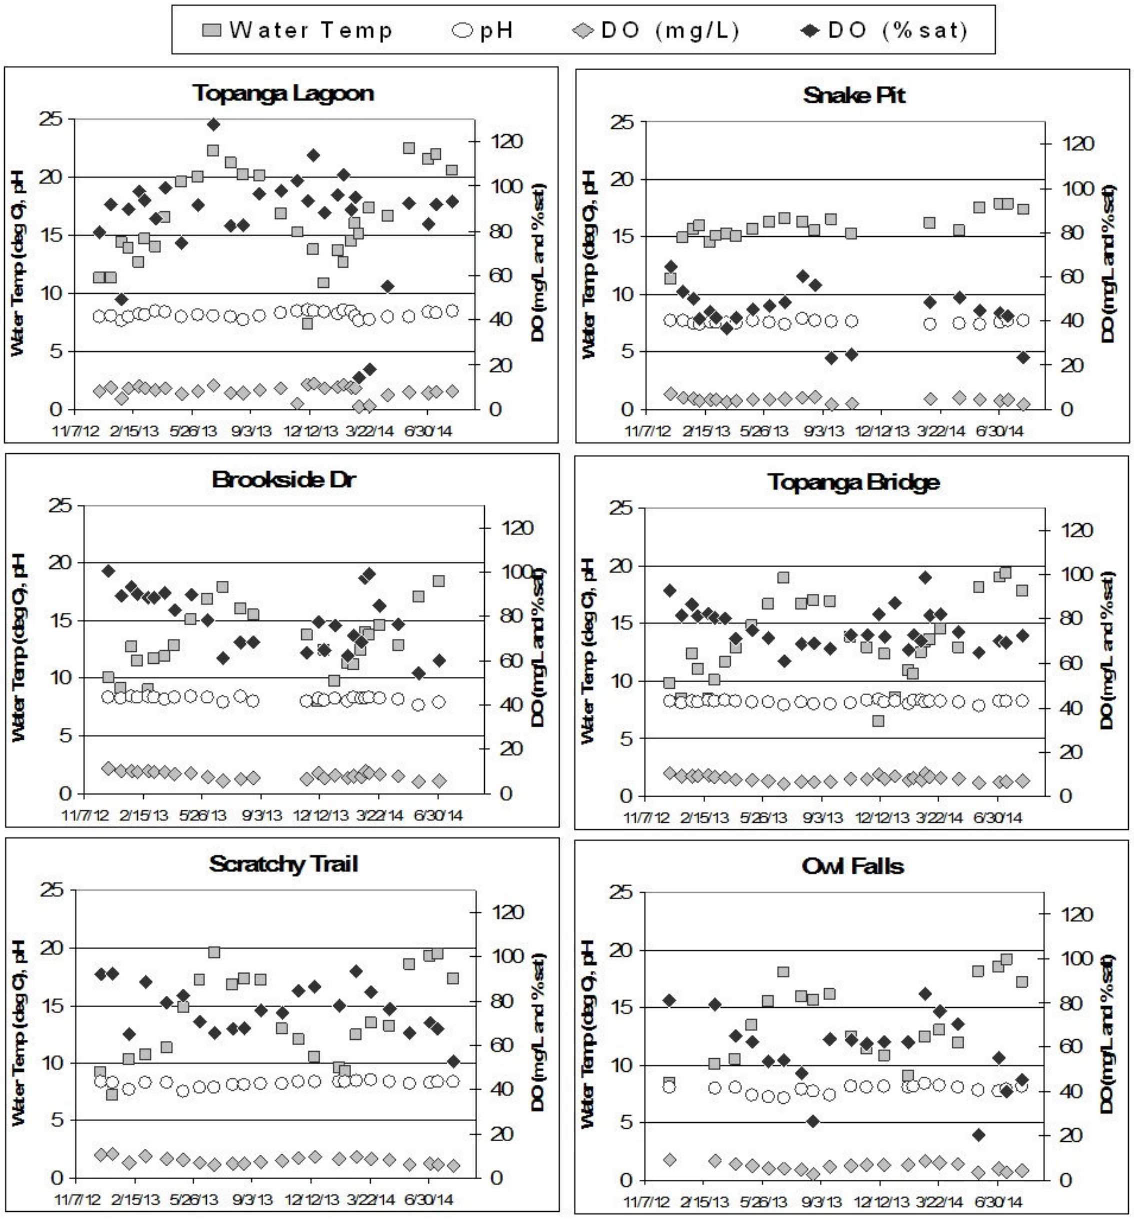

Figure 6-8 Water temperature (ºC), pH, and dissolved oxygen (mg/L, %sat) for all sites, Dec 2012-Aug 2014. (Dissolved Oxygen (DO) is on the right axis).

6.3.2.5 Salinity

Surface salinity levels in Topanga Lagoon were mostly low, with a few higher saline events observed when overwash or tidal exchange occurred (Table 6-9). Salinity levels in Topanga Creek never exceeded 3 parts per thousand (ppt), and, on average, were generally less than 1.

Table 6-9 Summary of salinity (ppt) in Topanga Lagoon and Creek, Dec 2012- Aug 2013

		First Flush (FF) Events		Non-FF Events

*Two sets of data were taken at Snake Pit (300 m) during the first flush event on 24 Jan 2013. The first set was taken at 13:30, followed by a surge in flow and resampling at 14:45. Both data points are presented respectively.

6.3.2.6 Conductivity

Perhaps related to the slightly higher salinity levels of the lagoon, conductivity was consistently higher there than throughout the rest of the creek, which remained fairly constant (Table 6-10). At standard temperatures, conductivity is a measure of the number of dissolved ions in the water, and is recorded as µS/cm (microsiemens per centimeter). Ranges are usually from 0.5-3.0 µS/cm for distilled water, with potable water ranging from 30-1500 µS/cm and seawater up to 53,000 µS/cm. No specific water quality range is included in the Water Quality Control Plan Los Angeles Region. This measurement is an indirect way to evaluate the amount of dissolved salts in the water that are conductors. In conjunction with pH and salinity, conductivity is used to evaluate inputs from groundwater sources or sewage.

Again, Snake Pit (300 m) stood out among the other creek sites, having a generally higher conductivity level than the sites further upstream. Snake Pit is located in what historically would have been part of the upper estuary, which could be contributing to the higher conductivity.

Conductivity was also measured for the ocean sites. These levels did not vary from site to site along the beach front, remaining between 46,600-53,600 µS/cm, which is typical for marine waters.

Table 6-10 Summary of Conductivity Topanga Lagoon and Creek Dec 2012- July 2013

*Two sets of data were taken at Snake Pit (300 m) during the first flush event on 24 Jan 2013. The first was taken at 13:30, followed by a surge in flow and resampling at 14:45 (both points are presented respectively).

6.3.2.7 Nitrate–N

The nitrate levels in Topanga Lagoon and creek were consistently well below the 1 ppm threshold for concern for aquatic species (EPA 2012; Table 6-11). Only one time did nitrate-N levels exceed 1ppm, and that was at Owl Falls, the closest site to town, during a first flush event. The standard for drinking water is <10 ppm. Levels of nitrate greater than 3.5 ppm are thought to contribute to increased algal production and eutrophication in Southern California streams (Luce and Abramson 2005). Natural background readings vary depending on underlying geologic conditions, but can range from 0.0- 0.08 ppm (EPA 2012). The pending TMDL limit for Malibu Creek is <1 ppm (EPA 2012). Compared to both maximum and average levels documented at Topanga Lagoon (max=0.87, mean=0.14) and Topanga Bridge (max=0.84, mean=0.15) in 2003-2004, current levels are even lower and consistent throughout the creek and lagoon.

Table 6-11 Summary of nitrate-N (ppm) in Topanga Lagoon and Creek sites, Dec 2012- Aug 2014. Water Quality target <1 ppm.

		First Flush (FF) Events		Non-FF Events

6.3.2.8 Nitrite–N

Nitrite-N can have serious health effects for infants, and is the cause of the blue baby syndrome (EPA 2014). The tolerance levels for aquatic species are not well documented. The target for nitrite–N is 1 ppm (LARWQCB 1994 with 2011 updates). All sites within Topanga Lagoon and creek are consistently well below that threshold.

Table 6-12 Summary of nitrite-N (ppm) in Topanga Lagoon and Creek sites, Dec 2012- Aug 2014.
(Water Quality target is < 1 ppm)

6.3.2.9 Ammonia -N

Although the maximum levels of ammonia–N observed at Snake Pit (300 m), Brookside Drive (1700 m) and Topanga Bridge (3600 m) were somewhat high, these levels were observed in conjunction with transient and recreational activity at those locations (Table 6-13). The high average observed at Brookside Drive is difficult to explain, as transient activity there has been episodic rather than chronic, although there was an observed wet spot and associated urine smell on Topanga Canyon Boulevard near Brookside Drive where an RV was apparently emptying its waste. The most curious result was the levels of ammonia observed at Scratchy Trail (4800 m), which should have the least amount of anthropogenic input. There have been a few encampments observed upstream, but none in that vicinity. Average levels were well below the 0.4 ppm target for freshwater systems but it is curious that this is the only variable that increases as water moves downstream from town. The most common sources of ammonia –N in freshwater systems are human effluent and animal wastes. Most aquatic species are quite sensitive to increased levels of ammonia, with toxicity occurring between 1-25 ppm. The Water Quality Control Plan Los Angeles Region utilizes the EPA pH adjusted range of 2.5 – 10.5 ppm.

Table 6-13 Summary of ammonia-N (ppm) in Topanga Lagoon and Creek, Dec 2012- Aug 2014.
(Water Quality target < 0.4 ppm)

6.3.2.10 Orthophosphate

Maximum orthophosphate levels exceeded the target of 0.10 ppm for all locations throughout Topanga Lagoon and Creek at some point (Table 6-14. Average levels also exceeded the target limit at Brookside Drive (1700 m), Scratchy Trail (4800 m) and Owl Falls (6500 m). However, these levels are still under those documented at Topanga Lagoon (max=0.37, mean=0.11) and Topanga Bridge (max=0.47, mean=0.10) observed in 2003-2004 (Dagit et al. 2004). Common sources of levels exceeding 0.65 ppm in freshwater include organic elements from septic systems, graywater systems and inorganic sources like fertilizers and soaps from detergents. Natural readings range from 0.0-0.65 ppm. The higher levels at Owl Falls make sense, as this site is closest to human inputs such as graywater. The levels at Brookside Drive and Topanga Bridge appear related to transient activity, but the level at the more remote Scratchy Trail is unclear. It is possible that the orthophosphate is dissipating and being diluted as it moves downstream from Owl Falls, but incompletely.

Table 6-14 Summary of orthophosphate (ppm) in Topanga Lagoon and Creek, Dec 2012- Aug 2014.
(Water Quality target is < 0.10 ppm)

6.3.2.11 Turbidity

The amount of suspended particles, phytoplankton, pollutants, and other materials is measured as turbidity. Not only does turbidity affect water clarity, it can also increase heat absorption and impair breathing and foraging of aquatic animal species (Yamamoto 2010). Other than a few incidents of high turbidity observed at Topanga Lagoon and Owl Falls (6500 m), most of the sites in Topanga creek are below the drinking water standard of 5 NTU (Table 6-15). However, as the summer progressed in 2013 and 2014, visibility in the mid-upper reaches of the creek between Topanga Bridge (3600 m) and Owl Falls (6500 m) decreased markedly. These locations are also where there has been an explosive population increase of introduced red swamp crayfish. Turbidity levels at Topanga Lagoon (max = 44.7 NTU, mean = 2.53 NTU) and Topanga Bridge (max = 35.6 NTU, mean = 1.53 NTU) were significantly higher in 2003-2004 than they are today. The higher NTU levels at Scratchy Trail (4800 m) could well be a result of crayfish disturbance, as this site is small, confined and full of crayfish.

The Los Angeles Region Basin Plan objective for turbidity is a mix of numeric and narrative: "The secondary drinking water standard for turbidity is 5 NTU. Waters shall be free of changes in turbidity that cause nuisance or adversely affect beneficial uses. Increases in natural turbidity attributable to controllable water quality factors shall not exceed the following: where natural turbidity is between 0 and 50 NTU, increases shall not exceed 20%; where natural turbidity is greater than 50 NTU, increases shall not exceed 10%."

Table 6-15 Summary of Turbidity (NTU) in Topanga Lagoon and Creek, Dec 2012- Aug 2014. Drinking water standard is less than 5 NTU.

6.3.3 Biological Conditions

6.3.3.1 Nutrients and algae among sites

Figure 6-9 shows all nutrient and algae levels at all sites throughout the study period (see Appendix A for more details). Levels of all nutrients and algae were generally low with only a few spikes at during first flush events. Some nutrients, especially orthophosphates were above the water quality objective for several of the sites.

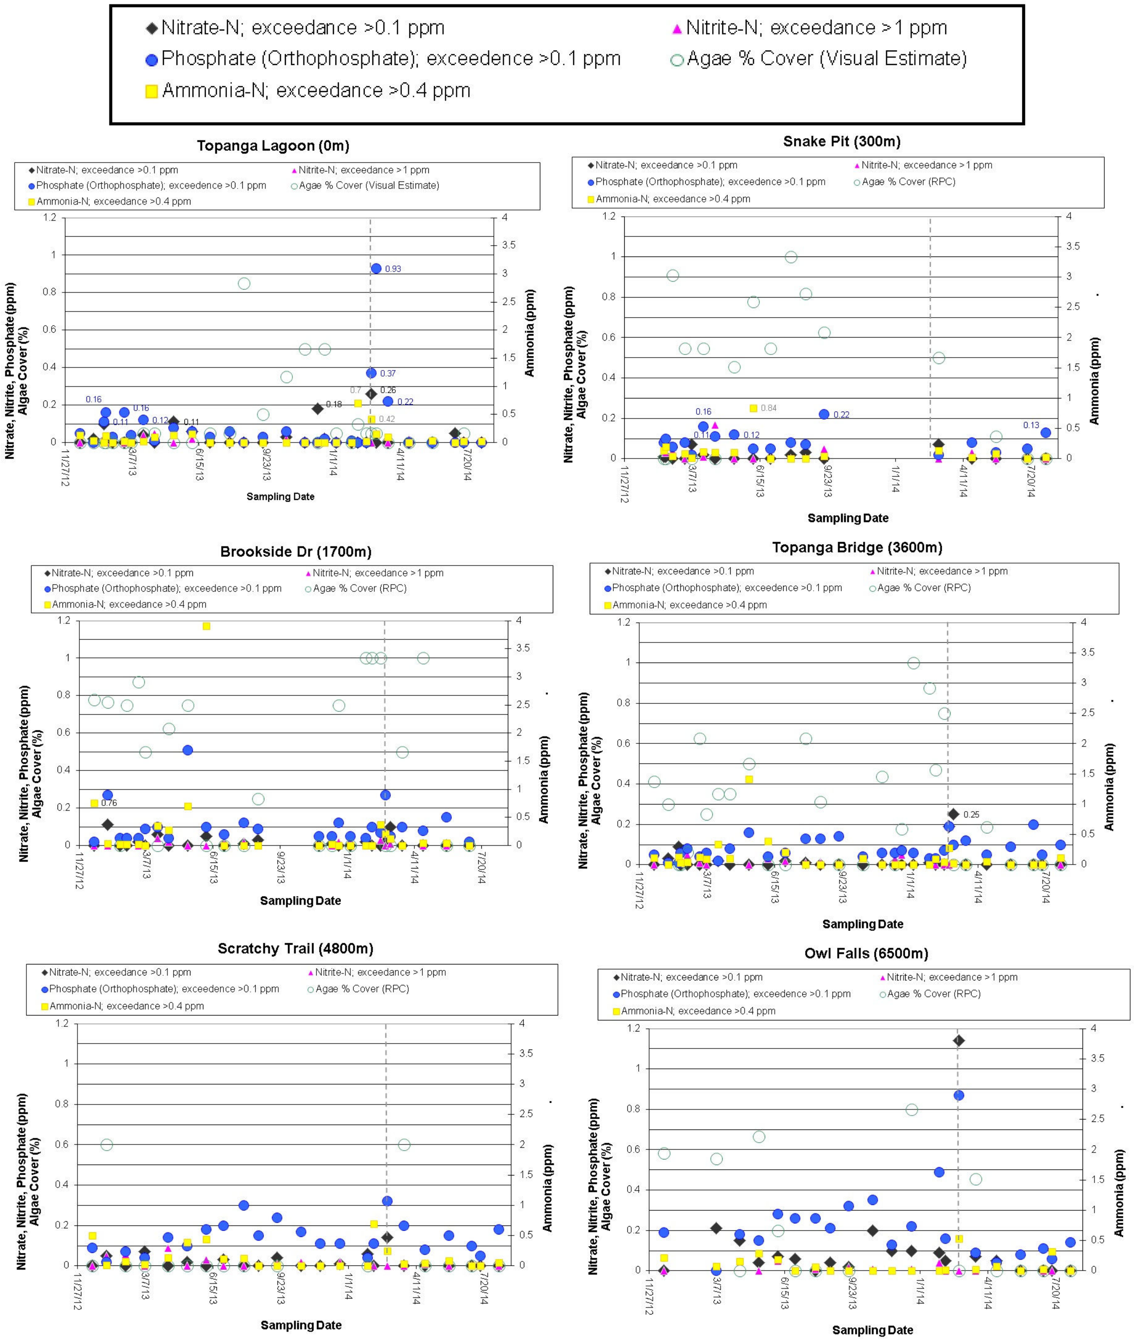

Figure 6-9 Nutrients and algae at all sites, Dec 2012-Aug 2014.

6.3.3.2 Algae

In order to track the presence and abundance of algae in the lagoon and creek over time, two types of algae data were taken during each sampling event – a visual estimate of percent cover and random point contact method data concurrently with flow and depth. Algal types and percent cover were surveyed at creek sites (Snake Pit (300 m), Brookside Drive (1700 m), Topanga Bridge (3600 m), Scratchy Trail (4800 m), Owl Falls (6500 m)) during each sampling date using the RPC method. Using the same transect where flow was measured, random points were generated, and presence/absence and type of algae was recorded at each point. If algae were present, the type of algae was recorded. *Cladophora* sp. and *Enteromorpha* sp. were the only species of algae observed in Topanga Creek during this sampling period. If an alga was observed, but the type was not known, it was recorded as "other" or "unknown." Voucher specimens of unknown algae were collected for future identification. If algae were absent from the point, the substrate was recorded as bare substrate (sand, pebble, cobble, rock, boulder was noted), biological debris (leaves, sticks), aquatic or terrestrial plants (if type was known, it was recorded), or diatoms.

For Topanga Lagoon, percent cover of algae was visually estimated for the lagoon as a whole, with the observations generally made from the bank above or from the east bank, which provided a good view of the whole lagoon area south of the PCH bridge.

Table 6-16 outlines the types of algae observed in Topanga Lagoon and creek from December 2012 to August 2014. *Macrocystis* was observed floating (unattached) in Topanga Lagoon, especially following high tide/overwash or breach events. *Cladophora* sp. was observed in Topanga Lagoon occasionally as well. *Cladophora sp*. was also observed at Snake Pit, Topanga Bridge and Owl Falls. *Enteromorpha sp*. was observed at Owl Falls and Snake Pit.

Table 6-16 Algal species observed in Topanga Lagoon and Creek during sampling events December 2012 to August 2014.

	ALGAE TYPE		
Location	*Cladophora* sp.	*Enteromorpha* sp.	*Macrocystis pyrifera*
Topanga Lagoon	X		X
Topanga Creek	X	X	

In general, the percent cover of algae was low (<20%) for all sampling dates and all sites (see Figure 6-10). Snake Pit (300 m) had the highest percent cover of algae recorded, 78% cover of *Enteromorpha* sp. on June 5, 2013. This could be contributing to the low dissolved oxygen levels at this location. Brookside Drive (1700 m) had the lowest percent cover of algae, with no algae recorded during any sampling event. The substrate at

Brookside Drive (1700 m), however, was covered with a layer of diatoms almost 40% of the time.

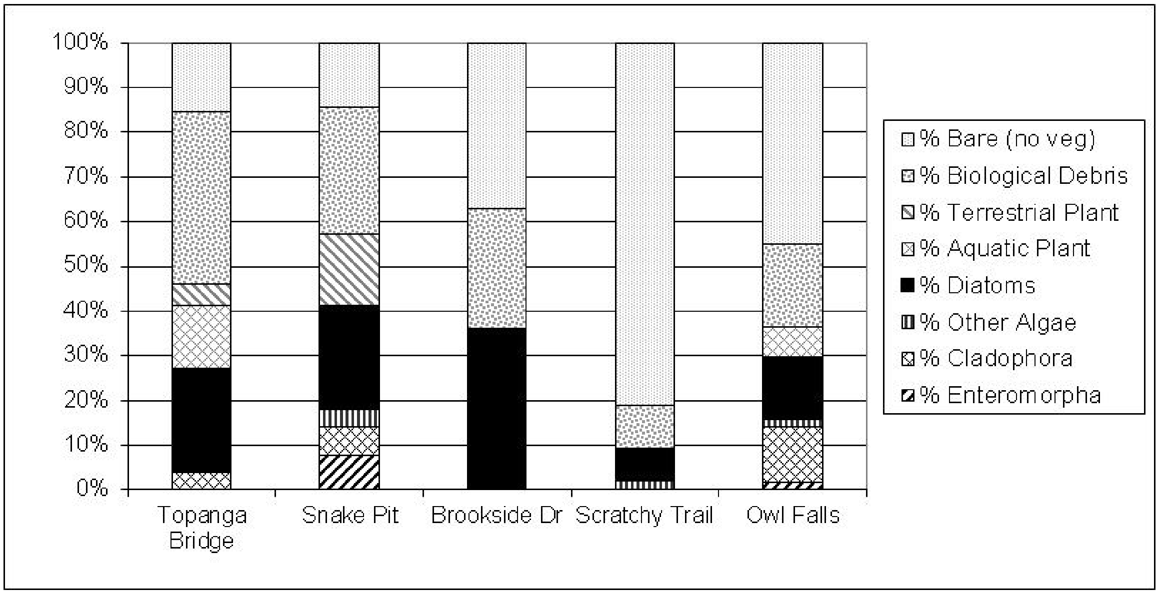

Figure 6-10 Summary of the percent cover of algae and other substrate types at each site Dec 2012-Aug 2014.

On average, Snake Pit (300 m) had about 18% cover algae, Brookside Drive (1700 m) had 0%, Topanga Bridge (3600 m) had less than 5%, Scratchy Trail (4800 m) had 3.2%, and Owl Falls (6500 m) had slightly less than 18%. Owl Falls (6500 m) is the site closest to the town of Topanga, and Snake Pit (300 m) and Topanga Bridge (3600 m) are also sites that are frequented by humans, and potentially dogs or other animals.

6.3.4 Stream continuum and spatial correlations between nutrients and FIB

It was hypothesized that natural processes are removing anthropogenic inputs from the water in the creek as it flows from town to the lagoon; therefore we looked at nutrient levels from Owl Falls (OF), the site closest to town, to the lagoon (Figure 6-11). Nitrate and orthophosphate were the highest at Owl Falls. Nitrate levels dropped dramatically from Owl Falls to Scratchy Trail (4800 m), and stayed at about the same level to the Lagoon (TL), where it increased. Orthophosphate levels dropped as well between Owl Falls and Scratchy Trail, and continue to drop further downstream at Topanga Bridge (TB, 3600 m), go back up again at Brookside Drive (BR, 1700 m), and drop again to TL. Nitrite levels were generally low throughout the creek, with the highest average of 0.017 ppm at Snake Pit (300 m). Ammonia was highest at BR, and dropped downstream of there. At sites above BR, ammonia levels were lower than at BR and SP, and OF and TL had the lowest overall ammonia levels.

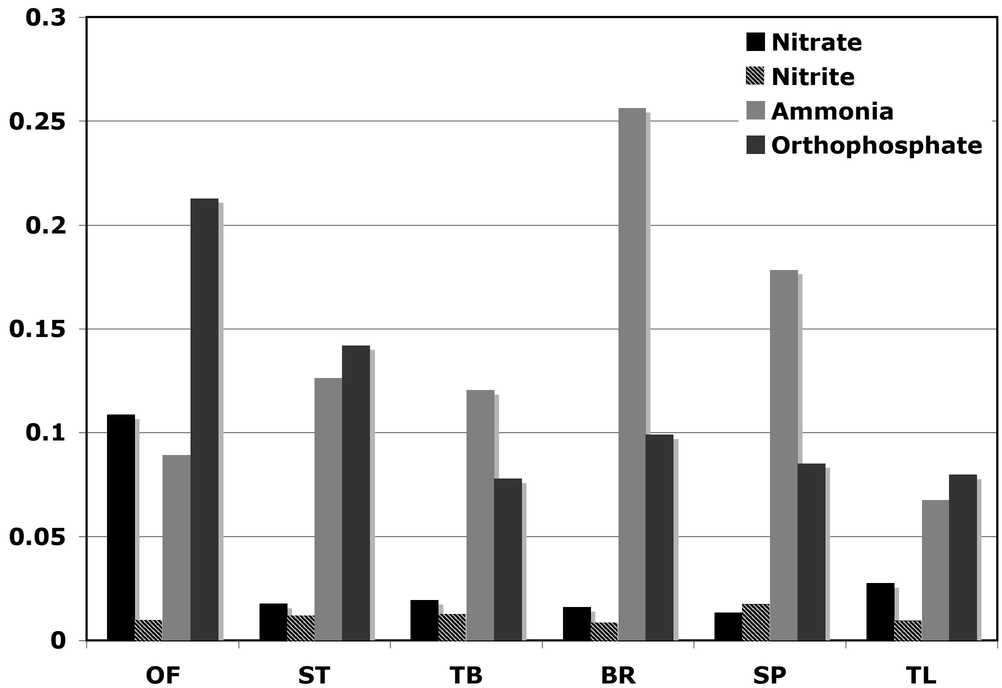

Figure 6-11 Average nutrient levels at each site, from the site closest to town (Owl Falls, 6500 m) to the lagoon, Dec 2012-Aug 2014.

A total of 17 variables were analyzed including FIB, physical and chemical parameters across all sites. This analysis showed a fairly high correlation between nitrate and enterococcus (Pearson's r correlation coefficient = 0.83), and a slight correlation between orthophosphate and enterococcus (0.58) and nitrate (0.60). When analyzed by site (Appendix A), FIB was frequently correlated with orthophosphate, turbidity, flow, nitrate and orthophosphate depending on the site. Many of the FIB values correlated highly (>0.95) with flow and turbidity, especially at the upstream sites. Furthermore, the number of correlated variables decreased from upstream to downstream, especially Owl Falls, where flow, turbidity, orthophosphate, nitrate, ammonia, and all three FIB values are highly correlated (Table 6-17).

Summary of variables with correlation coefficients greater than ±0.70 of the 17 variables analyzed for each site. Coefficient values r>0.9 are highlighted.

Table 6-17 Summary of variables with correlation coefficients greater than ±0.70 of the 17 variables analyzed for each site. Coefficient values r>0.9 are highlighted.

Site	Variable 1	Variable 2	Pearson's r

In order to determine whether there were relationships among sites, we tested for correlations between nutrients, FIB, water temperature and dissolved oxygen. Raw data was averaged over time for each site, and mean site data were compared using regression analyses. Only three pairs of variables were significantly spatially correlated. *E. coli* and ammonia were positively correlated (R^2=0.65, P=0.002, df=11), such that, on average, sites with high levels of *E. coli* also had high levels of ammonia. Enterococcus and ammonia were also positively correlated (R^2=0.50, P=0.01, df=11), and nitrite and dissolved oxygen were marginally significantly correlated in a negative direction (R^2=0.60, P=0.07, df=5), such that sites with high levels of nitrite, on average, had low levels of dissolved oxygen.

6.4 QA/QC Protocols

This section is an overview of the quality assurance/quality control measures taken to assure quality data is being collected as well as disseminated. See Appendix G. for the complete Topanga Source ID Study Quality Assurance/Quality Control Plan (April 2013) which provides all details and was reviewed and approved by the TAC. QA/QC includes measures to ensure the accuracy, precision and completeness of all data collected. These standards of practice were implemented throughout the study.

6.4.1 Accuracy and Precision

a. Equipment Calibration

In-situ water quality testing equipment (YSI 55 DO meters, Oakton pH meters, Oakton conductivity meters, and refractometers) were calibrated before each sampling event. The membranes and solution in the DO meters were checked as well and replaced as needed.

b. Training

A training was held at the beginning of the study in December 2012, as well as June and October 2013 to teach all scientists and volunteers how to use, calibrate and maintain the water quality testing equipment, as well as how to properly collect nutrient, bacteria samples, flow and algae data. New scientists and volunteers that did not attend the training were always partnered with experienced people to avoid collecting inaccurate data. Refer to Appendix G for more information on training requirements.

c. Chain of custody and Data sheets

Data sheets and Chain of custody (COC) forms were used to document sample collection, processing, and storage. Lab notebooks were used to document PCR/qPCR analyses.

Although this data is not being used in a regulatory setting, documenting who has physical control of each sample at ALL TIMES was a standard operating procedure. The name and times need to be correct for each step of the process.

Time and Name of person who collected the sample
Time and Name of the person who transports the sample to the lab/RCDSMM
Time and Name of the person who fixes or manipulates the sample for testing
Time and Name of the person who reads the results
Time and Name of the person who enters the data
Time and temperature of ice chest where samples being stored prior to fixing.

All COC forms were compiled in both an electronic and hard copy file at the RCDSMM. All field data forms are also archived at the RCDSMM in chronological order. See Appendix G for samples of data sheets and forms, and for more information on documentation and record keeping.

d. Data Management

Data was entered into an excel spreadsheet as soon as possible following each collection event, and as of July 2013, linked to an access database. Having the data in an access database made it easy to export tables and summary results, which were then used to make graphs or figures. The data transfer from excel to access was checked by one person to verify accurate data was transferred. In the field, data sheets were checked by the lead scientists immediately following data collection, and data entry was checked again when making graphs or tables (can check for outliers).

Furthermore, the Project Manager/Principal Investigator reviewed and validated data against the Project's defined objectives and standard operating procedures in summer 2013, and prior to preparing the final report. If any problems with sampling and analysis were identified, these issues were addressed immediately and methods modified to ensure that data quality objectives are being met. Modifications to monitoring require edits to the approved QA/QC Plan. Only data that have been validated and qualified, as necessary, were entered into the applicable database.

e. Completeness

Since different sites had different sampling events and effort (Tables 6-18 to 6-20) summarizes what type of data was collected for each sampling site (for Beach Upcoast (BU), there were a total of 12 dates where FIB and marker data was collected, some water quality information (temperature, salinity/conductivity) but not nutrients).

Table 6-18 Summary of Sampling Site Completeness for FIB and markers.

Site Name	Total Possible Dates	Total TC/EC/ENT	Total HF gene marker	Total BH gene marker	Total Gull marker	Total Dog marker	Missing Data Points/ Total	% Complete

6.5 Discussion

Nitrate-N, nitrite-N, ammonia-N, and orthophosphate are all generally associated with anthropogenic inputs into aquatic systems and are directly related to amount of algal growth and potential eutrophication cycles. Observations during this study indicate that while levels of ammonia and orthophosphate are a concern associated with septic, graywater, transient and recreational impacts, overall nutrient loading continues to be low overall. This is consistent with previous study results for the lower reaches of the creek below town (Dagit et al. 2004).

The impact of recreational visitors and transient encampments, as well as potential inputs from illegal marijuana farms seems correlated to the spikes we see of ammonia and orthophosphate. The potential for a marijuana farm in this area is high. Transient activity and RV dumping appears to contribute greatly to the water quality issues in Topanga Creek. For several months during snorkel surveys and water quality monitoring events, a wet spot was observed in the pullout along Topanga Canyon Boulevard near Brookside Drive (1700 m). The wet spot was associated with a strong urine smell. Brookside Drive had the highest levels of ammonia followed by Snake Pit. Snake Pit is an area close to the PCH, which also gets a lot of transient activity, and so the high levels at this site could be due to that.

Overall, our initial hypothesis that nutrient levels decreased downstream from the town and upper watershed appears to be true for some nutrients but not all. Nitrate and orthophosphate are highest at the site closest to town (OF) and then drop, fairly dramatically at the next site, approximately 1700 m downstream (ST). Nitrite and ammonia are higher at ST than OF, although only slightly and levels of those two nutrients jumps around through the rest of the creek. The high levels of ammonia at Brookside Drive (BR) could be attributed to the RV dumping of urine waste along a nearby Topanga Canyon Blvd. pullout. Further monitoring and patrolling of this site along Topanga Canyon Blvd. could potentially solve the high ammonia levels at this site.

Algae cover, in general, was very low throughout the study period with two common species primarily found. This is another indication that eutrophication did not appear to be an issue during this study period. Rainfall was extremely low throughout the study period as well. It's possible that with more rainfall, and more runoff from town, eutrophication and algae blooms could be a problem in Topanga Creek, and therefore, runoff from town and overall watershed management should not be ignored as a potential issue.

Standards for pollutants of concern have been established in the Basin Plan (LARWQCB 1994 with 2011 updates) and through the California Toxics Rule (CTR) (EPA 2000), with the goal of ultimately setting Total Maximum Daily Loads (TMDL's) for each of these parameters in order to achieve compliance to all standards. The Basin Plan generally establishes a numeric and/or narrative objective for conventional pollutants and minerals, while the CTR has objectives for metals and organics. The 303(d) list identifies the parameters for which each watershed is impaired. Topanga Creek has been listed for lead in the upper watershed and bacteria at Topanga Beach. No other pollutants of concern have been listed for the watershed.

However, levels of nutrients, pathogens, sediments, trash and heavy metals are all potential problems in every watershed. The studies in Topanga Lagoon and creek have directed sampling to identify if any of these parameters are currently a concern and if so, to identify potential sources and trends of exceedance.

The Basin Plan also identifies the beneficial use of water quality objectives, which are summarized below for Topanga Lagoon and creek (Table 6-21). Although there have been some exceedances for FIB, the nutrient, water temperature and dissolved oxygen levels are all within the water quality objective ranges.

Table 6-21 Beneficial uses and pollutants of concern for Topanga Lagoon and creek, Los Angeles Regional Water Quality Control 1994.

Parameter	**Beneficial Use Water Quality Objective or Definition**	**Topanga Lagoon Results**	**Topanga Creek Results**
Navigation		NA	NA
REC 1 (Water contact recreation)	Fecal coliform shall not exceed a single sample limit of 400 MPN/ 100 mL	Exceedances	Exceedances
REC 2 (Non-water contact recreation)	Fecal coliform shall not exceed a single sample limit of 400 MPN/ 100 mL	Exceedances	Exceedances
Warm Water	Remain < 80^0F, raise no more than 5^0F above normal	No exceedances	No exceedances
Cold Water	Not be altered more than 5^0F above normal	No exceedances	No exceedances
Estuary	Uses of water that support, preserve or enhance estuarine habitats	Limited function	NA
Rare	Uses that support habitats necessary for state or federally listed species	Supports endangered Tidewater gobies	Supports several state and federally listed aquatic species
Migratory	Uses supporting anadromous fish	Limited function	Limited function, Passage opportunities limited
Spawning	Uses supporting high quality habitat for reproduction and early development of fish	Passage opportunities limited	Functional areas limited in lower reach of creek
Wetlands	Uses that support preservation, enhancement of wetland habitats	Limited function	NA

When we compare the levels of nitrates, nitrites, orthophosphates and ammonia observed in Topanga Creek with those found in other creeks within the Santa Monica Mountains, including both Malibu Creek, and reference sites such as Arroyo Sequit, Solstice and Cold Creeks, it appears that Topanga remains in fairly good shape. The levels of nutrients measured in Topanga Creek are significantly lower than those found at the mouth of Malibu Creek (Table 6-22).

Table 6-22 Comparison of Water Quality Parameters from Creeks in the North Santa Monica Bay December 2012- July 2013.

Site	Average Water Temp	Average Dissolved Oxygen	Average pH	Average nitrate-N	Average nitrite -N	Average ammonia-N	Average ortho-phosphates
WQ Target Guideline	**<26^{o}C**	**>5 mg/l**	**6.5-9**	**<1 ppm**	**<1 ppm**	**0.4 ppm (pH adjusted)**	**<0.10 ppm**
Topanga Lagoon (n=13)	16	8.7 (90%)	7.7	0.03	0.02	0.06	0.07
Topanga Bridge (n=13)	12	8.5 (79%)	7.9	0.01	0.02	0.22	0.06
Arroyo Sequit * (HTB-19) (n= 9)	14	8.05	7.7	0.01		0.16	0.15

6.6 Summary

- Nutrient and algae levels were, in general, low throughout the study period, with only occasional exceedances. Orthophosphates were frequently in exceedance at Owl Falls and Scratchy Trail.
- In-situ parameters (water temperature, dissolved oxygen, pH, conductivity, salinity) were, in general, within the standard ranges for wildlife.
- Rainfall was below normal for both years the study took place, and significant rain events were few and far between. Therefore, flow was consistently low throughout the study period as well.
- On average, nitrate and orthophosphate levels decrease from Owl Falls (OF, 6500 m; the site closest to town) downstream, especially between OF and ST (4800 m)
- On average, Brookside Drive (BR, 1700 m) had the highest levels of ammonia

- Further patrolling of the state park for transient and RV dumping activity could help with any exceedances in the creek, similar to the fact that further enforcement of the no-dogs-allowed-on-beach rule could probably help with the FIB issues at the beach/lagoon.

7 Physical Habitat Assessment Results

7.1 Introduction

Physical habitat data was collected as part of the Surface Water Ambient Monitoring Program (SWAMP) Bioassessment Procedures (Ode 2007) to quantify physical and chemical characteristics of stream habitat associated with concurrent benthic macroinvertebrate, diatom and soft-body algae collection (Herbst and Silldorff 2006, Ode et al. 2005). The protocol allows for repeatable data collection measures in order to obtain quantitative data on a stream's physical/habitat condition and benthic invertebrate assemblages. It also allows for comparison of stream conditions throughout the state of California.

For the purpose of this report, we have presented the physical habitat data as a separate section, although the information is relevant to the analysis and discussion of the benthic macroinvertebrates (Chapter 9), diatoms and soft-body algae (Chapter 11), and most importantly, to the examination of the trophic level interactions associated with the trophic level analysis of Topanga (Chapter 12).

7.2 Methods

Data Collection

Physical habitat data was collected in Topanga Creek on 30 April 2013 (Upper Topanga: 4500-4650m; 34º04.314 118º35.213) and 2 May 2013 (Lower Topanga: 3200-3350m; 34º03.685 118º35.123) as part of the SWAMP Bioassessment protocol. Data was also collected in Upper Topanga on 6 May 2014 and in Lower Topanga on 5 May 2014. This data was collected for each of the 150 meter reaches where sampling for benthic macro-invertebrates, diatoms, soft-body algae, and chlorophyll a were also collected. The presence, life-stage and abundance of all amphibians, reptiles, and fish were noted throughout a 500 meter reach (3200-3700m and 4500-5000m) which has been surveyed since 2000.

For each location, 21 main transects were placed systematically along a 150 meter reach of the creek. Eleven transects were placed 15 meters apart perpendicular to the direction of flow. Ten additional inter-transects were placed equidistant between each of the main transects. Prior to collecting transect data, ambient water chemistry measurements (pH, dissolved oxygen (mg/L and % sat), specific conductivity (µS/cm), water temperature (ºC), air temperature (ºC), and salinity (ppt) were taken. Alkalinity and hardness were measured using test strips in 2013. In addition, water samples were collected for later analysis of turbidity (NTU) with the LaMotte Turbidimeter 2020, nutrients were tested using the LaMotte Smart3 Colorimeter, and fecal indicator bacteria were processed according to standard protocol. Flow (cfs) was measured using a Marsh-McBirney Flowmate 3000.

After benthic macroinvertebrates, diatoms and soft-body algae were collected at each of the 11 main transects using the reachwide benthos (RWB) procedure, the following habitat data was collected for each transect: wetted width (m), depth (cm), bankfull width (m), bankfull height (cm), canopy cover (measured using a convex spherical densiometer), and transect substrate measurements (below). Visual estimates were used to collect data on riparian vegetation, human influence, instream habitat complexity, and bank stability.

The transect substrate measurements quantify particle size frequency distribution, which provides valuable data on stream habitat conditions that can affect benthic macroinvertebrate distribution. As part of this, the Wolman pebble count technique (Wolman 1954) was employed. If the particle was cobble-sized, the percent embeddedness was recorded. Additional cobble particles were used to estimate the percent embeddedness if too few cobbles were found along transects. The presence of course particulate organic matter (CPOM), algae and macrophytes was also recorded as part of the transect substrate data.

For each of the ten inter-transects, wetted width, depth, transect substrate measurements, and visual estimates of in-stream channel type were also collected. Inter-transect gradient was not directly measured, but inferred for the whole reach based on previously collected gradient data.

Data Analysis

Data was entered into Microsoft Excel for further analysis. Summary tables were generated to show the results for physical habitat characteristics, water quality, canopy cover and substrate composition.

For instream habitat complexity, the cover values (from 1 to 5) for nine different channel features along each transect were tabulated for each reach. To get an indication of how much each feature contributed to overall instream complexity for each reach, the frequency of occurrence was calculated as the number of transects with at least sparse cover (>1)/total possible (n = 11 transects). The resulting frequencies for both reaches were represented graphically.

To characterize the riparian vegetation along the length of each reach, the proportion of each of four cover values (0=absent, 1=sparse, 2=moderate, 3=heavy, 4=very heavy) were graphed for the lower and upper reach for 2013 and 2014. The cover values for each riparian vegetation type at the left and right bank for each of the 11 transects were used to calculate the proportion values.

7.3 Results

7.3.1 Physical Habitat Characteristics and Water Chemistry

As shown in Table 7-1 in 2013 the average wetted width and average depth for the upper reach (4.4 m and 12.6 cm) were slightly greater than that of the lower reach (4.2 m and 12.0 cm). In 2014 the average wetted width remained about the same as the previous year for the upper reach (4.5 m), although the average depth was slightly less (10.9 cm) than in 2013. The lower reach had a lower average wetted width (4.0 m) and average depth (9.9 cm) than the previous year.

Stream discharge was generally low, although the value in the lower reach in 2013 (0.006 m^3/s) was double that of the same reach in 2014 (0.003 m^3/s). The upper reach discharge was 0.004 m^3/s in 2013, and a discharge value was not recorded in 2014 because flows were so low. In 2013 bank stability was greatest in the upper reach (91%) but the lower reach was also high (82%). Bank stability was slightly higher in 2014 for the upper reach (100%) but remained the same in the lower reach (82%).

In 2013 the majority of the lower reach consisted of riffles and runs (25 and 75%, respectively) while the upper reach was more complex with 5 flow habitats (cascade/fall, riffle, run, glide and pool). In 2014 a majority of the lower reach consisted of riffles (30%) and glides (70%) while the upper reach continued to have a mix of flow habitats. None of the flow habitats were dry during either year.

In 2013, water temperature, pH, and specific conductivity were all greater for the upper watershed than the lower, but consistent with previous data collected in the spring (2000-2012 *RCDSMM unpublished data*).

Table 7-1 Summary of Physical Habitat Conditions Topanga Creek Spring 2013 and 2014.

Location	TC3200-3350m 2013	TC4500-4650m 2013	TC3200-3350m 2014	TC4500-4650m 2014

NR= Not recorded; *Microalgae thickness code was 0 for all reaches and years, which corresponds to (absent=<1mm) ; **% Presence includes unattached and attached macroalgae.

In 2014 water temperature was greater in the lower watershed, while pH was about the same in the lower and upper watershed. However, dissolved oxygen (mg/L) was slightly higher in the lower watershed than the upper in both 2013 and 2014.

7.3.2 Streambed Substrates, Embededness and Canopy Cover

The average embeddedness was greater (49%) in the lower reach than the upper (26%) in 2013. By contrast the embeddedness in the lower reach (49%) was similar to the upper (44%) in 2014. In 2013 and 2014 both reaches were composed of a fairly even distribution of fines, gravel, cobble, and boulders. The lower reach, which has a lower gradient (<3%), did not have any bedrock. Smaller substrates (< 2”) such as fines and gravel were more frequent in the lower reach, whereas larger substrate (> 2”) such as cobbles, boulder, and bedrock were more frequent in the upper reach, which has a higher gradient (> 3%).

The data summarized in Table 7-1 indicates that although the channel width, depth and flow were relatively consistent between the two reaches, gradient plays a role in the flow habitats present. The upper gradient reach (4500-4650m) was pool dominated, and the lower gradient reach (3200-3350m),was dominated by run-riffle complexes. This pattern is also consistent with the higher percent of fines and gravel in the lower gradient reach and more cobble-boulder substrate in the upper gradient reach.

Vegetative canopy cover was generally high, with 82% cover observed in the lower reach in 2013 and 95% in 2014. Similarly, an increase in percent canopy cover was observed in the upper reach from 2013 (65%) to 2014 (83%).

In 2013, the macroalgae presence was higher in the lower reach (24%) than the upper reach (10%). However, in 2014 the macroalgae presence in the lower (5%) and the upper (4%) were almost equal.

7.3.3 Instream Habitat Complexity and Riparian Vegetation

Instream habitat complexity includes abundance levels of filamentous algae, aquatic macrophytes, boulders, woody debris, undercut banks, overhanging vegetation, living tree roots and artificial structures. Scores for physical/habitat conditions were not generated. However, instream habitat complexity for each reach was evaluated, and the frequency of channel features recorded along each reach that had a cover value greater than (1) is shown (Figure 7-1)

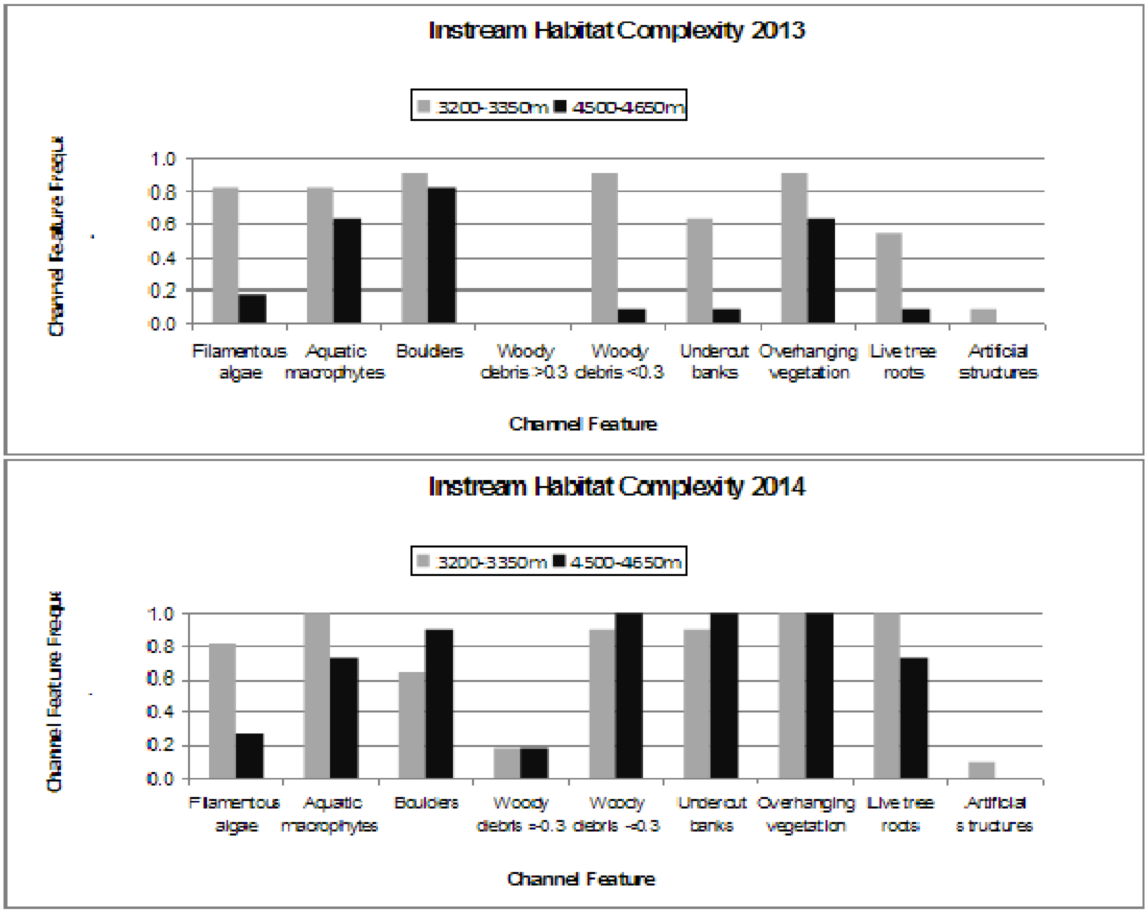

Figure 7-1 Instream habitat complexity of two reaches in the Topanga Creek watershed (3200-3350m and 4500-4650m) for 2013 and 2014. The frequency of each feature represents the number of times each feature was present (cover value ≥ 1) over the 11 transects of each reach.

In 2013, the lower reach (3200-3350 m) had greater instream habitat complexity, with each channel feature occurring more frequently than the upper reach. Neither of the reaches had large woody debris (> 0.3 m), and only the lower reach had artificial structures, due to proximity of Topanga Canyon Boulevard. Aquatic macrophytes, boulders, and overhanging vegetation were frequent for both reaches.

In 2014, both the lower reach (3200 -3350 m) and upper reach (4500-4650 m) had greater habitat complexities than in 2013. Each reach exhibited an increase in the frequency of almost every channel feature present in 2013. In addition, large woody debris (> 0.3 m) was observed in 2014, compared to none observed the previous year. Aquatic macrophytes, boulders, woody debris (<0.3 m), undercut banks, overhanging vegetation and live tree roots were frequent for both reaches.

Finally, the different classes of riparian vegetation contributing to each reach are shown in Figures 7-2 and 7-3. Figure 7-2 shows the proportion of riparian vegetation cover values for the lower reach (3200-3350m) and upper reach (4500-4650 m) in 2013. Figure 7-3 shows the same values for each reach in 2014.

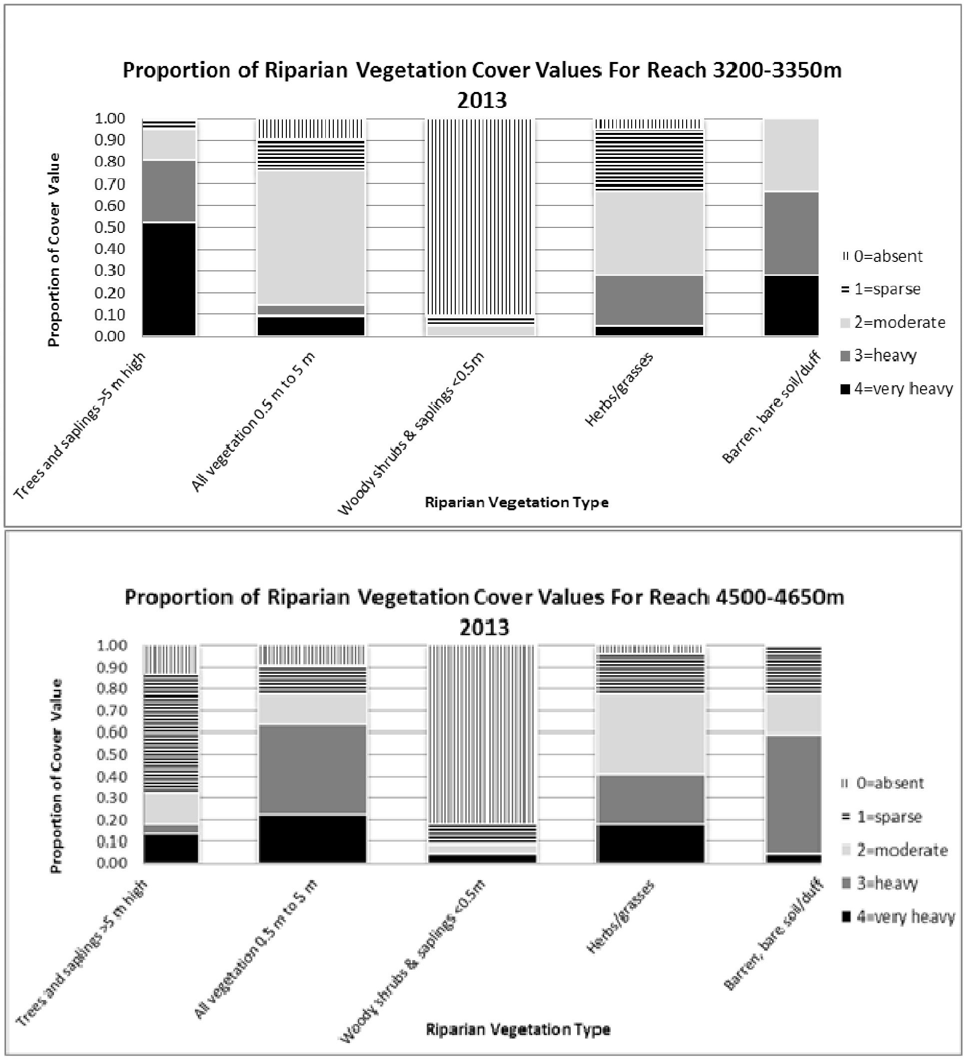

Figure 7-2 Proportions of riparian vegetation cover values of two reaches in the Topanga Creek watershed (3200-3350m and 4500-4650m) for 2013 where areal cover (shading) for each of the vegetation types is represented as 0) absent, 1) sparse (<10%), 2) moderate (10-40%), 3) heavy (40-75%), or 4) very heavy (>75%).

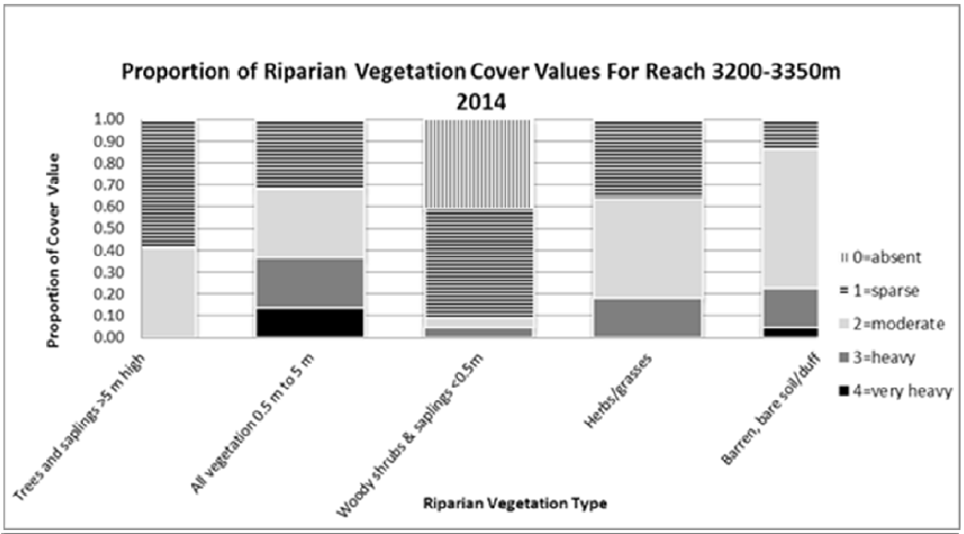

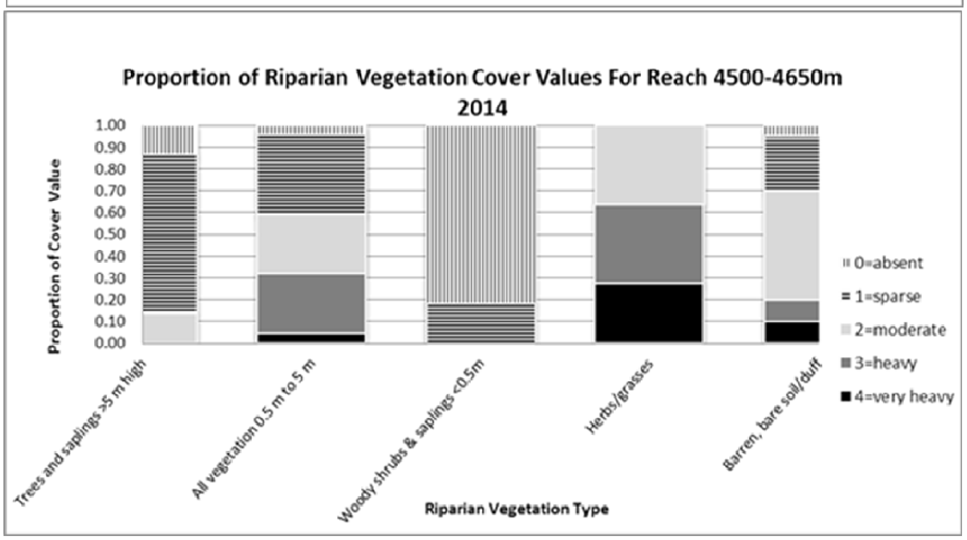

Figure 7-3 Proportions of riparian vegetation cover values of two reaches in the Topanga Creek watershed (3200-3350m and 4500-4650m) for 2014 where areal cover (shading) for each of the vegetation types is represented as 0) absent, 1) sparse (<10%), 2) moderate (10-40%), 3) heavy (40-75%), or 4) very heavy (>75%).

For both reaches, herbs and grasses had a fairly even distribution of sparse (1), moderate (2) and heavy (3) cover values in 2013 and 2014. In 2013 trees and saplings > 5m had the highest proportion of very heavy cover in the lower reach. However, the upper reach had a sparse cover of this vegetation type. Barren/bare soil/duff was a combination of moderate, heavy and very heavy cover for the lower reach, and mostly heavy in the upper reach. All vegetation from 0.5m to 5m was mostly moderate in the lower reach but heavy to very heavy in the upper reach.

In 2014 trees and saplings > 5m had the highest proportion of sparse cover in the lower and upper reaches, in contrast to 2013. Barren/bare soil/duff was mostly moderate for both the lower and upper reaches. All vegetation from 0.5 to 5m had a fairly even distribution of sparse, moderate and heavy cover for both the lower and upper reaches.

Riparian vegetation is an important element of stream habitat. In Topanga Creek, the extent of riparian vegetation is limited both by proximity of steep canyon walls in the narrow section of the upper gradient reach (4500-4650 m), as well as the frequency of flood events. There has been substantial growth of riparian vegetation throughout the creek since the last flood events that occurred in 2005, 2010 and 2011.

7.4 Discussion

The past three years have been very dry, and the physical habitat conditions reflect that. We have not had a flushing pulse of flow since March 2011. The one major storm in February – March 2014 was short lived and insufficient to scour the channel. Systematic sampling of physical habitat data is essential to collecting representative and quantifiable data, especially for the highly variable elements that comprise stream habitat structure. Prior to 2013, the physical habitat characteristics were documented using the methods of the CA Rapid Bioassessment Protocol (CDFG 1999) and that data remains to be examined in comparison to the information gathered using the new SWAMP protocols (Ode 2007, Fetscher et al. 2009).

Physical habitat includes documenting the flow and sediment regimes, channel and flood-plain structure, hydrologic alterations, riparian vegetation quality and extent, and responses to anthropogenic stressors. All of these variables affect the abundance, diversity, and seasonal community structure of primary producers such as diatoms, soft-bodied algae, macroalgae, and benthic macroinvertebrates. They can ultimately dictate changes in a variety of trophic levels when the physical elements of habitat respond to changes in the environment. As such, physical habitat documentation is critical to understanding the relative importance of various environmental indicators.

Overall, both reaches of Topanga Creek have relatively stable banks and a variety of in-stream habitat types (runs, riffles, pools) that can support a complex assemblage of aquatic organisms. The higher level of fines and gravel in the lower reach are highly mobile. Snorkel survey and habitat typing focused on habitat for endangered steelhead trout documented the pulses of sediment moving downstream with storm events over time (Dagit and Krug 2011). While the specific location of the sediment slugs varies over time and results in decreased pool habitat in certain reaches, the overall amount of pool habitat and refugia for fish remained fairly constant, despite a very wet year in 2005.

Overall, channel morphology has also remained fairly constant over time (Dagit and Krug 2011).

7.5 Summary

- Rainfall was below normal for both years the study took place, and significant rain events were few and far between. Therefore, flow was consistently low throughout the study period as well.
- The average wetted width of the creek remained fairly constant throughout the study but average depths decreased in some locations in 2014.
- Water temperature, pH, and specific conductivity were relatively stable and consistent with previous data collected (Dagit et al 2004, 2000-2012 RCDSMM *unpublished data*).
- Habitat types remained consistent during the course of the study with riffles, runs and glides dominate in the lower reach of the creek (below 3600 m) and a more complex mix of flow habitats (cascade/fall, riffle, run, glide and pool) found upstream. None of the flow habitats were dry during either year.
- Geomorphology and gradient affect the types of flow habitats present, with the lower gradient reach below 3600 m (<3%) being dominated by run-riffle complexes and the upper gradient (3-6%) being pool dominated.
- Smaller substrates such as fines and gravel were more frequent in the lower reach, whereas larger substrate such as cobbles, boulder, and bedrock were more frequent in the upper reach, which has a higher gradient (> 3%).
- Instream habitat complexity includes abundance levels of filamentous algae, aquatic macrophytes, boulders, woody debris, undercut banks, overhanging vegetation, living tree roots and artificial structures. In 2014, both the lower and upper reaches had greater habitat complexities than in 2013 despite the low flows.
- The proportion of cover values for several riparian vegetation types were estimated for the lower and upper reaches. Trees and saplings > 5m had the highest proportion of sparse cover in both the lower and upper reaches.

8 Spatial, Temporal, and Regional Analyses of Benthic Macroinvertebrate Communities in Topanga Creek: 2002-2014

8.1 Abstract

Benthic macroinvertebrate bioassessment was conducted in Topanga Creek as part of a larger bacterial source-identification study. The Southern California Coastal Index of Biotic Integrity (SCC-IBI) was applied to samples collected 2003-2014 to analyze spatial and temporal correlations between biotic integrity and water quality conditions. A few distinct trends regarding the benthic macroinvertebrate (BMI) community of Topanga Creek emerged during the course of this study. 1. SCC-IBI scores for Topanga Creek range from 'Very Poor' to 'Fair' 2. SCC-IBI scores indicate a significant negative correlation between % non-insect taxa and levels of dissolved oxygen. 3. Taxa composition is more similar across samples collected on the same date, versus samples collected at any one site. 4. Functional feeding group composition is more stable than taxa composition per site and over time. 5. Worsening drought conditions through winter 2012/2013 may have caused a significant shift in species composition in Topanga Creek. 6. Regional comparison of Topanga Creek indicates relatively degraded conditions. 7. Such conditions may be a result of human and natural influences, particularly land development and drought.

8.2 Introduction

The benthic macroinvertebrate (BMI) community, such as snails, dragonfly nymphs, true fly larvae, worms, and other bottom-dwelling aquatic organisms of a freshwater stream, are vital indicators of riparian ecosystem health (Ode et al. 2005). Benthic macroinvertebrate sampling adds a biotic element to standard water quality testing procedures and is an invaluable tool for ecologists, resource management professionals, and anyone interested in investigating and maintaining healthy streams. As primary consumers of allochthonous (terrestrial leaf litter) and autochthonous (aquatic plant) detritus, benthic macroinvertebrates are the most basic link between both aquatic and riparian vegetation and the rest of the stream community (Voshell 2002). Filling distinct feeding niches, some species shred whole leaves and stalks, others scrape up the film left behind, ultimately releasing a large pool of nutrients that can be absorbed by higher trophic levels (Covich et al. 1999). Analysis of functional feeding group (FFG) diversity can shed light on how nutrients begin to flow at these primary trophic levels.

In addition to FFG designations, many families, genera, or species have assigned tolerance values 0-10 (CAMLnet. 2003) that describe the organism's ability to live in polluted waters. Another key feature of benthic macroinvertebrates is their tendency to reveal current and past ecological disturbance (Boulton 1992). Some taxa, such as mosquitoes, may appear and disappear within a week, while others, like some common dragonflies, develop underwater over the course of a year or more (Voshell 2002). Therefore, shifts in species composition may be the result of a current disturbance event or one that occurred within the year. Habitat preferences, limitations, and additional life-history traits have been described for 3,857 North American lotic macroinvertebrate species (Vieira et al. 2006). Indexes of Biotic Integrity (IBI) have been developed using this information to evaluate BMI community composition and distribution and to assign numeric and descriptive scores of ecological health (Fetscher et al. 2009, Ode 2007).

The Southern California Coastal Index of Biotic Integrity (SCC-IBI, Ode et al. 2005) allows for a regionally-focused quantification of the ecological condition of a sampling site as characterized by its benthic macroinvertebrate community. SCC-IBI scores are calculated as a sum of the following seven metrics: EPT taxa (Ephemeroptera, Plecoptera, Trichoptera), Coleoptera taxa, predator taxa, percent non-insect taxa, tolerant taxa, intolerant individuals, and percent collector-gatherer individuals. In this paper, the SCC-IBI is applied to three distinct BMI collections in order to gain spatial (water quality samples at five Topanga Creek sites 2013-2014), temporal (annual stream survey samples from two sites 2002-2014), and regional (Heal the Bay data from Arroyo Sequit, Cold Creek, Malibu Creek, Solstice Creek 2000-2013) perspectives on the biotic integrity of Topanga Creek (Figure 8-1).

Topanga Creek, a small southern California coastal drainage, lies within an approximately 47-km^2 watershed that drains into the Santa Monica Bay, in Los Angeles County. The watershed provides vital habitat for endangered steelhead trout, 22 species of amphibians and amphibians, nine species of bats, and numerous other plants and animals. Approximately 70% is protected parkland owned by California Department of Parks and Recreation. The remaining 30% is developed within the village of Topanga, (population 12,000 as of 2010, Los Angeles County Census 2010). Development along Topanga Creek begins at about 6500 m (upstream from the ocean) and continues upwards. The mouth of the creek lies within Topanga Beach which received poor grades for bacterial levels on Heal the Bay's Beach Report Card between 2006 and 2014.

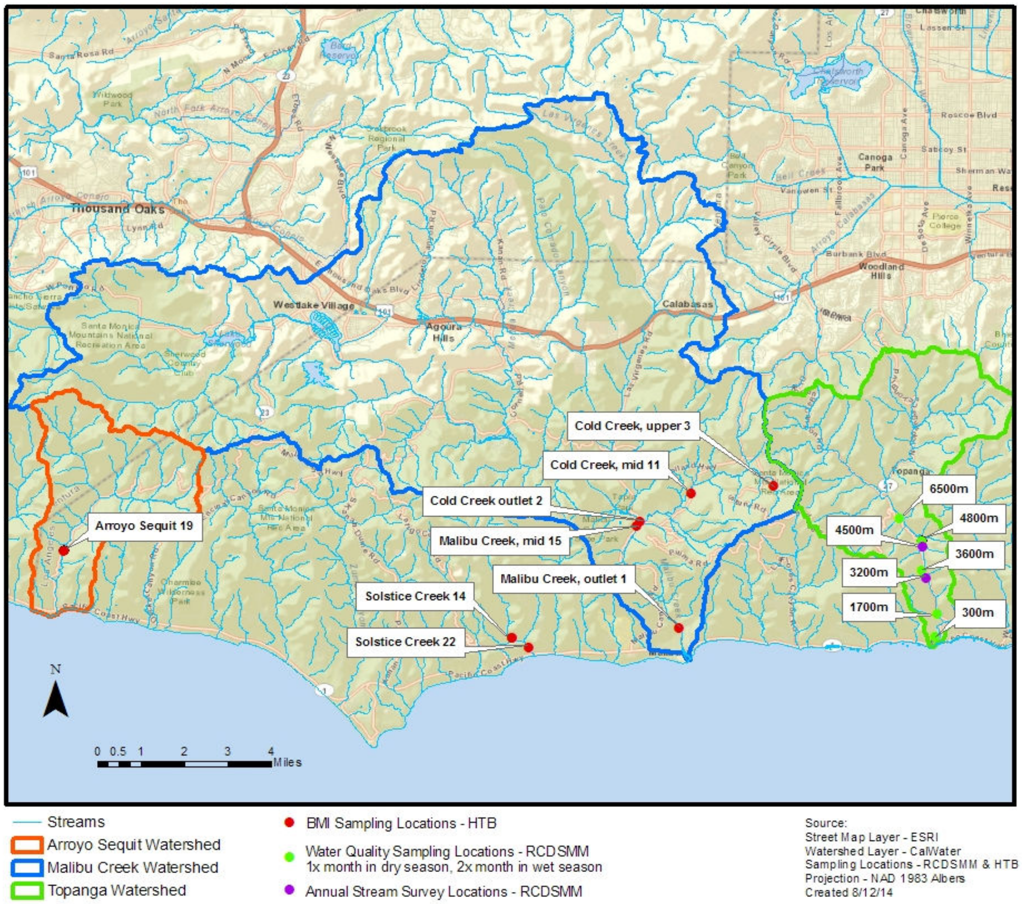

Figure 8-1 Topanga Creek and Santa Monica Mountain sampling sites 2000-2014.

In 2012, a source identification study was launched in collaboration with Los Angeles County, the Resource Conservation District of the Santa Monica Mountains (RCDSMM), and the Jay Lab University of California at Los Angeles (UCLA) to investigate potential sources of bacteria observed at Topanga Beach. Water quality testing occurred at eight sites between the ocean outlet and 6500 m upstream from to December 2012 to August 2014, documenting habitat condition observations and water sample sampling for nutrients and fecal indicator bacteria (FIB) analysis. Benthic macroinvertebrates were collected from six of these sites on four occasions in 2013-2014.

Comparing water quality conditions to the community composition and distribution of BMI provides an opportunity to identify correlations between the biotic integrity of Topanga Creek with instances of nutrient pollution, low flows, low dissolved oxygen, and more. Additional BMI and water quality sampling during annual stream surveys in spring (Apr/May) 2003-2014 at two reaches were also incorporated into this study to provide a longer-term context of how creek conditions or climate may affect BMI community diversity over time. These results were compared to other sampling locations within the Santa Monica Bay allowing comparison of regional SCC-IBI scores and to place Topanga Creek within that regional context. The application of SCC-IBI, alongside additional analyses such as Simpson's Diversity Index and Bray-Curtis Dissimilarity measure, provide a comprehensive evaluation of the health of the Topanga Creek watershed and the relationship between various stressors and its biological condition.

8.3 Methods

Sample Collection

BMI collections occurred in conjunction with water quality testing in May and September 2013, as well as April and July 2014 along a continuum (6500 m to 300 m) of five sites (Owl Falls- OF, Scratchy Trail - ST, Topanga Bridge -TB, Brookside - BR, and Snake Pit- SP) according to California Rapid Bioassessment Procedure (Ode 2007) (Table 8-1). Starting at the downstream end of the site, a riffle within the reach was randomly selected and a total of nine 1-ft. wide kick net samples were collected at each left, center, and right of three consecutive riffles, and combined for a composite sample of nine kicks. SP was only sampled in 2014, and BR was not sampled in September 2013, as the site was dry.

For the annual stream surveys in Topanga Creek, the California Rapid Bioassessment Procedure (Ode 2007) was used from 2003-2014, but in 2013 and 2014 the SWAMP Bioassessment Procedure (Fetscher et al. 2009) was used. A 1ft^2 kick net sample was collected every 15 m along a 150 m transect, alternating along the way between 25%, 50% and 75% from right bank, for a composite sample of 11 kicks.

Annual stream survey collections took place in spring (April or May) of 2003, 2004, 2005, 2006, 2009, 2010, 2011, 2012, 2013, and 2014 at two locations: Upper Topanga (UT) and Lower Topanga (LT)(Table 8-1). Upper Topanga is above the Topanga Canyon Bridge (MM2.02) in the main stem of the higher gradient (3-6%) reach (4500 m). Lower Topanga Creek is in the main stem of the creek in the low gradient (<3%) reach (3200 m). Samples collected from UT 2004 and 2007, and LT and UT in 2008 and 2009 were not viable for processing and are not included in analysis.

Table 8-1 Topanga Creek Benthic Macroinvertebrate Sampling Sites 2003-2014.
Samples highlighted in gray had at least 500 individuals for SCC-IBI analysis.

				6/19/2014	4757

Annual stream survey samples were also collected from nearby creeks, such as Arroyo Sequit, Cold Creek, Solstice, and Malibu from 2000-2013 by the Heal the Bay (HTB) Stream Team and processed by Sustainable Land Stewards International (SLSI) (Table 8-5). From 2000-2012 annual stream surveys were done according to the California Rapid Bioassessment Method (2005, 2009). Standard 1-ft. wide kick nets were deployed and collected at each left, center, and right of three consecutive riffles, and combined for a composite sample of 9 kicks. Thereafter (2013-2014), SWAMP protocol was followed. All samples were preserved either in 90% ethanol or by freezing and were archived at the RCDSMM until processing began.

Sample Processing and Analysis

Processing of archived BMI samples began in June 2013. Each sample was strained and, in most cases, samples were processed entirely. Using a dissecting microscope, organisms were sorted and identified to the lowest practical taxon- family, sub-family or species level when possible. Identifications were confirmed using the California Aquatic Bioassessment Laboratory (ABL) and Merritt et al. (2008). Processors also referred to Heal the Bay's benthic macroinvertebrate data from other nearby creeks within the Santa

Monica Bay 2000-2013. A second processor and/or supervisor checked a subsample of each sample to ensure completeness, and accuracy of identification. When identification was not possible, photographs were sent to Dan Pickard at CDFW ABL or identified to the lowest taxonomic level possible and recorded as non-distinct within that taxon. Data was recorded on a standardized processing sheet and transferred into an Excel database. Processing was evaluated for overall error by randomly selecting a subset of 10% of all samples having more than 500 individuals by assigning a random number to each sample. Ten percent of those samples' vials were then re-identified by another processor, and identification outcomes were compared. This resulted in an overall error of <10% to be applied to BMI data reporting.

Processed samples were assessed according to the Southern California Coastal Index of Biotic Integrity (Ode et al. 2005). For this index, seven metrics are used to assess ecosystem health: EPT taxa, Coleoptera, and predator taxa richness, % non-insect taxa, % tolerant taxa (TV>7), % intolerant individuals (TV<3), and % collector-gatherer + collector-filterer (CG+CF) individuals. Information regarding tolerance values and functional feeding groups was obtained on CAMLnet (2003). These seven metrics were scored according to Ode et al. (2005) in order to provide a single measure of overall ecosystem health (Table 8-2). As this metric was designed for samples of 500 individuals, samples with less than 500 organisms were not used for IBI calculations. For samples with more than 500 organisms, each individual was assigned a number and 500 random numbers were generated in order to create a subsample of 500 random individuals for IBI calculations.

Table 8-2 SCC-IBI metric scoring as adapted from Ode et al. 2005.

Total IBI score	Score of biotic integrity
0-13	Very Poor
14-26	Poor
27-40	Fair
41-55	Good
56-70	Very Good

Simpson's Index of Diversity was applied to measure species richness and evenness, which defines high diversity as having several different species of similar abundance, or 'evenness' (Simpson 1949). Simpson's Index (D) was calculated according to the following equation, where "n" is equal to the number of individuals of a particular species and "N" is equal to the total number of organisms found:

$$D = 1 - \left(\frac{\sum n(n-1)}{N(N-1)} \right)$$

Subtracting from one provides a reciprocal index ranging from 0 to 1, where 1 represents high diversity and vice versa. The sum can be interpreted as the probability that two individuals randomly selected from a sample will belong to different taxon.

Bray-Curtis analysis (Bray and Curtis 1957) is a measure of dissimilarity between two samples. It accounts for both 'size' and 'shape', so dissimilarity is a measure of both total number and species composition. When the coefficient is subtracted from 1, a measure of similarity is acquired. The Bray-Curtis coefficient was calculated as follows:

$$B - C = \frac{\sum_{i=1}^{n} |y_{i1} - y_{i2}|}{\sum_{i=1}^{n} (y_{i1} + y_{i2})}$$

Simpson's Diversity Index and Bray-Curtis calculations were applied to whole samples, not sub-samples of 500, as they account for both sample size and shape. For water quality samples, this analysis was based on the species distribution between six primary taxa groups: *Baetis sp*., *Simulium sp., Chironomid sp.,* Ostracod, Amphipod, and other. For annual stream surveys, analysis was also based on species distribution to six different primary taxa groups: Chironomid, Crustacea, other-insecta, Gastropoda, EPT, and other. These groups were delineated to take into account dominant taxa in the different samples and the need for whole-sample inclusivity. At no point were water quality samples 2013-2014 compared to annual stream surveys 2003-2014.

Statistical analyses, including regression and t-tests were applied to compare results spatially and temporally within sampling types, and test for correlations between biotic indices and water quality conditions including average fecal indicator bacteria levels, nutrient levels (nitrite-N, nitrate-N, ammonia-N, orthophosphates), rainfall (inches), temperature (ºC), and dissolved oxygen (% sat.) to examine any possible relationships between those conditions and the BMI community assemblage.

8.4 Results

The results are organized by analyses type (1. SCC-Index of Biotic Integrity, 2. Taxa Composition and Diversity Measurements), as well as by sampling type (1. water quality samples 2013-2014, 2. annual stream surveys 2003-2014, 3. regional stream surveys 2000-2013).

8.4.1 Southern California Coastal - Index of Biotic Integrity Results

8.4.1.1 Water Quality Sampling 2013-2014

Out of 17 total samples collected during water quality events, seven had over 500 individuals (Table 8-3). These were subsampled to 500 individuals, and were included in statistical analyses. The April 14 SP (300 m) sample was also included (n=492). All were in the Fair to Very Poor ranges. OF (6500 m), the site closest to the town of Topanga and residential development, consistently scored the lowest at 10-18 (Very Poor-Poor). Scratchy Trail (4800 m), which is almost 2,000 m downstream, scored the highest of all samples with a score of 33 (Fair). Further downstream, TB (3600 m) scored a 22 (Poor), and BR (1700 m) scored a 25 (Poor). Both TB and BR are roadside adjacent.

The lowest metrics, consistently across all sites are percent intolerant individuals, and percent tolerant taxa. No significant correlations were found between SCC-IBI total scores and site conditions such as flow, depth, water temperature or dissolved oxygen (regression analysis, significance F >0.05). There was a significant correlation between dissolved oxygen and SCC-IBI metric % non-insect scores in Topanga Creek ($F<0.05$, $r^2=0.52$). In some instances, fecal indicator bacteria correlated with SCC-IBI scores. Average total coliform per site in 2014 (excluding first flush) was significantly and negatively correlated to EPT taxa, and also to total SCC-IBI scores ($F<0.05$, r2=0.88, $r^2=0.64$). Average nutrient levels did not seem to correlate with SCC-IBI scores.

Gray cells had n>500 are subsampled for SCC-IBI. SP0414, n=492, was included in statistical analysis.

8.4.1.2 Annual Stream Surveys 2003-2014

Three out of ten of the annual spring stream samples from Lower Topanga (LT; 3200 m) and five out of eight samples from Upper Topanga (UT; 4500 m) had >500 individuals and these eight samples were subsampled to 500 individuals for SCC-IBI scoring.

Overall, there did not seem to be a significant difference between sites, or a trend among sites or years for total IBI scores (Table 8-4). LT scored the highest overall in 2007 (40; Fair). The lowest scores were from LT in 2005 and UT in 2014 (16,15; Poor). There were two years, 2005 and 2014, when enough individuals were collected from both sites so that a comparison could be made. In 2005, UT scored higher (23 vs. 15), whereas in 2014, LT scored higher (19 vs. 15). The lowest metric across all 500 (n) samples was % intolerant individuals, which never surpassed score of 1. Conversely, the highest metric on average was % tolerant taxa. This stands in contrast to water quality samples from 2013-2014, when % tolerant taxa was the lowest. This may be the result of a shift in species composition discussed in Section 9.4.3. No significant correlations between SCC-IBI metrics and recorded creek conditions were found.

8.4.2 Taxa Composition and Diversity Measurements

8.4.2.1 Water Quality Sampling 2013-2014

In addition to SCC-IBI, taxa composition was analyzed and diversity measurements applied. Between Owl Falls (6500 m) and Snake Pit (300 m), taxa composition varied over time and reach (Figure 8-2), however Functional Feeding Group (FFG) composition was more consistent. Potential links between BMI community and water quality conditions are included in the following results, organized by site.

Starting with Owl Falls, the BMI community was dominated (Relative Abundance (RA) >50%) by planktonic crustaceans, Amphipoda (freshwater shrimp) and Ostracoda (seed shrimp), except in April 2014 where a Chironomid (non-biting midge) larvae bloom dominated all six sites. Oligochaeta and Planarian (flat and segmented worms) were present in high numbers in September 2013 and June 2014, 21-24% RA respectively. Other insect taxa (EPT, Coleoptera) at Owl Falls occurred in much smaller numbers (average RA <5% for all four dates). Insect taxa present all four months at OF include the nymphs or larvae of Leptohyphidae (Tolerance value (TV) =4), Haliplidae (TV=7), and Hydroptilidae (TV=6).

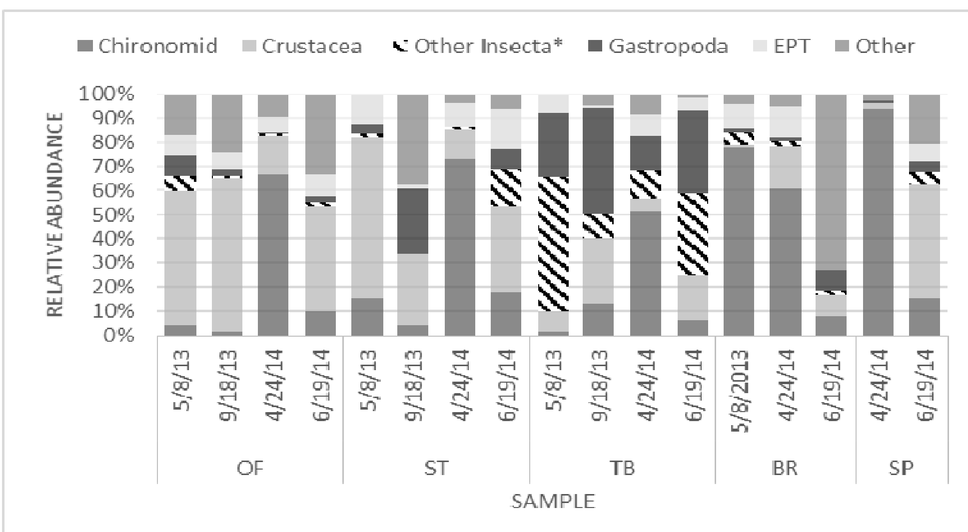

Figure 8-2 Relative Abundance of six major categories at OF, ST, TB, BR, SP.
*Other Insecta includes Coleoptera and Plecoptera. Crustacea includes Amphipoda and Ostracoda.

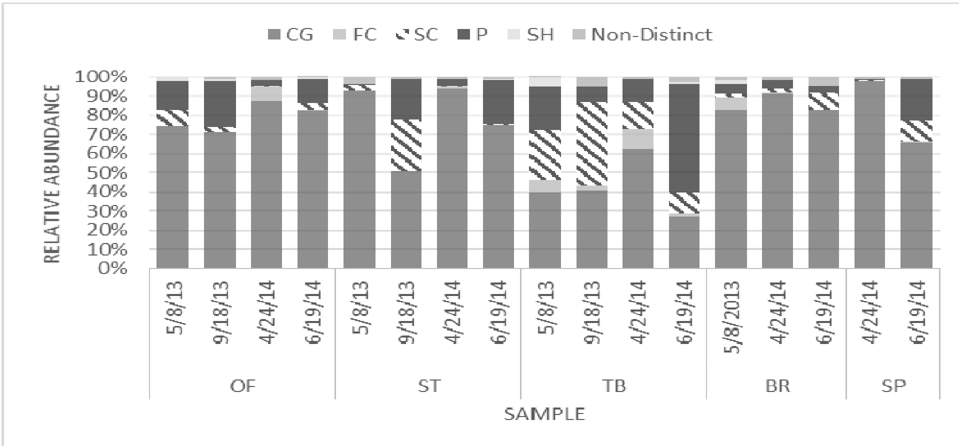

Figure 8-3 Relative abundance of functional feeding groups at OF, ST, TB, BR, SP.

Leptohyphidae, or little stout crawler mayflies, have gills that are specialized for waters that are warm, silted, and/or have low-dissolved oxygen (Voshnell 2002). Dissolved oxygen levels at OF was relatively low, measuring 35-71%. While mayflies are usually an indicator of good water quality, Letohyphidae is an exception (Voshnell 2002). Other exceptions include Caenidae and Baetidae, which comprise the majority of Ephemeroptera in Topanga Creek. While average depths from 9/13 to 6/14 were relatively high (12.7-16.2 in) levels in 5/13 were as low as 4.7 in, flow varied from 0.11-0.18 f^3s. Haliplidae, crawling water beetles, are often associated with macroalgae like *Chara*, and Hydroptilidae (microcaddisflies) with filamentous algae, both potentially indicative of nutrient pollution. An algae bloom was observed in August 2014. OF did have the highest average ppm nitrate (0.06) and orthophosphates (0.19) across all sampling dates (Table 6-11 and Table 6-14, respectively).

Both Owl Falls (6500 m) and Scratchy Trail (4800 m) simultaneously experienced Ostracoda (May ’13) and Amphipoda dominance (Sept ’13), when neither taxon prevail downstream, suggesting some level of connectivity between sites. Three out of four months ST had the highest Simpson’s Diversity Index (Figure 8-4), primarily due to greater species evenness. Plankton remain highly abundant overall. Insect taxa that were present in at least 75% of ST samples include Leptohyphidae, Baetidae, Elmidae, Hydroptilidae, and Ceratopogonidae. While these additional taxa are also present in Owl Falls, their increased abundance at Scratchy Trail may illustrate improved habitat conditions. Dissolved Oxygen at ST was measured between 76-83%, and average depth 10.11-17.2 in on sampling days. The highest SCC-IBI scores in April and July 2014 (20, 33) support this observation.

Topanga Bridge (TB) had the most stable Simpson’s Diversity Index (Figure 8-4) and SCC-IBI scores (18-26). Although water levels at TB were low (2-3 in.), DO remained

62-75%. TB has the first or second highest SCC-IBI scores in April and July 2014. One of three Gastropoda families are the first or second most abundant taxa each month, *Physa sp*. (5/13), Hydrobiidae (9/13,4/14), and Viviparidae (6/14). Odonata diversity is also higher at TB, with nymphs of the three genera: *Argia sp*., *Enalgamma sp*., and *Libellulidae sp*. In May 2013, Elmidae 'riffle beetle' larvae, comprised 30% relative abundance. Elmidae require high levels of dissolved oxygen and are found in waters with near saturation. Plecoptera, a family synonymous with good water quality, makes its first appearance at TB in the form of *Ispoerla sp*. nymphs (common stoneflies) collected 6/19/14.

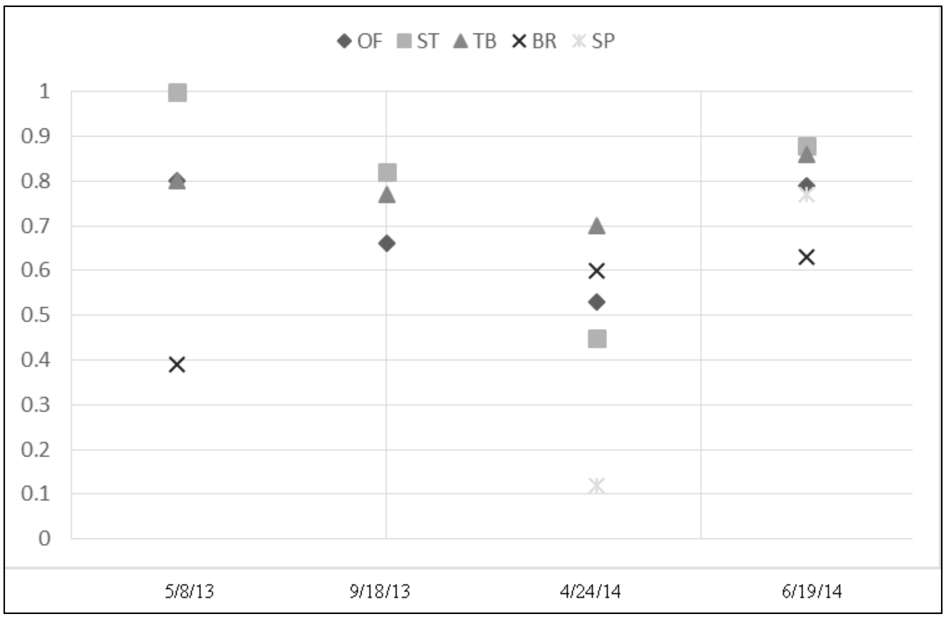

Figure 8-4 Simpson's Diversity Index scores for Source ID sites May 2013-July 2014.

At Brookside (BR 1700 m), which went dry in September 2013, mosquitoes or non-biting midges dominated in each sample. After water returned, *Culex sp*. larvae comprised 60% RA in July 2014. At that time, DO hit a low of 50%. Many species of Culicidae prefer temporary habitats. BR had the highest levels of Ammonia (average 0.27 ppm), potentially due to the consistent dumping of urine waste by an RV along Topanga Canyon Blvd above the site (Figure 6-2). Culicidae reproduction and Chironomid abundance have been observed to increase in Southern California wetlands enriched with ammonia (Sanford et al. 2005). While both of these Dipteran taxa are tolerant of nutrient enriched waters, other less-tolerant taxa also are found at BR. Nemourid stone fly nymphs, and Carabidae 'ground beetle' larvae with a tolerance value 4, each made up 2% RA in May 2014.

Snake Pit, sampled only in April and July 2014 also displayed variability. In April, SP had the lowest SCC-IBI and Simpson's Diversity score of 1 (Very Poor). All 16 taxa found at this time were from Diptera, Hemiptera, or non-insect; Chironomidae composed 94% RA. In July 2014, scores improved, although no significant site condition changes occurred. Chironomidae RA was reduced to 15%, while Ostracoda made up 24%, and Simpson's Diversity Index increased (from 0.1 to 0.8). In addition to the previously sampled families/phylums, Trichoptera, Odonata, and Coleoptera appeared in July. According to Bray-Curtis analysis that was applied to eight primary taxa groups, samples taken from all sites on the same date had a higher similarity (37%) than those taken from the same site across four dates (27%). This trend holds true for FFG composition as well. This suggests homogeny throughout the system. Additionally, the similarity coefficient between FFG composition (Figure 8-3) across both time and place, was significantly higher than taxa composition (t-test, $p<0.05$). This upholds the findings of Vannucchi et al. (2013) that feeding niches filled by benthic macroinvertebrates may remain filled, even though the specific species change. Therefore, systematic stability of nutrient flow and energy flux may remain, even without stability of distinct species populations.

8.4.3 Annual Stream Surveys 20013-2014

The number of individuals collected from the annual spring stream surveys from Upper and Lower Topanga Creek ranged from 104 to 3,516, representing six phyla, 21 orders, and a total of 76 taxa. The majority of individuals fell within the phylum Arthropoda and class Insecta, followed by the subphylum Crustacean, including class Ostracoda and order Amphipoda. To date, the invasive New Zealand mud snails (*Potamopyrgus antipodarum*) have not been observed in Topanga Creek.

Between 2003-2012, *Baetis sp.* (blue-winged olives), a prolific genera of small minnow mayfly, was the first or second most abundant taxon every year in both Upper and Lower reaches (Figure 8-5). *Baetis sp.* made up between 33-79% relative abundance (RA) in Upper Topanga, and 13-67% in Lower. The family Baetidae are characterized as strong swimmers, most prevalent in flowing, shallow waters with ample cobbles and/or pebbles (Voshell 2002). *Baetis sp.* are collector-gatherers with a tolerance value of 6. In 2013 and 2014, *Baetis sp.* no longer dominated and in fact comprised less than 10% RA of all four samples. Chironomidae, which had previously made up between 5-36% shifted to occupy the top spot, comprising 63-72% of all samples in 2013-2014. Chironomids are also primarily collector-gatherers, and are ascribed a family-wide tolerance value of six. However, the Chironomidae family is extremely diverse, including over 1,000 species, and thrive in equally diverse habitats. Chironomids were identified to sub-family or tribe for a few select samples, and similar taxa were found before and after 2013.

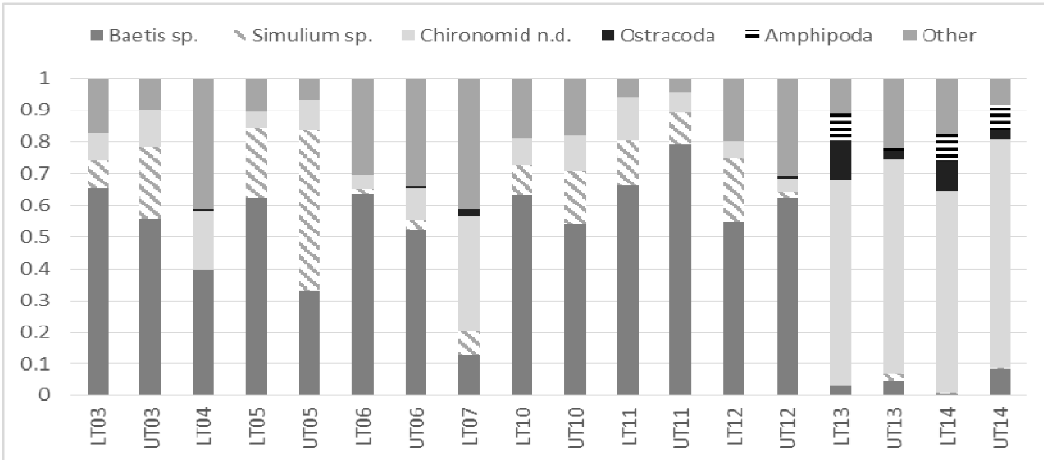

Figure 8-5 Relative Abundance of 6 Major Taxon Categories: Upper and Lower Reaches Topanga Creek 2003-2014.

Two concurrent phenomena occurred between the 2003-12 period as compared to 2013-14. Between 2003-12 *Simulium sp*. (a member of the black fly family) was present in all six Upper Topanga samples with an average relative abundance 18%, and 12% in seven out of eight Lower Topanga samples. However, in 2013 and 2014 *Simulium sp.* made up only 2% average relative abundance in Upper Topanga, and were not present at all in Lower samples. Simulidae, which occur only in flowing waters (Voshnell 2002), are collector-gatherers, with a tolerance value of six.

Another stark difference between 2003-12 and 2013-14 was the presence of Amphipoda or 'scuds.' A subsample of scuds were identified to be of the family Hyallelidae. Of all 14 samples from 2003-12, Amphipods were only found in Upper 2003 at 0.13% RA. Beginning in 2013, scuds appeared again at 1-8% RA (Upper-Lower), and jumped to 3-29% in 2014. Scuds are bottom-dwellers and are rarely found in waters deeper than 1 m (Voshnell 2002). Scuds are predominantly collector-gatherers, and have a tolerance value of eight. Scuds are most often found in large numbers where fish are not present, as they are a preferred food source. However, snorkel survey observations document that fish are present at all sampling sites (RCDSMM, *unpublished data*), and thus they are either not selectively preying upon scuds, or the reproductive rate of scuds exceeds the predation rate. Despite these changes, functional feeding group composition remained dominated by collector-gatherers. (Figure 8-6) There may be a decline in evenness of FFG in 2013-2014.

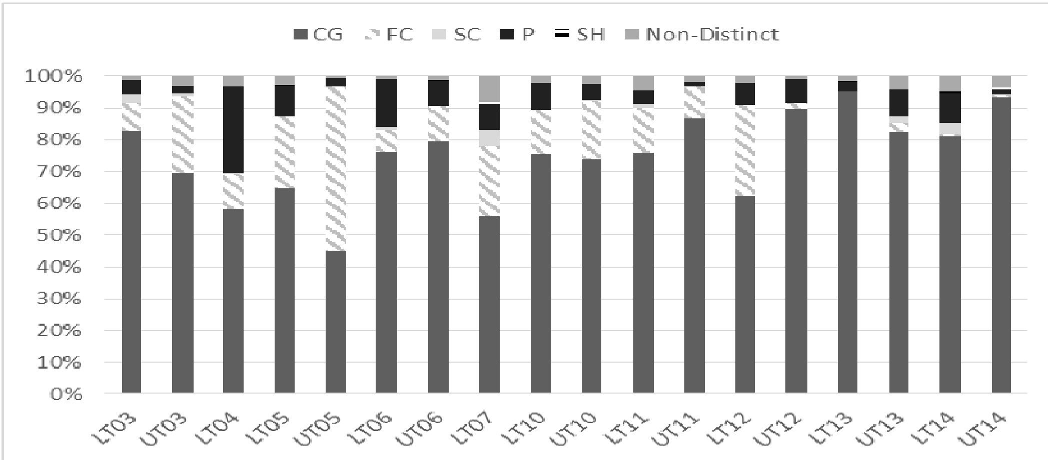

Figure 8-6 Relative Abundance of 6 Major Feeding Group Categories: Upper and Lower Reaches Topanga Creek 2003-2014

Bray-Curtis analysis of dissimilarity points to a trend between rain patterns and BMI species composition in Topanga Creek (Figure 8-7). Excluding the two wettest years (rainfall >30 inches), analysis of the annual stream survey samples showed that the dissimilarity coefficient (how different from all other years) was negatively correlated to rainfall (regression test, significance F<0.05). This suggests a threshold equal or less to 30 inches, over which high rainfall also disturbs BMI communities.

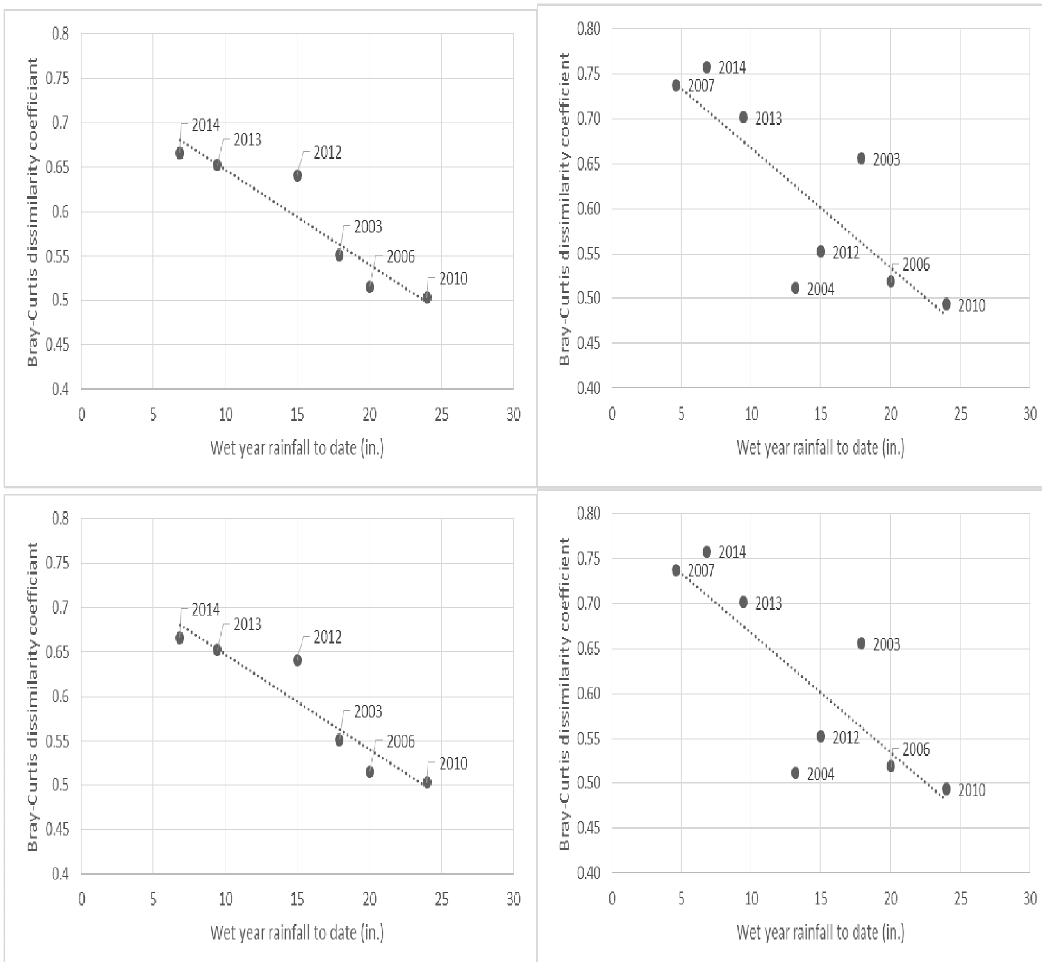

Figure 8-7 Rainfall vs. Curtis-Bray dissimilarity coefficient Upper (left) and Lower (right) Topanga. (R^2 = 0.88, 0.67 respectively)

8.4.4 Comparison of Topanga Creek IBI with other Santa Monica Bay sites

Although this study focused on Topanga Creek specifically, Heal the Bay has monitored BMI at a variety of locations within the Santa Monica Bay since 2000 (Figure 8-1). Table 8-5 summarizes the SCC-IBI information for sites considered to be reference (Arroyo Sequit AS19, and Cold Creek CC2, CC3, CC11) as well as for Malibu Creek (MC1, MC 15), which represents the more impacted reaches of lower Malibu Creek downstream of the Tapia Wastewater Treatment Plant that also support a population of steelhead trout.

SCC-IBI scores in Malibu Creek remained low since 2000, but reference sites such as those in Cold Creek, Solstice and Arroyo Sequit showed declines beginning in 2012. This regional pattern may be a reflection of the drought conditions affecting all local streams. Topanga Creek faced a sharp decline in SCC-IBI scores after 2001. The current drought period began in January 2002 entering a period of D0 intensity: 'abnormally dry;' and by mid 2002 the drought reached a level of D2: 'severe drought' until the winter rains in November 2002 (US Drought Monitor). It is not clear why scores in Topanga Creek began to fall in 2002, but this did not become apparent in other creeks until 2012. Although Topanga Creek is facing severe impacts from drought, reflected both by SCC-IBI scores and BMI species composition, it remains an important reference stream as it continues to flow where others in the region have gone dry.

Table 8-5 Adjusted[1] IBI Scores for Topanga and surrounding creeks 2000-2013.

8.4.5 Annual stream survey correlation to rainfall

During the course of the annual sampling in 2013 and 2014, water levels were consistently low, with little to no flow observed. While flow was not correlated to SCC-IBI scores, low dissolved oxygen levels did correspond to higher percentage of non-insect taxa, which did in turn lower overall SCC-IBI scores. Comparing scores with yearly rainfall to date, SCC-IBI scores 2003-2014 do not show any correlation. However, the observed shift in species composition from *Baetis sp./Simulium sp*. to Chironomid nd.

/Amphipod nd. occurred between 2012 and 2013. That winter was the first year since at least 2000 when wintertime rains did not alleviate drought conditions in the upper Santa Monica Bay. Drought intensity remained at D0: 'Abnormally Dry' or higher through the wet season, signaling an intensification of drought conditions in Los Angeles County (US Drought Monitor 2014).

8.5 Discussion

Benthic macroinvertebrate bioassessment of Topanga Creek at five water quality sites (2013-2014) provided additional insight to the biotic implications of water quality conditions. SCC-IBI scores indicated that the biotic integrity was lowest just below the town of Topanga at OF (6500 m). The highest scores were found at ST (4800 m), which was the only location to receive a 'Fair' rating. Without the anthropogenic influences of land grading, road or building development, ST is the least human-influenced site in the study. Simpson's Diversity was also highest at ST, due to a higher abundance of multiple taxa creating a more even distribution. This marked increase in biotic integrity suggests that water quality improves as water moves through the watershed from 6500 m to 4800 m. However, the high relative abundance of non-insects and dearth of low-tolerant taxa throughout the system support more consistent 'poor' SCC-IBI ratings further downstream, and suggests overall habitat degradation or disturbance.

Observed creek conditions that may influence these low scores include the input of fecal indicator bacteria, low dissolved oxygen, nutrient enrichment, and drought. Sites with higher average total coliform levels had significantly lower SCC-IBI total and EPT taxa scores. Low dissolved oxygen was found to correlate significantly with higher % non-insect taxa. The site (OF) with the highest average levels (ppm) of nitrate and orthophosphates, received the lowest SCC-IBI scores. High levels of ammonia, in conjunction with drought-related drying events likely created ideal habitat conditions for high abundance of mosquitoes (Culicidae) and midges (Chironomidae) at BR (Sanford et al. 2005).

Based on the Bray-Curtis analysis, samples collected on a particular date at all sites throughout the creek are significantly more similar to each other than samples collected at a single site over time. This suggests that although site conditions may influence the BMI community throughout Topanga Creek, overall system homogeny creates an environment in which cumulative effects over time may be a stronger driving force than location within the creek.

SCC-IBI scores for annual stream survey samples (2003-2014) found that Topanga Creek's lowest integrity metrics is percent intolerant individuals. Throughout this period, the percent tolerant taxa was the highest metric score, as the system was not dominated by pollution-tolerant organisms. However, when looking at the 2013-2014 water quality samples collected throughout the creek, the percentage of intolerant taxa remained the lowest and the percentage of tolerant taxa fell to the second lowest score. This suggests a shift to increased abundance of pollution tolerant organisms. Also, a drastic species composition change observed in the annual stream survey samples between 2012 and 2013 from *Baetis/Simulium* to Chironomid/Amphipoda signals a system-wide disturbance or condition change. Drought conditions did intensify between 2012 and 2013, as winter rains failed to alleviate drought conditions for the first year in at least a decade.

Future sampling to determine if this condition is persistent year-round or due to springtime blooms that correspond with sampling events should be considered. *Baetis* and Chironomids are both short lived species that can produce multiple generations per year in the Southwest; some species of *Baetis* complete their life cycle in 8-14 days (Gray 1981). Some species rely on specific life cycle cues, with only 1-2 generations a year, and so phenology changes could be potential driver of this observed phenomenon. Recent work has found that increasing water temperatures can induce earlier hatches of *Baetis* in the Western United States (Harper et al. 2006). Further analysis of water temperatures in Topanga Creek is recommended. The shift from *Baetis* dominance to Chironomids could also reflect a change in physical habitat conditions. The replacement of *Simulium sp*. with Amphipoda, particularly in Lower Reach samples, supports this hypothesis.

Our data suggested a correlation between community stability and rainfall. Years with low rain were more dissimilar than those with more rain. However, this no longer holds true with rainfall over 30 inches, suggesting that both drought and heavy flows can create disturbance to the BMI community.

In comparison with nearby creeks, including Malibu Creek, Cold Creek, Solstice, and Arroyo Sequit Creek, SCC-IBI BMI scores for Topanga from 2003-2013 are relatively low (Table 8-5). Topanga Creek remains one of the few perennial streams within the Santa Monica Mountains while many of these other locations are dry for much of the year. Although the SCC-IBI scores are low, the year round water in Topanga Creek supports a more complete assemblage of native amphibians and fish. It is difficult to explain why Arroyo Sequit, another perennial system that goes dry regularly, out-performs Topanga Creek by over 25 points on average.

The main limitation of applying the SCC-IBI metrics within this sample set was low abundance, as the majority (19 of 35) of our samples had fewer than 500 organisms. Seasonal variability within Mediterranean climates can be driven by short-term climatic factors and can vary greatly creating distinct seasonally-based communities (Gait and Resh 1999). However, It is important to note that it has been suggested that bioassessments like SCC-IBI may be less applicable to perennial streams, as survival in degraded streams requires many of the same life-history traits that also support survival of benthic macroinvertebrates in non-perennial streams (Mazor et al. 2013).

8.6 Summary

- Owl Falls was consistently the lowest SCC-IBI scores, and Scratchy Fall the highest. This may be a result of proximity to development.
- Average total coliform per site in 2014 corresponded to lower total and EPT taxa SCC-IBI scores.
- The SCC-IBI metric percentage of non-insect taxa is significantly higher when levels of dissolved oxygen are lower.
- Samples from a particular site were less similar, overall, than samples from the same date, suggesting homogeny throughout the creek.
- Functional feeding group composition was more stable than taxa composition per site and over time.
- Regional comparison of Topanga Creek indicated relatively degraded conditions.
- Both high and low flow conditions resulted in disturbed BMI communities.
- Worsening drought conditions during the winter 2012/13 may be causing a significant shift in species composition in Topanga Creek.

9 Red Swamp Crayfish (*Procambarus clarkii*) In Topanga Creek: Removal Efforts And Ecosystem Effects

9.1 Abstract

The presence of invasive red swamp crayfish (*Procambarus clarkii)* in Topanga Creek was first recorded in 2001. The population has since increased, with a population explosion in 2011, during an extended period of low flow. Within the Santa Monica Mountains, *P. clarkii* has been linked to diminishing numbers of California newt (*Taricha torosa*), a species of special concern (Katz 2013). To address these concerns, a student citizen science program was conducted from September 2013 through February 2014 to remove crayfish from a 200 meter reach of Topanga Creek. The following metrics were collected and compared between the removal reach and an upstream, adjacent 200 meter non-removal reach: water quality (temperature, salinity, pH, conductivity, dissolved oxygen, turbidity), nutrient levels (nitrate, nitrite, ammonia, orthophosphate), crayfish abundance, and macroinvertebrate communities. The following metrics were collected within the Removal Reach: catch per unit effort, average crayfish length, and sex distributions of removed crayfish. The results indicate that the effects of crayfish on nutrient levels are low or non-existent; however, the presence of crayfish seems to correlate with lower BMI biodiversity. This study was conducted to gain a better understanding of the effects of *P. clarkii* in the Topanga Creek ecosystem.

9.2 Introduction

Red swamp crayfish (*Procambarus clarkii*) have spread far across the globe, posing an invasive threat to freshwater species abundance and community diversity (Ficetola et al. 2011). Without checks to their population, red swamp crayfish easily become a threat. They can grow rapidly, maturing within three months after hatching and can reproduce twice a year in warm conditions (Barnes 1974; Vodopich and Moore 1999; Safra et al. 1999). Furthermore, large healthy females typically produce 600 viable young (Barnes 1974; Vodopich and Moore 1999; Safra et al. 1999). The generalist and predatory feeding habits of this Gulf Coast native have been linked to observed declines in macrophyte abundance (Feminella et al. 2006; Rodriguez et al. 2005), macroinvertebrate diversity (Correia et al. 2008), increased bioturbation (Mueller 2007; Yamamoto 2010), and amphibian species richness and recruitment (Gamradt and Kats 2002; Cruz et al. 2006; Ficetola et al. 2011). *P. clarkii* consume an array of plant and animal matter, aquatic vertebrate eggs and larvae, aquatic invertebrates, and can affect food webs on a polytrophic scale. In Northern Italy, Ficetola et al. (2011) found that the presence of crayfish reduces the number of newt, salamander, toad, and tree frog breeding sites. They concluded that many of these amphibians actively avoid crayfish infested waters. For individuals that remained to breed, there was a negative association between larval abundance and crayfish presence across all seven species sampled. Pease and Wayne (2013) also observed that Pacific tree frog tadpoles (*Pseudarcris regilla*) responded to predation by crayfish both behaviorally and morphologically by selecting for deeper tail muscles. Gamradt and Kats (2002) conducted amphibian surveys from 1981-1986, and identified 10 Santa Monica Mountain streams supporting populations of California newts. When the surveys were repeated in 1994, newts were missing from three of those 10 streams. Further study documented that *P. clarkia* consumed newt egg masses, as well as attacked adults (RCDSMM *unpublished data*). It was also observed that adult newts recolonized a stream if the crayfish were removed by winter storms and there was sufficient water flow (Gamradt and Kats 2002).

P. clarkii entered southern California as early as 1924 (Holmes 1924), although they were not observed in Topanga Creek until 2001 (RCDSMM *unpublished data*). The crayfish population in Topanga Creek was limited in the first five years by active removal efforts and wintertime rain events, with significant flows that have been shown to be sufficient to wash crayfish from the system (Kats et al. 2013). As the Mediterranean climate eased into drought in 2011, the population expanded rapidly (RCDSMM *unpublished data*).

Environmental conditions of Mediterranean wetlands in periods of drought are a preferred habitat for *P. clarkii* (Geiger et al. 2005). This habitat was characterized by low-flows, shallow water of depths between one and two meters (Voshell 2002), and optimal water temperatures of 25^{o} Celsius (Invasive Species Compendium 2013). The introduction of *P. clarkii* in Topanga Creek raised concerns about possible implications for two sensitive native species, the California newt (*T. torosa*, CA state species of special concern) and southern California steelhead trout (*O. mykiss*, federally endangered). In September 2013, the Resource Conservation District of the Santa Monica Mountains (RCDSMM), in conjunction with the Watershed Stewards Project, launched a citizen science program to remove crayfish from a 200 meter reach of Topanga Creek and monitor crayfish dynamics, water quality, nutrients, and benthic macroinvertebrates.

The goals of this project were to (1) intensively remove crayfish from several refugia pool and step-pool habitats within a 200 meter stretch of Topanga Creek (2) record changes in water quality (dissolved oxygen, pH, salinity, conductivity, turbidity, water temperature) and nutrient levels (nitrate, nitrite, ammonia, orthophosphate) within the study reaches, and (3) measure the benthic macroinvertebrate community composition.

Study Area

Topanga Creek (34º 6’11”N 118º 36’18” W, elev. 1 to 6%) is the mainstem of a small coastal watershed (approximately 47 km^2) located within the Santa Monica Mountains National Recreation Area in southern California. The study reach consisted of 400 continuous meters of Topanga Creek, starting at 3500 meters and ending at 3900 meters from the ocean at a 61.96 meter elevation; this is considered a low elevation (Cuellar and Underwood 2012). The study area is relatively uniform in its geomorphological features, including pools, step-pools, runs, and riffles. This 400 meter stretch was split into a downstream 200 meter crayfish Removal Reach (RR), and the upper 200-meter Non-Removal Reach (NRR). No barriers of any sort were incorporated into the study reaches however natural low flow boulder barriers separated the RR from the NRR.

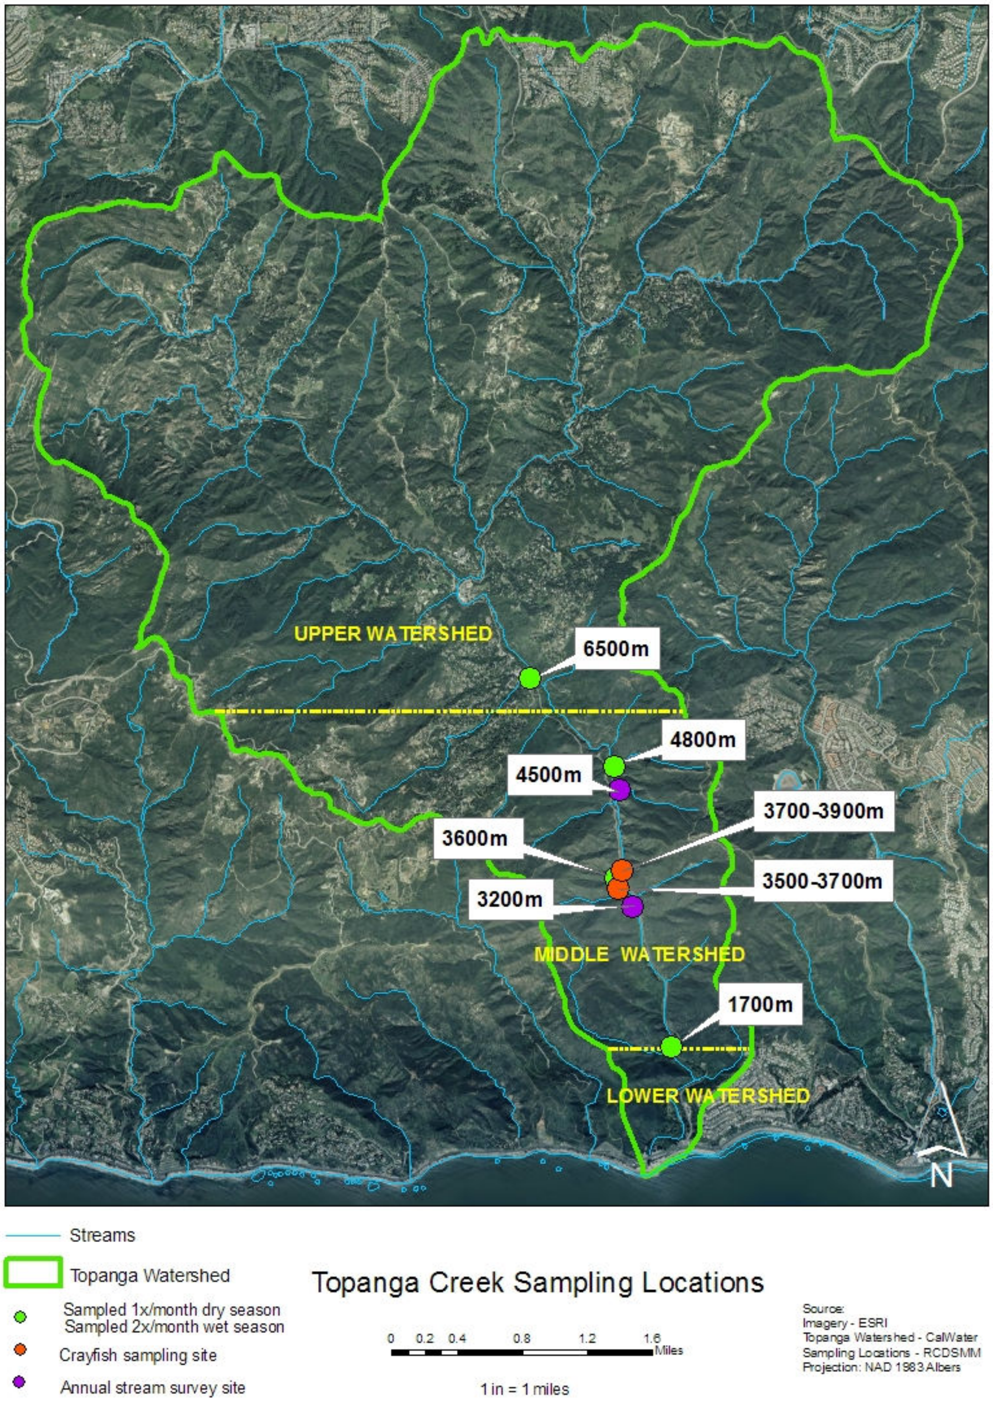

Figure 9-1 Topanga Creek Watershed and the Crayfish Study Reaches. The red points represent the study Removal Reach (3500-3700m) and Non-Removal Reach (3700-3900m).

9.3 Methods

Water quality, nutrient, and benthic macroinvertebrates (BMI) samples were collected and samples were analyzed for both 200 meter reaches in conjunction with ten volunteer events between September 2013 and February 2014. Due to the presence of federally listed southern steelhead trout, it was not permitted to set traps of any kind and removal was restricted to supervised hand capture only. Volunteers removed crayfish throughout the 200 meter RR using 3 inch pieces of hotdogs attached to hemp strings. Once crayfish held on to the bait, volunteers would slowly pull them out and net them. The crayfish were then counted, sexed, and measured in centimeters from head to tail using standard rulers. The crayfish were donated to a local wildlife rescue or used for educational purposes. Removal efforts occurred on the following dates: 09/21/2013, 10/11/2013, 11/12/2013, 11/26/2013, 12/03/2013, 12/17/2013, 01/07/2014, 01/21/2014, 01/28/2014, and 02/04/2014.

Water quality samples were collected from three similar pools within each 200 meter reach. An hour prior to each of the removal effort events, each site was tested for air temperature (mercury thermometer), salinity (ATC 300011 SPER SCIENTIFIC salt refractometer), pH (Waterproof pHTestr 30), conductivity (Waterproof ECTestr11), and dissolved oxygen (DO) and water temperature (YSI 55 dissolved oxygen meter). All probes were calibrated within a week prior to the collection date.

Nutrient sampling was conducted once a month from November 2013 through April 2014 at 3600 m, located midway between the RR and NRR sites. Samples were tested for nutrients within eight hours of collection using a LaMotte SMART3 colorimeter and LaMotte 2020we turbidity meter. Samples were tested for nitrate-N, nitrite-N, ammonia-N, orthophosphate and turbidity.

Benthic macroinvertebrate (BMI) samples were collected according to California's Rapid Bioassessment protocols (Ode et al. 2005) in November 2013, December 2013, February 2014, and April 2014 at similar pools and riffles for each 200 meter reach using D-Shape kicknets. Each sample was composed of a total of nine kicks (three transects and three kicks per transect). Samples were preserved in 95 percent ethanol or frozen within eight hours from the collection time and processed and analyzed within a month from the collection date. Most BMI were identified to the family or genus level using a 40x magnification, dissecting microscope.

Using the NRR as a control, t-tests were used to determine any correlation between crayfish presence and water quality, nutrient levels, and BMI presence in Topanga Creek. The Southern Coastal California Index of Biotic Integrity (SCC-IBI) metrics were applied to every BMI sample collected for the study (Ode et al. 2007). In addition to the

SCC-IBI, the total number of individuals, total number of taxa, dominant taxa, percent dominant taxa, percent collector-gatherer, percent filterer-collector, percent scraper, percent predator, percent shredder, average tolerance value, number of Ephemeroptera taxa, number of Plecoptera taxa, and number of Trichoptera taxa were also calculated. However, none of the NRR samples contained 500 individuals as required by the SCC-IBI metrics. As a result, the NRR samples were pooled into one data set and the RR into another. After pooling, the data sets were sub sampled, using Excel and a random number generator to select 500 individuals and perform more reliable SCCI-IBI metrics and scores.

9.4 Results

9.4.1 Removal Effort

The ten volunteer events resulted in a total of 203.25 person-hours and a total of 345 crayfish removed (Figure 9-2); 166 females and 179 males (Figure 9-3). Measurements were taken midline from the tip of the rostrum to end of the tail. The average length of crayfish removed was 7.61 centimeters, and there was no significant difference in length between males and females (p= 0.733) or statistical trend in the length of crayfish over time (R^2=0.008). There was also no significant difference found between the number of females and males caught.

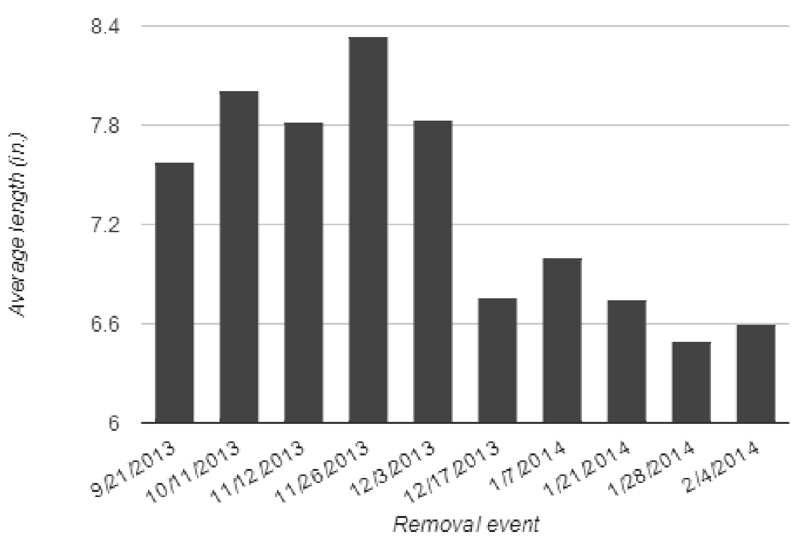

Figure 9-2 Average Length of Removed Crayfish by Event.

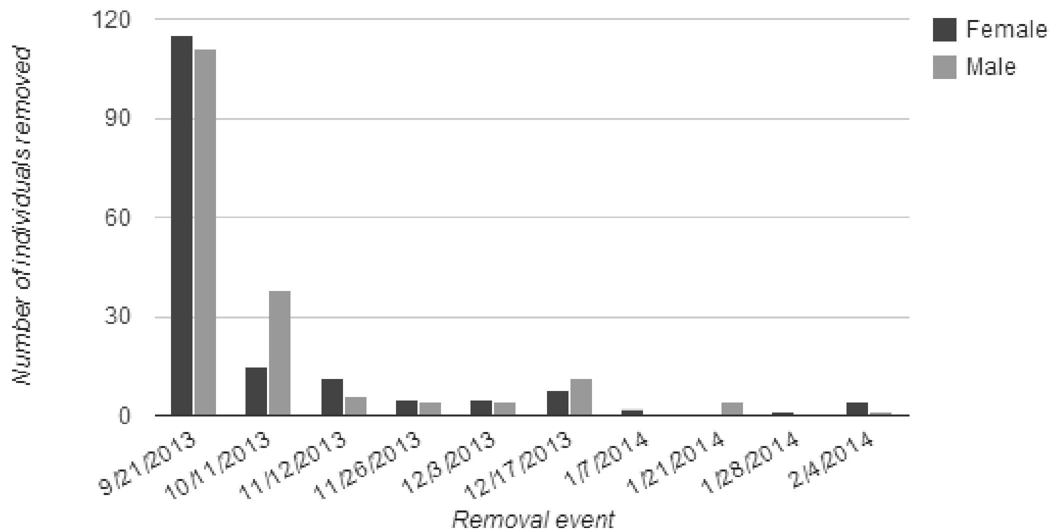

Figure 9-3 Number of Male Versus Female Crayfish by Event.

The catch per person per hour declined from 2.26 crayfish to 0.83 over the course of study. No statistical trend was found linking removal efforts to the decrease in the catch per person per hour (R^2 =0.315) (Figure 9-4). Water temperatures and catch per person per hour were found to have a correlation coefficient of 0.726, but had an R^2 value of 0.173 that suggests an unreliable best-fit line (Figure 9-5). However, as water temperature cooled fewer crayfish were observed and were more difficult to capture.

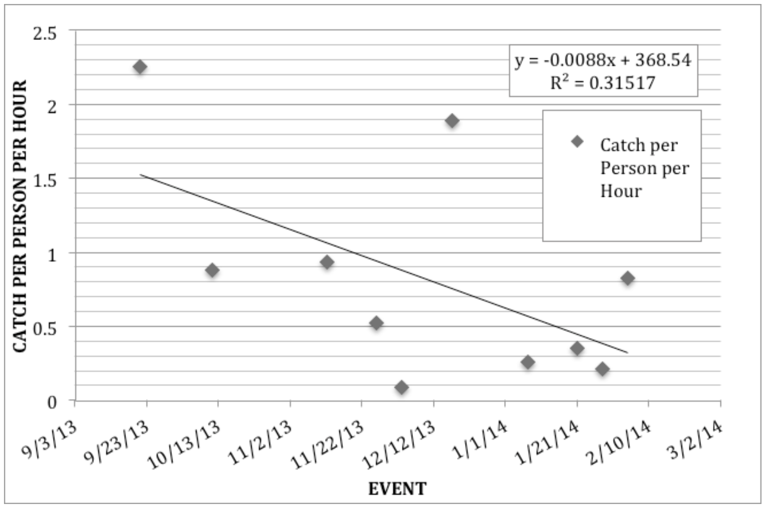

Figure 9-4 Catch Per Person Per Hour Over Time.

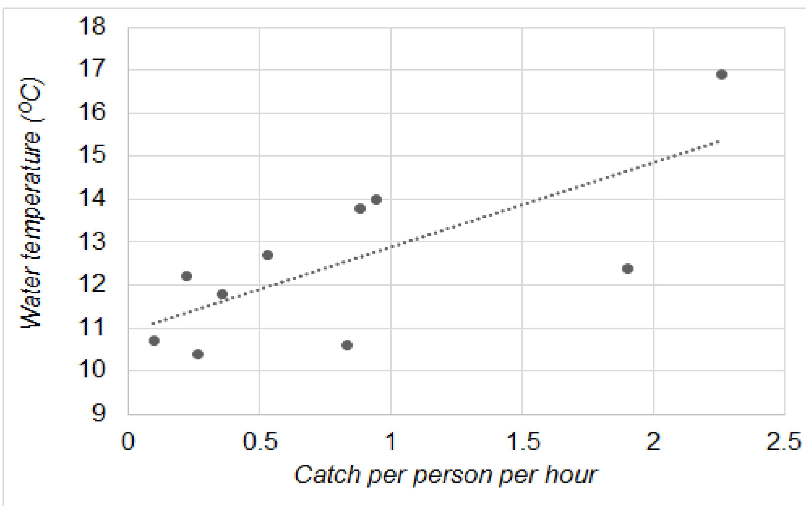

Figure 9-5 Catch Per Unit of Effort Versus Water Temperature.

9.4.2 Water Quality and Nutrients

Water quality and nutrient data were compiled into a database. The data was analyzed for any significant difference between the RR and NRR. None of the parameters showed a statistical difference or a general trend, except for salinity. A significant difference of 0.000011 ($P<0.05$) in salinity levels was found, with higher salinity in the non-removal reach (Figure 9-6). However, the salinity levels do not correlate with crayfish removal; the crayfish catch per event were plotted against salinity for the reach, giving an R^2 value of 0.001.

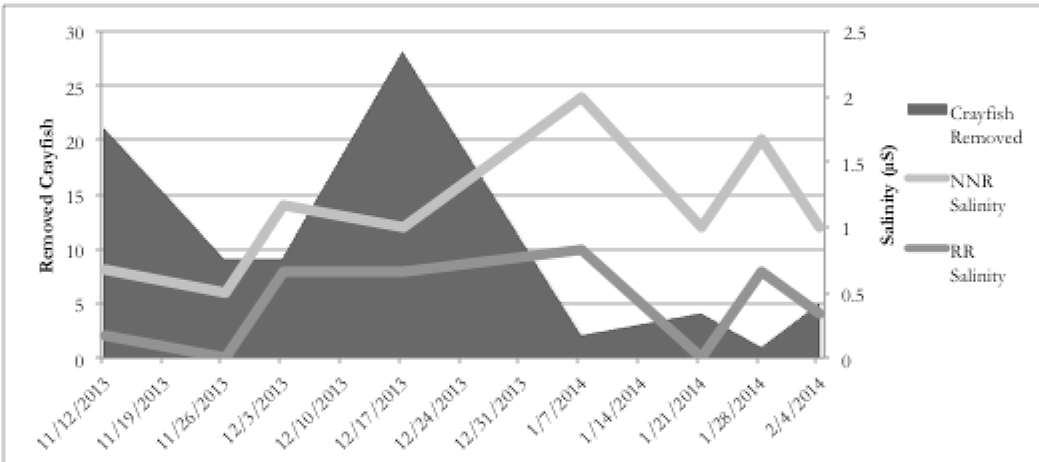

Figure 9-6 Salinity Levels and Numbers of Removed Crayfish.
(Note: This graph represents non-continuous data points.)

9.4.3 Benthic Macroinvertebrate (BMI) Sampling

The four BMI samples collected from the NRR in November 2013, December 2013, February 2014, and April 2014 contained a total of 676 individuals from four phyla, 14 orders, 35 families, and a total of 37 taxa. The samples collected from the RR contained a total of 3,195 individuals from three phyla, 14 orders, 37 families, and a total of 56 taxa (Appendix C). The three phyla represented in both samples were Arthropoda, Annelida, and Mollusca. In the NRR sample Nematoda were also present.

The most abundant taxa in the pooled NRR were Ostracoda (bean clams) with a relative abundance of 37.8%, Amphipoda (freshwater shrimp) with a relative abundance of 17.6%, and Physidae (pouch snails) with a relative abundance of 14%. In the pooled RR, the most abundant were Hydrobiidae (mud snails) with a 29.7% relative abundance, Amphipoda (freshwater shrimp) with a 26.1% relative abundance, and Chironomidae (non-biting midges) with a 15.3% relative abundance. The three most abundant orders comprise 69% of the NRR sample, and 71% or RR.

The five most abundant taxa for each event are depicted in Figure 9-7. This graph shows the transitions of the top five most abundant taxa during removal efforts from November 2013 - February 2014 and in April, two months after the efforts ended. Diversity of functional feeding groups (FFG) within the top five dominant taxa shifted from November - February. The removal reach maintained a higher diversity for most samples. Crayfish were the most abundant taxa for the NRR in November shifting to

Chironomidae in April. In contrast, the RR had a high abundance of Chironomidae in November, transitioned to Amphipoda and Hydrobiidae through February, and returned to Chironomidae in April.

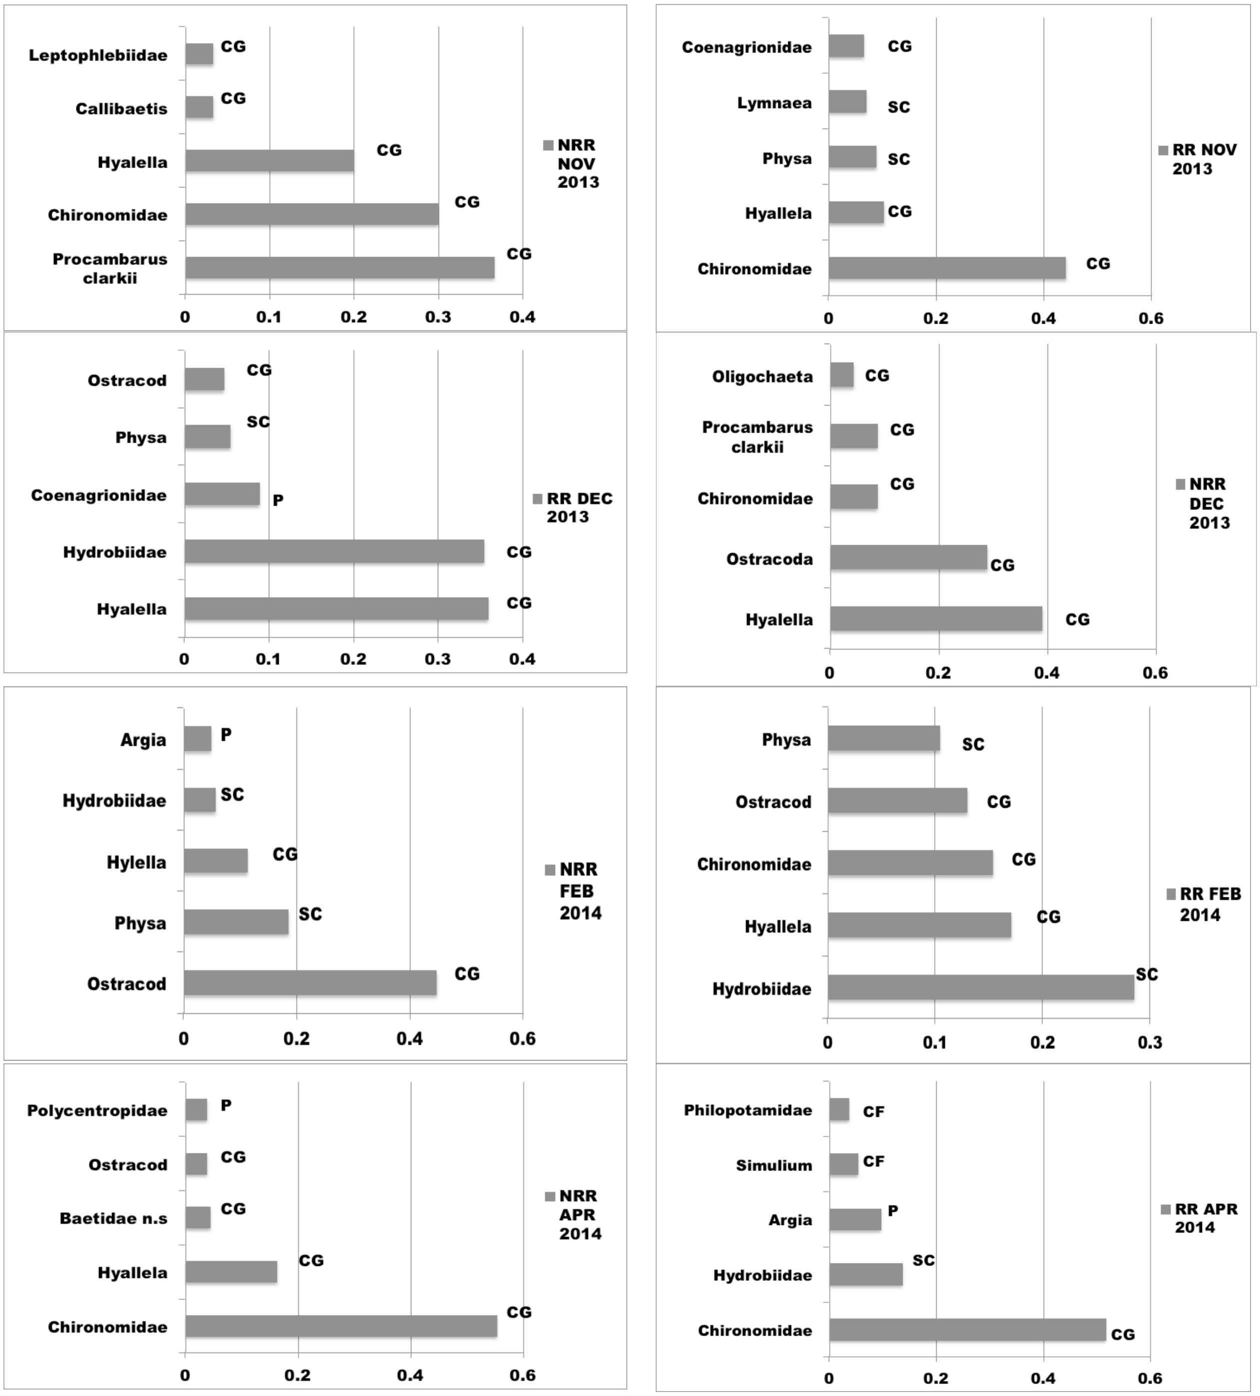

Figure 9-7 Comparison of BMI dominant taxa between the removal and non-removal reaches, Topanga Creek 2013-2014. Gastropoda were considered Scrapers; Simulium and *Philopotamidae* were considered Collector-Filterers; *Argia* were considered Predators; the rest were considered Collectors-Gatherers.

Table 9-1 shows the SCC-IBI metrics and scores of each BMI sample, with some additional metrics: the total number of individuals, total number of taxa, the dominant taxa, percent of dominant taxa, percent collector-gatherer, percent filterer-collector, percent scraper, percent predator, percent shredder, average tolerance value, number of Ephemeroptera taxa, number of Plecoptera taxa, number of Trichoptera taxa, percent of collector-gatherer plus filterer-collector, percent of non-insect, percent of tolerant taxa, number of Coleoptera taxa, number of predator taxa, percent of intolerant individuals, and the number of EPT taxa.

In both reaches, there was an increase in the BMI from November 2013 to April 2014. However, the BMI abundance in the NRR never reached 500 individuals. The BMI in the RR increased dramatically from 210 (November) to more than 1000 individuals (April). The percent dominant taxa remained high in both reaches.

The diversity of FFG also increased in both reaches over time. Collector-gatherers and predators were present throughout the samples, and scrapers, collector-filterers, and shredders started to appear respectively through February 2014 (see Table 9-1). The order of FFG dominance was as follows: collector-gatherer, scraper, predator, collector-filterer, and shredders. Shredders only appeared in the February 2014 RR sample when they had a higher dominance than collector-filterers. Once removal ceased, collector-gathers again increased to pre-removal levels.

The percent of EPT taxa tended to be higher in the RR, but evened out with the NRR after the removal efforts ended. There was no significant difference of percent tolerant, intolerant taxa, or average tolerance values between the RR and NRR reaches. Though the SCC-IBI metrics and scores were calculated for each sample, it is important to remember that none of the NRR samples and one RR sample did not meet the minimum 500 BMI abundance required by protocol. These samples are presented in Table 9-1 to provide a qualitative rather than quantitative comparison of the reaches over time.

To address the minimum abundance requirement, all BMI samples were pooled. The metrics and scores on Table 9-2 were then calculated from the pooled samples of each reach. The additional BMI metrics calculated in Table 9-1 were not calculated for this table. Using this analysis, both reaches fall within the fair range, with the removal site scoring slightly higher.

Figure 9-8 depicts the SCC-IBI metrics for each of the event samples and the pooled samples. This graph illustrates an increased percentage of intolerant and predator taxa between fall and spring. During active removal efforts, there is a large disparity between the two reaches from November through February; however by April (two months post removal), there was no significant differences observed.

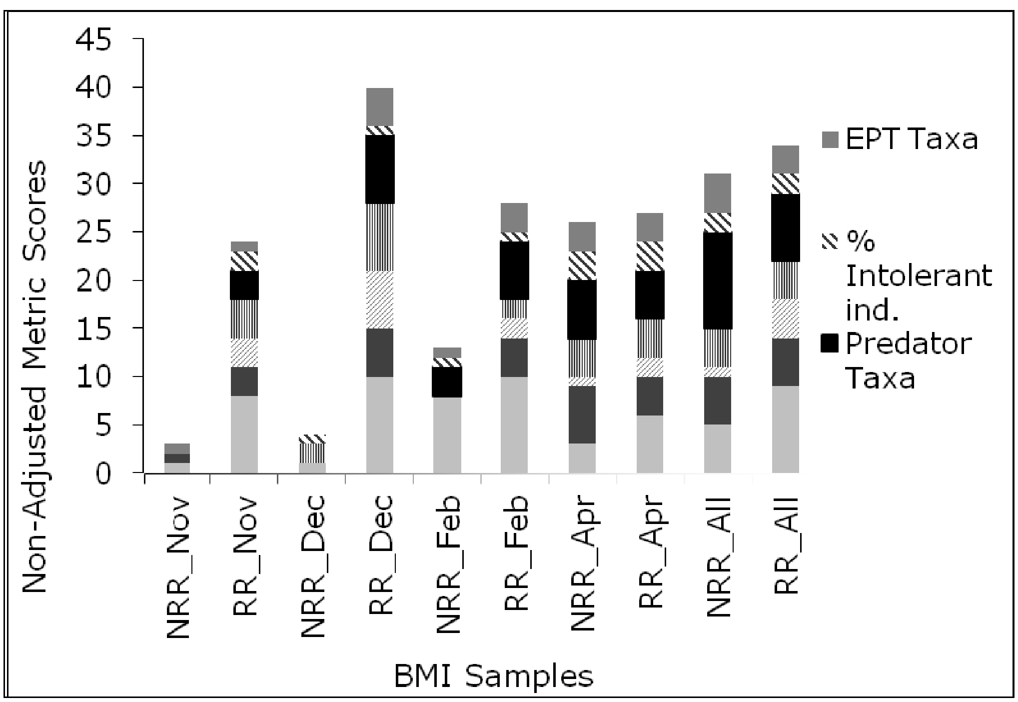

Figure 9-8 Breakdown of Non-Adjusted SCC-BMI Scores.
"All" represents the pooled samples.

Although all of the NRR samples and the November RR sample had BMI counts lower than 500, the SCC-IBI metrics were still calculated and used to describe changes over time. The individual event scores should not be ignored on the basis of low BMI numbers. It is true that the SCC-IBI metrics were not designed to deal with lower BMI counts, but the metrics do provide an idea of the relative state of the BMI community. The species richness, the percentage of each FFG, dominant taxa, and total abundance were also IBI indicators of BMI community health that were taken into account. When samples for each reach were pooled to get an overall status of the BMI community that adhered to the required statistics for the SCC-IBI metrics, the RR's BMI community appeared to be in a better condition than the NRR.

The SCC-IBI scores give a wider context to the overall condition of Topanga Creek when compared to other creeks in southern California. Topanga Creek would not be considered a reference creek based solely on the SCC-IBI score. The scores of the samples containing at least 500 BMI, consistently put the creek in the "Poor" to "Fair" range and the pooled scores have a range of "Fair." The reaches scores fall among the lowest in the Santa Monica Mountains. When compared to Heal the Bay's 2013 SCC-IBI scores for Arroyo Sequit Creek, Solstice Creek, Cold Creek, and Malibu Creek, the Topanga Creek crayfish pooled scores ranked second lowest, with Malibu Creek having the worst scores.

Using historic data from Topanga Creek collected during snorkel and other visual surveys (2001-2014), crayfish presence was compared to the presence of amphibians, and crayfish found in *O. mykiss* stomach contents (Krug et al. 2012). There was no evidence to suggest that crayfish impacted the presence of California tree frogs or the pacific tree frogs as observations of those species remained consistent over time. However, there was a distinct negative correlation between crayfish presence and California Newts (RCDSMM *unpublished data*). Local researchers have observed crayfish eating newts (Kats et al. 2013; RCDSMM *unpublished data*). Since the crayfish population explosion in 2011 in Topanga Creek, there has also been an increased incidence of crayfish found within large (10 inches and up) rainbow trout's diet (Krug et al. 2012). The increased number of crayfish appears to have changed the BMI community for the worse and they appear to have also impacted the newt population, (Figure 9-9). To make circumstances worse, the drought that has plagued southern California for the last few years has only been increasing the preferred habitat for crayfish and worsening habitat conditions for native wildlife.

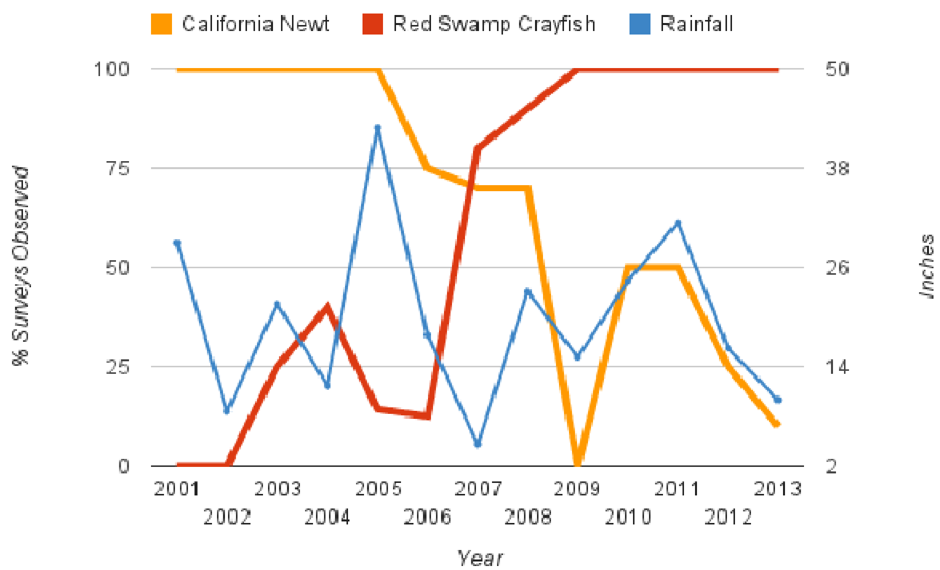

Figure 9-9 Observations of Crayfish and CA Newts compared to Water Temperature in Topanga Creek 2001-2014.

Sustained crayfish removal efforts produced positive results in the BMI community and volunteer actions, through citizen science efforts, can promote a wide public involvement in active restoration efforts. In just a few months of removal, the BMI community improved into the “fair” SCC-IBI range. In the future, more study reaches and BMI collection sites should be established to provide more in-depth comparisons. While it is not feasible to conduct removal throughout the entire creek, the results of this study suggest that a focused removal effort following strong winter storm pulses that reduce the population throughout the creek could be beneficial.

9.5 Summary

- Crayfish removal had no effect on water quality or nutrient levels.
- Crayfish removal improved BMI community compositions while on-going but the effect was not observed two months after removal ceased.
- Crayfish removal could be beneficial in improving ecosystem health and nutrient cycling within the creek.

10 Benthic Algae in Topanga and Malibu Creeks

10.1 Abstract

Water quality monitoring has historically relied on chemical parameters but recent work has recognized that integrating biological responses to water quality changes can provide a more complete understanding of ecosystem sensitivity, resiliency and status. Periphyton are found in all aquatic environments and can tolerate a wide range of nutrient levels and overall water quality (Hoffman 1994). Monitoring benthic algae is becoming more common as tools are developed to allow for a better understanding of the relationship and response of these sensitive organisms to the aquatic environment. Topanga and Malibu Creeks represent the second and third largest watersheds within the Santa Monica Mountains and support a variety of special status aquatic species. Comparison of the benthic algae community conditions in 2013 utilizing both standard metrics (Rhithron Associates, Inc. 2014) and relatively new southern California Index of Biotic Integrity (Fetscher et al. 2014) indices suggests that although Malibu Creek is listed as impaired for nutrients, sediment and trash, the more consistent flow regime provided by summer flow augmentation supports a spring benthic algal community that is not substantively different from that found in Topanga Creek, which is not listed for any impairments and has no summer flow augmentation. This suggests that a complex, synergistic pattern of abiotic and biotic variables are shaping the biological integrity of these creeks. It is hoped that the use of both diatoms and soft-body algae as diagnostic tools to provide secondary indicators and multiple lines of evidence will better characterize the responses of southern California creeks to both natural events (floods, wildfire) and anthropogenic inputs providing a more complete picture of stream health in these systems. That being the case, some of the common diatom indicator species with fairly well described Total Nitrogen (TN) preferences, both high and low, were found in both Topanga and Malibu, which provides a somewhat confusing result. This could possibly be a result of inability to differentiate between species in the same genus that appear taxonomically similar, but in fact represent different species with different tolerance preferences. It could also mean that further refinement of the tolerance limits and preferences is needed. This study provides a snapshot of baseline conditions for future comparison.

10.2 Introduction

Periphyton abundance and diversity, specifically diatom and soft-bodied algae species, are a potentially useful indicator of water quality and are often used in California and elsewhere in conjunction with water quality and benthic macroinvertebrate monitoring (Fetscher et al. 2009, Fetscher et al. 2014). Benthic algae (both diatoms and non-diatoms) are a primary energy source in stream food webs (Stevenson 1996) and an important component of periphyton. This variable of water quality testing is relatively new to the regulatory testing framework, but a well-established national database of diatoms suggests that much can be learned by identifying species presence and abundance (Potapova and Charles 2003, Potapova 2005, Potapova and Charles 2007). In order to function as a useful water quality indicator, a species needs to have a narrow range of ecological tolerances, a wide distribution range and be relatively commonly observed. Following the framework promoted by Potapova (2005), we have documented the abundance and distribution of diatom and non-diatom species found in Topanga Creek and then examined the habitat and water quality characteristics associated with their presence to begin developing an ecological profile of southern California taxon. Recent work in Malibu Creek supports this concept and data collection is in progress to further investigate diatom community structure and distribution relative to variables such as conductivity (Orton 2012).

Diatoms (phylum Bacillariophyta) are single celled algae that come in a variety of shapes, although primarily centric (round) or pennate (elongate). They are characterized by a silicon based shell called a frustule, that has two halves that fit tightly together, but have pores that allow for nutrient movement into the cell, and wastes to pass out of the cell. They are particularly sensitive to changes in dissolved oxygen, pH, nitrogen and especially conductivity. One of the benefits of using diatoms as water quality indicators is that they respond quickly (within hours to days) to changes in the environment such as variation in pH or water temperature by modifying their exoskeleton shape (Prygiel and Coste 2000).

Soft-body algae include a variety of taxa that are widely distributed, colonize almost every stream substrate, reproduce quickly and respond rapidly to changes in the environment; thus, they are useful not only as a way of detecting impairments, but also can assist in diagnosing impairment causes (Fetscher et al. 2009). Recent advances in the development of algae-based Indices of Biotic Integrity (IBI) suggest that in southern California streams, these non-diatom species provide additional insight into water quality conditions (Fetscher et al. 2014).

In addition to documenting the diversity of the diatom and soft-bodied algal communities, chlorophyll a and ash free dry mass (AFDM) are used to estimate the relative amount of algal biomass, which is a proxy for estimating stream productivity. Chlorophyll a is a specific form of chlorophyll present in algal cells that is critical for photosynthesis. The concentration of chlorophyll a varies with depth, water temperature, and season, and provides a way of quantifying the amount of active photosynthesis at the time of sampling. Ash free dry mass is the difference between the wet and post combustion weight of the sample, providing a complimentary way of quantifying algal biomass (Fetscher et al. 2009). These measurements can assist in developing an autotrophic index, which is the ratio of ash free dry mass to chlorophyll a that can reflect response to nutrient enrichment (index value increases) and biological oxygen demand fluctuation (Biggs 1989).

It is hoped that the use of both diatoms and soft-bodied algae as diagnostic tools will provide secondary indicators and multiple lines of evidence to better characterize the responses of southern California creeks to both natural (floods, wildfire) and anthropogenic inputs. This will enhance analysis of these metrics within two major creeks in the Santa Monica Bay. By including these additional metrics to the water quality assessment effort, we hope to assist in developing regional ambient and exceedance level data.

10.3 Methods

Sample Sites

Topanga Creek is the third largest drainage into the Santa Monica Bay and over 70% of the watershed is public open space wildlands within Topanga State Park.

Samples were collected in the main stem (stream order 2) 4,662 hectare Topanga Creek during stream surveys on 30 April 2013, 6 May 2014 in the upper reach approximately 4500-4650 m upstream of the ocean, and on 2 May 2013, 5 May 2014 in the lower reach located approximately 3200-3350 m from the ocean, concurrently with physical habitat condition (Fetscher et al. 2009), and in-situ water quality (temperature, dissolved oxygen, pH, conductivity) (Figure 10-1). At the same time, grab samples for fecal indicator bacteria (total coliform, *E. coli* and enterococcus), nutrients (nitrate-N, nitrite- N, ammonia – N, orthophosphate) and turbidity were collected, put on ice and analyzed within six hours. Benthic macroinvertebrate samples were collected in the same reaches, along with presence and abundance of amphibians and fish.

These 150 meter reaches were initially selected to represent portions of the main stem of Topanga Creek below town. Since 2001 steelhead trout have been present in the lower gradient portion (3200-3350 m, average gradient <3%); and since 2005 in the higher gradient reaches from 4500-4650 m (average gradient 3-6%). Additionally, the lower gradient reach (3200-3350 m) is adjacent to Topanga Canyon Boulevard, and subject to higher level of anthropogenic disturbance than the higher gradient reach (4500-4650 m), which is deeper in the canyon, away from the road and while subject to some disturbance, is much less accessible than the lower reach.

Diatom and soft-bodied algae data was also available for Malibu Creek in 2013. The Malibu Creek Watershed is the second largest system draining into the Santa Monica Bay at 28,231 hectares. Samples were collected on 24 April 2013 at two locations (R-3 and R-4, Figure 10-2) in lower Malibu Creek (stream order 4) below Rindge Dam. Physical habitat, water quality documentation, and benthic macroinvertebrate sampling as per Ode (2007) and Fetscher et al. (2009) protocols were also collected.

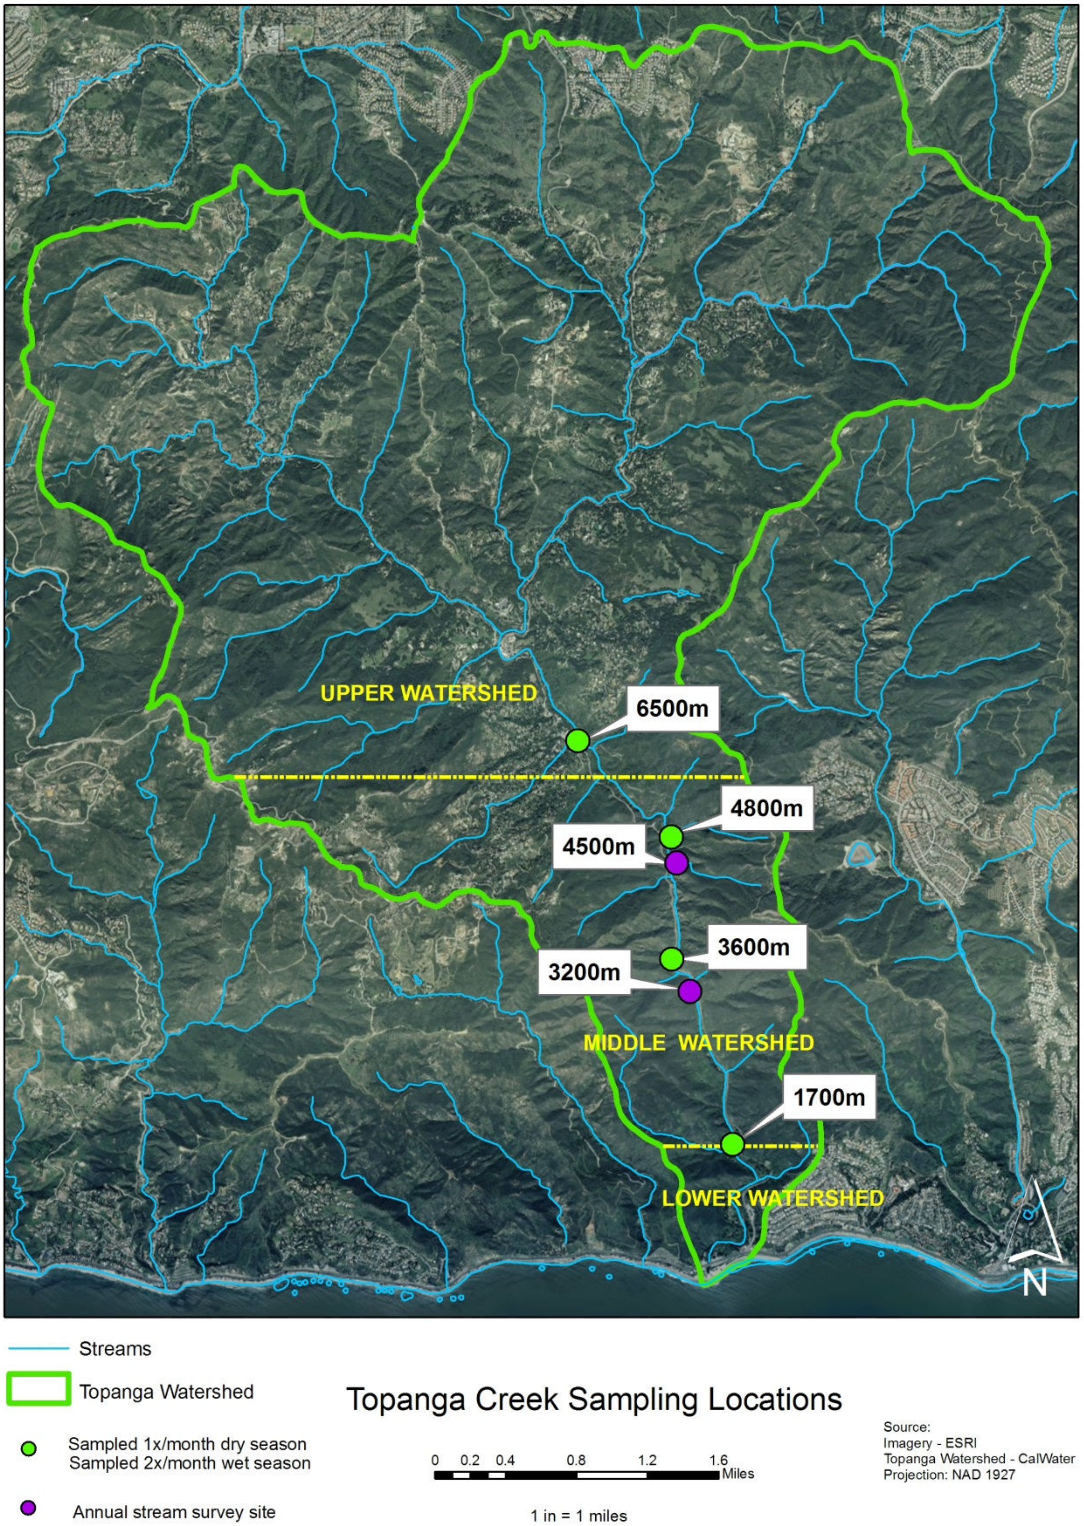

Figure 10-1 Map of Topanga Creek Sampling Locations as distance measured from the ocean 2013-2014.

Figure 10-2 Map of Malibu Creek Sampling Locations 2013. R3 and R4 are sampling locations for the Las Virgenes Municipal Water District. Start Pool is the location of a data sonde.

Sample Collection

Stream algae and diatom samples were collected with assistance from biologists at Aquatic Bioassay and Consulting Laboratories, Ventura, CA. Methods followed the sampling protocols identified by Surface Water Ambient Monitoring Protocol (Fetscher and McLaughlan 2008, Fetscher et al. 2009). This method established 11 transects in a 150 meter stream reach. Samples were collected from substrate present at each transect (alternating right side, center and left side of wetted width) located 1 meter downstream from the transect and combined into a single composite sample. Collection methods varied according to substrate and habitat type according to the protocol. An ABS delimiter (plastic coring device) was used to collect loose substrate up to 1 cm deep in a depositional habitat with fine gravel, sand or silt substrate. A metal spatula was placed underneath the delimiter to ensure collection of any loose material. A rubber delimiter was used to isolate a 12.6 cm^2 area of algae when wrapped around cobble or other erosional and removable object. A toothbrush was used to scrub the algae from the surface. For immovable substrate (i.e. boulders, bedrock or concrete), a syringe scrubber was used to collect algae from underwater. The plunger was retracted and the scrubber was removed and rinsed into a wash bucket.

Upon collection of all 11 subsamples, field processing was done according to three protocols. A 25 ml composite sample was filtered through glass fiber pre-filters using a hand pump. The filter was placed into a petri dish, covered in aluminum foil and placed on dry ice until analyzed in order to determine ash free dry mass and chlorophyll a. Diatom samples were prepared by combining 10 ml formalin preservative with a 40 ml of composite sample water in a 50 ml centrifuge tube, covered in foil and placed on wet ice. Soft-bodied algae was mixed with 5ml of glutaraldehyde solution with 45 ml of the composite sample water in a 50 ml centrifuge tube covered in foil and stored on wet ice.

Sierra Environmental (Reno, NV) did the analysis of Ash Free Dry Mass (SM 2540) and Chlorophyll a (SM 10200). Diatom and soft-bodied algae samples were identified and enumerated by Academy of Sciences, Philadelphia, PA in 2013 and by Rhithron Associates, Inc (Missoula, MT) in 2014.

Index of Biotic Integrity Analysis

Recent work has evaluated a variety of possible stream indices using diatom and non-diatom soft-bodied algae to compare biotic integrity, providing more reliable comparisons between sites both spatially and temporally. Using an online calculator provided by SCCWRP to calculate the southern California Diatom and non-diatom species IBI described by Fetscher et al. (2014), data from two sites located in Topanga and Malibu Creeks were compared. Unfortunately data on benthic macroalgae for Malibu Creek was only available for 2013 at this time.

Diatoms Metrics

Metrics used to describe and quantify the diatom community in relation to stream water quality have been selected to examine the response of diatoms to impairments. The multi-metric analysis contains five subsets that are designed to quantify various components of diversity as compiled by Rhithron Associates, Inc (Table 10-1).

Species richness, diversity and dominant taxon of the diatom species collected reflects the community structure at each site. Species richness and Shannon diversity values decrease with increasing water quality impairments. Dominance values increase with increasing water quality impairments.

Sediment metrics characterize species found in unstable habitats (Barbour et al. 1999). Diatoms are designated as highly motile, moderately motile, not motile and having variable motility. The percentage of highly motile species that are able to hold their position on the substrate surface increases with increased sedimentation (Lange-Bertalot 1979). Some species in the genus *Navicula*, *Nitzschia* and *Surirella* are associated with increases in siltation and sedimentation. However, *Nitzschia palea* has been identified as an oligotraphentic low –nutrient indicator (Potopova and Charles 2007) and was only observed in Topanga Creek.

Organic nutrient measures include several metrics related to organic pollution tolerance. Species are rated as 1(most tolerant to organic pollution) to 3 (sensitive to organic pollution) (Van Dam et al. 1994). To obtain the pollution tolerance index, the species tolerance value is multiplied by its abundance, and then that value is divided by the total abundance for the site. A low pollution index score indicates poor water quality (Van Dam et al. 1994).

Halophytic algae have wide osmoregulation ranges/tolerances but also increase with increased nutrients and suspended sediment levels. Eutrophic water often have higher pH levels.

Other metrics for pollution include the percent relative abundance of facultative and obligate nitrogen heterotrophs based on their nitrogen (N) uptake. The percentage of heterotrophic taxa increases with decreased water quality thus the relative abundance of nitrogen hetrotrophs can be used as an indicator of organic nitrogen compounds and/or reduced light available (Van Landignam 1982, Porter 2008). For example, *Rhopalodiales* species fix nitrogen and are extremely responsive to nutrient loading because they are less competitive in a eutrophic environment.

The diatom values are:
1. Nitrogen autotroph tolerates very small concentration of organic nitrogen
2. Nitrogen autotroph tolerates elevated concentration of organic nitrogen
3. Facultative nitrogen heterotroph need periodically elevated levels of organic nitrogen
4. Obligate nitrogen heterotroph need continuously elevated levels of organic nitrogen

Polysaprobous species thrive in waters rich in decomposing organic material and having greater than 10% oxygen (Van Dam et al. 1994). Values assigned to diatom taxa are as follows:
1. Oligosaprobous (intolerant to organic pollution)
2. Beta – mesosaprobous
3. Alpha – mesosaprobous
4. Alpha-meso/polysaprobous
5. Polysaprobous (organic pollution tolerant species)

Low Dissolved Oxygen (DO) Taxa are diatom species that are tolerant of very low, to low dissolved oxygen levels (below 10% saturation, assigned a value of 5). High Dissolved Oxygen Taxa are those that require ~100% saturation continuously. As the levels of dissolved oxygen available decreases, the percentage of these tolerant taxa increases,.

Inorganic nutrients metrics compares the level of nutrient autotrophism based on the relative abundance of nitrogen autotrophs that tolerate small concentration of organic N to those that tolerate higher concentration of organic N. As water quality degrades, the percent abundance of nitrogen autotrophs decreases. The other metric included here compares the percent relative abundance of eutraphentic (preferring high nutrient levels) and hypereutraphentic diatom taxa.

Metals tolerant taxa, abnormal cells and percent disturbance taxa can be indicators of elevated concentrations of heavy metals. The presence of the cosmopolitan species *Achnanthidium minutissimum* is an indication of disturbance related to a recent scour event or some type of toxic organic pollution input. However, in southern California, *A. minutissimum* is also associated with clean water (Dr. Fetscher, *personal communication*).

Table 10-1 Definitions of Metrics.
Aquatic Bioassay and Consulting Laboratories (2014)

Metric Group	Definition	Reference
Pollution Tolerance Class	Tolerance to organic pollution according to Lange-Bertalot 1979; 1=most tolerant of pollution; 2=tolerant of pollution; 3=sensitive to pollution	Lange-Bertalot 1979
Habitat	A = aerophile; P = planktonic	
pH	1 acidobiontic, optimum pH <5.5; 2 acidophilous, pH <7; 3 circumneutral, pH ~7; 4 alkaliphilous, mainly pH >7; 5 alkalibiontic, exclusively pH >7; 6 indifferent, no apparent optimum	
Salinity	1 fresh; 2 fresh brackish; 3 brackish fresh; 4 brackish; 5 marine (see Van Dam et al. 1994 for criteria)	Van Dam et al. 1994
Nitrogen Uptake Metabolism	1 nitrogen autotroph tolerating very small concentrations of organic nitrogen; 2 nitrogen autotroph tolerating elevated concentrations of organic nitrogen; 3 facultative nitrogen heterotroph; 4 obligate nitrogen heterotroph	
Oxygen Requirements	1 continuously high (~100% saturation); 2 high (>75%); 3 moderate (>50%); 4 low (>30%); 5 very low (~10% saturation)	Van Dam et al. 1994
Saprobity	Amount of organic matter decomposing: 1 oligosaprobous (poor); 2 beta-mesosaprobous; 3 alpha-mesosaprobous; 4 alpha-meso-/polysaprobous; 5 polysaprobous (rich) (see Van Dam et al. 1994 for criteria)	Van Dam et al. 1994
Trophic State	1 oligotraphentic; 2 oligo-mesotraphentic; 3 mesotraphentic; 4 meso-eutraphentic; 5 eutraphentic; 6 hypereutraphentic; 7 oligo- to eutraphentic (variable); 8 dystrophic	Van Dam et al. 1994
Moisture	1 rarely occurs outside water bodies; 2 mainly in water but sometimes on wet places; 3 mainly in water but regularly on wet or moist places; 4 mainly on wet, moist, or temporarily dry places; 5 occurs almost exclusively outside water bodies	
Motility	H = highly motile; M = moderately motile (diatoms with raphes but not highly motile); N = not motile; V = variable motility (source: Jan Stevenson)	Jan Stevenson, This one is not really well documented, but see: Bahls 1993 and Barbour et al. 1999
Distribution	N = North American endemics; C = cosmopolitan in temperate regions, broad ecological niche, generally aggressive and opportunistic species that develop large populations in response to disturbance and may exclude native species	Lange-Bertalot 1996

10.4 <u>Results</u>

10.4.1 <u>Diatoms</u>

Table 10-2 compares the metrics from each location in Topanga Creek in 2013 and 2014. A total of 125 diatom species were observed in Topanga Creek in 2013-2014. A total of 46 species, many of them of cosmopolitan distribution, were common to both years, with 40 different species found only in 2013 and 39 species found only in 2014. As shown in Table 10-2, the majority of metrics remained similar, with the exception of a decrease in motile taxa present in 2014 at both sites, a decrease in low DO taxa present at both sites in 2014, and a decrease in percent Rhopalodiales in 2014. Percent of sediment tolerant taxa increased slightly in both locations.

The percent dominant taxa increased slightly in the lower reach, but more in the upper reach. In 2013, the 4500 m higher gradient reach had only 23 species unique to that section, as compared to 26 species unique to the 3200 m lower gradient reach. In 2014, the species unique to each site declined in both the upper reach (18 species) and lower reach (23 species).

The percentage of pollution tolerant taxa increased in the lower reach in 2014, while it decreased in the upper reach. While these differences could be due to sampling error or patchy distribution, it could also suggest that conditions in the creek are changing, even though the pollution index values are not significantly different from year to year or even between sites.

The percentage of species tolerating nutrient enriched waters is slightly higher in the lower gradient reach as compared to in the upper gradient reach.

Table 10-2 Metrics for Diatoms in Topanga Creek Spring 2013 and 2014.

10.4.2 Soft-bodied Algae in Topanga Creek

The samples collected during the annual spring stream survey were complemented by both qualitative and quantitative algae data from monthly sampling at six sites throughout Topanga Creek between December 2012 and August 2014. The dominant algal species observed throughout the creek were *Cladophora sp.* and *Ulva sp.* Percent cover at transects was low throughout (<20% at all sites) with a seasonal increase in summer (graphs are found in Appendix A).

In 2013, the dominant species of algae observed in both study reaches in Topanga Creek was *Cladophora glomerata*. The loss of all epiphytes as well as *Cladophora* in the lower reach in 2014 documents a major shift of the algal community between years. This could be a result of the drought condition in the creek during the winter of 2013-2014.

Only four algal taxa were common to both locations in 2013. *Heteroleibleinia*, a filamentous cyanobacteria, was the only species common to both sites in 2014 (Table 10-3). The upper gradient reach had a total of 10 taxa represented, while the lower gradient reach had 13 taxa (Table 10-4). In 2014, no epiphytes, macroalgae, or quantitative algae samples were collected, and the number of species in the upper reach increased to 25 species, while the diversity at the lower reach decreased to eight.

Most of these species are widespread and tolerate a wide variety of water quality conditions, but the 22 species of cyanobacteria are mostly indicative of a low nitrogen environment. *Phormidium sp* found only in 2013 are considered indicative of a medium level of pollution (Potapova 2005).

10.4.3 Comparison of benthic algae in Topanga and Malibu Creeks 2013

In addition to collecting samples in Topanga, biologists from Aquatic Bioassay Consulting Inc. assisted the Las Virgenes Municipal Water District (LVMWD) in collecting samples from Malibu Creek using the same protocol and analysis as used in Topanga (Aquatic Bioassay 2014).

Topanga sites had a higher diatom species richness and diversity as compared to Malibu sites, with 26 species common to both creeks (Table 10-5). Several species, including *Encynoma silesiacum, Pseudostaurosira brevistriata, Nitzschia liebethruthii,* and *Gomphonema parvulum* are only found at R4 in Malibu. Although there is high variability in species richness and diversity information associated with the patchy nature of distribution and sampling biases/errors, 60 species is a typical mean number of species collected in southern California (Dr. E. Fetscher *pers. communication*).

The total number of diatom species observed in the two lower Malibu Creek sites (both located downstream of Rindge Dam), exhibited less overall community diversity by all metrics. The site adjacent to anthropogenic inputs (R4) had a higher species richness than the less disturbed location approximately 400 meters upstream in Malibu Creek State Park (R3) (Aquatic Bioassay Consulting Inc. 2014).

Table 10-5 Metrics Comparing Diatoms in Topanga and Malibu Creeks Spring 2013.

All of the most abundant diatom species (Table 10-6) except *Nitzschia* are considered to be sensitive to pollution, suggesting that water quality conditions overall are within their tolerance limits. Additionally, most are non-motile species and require high levels of dissolved oxygen, but can tolerate elevated concentrations of nitrogen. *Nitzschia* is a very rich genus with several hundred species and wide tolerance ranges and is usually associated with brackish and organically polluted water with high nutrients and low dissolved oxygen (Van Dam et al. 1994).

Table 10-6 Most abundant species in both Topanga and Malibu Creeks 2013-2014.

NA = not available

Using a one-tailed t-test to compare the diatom communities between the two samples and sites, the Shannon H diversity measure was significantly higher ($p<0.05$) in Topanga than Malibu. Motile taxa are more significantly abundant ($p<0.05$) in Topanga than in Malibu, as are the percentage of Rhopalodiales ($p< 0.05$). However, comparison of the pollution tolerant index shows that Malibu has significantly higher ($p< 0.05$) levels of pollution tolerant taxa than Topanga. The only other significant result was that dissolved oxygen levels were lower in Topanga ($p< 0.05$) than in Malibu. The difference in flow regimes (augmentation in Malibu, none in Topanga) may be a factor in this result.

The soft-bodied algae species composition and abundance was quite different both qualitatively (Table 10-7) and quantitatively (Table 10-8) between Topanga and Malibu. A total of nine non-diatom species including epiphytes, microalgae and macroalgae were found in both creeks. Topanga also had an additional six species compared to 18 additional species found only in Malibu.

10.4.4 Index of Biotic Integrity (IBI) Analysis

Table 10-9 summarizes the results of three different possible indices, S2 (soft algae only), D18 (diatoms only) and H20 (hybrid incorporating both diatoms and soft algae). Each index was based upon different metrics, but when combined provide relative comparisons that suggest that results for Topanga and Malibu are consistent between indices.

Fetscher et al. (2104) provided a detailed explanation of how these indices were developed, vetted and scaled. Reference conditions were based on evaluation of sites with minimal anthropogenic influences and then checked against possible landscape level factors such as basin geology, gradient, elevation and land cover. Based on their analysis, the boundary between reference and non-reference sites for the H20 index was 57. The upper reach in Topanga meets the reference criteria in 2014 and is just a bit under in 2013. The lower reach in Topanga and both reaches in Malibu would fall into the stressed and disturbed category.

Table 10-9 Comparison of southern California Periphyton IBI Indices for Topanga and Malibu 2013.

Year	SampleID	S2	D18	H20	totalDiatomCount

2013	Malibu- R4	22	46	42	556

10.4.5 Chlorophyll a and Ash Free Dry Mass

Dodds et al. (1998) developed a trophic classification system for stream based on mean chlorophyll values. Oligotrophic systems usually have less than 20 mg m-2, mesotrophic systems range between 20-70 and eutrophic systems are greater than 70.

Using that scale, both Topanga and Malibu Creeks are in the oligotrophic (non-eutrophic) category, although this data represents a snapshot collected during a drought condition and may not be representational of the creek system over time. Levels of chlorophyll a in excess of >0.66 mg m-2 can be found in either nutrient poor waters with higher than normal temperatures, or in cold water where they can be indicative of excessive nutrient inputs (CWAM 2013). As shown in Table 10-10, the Topanga samples showed mixed results, but the Malibu samples, although higher than the CWAM threshold, were still within the limits of the reference site range (Fetscher et al. 2013)

Recent South Coast ecoregional analysis of 331 sites in 2007-2009 evaluated both methods and found that Ash Free Dry mass (AFDM) results may be more representative of algal biomass and that chlorophyll a has more potential for rapid degeneration and laboratory error, which can cause lots of variation (Fetscher, et al 2013).

Table 10-10 Chlorophyll a and Ash Free Dry Mass Results, Topanga Creek (2013, 2014) collected by RCDSMM and Malibu Creek (2013) collected by Aquatic Bioassay Consulting Laboratories, Inc.

Metric	TC4500-4650m 2014	TC4500-4650m 2013	TC3200-3350m 2014	TC3200-3350m 2013	Malibu R-4 2013	Malibu R-3 2013	**Reference Site Range**

10.4.6 Water Quality and Physical Habitat Conditions

Comparison of the physical habitat characteristics of both sampling sites in Topanga and Malibu Creeks suggests that Topanga has more optimal conditions overall, but Malibu has greater average depth at the sampling sites (Table 10-11and 12). The percent canopy is also much higher in Malibu than Topanga. The percent cover of macroalgae (filamentous algal mats) was significantly higher in Malibu compared to the higher level of macrophytes (vascular herbaceous plants in the wetted channel) observed in Topanga. This relates to the very low flow condition resulting in shallow depths in Topanga Creek, which has fostered extensive growth of watercress, various mint and Cyperus species in the channel. The concern with high levels of either macroalgae or macrophytes is that they can limit growth of beneficial microalgae by shading the substrate, reducing the food source (e.g. primary consumers such as diatoms), benthic scraper/grazers and in extreme cases even alter hydrologic patterns (Fetscher et al 2013). Subsequent decomposition of the macroalgae can reduce available dissolved oxygen as well (Quinn and Gilliland 1989).

10.5 Discussion

Periphyton are found in all aquatic environments and tolerate a wide range of nutrient levels and overall water quality (Hoffman 1994). Benthic diatoms and soft-bodied algae are important primary producers that rapidly and predictably respond to environmental condition in terms of changes in community composition. Several research efforts in southern California and throughout the United States are examining the potential of utilizing these organisms as water quality indicator species (Porter et al. 2008, Fetscher 2008, Fetscher et al. 2009, CWAM 2013) because of their rapid response to water quality condition changes in nutrient levels (primarily nitrogen and phosphorus), pH and conductivity. For example, diatom saprobity values near sewage outlets showed high correlation to chironimid pollution index, diversity of BMI and diversity of macrophytes (Van Dam et al. 1994). Despite limitations due to increased cost, patchy distribution and sampling errors common to biological assessments, the addition of benthic algae analysis to water quality monitoring provides some important advantages and complements grab water samples and benthic macroinvertebrate data by providing insights into short and long term dynamics of the system. Soft algae are often the dominant biomass in southern California creeks, as in other places, and most likely to exhibit “nuisance blooms”, providing greater insight into nutrient loading and uptake patterns (Busse et al. 2003, Luce and Abramson 2005). Benthic algae normally exhibits seasonal patterns related to flow velocity and light availability, but it appears that nutrient loading in the winter months can result in higher benthic algal growth in summer months (Luce and Abramson 2005).

Diatoms in particular have high dispersal rates and short reproduction/growth times that respond quickly to changes in environmental conditions (Lavoie et al. 2008) and the two largest national surface water monitoring programs (Environmental Protection Agency Environmental Monitoring and Assessment Program (EMAP) and the US Geological Survey national Water Quality Assessment Program) both use periphyton indicators due to these characteristics.

Diatoms and soft-body algae can have direct influence on the substrate and flow characteristics, as well as on water quality by increasing nutrient uptake and increasing dissolved oxygen levels (Porter 2008). They are important primary producers and improve habitat for other aquatic species (Porter 2008). They are the foundation of the food web and the basis of the trophic levels found in lower watershed streams. Both diatoms and soft-body algae metrics exhibit rapid responses to levels of stressors and thus examining the changes over time and between locations can help characterize the productivity of the creek (Rimet et al. 2005).

One important caveat to note is that the assignment of a species to a particular metric can vary widely based on geographic range and their consistency as nutrient indicators can vary (Potopova and Charles 2007). This supports the need for development of data specific to southern California in order to properly associate species to water quality tolerances. That being the case, some of the common diatom indicator species with fairly well described Total Nitrogen (TN) preferences, both high and low, were found in both Topanga and Malibu, which provides a somewhat confusing result. This could possibly be a result of inability to differentiate between species in the same genus that appear taxonomically similar, but in fact represent different species with different tolerance preferences. It could also mean that further refinement of the tolerance limits and preferences is needed.

In Topanga Creek, our water quality data indicates that nutrient levels detected in monthly grab samples decreases as water flows downstream from the town, which is the last input of any anthropogenic nutrients. However, the percentage of more tolerant species was higher in the lower reach located approximately 3000 meters downstream of any inputs. A possible cause of this result could be decreasing flows, absorption by macroalgae, or may be associated with the increasing population of invasive red swamp crayfish, which can increase turbidity. These conditions could also possibly explain the increase in Disturbance Taxa observed in 2014 in the lower reach where pools are shallow and runs and riffles are the dominant habitat type.

In addition to responding to nutrient changes and inputs, other factors such as massive growth of *Cladophora sp.* can mask high inputs of nutrients by utilizing and storing nutrients, reducing their detection in the water column. *Cladophora* was the dominant macroalgal species collected in spring 2013 in both survey reaches in Topanga Creek, but it was only observed in the upper reach in 2014. It is also the dominant genus noted with the Rapid Point Count data collected monthly at each water sampling site throughout Topanga Creek and into Topanga Lagoon.

Growth of soft-bodied algae is often controlled by limited available nitrogen or phosphorus. Nuisance blooms are often associated with anthropogenic inputs of these nutrients (Carpenter et al. 1998). Excessive growth of *Cladophora* has been considered to be an indicator or eutrophication (Biggs 1996, Luce and Abramson 2005), although data derived from the NAWQA database (Potapova 2005) found *Cladophora* in a wide range of nutrient concentrations and in moderately alkaline waters having optimum pH of 8.0, and conductivity of 566 µS/cm. It is also more frequently found on rocky rather than softer sediment substrates (Potapova 2005).

Cladophora glomorata is the most common taxa found throughout southern California and appears to be a reliable indicator of high total nitrogen (optimum of 3.14 mg l^{-1}) (Stancheva et al. 2012) and was also the dominant species observed in both Topanga and Malibu. Recent advances in taxonomy suggest that it is possible to distinguish between *C. glomorata* (an indicator of high TN concentrations) and *C. fracta,* which is an indicator of low TN conditions. It is possible that due to the difficulty in making this species level distinction, the lab that analyzed our samples identified everything as *C. glomorata*. Additional investigation of taxonomic effort is needed to explain why such a high TN species is abundant in the low N environment found in Topanga Creek.

Algal abundance can also be limited by hydrological fluctuations when scoured by floods but growing extensively during low flow periods with stable bed sediments typical of southern California summers (Biggs and Close 1989). During the course of this study, there were no flood events. Another potential factor that can affect algal biomass is the abundance of benthic macroinvertebrate grazers and their response to predators (Diehl et al. 2000).

Intensity of grazer foraging can respond to predation threats and result in changes in algal density (Diehl et al 2000). It was beyond the scope of this study to address this directly, but a discussion of possible food web interactions is provided in Chapter 12.

Stancheva et al. (2012) also found that algal species number was significantly correlated with water temperature and increased canopy cover reduced algal biomass. In Topanga, water temperatures ranged between 15-16^{o}C, with canopy cover greater than 65%, which was comparable to the conditions in Malibu site R3, but site R4 had much less canopy cover. The overall IBI scores were not significantly different between the sites. Species in the green algae class Zygnemataceae are considered frequent and abundant in low nutrient streams in southern California and a single species (*Mougeotia sp 1)* was observed in Topanga, as well as *Spirogiyra sp* 1 in Malibu. Given the negligible nutrient levels in Topanga, this is somewhat confusing and contradictory, suggesting that other factors may play a roll in species distribution and/or tolerance ranges.

Some species of cyanobacteria, the next most abundant taxonomic group observed in Topanga Creek, have the ability to fix atmospheric nitrogen and thus are often indicative of streams with low nitrogen levels. These species are usually not found in streams with high nitrogen levels (Porter et al. 2008) and the 11 species found in Malibu Creek were different than the eight species found in Topanga, suggesting a different tolerance to the consistently higher nitrogen levels (>2 mg/l nitrate) found in Malibu Creek (Heal the Bay 2014).

Overall the three different indices of biologic integrity applied showed a consistent picture between sites and creeks for the soft body algae only (S2), diatoms only (D18) and combination of both (H20). These metrics are only recently available and so it is not yet possible to compare the snapshot of conditions in Topanga and Malibu Creeks in 2013 to other sites regionally. Therefore, this information provides a baseline starting point for comparisons over time and in other coastal creek systems.

However, regional and statewide Beneficial Use Risk Classification delineates nutrient unimpaired versus impaired water bodies based on levels of benthic algal biomass measured as chlorophyll a, ash free dry mass, dissolved oxygen levels and pH levels (Fetscher et al. 2013). Disturbance classes were scaled with variables such as land use, road density and number of crossings, presence of dams, pipelines, canals, instream gravel mines and producer mines. Over 500 sites statewide were evaluated, and values from the South Coast ecoregion were consistently higher than for the North Coast or Sierra Nevada ecoregions, which were the lowest. Stressed sites had consistently higher levels of AFDM, chlorophyll a and percent macroalgal cover, but even reference sites in the South Coast ecoregion exhibited consistently high values for these metrics.

Throughout the state, chlorophyll a values ranged from 0.22-1504 mg m^{-2} with a mean of 47 mg m^{-2}, however the south coast median was 25.7 mg m^{-2} (range 8-27 mg m^{-2}). The snapshot data from Topanga and Malibu 2013 were well below that average. The ash free dry mass (AFDM) range throughout the state was 0.07-489 mg $m^{-2}$with a mean of 40 mg m^{-2}, although the south coast median was 17.2 mg m^{-2} (range 6-27 mg m^{-2}). The 2013 data from both Topanga and Malibu creeks were also on the low end of this range (7 -1 2 mg m^{-2}). Scores in southern California are considered to be stressed if they are below 57, which is two standard deviations below the mean for the reference streams (Fetscher et al. 2013). The data from Topanga and Malibu Creeks falls well below the threshold of 30% cover identified by Biggs (2000) and is on the lower end of the reference range (Fetscher et al. 2013), which would suggest that they are stressed, but not yet degraded.

Due to limited data available at this time, it is not possible to develop a consistent hypothesis to explain why there is so little difference between benthic algae communities in Topanga and Malibu Creeks, despite the abiotic differences in stream habitat, flow regimes and nutrient loading patterns. However, this information does provide a snapshot baseline under drought conditions that can be built upon over time.

10.6 Summary

- Examination of diatom and soft-bodied algae communities can provide secondary indicators and multiple lines of evidence to better characterize the responses of southern California creeks to both natural (floods, wildfire) and anthropogenic inputs will allow for better understanding of the dynamics of aquatic systems.
- Diatom and soft-bodied algae data from Topanga 2013-2014 provides a baseline snapshot of low flow conditions.
- A total of 125 diatom species were observed in Topanga Creek in 2013-2014. 46 species, many of them of cosmopolitan distribution, were common to both years, with 40 different species found only in 2013 and 39 species found only in 2014.
- As shown in Table 10-5, the majority of metrics remained similar, with the exception of a decrease in motile taxa present in 2014 at both sites, a decrease in low DO taxa present at both sites in 2014, and a decrease in percent Rhopalodiales in 2014. Percent of sediment tolerant taxa increased slightly in both locations.
- *Cladophora glomorata* is the most common taxa found throughout southern California and appears to be a reliable indicator of high Total Nitrogen (Stancheva et al. 2012) and was also the dominant species observed in both Topanga and Malibu despite their different nutrient levels. This could possibly be a result of inability to differentiate between species in the same genus that appear taxonomically similar, but in fact represent different species with different tolerance preferences. It could also mean that further refinement of the tolerance limits and preferences are needed.
- Using the Southern California Index of Biotic Integrity (Fetscher et al. 2014), application of three different indices of biologic integrity showed a consistent picture between sites and creeks for the soft body algae only (S2), diatoms only (D18) and combination of both (H20). These metrics are only recently available and so it is not yet possible to compare the snapshot of conditions in Topanga and Malibu Creeks in 2013 to other sites regionally.

11 Conceptual Framework of the Food Web in Topanga Creek

11.1 Introduction

Water quality conditions can in many ways control biological communities, affecting the species diversity, abundance and community structure at a variety of trophic levels. Organisms from diatoms to fish are sensitive to multiple interactions of the physical and chemical conditions within a freshwater system. This study provided a unique opportunity to examine the physical, chemical and biological variables at work in Topanga Creek, which has been colloquially referred to as Topanga “magic”. Examination of the fecal indicator bacteria (FIB), in-situ water quality conditions and nutrient levels confirms that although there are numerous anthropogenic inputs into the creek in the upper watershed, these inputs are not responsible for the bacterial exceedances observed at Topanga Beach.

Investigation into FIB, nutrient levels, water quality and benthic macroinvertebrate communities at five creek sites between the town of Topanga (Owl Falls 6500 m) downstream to the upper end of Topanga Lagoon known as the Snake Pit (300 m) was conducted between 2012-2014. Examination of the physical, chemical, and biological variables at each of these sites has begun to illustrate how inputs from the town of Topanga and at other sites further downstream cycle through the system as they move towards the lagoon. While FIB occurrences do occur at creek sites, most prevalently at Owl Falls (immediately downstream of town development) and Topanga Bridge (bridge crossing), they do not translate to beach outlet exceedances. Due to the interrupted subsurface flow that sometimes occurs in summer between 1700 m and 300 m there is no surface connection between the upper lagoon and the creek except during storm events.

Numerous studies have looked at each of these variables independently. Previous studies have also assessed the role that streambed sediments play on fecal indicator bacteria (FIB) survival and decay (Kinnaman et al. 2012, Garzio-Hadzick et al. 2010) as well as the effect of biological influences such as predation and indigenous microbiota on FIB persistence (Korajkic et al 2013). Few studies attempt to examine relationships across trophic levels and between physical and chemical conditions to biological responses in species abundance and diversity, from bacteria to periphyton, benthic macroinvertebrates (BMI) and fish (Feio et al 2007, Griffith et al. 2005).

Although time and resources precluded definitive stable isotope analysis of the food web or development of either a mixing model or structure equation model to more quantitatively characterize the energy flow through the food web, we took this opportunity to qualitatively examine the various trophic levels. The goal was to describe the interactions between FIB, nutrients, sediments (influence on decay rates and nutrient availability), diatom and soft-bodied algae, benthic macroinvertebrates, amphibians, fish and introduced crayfish in Topanga Creek. We incorporated long-term data from annual stream surveys (2001-2014), as well as more detailed data collected as part of the Topanga Source Identification Study in 2012-2014.

One of the more interesting patterns observed in Topanga Creek is that despite inputs of nutrients and FIB in the upper watershed above the town, levels of nutrients and FIB appear to diminish before reaching Topanga Lagoon. First documented in the 1999-2001 water quality study (Dagit 2001), observed again in the 2003-2004 study (Dagit et al. 2004), and continuing to date, this intriguing pattern of sources accumulating in the upper watershed (Owl Falls at 6500 m), a sink in the most natural reach (Scratchy Trail at 4800 m), followed by additional inputs at Topanga Bridge (3600 m), with continued decline downstream when measured at Brookside Drive (1700 m). This strongly suggests that inputs from the upper developed portion of the watershed are not involved with the bacterial exceedances observed at Topanga Beach. It also suggests that nutrient and bacteria levels within the creek are possibly controlled by a complex, synergistic effect of a dynamic carbon, nitrogen and phosphorus energy cycle and a potentially lengthy food web incorporating numerous trophic levels that are able to absorb/utilize nutrient inputs in the more undisturbed reaches of the creek. This discussion therefore focuses on the interactions in Topanga Creek rather than the lagoon and ocean interface.

Increased urbanization resulting in increased percentage of impervious surfaces can affect stream ecology by increasing nutrient concentrations, altering hydrologic patterns, increasing water temperature and light levels (Paul and Meyer 2001). Greater than 10-15% urbanization or conversion to impervious surfaces has been show to negatively affect algae, macroinvertebrates and fish communities (Paul and Meyer 2001). It has been observed that the diversity of aquatic species decreases once the threshold of 8% impervious surface is reached (Riley et al. 2005). The Topanga Creek Watershed has almost 12% impervious surface, yet it retains a diversity of native aquatic species, some of which are sensitive to water quality degradation, such as the endangered southern steelhead trout.

11.2 <u>Elements of the Topanga Creek Food Web</u>

In order to characterize the Topanga Creek food web, it was necessary to summarize the abiotic and biotic elements that contribute to the dynamics of the system. Each of these factors is discussed in detail in other Chapters of this report, as well as in other documents. To facilitate this discussion, the most salient points are summarized below.

11.2.1 <u>Abiotic Factors</u>

Water quantity is quite variable both seasonally and inter-annually. Table 11-1summarizes the wetted width, flow, water temperature and nutrient levels collected in-situ using the California Rapid Bioassessment Protocol (CDFG 1999) during annual stream surveys at two sites in Topanga Creek. The lower reach (3200m) has a lower gradient (<3%) and is located within 100 meters of Topanga Canyon Boulevard. The upper reach (4500m) is isolated from adjacent anthropogenic influences, has a gradient of 3-6% and is more difficult to access. Both of these sites remained fairly stable in wetted width, although flow and depth varied with rainfall. The water temperature was also fairly consistent seasonally, with the highest temperature recorded in 2005 at 3200m when flows persisted for more than 200 days due to the high rainfall and at 4500m during the low flow year 2000. Table 11-1 summarizes the average stream conditions during the 2001-2014 study period.

Precipitation

The pattern of precipitation varied dramatically over the years as shown in Figure 11-1. Additionally, the intensity, duration and pulses of storm events also varied, from years with rainfall distributed over several months, to a more recent pattern of isolated storms separated by long dry interludes. It was not possible to correlate these observations with the larger climatic cycles of the El Nino Southern Oscillation or the Pacific Decadal Oscillation, although both could play a role in the rainfall received in the watershed. Complex multi-year cycles of drought, shifting rainfall patterns and intensity of storms characteristic of southern California Mediterranean conditions can play an important role in the variability of streams, which are then linked to changes in the biotic community, and particularly influence the diversity and persistence of BMI (Durance and Ormerod 2007). The County of Los Angeles has been in and out of drought conditions since 2000. However, winter rains were enough to alleviate drought and remove the lowest drought distinction of 'D0 abnormally dry' at least temporarily. The winter of 2012/13 was the first winter in a decade that this alleviation did not occur, and the county dove into a more intense drought 'D3 extreme drought' (US Drought Monitor 2014).

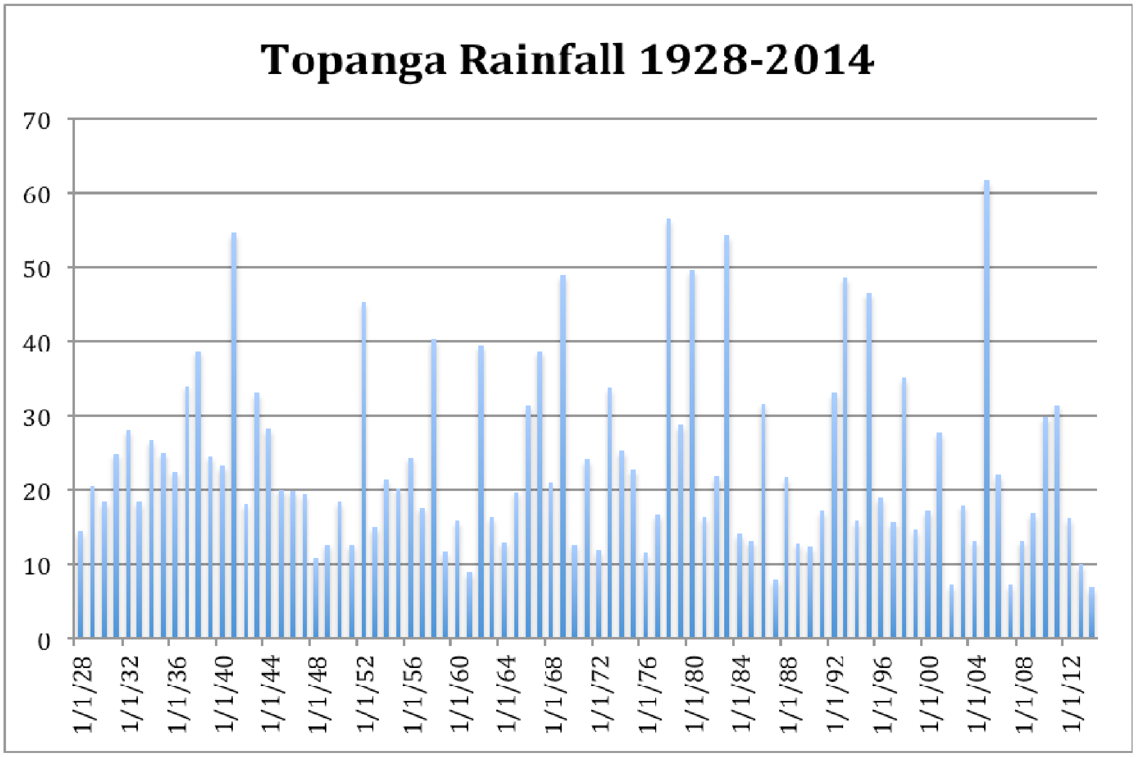

Figure 11-1 Summary of Precipitation in Topanga Creek (based on Los Angeles County Rain gage #318).

Groundwater Influences

The locations of seeps and springs contributing groundwater year round to the main stem of Topanga Creek were mapped in 2005 (GeoPentech 2006). These groundwater inputs are not directly related to the distribution of steelhead trout, although the main refugia pools consistently used by trout receive inputs from groundwater, which may help moderate summer/fall water temperatures (Tobias 2006). Input from these sources can augment flows adjacent and downstream of the sources.

Flow Habitats

The variety and complexity of flow habitats (riffles, runs, pools, etc.) contribute to the diversity of niches available for aquatic species. Underlying geomorphology, especially gradient, determine the distribution and abundance of each habitat type. Topanga Creek contains a wide range of habitat types, but is primarily pool and riffle dominant (Table 7-1). Analysis of the relationship between habitat types and steelhead trout (*Oncorhynchus mykiss*) distribution showed that adults tend to be associated with pools of greater depth and higher gradient (upstream reach), whereas juveniles are found more often in lower gradient (lower reach) and shallow habitats (Krug et al. 2014). Distribution and abundance of this top-level predator can influence the dynamics of the prey community.

Water Quality

Water quality sample sites for this study (Figure 2-1) were selected to reflect the variety of conditions found as Topanga Creek flows downstream from the town through the more isolated canyon, and then adjacent to the highway before reaching the creek mouth at Topanga Lagoon. Sites are as follows: Owl Falls (6500 m), Scratchy Trail (4800 m), Topanga Bridge (3600 m), Brookside (1700 m), and Snake Pit (300 m).

Levels of nutrients measured including nitrate-N, nitrite-N, ammonia-N and orthophosphate were consistently low with isolated spikes, however even the highest levels documented in Topanga Creek were significantly lower than those observed in other regional creeks such as Malibu (Table 6-22). Levels of nitrogen, phosphorus or light can limit stream algal growth, and increases in any of these resources can result in algal blooms (Borchardt 1996). Figure 11-2 summarizes the FIB, nutrient and turbidity levels observed between 2012-2014. The highest values occurred during first flush rain events, which is consistent with observations in most river systems (Surbeck et al. 2006). Phosphates were often in exceedance at Owl Falls, and to lesser degrees at Scratchy Trail and Topanga Bridge downstream. Correlations between high phosphate levels and ENT at Owl Falls suggest there may be a septage or graywater input somewhere in town, but that its effects are diluted to a point where they are undetectable at Scratchy Trail (low ENT).

The role turbidity is playing in the overall dynamics of the food web is not clear. Bioturbation may be having an influence on the BMI community either directly or indirectly, perhaps related to the effects of crayfish (Yamamoto 2010). The effects of turbidity on BMI need further study in Topanga Creek.

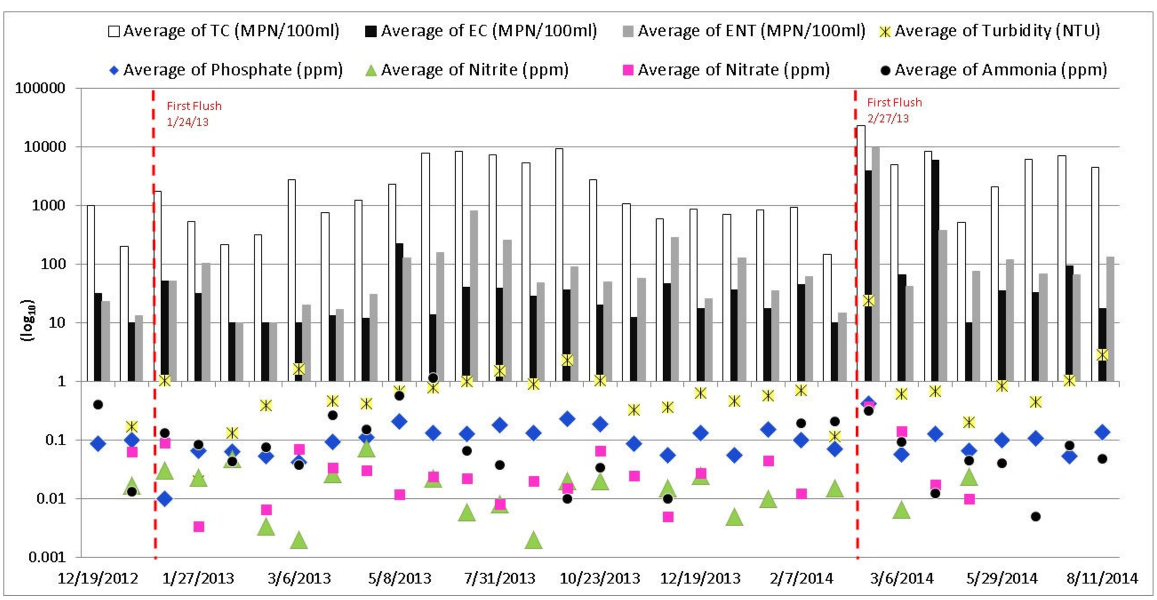

Figure 11-2 Summary of Average FIB and Nutrient Levels in Topanga Creek 2012-2014.

It has been shown that algal communities have a complicated relationship with nitrogen and phosphorus levels in the water column due to storage, uptake patterns that fluctuate depending on seasonal loads, substrate availability and flows which can result in delayed growth responses (Busse et al. 2006, Luce and Abramson 2005). With the low nutrient levels observed in Topanga Creek it is hard to determine if either nitrogen or phosphorus are limiting factors in algal growth or if algal growth is more synergistic with other factors such as flow and light. Biggs (2000) suggests that nutrients influence algal biomass concentration more during periods of low flow. Observations in Topanga Creek suggest that during the low flow period between 2012-2014, overall algal growth was not as high as had been observed during previous low flow periods (Krug et al 2014), potentially suggesting that nutrients were limiting during this time.

The relationship between dissolved oxygen (DO) levels and water temperatures are well documented and levels of DO below 5 mg/l are considered stressful for steelhead trout. These low levels were observed in five out of 21 sample events at Owl Falls (6500 m) and 17 out of 21 sample events at Snake Pit (300 m) during the low flow dry conditions when the pool was isolated and stagnant. Steelhead have not been able to reach 6500 m upstream due to natural stream barriers and only pass through Snake Pit when rains reconnect surface flow sufficiently to permit fish passage. Lower DO levels were significantly correlated to a higher percentage of non-insect taxa and higher DO levels were correlated to lower percentage of non-insect taxa.

Substrate and Embeddedness

Habitat mapping done for the watershed characterization as part of the steelhead trout monitoring program found that the composition of substrate remained fairly consistent over time (Dagit et al. 2007). Pulses of sediment were observed to move through the system driven by storm events, but despite a shift in pool depth at specific sites, overall amount of stream suitable to support steelhead remained fairly constant. The percent embeddedness ranged from 20 to 50% (Stillwater et al 2010). In 2013, the 3200m site was considerably more embedded (49%) than the upper 4500m site (26%), but while the lower site remained the same in 2014, the upper site increased to 44% (Table 7-1). This could reflect either the loss of wetted width as the flows diminished, increased sedimentation, or both. Trout prefer loosely embedded gravels for preparing their redds, and increased embeddedness reduces interstitial niches for many other aquatic organisms. High levels of embeddedness are also associated with reduced biodiversity and abundance of BMI (McGinley et al. 2013).

Bank Stability

Bank instability and erosion can negatively affect aquatic communities by altering substrate composition (increasing fines) and changing habitat types from pools to riffles, or other variations depending on the intensity of the failure. The impacts of bank instability were observed in Topanga Creek in 2008, when Caltrans blew up a boulder that blocked Topanga Canyon Boulevard, resulting in the collapse of a rip rap bank into the creek channel, which changed a consistent refugia pool habitat into a riffle habitat (RCDSMM *unpublished data*).

Due to the geology of the steep canyon walls that define much of the main stem of Topanga Creek, overall bank stability is quite high (Table 7-1) and erosion from upstream sources is episodic.

Instream Habitat Complexity

Instream habitat complexity includes abundance levels of filamentous algae, aquatic macrophytes, boulders, woody debris, undercut banks, overhanging vegetation, living tree roots and artificial structures. These provide a variety of niches for aquatic species from bacteria to fish. In 2013 and 2014, pools, riffles, glides and runs were the dominant habitat available. As flows decreased during 2014, the proportion of runs decreased in the lower reach (3200m) and the percentage of glides and pools decreased in the upper reach (4500m) (Table 7-1).

Canopy Cover and Riparian Vegetation

Canopy cover is fairly high (>80%) throughout Topanga Creek and appears to be increasing with the low flow condition and lack of storm events to clear the channels of macrophytes. The riparian vegetation of Topanga Creek is dominated by trees and saplings (>5 m) in the lower reach, but is dominated by herbs and grasses in the upper reach, which is more defined by steep rock walls (Table 7-1). Invasive plants are found throughout the watershed, including large stands of *Arundo donax*, and increasing spread of cape ivy.

11.2.2 *<u>Biotic Factors</u>*

Microbial Communities

Although it was not possible to characterize the non-fecal microbial community in Topanga Creek, it is important to recognize that the growth and decay of both fecal and non-fecal microbes is a critical underlying factor in the function and response of Topanga Creek to natural and anthropogenic inputs. The role of indigenous microbiota on the persistence and rate of decline of FIB is still not clearly identified but predation and competition impacts, as well as limits to FIB reproduction are important considerations when examining the dynamics of the creek. Using laboratory microcosms to examine samples from Topanga Creek, the growth and decay of bacteria in sediment identified that decay rates were faster in the more natural undisturbed reach samples at Scratchy Trail when compared to the upstream site at Owl Falls, which is closest to urban inputs (Zimmer-Faust *unpublished data*). This is consistent with observations that Scratchy Trail represents a reach where natural cycling of nutrients is most functional. However, the sediment microcosm results from Brookside Dr. (1700 m) suggest that nutrient cycling may be less downstream of Scratchy Trail. More information on these interactions was beyond the scope of this study but presents an interesting question for subsequent work.

Benthic Algae

The abundance of benthic algae can be influenced by abiotic factors such as flows and flood scouring, stability of the sediments, by inputs of nutrients or limitations of nitrogen and phosphorus in low nutrient systems, and finally by the effects of grazing by aquatic organisms. There were no flood events during the course of this study (2012-2014) that were sufficient to mobilize the substrate or scour benthic algae, macroalgae or macrophytes, although such flows were observed in 2005, 2008, 2010 and 2011. Topanga Creek has relatively low levels of nutrients, making it is possible that nitrogen (N) and phosphorus (P) are limiting factors for growth. The Mediterranean climate is characterized by long undisturbed growing season for algae, which suggests that available N and P may ultimately not be the only limiting factor, but rather that available light, stream substrate composition and wetted channel may also be important factors (Busse et al. 2006).

Although a dense benthic diatom algal biomass was not observed during this study, our data were unable to distinguish between possible nutrient uptake/availability limitations versus effects of grazers. Once established, filamentous algae are inedible for many aquatic insects (Cummins 1973) but foraging by grazers can both stimulate (under less intense conditions) and reduce (under more intense foraging pressure) density and cover of benthic algae (Diehl et al. 2000). For example, mayflies (*Baetis sp*) are important benthic algal grazers and their population fluctuates with availability of algae, especially that on epibenthic substrates. Additionally, their use of these food resources is dependent on the type of predators they are avoiding. When present, trout can alter the behavior pattern of *Baetis* foraging by making it more risky to forage during the day, or in particular areas, thus potentially increasing the algal density in more exposed areas, and decreasing the density in more protected areas (Diehl et al. 2000).

The species composition of benthic diatoms and soft-bodied algae observed in Topanga is based on such limited samples that it would be premature to make much of the snapshot baseline available at this time.

Benthic Macroinvertebrates

As primary consumers of allochthonous (terrestrial leaf litter derived) and autochthonous (aquatic plants derived) detritus, benthic macroinvertebrates are the most basic link between both aquatic and riparian vegetation and the rest of the river community. Filling distinct feeding niches, some species shred whole leaves and stalks, others scrape up the film left behind, ultimately releasing a large pool of nutrients that can be absorbed by higher trophic levels. Analysis of functional feeding group (FFG) diversity can shed light on how nutrients begin to flow at these primary trophic levels. In addition to FFG designations, many families, genera, or species have assigned tolerance values 0-10 (CAMLnet. 2003) that designate the organism's ability to live in polluted waters.

Another key feature of benthic macroinvertebrates is their tendency to reveal current and past ecological disturbance. Some taxa, such as mosquitoes, may appear and disappear within a week, while others, like some common dragonflies, develop under water over the course of a year or more (Voshell 2002). Therefore, shifts in species composition may be the result of a current disturbance event or one that occurred within the year. Habitat preferences, limitations, and additional life-history traits have been described for many macroinvertebrate species (Vieira et al. 2006). Indexes of Biotic Integrity (IBI) have been developed using this information to evaluate BMI community composition and distribution and to assign numeric and descriptive scores of ecological health.

A total of 17 BMI samples were collected at each sampling location from upstream to downstream as part of this study. This augmented information compiled by analyzing the annual stream survey BMI collections between 2003-2014. A summary of the SCC-IBI for Topanga Creek is found in Table 8-3 and 8-4. Examination of the samples from upstream to downstream confirm our hypothesis that BMI communities improved the further they were from human influences.

The number of BMI individuals collected from the annual springtime stream surveys from Upper and Lower Topanga Creek ranged from 104 to 3516, representing six phyla, 21 orders, and a total of 76 taxa. The majority of individuals fell within the phylum Arthropoda and class Insecta, followed by the subphylum crustacean including class Ostracoda and order Amphipoda. To date, the invasive New Zealand mud snails (*Potamopyrgus antipodarum*) have not yet been observed in Topanga Creek.

From 2003-2012, *Baetis sp. (blue-winged olives),* a prolific genera of small minnow mayfly was the first or second most abundant taxon every year in both Upper and Lower reaches (Figure 8-5). *Baetis sp.* made up between 33-79% relative abundance (RA) in Upper Topanga, and 13-67% in Lower. The family Baetidae are characterized as strong swimmers, most prevalent in flowing, shallow waters with ample cobbles and/or pebbles (Voshell 2002). *Baetis sp.* are collector-gatherers and have a tolerance value of 6. In 2013 and 2014, *Baetis sp.* were no longer dominant and in fact comprised less than 10% RA of all four samples. Chironomidae, or non –biting midges, which had previously made up between 5-36% shifted to occupy 63-72% of all samples 2013-2014. Chironomids are also primarily collector-gatherers, and are ascribed a family-wide tolerance value of 6. However, the Chironomidae family is extremely diverse, including over 1,000 species, and thrive in equally diverse habitats. Chironomids were identified to sub-family or tribe for a few select samples, and similar taxa were found before and after 2013.

Overall SCC-IBI scores for Topanga Creek were Fair to Very Poor between 2003-2014. Many of the samples had too few individuals collected to be analyzed by the SCC-IBI, which means that they were extremely poor. It is not clear if this might be due to heavy predation by amphibians, crayfish and steelhead or if it is an accurate reflection of the BMI community response to environmental conditions (low flow, low dissolved oxygen). In any case, it is a cause for concern.

Invertebrates – Crayfish

Low flow, shallow conditions such as have been present since 2011 provide preferred habitat for red swamp crayfish (*Procambarus clarkii*) (Voshell 2002), and the lack of flushing storm pulses that have been shown to reduce their numbers has resulted in the population explosion of this species in Topanga Creek.

P. clarkii grow rapidly, maturing within three months after hatching and can reproduce twice a year in warm conditions (Barnes 1974, Vodopich and Moore 1999, Safra et al. 1999). Furthermore, large healthy females typically produce 600 viable young (Barnes 1974, Vodopich and Moore 1999, Safra et al. 1999). The generalist and predatory feeding habits of this Gulf Coast native have been linked to observed declines in macrophyte abundance (Feminella et al. 2006, Rodriguez et al. 2005), macroinvertebrate diversity (Correia et al. 2008), increased bioturbation (Mueller 2007, Yamamoto 2010), and amphibian species richness and recruitment (Gamradt and Kats 2002, Cruz et al. 2006, Ficetola et al. 2011). *P. clarkii* consume an array of plant and animal matter, aquatic vertebrate eggs and larvae, aquatic invertebrates, and can affect food webs on a polytrophic scale.

Pease and Wayne (2013) also observed that Pacific tree frog tadpoles (*Pseudarcris regilla*) responded to predation by crayfish both behaviorally and morphologically by selecting for deeper tail muscles. Gamradt and Kats (2002) conducted amphibian surveys from 1981-1986, and identified ten Santa Monica Mountain streams supporting populations of California newts. When the surveys were repeated in 1994, newts were missing from three of those 10 streams. Further study documented that *P. clarkii* consumed newt egg masses, as well as attacked adults (RCDSMM *unpublished data*).

A short term removal effort conducted by the Watershed Steward Members and RCDSMM Stream Team volunteers between Fall 2013 and spring 2014 suggests that these indiscriminant predators are directly affecting the BMI community and potentially competing for scarce food resources with native amphibians and fish. Additionally, they have been observed to directly attack CA Newts and the numbers of young of the year trout was reduced as the population of crayfish increased (Figure 11-3). While there are numerous other factors that could play a role in that observation (reduced numbers of redds, increased young of the year mortality from drought or predation), it is difficult to ignore the potential for crayfish to be impacting recruitment of steelhead.

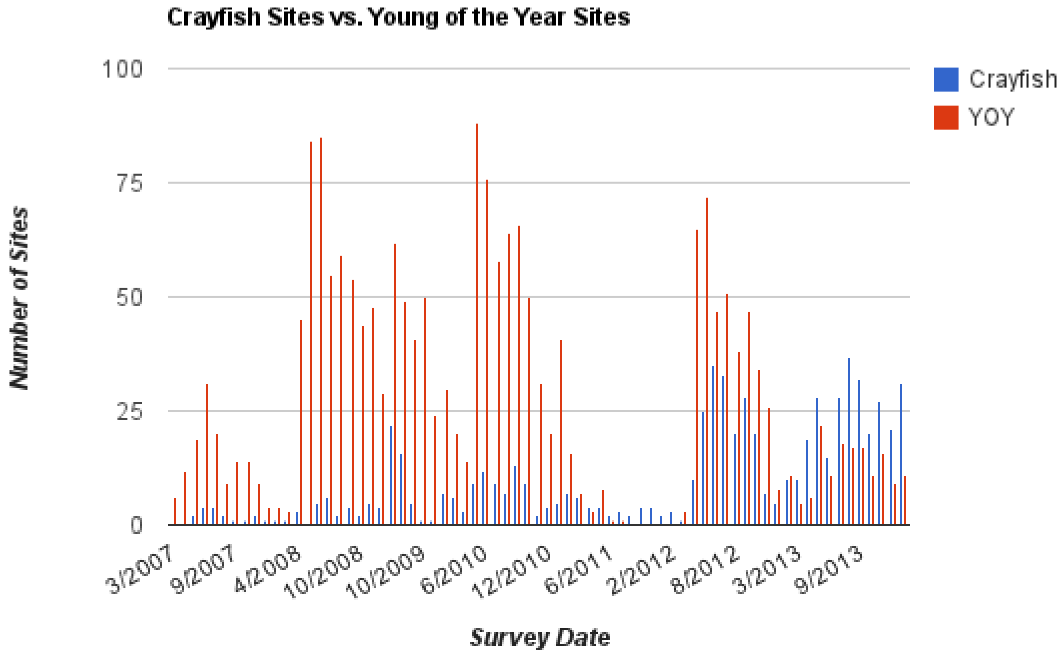

Figure 11-3 Comparison of Young of the Year Trout and Crayfish populations based on snorkel surveys in Topanga Creek 2007-2014.

Herpetofauna

Topanga Creek is home to 23 of a possible 33 species of amphibians and reptiles known from the Santa Monica Mountains (De Lisle 1986, Dagit and Webb 2002). A number of these species are commonly or sporadically observed inhabiting the main stem of Topanga Creek below town. The most commonly observed species are the Pacific tree frog (*Pseudarcris regilla*) and the California tree frog (*Pseudarcris cadaverina*) both of which feed on a variety of invertebrates. Preliminary results of data collected during the annual stream surveys suggests that their numbers are declining as the number of crayfish increase, although this could be related to the rainfall patterns as well. Additional analysis of data is needed to confirm this observation (RCDSMM *unpublished data*).

Prior to the increased abundance of crayfish, California newts (*Taricha torosa*) were regularly observed. They too rely upon a variety of small invertebrates as their food source as adults, and may consume decaying organic matter during their larval stage. The number of CA newt egg masses and adults observed within the study reaches have dropped as the number of crayfish has increased (Figure 11-4). Gamardt and Kats (2002) have documented that newts avoid streams with crayfish but return to them following crayfish removal by flood events.

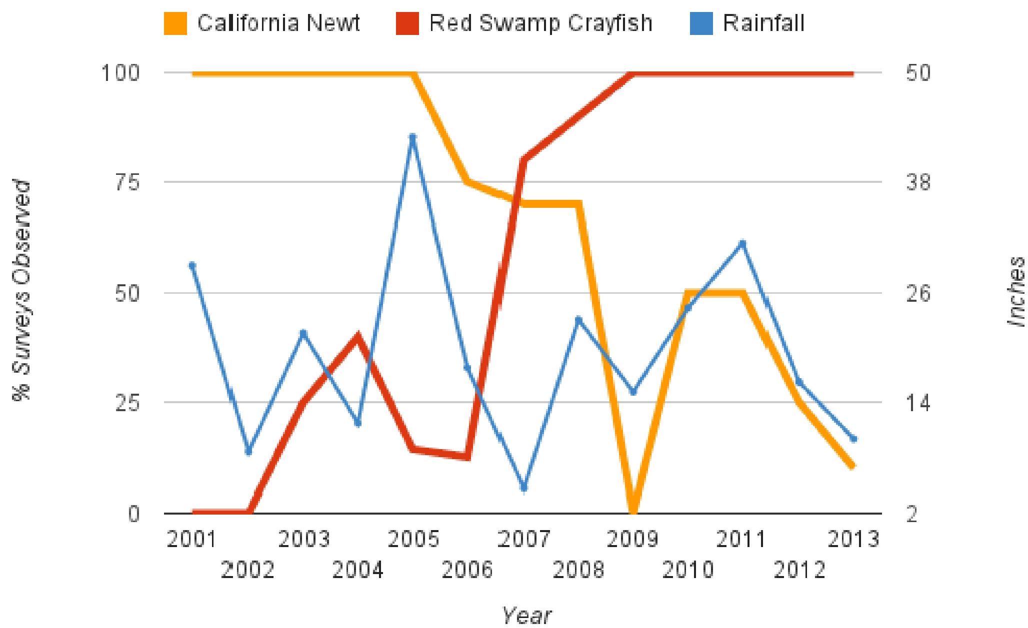

Figure 11-4 Comparison of CA newt and Crayfish observations during annual stream surveys in Topanga Creek. (Note: data is not continuous, but lines were used to highlight the changes observed).

Another aquatic species frequently observed in the study reach is the two-striped garter snake (*Thamnophis hammondi*). The preferred diet of these snakes include tadpoles, newt larvae, small frogs and fish and occasionally fish eggs.

Potentially present and contributing to the diversity of the aquatic food web but rarely observed in the study reach are western toads (*Anaxyrus boreas*) who consume invertebrates as adults and algae and detritus as tadpoles; western garter snakes (*Thamnophis elegans*) which will eat whatever they can find, and occasionally a southwestern pond turtle (*Actinemys marmorata*) straying from the upper watershed (DeLisle 1986). These omnivores will eat algae, some macrophytes, invertebrates, tadpoles, crayfish, and small fish or frogs that are captured and consumed in the water.

Fish

Three native fish species are found in lower Topanga Creek, but the tidewater goby (*Eucyclogobius newberryi*) is confined to the lower and upper portion of the lagoon and rarely observed further upstream. Both southern steelhead trout (*Oncorhynchus mykiss*) and arroyo chub (*Gila orcutti*) are distributed throughout the study reach (Krug et al. 2014). In spring 2014, fathead minnows (*Pimephales promelas*), an invasive exotic fish most often used for bait were detected throughout the study reach of Topanga Creek. All of these species are known to consume a wide variety of aquatic invertebrates and even some algae, but only steelhead trout have been documented eating other fish and crayfish (Krug et al. 2012). The abundance of arroyo chub varies seasonally with increased numbers in summer and fall

(RCDSMM *unpublished data*). This corresponds with the increased numbers of amphibian tadpoles, larval newts and juvenile steelhead trout observed during the same time frame. It is possible that the increased competition for BMI resources at the time of the annual spring stream surveys plays a role in the low numbers of individuals collected.

Steelhead trout were extirpated from Topanga Creek during the 1970-80's but recolonized in the 1990's (Bell et al. 2011). Since that time, the population has increased both in abundance and distribution throughout the creek. Prior to the high flows in 2005, trout were restricted to the reaches below 4400m, but have expanded upstream to the natural limit of anadromy since (Krug et al. 2014). The variability of the population reflects both seasonal trends (increases with young of the year in spring) and response to rainfall (Table 11-2). During low rain years, habitat limitations due to low flow conditions restrict movement through the creek, often isolating individual fish in specific reaches for extended periods of time. Adults are most often found in refugia pools, and juvenile fish are found more often in shallow habitat types, including riffles, runs and glides. A large decline in the number of fish observed occurred following a major storm event in March 2011, when the creek was connected to the ocean for several days, allowing juvenile smolts to out-migrate (Krug et al. 2014). Predation by trout in specific pools and short reaches of the creek can be intense and consistent over time (RCDSMM *unpublished data*).

Table 11-2 Average number of each size class based on Topanga Creek snorkel survey observations 2001–2013. (Krug et al. 2014)

Year of observation	Juvenile (<100 mm)	Intermediate (100–250 mm)	Adult (>250 mm)	Total
2001	25	25	3	53
2002	34	56	6	95
2003	6	34	19	59
2004	46	50	12	103
2005	6	46	20	71
2006	62	68	40	170
2007	35	36	16	86
2008	250	47	18	316
2009	112	81	14	209
2010	115	125	13	253
2011	9	85	20	114
2012	68	21	7	95
2013	28	26	2	56

Stomach contents taken from trout during mark recapture events in November and March of 2010-2013 using gastric lavage, showed that trout in Topanga Creek, similar to elsewhere, are opportunistic feeders (Figure 11-5). Aquatic insects are the preferred prey of trout as they are generally higher in caloric values compared to other potential prey items. When aquatic insects were readily available, trout in Topanga Creek consumed mainly aquatic insects, however, during summer months when aquatic insects were less available, they supplemented with terrestrial insects. Arroyo chub, crayfish and snails were also eaten occasionally. After 2012, as low flows persisted due to lack of rainfall, crayfish increased in abundance throughout the creek, and prey found in trout stomachs consisted more of crayfish and less of aquatic macroinvertebrates (Krug et al. 2012). This could have been due to a number of factors, including lower aquatic insect abundance and biomass, increased biomass of crayfish and increased ease of catching crayfish. A switch in prey consumption by a top-level predator can affect prey population dynamics. Here, it seemed like the lack of rainfall and low flow conditions were a major factor contributing to the increase in crayfish and decrease in benthic macroinvertebrates, suggesting that abiotic factors are an important driving force behind food web dynamics in Topanga Creek.

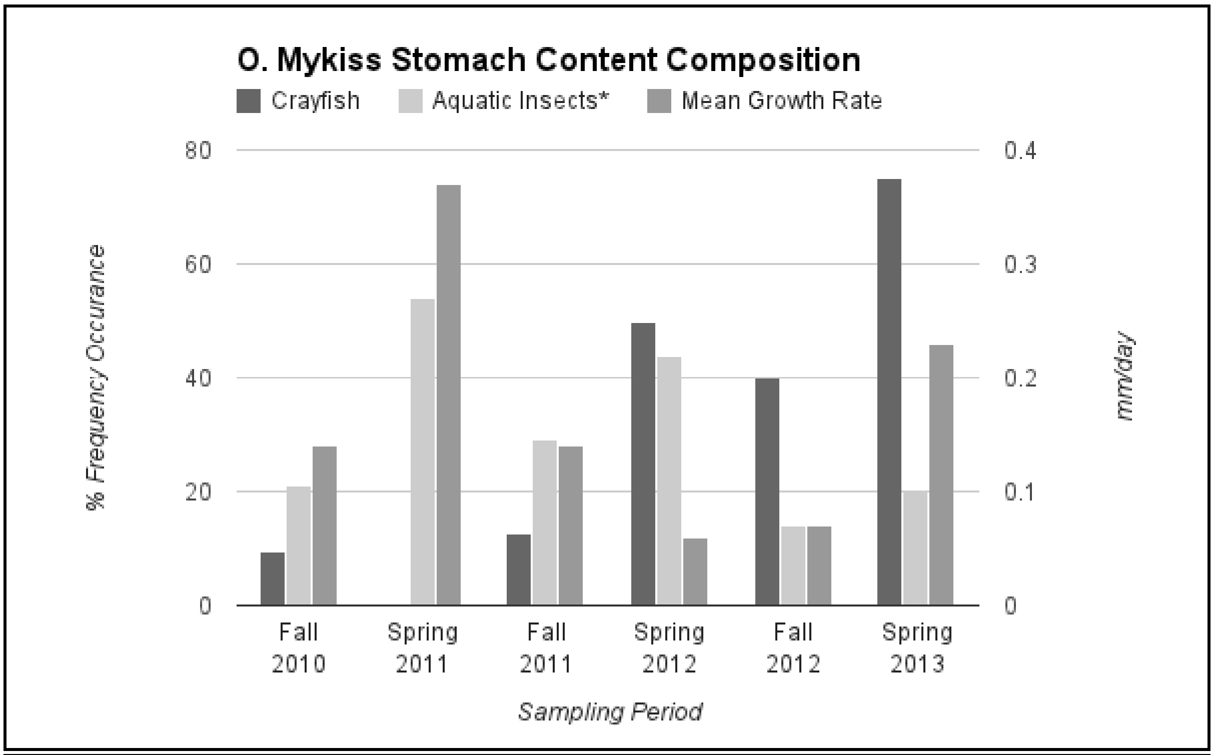

Figure 11-5 *O. mykiss* stomach content composition (Krug et al. 2014)

11.3 <u>PRELIMINARY Conceptual Model of the Topanga Creek Food Web</u>

One of the principle questions in ecology is how a variety of abiotic and biotic factors limit or regulate resources throughout a system. Are predators controlling the abundance of primary producers, which is known as top-down theory, or is the availability of resources (i.e. carbon, nitrogen, phosphorous, organic matter) needed to support primary producers limiting their abundance (bottom-up theory)? How do biological communities respond to changes in flow or other disturbances? The debate continues concerning the relative importance of each of these forces, as well as the recognition that most biological systems are extremely complex and that both forces are important and dynamic (Porter 1992).

The model of algal growth and biomass controlled by resource supply (bottom-up), disturbance, and grazing may not fit Mediterranean stream conditions because of the extended low flow summer periods and the effects of abiotic factors on algae productivity patterns (Busse et al. 2006). Flow patterns can also cause seasonal changes in BMI (Hurtubia 1973) resulting in fluctuating abundance and functional feeding group composition, that in turn impacts the density and abundance of benthic algae. One of the limitations of the top-down model is that it is often difficult to accurately identify the diversity of prey species taken by each predator species, the breadth of food niches, and the competitive impacts of multiple predators in a limited system (Hurtubia 1973, Diehl et al. 2000, Power 1992).

Finally, it is important to examine these relationships within the context of watershed landscape conditions, especially the potential implications of both direct and indirect influences of urbanization, such as the percent of impervious surface (Riley et al. 2004).

Below we attempt to examine the possible constructs of top-down forces, bottom-up forces and a more complex interaction using abiotic and biotic observations from Topanga Creek.

Top-Down Scenario:

In this scenario, the key driver of the Topanga Creek food web would be steelhead trout as the top predator, consuming crayfish, other fish, tadpoles and both terrestrial and aquatic insects. Crayfish, arroyo chub, tree frogs and newts make up the intermediate trophic levels, as they are both prey of steelhead and predators on BMI. The composition of the BMI community changed in 2013, shifting away from dominance by Baetidae, and becoming more dominated by chironimids, amphipods and snails. Since 2001, the numbers of both trout and crayfish have increased, suggesting that food was sufficiently available to support growth and reproduction. The different styles of predation (trout are visual predators more active during the day as compared to crayfish who are more nocturnal feeders) could mean that these predators are able to co-exist by creating predation pressure 24 hours a day. This continued predation pressure, combined with the low flow conditions of the past two years could be a factor associated with the observed decline in Southern California Coastal Index of Biotic Integrity (SCC-IBI) BMI scores.

Bottom-Up Scenario:

Availability of resources (carbon, nitrogen, phosphorous, organic matter) are potential factors that can limit growth of microbes and algae, as well as BMI. BMI are key to the recycling of detritus, resulting in conversion of leaf litter into dissolved nutrients that can be easily accessed by bacteria, algae and other microbes, accelerating and supporting their growth. Low levels of both course and fine organic matter, combined with a limited number of representatives of various functional feeding groups were observed. The overall low levels of nitrates, nitrites, ammonia and phosphorous observed throughout Topanga Creek could be due either to efficient uptake and absorption of these resources by the biological community, or simply that Topanga Creek is limited by low input levels of these resources. This condition can shift in response to nutrient loading such as occurs during storm events. The pattern of low nutrient levels in the water samples, low density of algae, as well as the low

SCC-IBI scores for BMI, suggests that the creek could either be resource limited, or that the low levels of primary producers are strongly influenced by heavy predation by amphibians, crayfish and fish.

Integrated Food Web Scenario:

Figure 11-6 illustrates the integration of both the top-down and bottom-up processes that may be occurring in Topanga Creek. In the integrated scenario, top-down and bottom-up forces are in a continuous feedback loop, with each trophic level responding to on-going changes throughout the system. The pattern of water column nutrient reduction observed between the inputs at Owl Falls (6500 m) and the levels observed at Scratchy Trail (4800 m) suggests that these inputs support increased productivity at Scratchy Trail, which is reflected in a more abundant benthic algae and BMI community, which in turn supports a higher density of predators (amphibians, crayfish and fish). Snorkel survey data shows increasing numbers of crayfish, chub and larger trout individuals also observed in that reach (RCDSMM *unpublished data*).

However, nutrient levels downstream of Scratchy Trail are relatively consistent, and both the benthic algae and the BMI community metric scores decline from Topanga Bridge (3600 m) downstream to the lagoon. This suggests that resource limitations, combined with the presence of predators could be controlling the community structure in these lower reaches of the creek. These observations occurred within the context of variable, but predominately low flow conditions experienced since 2002, especially downstream of Topanga Bridge. A shift in the dominant BMI taxa from Baetid/Simulidae to Chironomid/Amphipod suggests that the combination of flood events, as well as extended low flow periods has restructured the BMI community. Combined with the increasing numbers of steelhead trout and crayfish since 2001, it appears that the overall condition of Topanga Creek has changed.

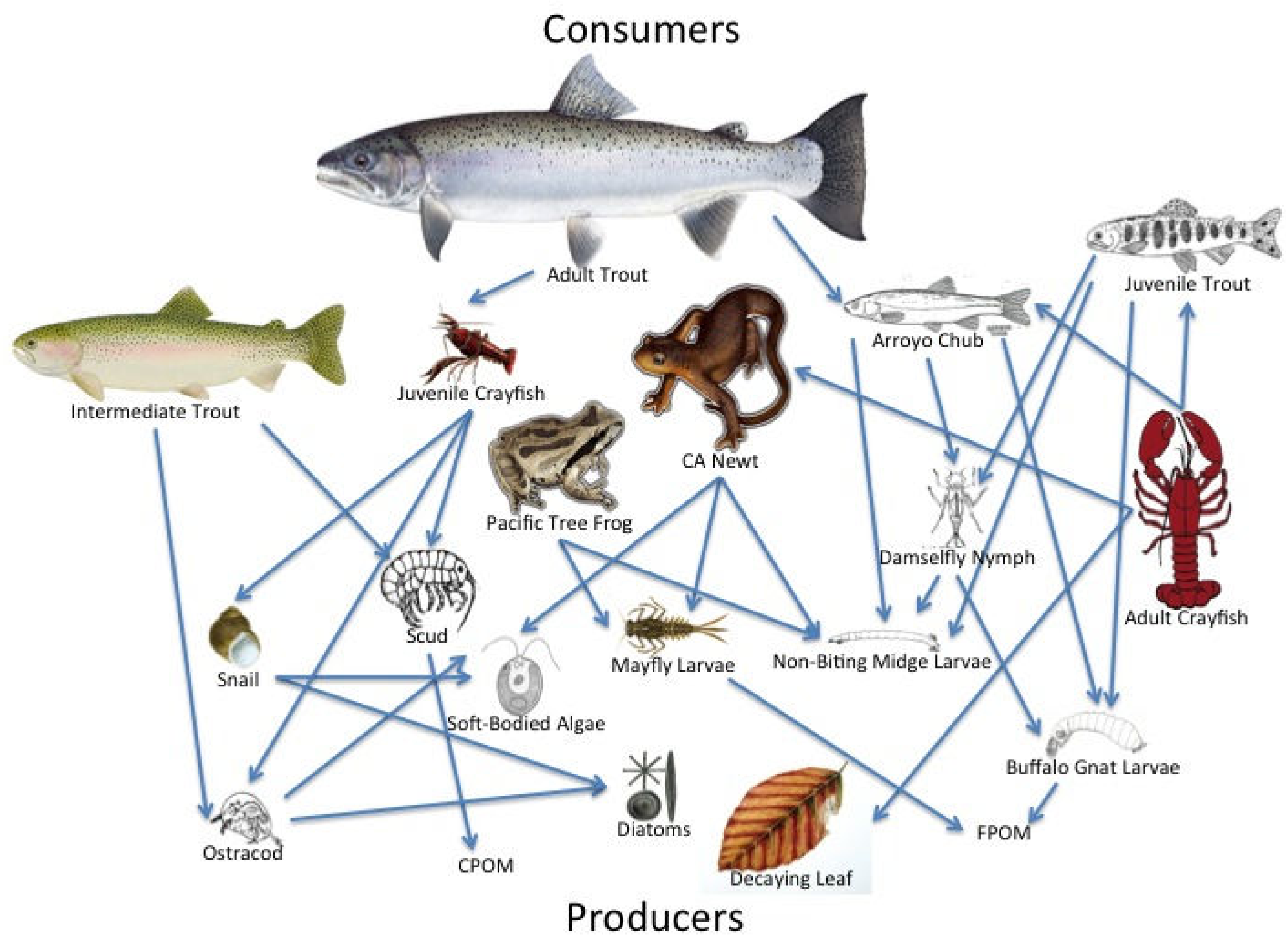

Figure 11-6 Conceptual model of the Topanga Creek Food Web.

11.4 Discussion

Food web interactions in aquatic systems can strongly influence biogeochemical cycling, fisheries production, and responses to anthropogenic influences (Brett and Goldman 1997). Due to the complexity of both abiotic (fires, floods, drought, climate change and anthropogentic inputs) and biotic (introduced invasive species) stresses over time it is important to have long-term perspectives on trophic level and food web dynamics, especially in Mediterranean ecosystems, where both seasonal and annual changes, especially drought, can shift community structure on many levels (Resh et al. 1988, Resh et al. 2013). In Topanga Creek, we are interested in determining how these processes are involved in uptake of nutrients and how they accomplish the absorption of anthropogenic inputs from the upper watershed. We are also concerned about the possibility that excessive loading could unhinge these processes and the consequences to aquatic diversity that might result from that failure. Abiotic changes can confound our ability to distinguish changes caused by natural variability from changes caused by anthropogenic stressors (Morais et al. 2004). Biotic pressures like predation and intensify as space and resources become limited as water levels drop (Robson et al 2011). These synergistic and dynamic factors make it extremely difficult to identify tolerance thresholds for anthropogenic inputs over which the creek will no longer be resilient.

Collected information on BMI, crayfish and trout abundance provide the most information on food web interactions at this time. Since 2001, the populations of both crayfish and trout have continued to increase, while the BMI community biotic integrity appears to have declined. There are several ways to interpret this information. The redundancy hypothesis posits that as long as the functional feeding group is represented, and that as long as trophic levels remain uniform (even with different species present at each level) both energy flow and ecosystem processes will continue to work in the same way (Power 1992). By contrast, the keystone species hypothesis suggests that certain species are critical to the function of the food web and cannot be replaced by others with similar, but not exactly the same role (Power 1992, Morais et al. 2004). This is of concern in Topanga, where management is focused on supporting the continued survival of steelhead trout, which are considered to be an umbrella species. The theory has been that if the creek is able to support a reproducing population of steelhead, then other aquatic species will benefit as well.

Other studies have found that the food web interactions of BMI are often species specific, and influence nutrient cycling and energy flow throughout the food web (Covich et al. 1999), thus even slight shifts from baetids to chironomids, could potentially have ripple effects on the dynamics of a system. Forrester et al. (1999) examined the relationship between fish biomass, baetid productivity and nutrient inputs finding that the distribution of baetids responded to predation pressure with patchy distribution and emigration, and that nutrient inputs that increased algal biomass also increased the number of herbivores, such as baetids. In Topanga Creek, we observed that the shift from baetids to chironomids, although both in the same FFG, was associated with decreased IBI scores, reflecting a less robust BMI community. BMI species can take many years to recover from local extirpation to pre-disturbance levels of multi-age population, suggesting that hydrologic conditions and changes can have population level consequences (Resh et al. 2013). Continued monitoring of the BMI community in Topanga Creek is one of the only ways to identify how the creek food web responds as drought conditions either change or continue.

Despite these fluctuations during the drought, steelhead continue to reproduce and survive throughout Topanga Creek. Their abundance has increased or at least remained steady during the past 14 years. This is in contrast to observations in Malibu Creek, where abundance levels are much more variable, despite the documented influence of anadromous adults in reproduction. Understanding the dynamics of these complex interactions will help inform recovery actions for this endangered species in southern California.

11.5 Summary

Current conditions in Topanga Creek suggest that at this time, the reach most inaccessible to humans at Scratchy Trail is the most functional and that other sample sites downstream of Topanga Bridge reflect more disturbances. It is unclear exactly where the tipping point occurs, but the low flow conditions, combined with the anthropogenic inputs, have resulted in reduced BMI diversity, a shift of BMI community, increases in exotic aquatic species (crayfish and fathead minnow), decreases in egg masses of frogs and newts, and lower numbers of both arroyo chub and steelhead trout.

Topanga Creek is in trouble, although it is still functional enough to support resident steelhead.

As we cannot control the rain or flow, the only positive actions we can take are to

- Reduce nutrient inputs (graywater and septic) into the creek,
- Protect the reach between Owl Falls and Topanga Bridge from increasing rock climbing, hiking and transient activity,
- Reduce impacts from transient encampments, marijuana farms, taggers in the more accessible reach between Topanga Bridge and the ocean.

12 Best Management Practices (BMP's)

12.1 Evaluation of BMP's

One of the main efforts of this study was to collect data to monitor current water quality conditions, compare the current levels to previous studies, and identify sources and recommend specific Best Management Practices to reduce, and eliminate if possible, identified contributions to bacteria and nutrient exceedances.

In the 2013-2014 summer dry season a total of 19 exceedances were recorded at Topanga Beach. Since April 2014, there have only been a total of four exceedances, which are potentially tied to the drought conditions.

The Los Angeles Region Sub-watershed Specific Implementation Plan (NSMR 11/4 Bacterial TMDP Implementation Plan 2005) identified target exceedance day reductions for creeks within the Santa Monica Bay watershed as a way of examining watershed specific compliance milestones. Topanga Creek is allowed 17 exceedance days, with a total required day reduction of nine exceedance days. To achieve the target reduction, the Plan recommends a series of Best Management Practices, benefits and performance evaluation measures and methods (Table 12-1).

In addition to the recommendations in the Basin Plan, our results suggest that there are a few specific actions that can be taken to reduce possible sources of FIB at Topanga Beach.

12.2 Recommended BMP's for Topanga Beach

1) Restore Topanga Lagoon and Lower Topanga Creek State Park. This is a longer-term project, but by restoring natural function to Topanga Lagoon, it would be possible to not only reduce the bacterial sources but also improve habitat for a variety of endangered species, especially tidewater gobies and southern steelhead trout.
2) Continued enforcement of the County code and additional signage may reduce impact and presence of dog feces. The marker data documents a rise in dog associated markers in the winter months when lifeguard supervision and peer-pressure from beach visitors are reduced. During the study, dogs and dog feces, were routinely observed on the beach. The winning student posters have been affixed to the lifeguard station to assist with public outreach.

3) Continue coordinated enforcement to reduce the number of homeless and transients camping in and around the beach and under the PCH underpass. A mass balance calculation of input of one direct deposit to the lagoon (~200g of human feces) was calculated to result in an exceedance of ENT (Riedel et al. 2014 submitted). Direct deposits were observed at both the lagoon and beach on multiple occasions during the study. Direct deposits associated with the transient population is again an enforcement issue but one that could potentially reduce exceedances.

4) Continued maintenance and monitoring of the Lifeguard Station shower and restrooms. Some drainage from the showers directly to the beach was observed on several occasions. When tides are high or storm events shift the lagoon mouth downcoast in front of the building, there is potential for this to become a source.

5) Investigate possible installation and maintenance of culvert filters along Pacific Coast Highway at Topanga Beach to prevent direct road surface run-off spills into Topanga Lagoon.

6) Upgrade the septic systems at the Topanga State Park along PCH as conditions change and opportunities arise. As the lagoon park plan evolves, incorporating state of the art septic systems into any visitor serving facilities is recommended.

7) Increase outreach to commercial facilities that are on septic systems along the beach. The Feed Bin has the last remaining septic system that is connected to a seepage pit. Upgrading that system should be a priority.

8) Additional patrolling of the state park for transient and RV dumping activity could help with any exceedances in the creek, similarly, further enforcement of the no-dogs-allowed-on-beach rule would probably help with the FIB issues at the beach/lagoon.

9) Increase public outreach concerning the problem with dog feces pollution. While changing behaviors is difficult, peer pressure to pick up after your dog, as well as to reduce the number of dogs visiting the beaches could help.

10) Participate in future monitoring and develop funding to initiate a quantitative microbial source identification study to evaluate the potential for developing appropriate site specific objectives.

Table 12-1 Summary of BMP's Benefits and Performance Evaluation Measures for Topanga Lagoon and Creek
(Excerpted from: NSMR 11/4 Bacterial TMDP Implementation Plan 2005)

BMP's and Activities	Water Quality Benefits	Integrated Water Resources Benefits	Performance Evaluation Measure and Method
TMDL Monitoring and studies:	Monitor bacteria, nutrients, metals and organics	N/A	Monitoring results (Note: metals and organics are not being monitored by this study)
Hydrologic Loading Estimates	N/A	Hydrology/ Geomorphology	Study results
Id most relevant Human Health Indicators Study	Bacteria and pathogens	N/A	Study results from this and SIPP
Hydrology vs. Bacteria loading	Bacteria	N/A	Study results from this and SIPP
Bacterial Seasonal Variation Study	Bacteria	N/A	Study results from this and SIPP
Non-Structural Measures:			
Outreach to pet owners (especially dogs on the beach) concerning link between animal wastes and health issues	Bacteria, nutrients and pathogens	N/A	Study results from this and SIPP
Locate areas with corralled animals and educate property owners on bacteria TMDL's	Bacteria and pathogens	N/A	Study results from this and SIPP, Community meetings
Identify horse stables and implement pilot program for manure management	Bacteria and pathogens	N/A	Study results from this and SIPP
Outreach at trailheads encouraging hikers to use restroom facilities	Bacteria and pathogens	N/A	Study results from this and SIPP
Commercial Facilities Control Programs:			
Provide outreach to all commercial facilities with corralled animals	Bacteria and pathogens	N/A	Study results from this and SIPP
Development Planning and Construction Programs:			
Further emphasize applicable existing BMP's in development planning and construction programs	Bacteria, nutrients, metals, organics, pathogens, trash	Water conservation, reuse/recycling, habitat, geomorphology, hydrology, flood volumes	Community meetings to highlight County recommendations
Structural Measures:			
Encourage residential cisterns	Bacteria, nutrients, metals, pathogens,	Water conservation, reuse/recycling,	Community meetings to highlight County

BMP's and Activities	Water Quality Benefits	Integrated Water Resources Benefits	Performance Evaluation Measure and Method
		habitat, geomorphology, hydrology, flood volumes	recommendations
On-site storage and reuse projects	Bacteria, nutrients, metals, organics, pathogens, trash	Water conservation, reuse/recycling, habitat, geomorphology, hydrology, flood volumes	Community meetings to highlight County recommendations
Small scale Infiltration projects	Bacteria, nutrients, metals, organics, pathogens, trash	Water conservation, reuse/recycling, habitat, geomorphology, hydrology, flood volumes	Community meetings to highlight County recommendations

12.3 Recommended Voluntary BMP's for the Topanga Creek Watershed

Although it does not appear that inputs into the upper watershed are associated with the exceedances at Topanga Beach there are indications that they negatively impact the creek's ecosystem. A number of BMP's could be implemented throughout the watershed in order to reduce inputs to the creek and possibly improve overall conditions in Topanga Creek.

1) Establish a community outreach program to inform residents of potential septic system impacts to the creek and encourage them to upgrade their existing septic systems by installation of effluent-filters in septic tank outlets to reduce particulates into leach fields or seepage pits, thus reducing bacterial and nutrient contamination potential. The community outreach program should include identifying funding sources to assist property owners in upgrading their septic systems.
2) Establish a community outreach program to inform residents of potential impacts to the creek from sub-surface and surface graywater discharges.
3) Through community outreach, encourage the installation of additional trash receptacles behind Topanga Market and Abuelita's.

4) Through community outreach, encourage the availability of public restrooms in Topanga Center.
5) Continue coordinated efforts to remove transient encampments and illegal marijuana farms located adjacent to the creek.
6) Implement the Santa Monica Mountains Local Coastal Program policy for existing equestrian facilities to encourage such facilities to come into compliance with all of the LCP policies and regulations as soon as possible.

Riedel, T. E., V. Thulsiraj, A. G. Zimmer-Faust, R., J. Krug, K. T. Hanley, K. Adamek, D. L. Ebentier, R. Torres, U. Cobian, S. Peterson and J. A. Jay. (Submitted 2014). Long-term molecular marker monitoring in the Topanga Creek Watershed, CA, USA, suggests that coastal fecal indicator bacteria are from multiple animal hosts, each with different seasonal pattern. Submitted to Marine Pollution Bulletin August 2014.

13 Recommendations

13.1 Recommendations for Further Study

The intention of this study was to enable the County to understand the sources of bacterial contamination at Topanga Beach, and identify possible ways to eliminate, reduce or mitigate those sources. As with most studies, answering one set of questions leads to more questions. Based on our final results, we would like to suggest several additional studies that would provide more in-depth understanding of this complicated problem, as well as actions that could help the County achieve the Basin Plan targets in the future.

13.1.1 FIB and host associated markers

- Cov- IMS/ATP methods can be used to adaptively track sources in the watershed, furthering our understanding of concentration and dispersal.
- Inv-IMS/ATP Bacteroides method can also be used to adaptively track potential sources of human associated fecal pollution.
- Examine the buoy data to look at the patterns of nearshore flow along Topanga Beach
- What more, if anything, do we need to know in order to identify sources of bacterial contamination?
- Examine ENT speciation when ENT levels are in exceedance at beach and lagoon sites-compare ENT speciation results to marker values for further understanding of sources.
- Further examine relationship between sand/sediment and water FIB and marker levels to better understand if resuspension of FIB/markers is contributing to water column FIB and marker levels. Further examine sediment/sand as potential reservoir for FIB and markers.
- What impacts might Sea Level Rise have on the movement and dilution of FIB between the lagoon and the ocean?
- In collaboration with Dr. Doug Hammond at USC, examine the isotope signatures of water leaching through the sand berm from the lagoon to the ocean to get a better idea of the time lag and potential for filtration.
- Expand field sampling to examine the patterns of gull and dog markers as they travel from the lagoon to the ocean. Examining persistence of these markers in situ in water and sand would allow for a better understanding of these patterns.

- Why does enterococci survive the transition from the lagoon to the ocean in higher concentrations?
- Identify types of bacterial colonies marketed to homeowners to improve their septic function and examine their potential contributions or impacts on FIB found in the creek and lagoon.
- Participate in future monitoring and develop funding to initiate a quantitative microbial source identification study to evaluate the potential for developing appropriate site specific objectives.

13.1.2 Ecological interactions

- Develop an ecosystem process model using stable isotopes to examine ecological controls such as nutrient cycling and predation on FIB, benthic macroinvertebrates, diatoms and soft-bodied algae dynamics.
- Compare diatom and soft-bodied algae species abundance, growth patterns and ecological tolerances between Malibu and Topanga, and within a southern California region context (work with Las Virgenes Municipal Water District, Aquatic Bioassay and Consulting Inc., and SCCWRP). Data for 2014 should be available in winter 2015.
- Continue annual stream surveys to track response to drought by BMI, amphibians and fish populations in relation to algae cover and water quality in Topanga Creek.
- Track the presence and abundance of beach wrack (kelp) and sea birds on the berm between Topanga Lagoon and the ocean.
- Continue monitoring and active removal efforts for invasive plants and animals, especially crayfish.

13.1.3 Best Management Practices and Community Outreach

- Develop a survey for the community regarding how pet wastes are handled to encourage active management. Conduct active outreach effort to provide information on the effects of dog waste on water quality. The 2014-2015 Watershed Stewards will work on this effort.
- Establish volunteer bird monitoring at Topanga Lagoon and Beach to obtain more information on numbers of birds and use/roosting patterns.
- Find funding to repair the Feed Bin OWTS in Topanga State Park.
- Investigate the correlation between marijuana farms and water quality in Topanga Creek.

EXECUTIVE SUMMARY

ES.1 Introduction

The Los Angeles County Flood Control District (LACFCD) has prepared this Draft Program Environmental Impact Report (Draft PEIR) to provide the public and responsible and trustee agencies with information about the potential effects, both beneficial and adverse, on the local and regional environment associated with implementation of the Enhanced Watershed Management Programs (proposed program). This Draft PEIR has been prepared pursuant to the California Environmental Quality Act (CEQA) of 1970 (amended), codified at California Public Resources Code Sections 21000 et. seq., and the CEQA Guidelines in the Code of Regulations, Title 14, Division 6, Chapter 3.

This document is being circulated to local, state and federal agencies, and to interested organizations and individuals who may wish to review and comment on the Draft PEIR. Publication of this Draft PEIR marks the beginning of a 45-day public review period, during which written comments may be directed to the address below. Comments on the project should be directed to:

Gregg BeGell, P.E.
County of Los Angeles Department of Public Works
Project Management Division II
900 South Fremont Avenue, 5th Floor
Alhambra, CA 91803
gbegell@dpw.lacounty.gov

ES.2 Background

The Los Angeles County Flood Control District (LACFCD) was created in 1915 when the State Legislature adopted the Los Angeles County Flood Control Act to provide flood risk management, water conservation, and recreation and aesthetic enhancement within its boundaries. The LACFCD owns and maintains a broad network of flood control facilities that convey stormwater to the local rivers and ultimately to the ocean. The LACFCD is governed as a separate entity by the County of Los Angeles Board of Supervisors, and is operated by the County's Department of Public Works. The LACFCD, the County of Los Angeles, and 84 incorporated cities within Los Angeles County (collectively referred to as Permittees) are covered under a Municipal Separate Storm Sewer System (MS4) Permit (Order No. R4-2012-0175; National Pollutant Discharge Elimination System [NPDES] Permit No. CAS004001) for the discharge of urban runoff to waters of the United States. The purpose of the MS4 Permit is to achieve and maintain water quality objectives to protect beneficial uses of the receiving waters in the Los Angeles region. Each of the Permittees identified in the MS4 permit is responsible for meeting the conditions of the permit for MS4 discharges occurring within their jurisdiction.

The 2012 MS4 Permit for Los Angeles County gives Permittees the option of implementing an innovative approach to Permit compliance through development of an Enhanced Watershed Management Program (EWMP). The EWMPs will identify potential and priority structural and non-structural Best Management Practices (BMPs) within the region's stormwater collection system to improve runoff water quality. The LACFCD, along with participating Permittees, has opted to exercise this option and has submitted to the LARWQCB 12 separate Notices of Intent (NOIs) for the development of EWMPs within 12 distinct watershed groups (refer to **Figure 1-1**). Implementation of the EMWPs would be the responsibility of each Permittee and would occur following approval of the EWMPs by the LARWQCB.

The LACFCD, as a regional agency, is a member of each of the 12 EWMP working groups, and as such provides a commonality within each EWMP group. However, LACFCD does not have a special status or authority designated by the MS4 Permit over any of the other Permittees. The LACFCD will be working with the applicable Permittees in all 12 EWMP watersheds as an equal partner to identify the types and locations of BMPs needed to achieve permit compliance within each watershed.

The timeline identified in the MS4 Permit requires that Permittees submit the EWMP to the LARWQCB by June 28, 2015, in order to be in compliance with the permit conditions. The LACFCD recognizes that implementation of the EWMPs may potentially result in changes to environmental conditions. As a result, the LACFCD has prepared this Program Environmental Impact Report (PEIR) in compliance with the California Environmental Quality Act (CEQA) to provide the public and the responsible and trustee agencies with information about the potential effects on the local and regional environment associated with implementation of the EWMPs. The LACFCD will submit the PEIR to its governing body, the Los Angeles County Board of Supervisors, for approval prior to submittal of the EWMPs. The EWMPs will be submitted by each EWMP to the LARWQCB.

This PEIR describes and evaluates each of the EWMPs being prepared by the Permittees collectively. The discretionary action prompting the need for CEQA compliance is the submittal of the completed EWMPs to the LARWQCB. The EWMPs will identify management strategies including hundreds of structural Best Management Practices (BMPs) that may be designed and implemented by the Permittees to meet permit compliance objectives. A few of the BMPs are currently well defined but most are yet to be fully developed under the EWMPs. A set of priority BMPs will be detailed in each of the EWMPs; these are being developed in parallel with the PEIR. The PEIR describes the details that are available for each of the EWMPs currently under preparation by the EWMP working groups.

The PEIR analysis is not intended to focus on the site-specific construction and operation details of each management strategy and project included in the EWMP. Rather, this PEIR serves as a first-tier environmental document that focuses on the effects of implementing the EWMPs to reduce urban runoff pollution. The analysis assesses worst case situations where construction or operation of projects may significantly impact environmental resources. The analysis outlines mitigation strategies to be followed by implementing agencies to avoid or minimize impacts wherever feasible.

LACFCD is the CEQA Lead Agency for this PEIR. This PEIR can be used by the LACFCD or other Permittees to streamline environmental review of individual EWMP projects. As individual projects identified in the EWMPs are fully developed, the implementing agency (i.e., the Permittee responsible for implementing the project) will conduct CEQA analysis for individual projects as appropriate or may determine that no additional CEQA analysis is required or that a project is exempt from CEQA.

ES.3 Project Objectives

The primary goals and objectives of the EWMPs are:

- To collaborate among agencies (Permittee jurisdictions) across the watershed to promote more cost-effective and multi-beneficial water quality improvement projects to comply with the MS4 Permit.
- To develop watershed-wide EWMPs that will, once implemented, remove or reduce pollutants from dry- and wet-weather urban runoff in a cost-effective manner.
- To reduce the impact of stormwater and non-stormwater on receiving water quality.

ES.4 Project Description

The 12 EWMPs will vary for each watershed group, but will generally provide the opportunity for Permittees to customize their stormwater programs to achieve compliance with applicable receiving water limitations (RWLs) and water-quality-based effluent limits (WQBELs) in accordance with the MS4 Permit through implementation of stormwater best management practices (BMPs) or watershed control measures. BMPs vary in function and type, with each BMP providing unique design characteristics and benefits from implementation. The overarching goal of BMPs in the EWMP is to reduce the impact of stormwater and non-stormwater on receiving water quality and address the water quality priorities as defined by the MS4 Permit. The development of each EWMP will involve the evaluation and selection of multiple BMP types, including nonstructural (institutional) and distributed, centralized, and regional structural watershed control measures, that will be implemented to meet compliance goals and strategies under the 2012 MS4 Permit. The LACFCD has limited jurisdictional authority for ordinance and code enactment or enforcement and therefore is limited in nonstructural BMPs to education and outreach measures. The structural watershed control measures that will be implemented by the LACFCD will be multi-benefit stormwater projects that emphasize flood risk mitigation and water conservation and supply.

The LACFCD has a vested interest in increasing opportunities for stormwater capture and groundwater recharge as a means of assisting local water supply augmentation. The LACFCD will be working with the applicable Permittees and other stakeholders in all 12 EWMP watersheds to develop such projects. The EWMPs will be implemented by the Permittees that have jurisdiction within each EWMP area. The implementing agencies will be responsible for the contents of the EWMPs affecting their jurisdictions and for implementing the projects developed by the EWMPs..

Structural control measures are constructed BMPs that reduce the impact of stormwater and non-stormwater on receiving water quality. They are broken into three categories:

- ***Distributed Structural BMPs***, which treat runoff close to the source and are typically implemented at a single- or few-parcel level (e.g., facilities typically serving a contributing area less than one acre).
- ***Centralized Structural BMPs***, which treat runoff from a contributing area of multiple parcels (e.g., facilities typically serving a contributing area on the order of tens or hundreds of acres or larger).
- ***Regional Structural BMPs***, which are meant to retain the 85th percentile storm over 24 hours from a contributing area. Generally, the 85th percentile storm is approximately 0.75 inches over 24 hours

Whether distributed, centralized, or regional, the major structural BMP functions are infiltration, treatment, and storage, which may be used individually or combination:

- ***Infiltration***, where runoff is directed to percolate into the underlying soils. Infiltration generally reduces the volume of runoff and increases groundwater recharge.
- ***Treatment***, where pollutants are removed through various unit processes, including filtration, settling, sedimentation, sorption, straining, and biological or chemical transformations.
- ***Storage***, where runoff is captured, stored (detained), and slowly released into downstream waters. Storage can reduce the peak flow rate from a site, but does not directly reduce runoff volume.

The types of structural BMPs to be implemented will vary between EWMPs, but most EMWPs will include a variety of distributed, centralized, and regional BMPs.

These are policies, actions, and activities which are intended to minimize or eliminate pollutant sources. Most institutional BMPs are implemented to meet Minimum Control Measure (MCM) requirements in the MS4 permit; MCMs are considered a subset of institutional BMPs. These BMPs are not constructed, but may have costs associated with the procurement and installation of items such as signage or spill response kits

ES.5 Project Alternatives

An EIR must describe a range of reasonable alternatives to the proposed project or alternative project locations that could feasibly attain most of the basic project objectives and would avoid or substantially lessen any of the significant environmental impacts to the proposed project. The alternatives analysis must include the "No Project Alternative" as a point of comparison. The No Project Alternative includes existing conditions and reasonably foreseeable future conditions that would exist if the proposed project were not approved (CEQA Guidelines §15126.6).

ES.6 Summary of Impacts

Table ES-1, at the end of this chapter, presents a summary of the impacts and mitigation measures identified for the proposed project. The complete impact statements and mitigation measures are presented in Chapter 3. The level of significance for each impact was determined using significance criteria (thresholds) developed for each category of impacts; these criteria are presented in the appropriate sections of Chapter 3. Significant impacts are those adverse environmental impacts that meet or exceed the significance thresholds; less-than-significant impacts would not exceed the thresholds. Table ES-1 indicates the measures that will avoid, minimize, or otherwise reduce significant impacts to a less-than-significant level if implemented by the Permittees.

ES.7 Areas of Controversy

Several comment letters from agency and public comments were received during the scoping period. Public comments received are provided in Appendix A of this PEIR. Some of the comments from non-governmental organizations and the public expressed concerns regarding the lack of project-specific details provided in the NOP for individual BMPs. Several comments were received questioning the funding strategies to be employed by Permittees. The full list of comments highlighting areas of potential controversy received during the public scoping period is included in Appendix A.

ES.8 Issues to be Resolved

Section 15123(b)(3) of the *CEQA Guidelines* requires that an EIR contain issues to be resolved, which includes the choice among alternatives and whether or how to mitigate significant impacts. The following major issues are to be resolved:

- Determine whether the PEIR adequately describes the environmental impacts of the proposed program;
- Choose among alternatives;
- Determine whether the recommended mitigation measures should be adopted or modified; and
- Determine whether additional mitigation measures need to be applied to the project.

ES.9 Organization of this PEIR

This Draft PEIR is organized into the following chapters and appendices:

Executive Summary. This chapter summarizes the contents of the Draft PEIR.

Chapter 1, Introduction and Project Background. This chapter discusses the CEQA process and the purpose of the PEIR and provides background info on the proposed project.

Chapter 2, Project Description. This chapter provides an overview of the proposed program, describes the need for and objectives of the proposed program, and provides detail on the characteristics of the proposed program.

Chapter 3, Environmental Setting, Impacts and Mitigation Measures. This chapter describes the environmental setting and identifies impacts of the proposed program for each of the following environmental resource areas; Aesthetics; Air Quality; Biological Resources; Cultural Resources; Geology and Soils / Mineral Resources; Greenhouse Gas Emissions; Hazards and Hazardous Waste; Hydrology and Water Quality; Land Use and Planning / Agriculture; Noise; Population and Housing; Public Services / Recreation; Transportation and Circulation; and Utilities and Service Systems. Measures to mitigate the impacts of the proposed program are presented for each resource area.

Chapter 4, Cumulative Impacts. This chapter analyzes the potential for the proposed program to have significant cumulative effects when combined with other past, present, and reasonably foreseeable future projects in each resource area's cumulative geographic scope.

Chapter 5, Growth Impacts. This chapter identifies areas of the EIR where significant environmental effects that cannot be avoided would occur, if any. It will also include an analysis of growth inducement impacts that would be provided by the program.

Chapter 6, Alternatives. This chapter presents an overview of the alternatives development process and describes the alternatives to the proposed program that were considered.

Chapter 7, Organizations and Persons Contacted.

Chapter 8, Report Preparers. This chapter identifies authors involved in preparing this Draft DEIR, including persons and organizations consulted.

Chapter 9, References.

TABLE ES-1
SUMMARY OF IMPACTS AND MITIGATION MEASURES FOR THE ENHANCED WATERSHED MANAGEMENT PROGRAMS

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
Aesthetics			
3.1-1: The proposed program could create a substantial adverse effect on a scenic vista.	**AES-1:** Aboveground structures shall be designed to be consistent with local zoning codes and applicable design guidelines and to minimize features that contrast with neighboring development.	Significant	Less than significant
3.1-2: The proposed program could substantially damage scenic resources, including but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway.	Implementation of **AES-1**	Significant	Less than significant
3.1-3: The proposed program could substantially degrade the existing visual character or quality of the site and its surroundings.	Implementation of **AES-1** **AES-2:** Implementing agencies shall develop BMP maintenance plans that are approved concurrently with each structural BMP approval. The maintenance plans must include measures to ensure functionality of the structural BMPs for the life of the BMP. These plans may include general maintenance guidelines that apply to a number of smaller distributed BMPs.	Significant	Less than significant
3.1-4: The proposed program could create a new source of substantial light or glare which would adversely affect day or nighttime views in the area.	None required	Less than significant	Not applicable
Air Quality			
3.2-1: The project could conflict with or obstruct implementation of the applicable air quality plan.	None required	Less than significant	Not applicable
3.2-2: The project could violate any air quality standard or contribute substantially to an existing or projected air quality violation.	**AIR-1:** Implementing agencies shall require for large Regional or Centralized BMPs the use of low-emission equipment meeting Tier II emissions standards at a minimum and Tier III and IV emissions standards where available as CARB-required emissions technologies become readily available to contractors in the region **AIR-2:** For large construction efforts that may result in significant air emissions, implementing agencies shall encourage contractors to use lower-emission equipment through the bidding process where appropriate.	Significant	Significant and unavoidable for construction; Less than significant for operations.

RB-AR 8213

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
3.2-3: The program could result in a cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable federal or state ambient air quality standard (including releasing emissions which exceed quantitative thresholds for ozone precursors).	Implementation of **AIR-1** and **AIR-2**	Significant	Significant and unavoidable for construction; less than significant for operations.
3.2-4: The project could expose sensitive receptors to substantial pollutant concentrations.	**AIR-3:** For large construction efforts associated with Regional or Centralized BMPs, implementing agencies shall conduct a project-specific LST analysis where necessary to determine local health impacts to neighboring land uses. Where it is determined that construction emissions would exceed the applicable LSTs or the most stringent applicable federal or state ambient air quality standards, the structural BMP project shall reduce its daily construction intensity (e.g., reducing the amount of equipment used daily, reducing the amount of soil graded/excavated daily) to a level where the structural BMP project's construction emissions would no longer exceed SCAQMD's LSTs or result in pollutant emissions that would cause or contribute to an exceedance of the most stringent applicable federal or state ambient air quality standards.	Significant	Less than significant
3.2-5: The proposed program could create objectionable odors affecting a substantial number of people.	**AIR-4:** During planning of structural BMPs, implementing agencies shall assess the potential for nuisance odors to affect a substantial number of people. BMPs that minimize odors shall be considered the priority when in close proximity to sensitive receptors.	Significant	Less than significant
Biological Resources			
3.3-1: The proposed project could have a substantial adverse effect, either directly or through habitat modifications, on any sensitive species identified as special-status in local or regional plans, policies, or regulations or by the California Department of Fish and Wildlife or U.S. Fish and Wildlife Service.	**BIO-1:** Prior to approving a Regional or Centralized BMP., the Permittee shall conduct an evaluation of the suitability of the BMP location. Appropriate BMP sites should avoid impacting large areas of native habitats including upland woodlands and riparian forests that support sensitive species to the extent feasible. The evaluation shall include an assessment of potential downstream impacts resulting from flow diversions. **BIO-2:** Prior to ground disturbing activities in areas that could support sensitive biological resources, a habitat assessment shall be conducted by a qualified biologist to determine the potential for special-status wildlife species to occur within	Significant	Less than significant

RB-AR 8214

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
	affected areas, including areas directly or indirectly impacted by construction or operation of the BMPs.		
	BIO-3: If a special-status wildlife species is determined to be present or potentially present within the limits of construction activities, a qualified biologist shall conduct pre-construction surveys of proposed work zones and within an appropriately sized buffer around each area as determined by a qualified biologist within 14 days prior to ground disturbing activities. Any potential habitat capable of supporting a special-status wildlife species shall be flagged for avoidance if feasible.		
	BIO-4: If avoidance of special-status species or sensitive habitats that could support special-status species (including, but not limited to, critical habitat, riparian habitat, and jurisdictional wetlands/waters) is not feasible, the Permittee shall consult with the appropriate regulating agency (USACE/USFWS or CDFW) to determine a strategy for compliance with the Endangered Species Act, California Fish and Game Code, and other regulations protecting special-status species and sensitive habitats. The Permittee shall identify appropriate impact minimization measures and compensation for permanent impacts to sensitive habitats and species in consultation with regulatory agencies. Construction of the project will not begin until the appropriate permits from the regulatory agencies are approved.		
	BIO-5: If construction and vegetation removal is proposed between February 1 and August 31, a qualified biologist shall conduct a pre-construction survey for breeding and nesting birds and raptors within 500-feet of the construction limits to determine and map the location and extent of breeding birds that could be affected by the project. Active nest sites located during the pre-construction surveys shall be avoided until the adults and young are no longer reliant on the nest site for survival as determined by a qualified biologist.		
	BIO-6: All construction areas, staging areas, and right-of-ways shall be staked, flagged, fenced, or otherwise clearly delineated to restrict the limits of construction to the minimum necessary near areas that may support special-status wildlife species as determined by a qualified biologist.		
	BIO-7: Prior to construction in areas that could support special status plants, a qualified botanist shall conduct a pre-		

RB-AR 8215

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
	construction floristic inventory and focused rare plant survey of project areas to determine and map the location and extent of special-status plant species populations within disturbance areas. This survey shall occur during the typical blooming periods of special-status plants with the potential to occur. The plant survey shall follow the CDFW Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Natural Communities (November 24, 2009). **BIO-8:** If temporary construction-related impacts to special-status plant populations are identified within a disturbance area, the implementing agencies shall prepare and implement a special-status species salvage and replanting plan. The salvage and replanting plan shall include measures to salvage, replant, and monitor the disturbance area until native vegetation is re-established under the direction of CDFW and USFWS.		
3.3-2: The proposed project could have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations, or by the CDFW or USFWS.	Implement **BIO-1** through **BIO-8**	Significant	Less than significant
3.3-3: The proposed project could have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means.	Implement **BIO-1** through **BIO-8** **BIO-9:** Prior to construction, a qualified wetland delineator shall be retained to conduct a formal wetland delineation in areas where potential jurisdictional resources (i.e., wetlands or drainages) subject to the jurisdiction of USACE, RWQCB, and CDFW, may be affected by the project. If jurisdictional resources are identified in the EWMP area and would be directly or indirectly impacted by individual projects, the qualified wetland delineator shall prepare a jurisdictional delineation report suitable for submittal to USACE, RWQCB, and CDFW for purposes of obtaining the appropriate permits. Habitat mitigation and compensation requirements shall be implemented prior to construction in accordance with Mitigation Measure BIO-4.	Significant	Less than significant
3.3-4: The proposed project could interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the	None required	Less than significant	Not applicable

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
use of native wildlife nursery sites.			
3.3-5: The proposed project could conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance.	**BIO-10:** Oak trees and other protected trees shall be avoided to the extent feasible. If trees may be impacted by project construction, a certified arborist shall conduct a tree inventory of the construction impact area. If any oak trees or other protected trees will be impacted by BMP construction, the implementing agency shall obtain any required County or City permits.	Significant	Less than significant
3.3-6: The proposed project could conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan.	None required	Less than significant	Not applicable
Cultural Resources			
3.4-1: The proposed program could cause a substantial adverse change in the significance of an historical resource as defined in §15064.5.	**CUL-1:** For individual EWMP projects that could impact buildings or structures (including infrastructure) 45 years old or older, implementing agencies shall ensure that a historic built environment survey is conducted or supervised by a qualified historian or architectural historian meeting the Secretary of the Interior's Professional Qualification Standards for Architectural History. Historic built environment resources shall be evaluated for their eligibility for listing in the CRHR or local register prior to the implementing agency's approval of project plans. If eligible resources that would be considered historical resources under CEQA are identified, demolition or substantial alteration of such resources shall be avoided. If avoidance is determined to be infeasible, the implementing agency shall require the preparation of a treatment plan to include, but not be limited to, photo-documentation and public interpretation of the resource. The plan will be submitted to the implementing agency for review and approval prior to implementation. **CUL-2:** Implementing agencies shall ensure that individual EWMP projects that require ground disturbance shall be subject to a Phase I cultural resources inventory on a project-specific basis prior to the implementing agency's approval of project plans. The study shall be conducted or supervised by a qualified archaeologist, defined as an archaeologist meeting the Secretary of the Interior's Professional Qualifications Standards for Archaeology, and shall be conducted in	Significant	Significant and Unavoidable

RB-AR 8217

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
	consultation with the local Native American representatives expressing interest. The cultural resources inventory shall include a cultural resources records search to be conducted at the South Central Coastal Information Center; scoping with the NAHC and with interested Native Americans identified by the NAHC; a pedestrian archaeological survey where deemed appropriate by the qualified archaeologist; and formal recordation of all identified archaeological resources on California Department of Parks and Recreation 523 forms and significance evaluation of such resources presented in a technical report following the guidelines in *Archaeological Resource Management Reports (ARMR): Recommended Contents and Format*, Department of Parks and Recreation, Office of Historic Preservation, State of California, 1990. If potentially significant archaeological resources are encountered during the survey, the implementing agency shall require that the resources are evaluated by the qualified archaeologist for their eligibility for listing in the CRHR and for significance as a historical resource or unique archaeological resource per *CEQA Guidelines* Section 15064.5. Recommendations shall be made for treatment of these resources if found to be significant, in consultation with the implementing agency and the appropriate Native American groups for prehistoric resources. Per *CEQA Guidelines* Section 15126.4(b)(3), preservation in place shall be the preferred manner of mitigation to avoid impacts to archaeological resources qualifying as historical resources. Methods of avoidance may include, but shall not be limited to, project re-route or re-design, project cancellation, or identification of protection measures such as capping or fencing. Consistent with *CEQA Guidelines* Section 15126.4(b)(3)(C), if it is demonstrated that resources cannot be avoided, the qualified archaeologist shall develop additional treatment measures, which may include data recovery or other appropriate measures, in consultation with the implementing agency, and any local Native American representatives expressing interest in prehistoric or tribal resources. If an archaeological site does not qualify as an historical resource but meets the criteria for a unique archaeological resource as defined in Section 21083.2, then the site shall be treated in accordance with the provisions of Section 21083.2. **CUL-3:** The implementing agency shall retain archaeological		

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
	monitors during ground-disturbing activities that have the potential to impact archaeological resources qualifying as historical resources or unique archaeological resources, as determined by a qualified archaeologist in consultation with the implementing agency, and any local Native American representatives expressing interest in the project. Native American monitors shall be retained for projects that have a high potential to impact sensitive Native American resources, as determined by the implementing agency in coordination with the qualified archaeologist. **CUL-4:** During project-level construction, should subsurface archaeological resources be discovered, all activity in the vicinity of the find shall stop and a qualified archaeologist shall be contacted to assess the significance of the find according to *CEQA Guidelines* Section 15064.5. If any find is determined to be significant, the archaeologist shall determine, in consultation with the implementing agency and any local Native American groups expressing interest, appropriate avoidance measures or other appropriate mitigation. Per *CEQA Guidelines* Section 15126.4(b)(3), preservation in place shall be the preferred means to avoid impacts to archaeological resources qualifying as historical resources. Methods of avoidance may include, but shall not be limited to, project re-route or re-design, project cancellation, or identification of protection measures such as capping or fencing. Consistent with *CEQA Guidelines* Section 15126.4(b)(3)(C), if it is demonstrated that resources cannot be avoided, the qualified archaeologist shall develop additional treatment measures, such as data recovery or other appropriate measures, in consultation with the implementing agency and any local Native American representatives expressing interest in prehistoric or tribal resources. If an archaeological site does not qualify as an historical resource but meets the criteria for a unique archaeological resource as defined in Section 21083.2, then the site shall be treated in accordance with the provisions of Section 21083.2.		
3.4-2: The program could cause a substantial adverse change in the significance of unique archaeological resources as defined in §15064.5.	Implementation of **CUL-2** through **CUL-4**	Significant	Less than significant

RB-AR 8219

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
3.4-3: The program could directly or indirectly destroy a unique paleontological resource or site or unique geologic feature.	**CUL-5:** For individual structural BMP projects that require ground disturbance, the implementing agency shall evaluate the sensitivity of the project site for paleontological resources. If deemed necessary, the implementing agency shall retain a qualified paleontologist to evaluate the project and provide recommendations regarding additional work, potentially including testing or construction monitoring. **CUL-6:** In the event that paleontological resources are discovered during construction, the implementing agency shall notify a qualified paleontologist. The paleontologist will evaluate the potential resource, assess the significance of the find, and recommend further actions to protect the resource.	Significant	Less than significant
3.4-4: The program could disturb any human remains, including those interred outside of a formal cemetery.	**CUL-7:** The implementing agency shall require that, if human remains are uncovered during project construction, work in the vicinity of the find shall cease and the County Coroner shall be contacted to evaluate the remains, following the procedures and protocols set forth in Section 15064.5 (e)(1) of the CEQA Guidelines. If the County Coroner determines that the remains are Native American, the Coroner will contact the Native American Heritage Commission, in accordance with Health and Safety Code Section 7050.5, subdivision (c), and Public Resources Code 5097.98 (as amended by AB 2641). The NAHC will then designate a Most Likely Descendant of the deceased Native American, who will engage in consultation to determine the disposition of the remains.	Significant	Less than significant
Geologic and Mineral Resources			
3.5-1: The proposed program could locate new facilities in areas susceptible to seismic impacts such as (1) rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault, (2) strong seismic groundshaking, or (3) seismically induced liquefaction or landslides, which could expose people, structures, or habitat to potential risk of loss, damage, injury, or death.	None required	Less than significant	Not applicable

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
3.5-2: The proposed program could result in substantial soil erosion or the loss of topsoil.	None required	Less than significant	Not applicable
3.5-3: The proposed program could be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the program, and potentially result in on-site or off-site non-seismically induced geologic hazards such as landslides, lateral spreading, subsidence, collapse or sinkholes, settlement, or slope failure.	**GEO-1:** Prior to approval of infiltration BMPs, implementing agencies shall conduct a geotechnical investigation of each infiltration BMP site to evaluate infiltration suitability. If infiltration rates are sufficient to accommodate an infiltration BMP, the geotechnical investigation shall recommend design measures necessary to prevent excessive lateral spreading that could destabilize neighboring structures. Implementing agencies shall implement these measures in project designs.	Significant	Less than significant
3.5-4: The proposed program could be located on expansive soil as defined in 24 CCR 1803.5.3 of the California Building Code (2013), creating substantial risks to life or structures.	None required	Less than significant	Not applicable
3.5-5: The proposed program could have soils incapable of adequately supporting the use of a septic tank or alternative wastewater treatment systems where sewers are not available for the disposal of wastewater.	None required	Less than significant	Not applicable
3.5-6: The proposed program could result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state or a locally important mineral resource recovery site delineated on a local General Plan, Specific Plan, or other land use plan.	None required	Less than significant	Not applicable
Cumulative Impacts	**GEO-2:** Prior to installing BMPs designed to recharge local groundwater supplies, the Implementing Agency shall notify local groundwater managers including the Upper Los Angeles River Area Water Master, the Water Replenishment District of Southern California, or the San Gabriel Water Master as well as local water producers such as local municipalities and water companies. The Implementing Agency shall coordinate BMP siting efforts with groundwater managers and producers to mitigate high groundwater levels while increasing local water supplies.	Significant	Less than significant
Greenhouse Gas Emissions			

RB-AR 8221

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
3.6-1: The proposed program could generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment.	None required	Less than significant	Not applicable
3.6-2: The proposed program could conflict with any applicable plan, policy or regulation of an agency adopted for the purpose of reducing the emissions of GHGs.	None required	Less than significant	Not applicable
Hazards and Hazardous Materials			
3.7-1: The proposed program would create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials or the accidental release during construction and maintenance activities.	None required	Less than significant	Not applicable
3.7-2: The proposed program could create a significant hazard to the public or the environment through the accumulation of potentially hazardous materials into BMPs.	**HAZ-1:** Implementing agencies shall prepare and implement maintenance practices that include periodic removal and replacement of surface soils and media that may accumulate constituents that could result in further migration of constituents to sub-soils and groundwater. A BMP Maintenance Plan shall be prepared by Implementing Agencies upon approval of the individual BMP projects that identifies the frequency and procedures for removal and/or replacement of accumulated debris, surface soils and/or media (to depth where constituent concentrations do not represent a hazardous conditions and/or have the potential to migrate further and impact groundwater) to avoid accumulation of hazardous concentrations and the potential to migrate further to sub-soils and groundwater. The BMP Maintenance Plan may consist of a general maintenance guideline that applies to several types of smaller distributed BMPs. For smaller distributed BMPs on private property, these plans may consist of a maintenance covenant that includes requirements to avoid the accumulation of hazardous concentrations in these BMPs that may impact underlying sub-soils and groundwater. Structural BMPs shall be designed to prevent migration of constituents that may impact groundwater.	Significant	Less than significant
3.7-3: The proposed program could emit hazardous emissions or handle hazardous	Implementation of **HAZ-1**	Less than significant	Not applicable

RB-AR 8222

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
or acutely hazardous materials, substances, or waste within one-quarter mile of an existing school.			
3.7-4: The proposed program could be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, could create a significant hazard to the public or the environment.	**HAZ-2**: Prior to the initiation of any construction requiring ground-disturbing activities in areas where hazardous material use or management may have occurred, the implementing agencies shall complete a Phase I Environmental Site Assessment (ESA) in accordance with American Society for Testing and Materials (ASTM) Standard E1527-13 for each construction site. Any recommended follow up sampling (Phase II activities) set forth in the Phase I ESA shall be implemented prior to construction. The results of Phase II studies, if necessary, shall be submitted to the local overseeing agency and any required remediation or further delineation of identified contamination shall be completed prior to commencement of construction.	Significant	Less than significant
3.7-5: For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, for a project within the vicinity of a private airstrip, the project could result in a safety hazard for people residing or working in the project area.	**HAZ-3:** Implementing Agencies shall require that those BMPs that are within an airport land use plan area are compatible with criteria specified in FAA Advisory Circular No: 150/5200-33B (FAA, 2007). If the proposed BMP is within the minimum separation criteria, the Implementing Agency shall consult with the airport and collaboratively evaluate whether the potential increase in wildlife hazards can be mitigated.	Significant	Less than significant
3.7-6: The proposed program could impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan.	None required	Less than significant	Not applicable
3.7-7: The proposed program could expose people or structures to a significant risk of loss, injury, or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands.	None required	Less than significant	Not applicable
Hydrology and Water Quality			
3.8-1: The proposed project would result in higher groundwater levels and could	**HYDRO-1:** Prior to approving an infiltration BMP, the Permittee shall conduct an evaluation of the suitability of the BMP location. Appropriate infiltration BMP sites should avoid	Significant	Less than significant

RB-AR 8223

SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
potentially affect groundwater quality.	areas with low permeability where recharge could adversely affect neighboring subsurface infrastructure. **HYDRO-2:** Prior to approving an infiltration BMP, the Permitee shall identify pre-treatment technologies, type, and depth of filtration media; depth to groundwater; and other design considerations necessary to prevent contaminants from impacting groundwater quality. The design shall consider stormwater quality data within the BMP's collection area to assess the need and type of treatment and filtration controls. Local design manuals and ordinances requiring minimum separation distance to groundwater shall also be met as part of the design. **HYDRO-3:** Prior to the installation of an infiltration BMP, the Permitee shall conduct a database review for contaminated groundwater sites within a quarter mile of the proposed infiltration facility. The Permittee shall identify whether any contaminated groundwater plumes are present and whether coordination with the local and state environmental protection overseeing agency and responsible party is warranted prior to final design of infiltration facility.		
3.8-2: The proposed project could substantially alter the existing drainage pattern of a site or area through the alteration of the course of a stream or river, or by other means, in a manner that would result in substantial erosion or siltation on- or off-site.	None required	Less than significant	Not applicable
3.8-3: The project could substantially alter the existing drainage pattern of a site or area through the alteration of the course of a stream or river or, by other means, substantially increase the rate or amount of surface runoff in a manner that would result in flooding on- or off-site.	None required	Less than significant	Not applicable
3.8-4: The proposed project could create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff.	None required	Less than significant	Not applicable

RB-AR 8224

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
3.8-5: The project could place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other authoritative flood hazard delineation map.	None required	No impact	Not applicable
3.8-6: The project could place within a 100-year flood hazard area structures that would impede or redirect flood flows.	None required	Less than significant	Not applicable
3.8-7: The proposed project could expose structures to a significant risk of loss, including flooding as a result of the failure of a levee or dam.	None required	Less than significant	Not applicable
3.8-8: The proposed project could place structures in areas subject to inundation by seiche, tsunami, or mudflow.	None required	Less than significant	Not applicable
Land Use and Agriculture			
3.9-1: The proposed program could physically divide an established community.	None required.	No Impact	Not applicable
3.9-2: The proposed program could conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the program (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect.	None required	No Impact	Not applicable
3.9-3: The proposed program could conflict with any applicable habitat conservation plan or natural community conservation plan.	None required	No Impact	Not applicable
3.9-4: The proposed program could convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the Farmland Mapping	None required	No Impact	Not applicable

RB-AR 8225

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
and Monitoring Program of the California Resources Agency, to non-agricultural use. The proposed program could involve other changes in the existing environment which, due to their location or nature, could result in conversion of agricultural land to non-agricultural use or conversion of forest land to non-forest use.			
3.9-5: The proposed program could conflict with existing zoning for agricultural use, or a Williamson Act contract.	None required	No Impact	Not applicable
3.9-6: The proposed program could conflict with existing zoning for, or cause rezoning of, forest land (as defined in Public Resources Code section 12220(g)), timberland (as defined by Public Resources Code section 4526), or timberland zoned Timberland Production (as defined by Government Code section 51104(g)). The proposed program could result in the loss of forest land or conversion of forest land to non-forest use.	None required	No Impact	Not applicable
Noise			
3.10-1: The proposed program could result in exposure of persons to, or generation of, noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies.	**NOISE-1:** The implementing agencies shall implement the following measures during construction as needed:: • Include design measures necessary to reduce the construction noise levels where feasible. These measures may include noise barriers, curtains, or shields. • Place noise-generating construction activities (e.g., operation of compressors and generators, cement mixing, general truck idling) as far as possible from the nearest noise-sensitive land uses. • Locate stationary construction noise sources as far from adjacent noise-sensitive receptors as possible. • If construction is to occur near a school, the construction contractor shall coordinate the with school administration in order to limit disturbance to the campus. Efforts to limit construction activities to non-school days shall be encouraged.	Significant	Significant and unavoidable for construction; less than significant for operations

RB-AR 8226

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
	• For the centralized and regional BMP projects located adjacent to noise-sensitive land uses, identify a liaison for these off-site sensitive receptors, such as residents and property owners, to contact with concerns regarding construction noise and vibration. The liaison's telephone number(s) shall be prominently displayed at construction locations. • For the centralized and regional BMP projects located adjacent to noise-sensitive land uses, notify in writing all landowners and occupants of properties adjacent to the construction area of the anticipated construction schedule at least 2 weeks prior to groundbreaking. **NOISE-2:** All structural BMPs that employ mechanized stationary equipment that generate noise levels shall comply with the applicable noise standards established by the implementing agency with jurisdiction over the structural BMP site. The equipment shall be designed with noise-attenuating features (e.g., enclosures) and/or located at areas (e.g., belowground) where nearby noise-sensitive land uses would not be exposed to a perceptible noise increase in their noise environment.		
3.10-2: The proposed program could result in exposure of persons to, or generation of, excessive groundborne vibration.	None required	Less than significant	Not applicable
3.10-3: The proposed program could result in a substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project.	Implementation of **NOISE-1** and **NOISE-2**	Significant	Less than significant
3.10-4: The proposed program could result in a substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project.	Implementation of **NOISE-1**	Significant	Significant and unavoidable
3.10-5: For a project located within an airport land use plan area, or, where such a plan has not been adopted, in an area within 2 miles of a public airport or public use airport, implementation of the proposed program could expose people residing or working in the area to excessive noise	None required	Less than significant	Not applicable

RB-AR 8227

SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
levels.			
3.10-6: For a project located in the vicinity of a private airstrip, the proposed program could expose people residing or working in the project area to excessive noise levels.	None required	Less than significant	Not applicable
Population and Housing and Environmental Justice			
3.11-1: Implementation of the proposed program could induce substantial population growth in an area, either directly (for example, by proposing new homes and businesses) or indirectly (for example, through extension of roads or other infrastructure).	None required	No Impact	Not applicable
3.11-2: Implementation of the proposed program could displace substantial numbers of existing housing, necessitating the construction of replacement housing elsewhere.	None required	No Impact	Not applicable
3.11-3: Implementation of the proposed program could displace substantial numbers of people, necessitating the construction of replacement housing elsewhere.	None required	No Impact	Not applicable
3.11-4: Implementation of the proposed program could affect the health or environment of minority or low income populations disproportionately.	None required	Less than significant	Not applicable
Public Services and Recreation			
3.12-1: The proposed program could result in substantial adverse physical impacts associated with the provision of, or the need for, new or physically altered governmental fire protection facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for fire protection services.	**PS-1:** The Permittee implementing the EWMP project shall provide reasonable advance notification to the service providers such as fire, police, local businesses, home owners and residents of adjacent to and within areas potentially affected by the proposed EWMP project about the nature, extent and duration of construction activities. Interim updates should be provided to inform them of the status of the construction activities.	Significant	Less than significant

RB-AR 8228

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
3.12-2: The proposed program could result in substantial adverse physical impacts associated with the provision of, or the need for, new or physically altered governmental police protection facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for police protection services.	None required	Less than significant	Not applicable
3.12-3: The proposed program could result in substantial adverse physical impacts associated with the provision of, or the need for, new or physically altered schools, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for schools.	None required	Less than significant	Not applicable
3.12-4: The proposed program could increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated.	None required	Less than significant	Not applicable
3.12-5: The proposed program could include recreational facilities or require the construction or expansion of recreational facilities which might have an adverse physical effect on the environment.	None required	Less than significant	Not applicable
Transportation and Circulation			
3.13-1: The proposed program could intermittently and temporarily increase traffic levels and traffic delays due to vehicle trips generated by construction workers and construction vehicles on area roadways.	**TRAF-1:** For projects that may affect traffic, implementing agencies shall require that contractors prepare a construction traffic control plan. Elements of the plan should include, but are not necessarily limited to, the following: • Develop circulation and detour plans to minimize impacts to local street circulation. Use haul routes minimizing truck traffic on local roadways to the extent possible. • To the extent feasible, and as needed to avoid adverse	Significant	Less than significant

RB-AR 8229

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
	impacts on traffic flow, schedule truck trips outside of peak morning and evening commute hours. • Install traffic control devices as specified in Caltrans' Manual of Traffic Controls for Construction and Maintenance Work Zones where needed to maintain safe driving conditions. Use flaggers and/or signage to safely direct traffic through construction work zones. • Coordinate with facility owners or administrators of sensitive land uses such as police and fire stations, hospitals, and schools. Provide advance notification to the facility owner or operator of the timing, location, and duration of construction activities.		
3.13-2: Construction of the proposed program could potentially cause traffic safety hazards for vehicles, bicyclists, and pedestrians on public roadways, and could increase traffic hazards due to possible road wear.	None required	Less than significant	Not applicable
3.13-3: The proposed program could result in inadequate emergency access during construction.	None required.	Less than significant	Not applicable
3.13-4: Construction of the proposed program could contribute to cumulative impacts to traffic and transportation (traffic congestion, traffic safety, and emergency vehicle access).	Implementation of **TRAF-1**	Significant	Less than significant
Utilities and Service Systems			
3.14-1: Implementation of the proposed program could exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board or result in the construction of new treatment facilities or expansion of existing facilities if the wastewater treatment provider has inadequate capacity to serve the proposed program.	None required	Less than significant	Not applicable
3.14-2: The proposed program could require or result in the construction of new storm water drainage facilities or expansion	None required	Less than significant	Not applicable

RB-AR 8230

TABLE ES-1 (continued)
SUMMARY OF IMPACTS AND MITIGATION MEASURES

Impacts	Mitigation Measures	Significance before Mitigation	Significance if Mitigation is Implemented
of existing facilities, the construction of which could cause significant environmental effects.			
3.14-3: The proposed program could require new or expanded water supply resources or entitlements or require or result in the construction of new water facilities or expansion of existing facilities, the construction of which could cause significant environmental effects.	**UTIL-1:** Prior to approval of BMPs, implementing agencies shall evaluate the potential for impacts to downstream beneficial uses including surface water rights. Implementing agencies shall not approve BMPs that result in preventing access to previously appropriated surface water downstream.	Significant	Less than significant
3.14-4: The proposed program could be served by a landfill with insufficient permitted capacity to accommodate the project solid waste disposal needs or the project could not comply with federal, state, and local statutes and regulations related to solid waste.	**UTIL-2:** Implementing agencies shall encourage construction contractors to recycle construction materials and divert inert solids (asphalt, brick, concrete, dirt, fines, rock, sand, soil, and stone) from disposal in a landfill where feasible. Implementing agencies shall incentivize construction contractors with waste minimization goals in bid specifications where feasible.	Significant	Less than significant
3.14-5: Construction and operation of the proposed program would require additional energy use that could result in wasteful consumption, affect local and regional energy supplies, or conflict with applicable energy efficiency policies or standards.	None required	Less than significant	Not applicable

CHAPTER 1
Introduction

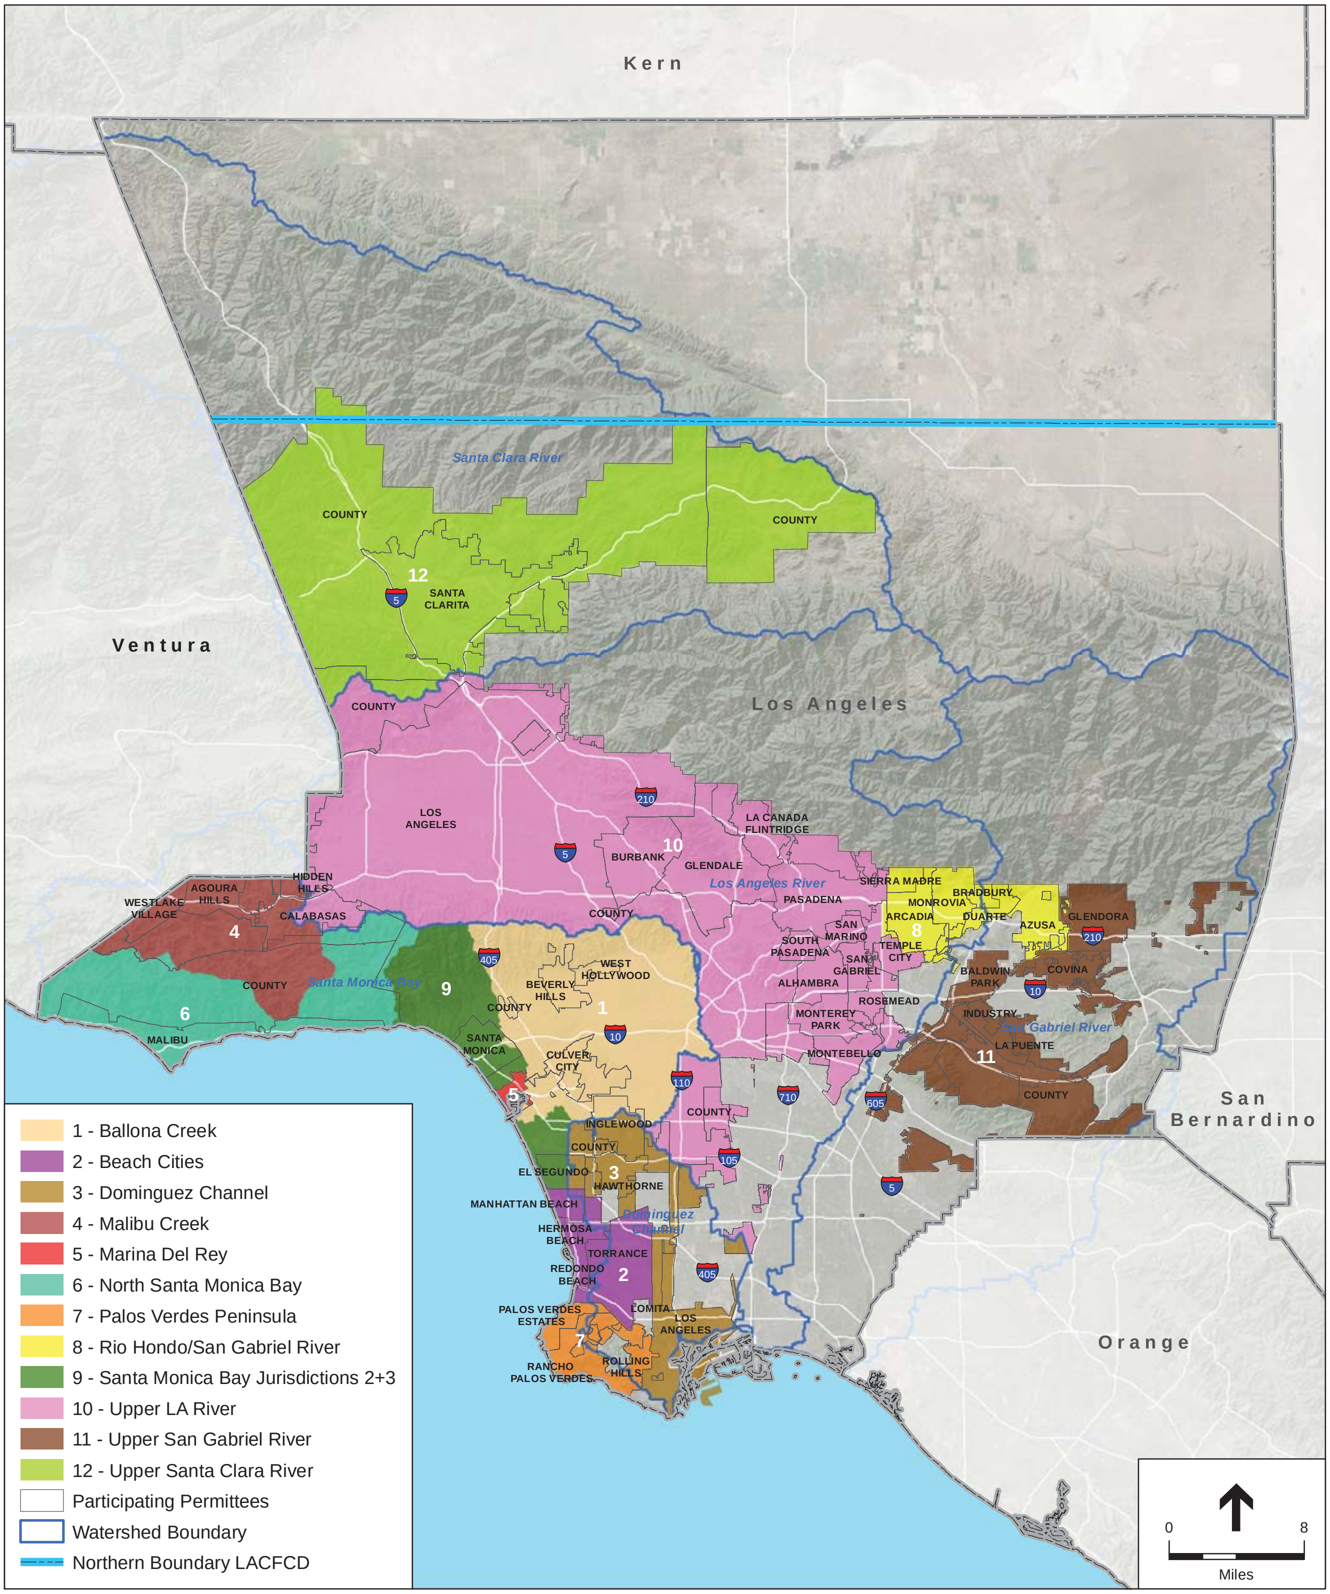
1.1 Introduction

The Los Angeles County Flood Control District (LACFCD) was created in 1915 when the State Legislature adopted the Los Angeles County Flood Control Act to provide flood risk management, water conservation, and recreation and aesthetic enhancement within its boundaries. The LACFCD owns and maintains a broad network of flood control facilities that convey stormwater to the local rivers and ultimately to the ocean. This vast network of regional flood control channels is interconnected with local flood control facilities owned and maintained by the both the LACFCD and the incorporated municipalities within Los Angeles County.

In December 2012, the Los Angeles Regional Water Quality Control Board (LARWQCB) issued a Municipal Separate Storm Sewer System (MS4) Permit (Order No. R4-2012-0175; National Pollutant Discharge Elimination System [NPDES] Permit No. CAS004001) covering discharges within coastal watersheds from the collective storm sewer systems in Los Angeles County (except from the City of Long Beach). The Permit regulates the discharge of stormwater runoff to waters of the United States from facilities owned and maintained by the LACFCD, the County of Los Angeles, and 84 incorporated cities within Los Angeles County (collectively referred to as Permittees). The purpose of the MS4 Permit is to achieve and maintain water quality objectives to protect beneficial uses of the receiving waters in the Los Angeles region. Each of the Permittees identified in the MS4 permit is responsible for meeting the conditions of the permit for MS4 discharges occurring within their jurisdiction.

The MS4 Permit gives Permittees the option of implementing an innovative approach to permit compliance through development of an Enhanced Watershed Management Program (EWMP). The EWMPs will identify potential and priority structural and non-structural Best Management Practices (BMPs) within the region’s stormwater collection system to improve runoff water quality. The LACFCD, along with participating Permittees, has opted to exercise this option and has submitted to the LARWQCB 12 separate Notices of Intent (NOIs) for the development of EWMPs within 12 distinct watershed groups (refer to **Figure 1-1**). Implementation of the EMWPs would be the responsibility of each Permittee and would occur following approval of the EWMPs by the LARWQCB.

RB-AR 8232



SOURCE: ESRI.

LA County PEIR EWMP . 140474

Figure 1-1
Watersheds and EWMP Groups within LACFD Boundaries

The LACFCD, as a regional agency, is a member of each of the 12 EWMP working groups, and as such provides a commonality within each EWMP group. However, LACFCD does not have a special status or authority designated by the MS4 Permit over any of the other Permittees. The LACFCD will be working with the applicable Permittees in all 12 EWMP watersheds as an equal partner to identify the types and locations of BMPs needed to achieve permit compliance within each watershed.

The timeline identified in the MS4 Permit requires that Permittees submit the EWMP to the LARWQCB by June 28, 2015, in order to be in compliance with the permit conditions. The LACFCD recognizes that implementation of the EWMPs may potentially result in changes to environmental conditions. As a result, the LACFCD has prepared this Program Environmental Impact Report (PEIR) in compliance with the California Environmental Quality Act (CEQA) to provide the public and the responsible and trustee agencies with information about the potential effects on the local and regional environment associated with implementation of the EWMPs. The LACFCD will submit the PEIR to its governing body, the Los Angeles County Board of Supervisors, for approval prior to submittal of the EWMPs. The EWMPs will be submitted by each EWMP group to the LARWQCB.

This PEIR describes and evaluates each of the EWMPs being prepared by the Permittees collectively. The discretionary action prompting the need for CEQA compliance is the submittal of the completed EWMPs to the LARWQCB. The EWMPs will identify management strategies including hundreds of structural Best Management Practices (BMPs) that may be designed and implemented by the Permittees to meet permit compliance objectives. A few of the BMPs are currently well defined but most are yet to be fully developed under the EWMPs. A set of priority BMPs will be detailed in each of the EWMPs; these are being developed in parallel with the PEIR. The PEIR describes the details that are available for each of the EWMPs currently under preparation by the EWMP working groups.

The PEIR analysis is not intended to focus on the site-specific construction and operation details of each management strategy and project included in the EWMP. Rather, this PEIR serves as a first-tier environmental document that focuses on the effects of implementing the EWMPs to reduce urban runoff pollution. The analysis assesses worst case situations where construction or operation of projects may significantly impact environmental resources. The analysis outlines mitigation strategies to be followed by the LACFCD and other implementing agencies that rely on this PEIR to avoid or minimize impacts wherever feasible. The determinations of significance after mitigation in this PEIR will apply to the LACFCD and other implementing agencies that rely on this PEIR and the mitigation measures proposed herein.

LACFCD is the CEQA Lead Agency for this PEIR. This PEIR can be used by the LACFCD or other Permittees to streamline environmental review of individual EWMP projects. As individual projects identified in the EWMPs are fully developed, the implementing agency (i.e., the Permittee responsible for implementing the project) will conduct CEQA analysis for individual projects as appropriate or may determine that no additional CEQA analysis is required or that a project is exempt from CEQA. Each implementing agency would determine the significance after mitigation for potential impacts of their proposed projects.

The PEIR provides the LACFCD a foundation for any necessary future environmental review documents that focus on individual projects of the EWMPs for which the LACFCD is the designated Lead Agency. In addition, the PEIR can provide several advantages during the development and implementation of the EWMPs that may include:

- More exhaustive consideration of effects and alternatives than would be practical in an environmental impact report (EIR) for an individual BMP project.
- Consideration of cumulative impacts that might not be evident in a case-by-case or project-by-project analysis.
- Consideration by LACFCD as Lead Agency of broad policy alternatives and program-wide mitigation measures early in the process when there is greater flexibility to deal with basic problems or cumulative impacts.

The EWMPs are to include a discussion of the environmental documents, assessments, and permitting required for the implementation of the priority projects. The PEIR can provide a basis for this discussion. The use of the PEIR in the development and implementation of the EWMPs is further discussed in this chapter in the *Purpose of the Program Environmental Impact Report*.

1.2 Project Background

Stormwater/Water Quality

MS4 discharges consist of stormwater and non-stormwater generated from point sources throughout a watershed, collected and conveyed through the MS4, and ultimately discharged into surface waters. The MS4 system includes curbs and gutters, man-made channels, catch basins, and storm drains throughout the Los Angeles region. Discharges may adversely affect receiving surface water quality with pollutants such as bacteria, nutrients (nitrogen and phosphorus), metals, pesticides, and other man-made organic compounds. Aquatic toxicity, particularly during wet weather, is also a concern. Stormwater and non-stormwater discharges of debris and trash are also a pervasive water quality problem in the Los Angeles region. Pollutants in stormwater and non-stormwater may have damaging effects on both human health and aquatic ecosystems when persistent at certain concentrations above water quality criteria/thresholds.

Through water quality assessments conducted by the LARWQCB, the LARWQCB and U.S. Environmental Protection Agency (USEPA) have established 33 Total Maximum Daily Loads (TMDLs) that identify Los Angeles County MS4 discharges as pollutant sources causing or contributing to water quality impairments. The TMDL development process is explained in more detail in Chapter 2.0, *Project Description*. The MS4 Permit (described briefly later in this chapter) is designed to reduce pollutant loads into local surface waters. The implementation of the 12 EWMPs and their watershed-specific compliance strategies (which are explained in more detail in Chapter 2.0) would address the need for reduction in urban runoff pollution through treatment and infiltration, as well as increasing stormwater retention throughout the Los Angeles region.

MS4 NPDES Permit

On November 8, 2012, the LARWQCB adopted the fourth NPDES MS4 Permit (Order No. R4-2012-0175) for discharges from the MS4s located within the coastal watersheds of Los Angeles County (excepting the City of Long Beach), which became effective on December 28, 2012. The MS4 Permit identifies conditions, requirements, and programs that municipalities must comply with to protect regional water resources from adverse impacts associated with pollutants in stormwater and urban runoff. The MS4 Permit contains effluent limitations, receiving water limitations (RWLs), minimum control measures, and TMDL provisions and outlines the process for developing watershed management programs, including EWMPs.

Watershed Management Programs

The MS4 Permit Section VI.C (page 47) includes provisions that allow Permittees to voluntarily choose to implement a Watershed Management Program (WMP). The purpose of this program is to "allow Permittees the flexibility to develop Watershed Management Programs to implement the requirements of [the] Order on a watershed scale through customized strategies, control measures, and BMPs." The permit states that "participation in a Watershed Management Program is voluntary and allows a Permittee to address the highest watershed priorities."

Several areas of the County covered in the permit chose to comply with the MS4 Permit through the preparation of WMPs only. In these areas, the structural BMPs needed to achieve local water quality objectives were primarily distributed BMPs that were found to be categorically exempt from CEQA. Actions needed to achieve MS4 Permit compliance in areas that have chosen to implement WMPs only are not evaluated in this PEIR.

Enhanced Watershed Management Programs

The Permit Section VI.C.1.g (page 48) allows for watersheds to collaborate in preparing an EWMP to achieve Permit compliance with RWLs. The intent of the EWMP is to comprehensively evaluate opportunities for collaboration on multi-benefit regional projects that retain MS4 discharges and also address flood control and/or water supply within the participating Permittees' collective jurisdictional boundaries. Twelve EWMP groups have formed to implement a collaborative approach to meeting the requirements of the 2012 MS4 Permit.

As required by the provisions of the MS4 Permit, each of the 12 EWMPs includes several components aimed at identifying priorities for water quality improvement and the mechanisms that will achieve those improvements. In general, these components include:

1. ***Stakeholder outreach and collaboration***, so that development and implementation of the EWMP is a collaborative effort between Permittees, stakeholders, and the public.
2. ***Identification of water quality priorities***, which serve as the basis for implementation and monitoring activities within the EWMP.

3. ***Identification of candidate watershed control measures*** that Permittees and stakeholders can customize to address water quality priorities.
4. ***Implementation of a Reasonable Assurance Analysis,*** so that the Permittees, stakeholders, and regulatory authorities can identify which control measures are likely to be the most effective, and have confidence in the performance of the selected watershed control measures.

These components are discussed in further detail below.

Stakeholder Outreach and Collaboration

According to Part VI.C.1.f.v (page 48) of the MS4 Permit, each EWMP must provide appropriate opportunities for meaningful stakeholder input, including the development of a watershed management program Technical Advisory Committee (TAC) that will advise and participate in the development of the EWMP. The MS4 Permit requires that at a minimum, the TAC include at least one Permittee representative from each Watershed Management Area (WMA) for which an EWMP is being developed (e.g., city administrators, stormwater program managers), one public representative from a non-government organization with public membership (e.g., environmental and community groups), and staff from the Regional Board, USEPA Region IX, and collaborating agencies (e.g., California Department of Transportation, U.S. Army Corps of Engineers).

Broader stakeholder groups will also be engaged through a series of workshops specific to each EWMP. The precise number and format of workshops will likely vary by watershed, with the overarching goal of providing a common and consistent orientation for stakeholders to the EWMP process, and a clear structure for stakeholders to contribute to the EWMPs. The TAC and stakeholders are expected to help define appropriate water quality priorities and identify suitable watershed control measures; these project elements are discussed further in this chapter.

Water Quality Priorities

The identification of water quality priorities is required in Section VI.C.5.a (p. 58) of the MS4 Permit as part of EWMP development. The Permit describes a four-step process for prioritizing and sequencing water quality concerns within each EWMP watershed:

1. Water quality characterization based on available monitoring data, TMDLs, 303(d) lists, stormwater annual reports, etc.
2. Water body-pollutant classification
3. Source assessment for the water body-pollutant categories
4. Prioritization of the water body-pollutant categories

The prioritization of pollutants under Step 4 is conducted for each EWMP watershed according to the following guidelines, established in the MS4 Permit:

- TMDLs (**first category**):

- Controlling pollutants for which there are water-quality-based effluent limitations and/or receiving water limitations with interim or final compliance deadlines within the permit term, or TMDL compliance deadlines that have already passed and limitations have not been achieved.
- Controlling pollutants for which there are water-quality-based effluent limitations and/or receiving water limitations with interim or final compliance deadlines between September 6, 2012, and October 25, 2017.

- Other Receiving Water Considerations (**second category**):
  - The second highest priority shall be considered controlling pollutants for which data indicate impairment of exceedances of receiving water limitations and the findings from the source assessment implicates discharges from the MS4.

The EWMP prioritization process includes identifying the priority pollutants and the schedule for implementing BMPs to meet the following criteria:

- For pollutants in the same class as TMDLs, the EWMPs evaluate the ability to consider these pollutants within the same time frame as the TMDLs.
- For pollutants on 303(d) list or in same class as 303(d) listings, the EWMPs develop a schedule to address these pollutants as soon as possible with milestones.
- For pollutants with exceedances that are not in the same class as the 303(d) listing, the EWMPs propose monitoring under CIMP to confirm exceedances and, if those exceedances are confirmed, the Permittees shall then develop a schedule to address these pollutants as soon as possible with milestones.
- For pollutants without exceedances in the last five years, the EWMPs will include them in monitoring plans but not prioritize them for BMPs.

The outcome of this process is the identification of water quality priorities in each EWMP and the proposed schedule for which BMPs are to be implemented to address these pollutants. Pollutants under a TMDL have higher priority and will be addressed under the timelines defined in the TMDLs. This further highlights that the EWMP is a continuation of water quality improvement efforts by the Permittees under existing TMDLs through adopted TMDL Implementation Plans. BMP types that are assessed in this PEIR therefore include BMPs that are under various stages of implementation and plan to meet TMDL waste load allocations.

Identification of Candidate Watershed Control Measures

The EWMPs describe a broad range of structural and non-structural control measures aimed at achieving compliance with the provisions of the MS4 Permit. These control measures are more commonly referred to as BMPs. BMPs vary in function and type, with each BMP providing unique design characteristics and benefits of implementation. Further description of both non-structural and structural BMP types, examples and anticipated distribution of the BMPs are presented in Chapter 2.0, *Project Description*, as these are the basis for the proposed program.

Reasonable Assurance Analysis

The Reasonable Assurance Analysis (RAA) is a critical component of the EWMPs and is used to demonstrate "that the activities and control measures will achieve applicable water-quality-based effluent limitations and/or RWLs with compliance deadlines during the Permit term" (Los Angeles MS4 Permit, Part VI.C.5.b.iv.(5), page 63). While the MS4 Permit prescribes the RAA as a quantitative demonstration that control measures (such as BMPs) will be effective, the RAA also provides an opportunity to use a modeling process to identify and prioritize potential control measures. The RAA for each EWMP uses a model to simulate a critical storm (design storm) and demonstrate that the selected BMPs for each watershed will achieve compliance with the TMDLs and water-quality-based effluent limitations.

The RAA is being performed as part of the preparation of the EWMPs, and in parallel with the preparation of this PEIR. The RAA demonstrates that the primary goal of the EWMP is to meet the water quality goals. The modeling being performed as part of the RAA will determine if the number and distribution of the BMP types and specific projects identified in the EWMP Work Plans will meet the water quality goals. This PEIR will assess the types of BMPs that may be implemented to meet these goals. Chapter 2.0, *Project Description,* provides examples of these types and maps showing the approximate location and potential distribution of these BMP types to meet these goals. These BMP examples are subject to change through the EWMP planning process that is developing on a parallel track to this PEIR. The EWMPs are also planning documents that will be revised periodically to reflect new data, further modeling, emerging technologies, and results of BMP monitoring and assessments.

1.3 CEQA Environmental Review Process

CEQA Process Overview

The basic purposes of CEQA are to: (1) inform the public and government decision makers regarding potential significant environmental effects of proposed activities, (2) identify ways in which potential environmental damage can be avoided or significantly reduced, (3) prevent significant, avoidable environmental damage by requiring changes in projects through the use of alternatives or mitigation measures, and (4) disclose to the public the reasons why a government agency approved the project if significant environmental effects are involved.

CEQA states that an EIR should use a multidisciplinary approach applying social and natural sciences to make a qualitative and quantitative analysis of all the foreseeable environmental impacts that a proposed project would exert on the surrounding area. As stated in Section 15151 of the CEQA Guidelines:

> "An EIR should be prepared with a sufficient degree of analysis to provide decision-makers with information which intelligently takes an account of environmental consequences. An evaluation of the environmental effects of a proposed project need not be exhaustive, but the sufficiency of an EIR is to be reviewed in the light of what is reasonable feasible."

This PEIR for the proposed program was prepared to comply with CEQA regulations, and is to be used by local agencies and the public in their review of the potential environmental impacts of the EWMP's implementation, proposed alternatives, and mitigation measures that would minimize, avoid, or eliminate the potential environmental effects. The LACFCD will consider the information presented in this PEIR, along with other factors, in the development and implementation of the EWMPs. The EWMPs are to include a discussion of the environmental documents, assessments and permitting required for the implementation of the priority projects. The PEIR can provide a basis for this discussion.

Significance criteria have been developed for each environmental resource analyzed in this Draft PEIR. The significance criteria are defined at the beginning of each impact analysis section. Impacts are categorized as follows:

- **Significant and Unavoidable:** Mitigation might be recommended but impacts are still significant.
- **Less than Significant with Mitigation:** Potentially significant impact but mitigated to a less-than-significant level.
- **Less than Significant:** Mitigation is not required under CEQA but may be recommended.
- **No Impact.**

Purpose of the Program Environmental Impact Report

The LACFCD determined that implementation of the 12 EWMPs could have a significant effect on the environment and therefore required preparation of a PEIR. The LACFCD prepared this Draft PEIR to provide the public and the responsible and trustee agencies with information about the potentially significant environmental effects of the proposed program, to identify possible ways to minimize potentially significant effects, and to describe and evaluate feasible alternatives to the proposed program.

This document has been prepared as a PEIR. According to the CEQA Guidelines, Section 15168(a), a PEIR is one type of environmental review document that may be used to evaluate a plan or program that has multiple components (projects and actions) or to address a series of actions that are related in any of the following ways:

- Geographically.
- As logical parts in the chain of contemplated actions.
- In connection with the issuance of rules, regulations, plans, or other general criteria to govern the conduct of a continuing program.
- As individual activities carried out under the same authorizing statutory or regulatory authority and having generally similar environmental affects that can be mitigated in similar ways.

The EWMPs would include multiple projects and actions that cover a broad geographic scale. This PEIR provides a foundation for any necessary future environmental review documents that focus on individual projects of the EWMPs. A PEIR can provide the following additional advantages (CEQA Guidelines, Section 15168[b]):

- Provide for a more exhaustive consideration of effects and alternatives than would be practical in an EIR on an individual action.
- Ensure consideration of cumulative impacts that might not be evident in a case-by-case or project-by-project analysis.
- Avoid duplicative consideration of basic policy issues.
- Allow Lead Agency to consider broad policy alternatives and program-wide mitigation measures early in the process when the agency has greater flexibility to deal with basic problems or cumulative impacts.
- Facilitate a reduction in paperwork.

A PEIR may be prepared on a plan before the details of each and every project within the long-term plan have been developed, as is the case for the EWMPs. Therefore, this PEIR addresses the environmental effects of the program as a whole. The analyses focus on the environmental effects of implementing the EWMPs as a program to improve surface water quality and increase water conservation. For the proposed program, many management strategies are only in the concept development or planning phase. The PEIR analysis is not intended to focus on the site-specific construction and operation details of each management strategy and project included in the EWMPs. Rather, this PEIR serves as a first-tier environmental document that focuses on the effects of implementing the EWMPs overall as a plan to reduce urban runoff pollution.

This PEIR evaluates the major environmental effects of implementing proposed EWMP projects from a broad perspective; this evaluation is a *program-level* analysis. While the Permittees are developing the design, construction, and operation details of the projects that would be included in the EWMPs, these project details are not the focus of this PEIR. Instead, the PEIR frames the nature and magnitude of the expected environmental impacts associated with these proposed EWMP projects and identifies program mitigation measures to reduce the impacts of the projects as proposed. As discussed further in this report, more detailed *project-level* analyses of individual EWMP projects may be conducted separately by each of the Permittees as required by CEQA. The EWMPs are to include a discussion of the environmental documents, assessments, and permitting required for the implementation of the priority projects. The PEIR can provide a basis for this discussion. This PEIR can be used by the LACFCD or other local implementing agencies to streamline environmental review of individual EWMP projects. The implementing agency may determine that a more detailed, *project-level* analysis is required, or may determine some projects to be exempt from CEQA. For non-exempt projects, project-level CEQA review will be conducted separately by the appropriate implementing agency. The separate environmental review of individual projects will evaluate site-specific impacts and incorporate feasible mitigation measures and alternatives (CEQA Guidelines, Section 15168[c]).

Impact Assessment Methodology

This PEIR provides a "program level" assessment, meaning that the type of BMPs that are envisioned for implementation are described and evaluated in concept, with examples of implemented projects provided to illustrate typical features. Each EWMP includes a list of potential locations where these BMP types may be installed, along with available information on the anticipated scale, location, and construction methods required for installation. Maps identifying potential and priority BMP locations are provided in Chapter 2, *Project Description*, with the overall EWMP watershed characteristics and BMP implementation strategy. The PEIR focuses its assessment on construction and operation of these potential and priority BMPs to be installed throughout the watersheds—but primarily within urbanized areas where the pollutant loading is greatest and where these BMPs can be most cost-effective in meeting water quality goals. The analysis assesses worst case situations where construction or operation of projects may significantly impact environmental resources. The analysis outlines mitigation strategies to be followed by Implementing Agencies to avoid or minimize impacts wherever feasible. Exact locations and BMP designs are not defined. Rather, the overall compliance strategy of BMP type, quantity, and geographic distribution is assessed on a cumulative, regional scale.

Scoping Period

A Notice of Preparation (NOP) was published by the LACFCD on August 29, 2014 (**Appendix A**). The NOP was circulated to federal, state, and local agencies, as well as other interested parties, for a period of 30 days. The distribution list is also located in Appendix A. The NOP was made available in print and electronic form, and the LACFCD accepted comments on the NOP for a 30-day period, closing on September 29, 2014. In addition, an email notification regarding the availability of the NOP was sent to over 700 interested EWMP stakeholders. The NOP discussed the purpose of the EWMPs and their management strategies, identified the EWMP Study Areas, and provided a brief and preliminary list of environmental issue areas that could be impacted. The initial 30-day comment period was extended an additional 30 days to October 29, 2014, to provide greater opportunity for public comment on the NOP. The notification for the extension of the comments period was sent by email to the over 700 interested EWMP stakeholders. The notice of the extension was also provided through the LACFCD Twitter account. In addition, a recording of the Scoping Meeting presentation was posted on the LACFCD website. A link to the website (www.LACoH2Osheds.com) was provided in the email and Twitter feed announcements.

Table 1-1 provides a list of the commenters that sent comments on the NOP. The comment letters are located in Appendix A.

TABLE 1-1
NOP COMMENTERS

	Date	Name	Organization
1	10/16/2014	Enrique Huerta	At-Large Stakeholder (Downey, CA)
2	10/23/2014	Enrique Huerta	At-Large Stakeholder (Downey, CA)
3	10/28/2014	George Ball	Citizen
4	10/29/2014	Jane Williams	Los Angeles County Arboretum
5	10/27/2014	Kenneth Hill	Los Angeles County Arboretum Foundation, President
6	10/23/2014	Marsha Perez	Citizen, Los Angeles County Arboretum
7	09/29/2014	Rex Frankel	Ballona Ecosystem Education Project, Director
8	10/29/2014	Rex Frankel	Ballona Ecosystem Education Project, Director
9	10/29/2014	Tom Williams	Sierra Club, Water Committee
10	10/08/2014	Elizabeth Byrne Debreu	Los Angeles Arboretum Foundation
11	09/29/2014	Dianna Watson	Department of Transportation
12	09/24/2014	Deirdre West	Metropolitan Water District
13	09/25/2014	Katy Sanchez	NAHC
14	09/29/2014	Douglas Fay	Citizen
15	09/29/2014	Donna Murray	Citizen
16	09/29/2014	Joyce Dillard	Citizen
17	10/03/2014	Patricia McPherson	Grassroots Coalition
18	10/14/2014	Jane Florentinus	Citizen
19	10/29/2014	Dale Carter	Arboretum volunteer and docent
20	08/29/2014	Scott Morgan	State Clearinghouse

Public Scoping Meetings

Pursuant to CEQA Guidelines Section 15083, the LACFCD held three public Scoping Meetings on September 9, 10, and 15 of 2014 to receive comments on the NOP, as detailed below. The purpose of the meetings was to present the proposed EWMPs to the interested stakeholders and receive public input regarding the proposed scope of the PEIR analysis. Attendees were provided an opportunity to voice comments or concerns regarding potential effects of the program. A scoping report was prepared to summarize the public scoping process and the comments received in response to the NOP; the scoping report is included in **Appendix B** of this PEIR. Appendix B also includes the written comments received on the NOP.

Scoping Meeting 1 — Tuesday, September 9, 2014
6:00 P.M.
Chace Park Community Room
13650 Mindanao Way
Marina del Rey, CA 90292

Scoping Meeting 2	Wednesday, September 10, 2014 6:00 P.M. County of Los Angeles Department of Public Works 900 South Fremont Avenue First Floor Conference Room C Alhambra, CA 91803
Scoping Meeting 3	Monday, September 15, 2014 6:30 P.M. K Dalton Room Monrovia Community Center 119 W Palm Ave Monrovia, CA 91016

Draft Program EIR Public Review

In accordance with Section 15105 of the CEQA Guidelines, the Draft PEIR is available for public review and comment for a 45-day review period. The Draft PEIR has been circulated to federal, state, and local agencies and interested parties who may wish to review and issue comments on its contents. All written comments should be sent to:

Gregg BeGell, P.E.
County of Los Angeles Department of Public Works
Project Management Division II
900 South Fremont Avenue, 5th Floor
Alhambra, CA 91803

All written comments received on the Draft PEIR will be commented on and included in the Final PEIR. Comments on the Draft PEIR must be received in writing by the end of the public review period. Copies of the Draft PEIR and related key documents, as well as documents incorporated by reference, are available for review at the following public locations:

Lead Agency	County of Los Angeles Department of Public Works Project Management Division II 900 South Fremont Avenue, 5th Floor Alhambra, CA 91803
Ballona Creek	Culver City Julian Dixon Library 4975 Overland Ave. Culver City, CA 90230
	View Park Library 3845 W. 54th Street Los Angeles, CA 90043

Beach Cities WMG	Hermosa Beach Library 550 Pier Ave. Hermosa Beach, CA 90254
	Manhattan Beach Library 1320 Highland Ave. Manhattan Beach, CA 90266
Dominguez Channel WMG	Hawthorne Library 12700 Grevillea Ave. Hawthorne, CA 90250
	Carson Library 151 E. Carson St. Carson, CA 90745
Malibu Creek	Agoura Hills Library 29901 Ladyface Court Agoura Hills, CA 91301

Upper Santa Clara River	Stevenson Ranch Express Library Dr. Richard H. Rioux Memorial Park 26233 W. Faulkner Dr. Stevenson Ranch, CA 91381

The Draft PEIR can also be accessed through the internet at: www.LACoH2Osheds.com.

Public Hearings

Public comments on the Draft PEIR will be accepted from January 16, 2015 to March 2, 2015. Public hearings on the Draft PEIR to accept written or oral comments are scheduled as follows:

1st Meeting	Thursday, January 29: 6:00 P.M. – 8:00 P.M. Florence-Firestone Service Center – Contact: Tony Brookins, Director 7807 S. Compton Ave., Los Angeles, CA 90001 Phone: (323) 586-6502
2nd Meeting	Tuesday, February 3: – 6:00 P.M. – 8:00 P.M. LA County Fire Camp #2 Classroom (Hahamongna Watershed Park) – Contact: Celia Hernandez 4810 Oak Grove Dr, La Cañada Flintridge, CA 91011 (818) 790-6434
3rd Meeting	Thursday, February 5 – 6:00 P.M. – 8:00 P.M. San Pedro Service Center – Contact: Lilia Andres, Regional Manager 769 W. Third St., San Pedro, CA 90731 Phone: (310) 519-6091
4th Meeting	Tuesday, February 10: 6:00 P.M. – 8:00 P.M. Topanga Library – Contact: Oleg Kagan, Library Manager 122 N. Topanga Canyon Blvd., Topanga, CA 90290 Phone: (310) 455-3480
5th Meeting	Wednesday, February 11: 6:00 P.M. – 8:00 P.M. Hacienda Heights Community Center 1234 Valencia Avenue, Hacienda Heights CA 91745

6th Meeting — Tuesday, February 17: 6:00 P.M. – 8:00 P.M.
East Los Angeles Library – Contact: Alice Medina, Librarian
4837 East 3rd Street, Los Angeles, CA 90022 Phone: (323) 264-0155

Final PEIR Publication and Certification

Written comments received on the Draft PEIR will be addressed in a Response to Comments document which, together with the Draft PEIR, will constitute the Final PEIR. As required by CEQA, responses to comments submitted by responsible public agencies will be distributed to those agencies for review prior to consideration of the Final EIR by the Board of Supervisors. The Board of Supervisors will decide whether to certify the Final PEIR at a public meeting. Upon certification of the PEIR, LACFCD may proceed to take action on program approval and submittal of the EWMPs to the LARWQCB.

CEQA requires the adoption of findings prior to approval of a project where a certified EIR identifies significant environmental effects (CEQA Guidelines, Sections 15091 and 15092). If the Board of Supervisors approves the program even though significant impacts identified by the PEIR cannot be mitigated, it will adopt a Statement of Overriding Considerations that states in writing the reasons for its actions (CEQA Guidelines Section 15093[b]). This Statement of Overriding Considerations must be included in the record of the project approval and mentioned in the Notice of Determination (CEQA Guidelines Section 15093(c)).

Mitigation Monitoring and Reporting Program

CEQA Section 21081.6(a) requires lead agencies to "adopt a reporting and mitigation monitoring program for the changes to the project which it has adopted or made a condition of project approval in order to mitigate or avoid significant effects on the environment." This Draft PEIR identifies and presents mitigation measures that would form the basis of such a monitoring program. Any mitigation measures adopted by the LACFCD will be included in a Mitigation Monitoring and Reporting Program (MMRP) to verify compliance. The MMRP will be included within the Final PEIR.

1.4 Documents Incorporated by Reference

The following documents are incorporated by reference in this PEIR:

Ballona Creek Watershed Management Group, *Enhanced Watershed Management Program (EWMP) Final Work Plan*, prepared by City of Beverly Hills, City of Culver City, City of Los Angeles, City of Inglewood, City of Santa Monica, City of West Hollywood, County of Los Angeles, and Los Angeles County Flood Control District, June 2014.

1.5 PEIR Organization

This Draft PEIR is organized into the following chapters and appendices:

Executive Summary**.** This chapter summarizes the contents of the Draft PEIR.

Chapter 1.0, *Introduction*. This chapter discusses the CEQA process and the background and purpose of the PEIR for the proposed program.

Chapter 2.0, *Project Description*. This chapter provides an overview of the proposed program and each EWMP group, describes the need for and objectives of the proposed program, and provides detail on the characteristics of the proposed program.

Chapter 3.0, *Environmental Impact Analysis*. This chapter describes the environmental setting and identifies impacts of the proposed program for each of the following environmental resource areas: Aesthetics; Air Quality; Biological Resources; Cultural Resources; Geology and Soils/Mineral Resources; Greenhouse Gas Emissions; Hazards and Hazardous Waste; Hydrology and Water Quality; Land Use and Planning/Agriculture; Noise; Population and Housing; Public Services/Recreation; Transportation and Circulation; and Utilities, Service Systems, and Energy. Measures to mitigate the impacts of the proposed program, if necessary, are presented for each resource area.

Chapter 4.0, *Cumulative Impacts*. This chapter evaluates the potential for the proposed program to result in secondary environmental cumulative effects.

Chapter 5.0, *Growth-Inducement Potential*. This chapter evaluates the potential for the proposed program to induce population growth and result in secondary environmental effects due to such growth.

Chapter 6.0, *Alternatives Analysis*. This chapter presents an overview of the alternatives development process and describes the alternatives to the proposed program that were considered.

Chapter 7.0, *Organizations and Persons Contacted*. This chapter identifies authors involved in preparing this Draft PEIR, including persons and organizations consulted.

Chapter 8.0, *Report Preparers*. This chapter identifies authors involved in preparing this Draft PEIR, including persons and organizations consulted.

Chapter 9.0, *References*. This chapter includes all citations for sources used in the preceding chapters.

CHAPTER 2
Project Description

2.1 Introduction

The preparation of the 12 separate Enhanced Watershed Management Programs (EWMPs) is a collective effort among the Los Angeles County Flood Control District (LACFCD) and the applicable Permittees in each Watershed Management Group (WMG). The 12 EWMPs are being prepared on a parallel schedule to the Program Environmental Impact Report (PEIR). The 12 EWMPs will vary for each watershed group, but will generally provide the opportunity for Permittees to customize their stormwater programs to achieve compliance with applicable receiving water limitations and/or water-quality-based effluent limits in accordance with the Municipal Separate Storm Sewer System (MS4) Permit through implementation of stormwater Best Management Practices (BMPs) or watershed control measures. Each Permittee is responsible for discharges in its jurisdiction and meeting the water quality goals for these discharges.

The EWMPs provide for a collaborative effort by Permittees on a watershed basis. The EWMP process allows for greater collaboration and accountability. The EWMPs, once complete, will include specific projects and identify Permittees that may benefit from the projects. Projects may be implemented individually or with partners. Each Permittee is responsible for the content of the EWMP projects that meet the water quality goals for the MS4 discharges within their jurisdiction.

This Project Description describes types of BMPs presented in the 12 Notices of Intent (NOIs), EWMP Work Plans, and input from the EWMP WMG. The BMPs listed in each EWMP are in various phases of planning or implementation. Examples of existing BMPs are used to illustrate the function, type of construction, and general locations of the BMP types for the purpose of the environmental assessment of the BMP types identified in the EWMPs.

BMPs vary in function and type, with each BMP providing unique design characteristics and benefits from implementation. The overarching goal of BMPs in the EWMPs is to reduce the impact of stormwater and non-stormwater on receiving water quality and address the water quality priorities as defined by the MS4 Permit. The development of each EWMP will involve the evaluation and selection of multiple BMP types, including nonstructural (institutional) and distributed, centralized, and regional structural watershed control measures, that will be implemented to meet compliance goals and strategies under the 2012 MS4 Permit. The LACFCD has limited jurisdictional authority for ordinance and code enactment or enforcement and therefore is limited in nonstructural BMPs to education and outreach measures.

The structural watershed control measures that will be implemented by the LACFCD will be multi-benefit stormwater projects that emphasize flood risk mitigation and water conservation and supply.

RB-AR 8251

The LACFCD has a vested interest in increasing opportunities for stormwater capture and groundwater recharge as a means of assisting local water supply augmentation. The LACFCD will be working with the applicable Permittees and other stakeholders in all 12 EWMP watersheds to develop such projects. The EWMPs will be implemented by the Permittees that have jurisdiction within each EWMP area. The implementing agencies will be responsible for the contents of the EWMPs affecting their jurisdictions and for implementing the projects developed by the EWMPs.

2.2 Goals and Objectives

The primary goals and objectives of the EWMPs are:

- To collaborate among agencies (Permittee jurisdictions) across the watershed to promote more cost-effective and multi-beneficial water quality improvement projects to comply with the MS4 Permit.
- To develop watershed-wide EWMPs that will, once implemented, remove or reduce pollutants from dry- and wet-weather urban runoff in a cost-effective manner.
- To reduce the impact of stormwater and non-stormwater on receiving water quality.

2.3 Watersheds, Participants, and Process

Following the adoption of the MS4 Permit by the Los Angeles Regional Water Quality Control Board (LARWQCB), some Permittees from each EWMP area formed WMGs to collaborate on the development of EWMPs. The proposed program includes several WMGs of Los Angeles County, covering the following EWMP areas: Ballona Creek, Beach Cities, Dominguez Channel, Malibu Creek, Marina del Rey, North Santa Monica Bay Coastal Watersheds, Palos Verdes Peninsula, Rio Hondo/San Gabriel River, Santa Monica Bay, Upper Los Angeles River, Upper San Gabriel River, and Upper Santa Clara River. The geographic scope covered by each of these 12 EWMPs is detailed in **Table 2-1** and shown in **Figure 2-1.**

TABLE 2-1 - EWMP PARTICIPANTS AND WATERSHEDS

Watershed Management Group	Affected Watersheds	Cities/Permittees	Lead/Coordinator
Ballona Creek	Ballona Creek Watershed	Beverly Hills, Culver City, Inglewood, Los Angeles, Santa Monica, West Hollywood, LA County, LACFCD	Los Angeles
Beach Cities	Santa Monica Bay Watershed Jurisdictional Group (SMB JG) 5 & 6, Dominguez Channel Watershed, and Machado Lake Watershed	Hermosa Beach, Manhattan Beach, Redondo Beach, Torrance, LACFCD	Redondo Beach
Dominguez Channel	Dominguez Channel Watershed, the Machado Lake Watershed, and the Los Angeles/Long Beach Harbors Watershed	El Segundo, Hawthorne, Inglewood, Los Angeles, Lomita, LA County, LACFCD	Los Angeles
Malibu Creek	Malibu Creek Watershed	Agoura Hills, Calabasas, Hidden Hills, Westlake Village, LA County, LACFCD	Calabasas
Marina del Rey	Marina del Rey Watershed	Culver City, Los Angeles, LACFCD, LA County	LA County
North Santa Monica Bay	SMB JG 1, SMB JG 4, and a portion of Malibu Creek within the City of Malibu's borders	LA County, LACFCD, Malibu	Malibu
Palos Verdes Peninsula	Most of the SMB JG7, the Los Angeles Harbor subwatershed, and the Machado Lake subwatershed	Palos Verdes Estates, Rancho Palos Verdes, Rolling Hills Estates, LA County, LACFCD	Rancho Palos Verdes
Rio Honda/San Gabriel River	Portions of the Los Angeles and San Gabriel River Watersheds	Arcadia, Azusa, Bradbury, Duarte, Monrovia, County, LACFCD, Sierra Madre	Sierra Madre
Santa Monica Bay	SMB JG2 and SMB JG3	Los Angeles, El Segundo, Santa Monica, LA County, LACFCD	Los Angeles
Upper LA River	Upper reaches of the Los Angeles River Watershed	Alhambra, Burbank, Calabasas, Glendale, Hidden Hills, La Canada Flintridge, Los Angeles, Montebello, Monterey Park, Pasadena, Rosemead, San Gabriel, San Marino, South Pasadena, Temple City, LA County, LAFCD	Los Angeles
Upper San Gabriel River	Portions of the San Gabriel River Watershed	Baldwin Park, Covina, Glendora, Industry, La Puente, LACFCD, LA County	LA County
Upper Santa Clara River	Upper Santa Clara River Watershed	LA County, LACFCD, Santa Clarita	Santa Clarita

Watersheds and EWMP Groups within LACFD Boundaries

2.4 EWMP BMP Types

A variety of BMP types are defined in the EWMP Work Plans and NOIs. The following section provides an overview of non-structural and structural BMP types that will be part of the EWMPs. This section also includes a summary of planned and ongoing projects listed in the EWMP Work Plans for each BMP type to provide information on the anticipated scale, construction methods, and general locations of these BMP types. Additional information and figures on the location and distribution of potential and priority BMPs based on available data at the time of publication of this PEIR, are presented in Section 2.5*, EWMP Watershed Characteristics and BMP Implementation Strategies*.

2.4.1 Non-Structural Control Measures/Institutional BMPs

These are policies, actions, and activities which are intended to minimize or eliminate pollutant sources. Most institutional BMPs are implemented to meet Minimum Control Measure (MCM) requirements in the MS4 permit; MCMs are considered a subset of institutional BMPs. These BMPs are not constructed, but may have costs associated with the procurement and installation of items such as signage or spill response kits. The MS4 Permit categorizes institutional BMPs into six program categories:

- ***Development Construction Programs***, which establish standards for stormwater management from construction sites of all sizes (e.g., with or without a stormwater pollution prevention plan [SWPPP]).
- ***Industrial/Commercial Facilities Programs***, which establish standards for pollutant reduction and control measures at industrial and commercial facilities.
- ***Illicit Connection and Illicit Discharges (IC/ID) Detection and Elimination Programs***, which describe procedures for identifying, eliminating, and reporting illicit connections and discharges to the stormwater system.
- ***Public Agency Activities Programs***, which describe a broad range of municipal practices such as street cleaning, landscape management, storm drain operation, and more.
- ***Planning and Land Development Programs***, which encourage the application of smart growth and low-impact development (LID) practices to development and redevelopment projects.
- ***Public Information and Participation Programs***, which educate and engage the public on a broad range of pollution- and stormwater-related issues.

Permittees can evaluate the MCMs, identify potential modifications that will address water quality priorities, and provide justification for modification or elimination of any MCM that is determined to be ineffective (with the exception of the Planning and Land Development Program, which may not be eliminated or modified). MCM customization may include replacement, reduced implementation, augmented implementation, focused implementation, or elimination.

Because the LACFCD has limited jurisdictional authority for ordinance and code enactment or enforcement, it is limited in application of MCMs to activities such as public information and participation programs.

2.4.2 Structural Control Measures/Structural BMPs – General BMP Types and Categories

Structural control measures are constructed BMPs that reduce the impact of stormwater and non-stormwater on receiving water quality. They are broken into three categories:

- ***Distributed Structural BMPs***, which treat runoff close to the source and typically implemented at a single- or few-parcel level (e.g., facilities typically serving a contributing area less than one acre).
- ***Centralized Structural BMPs***, which treat runoff from a contributing area of multiple parcels (e.g., facilities typically serving a contributing area on the order of tens or hundreds of acres or larger).
- ***Regional Structural BMPs***, which are meant to retain the 85th percentile storm over 24 hours from a contributing area. Generally, the 85th percentile storm is approximately 0.75 inches over 24 hours

Whether distributed, centralized, or regional, the major structural BMP functions are infiltration, treatment, and storage that may be used individually or combination:

- ***Infiltration,*** where runoff is directed to percolate into the underlying soils. Infiltration generally reduces the volume of runoff and increases groundwater recharge.
- ***Treatment***, where pollutants are removed through various unit processes, including filtration, settling, sedimentation, sorption, straining, and biological or chemical transformations.
- ***Storage***, where runoff is captured, stored (detained), and slowly released into downstream waters. Storage can reduce the peak flow rate from a site, but does not directly reduce runoff volume.

The types of structural BMPs to be implemented will vary between EWMPs, but most EMWPs will include a variety of distributed, centralized, and regional BMPs.

Table 2-2 describes the sub-types of distributed, centralized, and regional structural BMPs that form the basis of the water quality improvements proposed in the EWMPs. The following sub-sections provide further description and examples of the BMP types and subcategories under the categories of distributed, centralized, and regional structural BMPs.

TABLE 2-2
TYPICAL STRUCTURAL BEST MANAGEMENT PRACTICES

Main BMP Category	BMP Types to be Assessed	Sub-types of BMPs
Distributed Structural BMPs	Site-scale detention	Dry detention basin Wet detention pond Detention chambers
	Green infrastructure/Low-impact development (LID)	Bioretention Biofiltration Permeable pavement Green streets Infiltration BMPs Bioswales Planter boxes Rainfall harvest
	Flow-through treatment BMPs	Debris booms/nets End-of-pipe nets Floating trash booms Hydrodynamic separators Water clarifiers Stormwater quality vaults
	Source control treatment BMPs	
Centralized Structural BMPs (do not retain the 85th percentile storm)	Infiltration BMPs	Surface infiltration BMPs (infiltration basins, infiltration trenches, infiltration galleries, bioretention, permeable pavement – implemented as single or multiple types), subsurface infiltration galleries Multi-directional infiltration BMPs (dry wells, hybrid bioretention and dry wells)
	Capture and use BMPs	Underground cisterns, storage and use as irrigation
	Bioinfiltration BMPs	Generally implemented as multiple types for regional BMPs: Bioretention with underdrain, bioinfiltration, high-flow biotreatment and raised underdrain, vegetated swales, filter strips
	Detention (promote settling out of larger particles)	Aboveground, belowground
	Treatment facilities (capture, storage and treatment-train)	
	Low-flow diversion (dry-weather flow and low-flow storm events)	
	Engineered/constructed wetlands	Aboveground, belowground
	Creek/river/floodplain/estuary restoration	
	Multi-benefit flood management project	
Regional Structural BMPs (retain the 85th percentile storm)	Infiltration	Surface infiltration BMPs: Infiltration basins, infiltration trenches, infiltration galleries, and bioretention-implemented as single or multiple types Multidirectional infiltration BMPs: Dry wells, hybrid bioretention, and dry wells
	Capture and use BMPs	Underground cisterns, storage, and use as irrigation

RB-AR 8257

2.4.3 Distributed Structural BMPs – Overview and Example BMPs

The following discussion presents an overview of various types of distributed BMPs and illustrates these further through example projects. The example project lists are based on existing and planned projects that will be part of the EWMPs. Included with each overview of the types of these BMPs is a discussion of the anticipated construction activities to implement these projects.

Because of their nature (intended to treat runoff at the parcel-scale), distributed BMPs are most likely to be implemented in high-density urban, commercial, industrial, and transportation areas, where they will either replace or improve upon existing stormwater infrastructure. These types of BMPs are generally "retrofit" type projects that replace existing impervious surfaces with pervious surfaces such as bioinfiltration cells, bioswales, porous pavement, and filter strips that tie into existing stormwater management systems as part of the MS4. These projects may also augment the existing MS4 with additional inlet screens, filter media systems, sediment removal systems, and diversions to sanitary sewer lines. Types of distributed structural BMPs are discussed in the following pages; the definitions and photographs of these BMPs are from the "Structural Fact Sheets" as presented in some EWMP Work Plans (e.g., Ballona Creek).

Site-scale detention. Site-scale detention facilities are designed to detain runoff from an individual parcel and improve water quality through pollutant settling. Site-scale detention facilities can reduce peak flows and improve water quality by storing water in a basin before slowly draining the water through an orifice to the downstream waterway. Settling of sediment and sediment-bound pollutants is the primary pollutant removal mechanism. There are two primary types of site-scale detention: *dry detention basin*s, in which runoff fully drains during storm events, and *wet detention ponds*, which capture water in a temporary storage zone above a permanent pool. Both types are illustrated in the following photographs..

Drv Detention Basin

Wet Detention Pond

Anticipated Construction Activities: The construction of detention basins typically requires the permanent removal of aboveground infrastructure and/or surface materials such as asphalt and concrete for retrofit type projects and excavation and grading for projects on soil-covered sites. Ground disturbance for distributed detention is typically less than 1 to 2 acres in extent, but may extend in some limited applications up to 5 acres where space is available. Site soils must be excavated to create the desired storage volume for stormwater. The depth of excavation will vary with available space, existing grades, and desired storage volume. For these smaller-scale systems, excavation is likely to be several feet and up to 10 feet. Generally, excavation below

6 feet is limited by the size of these systems and available space to provide adequate slope grading for safety and stability. Berms may be used to increase storage to reduce cost of excavation. Berms for these types of projects are several feet. Higher berms may be possible in some limited locations where space is available. Increasing berm height increases the footprint of these facilities to accommodate side slopes for safety and stability factors. On parcels where there is adequate room, soils may be placed on-site to balance cut and fill; smaller parcels may necessitate the off-hauling of excavated soils. Construction of dry detention basins in areas with high groundwater may limit the depth of the basins to meet minimum groundwater separation distances. The construction of dry detention basins may include the installation of recreational elements (nets, benches, etc.) so that the basins can serve as playing fields when not inundated. Wet detention ponds may require engineering (separate outlet structures with low-flow orifices, circulation elements, etc.) to ensure that the permanent pool does not become stagnant and a magnet for mosquito production (must be emptied within 72 hours). Detention basin includes berms and outlet structures that control the volume stored and the flow and velocity of the discharge.

Green infrastructure/Low-impact development (LID). This BMP category describes a broad range of development elements that aim to manage and treat stormwater as a resource, and minimize the differences between pre- and post-development hydrology. BMP subtypes in this category include:

- ***Bioretention and Biofiltration.*** *Bioretention* areas are shallow, depressed, vegetated basins with permeable soil media and no underdrains. Runoff temporarily ponds on the surface of these basins before filtering through the soil. *Biofiltration* areas are bioretention areas with underdrains. Infiltration is these systems is considered incidental, although substantial infiltration can occur in some unlined systems. Both systems are illustrated below; these examples use planted filter media and an underdrain to remove pollutants from stormwater.

Residential Bioretention

Bioretention in an Alley

Parking Lot Biofiltration

Anticipated Construction Activities: Similar to distributed detention basins, distributed bioretention and biofiltration BMPs would typically require the permanent removal of aboveground infrastructure and/or surface materials such as asphalt and concrete for retrofit type projects and excavation and grading for projects on soil covered sites. Ground disturbance for LID distributed BMPs is typically less than 1 to 2 acres in extent, but may extend in some limited applications up to 5 acres where space is available and where linear projects extend to adjacent parcels. The extent of land disturbance depends on the type of distributed BMP and may be more linear for bioswales and filter strips, compared to larger continuous areas for bioretention cells that store and then filter or infiltrate stormwater. In areas proposed for biofiltration without suitably permeable soils, native soils will have to be excavated, amended, and put back in place, or replaced entirely with biofiltration media (e.g., coarse gravels). The replacement of local soils would likely require that those soils then be hauled off-site. Systems with underdrains may require more extensive excavation and construction so that the underdrain can be connected to the MS4. The depth of excavation for these distributed systems will vary from several feet and up to 10 feet depending on the thickness and number of filter and storage layers. Generally, excavation is limited to 4 to 6 feet below existing grade for these systems.

- ***Permeable Pavement.*** Permeable pavement is a stable load-bearing surface that allows for stormwater infiltration. Beneath the permeable surface is a crushed-rock/ aggregate reservoir that provides structural support while allowing runoff to percolate to the underlying soils. Permeable pavement can be fully infiltrating or can have an underdrain like biofiltration practices. There are multiple types of permeable pavement; three are illustrated below. The mixes for *pervious concrete* and *porous asphalt* exclude fines from the aggregate to create permeable void space. Permeable interlocking *concrete pavers* allow infiltration of stormwater through joints between the blocks.

Pervious Concrete

Permeable Interlocking

Porous Asphalt

Anticipated Construction Activities: Similar to distributed bioretention and biofiltration BMPs, porous pavement BMPs would typically require the permanent removal of aboveground infrastructure and/or surface materials such as asphalt and concrete for retrofit type projects and excavation and grading for projects on soil covered sites. Porous pavement projects are generally retrofit type projects to increase infiltration and/or filtering of stormwater, but may include installation in new development and redevelopment, which may require clearing and grubbing activities prior to installation. Ground disturbance for these systems is typically less than 1 to 2 acres in extent, but may extend in some limited applications up to 5 acres where space is available. The depth of excavation for these distributed systems will vary from several feet and up to 6 feet depending on the thickness and number of structural support, filter, underground stormwater storage, and underdrain transmission layers. Systems with underdrains will require additional excavation. Generally, excavation is limited to 2 to 6 feet below existing grade for these systems. The installation of permeable pavement is frequently associated with the reconstruction of transportation elements such as parking lots, sidewalks, non-motorized paths, and related features.

- ***Green streets.*** Green streets are systems of multiple BMPs arranged in a linear fashion within the street right-of-way (as opposed to a parcel-based implementation). Green streets are designed to reduce runoff and improve water quality of runoff from the roadway and adjacent parcels by replacing impervious surfaces with more porous ones, and directing stormwater to vegetated systems that can filter and infiltrate stormwater. Bioretention, biofiltration, and permeable pavement BMPs are commonly used in conjunction and can be hydraulically connected using subsurface stone reservoirs. The examples below show curb cuts that direct stormwater from the parking areas and roadways to a bioswale designed to collect, filter, and infiltrate stormwater.

Green Street

Green Street

Anticipated Construction Activities: The installation of green street BMPs is similar to the construction activities that are summarized for the porous pavement and the LID-type distributed BMPs provided above as these include elements of both these types. These BMPs would typically require the permanent removal of aboveground infrastructure and/or surface materials such as asphalt and concrete for retrofit type projects and excavation and grading for projects on soil covered sites. Ground disturbance for green streets is typically less than 1 to 2 acres in extent, but may extend in some limited applications up to 5 acres where space is available and where these more linear projects extend to adjacent parcels. In areas proposed for biofiltration without suitably permeable soils, native soils will either have to be excavated, amended, and put back in place, or replaced entirely with biofiltration media (e.g. coarse gravels). The replacement of local soils would likely require that those soils then be hauled off-site. Systems with underdrains may require more extensive excavation and construction so that the underdrain can be connected to the MS4. The depth of excavation for these distributed systems will vary from several feet up to 6 feet depending on the thickness and number of filter and storage layers. Generally, excavation is limited to 4 feet below existing grade for these systems.

- ***Infiltration BMPs.*** Infiltration BMPs capture and infiltrate runoff into unvegetated underlying soils. Runoff is typically stored in subsurface trenches or vaults filled with engineered soil media, gravel, or concrete chambers. There are multiple types of infiltration BMPs, including: *dry/wet wells*, which are gravel-surrounded vaults with perforated walls that receive runoff form a pipe and allow it to infiltrate into the ground, and infiltration trenches, which are media-filled trenches that capture runoff in pore space prior to infiltration. These following pictures illustrate these types of BMPs.

Various Dry-Well Sizes(Source: www.peerlessconcrete.com)

Infiltration Trench

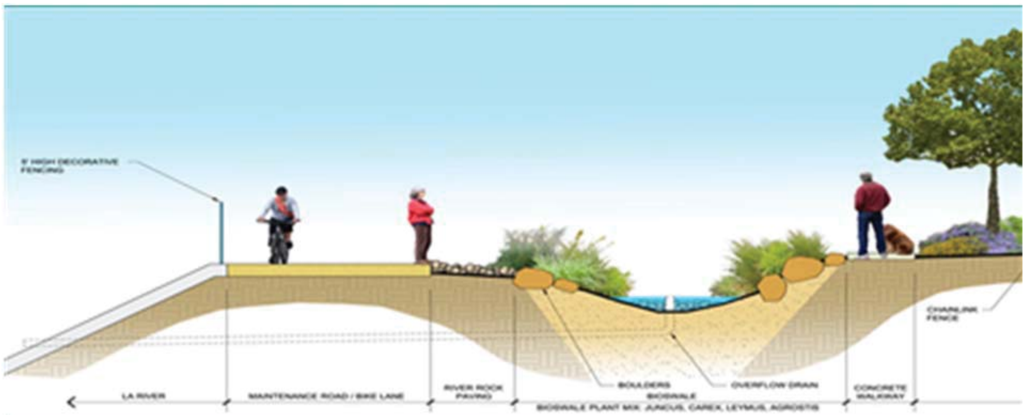
Infiltration Trench

Anticipated Construction Activities: The ground disturbance footprint necessary to install infiltration BMPs can vary depending on the project's size and location. As illustrated above, infiltration trenches tend to be linear features and as such typically have relatively small footprints (less than 1 acre) unless they are very long (e.g., associated with transportation upgrades – roads, rail corridors, etc.). Subsurface excavation is typically required to replace native soils with highly porous infiltration media, vaults or other subsurface storage structures that will retain runoff and allow it to infiltrate into the subsurface. Larger underground storage and infiltration structures will require greater depths and volume of excavation. These types of infiltration BMPs may disturb larger (2 to 3 acres) areas. Larger systems are designed for multi-parcels and are characterized as centralized BMPs rather than distributed BMPs that are for one to two parcels. Depth of excavation of infiltration BMPs will depend on the storage requirements and depth to groundwater. Minimum separation distances of 10 feet to groundwater are typical. Excavation for these distributed type infiltration projects is generally 2 to 4 feet for infiltration trenches and 4 to 8 feet for vault and dry well systems. Dry/wet wells require deeper excavation but are more localized and smaller in footprint.

- ***Bioswales.*** Bioswales are BMPs that convey storm flow through vegetated, shallow depressions to remove sediment-associated pollutants by settling and filtering mechanisms. Infiltration and filtration through soil media are not key components of bioswales; rather, bioswales are typically implemented to act as pretreatment and used to transport runoff to an associated bioretention cell or infiltration type of distributed BMP to provide additional pollutant removal and volume reduction. There are two primary types of bioswales: vegetated swales (which are linear), vegetated channels that convey concentrated flow to another structural BMP (detention, infiltration, storage), and vegetative filter strips (which are more broadly sloped than swales).

Vegetated Swale

Vegetative Filter Strip



Bioswale Integrated with Community Park/Trail

Anticipated Construction Activities: The construction of bioswales typically requires the removal and off-hauling of any impermeable surfaces within the bioswale footprint, and the regrading of site soils to facilitate drainage to the associated storage/infiltration BMP. Bioswales with more landscaping and natural contouring elements may have more complex grading.

- ***Planter Boxes.*** Planter boxes are bioretention systems enclosed in concrete structures. They are most commonly designed to drain runoff from paved areas or roofs. They are typically used in urbanize settings where space constraints limit the implementation of other LID elements such as bioswales and biorentention systems. Planter boxes may be designed to both filter and store runoff using a series of filter media and aggregate layers below the vegetated layers. They can be used in combination with rain barrels and cisterns that store the runoff and then direct it these boxes to filter the runoff.

  Anticipated Construction Activities: Construction activities associated with planter boxes will be in most cases much less than other types of distributed BMPs as the footprint of these BMPs are generally smaller and integrated into the construction and design of existing buildings and structures. The space saving advantages limits construction disturbance. Planter boxes for retrofit projects are generally fabricated off-site and installed after the ground surface is graded and prepared for the planters. Soil, filter media, and aggregate are generally brought to the site and placed in the planter boxes per the design requirements. Some excavation may be performed if portions of the planters

RB-AR 8263

are set below ground and connected to existing drainage pipes and MS4 through an underdrain system in the planter box.

- ***Rainfall Harvest.*** Rainfall harvesting improves water quality by intercepting rooftop runoff and lowering the overall impervious impact of a developed site. Runoff can be reduced through interception and evapotranspiration on green roofs or used for alternative uses with a cistern or rain barrel. There are multiple kinds of rainfall harvest mechanisms; two of the more common are *green roofs* and *cisterns/rain barrels*. Green roofs are engineered, vegetated roof structures meant to intercept rainfall within a plant growth medium. Cisterns and rain barrels are storage tanks used to intercept and store rooftop runoff for nonpotable use such as landscape irrigation or gradual infiltration.

Green Roof

Cistern

Anticipated Construction Activities: Similar to planter boxes, construction activities associated with green roofs and cisterns will be in most cases much less than other types of distributed BMPs as the footprint of these BMPs are generally smaller and integrated into the construction and design of existing buildings and structures. Construction activities associated with rainfall harvest systems tend to be minimal unless cisterns are placed underground, in which case subsurface excavation would be necessary. The depth and extent of excavation will depend on the size of the cisterns, but for single to several parcel distributed systems, the excavation will generally be limited to 4 to 6 feet and an area of less than an acre.

- ***Flow-Through Treatment BMPs.*** Manufactured flow-through devices are commercial products that aim to provide stormwater treatment using patented, innovative technologies. Typical types of manufactured devices for stormwater management include *cartridge/media filters* and *high-flow biotreatment devices*. Cartridge/media filters are proprietary filtration devices used to remove pollutants; high-flow biotreatment devices are modular, vault-type practices that contain high-flow media and typically incorporate vegetation.

Media/Cartridge Filter

High-Flow Biotreatment(Photo Source: Jonathan Page, NCSU-BAE)

Curb Inlet Biofilter

Anticipated Construction Activities: The construction activities necessary to install flow-through treatment BMPs can vary based on the location, size, and configuration of the BMP. These BMPs are generally installed as part of the MS4 within catch basins and curb inlets. Typically, flow-through BMPs have a relatively small footprint (< 1 ac) because they are designed to provide a higher rate of pollutant removal/transformation than less engineered approaches (e.g. infiltration trenches). Stormwater moves through most flow-through treatment BMPs via gravity flow. This may require expansion of existing catch basins or installation of new catch basin or vaults to intercept and direct storm flows to these treatment units and back into the MS4. This may then require limited subsurface excavation and off-hauling to create the below-grade space for the treatment device. The extent and volume of excavation is much less than LID, retention and Green Street projects.

- ***Source Control BMPs.*** Source control structural BMPs are commercial products designed to treat runoff in highly urbanized environments. Mechanical separation, or more complex physicochemical processes, provides separation of gross solids and other pollutants. Many models feature media or materials designed to sequester hydrocarbons and other pollutants. Two types of source control BMPs are illustrated below: *catch basin inserts*, which use nets, screens, fabric, or similar filtration media to separate sediment and gross solids from stormwater, and *hydrodynamic separators*, which use screens, baffles, or vertical flow to separate the two.

Catch Basin Insert

Hydrodynamic Separator

Connector Pipe Screen

Anticipated Construction Activities: Similar to flow-through devices, the construction activities necessary to construct source control BMPs can vary based on the location, size, and configuration of the BMP, but are generally less than other types of distributed BMPs. Source control measures such as catch basin inserts and connector pipe screens are typically installed as retrofits to the existing MS4 within catch basins and curb inlets, and generally do not result in an increased ground disturbance footprint. Hydrodynamic separators may require expansion of existing catch basins or installation of new catch basins or vaults to intercept and direct storm flows to these treatment units and back into the MS4. This may then require limited subsurface excavation and off-hauling to create the below-grade space for the treatment device. The extent and volume of excavation is much less than LID, retention and Green Street projects, and is usually limited to less than one acre.

Specific examples of distributed BMPs that are in various stages of planning and implementation and part of a possible EWMP are presented in **Table 2-3**. The locations of these examples of planned distributed BMPs are shown in **Figure 2-2**. Table 2-3 presents the locations, project description, and key elements of the distributed BMPs to further illustrate these types of structural BMPs that may be part of an EWMP. Additional information and figures on the location and distribution of potential and priority BMPs, where data is available, are presented in Section 2.5, *EWMP Watershed Characteristics and BMP Implementation Strategies*.

RB-AR 8266

EXAMPLES OF PLANNED OR INSTALLED DISTRIBUTED BMP PROJECTS

Photo	Status of Project	Project Description	Project: Treatment	Project: Recharge/ Infiltration	Project: Storage	Project: Habitat Restoration	Project: Water conservation/ Reuse
DL Implementation 	Installation of catch basin covers began the summer of 2013.	This project primarily proposes the installation of catch basin (CB) opening screen covers and inserts in those structures found in the Santa Monica Bay, Machado Lake, and Dominguez Channel watersheds of the City of Los Angeles. The CB opening screen covers are coarse screens that are installed in the CB openings and prevent trash from entering the storm drain system. Each CB opening screen cover has a self-opening device activated by a predetermined street gutter flow to disengage its locking mechanism. The CB inserts are perforated screens that are installed inside the CB in front of the outlet pipe of the catch basin.	●				
gation Control System 	Unknown	This project calls for the installation of a smart irrigation control system using evapotranspiration technology. This system would be put into place at all City of Calabasas-owned facilities, street medians, and parkways. This project will reduce irrigation run off and prevents pollutants from reaching the receiving waters. Replacement of irrigation controllers is projected to provide regional benefits by reducing urban runoff that is associated with nutrient loaded recycled water used for irrigation and will reduce discharges of other pollutants to the MS4 system carried by overwatering of landscaped areas. The City uses 66,431 gallons of water on annual basis for landscape irrigation. It's anticipated that with the new system, the City will save between 13,300 to 16,600 gallons of water. It will translate to approximately 5,000 to 7,000 gallon of reduction in run-off.					●

Photo	Status of Project	Project Description	Project				
			Treatment	Recharge/ Infiltration	Storage	Habitat Restoration	Water conservation/ Reuse
m Drain Improvements 	Construction work on the Wildlife Road Storm Drain Improvements project was scheduled to begin March 2014 and continue through August 2014.	This project is located within a developed residential neighborhood. Two existing storm drain inlets, SD-1 and SD-2 are located on Whitesands Place and Wildlife Road in the City of Malibu. The Project consists of the installation of bioretention swales and biofilters within the City Right of Way, treating stormwater and urban runoff prior to the entering of flows into City-owned catch basins. Due to the limited about of space within the City's Right of Way, the project will include a combination of bioretention swales and biofilters.	●				
Center RB-AR 8268 	Completion anticipated June 2015	The Model Equestrian Center project will use the existing municipal Peter Weber Equestrian Center, a 7.5-acre facility that houses 116 horses, to create a public demonstration site for environmentally sustainable horse-keeping practices while improving the quality of stormwater and other runoff. This project will be divided into two parts. Part A of this project will involve retrofits of the existing equestrian facilities to improve drainage and stormwater runoff quality. These retrofits will include downspout redirection, drainage correction from existing horse stalls, bioswale or similar water quality treatment system installation, cover for daily manure storage, and drainage improvements to existing arenas and the overall site. Water quality will be improved by providing a permanent cover for daily manure storage, directing runoff away from areas where horses are kept, and bioswales will provide stormwater treatment by filtering large particles in the swale and removing smaller particles and associated contaminants through the bioretention portion provided by the vegetation. Part B of this project involves new construction. A new 15,000-square-foot barn and associated improvements will be constructed on the 2.5-acre northwest portion of the site. Key water quality features will include a covered horse wash area with wash water captured and reused for subsurface irrigation to maintain appearance of habitat buffers and treatment bioswales, manure management to control vectors, odors and runoff, and a cistern or rain barrels to collect rainfall from the barn roof for use in irrigation. In addition, the facility will use low-impact development (LID) and green building techniques, integrated pest management through structural design, and equine-safe native and drought-proof plant buffers. Interpretive signage will demonstrate and educate the equestrian community on how the BMPs protect and improve stormwater quality. This signage will be installed to educate horse boarders and visitors on the specific BMPs integrated into the facilities and on the site.	●				●
d Green Street Improvements Project 	Construction Spring 2014 to Fall 2014	The project will reconstruct approximately 0.16 miles of roadway on Green Street and 0.39 miles on Brandon Street. The design includes several green street elements including permeable pavers, bio-retention planters, sediment filtration catch basins, and an underground infiltration basin. Much of the runoff from the streets and private properties that would have otherwise drained to the Rio Hondo will be directed to the infiltration area.	●	●			●

Photo	Status of Project	Project Description	Treatment	Recharge/ Infiltration	Storage	Habitat Restoration	Water conservation/ Reuse
s Multiuse Trail Project 	Constructed	The project will construct multiuse trails to provide a safer route to equestrian, bicycle, and pedestrian users away from existing traffic hazards. The majority of the existing roadway width will be reduced from 40 to 36 feet, thereby reducing the amount of impermeable surfaces as well as runoff. Approximately 2,300 feet of the multiuse trail on 5th Avenue will be constructed with decomposed granite to provide 14,000 cubic feet of infiltration capacity. In addition, an infiltration swale will be constructed at the end of 5th Avenue immediately adjacent to San Jose Creek to provide 3,200 cubic feet of capacity. Combined together, up to 115 acre-feet of groundwater will be recharged annually.	●	●	●		
MPs 	Planned Implementation Date July 2015	Trash removal BMPs for 79 storm drains in a commercial/industrial park (County of LA) and 110 storm drain inlets in a commercial/industrial park (City of Santa Clarita).	●

Figure 2-2
Location of Example Planned and Installed Distributed BMP Projects

2.4.4 Centralized Structural BMPs

Centralized structural BMPs use similar elements to the LID, infiltration and biofiltration type BMP used in distributed structural BMPs, but collect, store, treat and filter stormwater from multiple parcels and much larger drainage areas. Centralized BMPs also include diversion and treatment type BMPs that use similar technologies for these types of BMPs under distributed BMPs, but can be implemented on a much larger scale collecting, diverting and treating urban runoff (dry-weather flows) or limited stormwater flows from multiple parcels and large drainage areas. Therefore, centralized structural BMPs require greater footprints for construction and implementation, but provide a greater potential for water quality improvement through the filtering, treatment and/or infiltration of greater volume and rates of stormwater and urban runoff. Centralized BMPs that include storage and infiltration or storage and use have similar functions and construction methods to regional BMPs using the same stormwater management elements. However, regional BMPs have the distinct requirement per the Permit to retain on-site the 85th percentile 24-hour storm event for the drainage area served by the BMP (i.e., in the Los Angeles area, the 85th percentile storm is around 0.75 inch of rain in a 24-hour period). Finally, centralized BMPs include two unique BMP types, treatment wetlands and stream/creek restoration projects. Unlike the other structural BMP types described, these BMPs use natural systems to filter and clean the water. Treatment wetlands are typically off-line treatment systems that are not in the receiving waters, but may have habitat benefits through the establishment of more native plants and ecosystems. Creek, river, and estuary restoration projects provide a unique opportunity to restore natural cleansing processes, reestablish habitats and address impacts from hydromodification and urban runoff. These projects are the only BMPs that are implemented within the receiving water. Types of centralized structural BMPs and the definitions for these BMPs (which were taken from Los Angeles Department of Public Works' "Structural Fact Sheets") include the following:

- ***Infiltration BMPs.*** Infiltration facilities are designed to decrease runoff volume through groundwater recharge and improve water quality through filtration and sorption. Facilities can incorporate engineered media to improve percolation into native soils. Infiltration facilities can be *open-surface basins* or *subsurface galleries* (see the following photographs). Surface infiltration basins can be vegetated to encourage evapotranspiration and aesthetics; subsurface infiltration galleries are often used when limited land is available for BMP implementation. An example of a centralized infiltration BMP is the infiltration gallery that was installed as part of the Elmer Avenue Neighborhood Retrofit Project in Los Angeles. The project includes two infiltration galleries capable of infiltrating over 1,300 gallons a minute from a 40-acre drainage area (CWH 2014). Catch basins divert stormwater to the infiltration galleries, while bioswales capture and treat additional urban runoff.

Surface Infiltration Basin

Subsurface Infiltration Gallery

Anticipated Construction Activities: Centralized infiltration facilities are generally larger than distributed BMPs and can vary from 2 to 10 acres in size, depending on the number of parcels (drainage area). Subsurface excavation is typically required to replace native soils with highly porous infiltration media, vaults or other subsurface storage structures that will retain runoff and allow it to infiltrate into the subsurface. Larger underground storage and infiltration structures will require greater depths and volume of excavation. Depth of excavation of infiltration BMPs will depend on the storage requirements and depth to groundwater. Minimum separation distances of 10 feet to groundwater are typical. Excavation for these centralized infiltration project is generally 2 to 6 feet for surface infiltration and 4 to 10 feet for vault or infiltration gallery systems. Excavated soils must also be off-hauled unless the site is of an adequate size to allow balancing of cut and fill on-site. Subsurface infiltration galleries require that subsurface soils be excavated and replaced with highly permeable structures that rapidly infiltrate stormwater. These structures are typically transported to the site on flatbed trucks and then lowered into the ground using specialized cranes and related equipment. Subsurface infiltration galleries also require pretreatment facilities to remove sediment and debris prior to entering the galleries or vaults to reduce the potential for clogging. These systems increase the project footprint and required excavation by 25 to 50 percent of the vault footprint.

- ***Capture and Use BMPs.*** Capture and use BMPs capture stormwater runoff and store it for later use, typically as irrigation water. An example of a centralized capture and use BMP is the cistern at the Tuxford Green Project in Los Angeles. The cistern can hold up to 45,000 gallons of treated stormwater, which is then used to irrigate native landscaping.

  Anticipated Construction Activities: The construction activities for these BMPs are similar to those summarized for the infiltration galleries above with the exception that these galleries and vaults are designed to retain and reuse (not infiltrate) the stormwater. In addition to the anticipated ground surface disturbance and excavation for the installation of the underground storage units, these systems also require a pre- and post-treatment system that generally consist of additional and more sophisticated treatment steps and thereby a larger footprint. In addition, these systems need to be connected to a distribution system for the treated water that can be used for irrigation or for grey water or groundwater recharge systems. This additional infrastructure will require additional construction grading, excavation, and transportation of materials and equipment on--- and off-site.

- ***Bioinfiltration BMPs.*** Centralized bioinfiltration BMPs are a larger-scale version of their distributed counterpart, and typically incorporate elements of both infiltration (using native soils or underdrains) and treatment (using vegetated swales or filter strips).

  Anticipated Construction Activities: Bioretention and biofiltration BMPs typically require the permanent removal of aboveground infrastructure and/or surface materials such as asphalt and concrete for retrofit type projects and excavation and grading for projects on soil covered sites. Ground disturbance for bioinfiltration centralized BMPs is typically 2 to 5 acres in extent, but may extend in some limited applications up to 10 acres where space is available. The extent of land disturbance depends on the type of BMP and may be more linear for bioswales and filter strips, compared to larger continuous areas for bioretention cells that store and then filter or infiltrate stormwater. In areas proposed for biofiltration without suitably permeable soils, native soils will either have to be excavated, amended, and put back in place, or replaced entirely with biofiltration media (e.g., coarse gravels). The replacement of local soils would likely require that those soils then be hauled off-site. Systems with underdrains may require more extensive excavation and construction so that the underdrain can be connected to the MS4. The depth of excavation for these distributed systems will vary from several feet to up to 10 feet depending on the thickness and number of filter and storage layers. Generally, excavation is limited to 4 to 6 feet below existing grade for these systems.

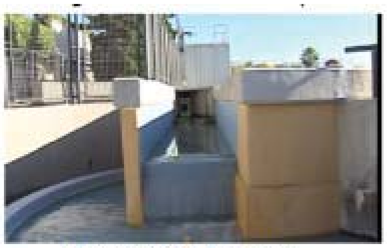
- ***Detention BMPs.*** Centralized detention facilities are designed to detain runoff and improve water quality through pollutant settling. Facilities encourage settling by decreasing runoff flow rates and allowing ponding to occur. Detention facilities can be open-surface practices or subsurface galleries and can be dry during non-rainy seasons or wet year-round. *Surface detention basins* are designed to detain stormwater runoff for a specified amount of time so that particle-bound pollutants can settle. *Subsurface detention galleries* are underground storage systems designed to detain water in areas where limited land is available for BMP implementation.

Surface Detention Basin

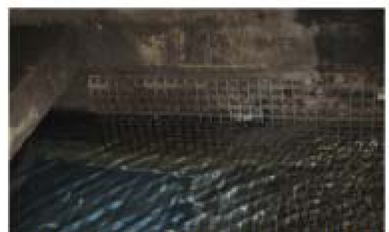
Subsurface Detention Gallery

  Anticipated Construction Activities: Centralized detention facilities can range from between an acre to 5 acres in size, and up to 10 acres. Surface detention basins require the removal and off-hauling of surface armoring and infrastructure, as well as the excavation of adequate soil to create the target storage volume. Excavated soils may either be balanced on-site or hauled off-site; the latter is more likely in most cases due to the larger size of centralized basins. Surface detention basins may in some cases be utilized as recreational facilities during the dry season, allowing for the installation of features such as athletic fields and benches. Subsurface detention galleries require the excavation of native soils and their replacement with engineered structures that detain water underground. The construction and installation of these structures can be complex and require the use of specialized cranes and related construction equipment.

- ***Treatment Facilities and Low-Flow Diversions.*** Other centralized water quality technology falls into the *low-flow diversion* (LFD) and *treatment facilities* subcategories. LFDs reduce stormwater pollution by diverting a design flow rate to a sanitary sewer for treatment. Treatment facilities convey stormwater through a physical, chemical, or radiological treatment system before returning it to the original channel, or diverting it for beneficial reuse. Below are photographs of an example LFD. LFDs may include on-site treatment of the diversion low flows prior to discharge back into the storm drain, or diversion to a local wastewater treatment plant. The LFD that has been installed at Marie Canyon in Malibu, shown in the photographs below, has an on-site treatment facility to reduce indicator bacteria concentrations prior to discharge back into the storm drain. This LFD is designed to filter and treat as much as 100 gallons per minute of dry-weather flows (Los Angeles Department of Public Works, 2007).



Treatment Facility



Low-Flow Diversion Dam and Inlet in a Storm Drain

Marie Canyon Low-Flow Diversion – Flat Gate Diverting flow to treatment unit for bacteria

Anticipated Construction Activities: Low-flow diversions and treatment facilities usually have a relatively small footprint of less than 2 acres. Construction typically requires subsurface excavation and off-haul of excavated soils in order to create adequate room for the subsurface engineered structures. The installation of these BMPs can often be complex due to the need to retrofit existing stormwater infrastructure and, in the case of LFDs, connect to active wastewater treatment infrastructure.

- ***Constructed Wetlands.*** Constructed wetlands are engineered, shallow-marsh systems designed to control and treat stormwater runoff. Particle-bound pollutants are removed through settling, and other pollutants are removed through adsorption and biogeochemical transformation. Constructed wetlands must always maintain a baseflow into the system, which can come from an intersected groundwater or an associated LFD using dry-weather flows. There are two primary types of constructed treatment wetlands: *wetland basins*, which have shallow permanent pools and outlet structures that regulate dewatering, and *flow-through/linear wetlands*, which are typically constructed parallel to existing channels so water can be easily diverted in/out of the wetland. An example of a treatment wetland includes the South LA Wetland Park, which will use an approximately 4.5-acre constructed wetland to treat a portion of the runoff from a 525-acre tributary watershed.

Wetland Basin

Flow-Through/Linear Wetland

Anticipated Construction Activities: Due to their multi-benefit nature and their ability to provide significant habitat benefits (most wetlands within the Los Angeles Basin have been lost to development and urbanization), most constructed wetland projects are greater than 5 acres in size and may be up to 10 acres or larger. Typical constructed wetland projects require extensive grading of site soils, though excavated soils are often balanced on-site to provide material for levees, berms, ecotones, and other flood control/habitat features. Many constructed wetland projects require the construction/installation of water control structures such as screw gates and culverts to manage how water is directed into, out of, and through the wetland. Constructed wetlands are often actively planted to accelerate the establishment of mature wetland vegetation and resultant stormwater treatment.

- ***Creek/River/Floodplain/Estuary Restoration.*** This category includes multi-benefit projects that typically combine elements of habitat restoration for fish and wildlife as well as flood management and water quality improvement. Project components such as setback levees, floodplain bench excavation, levee breaches, and other actions can increase the flood storage capacity of a water body and thereby slow flow rates. An example of a multi-benefit creek restoration project is the Tujunga Wash Greenway and Stream Restoration Project in Los Angeles. This project restored 1.2 miles of natural-bottomed creek habitats, which are capable of infiltrating up to 118 million gallons of stormwater form the wash into the local groundwater aquifer. Plants in the wash also aid the biogeochemical removal of pollutants such as nitrogen.

Before and After – Tujunga Wash Greenway Restoration Project

Anticipated Construction Activities: These projects may require ground disturbance and construction to convert lined flood channels into more naturalized creek/river systems. Projects are typically greater than 5 acres in size, and many have footprints of over 10 acres. This category of BMP may require removal and off-hauling of concrete and asphalt, grading/excavation/off-hauling of site soils (particularly if contaminants are present, since they could pose a threat to the health of fish and wildlife), the construction of elements such as setback levees and water control structures, and active revegetation with native plants. Projects that aim to enhance habitats within more naturalized settings (e.g., floodplain expansion along an unarmored/channelized creek) would have to account for the potential for construction to disturb existing natural communities, and incorporate appropriate impact avoidance/minimization/mitigation measures, though most projects are designed to be self-mitigating.

- ***Multi-benefit flood management projects.*** This category includes a broad range of redevelopment, transit, transportation improvement, and related projects that are designed to result in direct or indirect benefits to flood management. For example, greenway projects such as the Tujunga Wash Greenway project that incorporates infiltration and/or detention elements can improve flood management by reducing stormwater flow rates and/or volumes.

  Construction Impacts. Multi-benefit flood management projects are typically expansive projects that range from a few to tens of acres in size. Construction requirements can vary extensively based on the nature of the project. Because of their scale, multi-benefit flood management projects usually require extensive excavation and grading of site soils, off-hauling of soils and related materials, utility relocation, infrastructure construction, and related activities. It is not uncommon for these types of projects to be constructed over multiple construction seasons.

Specific examples of centralized BMPs that are in various stages of planning and implementation and are part of the EWMP are presented in **Table 2-4**. The locations of these examples of planned and implemented centralized BMP are shown in **Figure 2-3**. Table 2-4 presents the location, project description and key elements of the centralized BMPs to further illustrate these types of structural BMPs that are part of the EWMP. Additional information and figures on the location and distribution of potential and priority BMPs, where data is available, are presented in Section 2.5, *EWMP Watershed Characteristics and BMP Implementation Strategies*.

EXAMPLES OF PLANNED CENTRALIZED BMP PROJECTS

oto	Status of Project	Project Description	Project: Treatment	Recharge/ Infiltration	Storage	Habitat Restoration	Water conservation/ Reuse
sta Recreation Center Stormwater BMP 	Phase II is expected to be completed by December 2014.	The Phase II project components are expected remove 6,000 gallons per day (5.5 acre-ft/year) of stormwater and provide additional storage space for the underground cisterns that were constructed during Phase I. Phase I facilities include : 1) storm drain diversion structure; 2) trash maintenance hole; 3) stormwater lift station; 4) hydrodynamic separator; 5) 270,000-gallon underground detention tank; 6) disinfection facility; 7) overflow/return piping; and 8) pump and control systems. Phase I was completed and is operational at limited capacity. Phase II includes the following stormwater beneficial reuse components: • Stormwater drip irrigation system for 43 shrubs, 86 bushes, and 68 trees • Installation of an irrigation pump station and associated components • Creation of 3,800 square feet of plant community • Installation of back-flow prevention system • Construction of flow containment curbs The objective of Phase II is to include an irrigation system to beneficially use the treated water at the park, to increase the treatment capacity of the facility and associated pollutant load reductions and to conduct a facility optimization project to fine-tune the grey and green infrastructure components of the project and optimize overall performance of the facility.	●		●		●
enbelt Infiltration System  	The project construction was completed February 19, 2013.	The Manhattan Beach Greenbelt Infiltration project was designed to utilize the linear greenbelt parkland which runs through the City of Manhattan Beach to intercept and infiltrate dry-weather and wet-weather low flows from existing storm drains that cross or abut the parkway. Low flows from a 50-acre drainage area are screened to remove trash and gross solids before flowing by gravity to a subsurface infiltration system which also provides limited storage of storm flows for subsequent percolation into the sandy soils below the greenbelt. The Greenbelt Low Flow Infiltration system was designed to effectively divert dry-weather and wet-weather low flows from the storm drain system year round.	●	●	●		

...oto	Status of Project	Project Description	Treatment	Recharge/ Infiltration	Storage	Habitat Restoration	Water conservation/
...se Enhancement Project 	LACFCD anticipates the project to commence construction by the end of this year or early 2015.	The project involves removing approximately 3,000 cubic yards of accumulated contaminated sediment from the bottom of Oxford Basin, constructing a berm in the center of Oxford Basin to enhance water quality through circulation, planting new native or drought-resistant plants, and installing new bioswales. The proposed berm that will be installed to improve circulation, in conjunction with the reprogramming of the operating cycles of the existing tide gates, will maximize the circulation of the water around the berm during the daily tidal cycles. During a rising tide, the water will enter via one of the tide gates on one side of the new berm, circulate around Oxford Basin, and then exit via a second tide gate during a falling tide. This innovative approach to improving water quality through circulation will increase dissolved-oxygen levels in the water within Oxford Basin, which is expected to result in less algae growth, lower bacteria levels, and reduction of unpleasant odors. The proposed project will also implement Low-Impact Development features to reduce the impacts of the existing roads adjacent to Oxford Basin. The project's Low-Impact Development features include a bioswale along the bike path at Washington Boulevard to collect surface runoff and two bioretention systems along Admiralty Way to collect local runoff from the roadway. The project will also enhance recreational opportunities for visitors through the installation of observation areas and decks, interpretive signage, a lighted walking/jogging path, and fencing that will provide enhanced viewing of the improved habitat.	●			●	
...rovements  	Construction of the proposed improvements is expected to commence either Spring 2015 or early Summer 2015.	The project is part of an overall City of Westlake Village streetscape improvement project that creates infiltration and urban pollutant mitigation opportunities along all arterial medians and parkways. This parkway project is 30 foot wide by over a mile long. Half of this parkway was originally a flood control maintenance road and the other half a landscaped area. This project will have a Riparian Zone theme. With the new project, the combined width of the old maintenance road and landscaped area, this area will become a new walking path where there is currently no sidewalk. This project, when completed, will provide a long and meandering walking path with conversation seating areas. This project will also include drainage facilities that will include specific BMP's. The newly renovated area will be drained via bio-swales throughout the entire length of the project. These swales will meander thru the entire length with the main goal of percolation and evaporation of all nuisance flows throughout the year. Stormwater runoff would then be treated in the bio-swale followed by discharge into Westlake Lake. This project will also have educational signage on a riparian zone and the stormwater cleanup objectives of this project.	●			●	

RB-AR 8280

oto	Status of Project	Project Description	Project				
			Treatment	Recharge/ Infiltration	Storage	Habitat Restoration	Water conservation/ Reuse
tion Project 	January 2014 (Commencement of Construction) June 2014 (Completion)	The Project consists of the installation of different types of biofilters at nine catch basins within the City of Malibu Right of Way, treating stormwater and urban runoff prior to the entering of flows into City-owned catch basins, which discharge to privately owned storm drain systems. The Project includes a combination of biofilters, and flow control, with potential to incorporate harvest and use systems for Malibu drains. Three types of biofilters are contemplated; small footprint biofilters, biofilters with volume control, and harvest and use systems.	●				●
Stormwater Flood Reduction Project 	Anticipated to be completed June 2015.	The San Ramon Canyon provides a natural drainage course for areas near Palos Verdes Drive East. Because of the geographical characteristics of the San Ramon Canyon, landslide induced rock and soil deposits in the canyon bottom are transported during heavy rainfall events. This creates flooding of the roadway, overwhelming existing drainage facilities, endangering nearby roadway integrity and threatening downstream residents. The San Ramon Canyon Stormwater Flood Reduction Project, involves significant drainage restoration work to stabilize Palos Verdes Drive East and Palos Verdes Drive South.					
are/Transit Village Multi-Benefit Park and 	Planned Implementation Date Spring 2015.	This project will include design and development of a 2.5-acre multi-benefit green space along the future Metro Gold Line Foothill Extension. The project includes a multi-use trail, native trees and shrubs, runoff storage and infiltration systems prior to discharging into Sawpit Wash and Peck Road Water Conservation Park to the south.	●	●	●		

...oto	Status of Project	Project Description	Treatment	Recharge/ Infiltration	Storage	Habitat Restoration	Water conservation/ Reuse
...ration Project	Planned Implementation Date Spring 2016.	The City of Azusa in coordination with the Foothill Construction Authority for the Gold Line Project has constructed infiltration systems at some of the major crossings in town. Infiltration will occur at the catch basins which are soft bottom. Anticipated tributary areas are approximately 17 acres and will include the rail corridor. The 10 year storm event is to be infiltrated.		●	●		
...y Improvement Project (Phase I and Phase 	Phase II – expected completion by Spring 2015.	Phase II of the Penmar project is expected to supply approximately 34.7 million gallons of treated water per year for irrigation of Penmar Golf Course and the Penmar Park & Recreation Center in the City of Los Angeles and the Marine Park in the City of Santa Monica. Replacing this volume of potable water with treated storm water produced in Phase II provides 34.7 million gallons per year increase to annual runoff diversion capacity of Phase I, resulting in a significant pollutant load reduction into the Santa Monica Bay. Phase II entails the incorporation of the reuse component of the project offering additional water quality benefits as well as multi-regional benefits. By installing the reuse option, the overall project capacity will increase, thereby also increasing the volume of urban runoff that can be retained by the project for use as an alternative source of water to potable water for landscape irrigation.	●				●
...Project 	Under Construction	This project will intercept an existing storm drain system and construct a stormwater greenway with a “stream” eco-system through the corridor on Humboldt Street with a pedestrian path connecting Avenue 18 and Avenue 19. The project is adjacent to the Los Angeles River, just north of Civic Center area of the City of Los Angeles. The bioremediation elements include a pollution reduction/infiltration system and an approximately 175-foot-long graded swale/open-channel, which is surrounded by a vegetated basin. Work also includes a) an overflow structure; b) a pedestrian bridge; c) an irrigation system; d) landscaping and tree planting; and e) solar lighting.	●	●			●

Figure 2-3
Location of Example Planned and Installed Centralized BMP Projects

2.4.5 Regional Structural BMPs

Regional structural BMPs are those that can capture the volume of water from an 85th percentile, 24-hr storm in a contributing watershed, known as the *design volume (*Generally, the 85th percentile storm is approximately 0.75 inches over 24 hours). The two types of regional BMPs are retention/infiltration and capture and use, though many regional projects would incorporate more than one BMP type. The definitions of these BMPs are the same as for centralized BMPs with the exception that they can capture the design volume. Like centralized BMPs, regional BMPs can be implemented in a broad range of land use types, from high-density urban to open space, and can have multiple benefits (e.g. habitat, recreation, aesthetics). An additional example of a multi-benefit/multi-type regional BMP is the suite of improvements being made to Sun Valley Park in Los Angeles. The project's BMPs improve stormwater quality and alleviate local flooding by collecting runoff from a 21-acre drainage area, routing it through flow-through treatment units (hydrodynamic separators and settling units) to remove suspended solids and heavy metals, and directing it into two underground infiltration galleries buried beneath soccer and baseball fields. Bioswales at the site treat local runoff and are vegetated with native plants.

Sun Valley Park Regional Infiltration Project – (from upper left to lower right) Storm water Pre-Treatment Devices to Remove Trash and Sediment / Bioswale and Bioretention Area / Construction of Underground Storage and Infiltration Vaults

Anticipated Construction Activities: The construction activities for regional BMPs are generally similar to those of their centralized counterparts, with the exception of regional retention BMPs, which must have adequate storage capacity to hold runoff from the design storm. The need for this capacity will generally result in more extensive excavation and off-hauling of site soils. Larger, multi-benefit regional BMPs are similar to centralized multi-benefit regional flood management projects (above) that their scale and complexity often requires an intensive construction effort executed over multiple seasons.

Specific examples of regional BMPs that are in various stages of planning that are part of the EWMP are presented in **Table 2-5.** The locations of these examples of regional BMPs are shown in **Figure 2-5**. Table 2-5 presents the location, project description, and key elements of the regional BMPs to further illustrate these types of structural BMPs that are concepts being developed through the EWMP process. Additional information and figures on the location and distribution of potential and priority BMPs, where data is available, are presented in Section 2.5, *EWMP Watershed Characteristics and BMP Implementation Strategies*.

			Treatment	Recharge/ Infiltration	Storage	Habitat Restoration	Water conservation/ Reuse
water Basin Recharge and Enhancement 	Construction was scheduled for Spring 2014.	The Torrance Stormwater Basin Recharge and Enhancement Project will retrofit three existing detention basins serving 1,453 acres of drainage area in total within the City of Torrance. The project will use a number of BMPs to conserve water, recharge the aquifer, create critical habitat, and improve stormwater quality that discharges into the Santa Monica Bay, and eliminate non-stormwater discharges to the Dominguez Channel. This Stormwater Basin Recharge and Enhancement project proposes significant advances over the current system by providing wetland treatment of stormwater and non-stormwater runoff at the detention basins, recharging vitally needed groundwater supplies, and sustaining wetland habitat during the dry season in the basins. The Project will eliminate dry-weather runoff and associated load for multiple pollutants. The Project will treat all stormwater from 1,453 acres for multiple pollutants, including priority pollutants such as trash and sediments by a combination of wetland treatment and infiltration. The project will capture and recharge an estimated 20 acre feet per year of runoff that would have otherwise been discharged to the Santa Monica Bay. The project will enable the elimination of all discharges from the drainage area to Dominguez Channel, will eliminate dry-weather discharges to Santa Monica Bay and will reduce the wet-weather discharge to the Santa Monica Bay from this system.	●	●	●	●	●
rk Pump Station Improvements 	Anticipated to be completed June 2015.	Malibu Legacy Park is a regional project that provides water quality and water resources benefits. The project exceeds requirements to put over 300 acres of Malibu (including City Hall) into full compliance with Malibu Creek Bacteria TMDL requirements, providing a capture volume consistent with Los Angeles Standard Urban Stormwater Mitigation Plan requirements (assuming no upstream LID or source control measures). Captured water is managed, disinfected, and used to offset potable water uses for park irrigation.	●	●	●		●

Figure 2-4
Location of Example Planned and Installed Regional BMP Projects

2.5 EWMP Watershed Characteristics and BMP Implementation Strategies

Summarized below are the general characteristics of the watersheds within the EWMP Groups and the overall strategies for BMP implementation that reflect these characteristics. The twelve EWMPs are consolidated to six watershed areas grouped by similar watershed characteristics. This summary provides additional detail on the distribution and location of potential and priority BMPs, where data is available, based on the overall BMP implementation strategy and maps of BMP distribution. These maps are presented for each EWMP and show the location and distribution of planned and priority regional/centralized BMPs for which data are available at the time of publication of this PEIR. The priority BMPs are a subset of the potential BMPs that have undergone a site review and project evaluation that has identified these BMPs as a priority. These priority projects are shown based upon available data at the time of publication of this PEIR. **Appendix G** provides the location and general description of the priority BMPs shown on the figures referenced in this discussion. Distributed BMPs are planned to be implemented throughout the urbanized areas of each EWMP.

1. **South Santa Monica Bay EWMP Watersheds** (Marina del Rey, Ballona Creek, Beach Cites, South Santa Monica Bay Jurisdictional Group 2 and 3, and Peninsula Cities EWMP groups) – These watershed groups are dominated by urbanized beach communities with high density residential and commercial land uses throughout the watershed. Key BMP strategies in these watersheds are to address dry and wet-weather flows that may impact beach water quality through bacteria loading. Other water quality priorities include trash, marine debris, metals, and toxics. The BMP strategy includes LFDs to comply with dry-weather metals and bacteria Total Maximum Daily Loads (TMDLs). Although large regional and centralized retention and infiltration BMPs will be part of the wet-weather pollutant load reduction strategy, the predominate structural BMP will be smaller distributed BMPs such as bioinfiltration, media filtration, and flow-through BMPs located in street right-of-ways, parking lots, landscaped areas, and as part of green streets and buildings.

   Because of the high ground water near the shore, capture and reuse regional projects or treatment BMP opportunities will be preferred. The receiving waters for the South Santa Monica Bay include the Santa Monica Bay, the Ballona Creek, and the Marina del Rey Harbor.

   Marina del Rey EWMP – Figure 2-5 provides the location and distribution of potential regional/centralized BMPs for the Marina del Rey EWMP. Distributed BMPs will be located throughout the urbanized areas of the EWMP. Because of the tidal influence of the marina to most of the watershed, regional projects will be located near the upstream end of the watershed where ground water depths are favorable. The tidally influenced areas will consist of mostly treatment distributed BMPs, including bioinfiltration or tree wells.

Ballona Creek EWMP – Figure 2-6 provides the locations and distribution of potential regional/centralized BMPs for the Ballona Creek EWMP. Regional infiltration BMPs will be well distributed throughout the watershed and will be incorporated with distributed BMPs consisting mostly of distributed BMPs such as green streets. LFDs may also be pursued to comply with dry-weather TMDL requirements.

Beach Cities EWMP – Figure 2-7 provides the location and distribution of potential regional/centralized BMPs for the Beach Cities EWMP. Distributed BMPs will be located throughout the urbanized areas of the EWMP. The Beach Cities will focus their efforts on regional projects near the outlet on the Beach similar to the Hermosa Beach Infiltration Trench or the Torrance infiltration basins. Where regional projects are infeasible, distributed projects will be implemented such as green streets.

Santa Monica Bay J2/3 – Figure 2-8 provides the location and distribution of potential regional/centralized BMPs for the Santa Monica Bay J2/3 EWMP. Many efforts have already been completed for the Santa Monica Bay J2/J3 Watershed including LFDs and reuse facilities. The group will investigate the possibility of more regional projects that are able to capture and reuse the flow. Remaining areas will be subject to distributed BMPs.

Peninsula Cities – Figure 2-9 provides the location and distribution of potential regional/centralized BMPs for the Peninsula Cities EWMP. Distributed BMPs will be located throughout the urbanized areas of the EWMP. The Santa Monica Bay J7 side of the Peninsula Cities area is mostly comprised of anti-degradation sites so there will not be many control measures in this subwatershed.

2. **Northern Coastal EWMP Watersheds** (Malibu Creek and North Santa Monica Bay Coastal Watersheds EWMP groups) – These watersheds are characterized by lower density development along the coast and the larger creeks with greater open space and park areas inland. There is increased development in the upper areas of the Malibu Creek Watershed. Receiving waters in these watersheds are largely unlined and riparian corridors remain.

   Water quality priorities include bacteria, toxics, trash, and nutrients as well as benthic community impairments. **Figures 2-10 and 2-11** provide the location and distribution of potential regional/centralized BMPs for the Malibu Creek and North Santa Monica Bay Coastal Watersheds EWMP groups, respectively. Smaller distributed BMPs that include biofiltration, media filtration, green streets, and flow-through BMPs will be used in greater percentage than larger centralized BMPs and will be located in developed areas as retrofit BMPs.

3. **Upper San Gabriel Watershed –** This watershed is characterized by higher density development in the lower watershed area and lower density and open space in the upper watershed where the foothills to the San Gabriel Mountains begin. The priority pollutants in these watersheds include selenium in dry-weather flows, and metals in wet weather flows. This watershed is further differentiated by the importance of groundwater recharge basins that are supplied by a series of reservoirs further upstream in the mountains. The San Gabriel

River is unlined in the upper watershed and conveys controlled non-storm and storm flows to recharge basins and downstream sections of the river. **Figure 2-12** provides the location and distribution of potential regional/centralized BMPs for the Upper San Gabriel EWMP. The BMP strategy in this watershed focuses more on regional and centralized retention and infiltration BMPs that take advantage of the favorable groundwater recharge characteristics of this area. These BMPs are located near or adjacent to the river. Distributed smaller BMPs are located in urbanized areas as retrofits in existing developments and streets.

4. **Rio Hondo/San Gabriel and Upper Los Angeles River Watersheds** (Rio Hondo/San Gabriel and Upper Los Angeles EWMPs) – These watersheds traverses a large diverse area of the Los Angeles Basin with characteristics of Upper San Gabriel in the farthest upper reaches near the foothills, but most of this watershed is characterized by greater urbanization similar to Ballona Creek watershed. The greater urbanization also results in additional priority pollutants compared to Upper San Gabriel watershed, and include nutrients, trash, metals, bacteria and sediment impacted by metals and organic compounds (DDT, PCBs, PAHs).

   The Rio Hondo/San Gabriel EWMP is characterized by increasing urbanization south of the foothills and industrial and commercial development along the 210 corridor. **Figure 2-13** provides the location and distribution of potential regional/centralized BMPs for the Rio Hondo/San Gabriel EWMP. The strategy for the locations and types of regional/centralized BMPs is to use remaining available sites for retention and infiltration, which takes advantage of the favorable infiltration rates of this area, including existing groundwater recharge basins near the San Gabriel River. Distributed BMPs will be located in throughout the urbanized areas of the EWMP.

   The Los Angeles River is approximately 51 miles long, and five of six reaches lie within the Upper Los Angeles River EWMP. The natural hydrology of the Los Angeles River watershed has been altered by channelization and the construction of dams and flood control reservoirs. The Los Angeles River and many of its tributaries are lined with concrete for most or all of their length. Soft-bottomed segments of the Los Angeles River occur where groundwater upwelling prevents armoring of the river bottom. **Figure 2-14** provides the location and distribution of potential regional/centralized BMPs for the Upper Los Angeles River EWMP. Because of the greater extent and number of pollutant priorities, the BMP strategy in the Upper Los Angeles River watershed includes well over a hundred planned regional and centralized retention and infiltration BMPs that take advantage of the favorable groundwater recharge characteristics in defined areas of the watershed. Also planned are centralized treatment wetlands and bioinfiltration BMPs in parks and open spaces with favorable subsurface soils that promote higher infiltration rates. The BMP strategy also includes distributed smaller BMPs located throughout the urbanized areas of the watershed as retrofits in existing developments and streets. LFDs to comply with dry-weather bacteria TMDLs may also be included.

5. **Dominguez Channel Watershed** (Dominguez Channel EWMP, Beach Cities, Peninsula Cities) **–** This watershed is differentiated by a larger area of industrial land use, but also includes Beach Cities and Machado Lake. Because of the high density of development and industrial land uses, large regional and centralized infiltration type BMPs will be limited. **Figure 2-15** provides the location and distribution of potential regional/centralized BMPs for the Dominguez Channel EWMP. The structural BMP strategy will be more LFDs, both large (centralized) and small (distributed), located at MS4 outfalls near the channelized Dominguez Chanel. The other BMP strategy are smaller distributed BMPs that include the LID type BMP such as Green Streets and biofiltration BMPs throughout the Beach Cities. These distributed BMPs will be retrofit type BMPs that treat runoff from already developed properties and are located in street right-of-ways, parking lots, and limited open areas on public and private parcels. Distributed flow-through treatment BMPs will also be the other predominant BMP that will be retrofitted to the existing MS4 systems.

6. **Upper Santa Clara River Watershed –** The Santa Clara River Watershed is distinctive in that it is predominantly open space—nearly ninety percent of the watershed—is open space with approximately 88 percent being undeveloped. The watershed contains one of the last remaining natural rivers in Southern California. In years of significant rainfall, ephemeral springs and year-round flows exist in some tributaries and natural upstream areas. Flows in Santa Clara River reaches that pass through the EWMP area are predominantly stormwater runoff during wet-weather months and water reclamation plant effluent discharges in the drier months. Priority pollutants in the watershed are bacteria, nutrients, and chloride. In the source assessments for the Nutrients TMDL and the Chloride TMDL for the Santa Clara River, the storm drain system is not considered the primary source of these pollutants. Lake Elizabeth is also subject to a trash TMDL. The EWMP will evaluate potential MS4 nutrients and chlorides contributions and serve as the implementation plan for the Bacteria TMDL. BMP strategies for this watershed are likely to include a focus more on regional and centralized retention and infiltration BMPs and less on filtration type BMPs, which are not as effective at addressing bacteria. **Figure 2-16** provides the location and distribution of potential regional/centralized BMPs. Distributed BMPs will be located in the urbanized areas of the EWMP.

As shown in Figures 2-5 through 2-16, each of the EWMPs involves a wide distribution of BMPs to achieve permit compliance. Appendix G provides the locations and general descriptions of the priority BMPs (where data is available), shown in Figures 2-5 through 2-16. Priority Projects are projects that have been identified through the EWMP process as targeted for implementation within the first years following the EWMPs approval by the LARWQCB. Identification of Priority Projects is underway and has not been completed by all EWMPs at this time. The PEIR is being prepared in parallel to the EWMPs. Priority Projects will be defined in all the EWMPs to be submitted for public comment in June 2015. Priority Projects that have been identified at this time through the EWMP process are shown on the following figures. Priority Projects may be regional, centralized or distributed type BMPs. For potential projects that are shown on the following figure, the location of potential regional and centralized BMPS are shown. Distributed BMP will be distributed throughout the urbanized areas and are not shown on the following figures. Because of land availability restrictions, large parcels that can support regional or centralized BMPs are fewer and more difficult to obtain than smaller parcels or easements needed for distributed BMPs. The overall strategy engaged by each of the WMGs is to maximize the benefits of regional and centralized BMPs while relying on distributed and non-structural BMPs to achieve a larger majority of the water quality improvement benefits provided by the EWMP. The distributed BMPs will be scattered throughout the watersheds, predominantly in urbanized areas, resulting in widely distributed implementation impacts as discussed in Chapter 3.

2.6 EWMP BMP Implementation Schedule

The EWMPs that are being prepared in parallel to the PEIR will provide a timeline for the implementation of the BMPs. The priority BMPs are a subset of the potential BMPs that have undergone a site review and project evaluation and have been identified as a priority project, based on available data at the time of publication of this PEIR. The EWMPs will be submitted to the LARWQCB in June 2015. Implementation of priority BMPs will begin following approval of the EWMPs by the LARWQCB, which is anticipated in the later part of 2015 or early 2016. Implementation of BMPs will depend on the approval of the EWMPs, further environmental assessment, permitting, and availability of funding sources. The RAA as part of the EWMPs provides a basis for the needed level of BMP implementation to meet water quality goals.

2.7 Operation and Maintenance

Once constructed, structural BMPs will require periodic maintenance. The level and frequency of operation and maintenance (O&M) will depend on the BMP type, size, and complexity. BMPs implemented and under the jurisdiction of the LACFCD would be maintained and operated to meet design performance standards and the efficiencies needed to meet the waste load reductions in accordance with the EWMPs. O&M will also include addressing identified minimum mitigation measures to avoid potential impacts.

Project Costs

Funding for installation and maintenance of the BMPs identified in each EWMP will be the responsibility of the implementing agencies. The EWMPs will include development of cost estimates for proposed watershed control measures. Financial strategies to implement the EWMP will also be developed and included in the EWMP Plan. The financial strategies may include available State grants, recent Water Bond funding, and partners that can benefit from these projects (e.g. Water agencies).

Each EWMP will define priority projects, and installation of these projects will move forward depending on the availability of funding and outcome of further project-specific CEQA review. Funding options for implementing agencies would include obtaining grant funds, low-interest loans, tax-based general funds, or special assessments. Each jurisdiction will be responsible for securing the necessary funds over time to achieve permit compliance.

2.8 Required Approvals

LACFCD intends to use this PEIR to consider implementation of the proposed program. As Lead Agency, LACFCD may use this PEIR to approve the proposed program, make Findings regarding identified impacts, and, if necessary, adopt a Statement of Overriding Considerations regarding these impacts. The LARWQCB has discretionary approval over the EWMPs themselves, while a broad range of responsible agencies have discretionary approval over the BMPs described in the EWMPs. These agencies and their approvals are described in **Table 2-**. The specific approvals necessary for each BMP will vary by BMP; for example, BMPs that do not result in fill of jurisdictional waters of the United States will not need a Clean Water Act Section 404 Permit.

TABLE 2-6
REQUIRED APPROVALS

Approving Agency	Approval
Implementing Agencies	CEQA approval
LA County Flood Control District	CEQA approval, Encroachment Permit
California Department of Transportation	Encroachment Permit
Local Railroad Authorities	Encroachment Permit
Local Cities/Permittees	Encroachment Permits, certification of compliance with local historic/cultural preservation policies
U.S. Army Corps of Engineers	Clean Water Act Section 404 Permit, Rivers and Harbors Act Sections 9 and 10 Permits
California Department of Fish and Wildlife	Lake/Streambed Alteration Agreement (1600 Permit)
U.S. Fish and Wildlife Service and National Marine Fisheries Service	Endangered Species Act consultations for Clean Water Act and Rivers and Harbors Act permits
California Coastal Commission	Coastal Development Permits
Regional Water Quality Control Board	Clean Water Act Section 401 Water Quality Certification
	Waste Discharge Requirements for discharge to waters of the state or to land
	Groundwater Anti-Degradation Analysis
	Water Recycling Requirements
	NPDES permits for discharges to waters of the United States
	Groundwater Recharge Recycled Water Project approval (currently draft regulations)
	General Construction Permit/SWPPP approval

CHAPTER 3

Environmental Setting, Impacts, and Mitigation Measures

3.1 Aesthetic Resources

This section addresses the aesthetic and visual quality of the region and potential impacts associated with the implementation of the Enhanced Watershed Management Program (EWMP). It includes a description of existing visual conditions and an evaluation of potential effects on aesthetic resources.

3.1.1 Environmental Setting

Regional Setting

Visual resources consist of natural landscapes and scenic views, including landforms, vegetation, and water features, as well as unique elements of the built environment. The proposed program would be located in various watershed areas in the County of Los Angeles (County). Although much of the County is densely populated, the region also has a significant amount of scenic resources, from the coastline to the mountain vistas, including hillsides, scenic viewsheds, and ridgelines. The San Gabriel Mountains, Sierra Pelona Mountains, Verduga Hills, Santa Susana Mountains, Simi Hills, Santa Monica Mountains, and Puente Hills help shape the region physically, and also provide aesthetic, environmental, and recreational benefits to residents. The majority of native plants and animals reside in the hillside terrain, which indicates the biological and aesthetic importance of these areas (Los Angeles County Draft General Plan, 2014). Ridgelines or mountain edges with steep drops on either side, located in the Los Angeles region provide dramatic views and are protected and preserved by individual communities. Significant ridgelines are dispersed throughout the County, but are generally located in the Angeles National Forest and the Santa Monica Mountains. The urban landscape varies, and includes low-lying residential, industrial, and commercial buildings along with high-density, high-rise residential and commercial buildings in downtown areas.

Program Area

Each Watershed Management Area, and EWMP group, associated with the proposed program has its own unique aesthetic resources depending on its location within the County. For example, the coastal watersheds will have significantly different aesthetic resources than the inland watersheds near the mountains. Specific locations of projects have not been established at this point; therefore, the discussion remains at a broader watershed-area level. Existing aesthetic resources within each Watershed Management Area group are summarized in this section.

Santa Monica Bay Watershed Management Area

The Santa Monica Bay Watershed Management Area includes the Malibu Creek Watershed EWMP, North Santa Monica Bay EWMP, Santa Monica Bay Jurisdictions 2 and 3 EWMP, Marina del Rey EWMP, Ballona Creek EWMP, and a portion of Beach Cities EWMP and Palos Verdes Peninsula EWMP groups.

The Santa Monica Bay Watershed Management Area, which encompasses an area of 414 square miles, is quite diverse. Its borders reach from the crest of the Santa Monica Mountains on the north and from the Ventura–Los Angeles County line to downtown Los Angeles. From there it extends south and west across the Los Angeles plain to include the area east of Ballona Creek and north of the Baldwin Hills. The Santa Monica Bay Watershed Management Area includes several watersheds, the two largest being Malibu Creek to the north and Ballona Creek to the south. The Malibu Creek area contains mostly undeveloped mountain areas, large-acreage residential properties, and many natural streams, while Ballona Creek is predominantly channelized and highly developed with both residential and commercial properties (LARWQCB, 2011).

There are large industrial centers in El Segundo, Manhattan Beach, Redondo Beach, and Torrance, which serve as a base for aerospace and other high-tech manufacturing. Other concentrated commercial/industrial areas in the watershed include Westchester–Los Angeles Airport (LAX)–Playa del Rey (commercial), Santa Monica–West Los Angeles–Century City (commercial and light industry), Culver City (entertainment industry), Los Angeles Civic Center, and the Highway 101 corridor in Thousand Oaks–Westlake Village (light industry and commercial) (LARWQCB, 2011).

Of the Santa Monica Bay's 414-square-mile watershed, 121 square miles (29 percent) are developed or impervious. The Ballona Creek subwatershed accounts for most of the impervious area, with 72 square miles of impervious surface. The Malibu Creek watershed, with its large expanse of open area, has nearly 14 square miles of impervious surface (LARWQCB, 2011).

The Ballona Creek Wetlands are currently located within the area identified as the Ballona Wetlands Ecological Reserve, which is located at the mouth of Ballona Creek. The Ballona Creek Wetlands encompass approximately 600 acres and is the last remaining major coastal wetland in the Santa Monica Bay. The Ballona Creek Wetlands comprise salt marsh and freshwater wetlands, coastal bluffs, dunes, and upland habitats. The Ballona Creek Wetlands supports several state- and federally-listed species of concern. Developed urban areas surrounding the wetlands, as well as many other human activities, have significantly impacted the wetlands (USEPA, 2012).

Riparian habitat exists along each natural watercourse flowing to the ocean and around the lakes of the watershed. Riparian corridors include those found throughout the Ballona Creek Wetlands, Malibu Creek watershed, in other Santa Monica Mountain watersheds such as Arroyo Sequit and Solstice Creek, and adjacent to lakes such as Westlake Lake, Lake Sherwood, and Malibu Lake. The land in the Santa Monica Mountains to the north by contrast is still mostly open space and remains in a somewhat natural state, mostly free of alteration or development but impacted by invasive species and mostly bacteria- and nutrient-related water quality issues (LARWQCB, 2011).

There are approximately 22 “scenic resources” in the City of Malibu and surrounding areas identified in the Malibu Local Coastal Program. There are numerous vista points in the Malibu area. There are five areas in and adjacent to Malibu that display characteristics which make them suitable as vista points. Significant ridgelines also constitute a scenic resource of the coastal zone because of their high visibility from many vantage points. Ridgelines are typically defined as the line separating drainage basins. Significant ridgelines are those whose ridges silhouette the sky or the ocean, and are clearly visible from scenic roads. These ridgelines are located throughout Malibu and the Santa Monica Mountains (City of Malibu, 1995).

Agoura Hills is known as the “Gateway to the Santa Monica Mountains National Recreation Area.” The hills of the Santa Monica Mountains provide panoramic vistas, majestic oak trees, and dramatic backdrops of picturesque canyons and hillsides. Four road segments are valuable scenic resources in Agoura Hills that provide scenic views of the Santa Monica Mountains. Important scenic resources include Strawberry Hill, Morrison Ranch Hills, Palo Comado Hills, and the higher more distant Simi Hills that border the city on the north (City of Agoura Hills, 2010).

Dominguez Channel Watershed Management Area

The Dominguez Channel Watershed Management Area includes the Dominguez Channel EWMP group and a portion of the Beach Cities EWMP and Palos Verdes Peninsula EWMP groups.

Approximately 81 percent of the watershed or 93 percent of the land is developed. Residential development covers nearly 40 percent of the watershed, and another 41 percent comprises industrial, commercial, and transportation uses. It is estimated that 62 percent of the land is covered with impervious surfaces (e.g., asphalt, concrete), which represents the highest percentage for any watershed area in Los Angeles County. Parkland and open space are in short supply and generally are deficient in meeting the goal ratio of 0.4 hectare (1 acre) of park per each 1,000 population. Vacant land and open space areas account for 16 percent of the entire watershed. The largest “natural” habitat is associated with the Los Angeles and Long Beach Harbors, which cover 3,289 hectares (8,128 acres), or approximately 9.5 percent of the watershed. The Dominguez Watershed has an extensive transportation system consisting of streets, major highways, and freeways; rail service; three airports; and commercial shipping (Los Angeles County, 2004).

The cities with the largest amount of land in the watershed are Los Angeles (22 percent), Carson (14 percent), and Torrance (13 percent). These communities are dominated by high density and multi-family residential land use types, with a fair amount of active redevelopment. The watershed is also home to several smaller, upscale communities, including Palos Verdes Estates, Rancho Palos Verdes, Rolling Hills, and Rolling Hills Estates, which are characterized by low density residential and equestrian land uses (Los Angeles County, 2004).

Approximately 50.6 square kilometers (19.5 square miles) of the Dominguez watershed, including Lomita and portions of Rolling Hills, Rolling Hills Estates, Torrance, and the City of

Los Angeles, drains to Machado Lake near the intersection of Vermont Avenue and Anaheim Street in the City of Los Angeles. Much of the Machado Lake subwatershed consists of the hilly regions of Rolling Hills and Rolling Hills Estates. This portion of the watershed is unique for Dominguez by consisting of relatively steep hills with drainage ways in canyons. These drainage ways flow generally northwest from the hills toward Machado Lake (Los Angeles County, 2004). Machado Lake (16 hectares, 40 acres) and the Machado Lake wetlands (25 hectares, 64 acres) are located within the Ken Malloy Harbor Regional Park, in the southeastern corner of the Machado Lake subwatershed. Both Machado Lake and the Machado Lake wetlands serve as flood retention basins for the Machado Lake subwatershed. Machado Lake receives urban and stormwater runoff from a complex network of storm drain systems. Machado Lake discharges at the southern end by overflowing a concrete dam into the Machado Lake wetlands. Water discharges from the wetland through the Harbor Outflow structure and into the West Basin of the Los Angeles Harbor (Los Angeles County, 2004).

Several types of habitats occur within the Dominguez watershed; the largest is urban land that supports few natural resources. To a lesser extent, biological resources use several small, disturbed pocket wetlands scattered throughout the watershed and retention and detention basins located in the City of Torrance. These biological resources within the Dominguez watershed are highly fragmented and are impacted by a variety of problems directly related to the surrounding urban environment. Several stresses also affect habitats within the Dominguez Channel. The most notable impact to biological resources is the channelization of drainages throughout the system, many of which are concrete-lined (Los Angeles County, 2004).

Los Angeles River Watershed Management Area

The Los Angeles River Watershed Management Area includes the Upper Los Angeles River EWMP and a portion of the Rio Hondo/San Gabriel River Quality Group EWMP.

The Los Angeles River Watershed is one of the largest in the region. It is also one of the most diverse in terms of land use patterns. Approximately 324 square miles of the watershed are covered by forest or open space land, including the area near the headwaters that originate in the Santa Monica, Santa Susana, and San Gabriel Mountains. The rest of the watershed is highly developed (LARWQCB, 2006).

The river flows through the San Fernando Valley past heavily developed residential and commercial areas. From the Arroyo Seco, north of downtown Los Angeles, to the confluence with the Rio Hondo, the river flows through industrial and commercial areas and is bordered by rail yards, freeways, and major commercial and government buildings. From the Rio Hondo to the Pacific Ocean, the river flows through industrial, residential, and commercial areas, including major refineries and petroleum products storage facilities, major freeways, rail lines, and rail yards serving the Ports of Los Angeles and Long Beach (LARWQCB, 2006).

Also in various parks in the watershed are a number of lakes, including Peck Road Park, Belvedere Park, Hollenbeck Park, Lincoln Park, and Echo Park Lakes as well as Lake Calabasas. These lakes are heavily used for recreational purposes (LARWQCB, 2006).

San Gabriel River Watershed Management Area

The San Gabriel River Watershed Management Area includes a portion of the Rio Hondo/San Gabriel River Quality Group EWMP and the Upper San Gabriel River EWMP.

The entire San Gabriel River watershed covers more than 640 square miles and includes portions of 37 cities in Los Angeles and Orange Counties, as well as communities in unincorporated Los Angeles County. More than one-third of the upper watershed falls within the Angeles National Forest, including significant portions of the San Gabriel Mountains. The watershed also contains the Merced and San Jose Hills, and the Puente-Chino Hills, as well as the major urban populations of the San Gabriel and Pomona Valleys and the coastal plain of the Los Angeles Basin (Los Angeles County, 2006).

About 26 percent of the watershed's total area is developed with urban and related land uses. The San Gabriel River consists of 22 creeks, washes, and streams, including four major tributaries or subwatersheds, which join to form the overall watershed (Los Angeles County, 2006).

The river environment changes dramatically during the 58-mile course. The river is divided into seven reaches; each reach is defined by distinct landscape, cultural, geological, and hydrological features, which naturally change as the river flows from the mountains through the valley, into the coastal plain, and eventually out to sea (Los Angeles County, 2006).

Santa Clara River Watershed Management Area

The Santa Clara River Watershed Management Area includes the Upper Santa Clara River EMWP.

The Santa Clara River watershed encompasses approximately 1,030 square miles. The Upper Santa Clara River Watershed is approximately 786 square miles within County of Los Angeles limits with approximately 243 square miles within Ventura County and 1 square mile within Kern County. The Santa Clara River Watershed Management Area is dominated by vacant land, which comprises 88 percent of the total land use. Much of the watershed is in mountainous terrain within either the Angeles or Los Padres National Forests (LARWQCB, 2006). Only small portions of agriculture (4 percent) and urban land (6 percent) exist. Much of the residential area (3 percent) is located near the City of Santa Clarita in the center of the watershed. The Santa Clara River Watershed Management Area is the least developed and urbanized of the watershed management areas in Los Angeles County (Weston, 2005).

The Santa Clara River watershed's impervious area is estimated to be 7 percent based on assumptions on impervious areas in each land use type. This is the lowest ratio of impervious land area in the Watershed Management Areas of Los Angeles County (Weston, 2005). The Santa Clara River is the largest river system in Southern California remaining in a relatively natural state (LARWQCB, 2006). Extensive patches of high-quality riparian habitat are present along the length of the river and its tributaries (LARWQCB, 2006).

One of the largest of the Santa Clara River's tributaries, Sespe Creek, is designated a wild trout stream by the State of California and supports significant spawning and rearing habitat. The Sespe Creek is also designated a wild and scenic river (LARWQCB, 2006).

State Scenic Highways

There are several Designated State Scenic Highways, Eligible State Scenic Highways, and Historic Parkways with the EWMP areas. Refer to **Figure 3.1-1**, Scenic Highways. Santa Monica Bay, Los Angeles River, and San Gabriel River watersheds contain both officially designated County scenic highways and Eligible State Scenic Highways not officially designated (State Route 1 and Highway 101) (see Figure 4.1-1). In addition, the Los Angeles River watershed also includes historic parkways and the Santa Clara River watershed includes Eligible State Scenic Highways. Many roads in Malibu are considered scenic, but only the Pacific Coast Highway has been officially designated as an eligible scenic highway by the California Department of Transportation (Caltrans) (City of Malibu, 1996).

Light and Glare

There are two types of light intrusion: the first source emanates from the interior of structures and passes through windows, while the second type emanates from exterior sources such as parking lot lighting and street lamp lighting. Glare is the result of sunlight or an artificial light source being reflected on a flat surface or reflective exterior coatings. Light and glare can disturb wildlife in natural habitat areas and act as a nuisance to adjacent residential areas and motorists.

Light and glare are typical features of urbanized settings, such as the EWMP project areas. The primary sources of light within the project areas are associated with transportation, including car headlights associated with vehicular traffic and commercial and residential land uses.

3.1.2 Regulatory Setting

State

State Scenic Highway Program

In 1963, the California legislature created the Scenic Highway Program to protect scenic highway corridors from changes that would diminish the aesthetic value of lands adjacent to the highways. The state regulations and guidelines governing the Scenic Highway Program are found in the Streets and Highways Code, Section 260 et seq. A highway is designated under this program when a local jurisdiction adopts a scenic corridor protection program, applies to Caltrans for scenic highway approval, and receives notification from Caltrans that the highway has been designated as a Scenic Highway. When a city or county nominates an eligible scenic highway for official designation, it defines the scenic corridor, which is land generally adjacent to and visible to a motorist on the highway.

LA County PEIR EWMP . 140474

Figure 3.1-1

Scenic Highways

RB-AR 8315

Local

Los Angeles County Existing General Plan, Adopted 1980

The following policy from the Conservation and Open Space Element of the Existing General Plan is relevant to the proposed program:

Policy C/OS 16: Protect the visual quality of scenic areas including ridge-lines and scenic views from public roads, trails and key vantage points.

Los Angeles County 2014 Draft General Plan 2035

The following policies from the Conservation and Natural Resources Element of the Draft General Plan are relevant to the proposed program:

Goal C/NR 13: Protected visual and scenic resources

Policy C/NR 13.1: Protect scenic resources through land use regulations that mitigate development impacts.

Policy C/NR 13.2: Protect ridgelines from incompatible development that diminishes their scenic value.

Policy C/NR 13.3: Reduce light trespass, light pollution and other threats to scenic resources.

City Land Use Regulations and Ordinances

Local regulations and ordinances vary widely in the EWMP project areas. Aesthetic-related policies included in General Plans typically concern protecting valuable scenic resources. Some local jurisdictions incorporate restrictions to their General Plans that pertain to protection of scenic resources and trees in their jurisdictional areas.

3.1.3 Impact Assessment

Thresholds of Significance

For the purposes of this Project Environmental Impact Report (PEIR) and consistency with Appendix G of the CEQA Guidelines, the project would have a significant impact on aesthetic resources if it would:

- Create a substantial adverse effect on a scenic vista.
- Substantially damage scenic resources, including but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway.
- Substantially degrade the existing visual character or quality of the site and its surroundings.
- Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area.

Program Impact Discussion

Scenic Vistas

Impact 3.1-1: The proposed program could create a substantial adverse effect on a scenic vista.

Structural (Regional, Centralized, and Distributed) BMPs

A scenic vista can be described as an expansive view of a highly valued landscape for the benefit of the general public. There are portions of the EWMP project areas that could be characterized as having scenic vistas, including undeveloped hillsides, ridgelines, and open space areas that provide a unifying visual backdrop to the urban environment of the Los Angeles Basin. Impacts to scenic vistas can occur when the visible scenic landscape itself is altered or when a new contrasting object is introduced that blocks or obstructs a scenic vista from a particular public vantage point.

The construction of structural Best Management Practices (BMPs) for the proposed program would require temporary ground disturbance, primarily on existing sidewalks, streets, parks, and city-owned lands. The presence of construction equipment and materials would be visible from public vantage points but would not affect any scenic views or vistas for longer than the temporary construction periods. Construction of aboveground structures, such as pump stations, would involve excavation, pump station construction, pump and motor installation, and final site completion. Similar to structural BMPs construction, site disturbance and the presence of construction equipment and materials during construction of pump stations could temporarily introduce contrasting elements into scenic views and vistas. However, given the predominantly urban character of potential pump station sites and the temporary nature of construction, impacts would be considered less than significant.

It is anticipated that the majority of structural BMPs would be located underground and not visible once construction is complete. Therefore, construction and operation of the majority of structural BMP improvements would not permanently affect views or scenic vistas. Although the exact locations of pump stations have not been determined, based on their proposed function and exterior design, they would not significantly affect views or scenic vistas from publically accessible vantage points. Aboveground structures such as pump station components of projects associated with structural BMPs typically would be single-story buildings; the project areas where pump stations may be located are generally characterized by urban development. As such, aboveground structures would be designed to be similar to and compatible with surrounding architecture and neighborhood character. However, impacts to scenic vistas from individual projects could be significant if inappropriately designed or located. With implementation of **Mitigation Measure AES-1**, aboveground structures would be designed to avoid obstructing scenic vistas or views from public vantage points. Impacts would be less than significant with mitigation.

Mitigation Measure:

AES-1: Aboveground structures shall be designed to be consistent with local zoning codes and applicable design guidelines and to minimize features that contrast with neighboring development.

Significance Determination: Less than significant with mitigation. (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.1-1.)

Non-Structural (Institutional) BMPs

Non-structural BMPs consist of policies, actions, and activities aimed at preventing pollutants from entering stormwater runoff; there would not be a physical impact to the environment. The non-structural BMPs associated with the proposed program would not create a substantial adverse effect on a scenic vista.

Mitigation Measures: None

Significance Determination: No impact

State Scenic Highway

Impact 3.1-2: The proposed program could substantially damage scenic resources, including but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway.

Structural (Regional, Centralized, and Distributed) BMPs

State scenic highways within the EWMP areas include portions of State Route 1 or Pacific Coast Highway, State Route 101, State Route 27, State Route 57, State Route 39, State Route 2, State Route 126, and portions of Interstate 5, Interstate 110, and Interstate 210, as shown in Figure 3.1-1. In addition, there are designated scenic roadways, including Mulholland Highway and Malibu Canyon Roadway. Some of the proposed program could be visible from any of these designated scenic highways or other locally designated scenic roadways. The proposed program would not likely involve damage to rock outcroppings or historic buildings because it is anticipated that the majority of structural BMPs would be located underground and would not be visible once construction is complete. Construction of the proposed program would involve the removal of vegetation, including possibly the removal of native and non-native trees from the individual project sites. Aboveground structures may be constructed as part of the structural BMPs. Small aboveground pump stations and supporting ancillary facilities would not substantially damage scenic resources of the area. Larger structures, such as single-story housing for pump stations and treatment facilities, would be compatible with existing visual character with implementation of **Mitigation Measure AES-1**. Therefore, construction and operation of the majority of structural BMPs would not permanently affect scenic resources within a state scenic highway with implementation of **Mitigation Measure AES-1**.

Mitigation Measure: Implementation of **Mitigation Measure AES-1**

Significance Determination: Less than significant with mitigation. (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.1-1.)

Non-Structural (Institutional) BMPs

Non-structural BMPs consist of policies, actions, and activities aimed at preventing pollutants from entering stormwater runoff; there would not be a physical impact to the environment. The non-structural BMPs associated with the proposed program would not substantially damage scenic resources, including but not limited to trees, rock outcroppings, and historic buildings within a state scenic highway.

Mitigation Measures: None

Significance Determination: No impact

Visual Character

Impact 3.1-3: The proposed program could substantially degrade the existing visual character or quality of the site and its surroundings.

Structural (Regional, Centralized, and Distributed) BMPs

Construction activities associated with all structural BMP projects would require the use of construction equipment and storage of materials on-site, thus introducing contrasting features into the visual landscape that would affect the visual quality of project sites and/or their surroundings. Contrasting features would include demolition materials, excavated areas, stockpiled soils, and other materials generated and stored on-site during construction. However, adverse effects to visual character associated with project construction would be temporary and are considered less than significant.

The purpose of the EWMPs is to improve upon the Permittee's structural BMPs and it includes the following elements, or BMPs: replacing existing impervious surfaces with pervious surfaces such as bioinfiltration cells, bioswales, porous pavement, and filter strips. Centralized BMPs also include diversion- and treatment-type BMPs that use similar technologies for these types of BMPs under distributed BMPs, but they can be implemented on a much larger scale for collecting, diverting, and treating urban runoff (dry weather flows) or limited stormwater flows from multiple parcels and large drainage areas. Therefore, centralized structural BMPs require greater footprints for construction and implementation. Centralized BMPs include two unique BMP types, treatment wetlands and stream/creek restoration projects. Unlike the other structural BMP types described, these BMPs use natural systems to filter and clean the water. Treatment wetlands are typically off-line treatment systems that are not in the receiving waters, but may have habitat benefits through the establishment of more native plants and ecosystems. Creek, river, and estuary restoration projects provide a unique opportunity to restore natural cleansing processes, reestablish habitats, and address impacts from hydromodification and urban runoff.

Once constructed, the proposed EWMP facilities would be located predominantly in urban areas. Underground facilities, such as storm drains, are not expected to have a permanent effect on visual character of an area. Implementation of the structural BMPs is anticipated to have an overall positive impact on the aesthetic environment. For example, there is anticipated to be more green space areas and less impermeable surfaces from pavement and concrete, thereby enhancing the level of greenness in the watersheds. Greenness includes “green spaces” that have well-defined boundaries that do not contain residential, commercial, or industrial structures or vehicular access or “green areas,” which are within the street grid and are landscape design features such as street trees, bioswales, green or vegetated roofs, or other vegetated small areas integrated into the built environment. These BMPs contribute to the natural open space character compared to the more built environment that it is replacing.

Aboveground structures within urban areas would be constructed on or adjacent to existing developed and built-up landscapes. Small aboveground pump stations and supporting ancillary facilities would have no significant effect on the visual character of the area. Larger structures, such as single-story housing for pump stations and treatment facilities, would be compatible with existing visual character with implementation of **Mitigation Measure AES-1**.

BMP maintenance is also important when considering long-term impacts on aesthetics. Poorly maintained BMPs, such as wet ponds or constructed wetlands, may be unsightly as a result of excess algal growth or public littering. Wet ponds and constructed wetlands can also become mosquito-breeding grounds. However, mosquito problems can usually be reduced or eliminated through proper design and/or organic controls such as mosquito-eating fish. Successful design avoids shallow or stagnant water and reduces large areas of periodic drying, which can occur in a dry detention basin. In addition, all BMPs need to have trash and debris removed periodically to prevent odor and preserve aesthetic values. With proper maintenance of all implemented BMPs as required in **Mitigation Measure AES-2**, impacts would be less than significant.

Mitigation Measures: Implementation of **Mitigation Measure AES-1**

AES-2: Implementing agencies shall develop BMP maintenance plans that are approved concurrently with each structural BMP approval. The maintenance plans must include measures to ensure functionality of the structural BMPs for the life of the BMP. These plans may include general maintenance guidelines that apply to a number of smaller distributed BMPs.

Significance Determination: Less than significant with mitigation. (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.1-1.)

Non-Structural (Institutional) BMPs

Non-structural BMPs consist of policies, actions, and activities aimed at preventing pollutants from entering stormwater runoff; there would not be a physical impact to the environment. The non-structural BMPs associated with the proposed program would not degrade the existing visual character or quality of the site and its surroundings.

Mitigation Measures: None

Significance Determination: No Impact

Light and Glare

Impact 3.1-4: The proposed program could create a new source of substantial light or glare which would adversely affect day or nighttime views in the area.

Structural (Regional, Centralized, and Distributed) BMPs

Security lighting used during the construction of all structural BMP projects, if necessary, may introduce new sources of light and glare to the immediate project areas; however, nighttime construction is not anticipated. If security lighting is needed, it can be shielded and directed away from surrounding light-sensitive land uses, consistent with implementing agency design standards. Temporary impacts associated with light and glare during construction activities would be less than significant.

It is not anticipated that the structural BMP projects would involve the installation of permanent new outdoor lighting for the distributed, centralized, and regional structural watershed control measures. The goal of the BMPs in the EWMP projects is to reduce the impact of stormwater and non-stormwater on receiving water quality. Whether distributed, centralized, or regional, the major structural BMP functions are infiltration, treatment, and storage; these may be used individually or in combination. Distributed BMPs are most likely to be implemented in high-density urban, commercial, industrial, and transportation areas where currently there are no BMPs. These types of BMPs are generally “retrofit”-type projects that replace existing impervious surfaces with pervious surfaces such as bioinfiltration cells, bioswales, porous pavement, and filter strips that tie into existing stormwater management systems as part of the MS4. These projects may also augment the existing MS4 with additional inlet screens, filter media systems, sediment removal systems, and diversions to sanitary sewer lines. In addition, many of the proposed EWMP programs would include underground storm drain facilities. Because these types of BMPs would not require lighting, they would not create a new source of light or glare that would adversely affect day or nighttime views in the area.

Aboveground pump stations and treatment facilities associated with potential structural BMP projects may require new exterior daytime and nighttime lighting for operational and security purposes. If security lighting is needed for these facilities, they would be shielded to avoid glare impacts to local areas, consistent with implementing agency design standards. Operational impacts associated with light and glare would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

Non-structural BMPs consist of policies, actions, and activities aimed at preventing pollutants from entering stormwater runoff; there would not be a physical impact to the environment. The non-structural BMPs associated with the proposed program would not create a new source of light or glare which would adversely affect day or nighttime views in the area.

Mitigation Measures: None

Significance Determination: No impact

Cumulative Impact Discussion

Structural (Regional, Centralized, and Distributed) BMPs

Cumulative projects located in the Los Angeles County region would have the potential to result in a cumulative impact to aesthetic resources if in combination they would result in the removal or substantial adverse change of one or more features that contribute to the valued visual character or image of a neighborhood, community, state scenic highway, or localized area, such as a landmark (designated), historic resource, trees, or rock outcropping. Changes in land use are not included in the proposed program and the structural BMPs are generally limited to portions of the EWMP areas that feature existing urban development. The introduction of structural BMPs in these areas would result in minor changes to the community character and visual appearance of the applicable EWMP areas. In addition, many of the structural BMPs are anticipated to result in more open space areas and less pavement and concrete, thereby enhancing the level of greenness in the watersheds. These BMPs contribute to the natural open space character compared to the more built environment that these BMPs are replacing. Overall, implementation of the structural BMPs is anticipated to have a positive impact on the aesthetic environment. Implementation of **Mitigation Measures AES-1** and **AES-2** would minimize cumulative impacts to aesthetic resources.

Mitigation Measures: Implementation of **Mitigation Measure AES-1** and **AES-2**

Significance Determination: Less than significant with mitigation. (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.1-1.)

Non-Structural (Institutional) BMPs

Non-structural BMPs consist of policies, actions, and activities aimed at preventing pollutants from entering stormwater runoff; there would not be physical impact to the environment. Non-structural BMPs would not include any direct impacts to aesthetic resources; therefore, there would be no cumulative impacts to aesthetic resources.

Mitigation Measures: None required

Significance Determination: No impact

3.1.3 Summary of Impact Assessment

Table 3.1-1 shows a summary of the structural BMPs requiring mitigation.

TABLE 3.1-1
SUMMARY OF AESTHETICS IMPACTS REQUIRING MITIGATION MEASURES

	Thresholds of Significance				
Structural BMPs	**Scenic Vistas**	**Scenic Highways**	**Visual Character**	**Light and Glare**	**Cumulative Impacts**
Applicable Mitigation Measures:	**AES-1**	**AES-1**	**AES-1; AES-2**	**None Required**	**AES-1; AES-2**
Regional BMPs					
Regional Retention and Infiltration	Yes	No	Yes	No	Yes
Regional Capture, Detention, and Use	Yes	No	Yes	No	Yes
Centralized BMP					
Biofiltration	Yes	No	Yes	No	Yes
Constructed Wetlands	No	No	Yes	No	Yes
Treatment/Low-Flow Diversions	Yes	No	Yes	No	Yes
Creek, River, Estuary Restoration	No	No	Yes	No	Yes
Distributed BMPs					
Site Scale Detention	Yes	No	Yes	No	Yes
LID – Infiltration/Filtration BMPs – Porous Pavement, Green Streets, Bioswale/Filter Strips, Downspout Disconnects	Yes	No	Yes	No	Yes
LID – Green Infrastructure – Capture and Use – Cisterns, Rain Barrels, Green roofs, Planter Boxes	Yes	No	Yes	No	Yes
Flow-through Treatment BMPs	Yes	No	Yes	No	Yes
Source Control Treatment BMPs (catch basin inserts/screens, hydrodynamic separators, gross solids removal devices)	Yes	No	Yes	No	Yes
Low-Flow Diversions	Yes	Yes	Yes	No	Yes

NOTE: These conclusions are based on typical size and function of BMPs.

3.2 Air Quality

This section of the Program Environmental Impact Report (PEIR) addresses potential air quality impacts associated with implementation of the proposed program. The environmental setting provides a description of the general air quality and meteorological conditions in the South Coast Air Basin (Basin). The regulatory setting provides a description of applicable federal, state, and local regulatory policies. The impact assessment section evaluates the potential for short-term and long-term air quality impacts to result from implementation of the proposed program. Mitigation measures are recommended as necessary to reduce significant air quality impacts.

3.2.1 Environmental Setting

Regional Setting

The proposed program is located in Los Angeles County (County), which covers an area of about 4,083 square miles and comprises 88 cities and approximately 2,650 square miles of unincorporated areas. The majority of the County is highly urbanized and consists of several cities, communities, and unincorporated areas. The proposed program is located in multiple jurisdictions of Los Angeles County, which include the Los Angeles County Flood Control District (LACFCD), County of Los Angeles, and the following 46 cities: Los Angeles, Beverly Hills, Culver City, Inglewood, Santa Monica, West Hollywood, Hawthorne, El Segundo, Lomita, Baldwin Park, Covina, Glendora, Industry, La Puente, Malibu, Calabasas, Agoura Hills, Westlake Village, Hidden Hills, Santa Clarita, Rancho Palos Verdes, Palos Verdes Estates, Rolling Hills Estates, Redondo Beach, Hermosa Beach, Torrance, Manhattan Beach, Arcadia, Azusa, Bradbury, Duarte, Monrovia, Sierra Madre, Alhambra, Burbank, Glendale, Hidden Hills, La Cañada Flintridge, Montebello, Monterey Park, Pasadena, Rosemead, San Gabriel, San Marino, South Pasadena, and Temple City (refer to Figure 1-1). Each of these jurisdictions have independent planning documents that guide the development of urban, agricultural and other land uses within their jurisdictional boundaries.

Climate and Meteorology

The program is located in the portion of Los Angeles County that lies within the Basin. The program area is under the jurisdiction of the South Coast Air Quality Management District (SCAQMD). The Basin is an approximately 6,600-square-mile coastal plain bounded by the Pacific Ocean to the southwest and the San Gabriel, San Bernardino, and San Jacinto Mountains to the north and east. The Basin includes the non-desert portions of Los Angeles, Riverside, and San Bernardino Counties, and all of Orange County.

The ambient concentrations of air pollutants are determined by the amount of emissions released by sources and the atmosphere's ability to transport and dilute such emissions. Natural factors that affect transport and dilution include terrain, wind, atmospheric stability, and sunlight. Therefore, existing air quality conditions in the program area are determined by such natural factors as topography, meteorology, and climate, in addition to the amount of emissions released by existing air pollutant sources.

Atmospheric conditions such as wind speed, wind direction, and air temperature gradients interact with the physical features of the landscape to determine the movement and dispersal of air pollutants. The topography and climate of Southern California combine to make the Basin an area of high air pollution potential. The Basin is a coastal plain with connecting broad valleys and low hills, bounded by the Pacific Ocean to the west and high mountains around the rest of the perimeter. The general region lies in the semi-permanent high-pressure zone of the eastern Pacific, resulting in a mild climate tempered by cool sea breezes with light average wind speeds. The usually mild climatological pattern is disrupted occasionally by periods of extremely hot weather, winter storms, or Santa Ana winds. During the summer months, a warm air mass frequently descends over the cool, moist marine layer produced by the interaction between the ocean's surface and the lowest layer of the atmosphere. The warm upper layer forms a cap over the cool marine layer and inhibits the pollutants in the marine layer from dispersing upward. In addition, light winds during the summer further limit ventilation. Furthermore, sunlight triggers the photochemical reactions that produce ozone. The region experiences more days of sunlight than any other major urban area in the nation except Phoenix (SCAQMD, 2012).

Criteria Pollutants

The California Air Resources Board (CARB) and the United States Environmental Protection Agency (USEPA) currently focus on the following air pollutants as indicators of ambient air quality: ozone, carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), respirable or breathable particulate matter with an aerodynamic diameter of 10 micrometers or less (PM_{10}), fine particulate matter with an aerodynamic diameter of 2.5 micrometers or less ($PM_{2.5}$), and lead. The pollutants are referred to as "criteria air pollutants" since they are the most prevalent air pollutants known to be harmful to human health, and extensive health-effects criteria documents are available about their effects on human health and welfare. Standards have been established for each criteria pollutant to meet specific public health and welfare criteria set forth in the federal Clean Air Act (CAA). California has generally adopted more stringent ambient air quality standards for the criteria air pollutants (referred to as State Ambient Air Quality Standards, or state standards) and has adopted air quality standards for some pollutants for which there is no corresponding national standard.

Ozone

Ozone, the main component of photochemical smog, is primarily a summer and fall pollution problem. Ozone is not emitted directly into the air, but is formed through a complex series of chemical reactions involving other compounds that are directly emitted. These directly emitted pollutants (also known as ozone precursors) include reactive organic gases (ROGs) or volatile organic compounds (VOCs), and oxides of nitrogen (NO_X). While both ROGs and VOCs refer to compounds of carbon, ROG is a term used by CARB and is based on a list of exempted carbon compounds determined by CARB. VOC is a term used by the USEPA and is based on USEPA's own exempt list. The time period required for ozone formation allows the reacting compounds to spread over a large area, producing regional pollution problems. Ozone concentrations are the cumulative result of regional development patterns rather than the result of a few significant emission sources.

Once ozone is formed, it remains in the atmosphere for 1 or 2 days. Ozone is then eliminated through reaction with chemicals on the leaves of plants, attachment to water droplets as they fall to earth (rainout), or absorption by water molecules in clouds that later fall to earth with rain (washout).

Short-term exposure to ozone can irritate the eyes and cause constriction of the airways. In addition to causing shortness of breath, ozone can aggravate existing respiratory diseases such as asthma, bronchitis, and emphysema.

Carbon Monoxide

CO, a colorless and odorless gas, is a relatively nonreactive pollutant that is a product of incomplete combustion and is mostly associated with motor vehicles. When inhaled at high concentrations, CO combines with hemoglobin in the blood and reduces the oxygen-carrying capacity of the blood. This results in reduced oxygen reaching the brain, heart, and other body tissues. This condition is especially critical for people with cardiovascular diseases, chronic lung disease, or anemia. CO measurements and modeling were important in the early 1980s, when CO levels were regularly exceeded throughout California. In more recent years, CO measurements and modeling have not been a priority in most California air districts because of the retirement of older polluting vehicles, lower emissions from new vehicles, and improvements in fuels.

Nitrogen Dioxide

NO_2 is a reddish-brown gas that is a by-product of combustion processes. Automobiles and industrial operations are the main sources of NO_2. Combustion devices emit primarily nitric oxide (NO), which reacts through oxidation in the atmosphere to form NO_2. The combined emissions of NO and NO_2 are referred to as NO_X, which are reported as equivalent NO_2. Aside from its contribution to ozone formation, NO_2 can increase the risk of acute and chronic respiratory disease and reduce visibility. NO_2 may be visible as a coloring component of a brown cloud on high-pollution days, especially in conjunction with high ozone levels.

Sulfur Dioxide

SO_2 is a colorless, extremely irritating gas or liquid. It enters the atmosphere as a pollutant, mainly as a result of burning high-sulfur-content fuel oils and coal, and from chemical processes occurring at chemical plants and refineries. When SO_2 oxidizes in the atmosphere, it forms sulfur trioxide (SO_3). Collectively, these pollutants are referred to as sulfur oxides (SO_X).

Major sources of SO_2 include power plants, large industrial facilities, diesel vehicles, and oil-burning residential heaters. Emissions of SO_2 aggravate lung diseases, especially bronchitis. It also constricts the breathing passages, especially in people with asthma and people involved in moderate to heavy exercise. SO_2 potentially causes wheezing, shortness of breath, and coughing. Long-term SO_2 exposure has been associated with increased risk of mortality from respiratory or cardiovascular disease.

Particulate Matter

PM_{10} and $PM_{2.5}$ consist of particulate matter that is 10 microns or less in diameter and 2.5 microns or less in diameter, respectively (a micron is one-millionth of a meter). PM_{10} and $PM_{2.5}$ represent fractions of particulate matter that can be inhaled into the air passages and the lungs and can cause adverse health effects. Acute and chronic health effects associated with high particulate levels include the aggravation of chronic respiratory diseases, heart and lung disease, and coughing, bronchitis, and respiratory illnesses in children. Recent mortality studies have shown an association between morbidity and mortality and daily concentrations of particulate matter in the air. CARB has estimated that achieving the ambient air quality standards for PM_{10} could reduce premature mortality rates by 6,500 cases per year (CARB, 2002). Particulate matter can also damage materials and reduce visibility. One common source of $PM_{2.5}$ is diesel exhaust emissions.

PM_{10} consists of particulate matter emitted directly into the air (e.g., fugitive dust, soot, and smoke from mobile and stationary sources, construction operations, fires, and natural windblown dust) and particulate matter formed in the atmosphere by condensation and/or transformation of SO_2 and ROGs. Traffic generates particulate matter emissions through entrainment of dust and dirt particles that settle onto roadways and parking lots. PM_{10} and $PM_{2.5}$ are also emitted by wood burning in residential wood stoves and fireplaces and open agricultural burning. $PM_{2.5}$ can also be formed through secondary processes such as airborne reactions with certain pollutant precursors, including ROGs, ammonia (NH_3), NOx, and SOx.

Lead

Lead is a metal found naturally in the environment and present in some manufactured products. There are a variety of activities that can contribute to lead emissions, which are grouped into two general categories, stationary and mobile sources. On-road mobile sources include light-duty automobiles; light-, medium-, and heavy-duty trucks as well as motorcycles.

Emissions of lead have dropped substantially over the past 40 years. The reduction before 1990 was largely due to the phase-out of lead as an anti-knock agent in gasoline for on-road automobiles. Substantial emission reductions have also been achieved through enhanced controls in the metals-processing industry. In the Basin, atmospheric lead is generated almost entirely by the combustion of leaded gasoline and contributes less than one percent of the material collected as total suspended particulates.

Toxic Air Contaminants

Concentrations of toxic air contaminants (TACs), or in federal parlance, hazardous air pollutants (HAPs), are also used as indicators of ambient air quality conditions. A TAC is defined as an air pollutant that may cause or contribute to an increase in mortality or in serious illness, or that may pose a hazard to human health. TACs are usually present in minute quantities in the ambient air; however, their high toxicity or health risk may pose a threat to public health even at low concentrations.

According to The California Almanac of Emissions and Air Quality (CARB, 2009), the majority of the estimated health risk from TACs can be attributed to relatively few compounds, the most important being particulate matter from diesel-fueled engines (diesel particulate matter). Diesel particulate matter differs from other TACs in that it is not a single substance, but rather a complex mixture of hundreds of substances. Although diesel particulate matter is emitted by diesel-fueled internal combustion engines, the composition of the emissions varies depending on engine type, operating conditions, fuel composition, lubricating oil, and whether an emission control system is present.

Unlike the other TACs, no ambient monitoring data are available for diesel particulate matter because no routine measurement method currently exists. However, CARB has made preliminary concentration estimates based on a particulate matter exposure method. This method uses the CARB emissions inventory's PM_{10} database, ambient PM_{10} monitoring data, and the results from several studies to estimate concentrations of diesel particulate matter. In addition to diesel particulate matter, the TACs for which data are available that pose the greatest existing ambient risk in California are benzene, 1,3-butadiene, acetaldehyde, carbon tetrachloride, hexavalent chromium, para-dichlorobenzene, formaldehyde, methylene chloride, and perchloroethylene.

Odorous Emissions

Odors are generally regarded as an annoyance rather than a health hazard. However, manifestations of a person's reaction to foul odors can range from psychological (e.g., irritation, anger, or anxiety) to physiological (e.g., circulatory and respiratory effects, nausea, vomiting, and headache). Offensive odors are unpleasant and can lead to public distress, generating citizen complaints to local governments. Although unpleasant, offensive odors rarely cause physical harm. The occurrence and severity of odor impacts depend on the nature, frequency, and intensity of the source, wind speed, direction, and the sensitivity of receptors.

Program Area Air Quality Setting

Existing Air Quality

SCAQMD maintains monitoring stations within district boundaries that monitor air quality and compliance with associated ambient standards. The Enhanced Watershed Management Program (EWMP) areas associated with the proposed program are located in multiple jurisdictions within the County of Los Angeles, all of which are located within in the Basin. Given the large geographic region of the EWMP areas, an extensive listing of the air quality monitoring data collected by each SCAQMD monitoring station located within the EWMP areas is not provided in this PEIR. As individual EWMP projects are not assessed separately in this PEIR, the presentation of the air quality data collected by the monitoring stations relevant to each EWMP project is more applicable for inclusion in the environmental documents for future individual EWMP projects.

Both CARB and USEPA use the data measured at air quality monitoring stations to designate areas according to their attainment status for criteria air pollutants. The purpose of these designations is to identify the areas with air quality problems and thereby initiate planning efforts for improvement. The three basic designation categories are nonattainment, attainment, and unclassified. Unclassified is used in an area that cannot be classified on the basis of available information as meeting or not meeting the standards. In addition, the California designations include a subcategory of nonattainment-transitional, which is given to nonattainment areas that are progressing and nearing attainment. The current attainment status for the Basin is provided in **Table 3.2-1**.

TABLE 3.2-1
SOUTH COAST AIR BASIN ATTAINMENT STATUS

	Attainment Status	
Pollutant	**California Standards**	**Federal Standards**
Ozone	Extreme Nonattainment	Severe Nonattainment
CO	Attainment	Unclassified/ Attainment
NO_2	Attainment	Unclassified/ Attainment
SO_2	Attainment	Attainment
PM_{10}	Nonattainment	Attainment
$PM_{2.5}$	Nonattainment	Nonattainment

SOURCE: CARB, 2013b; USEPA, 2013.

Sensitive Land Uses

Land uses such as schools, children's daycare centers, hospitals, and convalescent homes are considered to be more sensitive to poor air quality than the general public because the population groups associated with these uses have increased susceptibility to respiratory distress. In addition, residential uses are considered more sensitive to air quality conditions than commercial and industrial uses, because people generally spend longer periods of time at their residences, resulting in greater exposure to ambient air quality conditions. Recreational land uses are considered moderately sensitive to air pollution. Exercise places a high demand on respiratory functions, which can be impaired by air pollution, even though exposure periods during exercise are generally short. In addition, noticeable air pollution can detract from the enjoyment of recreation. Given that the majority of the County is highly urbanized with a variety of land use types (e.g., open space, residential, commercial, mixed-use, public and semi-public, and industrial uses), and that the proposed program would be located in various watersheds across the County that span multiple jurisdictions, existing sensitive uses such as residences, schools, hospitals, daycare centers, etc., would be located within and in proximity to the EWMP areas. As described in Section 3.9, *Land Use and Agriculture,* of this PEIR, many of the EWMP areas, including Ballona Creek, Beach Cities, Dominguez Channel, and Marina del Rey, have residential uses as the predominant land use.

3.2.2 Regulatory Setting

The EWMP areas associated with the proposed program are located in Los Angeles County within the Basin. Air quality in the County is regulated by USEPA, CARB, and SCAQMD. The

County of Los Angeles General Plan also contains an Air Quality Element in their 2014 draft document. This element summarizes air quality issues and outlines the goals and policies in the General Plan that will improve air quality and reduce greenhouse gas emissions (Los Angeles County, 2014). Los Angeles County's adopted General Plan has not yet been updated to include this element.

USEPA

Criteria Air Pollutants

At the federal level, USEPA has been charged with implementing national air quality programs. USEPA's air quality mandates are drawn primarily from the federal CAA, which was enacted in 1970. The most recent major amendments to the CAA were made by Congress in 1990.

The CAA requires USEPA to establish National Ambient Air Quality Standards (NAAQS). USEPA has established primary and secondary NAAQS for the following "criteria air pollutants": ozone, CO, NO_2, SO_2, PM_{10}, $PM_{2.5}$, and lead. **Table 3.2-2** shows the NAAQS for these pollutants.

The CAA also requires each state to prepare an air quality control plan, referred to as a state implementation plan (SIP). The CAA Amendments of 1990 (CAAA) added requirements for states with nonattainment areas to revise their SIPs to incorporate additional control measures to reduce air pollution. The SIPs are modified periodically to reflect the latest emissions inventories, planning documents, and rules and regulations of the air basins, as reported by their jurisdictional agencies. USEPA is responsible for reviewing all SIPs to determine whether they conform to the mandates of the CAA and its amendments, and to determine whether implementing the SIPs will achieve air quality goals. If USEPA determines a SIP to be inadequate, a federal implementation plan that imposes additional control measures may be prepared for the nonattainment area. If an approvable SIP is not submitted or implemented within the mandated time frame, sanctions may be applied to transportation funding and stationary sources of air pollution in the air basin.

USEPA also has regulatory and enforcement jurisdiction over emission sources beyond state waters (outer continental shelf), and those that are under the exclusive authority of the federal government, such as aircraft, locomotives, and interstate trucking. USEPA's primary role at the state level is to oversee state air quality programs. USEPA sets federal vehicle and stationary source emissions standards and provides research and guidance in air pollution programs.

In June 2004, USEPA finalized the adoption of a comprehensive national program/rule to reduce emissions from off-road diesel engines used primarily in construction, agricultural, and industrial applications by integrating engine and fuel controls as a system to gain the greatest emission reductions. Specifically, USEPA adopted new emission standards for off-road diesel engines and sulfur reductions in off-road diesel fuel aimed at dramatically reducing harmful emissions and helping states and local areas that have been designated as 8-hour ozone nonattainment areas to improve their air quality. The new engine standards, which are based on the use of advanced exhaust emission control devices, began to take effect in 2008 and would continue to be phased in until 2015. USEPA estimates particulate matter reductions of 95 percent, NOx reductions of 90

RB-AR 8331

TABLE 3.2-2
AMBIENT AIR QUALITY STANDARDS FOR CRITERIA POLLUTANTS

Pollutant	Averaging Time[a]	State Standard	National Standard	Pollutant Health and Atmospheric Effects	Major Pollutant Sources
Ozone	1 hour 8 hours	0.09 ppm 0.070 ppm[b]	--- 0.075 ppm	High concentrations can directly affect lungs, causing irritation. Long-term exposure may cause damage to lung tissue.	Formed when ROG and NO_X react in the presence of sunlight. Major sources include on-road motor vehicles, solvent evaporation, and commercial/industrial mobile equipment.
Carbon Monoxide (CO)	1 hour 8 hours	20 ppm 9.0 ppm	35 ppm 9 ppm	Classified as a chemical asphyxiant, carbon monoxide interferes with the transfer of fresh oxygen to the blood and deprives sensitive tissues of oxygen.	Internal combustion engines, primarily gasoline-powered motor vehicles.
Nitrogen Dioxide (NO_2)	1 hour Annual Arithmetic Mean	0.18 ppm 0.030 ppm	0.100 ppm 0.053 ppm	Irritating to eyes and respiratory tract. Colors atmosphere reddish-brown.	Motor vehicles, petroleum refining operations, industrial sources, aircraft, ships, and railroads.
Sulfur Dioxide (SO_2)	1 hour 3 hours 24 hours Annual Arithmetic Mean	0.25 ppm --- 0.04 ppm ---	75 ppb 0.5 ppm 0.14 ppm 0.030 ppm	Irritates upper respiratory tract; injurious to lung tissue. Can yellow the leaves of plants; destructive to marble, iron, and steel. Limits visibility and reduces sunlight.	Fuel combustion, chemical plants, sulfur recovery plants, and metal processing.
Respirable Particulate Matter (PM_{10})	24 hours Annual Arithmetic Mean	50 µg/m^3 20 µg/m^3	150 µg/m^3 ---	May irritate eyes and respiratory tract, decreases in lung capacity, increases cancer and mortality. Produces haze and limits visibility.	Dust and fume-producing industrial and agricultural operations, combustion, atmospheric photochemical reactions, and natural activities (e.g., wind-raised dust and ocean sprays).
Fine Particulate Matter ($PM_{2.5}$)	24 hours Annual Arithmetic Mean	--- 12 µg/m^3	35 µg/m^3 12.0 µg/m^3	Increases respiratory disease, lung damage, cancer, and premature death. Reduces visibility and results in surface soiling.	Fuel combustion in motor vehicles, equipment, and industrial sources; residential and agricultural burning; Also formed from photochemical reactions of other pollutants, including NO_X, sulfur oxides, and organics.
Lead (Pb)	30 Day Average Calendar Quarter Rolling 3-Month Average	1.5 µg/m^3 --- ---	--- 1.5 µg/m^3 0.15 µg/m^3	Disturbs gastrointestinal system, and causes anemia, kidney disease, and neuromuscular and neurological dysfunction (in severe cases).	*Present source:* lead smelters, battery manufacturing, and recycling facilities. Past source: combustion of leaded gasoline.
Hydrogen Sulfide	1 hour	0.03 ppm	No National Standard	Nuisance odor (rotten egg smell), headache, and breathing difficulties (higher concentrations)	Geothermal power plants, petroleum production and refining
Sulfates (SO_4)	24 hours	25 µg/m^3	No National Standard	Decrease in ventilatory functions; aggravation of asthmatic symptoms; aggravation of cardio-pulmonary disease; vegetation damage; degradation of visibility; property damage.	Industrial processes.
Visibility-Reducing Particles	8 hours	Extinction of 0.23/km; visibility of 10 miles or more	No National Standard	Reduces visibility, reduced airport safety, lower real estate value, and discourages tourism.	See $PM_{2.5}$.
Vinyl Chloride	24 hours	0.01 ppm	No National Standard	Short-term exposure to high levels of vinyl chloride in the air can cause dizziness, drowsiness, and headaches. Long-term exposure through inhalation and oral exposure can cause liver damage. Cancer is a major concern from exposure to vinyl chloride via inhalation. Vinyl chloride exposure has been shown to increase the risk of angiosarcoma, a rare form of liver cancer in humans.	Polyvinyl chloride (PVC) plastic and vinyl products.

NOTE: ppm = parts per million; ppb = parts per billion; µg/m^3 = micrograms per cubic meter.
[a] The averaging time is the interval of time over which the sample results are reported.
[b] This concentration was approved by CARB on April 28, 2005, and became effective May 17, 2006.

SOURCE: CARB, 2013c.

percent, and the virtual elimination of SO_X from off-road engines that meet the new standards. Because the emission control devices in the off-road diesel engines could potentially be damaged by sulfur, USEPA also targeted the reduction of sulfur levels in off-road diesel fuel as part of its rule. The rule aimed to reduce off-road diesel fuel sulfur levels by 99 percent, resulting in an Ultra Low Sulfur Diesel (ULSD) fuel that has a maximum sulfur concentration of 15 parts per million (ppm). The phase-in of fuel controls to reduce the sulfur levels in off-road diesel fuel began in 2007.

With respect to on-road diesel engines, USEPA promulgated the Heavy-Duty Highway Rule in 2007, which aims to reduce emissions from on-road, heavy-duty diesel trucks by establishing a series of increasingly strict emission standards for new engines. Manufacturers are required to produce new diesel vehicles that meet particulate matter and NO_X emission standards beginning with model year 2007.

Hazardous Air Pollutants

USEPA has programs for identifying and regulating HAPs. The first National Emission Standards for Hazardous Air Pollutants (NESHAPs) were originally required by the CAA in 1970, which were developed for sources and source categories of HAPs that were determined to pose adverse risk to human health. The USEPA Administrator was directed to set risk-based NESHAPs at a level that provided an ample margin of safety to protect the public health from HAPs. Subsequently, in Section 112(d) of the 1990 CAAA, Congress directed USEPA to develop technology-based standards to further regulate HAPs. As opposed to the original conception of NESHAPs as a risk-based standard, the technology-based NESHAPS were established according to Maximum Achievable Control Technology (MACT) requirements. The MACT NESHAP standards were different for major sources than for area sources of HAPs. Major sources are defined as stationary sources with potential to emit more than 10 tons per year (tpy) of a single HAP or more than 25 tpy of any combination of HAPs; all other sources are considered area sources. Section 112(f) of the 1990 CAAA also specified that USEPA determine whether or not to promulgate additional NESHAP standards beyond the MACT within 8 years after promulgation of the MACT standard (but within 9 years after promulgation of the 2-year MACT source categories). Thus, USEPA is required to evaluate the NESHAPs developed according to the MACT standards for any “residual risk” with 8 years of promulgation. If the “residual risk” for a source category does not protect public health with “an ample margin of safety,” then USEPA must promulgate health-based standards for that source category to further reduce HAP emissions.

The CAAA also required USEPA to promulgate vehicle or fuel standards containing reasonable requirements that control toxic emissions of, at a minimum, benzene and formaldehyde. Performance criteria were established to limit mobile-source emissions of toxics, including benzene, formaldehyde, and 1,3-butadiene. In addition, Section 219 required the use of reformulated gasoline in selected areas with the most severe ozone nonattainment conditions to further reduce mobile-source emissions.

CARB

Criteria Air Pollutants

CARB, a department of the California Environmental Protection Agency, oversees air quality planning and control throughout California. CARB is responsible for coordination and oversight of state and local air pollution control programs in California and for implementation of the California Clean Air Act (CCAA). The CCAA, which was adopted in 1988, requires CARB to establish the California Ambient Air Quality Standards (CAAQS). CARB has established CAAQS for sulfates, hydrogen sulfide, vinyl chloride, visibility-reducing particulate matter, and the above-mentioned criteria air pollutants. Applicable CAAQS are shown in Table 3.2-2.

The CCAA requires all local air districts in the state to endeavor to achieve and maintain the CAAQS by the earliest practical date. The act specifies that local air districts shall focus particular attention on reducing the emissions from transportation and area-wide emission sources, and provides districts with the authority to regulate indirect sources.

Among CARB's other responsibilities are overseeing compliance by local air districts with California and federal laws; approving local air quality plans; submitting SIPs to USEPA; monitoring air quality; determining and updating area designations and maps; and setting emissions standards for new mobile sources, consumer products, small utility engines, off-road vehicles, and fuels.

Toxic Air Contaminants

Air quality regulations also focus on TACs. In general, for those TACs that may cause cancer, there is no concentration that does not present some risk. In other words, there is no safe level of exposure. This contrasts with the criteria air pollutants, for which acceptable levels of exposure can be determined and for which the ambient standards have been established. Instead, USEPA and CARB regulate HAPs and TACs, respectively, through statutes and regulations that generally require the use of the MACT or best available control technology (BACT) for toxics and to limit emissions. These statutes and regulations, in conjunction with additional rules set forth by the districts, establish the regulatory framework for TACs.

TACs in California are regulated primarily through the Tanner Air Toxics Act (Assembly Bill [AB] 1807 [Chapter 1047, Statutes of 1983]) and the Air Toxics Hot Spots Information and Assessment Act (Hot Spots Act) (AB 2588 [Chapter 1252, Statutes of 1987]). AB 1807 sets forth a formal procedure for CARB to designate substances as TACs. This includes research, public participation, and scientific peer review before CARB can designate a substance as a TAC. To date, CARB has identified more than 21 TACs and adopted USEPA's list of HAPs as TACs. Most recently, diesel particulate matter was added to the CARB list of TACs. Once a TAC is identified, CARB then adopts an airborne toxics control measure (ATCM) for sources that emit that particular TAC. If there is a safe threshold for a substance at which there is no toxic effect, the control measure must reduce exposure below that threshold. If there is no safe threshold, the measure must incorporate BACT to minimize emissions.

The Air Toxics Hot Spots Information and Assessment Act requires existing facilities emitting toxic substances above a specified level to prepare a toxic-emission inventory, prepare a risk assessment if emissions are significant, notify the public of significant risk levels, and prepare and implement risk-reduction measures.

CARB published the *Air Quality and Land Use Handbook: A Community Health Perspective* (Handbook), which provides guidance concerning land use compatibility with TAC sources (CARB, 2005). Although it is not a law or adopted policy, the Handbook offers advisory recommendations for the siting of sensitive receptors near uses associated with TACs, such as freeways and high-traffic roads, commercial distribution centers, rail yards, ports, refineries, dry cleaners, gasoline stations, and industrial facilities, to help keep children and other sensitive populations out of harm's way.

SCAQMD

Criteria Air Pollutants

SCAQMD attains and maintains air quality conditions in the Basin through a comprehensive program of planning, regulation, enforcement, technical innovation, and promotion of the understanding of air quality issues. The clean air strategy of SCAQMD includes preparation of plans for attainment of ambient air quality standards, adoption and enforcement of rules and regulations concerning sources of air pollution, and issuance of permits for stationary sources of air pollution. SCAQMD also inspects stationary sources of air pollution and responds to citizen complaints; monitors ambient air quality and meteorological conditions; and implements programs and regulations required by the CAA, CAAA, and CCAA. Air quality plans applicable to the proposed program are discussed below.

Air Quality Management Plan

SCAQMD and the Southern California Association of Governments (SCAG) are responsible for preparing the air quality management plan (AQMP), which addresses federal and state CAA requirements. The AQMP details goals, policies, and programs for improving air quality in the Basin.

The 2012 AQMP was adopted by the SCAQMD Governing Board on December 12, 2012. The purpose of the 2012 AQMP for SCAG is to set forth a comprehensive and integrated program that will lead the Basin into compliance with the federal 24-hour $PM_{2.5}$ air quality standard, and to provide an update to the Basin's commitments toward meeting the federal 8-hour ozone standards. The AQMP also serves to satisfy recent USEPA requirements for a new attainment demonstration of the revoked 1-hour ozone standard, as well as a vehicle miles traveled (VMT) emissions offset demonstration.[1] Specifically, once approved by CARB, the AQMP would serve as the official SIP submittal for the federal 2006 24-hour $PM_{2.5}$ standard, for which USEPA has

1 Although the federal 1-hour ozone standard was revoked in 2005, the USEPA has proposed to require a new 1-hour ozone attainment demonstration in the South Coast extreme ozone nonattainment area as a result of a recent court decision. Although USEPA has replaced the 1-hour ozone standard with a more health protective 8-hour standard, the CAA anti-backsliding provisions require that California have approved plans for attaining the 1-hour standard.

established a due date of December 14, 2012.[2] In addition, the AQMP updates specific new control measures and commitments for emissions reductions to implement the attainment strategy for the 8-hour ozone SIP. The 2012 AQMP sets forth programs which require integrated planning efforts and the cooperation of all levels of government: local, regional, state, and federal. Currently, SCAQMD staff has already begun initiating an early development process for the 2015 AQMP.

SCAQMD Rules and Regulations

All projects are subject to SCAQMD rules and regulations in effect at the time of construction. Specific rules applicable to the construction anticipated under the proposed program would include the following:

Rule 401 – Visible Emissions. This rule is intended to prevent the discharge of pollutant emissions from an emissions source that results in visible emissions. Specifically, the rule prohibits the discharge of any air contaminant into the atmosphere by a person from any single source of emission for a period or periods aggregating more than 3 minutes in any 1 hour that is as dark or darker in shade than that designated No. 1 on the Ringelmann Chart, as published by the United States Bureau of Mines.

Rule 402 – Nuisance. This rule is intended to prevent the discharge of pollutant emissions from an emissions source that results in a public nuisance. Specifically, this rule prohibits any person from discharging quantities of air contaminants or other material from any source such that it would result in an injury, detriment, nuisance, or annoyance to any considerable number of persons or to the public. Additionally, the discharge of air contaminants would also be prohibited where it would endanger the comfort, repose, health, or safety of any number of persons or the public, or that cause, or have a natural tendency to cause, injury or damage to business or property. This rule does not apply to odors emanating from agricultural operations necessary for the growing of crops or the raising of fowl or animals.

Rule 403 – Fugitive Dust. This rule is intended to reduce the amount of particulate matter entrained in the ambient air as a result of anthropogenic (human-made) fugitive dust sources by requiring actions to prevent, reduce, or mitigate fugitive dust emissions. Rule 403 applies to any activity or human-made condition capable of generating fugitive dust, and requires best available control measures to be applied to earthmoving and grading activities.

Toxic Air Contaminants

At the local level, air pollution control or management districts may adopt and enforce CARB control measures. Under SCAQMD Regulation XIV (Toxics and Other Non-Criteria Pollutants), and in particular Rule 1401 (New Source Review), all sources that possess the potential to emit TACs are required to obtain permits from SCAQMD. Permits may be granted to these operations

2 Although the 2012 AQMP was approved by the SCAQMD Board on December 7, 2012, the plan did not get submitted to the USEPA by December 14, 2012 as it first required approval from CARB. The 2012 AQMP was subsequently approved by CARB on January 25, 2013, and as of February 13, 2013 the plan has been submitted by CARB to the USEPA.

if they are constructed and operated in accordance with applicable regulations, including new source review standards and air toxics control measures. SCAQMD limits emissions and public exposure to TACs through a number of programs. SCAQMD prioritizes TAC-emitting stationary sources based on the quantity and toxicity of the TAC emissions and the proximity of the facilities to sensitive receptors. As none of the proposed Best Management Practices (BMP) projects in the County would involve TAC-emitting stationary sources, no permits from SCAQMD would be required for operation of the proposed BMP projects.

The Air Toxics Control Plan (March 2000, revised March 26, 2004) is a planning document designed to examine the overall direction of SCAQMD's air toxics control program. It includes development and implementation of strategic initiatives to monitor and control air toxics emissions. Control strategies that are deemed viable and are within SCAQMD's jurisdiction will each be brought to the SCAQMD Board for further consideration through the normal public review process. Strategies that are to be implemented by other agencies will be developed in a cooperative effort, and the progress will be reported back to the Board periodically.

In September 2008, the SCAQMD completed the Multiple Air Toxics Exposure Study III (MATES III). MATES III is a monitoring and evaluation study conducted in the Basin and is a follow-up to previous air toxics studies. The study consists of several elements, including a monitoring program, an updated emissions inventory of toxic air contaminants, and a modeling effort to characterize risk across the Basin. The study focuses on the carcinogenic risk from exposure to air toxics. However, it does not estimate mortality or other health effects from particulate exposures. MATES III shows that areas within the County have an estimated carcinogenic risk ranging from 1,173 to 1,449 in a million. These model estimates were based on monitoring data collected at 10 fixed sites within the Basin. As of June 2012, SCAQMD began conducting the MATES IV.

County of Los Angeles

General Plan

The Conservation and Open Space Element of the 1980 County of Los Angeles General Plan sets the policy direction for management of the County's natural resources, including air quality. The specific policies in the County General Plan related to improving air quality include:

Policy 1: Actively support strict air quality regulations for mobile and stationary sources, and continued research to improve air quality. Promote vanpooling, carpooling and improved public transportation.

Policy 2: Support the conservation of energy and encourage the development and utilization of new energy sources including geothermal, thermal waste, solar, wind and ocean-related sources.

Policy 3: Promote the use of solar energy to the maximum extent possible.

The Air Quality Element of the Draft 2014 County of Los Angeles General Plan summarizes air quality issues and outlines goals and policies that will improve air quality and reduce greenhouse gas emissions. These specific policies include:

Policy AQ 1.1: Minimize health risks to people from industrial toxic or hazardous air pollutant emissions, with an emphasis on local hot spots, such as existing point sources affecting immediate sensitive receptors.

Policy AQ 1.2: Encourage the use of low or no volatile organic compound (VOC) emitting materials.

Policy AQ 1.3: Reduce particulate inorganic and biological emissions from construction, grading, excavation, and demolition to the maximum extent feasible.

Policy AQ 1.4: Work with local air quality management districts to publicize air quality warnings, and to track potential sources of airborne toxics from identified mobile and stationary sources.

Policy AQ 2.1: Encourage the application of design and other appropriate measures when siting sensitive uses, such as residences, schools, senior centers, daycare centers, medical facilities, or parks with active recreational facilities within proximity to major sources of air pollution, such as freeways.

Policy AQ 2.2: Participate in, and effectively coordinate the development and implementation of community and regional air quality programs.

Policy AQ 3.1: Facilitate the implementation and maintenance of the Community Climate Action Plan to ensure that the County reaches its climate change and greenhouse gas emission reduction goals.

Policy AQ 3.2: Reduce energy consumption in County operations by 20 percent by 2015.

Policy AQ 3.3: Reduce water consumption in County operations.

Policy AQ 3.4: Participate in local, regional and state programs to reduce greenhouse gas emissions.

Policy AQ 3.5: Encourage maximum amounts of energy conservation in new development and municipal operations.

Policy AQ 3.6: Support and expand urban forest programs within the unincorporated areas.

City General Plans

The numerous cities encompassed by the EWMP project area all have their own respective city General Plans, some of which may contain policies that address air quality. As implementation of the individual structural BMP projects proceed, specific policies and objectives pertaining to air quality from applicable city General Plans will be identified and evaluated on a project-by-project basis during subsequent California Environmental Quality Act (CEQA) environmental processes.

3.2.3 Impact Assessment

Thresholds of Significance

Based on Appendix G of the CEQA Guidelines, impacts related to air quality may be considered significant if the proposed program would:

- Conflict with or obstruct implementation of the applicable air quality plan.
- Violate any air quality standard or contribute substantially to an existing or projected air quality violation.
- Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is nonattainment under an applicable federal or state ambient air quality standard (including releasing emissions which exceed quantitative thresholds for ozone precursors).
- Expose sensitive receptors to substantial pollutant concentrations.
- Create objectionable odors affecting a substantial number of people.

As guided by Appendix G of the CEQA Guidelines, the significance criteria established by the applicable air quality management or air pollution control district may be relied upon to make the above determinations. As such, the significance thresholds and analysis methodologies in SCAQMD's *CEQA Air Quality Handbook* are used in evaluating project impacts. The SCAQMD has established daily mass emissions thresholds for criteria pollutants and ozone precursors, which are shown in **Table 3.2-3**

Program Impact Discussion

Air Quality Plan

Impact 3.2-1: The project could conflict with or obstruct implementation of the applicable air quality plan.

Structural (Regional, Centralized, and Distributed) BMPs

In preparation of the AQMP, SCAQMD and SCAG use land use designations contained in General Plan documents to forecast, inventory, and allocate regional emissions from land use and development-related sources. For purposes of analyzing consistency with the AQMP, projects that are consistent with the regional population, housing, and employment forecasts identified by SCAG are considered to be consistent with the AQMP growth projections, since the forecast assumptions by SCAG forms the basis of the land use and transportation control portions of the AQMP.

TABLE 3.2-3
SCAQMD REGIONAL AIR QUALITY SIGNIFICANCE THRESHOLDS

	Mass Daily Thresholds (lbs/day)	
Pollutant	**Construction**	**Operations**
Oxides of Nitrogen (NO_X)	100	55
Reactive Organic Gases (ROG)	75	55
Respirable Particulate Matter (PM_{10})	150	150
Fine Particulate Matter ($PM_{2.5}$)	55	55
Oxides of Sulfur (SO_X)	150	150
Carbon Monoxide (CO)	550	550
Lead[a]	3	3
TACs (including carcinogens and non-carcinogens	Maximum Incremental Cancer Risk ≥ 10 in 1 million Cancer Burden > 0.5 excess cancer cases (in areas ≥ 1 in 1 million) Chronic & Acute Hazard Index ≥ 1.0 (project increment)	

[a] As the proposed program would not involve the development of any major lead emissions sources, lead emissions are not analyzed further in the PEIR.

SOURCE: SCAQMD, 2011.

Additionally, since SCAG's regional growth forecasts are based upon, among other things, land uses designated in General Plans, a project that is consistent with the land use designated in a city's General Plan would also be consistent with the SCAG's regional forecast projections, and thus also with the AQMP growth projections.

Implementation of the proposed program would involve the installation of structural control measures that would be constructed as BMPs to reduce the impact of stormwater and non-stormwater on receiving water quality within the EWMP areas. As such, the proposed program is not a land use project and its implementation would not induce any additional growth within the EWMP areas in the County. Therefore, the proposed program would not conflict with, or obstruct, implementation of the AQMP. Overall, this impact would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, no impacts associated with implementation of the SCAQMD's AQMP would result.

Mitigation Measures: None required

Significance Determination: No impact

Air Quality Standards

Impact 3.2-2: The project could violate any air quality standard or contribute substantially to an existing or projected air quality violation.

Structural (Regional, Centralized, and Distributed) BMPs

Construction

Development of the proposed structural BMPs would generally involve construction phases such as site preparation, grading and excavation, and construction of the structural control measure. Construction activities associated with each structural BMP (regional, centralized, and distributed) would generate pollutant emissions from the following general activities: (1) site preparation, grading, and excavation; (2) construction workers traveling to and from a BMP site; (3) delivery and hauling of construction supplies to and soil and debris from the structural BMP site; (4) fuel combustion by on-site construction equipment; and (5) construction of the structural BMP. These construction activities would temporarily create emissions of dust, fumes, equipment exhaust, and other air contaminants. Construction activities involving site preparation and grading would primarily generate PM_{10} emissions. Mobile source emissions (use of diesel-fueled equipment on-site, and traveling to and from a BMP site) would primarily generate NO_X emissions. The amount of emissions generated on a daily basis would vary, depending on the intensity and types of construction activities occurring at the same time.

The timing and sequencing of the development of the proposed structural BMPs within the EWMP areas are currently unknown. Thus, the amount of program-related construction that would occur on a daily or annual basis cannot be determined with any certainty at this time. As such, it is expected that the construction activities for the structural BMPs in the EWMP areas would occur intermittently throughout the course of the program implementation period Construction impacts associated with each structural BMP development would be short-term in nature and limited to the period of time when construction activity is taking place for that particular development. Although it is beyond the scope of this PEIR to assess the construction emissions for each individual BMP project, for the purpose of this analysis an emissions estimate for a representative "worst-case" construction scenario of each structural BMP type (i.e., distributed, centralized, and regional) is provided to demonstrate the magnitude of the daily emissions that can be generated by each structural BMP type. As such, a worst-case construction scenario was defined for a small-, medium-, and large-scale structural BMP project, which corresponds to a distributed, centralized, and regional structural BMP project, respectively. In addition, the year 2015 was used as the construction analysis year to provide a conservative analysis, since construction equipment used in future years beyond 2015 would likely emit pollutants at a lower rate because of more stringent emission standards, advances in technologies and fuels, and equipment turnover.

The maximum daily construction emissions for the three structural BMP project types were estimated using the California Emissions Estimator Model (CalEEMod), which is designed to model construction emissions for land use development projects based on building size, land use and type, and disturbed acreage, and allows for the input of project-specific information. The construction-related emissions of criteria air pollutants for the three structural BMP types were modeled based on general information provided in the project description and CalEEMod default settings along with reasonable assumptions based on other similar types of projects. The specific modeling parameters pertaining to the types and amount of construction equipment used during each construction phase for a representative distributed, centralized, and regional structural BMP project that was used to generate construction emissions are shown in **Tables 3.2-4**, **3.2-5**, and **3.2-6**, respectively.

Tables 3.2-7, **3.2-8**, and **3.2-9** summarize the modeled worst-case daily emissions that are estimated to occur on peak construction days for a representative distributed, centralized, and regional structural BMP project, respectively. The CalEEMod modeling for each representative structural BMP project type assumes that appropriate dust control measures would be implemented during each phase of development as required by SCAQMD Rule 403—Fugitive Dust. These dust control measures generally include, but are not limited to, the following:

- All haul trucks shall be covered when loaded with fill.
- Paved streets shall be swept at least once per day where there is evidence of dirt that has been carried on to the roadway.
- Watering trucks shall be used to minimize dust. Watering should be sufficient to confine dust plumes to the project work areas.
- Active disturbed areas shall have water applied to them three times daily.
- Inactive disturbed areas shall be revegetated as soon as feasible to prevent soil erosion.
- For disturbed surfaces to be left inactive for four or more days and that will not be revegetated, a chemical stabilizer shall be applied per manufacturer's instruction.
- For unpaved roads, chemical stabilizers shall be applied or the roads shall be watered once per hour during active operation.
- Vehicle speed on unpaved roads shall be limited to 15 miles per hour.
- For open storage piles that will remain on-site for two or more days, water shall be applied once per hour, or coverings shall be installed.

- For paved road track-out, all haul vehicles shall be covered and shall maintain a freeboard height of 12 inches.
- During high wind conditions (wind speeds in excess of 25 miles per hour), all earthmoving activities shall cease or water shall be applied to soil not more than 15 minutes prior to disturbing such soil.
- Install wheel washers where vehicles enter and exit unpaved roads onto paved roads, or wash off trucks and any equipment leaving the construction site each trip on a gravel surface to prevent dirt and dust from impacting the surrounding areas.

NOTE: See Appendix C for CalEEMod model outputs.
[a] PM_{10} and $PM_{2.5}$ emission estimates are based on compliance with SCAQMD Rule 403 requirements for fugitive dust suppression.

As shown in Table 3.2-7, implementation of distributed BMPs would not result in significant air emissions when assuming worst-case construction methods. However, as shown in Tables 3.2-8 and 3.2-9, for some of the larger regional and centralized BMPs, the maximum daily level of construction-generated emissions of NO_X would exceed the applicable SCAQMD-recommended thresholds under the worst-case construction scenario. The remaining criteria pollutants (i.e., ROG, CO, SOx, PM_{10}, and $PM_{2.5}$) would not exceed the applicable SCAQMD-recommended thresholds. The exceedance of SCAQMD's threshold for NO_X emissions for larger BMPs would be generated primarily during the grading phase, when emissions associated with off-road construction equipment and on-road soil hauling activities would occur. Thus, impacts associated with NOx emissions during construction activities of centralized and regional structural BMPs are considered significant.

It should be noted that the sample construction scenarios provided in this analysis for a single distributed, centralized, and regional structural BMP project represent an estimation of construction methods and emissions. It is likely that the actual emissions associated with each structural BMP type would be less than those presented in this PEIR.

As discussed previously, it is anticipated that future structural BMP developments associated with the proposed program would be reviewed on a case-by-case basis to ascertain whether an individual development would generate potentially significant air quality impacts during construction, and, where it is necessary, will require the implementation of mitigation measures to minimize air emissions and reduce potentially significant impacts. As such, the identification of a significant program-level impact from construction in this PEIR for the proposed program does not preclude the finding of less-than-significant impacts from construction for future individual structural BMP projects within the EWMP areas.

For BMPs that may result in significant air emissions as determined by implementing agencies, **Mitigation Measures AIR-1** and **AIR-2** would need to be implemented to reduce construction emissions to less than significant levels. For smaller BMPs including distributed BMPs, air emissions would not be significant and would not require mitigation measures. Table 3.2-10 summarizes which BMPs would require mitigation measures.

While implementation of Mitigation Measures AIR-1 and AIR-2 would reduce construction-related emissions, they may not reduce these emissions to levels below the SCAQMD thresholds for every structural BMP project, as the amount of emissions generated for each structural BMP project would vary depending on its size, the land area that would need to be disturbed during construction, and the length of the construction schedule. Implementation of large regional or centralized BMPs could result in temporary significant and unavoidable air emissions during peak periods of construction.

Operation

Implementation of the proposed program would not result in substantial long-term regional emissions of criteria air pollutants. The proposed structural BMPs are not land use projects and, therefore, would not generate daily vehicle-exhaust emissions by the motor vehicles traveling to and from the individual project areas. While it is anticipated that implementing agencies would conduct visits to the structural BMP sites for inspection and maintenance activities, these visits would occur only periodically throughout the year and would result in minimal emissions. Additionally, while some of the centralized and regional structural BMPs may require the installation of pump stations and ancillary components, this equipment would be electrically powered and would not generate emissions at the BMP sites.

Some Regional BMPs may involve grading large areas to be used as percolation basins. Some of these areas may be unvegetated, which may result in dust erosion. Implementing agencies would be required to prepare a Dust Control Plan to be in compliance with Rule 403. Stabilizing soils with binders, gravel, or vegetation would reduce dust emissions from large graded areas and prevent significant PM_{10} emissions. Compliance with existing dust emission regulations, specifically Rule 403, would ensure that operational impacts would be less than significant.

Mitigation Measures:

AIR-1: Implementing agencies shall require for large regional or centralized BMPs the use of low-emission equipment meeting Tier II emissions standards at a minimum and Tier III and IV emissions standards where available as CARB-required emissions technologies become readily available to contractors in the region.

AIR-2: For large construction efforts that may result in significant air emissions, implementing agencies shall encourage contractors to use lower-emission equipment through the bidding process where appropriate.

Significance Determination: Impacts from construction emissions would remain significant and unavoidable for some of the larger projects as there are no other feasible mitigation measures available to reduce these impacts at this program level; impacts from operational emissions would be less than significant. (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.2-10.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, no air quality impacts associated with construction or operational activities would result.

Mitigation Measures: None required

Significance Determination: No impact

Cumulative Impacts

Impact 3.2-3: The program could result in a cumulatively considerable net increase of any criteria pollutant for which the project region is nonattainment under an applicable federal or state ambient air quality standard (including releasing emissions which exceed quantitative thresholds for ozone precursors).

Structural (Regional, Centralized, and Distributed) BMPs

As the Basin is currently in nonattainment for ozone, PM_{10}, and $PM_{2.5}$, cumulative development consisting of the proposed program along with other reasonably foreseeable future projects in the Basin as a whole could violate an air quality standard or contribute to an existing or projected air quality violation. However, based on SCAQMD's cumulative air quality impact methodology, SCAQMD recommends that if an individual project results in air emissions of criteria pollutants (ROG, CO, NOx, SOx, PM_{10}, and $PM_{2.5}$) that exceed the SCAQMD's recommended daily thresholds for project-specific impacts, then it would also result in a cumulatively considerable net increase of these criteria pollutants for which the proposed program region is in nonattainment under an applicable federal or state ambient air quality standard.

As discussed previously under Impact 3.2-2, under conditions where multiple structural BMPs would be constructed concurrently in the EWMP areas, it is anticipated that the total aggregate construction emissions generated from these multiple structural BMP projects on a daily basis would exceed the SCAQMD's significance thresholds for criteria pollutants. Even with implementation of **Mitigation Measures AIR-1** and **AIR-2**, the resulting aggregate daily emissions may not be reduced to levels below the SCAQMD thresholds should multiple structural BMP projects be constructed concurrently. Thus, construction-related air quality impacts associated with the proposed program would be considered significant and unavoidable. Therefore, as pollutants for which the Basin is in nonattainment (i.e., ozone, PM_{10}, and $PM_{2.5}$) associated with the proposed program could exceed SCAQMD's respective thresholds for construction, these pollutant emissions would, in conjunction with other past, current, and probable future projects, be cumulatively considerable, and cumulative impacts would be significant and unavoidable.

With respect to operational emissions, program implementation would not result in substantial long-term regional emissions of criteria air pollutants and would not exceed the SCAQMD thresholds of significance for criteria pollutants. As such, the proposed program's operational emissions would not be cumulatively considerable and cumulative air quality impacts would be less than significant.

Mitigation Measures: Implement **Mitigation Measures AIR-1** through **AIR-2**

Significance After Mitigation: Significant and unavoidable for construction; less-than-significant for operations. (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.2-10.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, no cumulative air quality impacts in the Basin would result.

Mitigation Measures: None required

Significance Determination: No impact

Sensitive Receptors

Impact 3.2-4: The project could expose sensitive receptors to substantial pollutant concentrations.

Structural (Regional, Centralized, and Distributed) BMPs

Construction and operation of new developments that would occur under the proposed program could potentially expose sensitive receptors in the EWMP areas of the County to localized air quality impacts from criteria pollutants and TACs. Separate discussions are provided below analyzing the potential for sensitive receptors to be exposed to these pollutant sources.

Carbon Monoxide Hotspots

A CO hotspot is an area of localized CO pollution that is caused by severe vehicle congestion on major roadways, typically near intersections. Projects may worsen air quality if they increase the percentage of vehicles in cold start modes by two percent or more; significantly increase traffic volumes (by five percent or more) over existing volumes; or worsen traffic flow, defined for signalized intersections as increasing average delay at intersections operating at Level of Service (LOS) E or F or causing an intersection that would operate at LOS D or better without the project, to operate at LOS E or F.

While construction-related traffic on the local roadways would occur during construction of each structural BMP project, the net increase of construction worker vehicle trips to the existing traffic volumes on the local roadways would be relatively small and would not result in CO hotspots. Additionally, the construction-related vehicle trips would only occur in the short-term, and would cease once construction activities for a structural BMP project has been completed. Thus, because trip-generating land uses are not associated with the proposed program and the amount of maintenance visits to the structural BMP sites would be minimal, impacts associated with CO hotspots would be less than significant and no mitigation is required.

Mitigation Measures: None required

Significance Determination: Less than significant

Localized Construction Air Quality Impacts – Criteria Air Pollutants

The EWMP areas associated with the proposed program are located in multiple jurisdictions within the County of Los Angeles, all of which are located within in the Basin. Given that the majority of the County is highly urbanized with a variety of land use types and that the proposed program would be located in various watersheds across the County that span multiple jurisdictions, existing sensitive uses such as residences, schools, hospitals, daycare centers, etc., would be located within and in proximity to the EWMP areas. During construction of the individual structural BMP projects in the EWMP areas, existing sensitive receptors that happen to be located adjacent to or near these structural BMP construction sites could be exposed to significant adverse localized air quality impacts. According to SCAQMD's localized significance threshold (LST) methodology, projects greater than 5 acres in size should perform air quality dispersion modeling to determine whether construction activities would cause or contribute to adverse localized air quality impacts. Where projects would be less than 5 acres in size, the SCAQMD provides screening tables that can be used to determine the maximum allowable daily emissions that would satisfy the LSTs without project-specific dispersion modeling. LSTs represent the maximum emissions from a project that will not cause or contribute to an exceedance of the most stringent applicable federal or state ambient air quality standard. According to SCAQMD's LST methodology, LSTs are only applicable to the on-site construction emissions that are generated by a project and do not apply to emissions generated off-site such as mobile emissions on roadways from worker, vendor, and haul truck trips.

SCAQMD has indicated, in its 2003 *Final Localized Significance Threshold Methodology* document, that LSTs are applicable to projects at the project-specific level and are not intended for regional projects.[3] Given the large geographic area associated with the project, an LST analysis would not be applicable to this PEIR. Depending on the size and scale of a particular structural BMP project and the intensity of the construction effort that would be required, the construction emissions generated by a new structural BMP project could potentially cause or contribute to an exceedance of the most stringent applicable federal or state ambient air quality standards at the existing sensitive uses located in the vicinity of that project. For individual structural BMP projects that would fit this scenario, **Mitigation Measure AIR-3** would be implemented, which requires a project-level LST analysis to be prepared to demonstrate that the construction emissions of a structural BMP project would not exceed SCAQMD's LSTs or result in pollutant emissions that would cause or contribute to an exceedance of the most stringent applicable federal or state ambient air quality standards.[4] With implementation of Mitigation Measures AIR-3, this impact would be reduced to less than significant. For smaller BMPs, including distributed BMPs, air emissions would not be significant and would not require mitigation measures.

Mitigation Measures:

AIR-3: For large construction efforts associated with regional or centralized BMPs, implementing agencies shall conduct a project-specific LST analysis where necessary to determine local health impacts to neighboring land uses. Where it is determined that construction emissions would exceed the applicable LSTs or the most stringent applicable federal or state ambient air quality standards, the structural BMP project shall reduce its daily construction intensity (e.g., reducing the amount of equipment used daily, reducing the amount of soil graded/excavated daily) to a level where the structural BMP project's construction emissions would no longer exceed SCAQMD's LSTs or result in pollutant

3 Page 1-1 of SCAQMD's 2003 *Final Localized Significance Threshold Methodology* document.

4 As discussed previously, the LSTs for NO_X, CO, PM_{10}, and $PM_{2.5}$ provided in SCAQMD's screening tables represent the maximum emissions from a project that will not cause or contribute to an exceedance of the most stringent applicable federal or state ambient air quality standard for those respective pollutants. For projects that are less than 5 acres, the SCAQMD's LST screening tables can be used to determine whether construction-related emissions would result in a potential significant air quality impact. For projects that exceed 5 acres in size, dispersion modeling should be conducted, per SCAQMD's LST methodology, to determine whether the most stringent applicable federal or state ambient air quality standards for pollutants would be exceeded, which would result in a significant air quality impact.

emissions that would cause or contribute to an exceedance of the most stringent applicable federal or state ambient air quality standards.

Significance Determination: Less than significant with mitigation. (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.2-10.)

Localized Construction Air Quality Impacts – Toxic Air Contaminants

Intermittent construction activities occurring throughout the program area over the implementation period of the individual structural BMPs would result in short-term emissions of diesel particulate matter, which is a TAC. During construction of each individual structural BMP project within the EWMP areas, the exhaust of off-road heavy-duty diesel equipment would emit diesel particulate matter during general construction activities, such as site preparation (e.g., excavation, grading, and clearing); materials transport and handling; structural BMP construction; and other miscellaneous activities. Similar to the localized criteria pollutant emissions during construction, the short-term emissions of diesel particulate matter associated with each structural BMP development would only affect its own remote group of existing sensitive receptors that are located nearby. SCAQMD has not adopted a methodology for analyzing such impacts and has not recommended that health risk assessments be completed for construction-related emissions of TACs.

The dose to which receptors are exposed is the primary factor used to determine health risk (i.e., the potential exposure to TACs to be compared to applicable standards). Dose is a function of the concentration of a substance or substances in the environment and the duration of exposure to the substance. Dose is positively correlated with time, meaning that a longer exposure period would result in a higher exposure level for the maximally exposed individual. Thus, the risks estimated for a maximally exposed individual are higher if a fixed exposure occurs over a longer period of time. According to the Office of Environmental Health Hazard Assessment (OEHHA), health risk assessments, which determine the exposure of sensitive receptors to TAC emissions, should be based on a 70-year exposure period; however, such assessments should be limited to the period or duration of activities associated with each of the future individual structural BMP development occurring in the EWMP areas under the proposed program.

The construction period for any individual structural BMP that would occur in the EWMP areas under the proposed program would be finite and much less than the 70-year period used for risk determination. Because off-road heavy-duty diesel equipment would be used only temporarily at each individual structural BMP site, the construction activities associated with each structural BMP project in the EWMP areas would not expose sensitive receptors to substantial emissions of TACs. This impact would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Operational Sources of Toxic Air Contaminants

Implementation of the program, which would involve the installation of structural control measures that would be constructed as BMPs to reduce the impact of stormwater and non-stormwater on receiving water quality, would not result in new land uses in the EWMP areas.

Operation of the structural BMPs would not involve TAC-emitting equipment, as the majority of the structural BMPs would operate passively without the use of mechanized equipment. While some of the centralized and regional structural BMPs may require the use of pump stations and associated components, such equipment would be electrically driven and would not result in direct emissions at the individual structural BMP sites. Therefore health risks from TAC emissions associated with project operations would not occur.

Mitigation Measures: None required

Significance Determination: No impact

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, no impacts associated with exposure of sensitive receptors to substantial pollutant emissions would result.

Mitigation Measures: None required

Significance Determination: No impact

Objectionable Odors

Impact 3.2-5: The proposed program could create objectionable odors affecting a substantial number of people.

Structural (Regional, Centralized, and Distributed) BMPs

According to the SCAQMD *CEQA Air Quality Handbook*, land uses associated with odor complaints typically include agricultural uses, wastewater treatment plants, food processing plants, chemical plants, composting, refineries, landfills, dairies, and fiberglass molding. The project does not include any uses identified by the SCAQMD as being associated with odors.

During the construction phases for each of the new structural BMP projects that would occur in the EWMP areas over the course of the implementation period, exhaust from construction equipment may produce discernible odors typical of most construction sites. Such odors would be a temporary source of nuisance to adjacent uses, but because they are temporary and intermittent in nature, would not be considered a significant environmental impact. Therefore, impacts associated with objectionable odors during construction would be less than significant.

Although rainfall in Southern California is limited to certain times of year, and most drainage channels are dry for most of the year, some structural BMPs may involve retaining intermittent stormwater or dry weather flows on a site that may result in organic odors as water levels fluctuate and decomposition occurs in saturated mud. Restored creeks and estuaries may be permanently wet, resulting in odors from saturated mud or algal blooms. Standing water may emit odors if algal blooms occur for periods of time before the water dries or percolates. If these facilities are near sensitive receptors such as residential areas, these odors may result in a severe nuisance, particularly during night time hours. Regular maintenance may be sufficient to reduce odors in some situations. **Mitigation Measure AES-2** requires implementing agencies to prepare and implement maintenance plans for all BMPs installed. Implementation of **Mitigation Measure AIR-4** promotes the consideration of odors when siting BMP locations and types.

Mitigation Measure: Implement **Mitigation Measure AES-2**

AIR-4: During planning of structural BMPs, implementing agencies shall assess the potential for nuisance odors to affect a substantial number of people. BMPs that minimize odors shall be considered the priority when in close proximity to sensitive receptors.

Significance Determination: Less than significant. (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.2-10.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, no impacts associated with objectionable odors would result.

Mitigation Measures: None required

Significance Determination: No impact

3.2.4 Summary of Impact Assessment

Table 3.2-10 shows a summary of the structural BMPs requiring mitigation.

TABLE 3.2-10

3.3 Biological Resources

This section establishes the existing conditions and provides an evaluation of potential impacts to biological resources associated with the proposed program.

3.3.1 Environmental Setting

The 12 Enhanced Watershed Management Program (EWMP) areas are each located within Los Angeles County (County), which exhibits native habitats corresponding with the California Floristic Province. The County experiences a mediterranean climate, which is generally characterized by relatively heavy winter precipitation and dry summers. The County encompasses the intersection of the Transverse and Peninsular mountain ranges, supporting a variety of habitats within mountain ranges, broad alluvial valleys, deserts, and coastal shorelines. Los Angeles County hosts one of the most dense and populous urban metropolises in the country, which has substantially altered the native habitats. However, within the mountainous areas and some drainage areas, native habitats still remain.

Habitat Types

The EWMP areas contain an array of coastal habitats such as: marine, intertidal, estuarine, coastal salt marsh, and beach dunes; freshwater aquatic habitat such as marshes, lakes, and ponds; riverine aquatic habitat including streambeds and associated riparian areas; and upland communities such as coastal sage scrub, chaparral, foothill woodlands, and coniferous forests in the mountains. The dominant native plant community in Los Angeles County is chaparral (Los Angeles County, 2012a). In general, communities that are relatively undisturbed and have connectivity to other open space areas function as higher-quality habitat for sensitive plants and wildlife. Non-native, disturbed, and/or isolated habitats generally provide lower-quality wildlife habitat, though some sensitive plants and wildlife are known to occur in such areas.

Habitats within the EWMP Areas

The proposed program comprises12 EWMP areas, each with a disparate mix of urban development and natural habitat features. Although diverse habitats may occur throughout the County and within each of the EWMP areas to varying degrees, the following summaries combine EWMP groups into the following six distinct watershed groups that have similar habitat types:

1. **<u>Southern Coastal EWMP Watersheds</u>** ***(Beach Cites, Peninsula, Southern Santa Monica Bay, Marina del Rey, Ballona, Peninsula)*** – These watersheds are dominated by urbanized inland and beach communities with high-density residential and commercial land uses throughout the watersheds. Sensitive habitats in these areas include coastal drainages, coastal lagoons, and dune scrub. However, the most of the drainages in these watersheds have been channelized with hard-bottom channels such as Ballona Creek and provide minimal habitat value to sensitive species. Most of the coastal creeks have been rechannelized and are largely underground with some exceptions in the Peninsula EWMP. The value of riparian and aquatic resources in these urbanized areas is generally low except for some key exceptions, including the Del Rey Lagoon and Ballona Lagoon

and wetlands where the Ballona Creek watershed meets the coast. **Figure 3.3-1** provides photographs of typical drainages in the watershed.

2. **Dominguez Channel (Dominugez Channel EWMP)** – This watershed is characterized by high-density inland communities and an industrial shoreline. Much of the drainages are urbanized and underground or otherwise concrete-lined, with notable exceptions such as Machado Lake. The Dominguez Channel is tidally influenced but is a man-made rip-rap or concrete-lined channel. Some vegetation occurs in localized drainages and some tributary drainages are being restored for wetland values. However, outside of the restoration areas and recreation features (such as Machado Lake), habitat values in this urban and industrial area are low. **Figure 3.3-2** provides photographs of typical drainages in the watershed.

3. **Northern Coastal EWMP Watersheds** ***(Malibu and Upper Santa Monica Bay)*** – These watersheds are characterized by dense residential development along the coast and less development and greater open space areas inland along the coast mountain range. Sensitive habitats in these areas are more prevalent than in the more urbanized watersheds, including coastal lagoons and dunes, streams and riparian habitats, and upland forests and scrub. Receiving waters in these watersheds remain unlined with significant riparian corridors. The developed areas have lower-density developments than in the Southern Coastal watersheds and are interspersed with canyons and creeks. The coastal streams provide important habitat for sensitive species, including arroyo toad, native fish, and avian species found in riparian forests. **Figure 3.3-3** provides photographs of typical drainages in the watershed.

4. **Upper Los Angeles River Watershed** – This watershed traverses a large diverse area of the Los Angeles Basin characterized by dense urbanization. The predominant urbanization results in limited biological value in the watershed. The natural hydrology of the Los Angeles River watershed has been altered by channelization and the construction of dams and flood control reservoirs. The Los Angeles River and many of its tributaries are lined with concrete for most or all of their length. Soft-bottomed segments of the Los Angeles River occur where groundwater upwelling prevents armoring of the river bottom. Numerous soft-bottom tributary streams feed into the river from the mountainous perimeter.

   Because of persistent dry-weather flows caused by irrigation run off and wastewater treatment plant discharges, vegetation within these drainages is common. The Los Angeles County Flood Control District routinely clears the vegetation from most of the vegetated drainages under permits from the U.S. Army Corps of Engineers (USACE) and California Department of Fish and Wildlife (CDFW). However, several stream segments exhibiting high-value habitats remain throughout this watershed, including Compton Creek and Bull Creek. When not cleared for flood control purposes, these areas can develop into substantial riparian habitats supporting sensitive species such as least Bell's vireo and southwest flycatcher as well as other diverse ecological communities. Lower in the watershed where perennial flows are substantial because of wastewater discharges, aquatic habitats occur that support waders, ducks, and gulls. **Figure 3.3-4** provides photographs of typical drainages in the watershed.

Upper Los Angeles River Watershed

5. **Upper San Gabriel and Rio Hondo and Watersheds** – These watersheds are characterized by high-density development in the lower watershed areas and lower-density development and open space in the upper watersheds in the San Gabriel Mountain foothills. Sensitive habitats in these areas range from sparse riparian areas and scrub within drainages in the urbanized lower watersheds to pristine mountain forests and riparian corridors the San Gabriel Mountains. The San Gabriel River and Rio Hondo are unlined in the upper watershed and convey controlled non-storm and storm flows to recharge basins and downstream sections of the river. Habitats within the soft-bottom river channels consist of chaparral and sage scrub with occasional riparian willow and sycamore riparian vegetation accustomed to long periods of dry weather with occasional ephemeral water flows. Upwelling of groundwater and dry-weather flows combine to support substantial riparian vegetation in the Whittier Narrows area. **Figure 3.3-5** provides photographs of typical drainages in the watershed.
6. **Upper Santa Clara River Watershed** – The Santa Clara River watershed is distinctive in that it is predominantly open space—nearly 90 percent of the watershed is open space with approximately 88 percent being undeveloped. The watershed contains one of the last remaining natural rivers in Southern California. In years of significant rainfall, ephemeral springs and year-round flows exist in some tributaries and natural upstream areas. The river is ephemeral in the upper watershed, experiencing groundwater-induced flows near Santa Clarita, and then wastewater treatment discharges create a perennial flow from Valencia to the Ventura County border. Habitat values in these areas are high, including extremely rare habitat for aquatic resources such as the three-spined stickleback, Santa Ana sucker, and arroyo toad. **Figure 3.3-6** provides photographs of typical drainages in the watershed.

Sensitive Habitats

The California Natural Diversity Database (CNDDB), managed by CDFW, identifies 20 natural communities of special management concern within the broad-ranging EWMP areas, as shown below. **Appendix D** contains a description of each of these habitats and **Figure 3.3-7** depicts their locations throughout the EWMP areas.

- California Walnut Woodland
- Canyon Live Oak Ravine Forest
- Mainland Cherry Forest
- Open Engelmann Oak Woodland
- Riversidean Alluvial Fan Sage Scrub
- Southern California Arroyo Chub/ Santa Ana Sucker Stream
- Southern California Coastal Lagoon
- Southern California Steelhead Stream
- Southern Coast Live Oak Riparian Forest,
- Southern California Threespine Stickleback Stream
- Southern Coastal Bluff Scrub
- Southern Coastal Salt Marsh
- Southern Cottonwood Willow Riparian Forest
- Southern Dune Scrub
- Southern Mixed Riparian Forest
- Southern Riparian Scrub
- Southern Sycamore Alder Riparian Woodland
- Southern Willow Scrub
- Valley Oak Woodland
- Walnut Forest

Special-Status Species

Special-status species are those plants and animals that, because of their recognized rarity or vulnerability to habitat loss or population decline, are recognized by federal, state, or other agencies. Some of these species receive specific protection that is defined by federal or state endangered species legislation. Others have been designated as "sensitive" on the basis of adopted policies and expertise of state resource agencies or organizations with acknowledged expertise, or policies adopted by local governmental agencies such as counties, cities, and special districts to meet local conservation objectives. These species are referred to collectively as "special-status species" and include the following categories:

- Plants or animals listed or proposed for listing as threatened or endangered under the federal Endangered Species Act (FESA) (50 Code of Federal regulations [CFR] 17.12 [listed plants], 17.11 [listed animals] and various notices in the Federal Register [FR] [proposed species])
- Plants or animals that are candidates for possible future listing as threatened or endangered under FESA (61 FR 40, February 28, 1996)
- Plants or animals listed or proposed for listing by the State of California (State) as threatened or endangered under the California Endangered Species Act (CESA) (14 California Code of Regulations [CCR] 670.5)
- Plants listed as rare or endangered under the California Native Plant Protection Act (California Fish and Game Code, Section 1900 et seq.)
- Plants that meet the definitions of rare and endangered under the California Environmental Quality Act (CEQA) (CEQA Guidelines Section 15380)
- Plants considered under the California Native Plant Society (CNPS) to be "rare, threatened or endangered in California" (Lists 1A, 1B, and 2 in CNPS 2014)
- Plants listed by CNPS as plants about which more information is needed to determine their status and plants of limited distribution (Lists 3 and 4 in CNPS 2014), which may be included as special-status species on the basis of local significance or recent biological information
- Animals fully protected in California (California Fish and Game Code, Sections 3511 [birds], 4700 [mammals], and 5050 [reptiles and amphibians])
- Plants or animals covered by a locally or state adopted species conservation plan, including sensitive plants and animals and narrow endemic plants that have reasonable potential to occur on-site

The database search yielded 72 plant species and 83 wildlife species within the EWMP area and immediate vicinity (CNDDB 2014). Special-status species are typically supported by native upland and riparian habitats, but they can also inhabit disturbed and urbanized areas. **Appendix E** contains a list of special-status species found within the combined EWMP areas and a figure that depicts their locations.

Wildlife Movement

Habitat linkages are contiguous areas of open space that connect two larger habitat areas. Linkages provide for both diffusion and dispersal for a variety of species within the landscape. In addition, linkages can serve as primary habitat for some smaller species. Corridors are linear linkages between two or more habitat patches. Corridors provide for movement and dispersal, but do not necessarily include habitat capable of supporting all life history requirements of a species.

Wildlife movement corridors are critical for the survivorship of ecological systems for several reasons. Corridors can connect water, food, and cover sources, spatially linking these three resources with wildlife in different areas. In addition, wildlife movement between habitat areas provides for the potential of genetic exchange between wildlife species populations, thereby maintaining genetic variability and adaptability to maximize the success of wildlife responses to changing environmental conditions. This is especially critical for small populations subject to loss of variability from genetic drift and effects of inbreeding. The nature of corridor use and wildlife movement patterns varies greatly among species.

Jurisdictional Resources

Wetlands and permanent and intermittent drainages, creeks, and streams identified as waters of the United States are subject to the jurisdiction of USACE and Regional Water Quality Control Board (RWQCB) under Section 404 and Section 401, respectively, of the Federal Clean Water Act. All of the rivers and flood control drainages that flow to the ocean within the EWMP area are within the jurisdiction of these agencies.

Streambeds are subject to regulation by the CDFW under Section 1602 of the California Fish and Game Code. A stream is defined under these regulations as a body of water that flows at least periodically or intermittently through a bed or channel having banks and that supports fish or other aquatic life. This definition includes watercourses having a surface or subsurface flow that supports or has supported riparian vegetation. CDFW jurisdiction typically extends to the edge of the riparian vegetation canopy.

3.3.2 Regulatory Setting

Federal

Federal Endangered Species Act

The U.S. Fish and Wildlife Service (USFWS) administers the federal Endangered Species Act (FESA) that provides a process for listing species as either threatened or endangered, and methods of protecting listed species. Species are listed as either endangered or threatened under Section 4 of the FESA that defines "endangered" as any plant or animal species that is in danger of extinction throughout all or a significant portion of its range and "threatened" if a species is likely to become endangered in the foreseeable future. Section 9 of the FESA prohibits take of listed threatened or endangered species. Except as provided in Sections 7 and 10 of the FESA, take of listed threatened or endangered species is prohibited. The term "take" means to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in such conduct. Harm under the definition of take includes disturbance or loss of habitats used by a threatened or endangered species during any portion of its life history. Under the regulations of the FESA, the USFWS may authorize take when it is incidental to, but not the purpose of, an otherwise lawful act.

Pursuant to the FESA, USFWS and National Marine Fisheries Service (NMFS) have designated critical habitat for several endangered and threatened species within Los Angeles County. Critical habitat is identified as a specific geographic area that contains features essential for the conservation of a threatened or endangered species and that may require special management and protection. Critical habitat may include an area that is not currently occupied by the species but that will be needed for its recovery (USFWS, 2014a). **Figure 3.3-8** identifies federally designated critical habitats in the County.

Migratory Bird Treaty Act

The Migratory Bird Treaty Act (MBTA) of 1918 (16 U.S.C. 703-711) makes it unlawful to possess, buy, sell, purchase, barter or take any migratory bird listed in Title 50 of the Code of Federal Regulations Part 10. Take in the context of the MBTA is the possession or destruction of migratory birds, their nests or eggs. Disturbances that causes nest abandonment and/or loss of reproductive effort or the loss of habitats upon which these birds depend would be in violation of the MBTA.

Although impacts to migratory birds are highly unlikely because of the disturbed nature of the proposed project's site locations, the applicant will be required to either avoid impacts to migratory birds and their nests, or to obtain a permit from the USFWS providing for the take of a migratory bird. Should the nesting of any migratory bird occur on or adjacent to the project site during grading or construction activities, a USFWS-qualified biological monitor would have the authority to halt all work activities and notify the city and corresponding resource agency.

Clean Water Act Section 404

Wetlands are generally considered to be areas that are periodically or permanently inundated by surface or ground water and support vegetation adapted to life in saturated soil. Wetlands are recognized as important features on a regional and national level because of their high inherent value to fish and wildlife, use as storage areas for stormwater and floodwater, and water recharge, filtration, and purification functions. Technical standards for delineating wetlands have been developed USACE which generally define wetlands through consideration of three criteria: hydrology, soils, and vegetation. Under Section 404 of the Clean Water Act (CWA), USACE is responsible for regulating the discharge of dredged or fill material into waters of the United States. The term "waters" includes wetlands and non-wetland bodies of water that meet specific criteria as defined in the Code of Federal Regulations. All three of the identified technical parameters (hydrology, soils, and vegetation) must be met for an area to be identified as a wetland under USACE's CWA Section 404 jurisdiction, unless the area has been modified by human activity. In general, a permit must be obtained before the discharge of dredged or fill material can be placed in wetlands or other waters of the United States. USACE, at its discretion, issues several types of permits (Nationwide, Individual, or General) depending on the acreage and purpose of discharge of fill or dredged material into waters of the United States.

Figure 3.3-8
Los Angeles County Significant Ecological Areas and Critical Habitat

State

California Endangered Species Act

The CDFW administers the CESA. The State of California considers an endangered species one whose prospects of survival and reproduction are in immediate jeopardy. A threatened species is one present in such small numbers throughout its range that it is likely to become an endangered species in the near future in the absence of special protection or management. And a rare plant species is one present in such small numbers throughout its range that it may become endangered if its present environment worsens. Except as provided in CESA Section 2081, State threatened, endangered, and candidate species are protected against take, which under the CESA is restricted to direct killing or harm of individual animals and does not apply to the loss of habitat as it does under FESA.

Clean Water Act Section 401 Certification or Waiver, and State Discharge Permit under the Porter-Cologne Act

The State of California regulates water quality related to discharge of fill material into waters of the State pursuant to Section 401 of the CWA. Section 401 compliance is a federal mandate regulated by the State. The local RWQCBs have jurisdiction over all those areas defined as jurisdictional under Section 404 of the CWA. Where a 404 permit is required, a 401 water quality certification from the RWQCB is also required.

In addition, the State regulates water quality for all waters of the State, that may also include isolated wetlands as defined under the California Porter-Cologne Water Quality Control Act (Porter Cologne; Ca. Water Code, Div. 7, Section 13000 et seq.). The State 401 Certification Program regulates all discharges that can affect water quality, even if there is no significant nexus to a traditional navigable water body required for USACE determination of jurisdiction over waters of the United States. In such instances, a Waste Discharge Permit is required even though federal CWA Section 401 water quality certification or 404 permits are not required.

Section 1602 Lake and Streambed Alteration Agreement

Jurisdictional authority of the CDFW over the bed, bank, or channel of a river, stream, or lake is established under Section 1600 et seq. of the Fish and Game Code, which pertains to activities that would disrupt the natural flow or alter the channel, bed, or bank of any lake, river, or stream. The Fish and Game Code stipulates that it is unlawful to substantially divert or obstruct the natural flow or substantially change the bed, channel or bank of any river, stream, or lake resulting in a substantial effect on a fish or wildlife resource without notifying the CDFW and completing the Streambed Alteration Agreement process.

Fish and Game Code of California

All birds, and raptors specifically, and their nests, eggs, and parts thereof are protected under Sections 3503.5 of the Fish and Game Code of California. Disturbance that causes nest abandonment and/or loss of reproductive effort (e.g., killing or abandonment of eggs or young) is considered a violation of this code. Additionally Section 3513 prohibits the take or possession of any migratory nongame bird listed by the MBTA.

Non-Listed Species Management and Conservation Concerns

Species of Special Concern is an informal designation used by CDFW for some declining wildlife species that are not proposed for listing as threatened or endangered. This designation does not provide legal protection, but signifies that these species are recognized as declining by CDFW.

The CNPS has developed an inventory of California's sensitive plant species. This inventory summarizes information on the distribution, rarity, and endangerment of California's vascular plants. The inventory is divided into four lists based on the rarity of the species. In addition, the CNPS provides an inventory of plant communities that are considered natural communities of special concern by the State and federal resource agencies, academic institutions, and various conservation groups. The determination of the level of significance of impacts on plant species and natural communities is based on the number and size of remaining occurrences as well as recognized threats.

Natural communities of special concern are those that support concentrations of special-status plant or wildlife species, are of relatively limited distribution, or are of particular value to wildlife. Natural communities of special concern are not afforded legal protection unless they are designated critical habitat for federally listed threatened or endangered species, support formally listed species, or are jurisdictional wetland habitats.

Local

Los Angeles County Significant Ecological Areas

As part of the General Plan Conservation/Open Space and Land Use elements, the County has identified and adopted policies for Significant Ecological Areas (SEAs). The purpose of establishing a SEA is to maintain biological diversity by establishing natural biological parameters, including species, habitat types, and linkages. The County General Plan includes recommended management practices for each SEA. Forty-eight SEAs fall within the EWMP area, as shown in Figure 3.3-7.

Santa Monica Mountains Conservancy

The Santa Monica Mountains Conservancy was established by the California State Legislature in 1980. The Conservancy's mission is to preserve and restore natural habitats in Southern California to form an interlinking system of parks and wildlife habitats that are easily accessible to the general public. The Conservancy's Comprehensive Plan outlines conservation priorities and recreational opportunities in the Santa Monica Mountains. Development projects in the Santa Monica Mountains area subject to review by the County for consistency with the Comprehensive Plan.

Los Angeles County Oak Tree Ordinance and City Tree Preservation Ordinances

Title 22, Part 16, of the Los Angeles County Code of Ordinances is the Oak Tree Ordinance. The ordinance was established to recognize oak trees within the County as a historical, aesthetic, and ecological resource. The ordinance applies to all unincorporated areas of the County. Several cities within the County may have adopted this or a similar ordinance. The Los Angeles County ordinance, in particular, prohibits a person to "cut, destroy, remove, relocate, inflict damage, or encroach into the protected zone of any tree of the oak genus" that is 8 inches or more in diameter. Other city ordinances, such as the City of Los Angeles, may protect other tree species in addition to oaks.

Los Angeles County Oak Woodland Management Plan

Los Angeles County adopted a California Oak Woodlands Conservation Management Plan pursuant to the requirements of Assembly Bill (AB) 242 in 2011. The Los Angeles County Oak Woodlands Conservation Management Plan provides consistent policy for the management of oak woodlands that can be incorporated into the Los Angeles County General Plan and other relevant planning documents, developing a comprehensive and cohesive strategy for dealing with loss, and creating opportunities for recovering oak woodlands.

3.3.3 Impact Assessment

Thresholds of Significance

To determine the level of significance of an identified impact, the criteria outlined in the CEQA Guidelines were used. CEQA Guidelines Section 15065 directs lead agencies to find that a project may have a significant effect on the environment if it has the potential to substantially degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, reduce the number or restrict the range of an endangered, rare, or threatened species, or eliminate important examples of the major periods of California history or prehistory. CEQA Guidelines Section 15206 further specifies that a project shall be deemed to be of statewide, regional, or area-wide significance if it would substantially affect sensitive wildlife habitats including, but not limited to, riparian lands, wetlands, bays, estuaries, marshes, and habitats for rare and endangered species as defined by the Fish and Game Code Section 903. CEQA Guidelines Section 15380 provides that a plant or animal species, even if not on one of the official lists, may be treated as "rare or endangered" if, for example, it is likely to become endangered in the foreseeable future. Additional criteria to assess significant impacts to biological resources due to the proposed project are specified in CEQA Guidelines Section 15382 (Significant Effect on the Environment) "…*a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project including land, air, water, minerals, flora, fauna, ambient noise, and objects of historic or aesthetic significance*."

Appendix G of the CEQA Guidelines indicates that a project would have a significant impact on biological resources if it would:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS.
- Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations, or by the CDFG or USFWS.

- Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means.
- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites.
- Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance.
- Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan.

Project Impact Discussion

Impact 3.3-1: The proposed project could have a substantial adverse effect, either directly or through habitat modifications, on any sensitive species identified as special-status in local or regional plans, policies, or regulations or by the California Department of Fish and Wildlife or U.S. Fish and Wildlife Service.

Structural (Regional, Centralized, and Distributed) BMPs

Construction

Construction of structural Best Management Practices (BMPs) would occur primarily within high-density urban, commercial, industrial, and transportation areas where they will either replace or improve upon existing stormwater infrastructure. Construction typically requires the permanent removal of aboveground infrastructure and/or surface materials such as asphalt and concrete, as well as excavation and grading for projects on soil-covered sites. The majority of the construction impact area would occur within developed and disturbed areas adjacent to existing infrastructure that do not support native vegetation or undisturbed habitat. However, since most of the BMPs would be located in existing drainages, each individual BMP could affect riparian vegetation during installation. Most of the smaller BMPs would avoid impacting high-value habitats during construction. Upland scrubs and native oak forests would be only incidentally affected if at all. In stream effects could occur to riparian scrub and aquatic habitats.

Construction of structural BMPs, regional and centralized BMPs in particular, may affect large open space or riparian habitats that would have a higher potential to support special-status wildlife species. For example, centralized BMPs include the construction of stream/creek restoration projects and low-flow diversion (LFD) projects which may require working within or adjacent to sensitive communities (i.e., streams or wetlands) that could support special-status wildlife species. Large projects could affect upland scrub or oak woodlands. **Mitigation Measure BIO-1** requires that implementing agencies evaluate the suitability of potential BMP sites for their potential to impact valued habitats such as oak woodland and riparian willow forests.

Common and protected migratory birds and raptors are likely to nest or forage in habitats found within the EWMP area. Implementation of the structural BMPs may result in temporary or permanent loss of foraging habitat for migratory birds, including raptor species. Similarly, proposed construction activities could impact nesting birds or roosting bats. Potential bat roost sites in the vicinity of the project areas may include abandoned structures and bridges.

Mitigation Measures BIO-2 through **BIO-8** require impact characterization, minimization and compensation for impacts to highly valued habitats in consultation with the USFWS and CDFW. Implementation of mitigation measures requiring careful consideration of suitable sites would reduce impacts to natural habitats on a regional scale to less-than-significant levels.

Operation

Maintenance of BMPs may involve accessing drainages through habitat areas or clearing vegetation. If BMPs require routine maintenance that affects habitat, those activities would need to be conducted in the non-bird nesting season to avoid impacts to nesting birds where feasible. Since drainages are within the CDFW jurisdiction, any vegetation-clearing activities would be subject to permits from CDFW as well as potentially the Los Angeles RWQCB and USACE. These permits would include provisions to avoid and mitigate impacts to sensitive habitats and species. Adherence to these conditions of approval would ensure that impacts to natural resources from maintenance would be less than significant.

BMPs designed to retain peak storm flows including regional BMPs would have no impact on downstream biological resources, since peak storm flows do not support perennial vegetation. The natural hydrology of the region experiences ephemeral flows that respond to seasonal precipitation, conveying water from the upper watersheds to the lower watersheds quickly. Urbanization has increased the speed of water flows through the system. The BMPs are designed to slow water flows and return to a hydrology closer to predevelopment conditions.

However, some drainages have developed new perennial flow regimes that support vegetation as a result of landscape runoff or wastewater discharges. Some of this vegetation may support special-status species including least Bell’s vireo or southwest willow flycatcher, particularly in suburban areas. If BMPs designed to retain dry-weather flows reduced the wetted area of drainages or completely eliminated flows in certain drainages that support riparian habitat, impacts to sensitive species would be significant.

This potential effect is most likely to occur within suburban areas, which are more prevalent in the Santa Clara River watershed, Malibu watershed, and San Gabriel watershed. The more urbanized watersheds in the southern coastal areas, such as Dominguez Channel and Ballona Creek, would be less likely to experience impacts to riparian vegetation from low-flow retention, with some noted exceptions such as the Ballona wetlands.

The primary threat to the local ecology in Los Angeles County is urban development. Returning the local hydrology to a more natural condition would occur over time and would result in improved natural habitat functions with little direct impact to protected sensitive species. Although riparian habitat may flourish in certain urban drainages, the vegetation is often a nuisance. Many soft-bottom channels are periodically cleared of vegetation by the Los Angeles County Flood Control District under a permit from the USFWS and CDFW that requires compensation elsewhere in the watershed. The reduction in perennial flows in most channels may result in less "choking" of flood control channels with nuisance vegetation, resulting in flood control benefits.

Furthermore, in many cases, it is difficult to attribute the health and extent of a wetted area supporting vegetation to specific Municipal Separate Storm Sewer System (MS4) discharge points. Individual BMP installation may reduce flows, but not eliminate wetted areas supporting certain habitat areas, resulting in no immediate observed reduction in riparian cover.

Over time, the addition of BMPs into suburban watersheds may reduce vegetation within certain drainages slowly as the cumulative effects of multiple BMPs combine to limit dry-weather flows. The gradual reduction in habitat would allow sensitive species to adapt to the changing conditions, particularly avian species such as least Bell's vireo would relocate to other nesting areas as conditions change. This is not dissimilar to natural conditions where riparian areas change over time with large flood flows. Although this gradual decrease in dry-weather flows in the region may reduce riparian vegetation in certain locations, the overall reduction is not expected to be significant, since the high-value habitats are limited and largely dependent on groundwater or wastewater treatment discharges.

Nonetheless, to ensure that impacts to downstream biological resources are less than significant, **Mitigation Measure BIO-1** requires that implementing agencies evaluate the potential direct impacts that could result from dry-weather flow reduction to downstream habitats. These conditions may be most prevalent in the Santa Clara River watershed, Malibu Watershed, the Upper Los Angeles River Watershed, and San Gabriel River Watershed where suburban landscape irrigation runoff has created isolated patches of riparian vegetation. **Mitigation Measures BIO-2** and **BIO-4** would require consultation with the wildlife agencies if flow reduction resulted in significant downstream habitat impacts. However, on a regional scale, a return to a more natural hydrology is not expected to significantly reduce the prevalence of high-value habitats or their use by sensitive species in the County. With implementation of Mitigation Measures BIO-1, BIO-2 and BIO-4, impacts to riparian vegetation from flow retention would be less than significant.

Future project-level environmental review processes will consider proposed projects as necessary to determine project-level impacts on special-status wildlife species and will require the implementation of project-specific mitigation measures to minimize and reduce potentially significant impacts to special-status wildlife species. Where potentially significant impacts to biological resources are identified for individual projects, implementation of Mitigation Measures BIO-1 through BIO-8 would avoid or reduce the impact to a less than significant level.

Summary of EWMP Groups

The following discussion provides additional detail to each of the watershed groups:

<u>Southern Coastal EWMP Watersheds</u> ***(Beach Cites, Southern Santa Monica Bay, Peninsula, Marine del Rey, Ballona)*** – Few direct impacts to biological resources from construction would be expected in these watersheds since the drainages are largely channelized. Large-scale lagoon restoration projects would temporarily affect habitats within the construction zones, but the

objective of these projects is to enhance biological functions. Otherwise, the urbanized drainages in these areas exhibit low-quality habitats and any work on the beach that could affect sensitive avian species would be minimal.

LFDs and dry-weather flow retention in this EWMP area would result in less fresh water reaching the tidal areas than is currently the case. However, at the lower end of the watershed, impacts to riparian and aquatic resources would be minimal since the areas are highly urbanized and the drainages are channelized with low habitat value. An exception to this is the Ballona freshwater marsh. Reduction in dry-weather flows to the coastal lagoons would reduce pollutant loading from the watershed and as a result improve water quality and native habitat values compared to existing conditions. In the upper portion of the watersheds, the reduction of perennial flows in drainages could affect urban-influenced low-value habitats. However, if these habitats were of sufficient value to support least Bell's vireo or other sensitive species, mitigation may be required. Implementation of mitigation measures BIO-1 through BIO-8 would reduce impacts to less-than-significant levels.

Northern Coastal EWMP Watersheds ***(Malibu and Upper Santa Monica Bay)*** – Installation of structural BMPs within drainages could affect existing habitats and sensitive species, particularly in the upper drainages that are largely undeveloped and exhibit high habitat values. Implementation of mitigation measures BIO-1 through BIO-8 would ensure that implementing agencies identify potentially affected resources and implement measures to avoid or reduce impacts to less-than-significant levels. Once installed, the modification to the hydrology created by the BMPs would more closely resemble historical conditions.

LFDs in the upper watersheds would return local coastal creeks to conditions resembling pre-urbanization. Native habitats along the coast have adapted to the climatological conditions and would continue to thrive with implementation of dry-weather-flow diversions and flow retention. However, in some localized areas, flow diversions could affect downstream riparian and aquatic habitat, reducing fresh water flow and wetted areas inhabited by willow forests. However, much of the high-value riparian and aquatic habitats in the upper coastal watershed that support sensitive birds and fish are fed from natural seepage. Infiltration BMPs would augment seepage and would serve to expand wetted areas supporting riparian and wetland habitats. Implementation of mitigation measures BIO-1 through BIO-8 would reduce impacts to less-than-significant levels.

Upper San Gabriel and Rio Hondo and Watersheds – Installation of structural BMPs in the upper San Gabriel and Rio Hondo watersheds have the potential to impact riparian and in-channel scrub habitats. The larger rivers are dry most of the year and habitat is adapted to the ephemeral cycle. If construction activities were to occur in an area exhibiting native vegetation, implementing agencies would need to implement measures to avoid, reduce, or compensate for significant impacts. Implementation of mitigation measures BIO-1 through BIO-8 would ensure that implementing agencies identify potentially affected resources and implement measures to avoid or reduce impacts to less-than-significant levels.

Upper Los Angeles River Watershed – The Upper Los Angeles River watershed is large and exhibits a large variety of habitats within drainages and within surrounding uplands and mountains. If construction activities were to occur in an area exhibiting native vegetation, implementing agencies would need to implement measures to avoid, reduce, or compensate for significant impacts. However, these construction effects would be temporary and would not result in significant reduction in habitat values within the watershed.

LFDs and retention in this highly urbanized watershed could result in substantial modifications to hydrologic conditions in the smaller channels and streams. Much of the higher value habitat occurs on the perimeter of the watershed and would not be affected by the BMPs. However, the vegetated channels in the mid and lower portions of the watershed could be cut off from perennial flows, resulting in a reduction of wetted area and associated habitat. Implementation of mitigation measures BIO-1 through BIO-8 would ensure that implementing agencies identify potentially affected resources and implement measures to avoid or reduce impacts to less-than-significant levels.

Dominguez Channel Watershed – These watersheds are highly urbanized, supporting little native vegetation. What vegetation does exist is associated with either the tidal channel or urban runoff. Construction within these areas would not encounter high-value upland, riparian, or aquatic habitats. Implementation of mitigation measures would ensure that impacts to habitat values would be less than significant.

Low-flow and dry-weather-flow retention in the Dominguez Channel watershed would not result in significant impacts to riparian or aquatic habitats downstream since very few high-value habitats exist in the watershed. One exception to this is Machado Lake, which relies on freshwater flows to maintain vegetation. However, returning the local hydrology to a more natural condition would result in less-than-significant impacts to biological resources.

Upper Santa Clara River Watershed – The Santa Clara River watershed exhibits the most open space and high-value riparian habitats of all the EWMP groups. Construction of structural BMPs could impact upland forests, scrub, riparian and aquatic habitats. If construction activities were to occur in an area exhibiting native vegetation, implementing agencies would need to implement measures to avoid, reduce, or compensate for significant impacts. In addition mitigation measure BIO-1 requires that implementing agencies evaluate the suitability of BMP locations prior to development in order to avoid impacts to sensitive habitats.

LFDs and dry-weather-flow retention may affect areas downstream of urbanized areas. However, the Upper Santa Clara River is ephemeral and generally dry upstream of the wastewater discharges. Furthermore, the stream is a gaining stream below the urbanized area, responding to rising groundwater levels. Any retention of dry-weather flow would have only minor effects on the aquatic or riparian habitats in tributary streams and no impacts to the Santa Clara River itself. In fact, increased underflow into the riverbed from groundwater would benefit the riparian and aquatic habitats. In addition, implementing agencies would be required to evaluate potential impacts from flow retention BMPs. Implementation of mitigation measures would ensure that impacts are less than significant.

Summary of Impact

BMPs designed to retain dry-weather flows could reduce wetted area or completely eliminate flows in certain drainages that support sensitive species. To ensure that impacts to downstream biological resources are less than significant for regional and centralized BMPs, Permittees would implement **Mitigation Measures BIO-1** through **BIO-8** which provide for the identification and minimization of potential effects. As a result, impacts to sensitive species resulting from the implementation the EWMPs would be less than significant. The smaller distributed BMPs would not result in significant impacts and would not be required to implement mitigation measures.

Mitigation Measures

BIO-1: Prior to approving a regional or centralized BMP, the Permittee shall conduct an evaluation of the suitability of the BMP location. Appropriate BMP sites should avoid impacting large areas of native habitats including upland woodlands and riparian forests that support sensitive species to the extent feasible. The evaluation shall include an assessment of potential downstream impacts resulting from flow diversions.

BIO-2: Prior to ground-disturbing activities in areas that could support sensitive biological resources, a habitat assessment shall be conducted by a qualified biologist to determine the potential for special-status wildlife species to occur within affected areas, including areas directly or indirectly impacted by construction or operation of the BMPs.

BIO-3: If a special-status wildlife species is determined to be present or potentially present within the limits of construction activities, a qualified biologist shall conduct preconstruction surveys of proposed work zones and within an appropriately sized buffer around each area as determined by a qualified biologist within 14 days prior to ground disturbing activities. Any potential habitat capable of supporting a special-status wildlife species shall be flagged for avoidance if feasible.

BIO-4: If avoidance of special-status species or sensitive habitats that could support special-status species (including, but not limited to, critical habitat, riparian habitat, and jurisdictional wetlands/waters) is not feasible, the Permittee shall consult with the appropriate regulating agency (USACE/USFWS or CDFW) to determine a strategy for compliance with the Endangered Species Act, California Fish and Game Code, and other regulations protecting special-status species and sensitive habitats. The Permittee shall identify appropriate impact minimization measures and compensation for permanent impacts to sensitive habitats and species in consultation with regulatory agencies. Construction of the project will not begin until the appropriate permits from the regulatory agencies are approved.

BIO-5: If construction and vegetation removal is proposed between February 1 and August 31, a qualified biologist shall conduct a pre-construction survey for breeding and nesting birds and raptors within 500-feet of the construction limits to determine and map the location and extent of breeding birds that could be affected by the project. Active nest sites located during the pre-construction surveys shall be avoided until the adults and young are no longer reliant on the nest site for survival as determined by a qualified biologist.

BIO-6: All construction areas, staging areas, and right-of-ways shall be staked, flagged, fenced, or otherwise clearly delineated to restrict the limits of construction to the minimum necessary near areas that may support special-status wildlife species as determined by a qualified biologist.

BIO-7: Prior to construction in areas that could support special-status plants, a qualified botanist shall conduct a pre-construction floristic inventory and focused rare plant survey of project areas to determine and map the location and extent of special-status plant species populations within disturbance areas. This survey shall occur during the typical blooming periods of special-status plants with the potential to occur. The plant survey shall follow the CDFW Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Natural Communities (November 24, 2009).

BIO-8: If temporary construction-related impacts to special-status plant populations are identified within a disturbance area, the implementing agencies shall prepare and implement a special-status species salvage and replanting plan. The salvage and replanting plan shall include measures to salvage, replant, and monitor the disturbance area until native vegetation is re-established under the direction of CDFW and USFWS.

Significance Determination: Less than significant with mitigation. (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.3-1.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no direct impacts to special-status species or their habitats. However, many of the non-structural BMPs would result in the reduction of dry-weather urban runoff that could reduce perennial flows in local drainages. Returning the local hydrology to a more natural condition would occur overtime and would reduce overall wetted areas within minor drainages and swales throughout the region. Local riparian and lake features that rely on urban runoff could gradually shift from riparian and marsh to upland and sparse riparian. Shorelines may shift and wetted areas may decrease over time as more water is retained in the upper watershed, but these changes would not significantly degrade biological resources in the region as a whole since the revised hydrology would be a more natural condition for the arid region. Groundwater seepage would continue to support the major riparian corridors in the Malibu, Santa Clara, Upper Los Angeles, and San Gabriel watersheds. Retention of flows in the upper watershed would even augment these groundwater resources, offsetting any impacts from surface flow reductions. Moreover, improved water quality in the region's drainages and lagoons would be beneficial to habitat health. Overall, implementation of non-structural BMPs will not significantly impact sensitive species in the EWMP areas.

Mitigation Measures: None required

Significance Determination: Less than significant

Riparian Habitat or Other Sensitive Natural Communities

Impact 3.3-2: The proposed project could have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations, or by the CDFW or USFWS.

Structural (Regional, Centralized, and Distributed) BMPs

As previously discussed, 20 sensitive natural communities tracked by the CNDDB occur within the EWMP area. In addition, Significant Ecological Areas are considered sensitive natural communities as identified by the Los Angeles County General Plan. The SEAs, riparian and other sensitive communities (which include riparian habitats such as Southern Cottonwood Willow Riparian Forest) are not expected to occur within the disturbance areas of the BMP projects since the majority of the structural BMPs would occur in developed or disturbed areas. While some regional and centralized structural BMPs (i.e., floodplain management and stream restoration projects) could occur within or adjacent to SEAs, riparian habitat or other sensitive natural communities, these types of BMPs would provide multi-beneficial water quality and habitat restoration improvements to the applicable EWMP watershed. Further, each development proposed within a designated SEA must undergo a performance review process for compliance with the SEA design compatibility criteria and other standards for approval by the Los Angeles County Department of Regional Planning (County of Los Angeles 2012).

In addition, future project-level environmental review processes would consider all proposed projects on a case-by-case basis to determine whether an individual project would impact riparian or other sensitive natural communities and where it is necessary, would require the implementation of site-specific mitigation measures to minimize and reduce potentially significant impacts to riparian and other sensitive natural communities. Impacts would be reduced to less-than-significant levels with the implementation of Mitigation Measures BIO-1 through BIO-8.

> **Mitigation Measures:** Implement Mitigation Measures BIO-1 and BIO-8.
>
> **Significance Determination:** Less than significant with mitigation. (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.3-1.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts to riparian or other sensitive natural communities from construction. However, many of the non-structural BMPs would result in the reduction of dry-weather urban runoff that could reduce perennial flows in local drainages. Returning the local hydrology to a more natural condition would occur overtime and would reduce overall wetted areas within minor drainages and swales throughout the region. Local riparian and lake features that rely on urban runoff could gradually shift from riparian and marsh to upland and sparse riparian. Shorelines may shift and wetted areas may decrease over time as more water is retained in the upper watershed, but these changes would not significantly degrade biological resources in the region as a whole since the revised hydrology would be a more natural condition for the arid region. Groundwater seepage would continue to support the major riparian corridors in the Malibu, Santa Clara, Upper Los Angeles, and San Gabriel watersheds. Retention of flows in the upper watershed would even augment these groundwater resources, offsetting any impacts from surface flow reductions. Moreover, improved water quality in the region's drainages and lagoons would be beneficial to habitat health. Overall, implementation of non-structural BMPs will not significantly impact riparian habitat or other sensitive natural communities in the EWMP areas.

Mitigation Measures: None required

Significance Determination: No impact

Wetland Habitats

Impact 3.3-3: The proposed project could have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means.

Structural (Regional, Centralized, and Distributed) BMPs

Construction through areas within or adjacent to waterways (creeks, stream, reservoir) or wetland features would require approval from one or more of the following: USACE, RWQCB, or CDFW. Wetlands occur throughout the EWMP Areas ranging from isolated segments of improved urban channels to the open river segments of the Santa Clara, Los Angeles, and San Gabriel Rivers. Once project facility locations and designs are determined, exact locations and acreages of jurisdictional areas located within or adjacent to impact areas shall be determined through a formal jurisdictional delineation.

For projects impacting native vegetation within jurisdictional drainages, the implementing agency would be required to obtain California Fish and Game Code Section 1602 compliance and Section 404 compliance from the USACE and Section 401 Certification from the RWQCB. In addition, implementation of Mitigation Measures BIO-1 through BIO-9 would ensure compliance with state and federal regulations relating to potentially jurisdictional features, including wash habitat vegetation that may fall under CDFW jurisdiction.

Mitigation Measures

Implement Mitigation Measures BIO-1 through BIO-8.

BIO-9: Prior to construction, a qualified wetland delineator shall be retained to conduct a formal wetland delineation in areas where potential jurisdictional resources (i.e., wetlands or drainages) subject to the jurisdiction of USACE, RWQCB, and CDFWmay be affected by the project. If jurisdictional resources are identified in the EWMP area and would be directly or indirectly impacted by individual projects, the qualified wetland delineator shall prepare a jurisdictional delineation report suitable for submittal to USACE, RWQCB, and

CDFW for purposes of obtaining the appropriate permits. Habitat mitigation and compensation requirements shall be implemented prior to construction in accordance with Mitigation Measure BIO-4.

Significance Determination: Less than significant with mitigation. (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.3-1.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts to wetlands or other jurisdictional features from construction. Non-structural BMPs would result in a reduction of urban dry-weather surface flows that currently may support wetlands. Returning the local hydrology to a more natural condition would occur overtime. Local wetland features that rely on urban runoff could gradually become non-hydric, resulting in a reduction in wetlands in the region. However, their functions as ephemeral water ways would not be reduced, but rather would reflect the more natural condition afforded by the Southern California climate. The revised hydrology would not result in a reduction of waters of the United States. Moreover, the retained water infiltrated into the ground would augment the shallow groundwater that serves to support local wetlands and riparian habitats. Increased groundwater seepage would increase the extent of wetlands and wetted areas and on a regional scale offset any reduction caused by surface flow reductions.

Implementation of BMPs would ensure compliance with the CWA requiring MS4s to reduce dry-weather flows in this region. Although compliance with Section 402 of the CWA may result in a reduction of wetlands in the region supported by surface flow, the infiltration of surface water into the ground would offset the potential impact, resulting in no net loss and a less-than-significant impact to wetlands.

Mitigation Measures: None required

Significance Determination: No impact

Wildlife Movement

Impact 3.3-4: The proposed project could interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites.

Structural (Regional, Centralized, and Distributed) BMPs

There are no established wildlife movement corridors within the EWMP area as described within the Los Angeles County General Plan directly affected by implementation of the EWMPs. While portions of the EWMP areas are located within the linkage design for the San Gabriel-Castaic and Santa Monica-Sierra Madre connections, implementation of structural BMPs would primarily be constructed within existing stormwater facilities or disturbed areas. Furthermore, the EWMPs would not reduce open water features used by migratory birds or reduce fresh water flows that support sensitive fish species.

Implementation of the EWMP would not be expected to interfere with wildlife movement or any migratory corridor/linkage, and would not be constructed within a native wildlife nursery site.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts related to the movement of any native resident or migratory fish or wildlife species, or with established native resident or migratory wildlife corridors.

Mitigation Measures: None required

Significance Determination: No impact

Local Policies or Ordinances

Impact 3.3-5: The proposed project could conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance.

Structural (Regional, Centralized, and Distributed) BMPs

The proposed project would mainly be constructed within highly urbanized and disturbed areas within existing infrastructure. Any impacts to oak trees within Los Angeles County would be required to comply with the Oak Tree Preservation Ordinance (or other tree ordinances established by the local city). A tree permit may be required if impacts to oak trees or other protected trees are determined to be necessary. No impacts to oak trees or other protected tree species is anticipated. However, the exact locations of the BMP projects have not been established. Implementation of **Mitigation Measure BIO-10** would reduce any potential impacts to protected tree species to a less-than-significant level.

Mitigation Measure

BIO-10: Oak trees and other protected trees shall be avoided to the extent feasible. If trees may be impacted by project construction, a certified arborist shall conduct a tree inventory of the construction impact area. If any oak trees or other protected trees will be impacted by BMP construction, the implementing agency shall obtain any required County or City permits.

Significance Determination: Less than significant with mitigation. (The application of this mitigation measures to specific BMP types and categories are identified in Table 3.3-1.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts related to conflicts with local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance.

Mitigation Measures: None required

Significance Determination: No impact

Adopted Habitat Conservation Plans

Impact 3.3-6: The proposed project could conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan.

Structural (Regional, Centralized, and Distributed) BMPs

The EWMP areas are not located within an adopted federal or state habitat conservation plan area, but 48 SEAs are located within the boundary of the EWMP area (Figure 3.3-1). In addition, the County Oak Woodland Management Plan covers habitats that exist within some EWMPs. The SEAs and Oak Woodland Management Plan provide protection to many of the sensitive natural communities and special-status species within the County; however, the majority of the structural BMPs would occur in developed or disturbed areas that are expected to be outside of adopted SEAs. As previously discussed, while some regional and centralized structural BMPs (i.e., floodplain management and stream restoration projects) could occur within or adjacent to SEAs, these types of BMPs would provide multi-beneficial water quality and habitat restoration improvements to the applicable EWMP watershed. Further, each development proposed within a designated SEA must undergo a performance review process for compliance with the SEA design compatibility criteria and other standards for approval by the Los Angeles County Department of Regional Planning (County of Los Angeles 2012). Therefore, conflicts with the management policies for each SEA are not anticipated, and impacts would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant.

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts related to conflicts with an adopted habitat conservation plan or the Los Angeles County General Plan.

Mitigation Measures: None required

Significance Determination: No impact

Cumulative Impact Discussion

Structural (Regional, Centralized, and Distributed) BMPs

BMPs would be constructed throughout the EWMP watersheds. Most of the distributed BMPs would be small in scale and would not result in cumulatively significant impacts, as they would occur within existing developed or disturbed areas at existing stormwater infrastructure/facilities. For regional and centralized BMPs at the larger scale, Mitigation Measures BIO-1 through BIO-10 would reduce potentially significant impacts to biological resources, and any additional or more site-specific mitigation measures developed during the future project-level environmental review processes may further reduce potential impacts.

Cumulatively, throughout the region, the retention of stormwater and treatment of pollutants within each watershed, and the reduction of pollutant loading in waterways would substantially benefit the water quality of the region's aquatic and coastal habitats, as well as the plants and wildlife dependent on them. Implementation of the BMPs would also return the local hydrology to a more natural condition. Much of the vegetation supported by urban runoff within these EWMP areas as discussed above is cleared to ensure sufficient flood control function of the channels. In addition, the majority of high-value habitats in the region rely on groundwater seepage rather than perennial urban runoff. Although some drainage segments may exhibit reduced riparian habitat or wetlands over time due to the reduced dry-weather flow, the cumulative effect would be offset by increased groundwater recharge and seepage supporting expanded wetland and riparian vegetation supporting local flora and fauna populations. Therefore, the program's potential contribution to cumulative effects on biological resources is considered less than significant.

Implementation of BMPs would ensure compliance with Section 402 of the CWA that requires MS4s to reduce dry-weather flows in this region. Although compliance with Section 402 of the CWA may result in a reduction of wetlands in the region supported by surface flow, the infiltration of surface water into the ground would offset the potential impact, resulting in a less than significant cumulative impact to biological resources in the region.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

As discussed previously, cumulatively, throughout the region, the retention of stormwater and treatment of pollutants within each watershed, and the reduction of pollutant loading in waterways would substantially benefit the water quality of the region's aquatic and coastal habitats, as well as the plants and wildlife dependent on them. Although some drainage segments may exhibit reduced riparian habitat or wetlands over time due to the reduced dry-weather flow, the cumulative effect would be offset by increased groundwater recharge and seepage supporting expanded wetland and riparian vegetation supporting local flora and fauna populations.

Therefore, the program's potential contribution to cumulative effects on biological resources is considered less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

3.3.4 Summary of Impact Assessment

Table 3.3-1 shows a summary of the structural BMPs requiring mitigation.

TABLE 3.3-1
SUMMARY OF BIOLOGICAL RESOURCE IMPACTS REQUIRING MITIGATION MEASURES

	Thresholds of Significance						
Structural BMPs	**Sensitive Species**	**Sensitive Habitats**	**Wetland Habitats**	**Wildlife Movement**	**Local Policies and Ordinances**	**Habitat Conservation Plans**	**Cumulative Impacts**
Applicable Mitigation Measures:	**BIO-1 through BIO-8**	**BIO-1 through BIO-8**	**BIO-1 through BIO-9**	**None Required**	**BIO-10**	**None Required**	**None Required**
Regional BMPs							
Regional Retention and Infiltration	Yes	Yes	Yes	No	No	No	Yes
Regional Capture, Detention and Use	Yes	Yes	Yes	No	No	No	Yes

Low-Flow Diversion	No	No	No	No	No	No	No

NOTE: These conclusions are based on typical sizes and locations of BMPs.

3.4 Cultural Resources

This chapter addresses the potential impacts of the proposed program on cultural resources. Cultural resources include prehistoric and historic sites, structures, districts, places, and landscapes, or any other physical evidence associated with human activity considered important to a culture, a subculture, or a community for scientific, traditional, religious, or any other reason. Under the California Environmental Quality Act (CEQA), paleontological resources, although not associated with past human activity, are grouped within cultural resources. For the purposes of this analysis, cultural resources may be categorized into the following groups: archaeological resources, historic resources (including architectural/engineering resources), contemporary Native American resources, human remains, and paleontological resources.

Archaeological resources are places where human activity has measurably altered the earth or left deposits of physical remains. Archaeological resources may be either prehistoric-era (before European contact) or historic-era (after European contact). The majority of such places in California are associated with either Native American or Euro-American occupation of the area. The most frequently encountered prehistoric or historic Native American archaeological sites are village settlements with residential areas and sometimes cemeteries; temporary camps where food and raw materials were collected; smaller, briefly occupied sites where tools were manufactured or repaired; and special-use areas like caves, rock shelters, and rock art sites. Historic-era archaeological sites may include foundations or features such as privies, corrals, and trash dumps.

Historic resources include standing structures, infrastructure, and landscapes of historic or aesthetic significance that are generally 50 years of age or older. In California, historic resources considered for protection tend to focus on architectural sites dating from the Spanish Period (1529–1822) through World War II (WWII) and Post War–era facilities. Some resources, however, may have achieved significance within the past 50 years if they meet the criteria for exceptional significance. Historic resources are often associated with archaeological deposits of the same age.

Contemporary Native American resources, also called ethnographic resources, can include archaeological resources, rock art, and the prominent topographical areas, features, habitats, plants, animals, and minerals that contemporary Native Americans value and consider essential for the preservation of their traditional values. These locations are sometimes hard to define and traditional culture often prohibits Native Americans from sharing these locations with the public.

Paleontology is a branch of geology that studies the life forms of the past, especially prehistoric life forms, through the study of plant and animal fossils. Paleontological resources represent a limited, nonrenewable, and impact-sensitive scientific and educational resource. As defined in this section, paleontological resources are the fossilized remains or traces of multicellular invertebrate and vertebrate animals and multicellular plants, including their imprints from a previous geologic period. Fossil remains such as bones, teeth, shells, and leaves are found in the geologic deposits (rock formations) where they were originally buried. Paleontological resources include not only the actual fossil remains, but also the collecting localities, and the geologic formations containing those localities.

3.4.1 Environmental Setting

Cultural Resources

Part of the program area is located in the Los Angeles Basin. The basin is formed by the Santa Monica Mountains to the northwest, the San Gabriel Mountains to the north, and the San Bernardino Mountains and San Jacinto Mountains to the east. The basin was formed by alluvial and fluvial deposits derived from these surrounding mountains. Prior to urban development and the channeling of the Los Angeles River, much of the program area was likely covered with marshes, thickets, dense woodland, and grassland. Historically, the Los Angeles River originated from a spring near what is present-day Encino. The river flowed eastward from Encino through the southern portion of the San Fernando Valley near the foot of the Santa Monica Mountains before turning southeast at what is present-day Griffith Park (Gumprecht, 2001). From there, it flowed to the Pacific Ocean along a frequently shifting course, sometimes flowing south to empty into San Pedro Bay near Long Beach, sometimes flowing west to the Santa Monica Bay along the course of what is present-day Ballona Creek. In its natural state, the river’s flow meandered dramatically, narrowed and widened intermittently, and even returned underground completely in certain locations. The floodplain forest of the Los Angeles Basin formed one of the most biologically rich habitats in Southern California. Willow, cottonwood, and sycamore and dense underbrush of alder, hackberry, and shrubs once lined the Los Angeles River as it passed near what is present-day downtown Los Angeles (Gumprecht, 2001). Although historically most of the Los Angeles River was dry for at least part of the year, shallow bedrock in the Elysian Park area north of what is present-day downtown forced much of the river’s underground water to the surface. This allowed for a steady year-round flow of water through the area that later became known as downtown Los Angeles (Gumprecht, 2001).

Prehistory

The abundant and diverse environmental resources of the coastal Los Angeles basin have attracted human inhabitants from the earliest times. The prehistory of the region has been summarized within four major horizons or cultural periods: Early, Millingstone, Intermediate, and Late Prehistoric (Wallace, 1955).

The Early period covers the interval from the first presence of humans in Southern California until post-glacial times. While people are known to have inhabited Southern California beginning at least 13,000 years Before Present (B.P.) (Arnold et al., 2004), the first evidence of human occupation of the Los Angeles area dates to at least 9,000 B.P. These occupations are associated with a period known as the Millingstone Cultural Horizon (7,000-4,000 B.P) (Wallace, 1955; McIntyre, 1990). Departing from the subsistence strategies of their nomadic big-game hunting predecessors, Millingstone populations established more permanent settlements. Settlements were located primarily on the coast and in the vicinity of estuaries, lagoons, lakes, streams, and marshes where a variety of resources, including seeds, fish, shellfish, small mammals, and birds, were exploited. Early Millingstone occupations are typically identified by the presence of handstones (manos) and millingstones (metates), while those Millingstone occupations dating later than 5,000 B.P. contain a mortar and pestle complex as well, signifying an increased dependence on new food sources, such as acorns and starchy tubers.

Although many aspects of Millingstone culture persisted, by 3,500 B.P., a number of socioeconomic changes occurred (Wallace, 1955; McIntyre, 1990). These changes are associated with the period known as the Intermediate Horizon (3,500–1,500 B.P.) (Wallace, 1955). Increasing population size necessitated the intensified use of existing terrestrial and marine resources (Erlandson, 1994). This was accomplished in part through use of the circular shell fishhook on the coast and more abundant and diverse hunting equipment. The Intermediate Horizon marks a period in which specialization in labor emerged, trading networks became an increasingly important means by which both utilitarian and non-utilitarian materials were acquired, and travel routes were extended. Archaeological evidence suggests that the margins of rivers, marshes, and swamps within the Los Angeles River drainage, with their rich variety of resources, served as locations of prehistoric settlement and travel during this period. Settlement around the Ballona Lagoon increased significantly during this period (Altschul et al., 2003).

The Late Prehistoric Period, spanning from approximately 1,500 years B.P. to the Spanish mission era, witnessed an increase in terrestrial and sea mammal hunting, along with continued seed collecting (Wallace, 1955). Small projectile points indicate the use of the bow and arrow. Although the location of Late Period villages does not significantly change, the villages become larger in size and fewer in number (McIntyre, 1990). Inter-village and inter-regional trade increased, and there is evidence for the use of shell beads as a form of money in economic exchanges.

Ethnographic Background

Tataviam

The northern part of the program area is located within the territory traditionally occupied by the Tataviam. Tataviam territory was concentrated along the upper reaches of the Santa Clara River drainage between the San Fernando Valley on the south and Pastoria Creek in the Tehachapi Mountains to the north. Their territory also included east Piru Creek and the southern slopes of Sawmill and Liebre Moutains, and also extended into the southern end of the Antelope Valley (King and Blackburn, 1978).

There are few historical sources regarding the Tataviam. The word “Tataviam” most likely came from a Kitanemuk word that may be roughly translated as “people of the south-facing slope,” because of their settlement on south-facing mountain slopes (King and Blackburn, 1978). What the Tataviam called themselves is not known. The Tataviam spoke a language that was part of the Takic branch of the Uto-Aztecan language family (King and Blackburn, 1978). The language was related to that spoken by the Gabrielino-Tongva.

Tataviam villages varied in size from larger centers with as many as 200 people, to smaller villages with only a few families (King and Blackburn, 1978). At the time of Spanish contact, the

Tataviam population is estimated to have been less than 1,000. Primary vegetable food sources included acorns, juniper berries, seeds, and yucca buds. Small game such as antelope and deer supplemented these foods. Trade networks between inland groups such as the Tataviam, the coastal regions, and desert regions enabled the trade of exotic materials such as shell, asphaltum, and steatite.

Gabrielino-Tongva

The southern portion of the program area is located in a region traditionally occupied by the Takic-speaking Gabrielino-Tongva Indians. The term "Gabrielino" is a general term that refers to those Native Americans who were administered by the Spanish at the Mission San Gabriel Arcángel. Many contemporary Gabrielino identify themselves by the name "Tongva." Prior to European colonization, the Gabrielino-Tongva occupied a diverse area that included: the watersheds of the Los Angeles, San Gabriel, and Santa Ana rivers; the Los Angeles basin; and the islands of San Clemente, San Nicolas, and Santa Catalina (Kroeber, 1925). The Gabrielino language, like the Tataviam language, was part of the Takic branch of the Uto-Aztecan language family.

The Gabrielino-Tongva Indians were hunter-gatherers and lived in permanent communities located near the presence of a stable food supply. Community populations generally ranged from 50 to 100 inhabitants, although larger settlements may have existed. The Gabrielino-Tongva are estimated to have had a population numbering around 5,000 in the precontact period (Kroeber, 1925). Villages are reported to have been the most abundant in the San Fernando Valley, the Glendale Narrows area north of downtown, and around the Los Angeles River drainage (Gumprecht, 2001). Maps produced by early explorers indicate that at least 26 Gabrielino villages were within close proximity to known Los Angeles River courses, while an additional 18 villages were within reasonably close proximity to the river (Gumprecht, 2001).

Subsistence consisted of hunting, fishing, and gathering. Small terrestrial game were hunted with deadfalls, rabbit drives, and by burning undergrowth, while larger game such as deer were hunted using bows and arrows. Fish were taken by hook and line, nets, traps, spears, and poison (Bean and Smith, 1978). The primary plant resources were the acorn, gathered in the fall and processed in mortars and pestles, and various seeds that were harvested in late spring and summer and ground with manos and metates. The seeds included chia and other sages, various grasses, and islay or holly-leafed cherry.

Coming ashore on Santa Catalina Island in October of 1542, Juan Rodriguez Cabrillo was the first European to make contact with the Gabrielino-Tongva; the 1769 expedition of Gaspar de Portolá also passed through Gabrielino-Tongva territory (Bean and Smith, 1978). Native Americans suffered severe depopulation and their traditional culture was radically altered after Spanish contact. Nonetheless, Gabrielino-Tongva descendants still reside in the greater Los Angeles and Orange County areas and maintain an active interest in their heritage.

Historic Setting

Spanish Period (A.D. 1769-1821)

Although Spanish explorers made brief visits to the region in 1542 and 1602, sustained contact with Europeans did not commence until the onset of the Spanish Period. In 1769 Gaspar de Portolá led an expedition from San Diego, passing through Los Angeles Basin, San Fernando Valley, and Santa Clarita Valley on its way to the San Francisco Bay (McCawley, 1996). This was followed in 1776 by the expedition of Father Francisco Garcés (Johnson and Earle, 1990).

In the late 18th century, the Spanish began establishing missions in California and forcibly relocating and converting native peoples. Two missions were located in the vicinity of the program area: Mission San Gabriel Arcángel, founded in 1771, and Mission San Fernando Rey de España, founded in 1797. Gabrielino-Tongva Indians were primarily sent to Mission San Gabriel to be baptized, although some were also baptized at Mission San Fernando. By 1820, most of the Tataviam population had been baptized at Mission San Fernando (California Missions Resource Center, 2012). Disease and hard labor took a toll on the native population in California; by 1900, the Native Californian population had declined by as much as 90 percent (Cook, 1978). In addition, native economies were disrupted, trade routes were interrupted, and native ways of life were significantly altered.

In an effort to promote Spanish settlement of Alta California, Spain granted several large land concessions from 1784 to 1821. At this time, unless certain requirements were met, Spain retained title to the land (State Lands Commission [SLC], 1982). Over 70 Spanish land grants were made within Los Angeles County.

On September 4, 1781, El Pueblo de la Reina de los Angeles was established not far from the site where Portolá and his men camped during their 1769 excursion. The original pueblo consisted of a central square surrounded by 12 houses and a series of agricultural fields (Gumprecht, 2001).

Mexican Period (A.D. 1821-1848)

The Mexican Period began when Mexico won its independence from Spain in 1821. Mexico continued to promote settlement of California with the issuance of land grants. In 1833, Mexico began the process of secularizing the missions, reclaiming the majority of mission lands and redistributing them as land grants. Many ranchos continued to be used for cattle grazing by settlers during the Mexican Period. Hides and tallow from cattle became a major export for Californios (native Hispanic Californians) (Pitt, 1994; Starr, 2007).

After Mexico gained its independence, the city of Los Angeles became the capital of the California territory in 1835. But few visited the area and the town remained a “sleepy agricultural village” until the Gold Rush in 1848 (Gumprecht, 2001).

American Period (A.D. 1848-present)

In 1846, the Mexican-American War broke out. Mexican forces were eventually defeated in 1847 and Mexico ceded California to the United States as part of the Treaty of Guadalupe Hildalgo in 1848. California officially became one of the United States in 1850.

The County of Los Angeles was established on February 18, 1850, as one of the 27 original counties, several months before California was admitted to the Union on September 9, 1850. It derived its name from the community of Los Angeles, which was designated the County seat. Parts of the county's territory were given to San Bernardino County in 1853, to Kern County in 1866 and to Orange County in 1889 (County of Los Angeles, 2014).

When the discovery of gold in Northern California was announced in 1848, a huge influx of people from other parts of North America flooded into California. The increased population provided an additional outlet for California cattle. As demand increased, the price of beef skyrocketed and California reaped the benefits. However, a devastating flood in 1861, followed by droughts in 1862 and 1864, led to a rapid decline of the cattle industry; over 70 percent of cattle perished during these droughts (McWilliams, 1949; Dinkelspiel, 2008). This event, coupled with the burden of proving ownership of their lands, caused many Californians to lose their lands during this period (McWilliams, 1949). Former ranchos were subsequently subdivided and sold for agriculture and residential settlement.

The first transcontinental railroad was completed in 1869, connecting San Francisco with the eastern United States. Newcomers poured into Northern California. Southern California experienced a trickle-down effect, as many of these newcomers made their way south. The Southern Pacific Railroad extended this line from San Francisco to Los Angeles in 1876. The second transcontinental line, the Santa Fe, was completed in 1886 and caused a fare war, driving fares to an unprecedented low. Settlers flooded into the region and the demand for real estate skyrocketed. As real estate prices soared, land that had been farmed for decades outlived its agricultural value and was sold to become residential communities. The subdivision of the large ranchos took place during this time (Meyer, 1981; McWilliams, 1949).

The city of Los Angeles would experience its greatest growth in the 1880s when two more direct rail connections to the East Coast were constructed. The resulting fare wars led to an unprecedented real estate boom. Despite a subsequent collapse of the real estate market, the population of Los Angeles increased 350 percent from 1880 to 1890 (Dinkelspiel, 2008). From 1890 to 1900, the city continued to grow, and many infrastructure projects were completed during this decade (McWilliams, 1949). E.L. Doheny discovered oil in 1892, adding fuel to the flame, and the population doubled by 1900. From 1900 to 1920, Los Angeles became a tourist mecca (McWilliams, 1949). The Los Angeles Aqueduct was constructed and a large portion of the San Fernando Valley annexed to the city during the first decade of the 20th century. From 1920 to 1930, Los Angeles experienced another population explosion, due in part to the automobile and the development of the movie industry. During the first three decades of the 20th century, more than two million people moved to Los Angeles County, transforming it from a largely agricultural region into a major metropolitan area with a population of 2.8 million within the city of Los Angeles and over 7 million within Los Angeles County by 1970 (U.S. Bureau of the Census, 1998; 1995).

Geoarchaeological Review

A project's probability for encountering archaeological resources depends upon three factors: (1) original formation of an archaeological deposit, (2) post-depositional (mainly geomorphic) processes following deposition of archaeological remains, and (3) project-specific ground disturbances. The original formation of an archaeological deposit in any particular place requires a past human presence as well as behaviors that result in material culture residue. The formation of archaeological deposits is conditioned by the dynamic interaction of paleoenvironmental factors (e.g., past climate, availability of water, abundance of subsistence resources) with a culture's economic, technological, social, and other behavioral systems. As Meyer et al. (2010) have pointed out: "Archaeological deposits are not randomly distributed throughout the landscape, but tend to occur in specific geo-environmental settings." While there seems to be no commonly agreed upon set of landform characteristics for predicting locations in which archaeological sites would be expected to form, landform slope and proximity to water have been invoked as useful predictors in central California (Meyer et al., 2010) and may be relevant to the program area. Stated simply, flat landforms near permanent sources of water tend to be strongly associated with archaeological deposits, while sloping landforms that lack water tend not to have archaeological deposits (Meyer et al., 2010).

Original formation of an archaeological deposit is a necessary, but not sufficient, condition to ensure that an archaeological site is still present centuries or millennia later. Post-depositional conditions must be suitable for preserving archaeological deposits for them to be discovered in the future. Geomorphological processes may work to either preserve or protect archaeological deposits, and their effects may vary depending on the specific setting. Landslides, for example, may displace and destroy archaeological sites at the top of a bluff, but may cover and protect sites at the bottom or toe of the bluff. In a similar vein, fluvial processes may erode archaeological sites along river cutbanks, but may deeply bury archaeological sites along the channel's floodplain. Absence of natural depositional forces—at the top a mountain ridgeline, for example—leave cultural materials exposed to the elements increasing their chance of destruction. Bedrock outcroppings, where little to no soil formation typically takes place, may lack sufficient matrix to cover and preserve traces of past human activity. One of the forces most capable of destroying archaeological sites is human activities. Agriculture, development of infrastructure, and urbanization especially can disturb and destroy archaeological sites, particularly surface or shallow sites, over immense areas.

If the various Enhanced Watershed Management Program (EWMP) projects and approaches may be likened to different types of infrastructure development, then their potential effects to archaeological deposits can be understood in terms of human activity impacts. Program actions that would result in large areas of deep ground disturbance would have a greater probability for encountering and impacting buried archaeological deposits than approaches resulting in more limited horizontal and vertical disturbances.

The program area is bounded on the northwest by the Santa Monica Mountains, on the northeast by the San Gabriel Mountains, on the southeast by the Orange County coastal plain, and on the west and southwest by the Pacific Ocean. The program area largely consists of the Los Angeles, Santa Clara, San Gabriel Rivers, Santa Monica Bay, and the Dominguez Channel Watersheds, and includes the Los Angeles Basin, San Fernando, and Santa Clarita Valleys. Topography varies regionally from sea level at the coast to several thousand feet in the surrounding mountains.

Broadly, erosion of bedrock out of the San Gabriel and Santa Monica Mountains during the Pleistocene and Holocene has resulted in construction of a broad and recent alluvial plain (Los Angeles Basin) between the mountain foothills and the coast. With few exceptions, this plain has been heavily urbanized and modified within the last century. Tectonism and over-steepening has resulted in formation of extensive landslide zones within the mountains and foothills, and many low-lying valleys are filled with colluvium and/or alluvium. Urbanization has occurred within of these valleys, as well as overlooking ridgelines.

The archaeological potential of the program area will be highly variable depending on local conditions. The low-lying alluvial plain and coastlines would be expected to have been preferred areas for past subsistence and occupation, and archaeological sites in these areas may have been subject to substantial burial. However, the extensive urbanization of these areas makes it likely that a high percentage of archaeological sites that once existed have been subject to disturbance or destruction by humans. On the other hand, while foothills and mountains may have been less favored for occupation because of their steeper slopes and more limited access to water, these areas have generally been subject to less development.

Paleontological Resources

The majority of the program area lies within the Los Angeles Basin, which is characterized by relatively flat (slight dip to the south) alluviated areas punctuated by tectonically uplifted highlands that drain into lower-lying areas and eventually the Pacific Ocean. It is these drainages that are, in part, responsible for the thick sequence of terrestrial sedimentary rocks that underlie much of the greater Los Angeles area and the diversity of fossils contained therein. During much of the early geological history of the program area, from the Early Miocene (approximately 23 million years before present) to the Late Pleistocene (approximately 11,000 years before present) sea level was much higher than today, and the much of the area was under water. Thick, richly fossiliferous (fossil-bearing) marine sedimentary sequences underlie much of the area, and where significant uplift has occurred because of tectonic forces, these fossil-rich rocks are exposed at the surface.

The following analysis of paleontological sensitivity within the program boundaries is based on available surficial geological mapping, published and unpublished technical reports, published scientific journals, and the University of California Museum of Paleontology online specimen database. No museum paleontological records searches were enlisted for this analysis. Because of the large geographic area and complex geology represented by the proposed program, surficial geological units and paleontological resources are outlined separately by each of the five watersheds (Santa Clara River, Los Angeles River, San Gabriel River, Santa Monica Bay, and Dominguez Channel), as shown in Figure 1-1. Furthermore, igneous and metamorphic rock units are omitted from this analysis because of they have no potential to yield significant paleontological resources.

Units are assigned a sensitivity rating based on Society for Vertebrate Paleontology (SVP) guidelines. The SVP has outlined criteria for screening the paleontological potential of rock units and has established assessment and mitigation procedures tailored to accommodating such potential. The SVP established four categories of paleontological sensitivity (potential) for rock units: high, undetermined, low, and no potential (SVP, 2010):

- **High Potential.** Rock units (or formations) in which vertebrate or significant invertebrate fossils have been found. These rock units include sedimentary and some volcanic formations that contain significant fossil resources anywhere within their geographic extent and sedimentary deposits formed in a time period or composed of materials suitable for the preservation of fossils. Only invertebrate fossils that provide new information on existing flora or fauna or on the age of a rock unit would be considered significant.
- **Undetermined Potential.** Rock units for which little information is available concerning their paleontological content, geologic age, and depositional environment are considered to have undetermined potential. Further study is necessary to determine if these rock units have high or low potential to contain significant paleontological resources. A field survey by a qualified professional paleontologist to specifically determine the paleontological resource potential of these rock units is required before a paleontological resource impact mitigation program can be developed. In cases where no subsurface data are available, paleontological potential can sometimes be determined by strategically located excavations into subsurface stratigraphy.
- **Low Potential.** Rock units that have few, if any, records of vertebrate fossils in institutional collections, or that have been shown in surveys or paleontological literature to be largely absent of fossil resources. Low-potential rocks also include metamorphic and igneous rocks other than some volcanic rocks.
- **No Potential.** Some rock units have no potential to contain significant paleontological resources, for instance high- grade metamorphic rocks (such as gneisses and schists) and plutonic igneous rocks (such as granites and diorites). Rock units with no potential require no protection or impact mitigation measures relative to paleontological resources. Units with no potential are not included in the following discussion.

Table 3.4-1 identifies paleontologically sensitive geologic formations within the region.

TABLE 3.4-1
PALEONTOLOGICALLY SENSITIVE GEOLOGIC UNITS/FORMATIONS WITHIN THE PROGRAM AREA

Geologic Unit/Formation	Sensitivity	Watershed
Recent Surficial Sediments (Quaternary alluvium, slopewash)	Low, higher at depth	All
Pleistocene (Older) Alluvium and Quaternary Terrace Deposit	High	All
Pacoima Formation	Undetermined	Los Angeles River
La Habra Formation	High	San Gabriel River
Saugus Formation	High	Santa Clara River and Los Angeles River
San Pedro Sand	High	Los Angeles River and Santa Monica Bay
Inglewood Formation	Undetermined	San Gabriel River
Fernando Formation	High	Santa Clara River and Los Angeles River
Pico Formation	High	Los Angeles River and Santa Monica Bay
Modelo Formation	High	Los Angeles River
The Towsley Formation	High	Santa Clara River and Los Angeles River
Ridge Basin Group	High	Santa Clara River
Sisquoc Formation	High	Santa Clara River and Los Angeles River
Puente Formation	High	San Gabriel River
Late Miocene Unnamed Marine Strata	Undetermined	Los Angeles River and Santa Monica Bay
Castaic Formation	High	Santa Clara River
The Monterey Formation	High	Santa Clara River
Mint Canyon Formation	High	Santa Clara River and Los Angeles River
Topanga Formation	High	Los Angeles River, Santa Monica Bay, and San Gabriel River
Trancas Formation	Undetermined	Santa Monica Bay
Tick Canyon Formation	High	Santa Clara River
Vasquez Formation	Low	Santa Clara River
Sespe-Vaqueros Formations	High	Santa Clara River and Santa Monica Bay
Llajas Formation	High	Los Angeles River and Santa Monica Bay
Eocene Unnamed marine strata	Undetermined	Los Angeles River and Santa Monica Bay
Santa Susana Formation	High	Los Angeles River and Santa Monica Bay
Martinez Formation	High	Los Angeles River
Chico Formation	High	Los Angeles River
Chatsworth Formation	High	Los Angeles River

3.4.2 Regulatory Setting

Federal, state, and local governments have developed laws and regulations designed to protect significant cultural resources that may be affected by actions that they undertake or regulate. The National Historic Preservation Act (NHPA) and CEQA are the primary federal and state laws governing preservation of historic and archaeological resources of national, regional, state, and local significance. If individual projects entail a federal nexus, such as a federal approval, federal funding, or federal property, federal historic preservation laws such as the NHPA may apply.

Federal

National Historic Preservation Act of 1966

Enacted in 1966, the NHPA declared a national policy of historic preservation and instituted a multifaceted program, administered by the Secretary of the Interior, to encourage the achievement of preservation goals at the federal, state, and local levels. Section 106 of the NHPA states that federal agencies with direct or indirect jurisdiction over federally funded, assisted, or licensed undertakings must take into account the effect of the undertaking on any historic property that is included in, or eligible for inclusion in, the National Register of Historic Places (NRHP) and that the ACHP must be afforded an opportunity to comment. The steps of the Section 106 process are accomplished through consultation with the State Historic Preservation Office, federally recognized Indian tribes, local governments, and other interested parties. The goal of consultation is to identify potentially affected historic properties, assess effects to such properties, and seek ways to avoid, minimize, or mitigate any adverse effects on such properties.

National Register of Historic Places

The NRHP was established by the NHPA of 1966, as "an authoritative guide to be used by federal, state, and local governments, private groups and citizens to identify the Nation's historic resources and to indicate what properties should be considered for protection from destruction or impairment" (Code of Federal Regulations 36 Section 60.2). The NRHP recognizes both historical-period and prehistoric archaeological properties that are significant at the national, state, and local levels.

To be eligible for listing in the NRHP, a resource must be significant in American history, architecture, archaeology, engineering, or culture. Districts, sites, buildings, structures, and objects of potential significance must meet one or more of the following four established criteria (U.S. Department of the Interior, 1995):

A. Are associated with events that have made a significant contribution to the broad patterns of our history.

B. Are associated with the lives of persons significant in our past.

C. Embody the distinctive characteristics of a type, period, or method of construction or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction.

D. Have yielded, or may be likely to yield, information important in prehistory or history.

Unless the property possesses exceptional significance, it must be at least 50 years old to be eligible for NRHP listing (U.S. Department of the Interior, 1995).

In addition to meeting the criteria of significance, a property must have integrity. Integrity is defined as "the ability of a property to convey its significance" (U.S. Department of the Interior, 1995). The NRHP recognizes seven qualities that, in various combinations, define integrity: location, design, setting, materials, workmanship, feeling, and association. To retain historic integrity a property must possess several, and usually most, of these seven aspects. Thus, the retention of the specific aspects of integrity is paramount for a property to convey its significance.

State

California Register of Historical Resources

Under the California Public Resources Code, Section 5024.19(a), the California Register of Historical Resources (CRHR) was created in 1992 and implemented in 1998 as "an authoritative guide in California to be used by State and local agencies, private groups, and citizens to identify the State's historical resources and to indicate what properties are to be protected, to the extent prudent and feasible, from substantial adverse change." Certain properties, including those listed in or formally determined eligible for listing in the NRHP and California Historical Landmarks numbered 770 and higher, are automatically included in the CRHR. Other properties recognized under the California Points of Historical Interest program, identified as significant in historical resources surveys or designated by local landmarks programs, may be nominated for inclusion in the CRHR. A resource, either an individual property or a contributor to a historic district, may be listed in the CRHR if the State Historical Resources Commission determines that it meets one or more of the following criteria, which are modeled on NRHP criteria:

- **Criterion 1.** It is associated with events that have made a significant contribution to the broad patterns of California's history and cultural heritage.
- **Criterion 2.** It is associated with the lives of persons important in our past.
- **Criterion 3.** It embodies the distinctive characteristics of a type, period, region, or method of construction; represents the work of an important creative individual; or possesses high artistic values.
- **Criterion 4.** It has yielded, or may be likely to yield, information important in history or prehistory.

Furthermore, under California Public Resources Code (PRC) 5024.1, Title 14 California Code of Regulations (CCR), Section 4852(c), a cultural resource must retain integrity to be considered eligible for the CRHR. Specifically, it must retain sufficient character or appearance to be recognizable as a historical resource and convey reasons of significance. Integrity is evaluated with regard to retention of such factors as location, design, setting, materials, workmanship, feeling, and association.

California Historical Landmarks

California Historical Landmarks (CHLs) are buildings, structures, sites, or places that have anthropological, cultural, military, political, architectural, economic, scientific or technical, religious, experimental, or other value and that have been determined to have statewide historical significance by meeting at least one of the criteria listed below. The resource also must be approved for designation by the County Board of Supervisors (or the city or town council in whose jurisdiction it is located); be recommended by the State Historical Resources Commission; and be officially designated by the Director of California State Parks. The specific standards now in use were first applied in the designation of CHL #770. CHLs #770 and above are automatically listed in the CRHR.

To be eligible for designation as a landmark, a resource must meet at least one of the following criteria:

- It is the first, last, only, or most significant of its type in the state or within a large geographic region (Northern, Central, or Southern California).
- It is associated with an individual or group having a profound influence on the history of California.
- It is a prototype of, or an outstanding example of, a period, style, architectural movement or construction or is one of the more notable works or the best surviving work in a region of a pioneer architect, designer, or master builder.

California Points of Historical Interest

California Points of Historical Interest (PHIs) are sites, buildings, features, or events that are of local (city or county) significance and have anthropological, cultural, military, political, architectural, economic, scientific or technical, religious, experimental, or other value. PHI designated after December 1997 and recommended by the SHRC are also listed in the CRHR. No historic resource may be designated as both a landmark and a point. If a point is later granted status as a landmark, the point designation will be retired. In practice, the point designation program is most often used in localities that do not have a locally enacted cultural heritage or preservation ordinance.

To be eligible for designation as a PHI, a resource must meet at least one of the following criteria:

- It is the first, last, only, or most significant of its type within the local geographic region (city or county).
- It is associated with an individual or group having a profound influence on the history of the local area.
- It is a prototype of, or an outstanding example of, a period, style, architectural movement or construction or is one of the more notable works or the best surviving work in the local region of a pioneer architect, designer, or master builder.

California Environmental Quality Act

CEQA is the principal statute governing environmental review of projects occurring in the state and is codified at PRC Section 21000 et seq. CEQA requires lead agencies to determine if a project would have a significant effect on the environment, including significant effects on historical or archaeological resources.

Under CEQA (Section 21084.1), a project that may cause a substantial adverse change in the significance of an historical resource is a project that may have a significant effect on the environment. The CEQA Guidelines (Title 14 CCR Section 15064.4) recognize that an historical resource includes: (1) a resource listed in, or determined to be eligible by the State Historical Resources Commission, for listing in the CRHR; (2) a resource included in a local register of historical resources, as defined in PRC Section 5020.1(k) or identified as significant in a historical resource survey meeting the requirements of PRC Section 5024.1(g); and (3) any object, building, structure, site, area, place, record, or manuscript which a lead agency determines to be historically significant or significant in the architectural, engineering, scientific, economic, agricultural, educational, social, political, military, or cultural annals of California by the lead agency, provided the lead agency's determination is supported by substantial evidence in light of the whole record. The fact that a resource does not meet the three criteria outlined above does not preclude the lead agency from determining that the resource may be an historical resource as defined in PRC Sections 5020.1(j) or 5024.1.

If a lead agency determines that an archaeological site is a historical resource, the provisions of Section 21084.1 of CEQA and Section 15064.4 of the CEQA Guidelines apply. If a project may cause a substantial adverse change (defined as physical demolition, destruction, relocation, or alteration of the resource or its immediate surroundings such that the significance of an historical resource would be materially impaired) in the significance of an historical resource, the lead agency must identify potentially feasible measures to mitigate these effects (CEQA Guidelines Sections 15064.4(b)(1), 15064.4(b)(4)).

If an archaeological site does not meet the historical resource criteria contained in the CEQA Guidelines, then the site may be treated in accordance with the provisions of Section 21083, which is a unique archaeological resource. As defined in Section 21083.2 of CEQA a "unique" archaeological resource is an archaeological artifact, object, or site, for which it can be clearly demonstrated that without merely adding to the current body of knowledge, there is a high probability that it meets any of the following criteria:

- Contains information needed to answer important scientific research questions and there is a demonstrable public interest in that information.
- Has a special and particular quality such as being the oldest of its type or the best available example of its type.
- Is directly associated with a scientifically recognized important prehistoric or historic event or person.

If an archaeological site meets the criteria for a unique archaeological resource as defined in Section 21083.2, then the site is to be treated in accordance with the provisions of Section 21083.2, which state that if the lead agency determines that a project would have a significant effect on unique archaeological resources, the lead agency may require reasonable efforts be made to permit any or all of these resources to be preserved in place (Section 21083.1(a)). If preservation in place is not feasible, mitigation measures shall be required.

The CEQA Guidelines note that if an archaeological resource is neither a unique archaeological nor a historical resource, the effects of the project on those resources shall not be considered a significant effect on the environment (CEQA Guidelines Section 15064.4(c)(4)).

Senate Bill 18

Senate Bill 18 (SB 18), which went into effect January 1, 2005, requires local governments (city and county) to consult with Native American Tribes before making certain planning decisions and to provide notice to tribes at certain key points in the planning process. The intent is to "provide California Native American tribes an opportunity to participate in local land use decisions at an early planning stage, for the purpose of protecting, or mitigating impacts to, cultural places" (Governor's Office of Planning and Research [OPR], 2005).

The purpose of involving Tribes at these early planning stages is to allow consideration of cultural places in the context of broad local land use policy, before individual site-specific, project-level, land use designations are made by a local government. The consultation requirements of SB 18 apply to general plan or specific plan processes proposed on or after March 1, 2005.

According to the *Tribal Consultation Guidelines: Supplement to General Plan Guidelines* (OPR, 2005), the following are the contact and notification responsibilities of local governments:

- Prior to the adoption or any amendment of a general plan or specific plan, a local government must notify the appropriate tribes (on the contact list maintained by the Native American Heritage Commission [NAHC]) of the opportunity to conduct consultations for the purpose of preserving, or mitigating impacts to, cultural places located on land within the local government's jurisdiction that is affected by the proposed plan adoption or amendment. Tribes have 90 days from the date on which they receive notification to request consultation, unless a shorter timeframe has been agreed to by the tribe (Government Code Section 65352.3).
- Prior to the adoption or substantial amendment of a general plan or specific plan, a local government must refer the proposed action to those tribes that are on the NAHC contact list and have traditional lands located within the city or county's jurisdiction. The referral must allow a 45-day comment period (Government Code Section 65352). Notice must be sent regardless of whether prior consultation has taken place. Such notice does not initiate a new consultation process.

- Local government must send a notice of a public hearing, at least 10 days prior to the hearing, to tribes who have filed a written request for such notice (Government Code Section 65092).

If an individual structural BMP project entailed the adoption or substantial amendment of a general plan or specific plan, the provisions of Senate Bill 18 may apply.

Local

County

The Conservation and Open Space Element of the 2008 Los Angeles County General Plan governs the natural and cultural resources of the county. The Los Angeles County General Plan has the following relevant goals and policies related to the protection of cultural and paleontological resources.

Goal C/OS-12: Protected cultural heritage resources.

Policy C/OS 12.1: Support an inter-jurisdictional collaborative system that protects and enhances the County's cultural heritage resources.

Policy C/OS 12.2: Support the preservation and rehabilitation of historic buildings.

Policy C/OS 12.3: Ensure proper notification procedures to Native American tribes in accordance with Senate Bill 18 (2004).

Policy C/OS 12.4: Promote public awareness of the County's cultural heritage resources.

Implementation Action C/OS 12.1 Evaluate the efficacy of the Landmarks Preservation Commission and the designation of historic landmarks within the unincorporated areas of the County.

In addition, the General Plan makes the following recommendation:

If a CEQA analysis determines that a project will impact a cultural resource area (historic, cultural, or paleontological), the following guidelines will apply:

1. A literature search for valid archaeological or paleontological surveys shall be conducted (for each initial study of a public or private project).
2. A study of the project site shall be made by a qualified archaeologist or paleontologist who shall determine the scientific value of finds, if any, and a recommendation as to their preservation or disposition.
3. The County Historical Landmarks Commission must be notified of all cultural, historical, or paleontological findings.
4. All significant impacts to cultural resource sites must be mitigated to the greatest extent feasible, and a reasonable period of time must be allowed to salvage the site.

5. The integrity of significant historical features of the structure and/or site should be maintained to the largest extent possible.
6. The integrity of sightlines to the structure or site should be maintained.
7. Development adjacent to a cultural resource site should consider design guidelines and appropriate building design, setbacks, landscaping, and other factors that will protect the integrity of the cultural resource area.
8. Materials collected during surface surveys or salvage operations should be donated to an appropriate nonprofit institution. In the event the property owner wishes to retain possession of the artifacts found, it is desirable that archaeologists or paleontologist be allowed to study and photograph the artifacts.

City General Plans

The numerous cities encompassed by the EWMP program area all have their own respective city General Plans, some of which may contain policies that address cultural resources. As implementation of the individual structural BMP projects proceed, specific policies and objectives pertaining to cultural resources from applicable city general plans will be identified and evaluated on a project-by-project basis during subsequent CEQA environmental processes.

Paleontological Resources

Federal

A variety of federal statutes specifically address paleontological resources. They are generally applicable to a project if that project includes federally owned or federally managed lands, or involves a federal agency license, permit, approval, or funding. Federal legislative protection for paleontological resources stems from the Antiquities Act of 1906 (PL 59-209; 16 United States Code 431 et. seq.; 34 Stat. 225), which calls for protection of historic landmarks, historic and prehistoric structures, and other objects of historic or scientific interest on federal lands.

State

Paleontological resources are explicitly afforded protection by CEQA, specifically in Section V(c) of Appendix G, the "Environmental Checklist Form," which addresses the potential for adverse impacts to "unique paleontological resource[s] or site[s]." PRC Section 5097.5 specifies that any unauthorized removal of paleontological remains is a misdemeanor. Further, the California Penal Code Section 622.5 sets the penalties for the damage or removal of paleontological resources.

Professional Standards

The SVP has established standard guidelines for acceptable professional practices in the conduct of paleontological resource assessments and surveys, monitoring and mitigation, data and fossil recovery, sampling procedures, specimen preparation, identification, analysis, and curation. Most practicing professional paleontologists in the United States adhere closely to the SVP's assessment, mitigation, and monitoring requirements as specifically provided in its standard guidelines. Most California state regulatory agencies accept the SVP standard guidelines as a measure of professional practice.

3.4.3 Impact Analysis

The proposed program's potential impacts have been assessed using the CEQA Guidelines Appendix G Checklist. The following sections discuss the key issue areas identified in the CEQA Guidelines with respect to the program's potential effect on cultural resources.

Method of Analysis

This impact analysis is a preliminary, program-level assessment of potential impacts on important cultural resources that could occur as a result of implementation of the proposed program. Because this a program-level analysis, impacts on specific cultural resources that could result from individual projects or structural BMPs are not addressed in this document, but may need to be assessed through additional analysis as project implementation actions are developed and further defined.

The impacts and mitigation measures identified in this section address types of activities that could significantly impact cultural resources including archaeological sites, historic buildings and structures, and locations of importance to Native Americans. Proposed program facilities for structural BMPs include aboveground and belowground facilities, construction of which could result in impacts to cultural and paleontological resources. Program implementation actions that include these types of activities would be required to implement the identified mitigation measures in an effort to reduce any impacts to a less-than-significant level.

The identification of specific impacts and mitigation measures that are appropriate for a specific project implementation action will depend on both the nature of the cultural resources that are present and on the nature of the action. In some instances, mitigation measures must be developed in consultation with multiple agencies and other interested parties.

Thresholds of Significance

For the purposes of this Program Environmental Impact Report (PEIR) and consistency with Appendix G of the CEQA Guidelines, applicable local plans, and agency and professional standards, the program would have a significant impact on cultural resources if it would:

- Cause a substantial adverse change in the significance of a historical resource as defined in §15064.5.
- Cause a substantial adverse change in the significance of an archaeological resource pursuant to §15064.5.
- Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature.
- Disturb any human remains, including those interred outside of a formal cemetery.

According to CEQA Guidelines (CCR Title 14, 15064.4), a project with an effect that may cause a substantial adverse change in the significance of a historical resource is a project that may have a significant effect on the environment (CCR Title 14, 15064.4(b)). The Guidelines further state that a substantial adverse change in the significance of a resource means the physical demolition, destruction, relocation, or alteration of the resource or its immediate surroundings such that the significance of a historic resource would be materially impaired. Actions that would materially impair the significance of a historical resource are any actions that would demolish or adversely alter those physical characteristics of a historical resource that convey its historical significance and qualify it for inclusion in the CRHR or in a local register or survey that meet the requirements of PRC Sections 5020.1(k) and 5024.1(g).

Identified cultural resources that may be impacted by individual structural BMP projects would be evaluated for eligibility for listing on the CRHR or local historic register. Cultural resources that are eligible for the CRHR or local historic register are considered to be significant historic resources. Cultural resources would also be evaluated for their qualification as a unique archaeological resource under CEQA. Cultural resources that are identified within individual structural BMP project areas subject to federal approval, permits, or funding would also be evaluated for eligibility for listing on the NRHP. Cultural resources determined to be eligible for listing on the NRHP are automatically eligible for listing on the CRHR and are considered to be significant cultural resources.

Paleontological resources are also afforded protection by CEQA. Appendix G (Part V) of the CEQA Guidelines provides guidance relative to significant impacts on paleontological resources. A project will have a significant impact on the environment if it adversely affects a paleontological resource or site, or a unique geological feature.

Program Impact Discussion

Historical Resources

Impact 3.4-1: The proposed program could cause a substantial adverse change in the significance of an historical resource as defined in §15064.5.

Structural (Regional, Centralized, and Distributed) BMPs

Distributed BMPs are most likely to be implemented in high-density urban, commercial, industrial, and transportation areas where they would either replace or improve upon existing stormwater infrastructure. These types of BMPs are generally “retrofit” type projects that replace existing impervious surfaces with pervious surfaces such as bioinfiltration cells, bioswales, porous pavement, and filter strips that tie into existing stormwater management systems. These projects may also augment the existing stormwater management systems with additional inlet screens, filter media systems, sediment removal systems, and diversions to sanitary sewer lines. Ground disturbance for distributed BMPs is typically less than 1 to 2 acres in extent, but may extend in some limited applications up to 5 acres where space is available. Centralized structural BMPs collect, store, treat, and filter stormwater from multiple parcels and much larger drainage areas. Like centralized BMPs, regional BMPs can be implemented in a broad range of land use types, from high-density urban to open space, and can have multiple benefits (habitat, recreation, aesthetics, etc.). Centralized and regional structural BMPs require greater footprints for construction and implementation.

Built Environment Resources

Any historic built environment resources (including buildings and structures) that are 50 years or older within the program area may be eligible for listing in the CRHR or local register, although such resources have not yet been identified. Historic built environment resources that are found eligible for the CRHR or local register would be considered historical resources under CEQA. A project that causes a substantial adverse change in the significance of a built environment resource that qualifies as an historical resource (i.e., physical demolition, destruction, relocation, or alteration of the resource or its immediate surroundings) would result in a significant impact to historical resources.

Implementation of structural BMPs occurring under the proposed program could impact significant historic built environment resources that exist within the program area. Built environment resources can include not only buildings and structures, but also built infrastructure such as concrete channels, dams, sidewalks, and roads. Impacts could include not only physical demolition or alteration of built environment resources, but also changes to the historic setting of a resource, and impacts that may adversely affect that ability of a resource to convey its significance. **Mitigation Measure CUL-1** would reduce impacts to significant historic built resources. However, in some circumstances, documentation of an historical resource, by way of historic narrative, photographs, or architectural drawings, as mitigation for the effects of demolition of the resource will not mitigate the effects to a point where clearly no significant effect on the environment would occur (CEQA Guidelines § 15126.4(b)(2)). Therefore, implementation of the proposed program may ultimately result in a "substantial adverse change" to historic resources through various development activities for which no possible mitigation may be available to maintain the historic integrity of the affected resource or its surroundings.

Archaeological and Other Cultural Resources

Historical resources can include not only buildings and structures, as discussed above, but also any object, site area, place, record, or manuscript which a lead agency determines to be historically significant, or which is listed in or determined eligible for listing in the CRHR (CEQA Guidelines Section 15064.5(a)).

The program area has a long history of human occupation, dating to at least 9,000 years before the present. The abundant natural resources within the program area, including rivers, creeks, the Pacific Ocean, and the flora and fauna associated with these water features, would have attracted and sustained human settlement. Significant archaeological resources have been recorded throughout the program area, and numerous Native American village sites are known to have existed within the program area (Altschul et al., 2003; Gumprecht, 2001; McCawley, 1996). Archaeological sensitivity varies across the program area based on specific environmental factors, as discussed above, but archaeological resources could potentially be present in any individual structural BMP project area.

Known archaeological resources, as well as unknown and unrecorded archaeological resources that may be unearthed during construction activities associated with implementation of structural BMPs, could be impacted by individual projects. Some of these resources may qualify as historical resources. Disturbance of previously unknown and unrecorded archaeological resources can occur even in already developed areas, as older buildings are known to have often been built on top of or within archaeological deposits. Although much of the program area is already heavily developed, potentially significant buried archaeological resources could nevertheless still exist within the program area, beneath and between structures and roads. If previously undiscovered artifacts or buried archaeological resources are uncovered during excavation or construction, significant impacts could occur.

Resources of importance to Native American Tribes or other cultural groups that may qualify as historical resources may also be present within individual EWMP areas. These resources may be identified through cultural resources studies and through consultation and coordination with local Native American Tribes or other cultural groups.

Given the above, the proposed program has the potential to adversely affect archaeological resources and other cultural resources that qualify as historical resources. Since the proposed program is at the programmatic level, specific project locations and design elements have yet to be finalized. As such, impacts to specific cultural resources are not addressed here. However, as program implementation actions move forward, individual projects would undergo additional CEQA review prior to construction. The program area should be considered sensitive for archaeological and other cultural resources, which should be taken into consideration during subsequent CEQA review. Any structural BMP that involves grading, trenching, excavation, vegetation removal, or other form of ground disturbance could impact archaeological resources or other cultural resources. Indirect impacts to archaeological resources, as a result of erosion or vandalism resulting from increased access to or visibility of resources, could also occur.

Implementation of **Mitigation Measures CUL-2**, **CUL-3**, and **CUL-4** would reduce impacts to archaeological and other cultural resources that qualify as historical resources. However, because the degree of impact and the applicability, feasibility, and success of these measures cannot be accurately predicted for each specific project at this time, the program level impact related to archaeological and cultural resources that qualify as historical resources is considered significant and unavoidable. In some circumstances, documentation and data recovery as mitigation for impacts to an historical resource of an archaeological nature will not mitigate the effects to a point where clearly no significant effect on the environment would occur. Data recovery as mitigation for historical resources that are eligible for the CRHR under Criterion 4, or that derive their significance from their scientific value or data potential, may effectively mitigate impacts to a less than significant level. However, for historical resources that are eligible to the CRHR under Criteria 1, 2, or 3, data recovery may not adequately mitigate impacts to those aspects of the resource that convey its significance and make it eligible for listing in the CRHR.

Impacts to historical resources would remain significant and unavoidable after implementation of Mitigation Measures CUL-1 through CUL-4 at this program-level analysis. It should be noted that not all individual EWMP projects may result in a significant and unavoidable impact with regard to historical resources, as the impacts associated with each individual EWMP project would be dependent on its location; the presence, nature, and significance of any historical resources within the construction area; and specific impacts to historical resources. It is anticipated that the implementing agencies of the EWMP projects would, through the environmental review process, consider each discretionary EWMP project on a case-by-case basis to ascertain whether an individual project would impact cultural resources. Therefore, the identification of a significant and unavoidable program-level impact in this PEIR does not preclude the finding of future less-than-significant impacts for the individual structural BMP projects occurring in the EWMP areas.

Mitigation Measures:

CUL-1: For individual EWMP projects that could impact buildings or structures (including infrastructure) 45 years old or older, implementing agencies shall ensure that a historic built environment survey is conducted or supervised by a qualified historian or architectural historian meeting the Secretary of the Interior's Professional Qualification Standards for Architectural History. Historic built environment resources shall be evaluated for their eligibility for listing in the CRHR or local register prior to the implementing agency's approval of project plans. If eligible resources that would be considered historical resources under CEQA are identified, demolition or substantial alteration of such resources shall be avoided. If avoidance is determined to be infeasible, the implementing agency shall require the preparation of a treatment plan to include, but not be limited to, photo-documentation and public interpretation of the resource. The plan will be submitted to the implementing agency for review and approval prior to implementation.

CUL-2: Implementing agencies shall ensure that individual EWMP projects that require ground disturbance shall be subject to a Phase I cultural resources inventory on a project-specific basis prior to the implementing agency's approval of project plans. The study shall be conducted or supervised by a qualified archaeologist, defined as an archaeologist meeting the Secretary of the Interior's Professional Qualifications Standards for Archaeology, and shall be conducted in consultation with the local Native American representatives expressing interest. The cultural resources inventory shall include a cultural resources records search to be conducted at the South Central Coastal Information Center; scoping with the NAHC and with interested Native Americans identified by the NAHC; a pedestrian archaeological survey where deemed appropriate by the qualified archaeologist; and formal recordation of all identified archaeological resources on California Department of Parks and Recreation 523 forms and significance evaluation of such resources presented in a technical report following the guidelines in *Archaeological Resource Management Reports (ARMR): Recommended Contents and Format*, Department of Parks and Recreation, Office of Historic Preservation, State of California, 1990.

If potentially significant archaeological resources are encountered during the survey, the implementing agency shall require that the resources are evaluated by the qualified archaeologist for their eligibility for listing in the CRHR and for significance as a historical resource or unique archaeological resource per CEQA Guidelines Section 15064.5. Recommendations shall be made for treatment of these resources if found to be significant, in consultation with the implementing agency and the appropriate Native American groups for prehistoric resources. Per CEQA Guidelines Section 15126.4(b)(3), preservation in place shall be the preferred manner of mitigation to avoid impacts to archaeological resources qualifying as historical resources. Methods of avoidance may include, but shall not be limited to, project reroute or redesign, project cancellation, or identification of protection measures such as capping or fencing. Consistent with CEQA Guidelines Section 15126.4(b)(3)(C), if it is demonstrated that resources cannot be avoided, the qualified archaeologist shall develop additional treatment measures, which may include data recovery or other appropriate measures, in consultation with the implementing agency, and any local Native American representatives expressing interest in prehistoric or tribal resources. If an archaeological site does not qualify as an historical resource but meets the criteria for a unique archaeological resource as defined in Section 21083.2, then the site shall be treated in accordance with the provisions of Section 21083.2.

CUL-3: The implementing agency shall retain archaeological monitors during ground-disturbing activities that have the potential to impact archaeological resources qualifying as historical resources or unique archaeological resources, as determined by a qualified archaeologist in consultation with the implementing agency, and any local Native American representatives expressing interest in the project. Native American monitors shall be retained for projects that have a high potential to impact sensitive Native American resources, as determined by the implementing agency in coordination with the qualified archaeologist.

CUL-4: During project-level construction, should subsurface archaeological resources be discovered, all activity in the vicinity of the find shall stop and a qualified archaeologist shall be contacted to assess the significance of the find according to CEQA Guidelines Section 15064.5. If any find is determined to be significant, the archaeologist shall determine, in consultation with the implementing agency and any local Native American groups expressing interest, appropriate avoidance measures or other appropriate mitigation. Per CEQA Guidelines Section 15126.4(b)(3), preservation in place shall be the preferred means to avoid impacts to archaeological resources qualifying as historical resources. Methods of avoidance may include, but shall not be limited to, project reroute or redesign, project cancellation, or identification of protection measures such as capping or fencing. Consistent with CEQA Guidelines Section 15126.4(b)(3)(C), if it is demonstrated that resources cannot be avoided, the qualified archaeologist shall develop additional treatment measures, such as data recovery or other appropriate measures, in consultation with the implementing agency and any local Native American representatives expressing interest in prehistoric or tribal resources. If an archaeological site does not qualify as an historical resource but meets the criteria for a unique archaeological resource as defined in Section 21083.2, then the site shall be treated in accordance with the provisions of Section 21083.2.

Significance Determination: Significant and unavoidable The application of these mitigation measures to specific BMP types and categories is identified in Table 3.4-2.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities, demolition, or any ground disturbance. Consequently, implementation of non-structural BMPs would not impact historical resources.

Mitigation Measures: None required

Significance Determination: No impact

Unique Archaeological Resources

Impact 3.4-2: The program could cause a substantial adverse change in the significance of unique archaeological resources as defined in §15064.5.

Structural (Regional, Centralized, and Distributed) BMPs

As discussed under Impact 3.4-1, the program area should be considered sensitive for archaeological resources. Archaeological sensitivity varies across the program area based on specific environmental factors, as discussed above, but archaeological resources could potentially be present in any individual structural BMP project area. Known archaeological resources, as well as unknown and unrecorded archaeological resources that may be unearthed during construction activities associated with implementation of structural BMPs, could be impacted by individual EWMP projects. Any structural BMP which involves grading, trenching, excavation, vegetation removal, or other form of ground disturbance could impact archaeological resources, some of which may qualify as unique archaeological resources. Implementation of **Mitigation Measures CUL-2**, **CUL-3**, and **CUL-4** would require that unique archaeological resources be treated in accordance with the provisions of Section 21083.2, which would reduce impacts to unique archaeological resources to a less-than-significant level.

Mitigation Measures: Implement **Mitigation Measures CUL-2**, **CUL-3**, **CUL-4**

Significance Determination: Less than significant (The application of these mitigation measures to specific BMP types and categories is identified in Table 3.4-2.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities or any ground disturbance. Consequently, implementation of non-structural BMPs would not impact unique archaeological resources.

Mitigation Measures: None required

Significance Determination: No impact

Paleontological Resources

Impact 3.4-3: The program could directly or indirectly destroy a unique paleontological resource or site or unique geologic feature.

Structural (Regional, Centralized, and Distributed) BMPs

As discussed, the program area is underlain by a number of high or undetermined paleontological sensitivity units. These sensitive geological formations/units may contain significant paleontological resources. The Los Angeles County General Plan Conservation Element requires that a paleontologist be retained to mitigate potential impacts to nonrenewable paleontological resources. However, significant paleontological resources can be uncovered even in areas of low sensitivity, and it is possible that ground-disturbing construction activities associated with implementation of the program could result in the inadvertent discovery of paleontological resources, which could be a significant impact. Implementation of **Mitigation Measures CUL-5** and **CUL-6** would reduce these impacts to less-than-significant levels at this program-level of analysis.

Mitigation Measures:

CUL-5: For individual structural BMP projects that require ground disturbance, the implementing agency shall evaluate the sensitivity of the project site for paleontological resources. If deemed necessary, the implementing agency shall retain a qualified paleontologist to evaluate the project and provide recommendations regarding additional work, potentially including testing or construction monitoring.

CUL-6: In the event that paleontological resources are discovered during construction, the implementing agency shall notify a qualified paleontologist. The paleontologist will evaluate the potential resource, assess the significance of the find, and recommend further actions to protect the resource.

Significance Determination: Less than significant (The application of these mitigation measures to specific BMP types and categories is identified in Table 3.4-2.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities or any ground disturbance. Consequently, implementation of non-structural BMPs would not impact paleontological resources.

Mitigation Measures: None required

Significance Determination: No impact

Human Remains

Impact 3.4-4: The program could disturb any human remains, including those interred outside of a formal cemetery.

Structural (Regional, Centralized, and Distributed) BMPs

Program-level development involving ground disturbance within the program area could impact human remains. In the event that human remains are discovered, including those interred outside of formal cemeteries, the human remains could be inadvertently damaged, which could be a significant impact. Implementation of **Mitigation Measure CUL-7** would reduce impacts to less-than-significant levels at this program-level of analysis.

Mitigation Measures:

CUL-7: The implementing agency shall require that, if human remains are uncovered during project construction, work in the vicinity of the find shall cease and the County Coroner shall be contacted to evaluate the remains, following the procedures and protocols set forth in Section 15064.5 (e)(1) of the CEQA Guidelines. If the County Coroner determines that the remains are Native American, the Coroner will contact the Native American Heritage Commission, in accordance with Health and Safety Code Section 7050.5, subdivision (c), and Public Resources Code 5097.98 (as amended by AB 2641). The NAHC will then designate a Most Likely Descendant of the deceased Native American, who will engage in consultation to determine the disposition of the remains.

Significance Determination: Less than significant (The application of this mitigation measure to specific BMP types and categories is identified in Table 3.4-2.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities or any ground-disturbance. Consequently, implementation of non-structural BMPs would not impact human remains.

Mitigation Measures: None required

Significance Determination: No impact

Cumulative Impact Discussion

Structural (Regional, Centralized, and Distributed) BMPs

The geographic area of analysis for cultural resources is defined as the jurisdictions within which the proposed program is located. This geographic scope of analysis is appropriate because the archaeological, historical, and paleontological resources within this radius are expected to be similar to those that occur on the individual project sites because of their proximity; similar environments, landforms, and hydrology would result in similar land-use—and, thus, site types. Similar geology within this vicinity would likely yield fossils of similar sensitivity and quantity. This is a large enough area to encompass any effects of the program on cultural and paleontological resources that may combine with similar effects caused by other projects, and provides a reasonable context wherein cumulative actions could affect cultural and paleontological resources. The program could cause impacts on cultural and paleontological resources during the construction period or as a result of operation and maintenance or closure and decommissioning activities.

Cumulative impacts to cultural resources in the cultural resources geographic scope of analysis could occur if other existing or proposed projects, in conjunction with the proposed program, had or would have impacts on cultural resources that, when considered together, would be significant.

Regional and centralized BMPs will not be well distributed throughout the watershed because of the limited feasible and applicable sites; however, distributed BMPs, which may comprise the majority of the BMPs implemented under the EWMPs, will be better distributed. Therefore, while the distributed BMPs may have limited or no impact on cultural resources on a project-by-project basis, when taken together, they may impact cultural resources on a regional scale.

Los Angeles County contains a significant archaeological and historical record that, in many cases, has not been well documented or recorded. There is the potential for ongoing and future development projects in the vicinity to disturb landscapes that may contain known or unknown historical resources. Thus, potential construction impacts of the implementation of the proposed program, in combination with other projects in the area, could contribute to a cumulatively significant impact on historical resources. Mitigation measures are included in this PEIR to reduce potentially significant program impacts to historical resources during construction. While implementation of **Mitigation Measures CUL-1** through **CUL-4** would reduce impacts to historical resources, implementation of the proposed program may ultimately result in a substantial adverse change to historical resources through various development activities for which no possible mitigation may be available to maintain the historic integrity of the affected resource or its surroundings, and impacts to historical resources would remain significant and unavoidable at a program level. Therefore, the implementation of structural BMPs may contribute to a cumulatively significant environmental impact to historical resources.

Implementation of **Mitigation Measures CUL-2**, **CUL-3**, and **CUL-4** would require that unique archaeological resources be treated in accordance with the provisions of CEQA Section 21083.2, which would reduce impacts to unique archaeological resources to a less-than-significant level. Therefore, the program would not contribute to a cumulatively significant environmental impact to unique archaeological resources.

Excavation activities associated with the implementation of individual structural BMPs in conjunction with other projects in the area could contribute to the progressive loss of fossil remains, associated geological and geographic data, and fossil bearing strata, which is a potentially significant impact. However, the proposed program would have a less-than-significant impact to paleontological resources with incorporation of **Mitigation Measure CUL-5** and

CUL-6. Therefore, with the implementation of Mitigation Measures CUL-5 and CUL-6, cumulative impacts to paleontological resources would be less than significant.

Furthermore, implementation of **Mitigation Measure CUL-7** provides a mechanism to reduce impacts to human remains should they be encountered during ground-disturbing activities, and cumulative impacts to human remains would be less than significant.
With implementation of applicable regulatory requirements and **Mitigation Measures CUL-1** through **CUL-7**, the implementation of the proposed program would not have a cumulatively considerable contribution to impacts to unique archaeological resources, paleontological resources, or human remains from decommissioning activities. Implementation of the proposed program may contribute to a cumulatively significant environmental impact to historical resources.

Mitigation Measures: Implement **Mitigation Measures CUL-1** through **CUL-7**

Significance Determination: Significant and unavoidable (The application of these mitigation measures to specific BMP types and categories is identified in Table 3.4-2.)

Non-Structural BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities or any ground disturbance. Consequently, implementation of non-structural BMPs would not contribute to a cumulatively significant environmental impact to cultural resources.

Mitigation Measures: None required

Significance Determination: No impact

3.4.4 Summary of Impact Assessment

Table 3.4-2 shows a summary of the structural BMPs requiring mitigation.

TABLE 3.4-2
SUMMARY OF CULTURAL RESOURCE IMPACTS REQUIRING MITIGATION MEASURES

	Thresholds of Significance					
Structural BMPs	**Built Environment Resources**	**Archaeological and Other Cultural Resources**	**Unique Archaeological Resources**	**Paleontological Resources**	**Human Remains**	**Cumulative Impacts**
Applicable Mitigation Measures:	**CUL-1 through CUL-4**	**CUL-1 through CUL-4**	**CUL-2; CUL-3; CUL-4**	**CUL-5 and CUL-6**	**CUL-7**	**CUL-1 through CUL-7**
Regional BMPs						
Regional Detention and Infiltration	Yes	Yes	Yes	Yes	Yes	Yes
Regional Capture, Detention and Use	Yes	Yes	Yes	Yes	Yes	Yes
Centralized BMP						
Bioinfiltration	Yes	Yes	Yes	Yes	Yes	Yes
Constructed Wetlands	Yes	Yes	Yes	Yes	Yes	Yes
Treatment/Low-Flow Diversions	Yes	Yes	Yes	Yes	Yes	Yes
Creek, River, Estuary Restoration	Yes	Yes	Yes	Yes	Yes	Yes
Distributed BMPs						
Site-Scale Detention	Yes	Yes	Yes	Yes	Yes	Yes
LID – Infiltration/Filtration BMPs – Porous Pavement, Green Streets, Bioswale/Filter Strips, downspout disconnects	Yes	Yes	Yes	Yes	No	Yes
LID – Green Infrastructure – Capture and Use – Cisterns, Rain Barrels, Green roofs, Planter Boxes [(1)]	Yes	Yes	Yes	No	No	Yes
Flow-through Treatment BMPs[(1)]	Yes	Yes	Yes	Yes	No	Yes
Source-Control Treatment BMPs (catch basin inserts/screens, hydrodynamic separators, gross solids removal devices)[(1)]	Yes	Yes	Yes	No	No	Yes
Low-Flow Diversions	Yes	Yes	Yes	Yes	No	Yes

[(1)] These type of BMPs are generally built as retrofits to existing MS4 systems and would require in most cases little or no excavation.

NOTE: These conclusions are based on typical location and need for ground disturbance.

3.5 Geologic and Mineral Resources

This section addresses the potential impacts to geology, soils, and seismicity associated with implementation of the proposed program. This section provides a description of the regional geology, a summary of the regulations related to geologic and seismic hazards, and an evaluation of the potential impacts that may result from implementing the proposed program and identifies mitigation measures to minimize potential effects. This section also evaluates whether the proposed program would result in a loss of available mineral resources.

3.5.1 Environmental Setting

Regional

The project area is located in the center portion of the Transverse Ranges Geomorphic Province (California Geological Survey [CGS], 2002b). California's geomorphic provinces are naturally defined geologic regions that display a distinct landscape or landforms with unique, defining features based on geology, faults, topographic relief, and climate. This province consists of an east-west trending series of steep mountain ranges and valleys that deviate from the normal northwest trend of other Coastal California geomorphic provinces due to intense north-south compression squeezing the ranges within this province. The east-west structure of the Transverse Ranges is oblique to the normal northwest trend of coastal California, hence the name "Transverse." The province extends offshore to include San Miguel, Santa Rosa, and Santa Cruz islands. The eastern extension, the San Bernardino Mountains, has been displaced to the south along the San Andreas Fault. As a result, this is one of the most rapidly rising regions on earth and it is seismically active. Cenozoic petroleum-rich sedimentary rocks have been folded and faulted, making this an important oil-producing area in the United States. The Los Angeles Basin is in the southern part of the province and separates the Transverse Ranges Province from the Peninsular Ranges Provinces to the south.

Project Area

Topography

The project area is bounded on the northwest by the Santa Monica Mountains, on the northeast by the San Gabriel Mountains, on the southeast by the Orange County coastal plain, and on the west and southwest by the Pacific Ocean. The project area largely consists of the watersheds for the Los Angeles, Santa Clara, San Gabriel Rivers, Santa Monica Bay, and the Dominguez Channel, and includes the Los Angeles Basin and the San Fernando and Santa Clarita Valleys. Topography varies regionally from sea level at the coast to several thousand feet in the surrounding mountains.

Geology

The project area geology consists of Tertiary and older (1.6 million years and older) bedrock mountain ranges and hills surrounding and separating Quaternary and younger (1.6 million years and younger) sediment-filled basins and valleys, as shown in **Figure 3.5-1**, Regional Geology (U.S. Geological Survey [USGS], 1990). To the northwest of the project area, the Santa Monica Mountains have a granitic and metamorphic core covered with marine sedimentary sandstone, shale, and conglomerate rocks. To the northeast of the project area, the San Gabriel Mountains consist mostly of granitic rocks with some metamorphic gneiss and schist rocks. Several lower hills separate the Los Angeles Basin and the San Fernando and Santa Clara Valleys. Marine sediments and erosion of the surrounding mountain ranges and hills within the project area have filled the intervening basins and valleys with thick deposits of sediments. The recent surface sediments are mostly sand and silt. Much of the basin and valley areas have been highly disturbed through development and much of the surface materials consist of undocumented fills.

Seismicity and Faults

This section characterizes the region's existing faults, describes historical earthquakes, estimates the likelihood of future earthquakes, and describes probable groundshaking effects.

Earthquake Terminology and Concepts

Earthquake Mechanisms and Fault Activity

Faults are planar features within the earth's crust that have formed to release strain caused by the dynamic movements of the earth's major tectonic plates. An earthquake on a fault is produced when these strains overcome the inherent strength of the earth's crust, and the rock ruptures. The rupture causes seismic waves that propagate through the earth's crust, producing the groundshaking effect known as an earthquake. The rupture also causes variable amounts of slip along the fault, which may or may not be visible at the earth's surface.

The State of California defines an active fault as one that has had surface displacement within Holocene time (the last 11,000 years).

Earthquake Magnitude

When an earthquake occurs along a fault, its size can be determined by measuring the energy released during the event. A network of seismographs records the amplitude and frequency of the seismic waves that an earthquake generates. The Richter magnitude (ML) of an earthquake represents the highest amplitude measured by the seismograph at a distance of 100 kilometers from the epicenter. While the Richter magnitude scale was historically the primary measure of earthquake magnitude, seismologists now use the moment magnitude (Mw) scale as the preferred way to express the size of an earthquake (USGS, 2009). The Mw scale is related to the physical characteristics of a fault, including the rigidity of the rock, the size of fault rupture, and the style of movement or displacement across the fault.

Figure 3.5-1

Regional Geology

Peak Ground Acceleration

A common measure of ground motion at any particular site during an earthquake is the peak ground acceleration (PGA) (USGS, 2007b). The PGA for a given component of motion is the largest value of horizontal acceleration obtained from a seismograph. PGA is expressed as the percentage of the acceleration due to gravity (g), which is approximately 980 centimeters per second squared. In terms of automobile acceleration, one "g" of acceleration is equivalent to the motion of a car traveling 328 feet from rest in 4.5 seconds. For comparison purposes, the maximum PGA value recorded during the Mw 6.7 1994 Northridge earthquake was 1.8 g, among the highest ever instrumentally recorded in an urban area in North America. Unlike measures of magnitude, which provide a single measure of earthquake energy, PGA varies from place to place and is dependent on the distance from the epicenter and the character of the underlying geology (e.g., hard bedrock, soft sediments, or artificial fills).

Modified Mercalli Intensity Scale

The Modified Mercalli Intensity Scale assigns an intensity value based on the observed effects of groundshaking produced by an earthquake (CGS, 2002a). Unlike measures of earthquake magnitude and PGA, the Modified Mercalli Intensity Scale is qualitative in nature in that it is based on actual observed effects rather than measured values. Similar to PGA, Modified Mercalli values for an earthquake at any one place can vary depending on the earthquake's magnitude, the distance from its epicenter, the focus of its energy, and the type of geologic material. The Modified Mercalli values for intensity range from I (earthquake not felt) to XII (damage nearly total), and intensities ranging from IV to X can cause moderate to significant structural damage. Because the Modified Mercalli scale is a measure of groundshaking effects, intensity values can be correlated to a range of average PGA values, as shown in **Table 3.5-1**.

Faults and Historical Earthquake Activity

The project area is located in a seismically active region of California. Major earthquakes have affected the region in the past and are expected to occur in the near future on one of the active faults in the area. The San Andreas transform fault system, which forms the boundary between the North American and Pacific tectonic plates, is responsible for the highly seismic nature of Southern California. The fault bends in an east-west direction from the Southern end of the San Joaquin Valley to the eastern end of the San Bernardino Mountains. This portion of the San Andreas Fault system is referred to as the "Big Bend" and generates major compression forces, which in turn create many smaller fault branches (SCEC, 2011). The active faults in the vicinity of the project area are shown in **Figure 3.5-2**, Local Faults with Recent Movement.

Table 3.5-2 identifies both historically active and active faults in the vicinity of the project area and their corresponding characteristics that are capable of generating significant groundshaking at the proposed EMWP facilities. Two other fault characteristics—the maximum moment magnitude and the slip rate—are also important in determining the potential damage a fault may cause. The maximum moment magnitude of a fault refers to the largest possible earthquake it can experience given its existing geology (USGS, 2009). A fault's slip rate is defined as how fast the two sides of a fault are slipping relative to one another. The fastest moving faults have more and larger earthquakes than faults that do not slip as fast.

TABLE 3.5-1
MODIFIED MERCALLI INTENSITY SCALE

Intensity Value	Intensity Description	Average Peak Ground Acceleration[a]
I	Not felt except by a very few people under especially favorable circumstances.	< 0.0017 g
II	Felt only by a few people at rest, especially on upper floors on buildings. Delicately suspended objects may swing.	0.0017 – 0.014 g
III	Felt noticeably indoors, especially on upper floors of buildings, but many people do not recognize it as an earthquake. Standing automobiles may rock slightly, vibration similar to a passing truck. Duration estimated.	0.0017 – 0.014 g
IV	During the day felt indoors by many, outdoors by few. At night, some awakened. Dishes, windows, doors disturbed; walls make cracking sound. Sensation like heavy truck striking building. Standing automobiles rocked noticeably.	0.014 – 0.039 g
V (Light)	Felt by nearly everyone, many awakened. Some dishes and windows broken; a few instances of cracked plaster; unstable objects overturned. Disturbances of trees, poles may be noticed. Pendulum clocks may stop.	0.035 – 0.092 g
VI (Moderate)	Felt by all, many frightened and run outdoors. Some heavy furniture moved; fallen plaster or damaged chimneys. Damage slight.	0.092 – 0.18 g
VII (Strong)	Everybody runs outdoors. Damage negligible in buildings of good design and construction; slight to moderate in well-built ordinary structures; considerable in poorly built or badly designed structures; some chimneys broken. Noticed by people driving automobiles.	0.18 – 0.34 g
VIII (Very Strong)	Damage slight in specially designed structures; considerable in ordinary substantial buildings, with partial collapse; great in poorly built structures. Panel walls thrown out of frame structures. Fall of chimneys, factory stacks, columns, monuments, walls. Heavy furniture overturned. Sand and mud ejected in small amounts. Changes in well water. People driving automobiles disturbed.	0.34 – 0.65 g
IX (Violent)	Damage considerable in specially designed structures; well-designed frame structures thrown out of plumb; great in substantial buildings, with partial collapse. Buildings shifted off foundations. Ground cracked conspicuously. Underground pipes broken.	0.65 – 1.24 g
X (Very Violent)	Some well-built wooden structures destroyed; most masonry and frame structures destroyed with foundations; ground badly cracked. Rails bent. Landslides considerable from riverbanks and steep slopes. Shifted sand and mud. Water splashed (slopped) over banks.	> 1.24 g
XI (Very Violent)	Few, if any, masonry structures remain standing. Bridges destroyed. Broad fissures in ground. Underground pipelines completely out of service. Earth slumps and land slips in soft ground. Rails bent greatly.	> 1.24 g
XII (Very Violent)	Damage total. Practically all works of construction are damaged greatly or destroyed. Waves seen on ground surface. Lines of sight and level are distorted. Objects are thrown upward into the air.	> 1.24 g

[a] Value is expressed as a fraction of the acceleration due to gravity (g). Gravity (g) is 9.8 meters per second squared. 1.0 g of acceleration is a rate of increase in speed equivalent to a car traveling 328 feet from rest in 4.5 seconds.

Seismic Hazards

Seismic hazards are generally classified into two categories: primary seismic hazards (surface fault rupture and groundshaking) and secondary seismic hazards (liquefaction and other types of seismically induced ground failure, along with seismically induced landslides).

Surface Fault Rupture

Seismically induced ground rupture is defined as the physical displacement of surface deposits in response to an earthquake's seismic waves. The magnitude, sense, and nature of fault rupture can vary for different faults or even along different strands of the same fault. Although future earthquakes could occur anywhere along the length of an active fault, only regional strike slip earthquakes of magnitude 6.0 or greater are likely to be associated with significant surface fault rupture and offset (CDMG and USGS, 1996). It is also important to note that unmapped subsurface fault traces could experience unexpected and unpredictable earthquake activity and fault rupture. Ground rupture is considered more likely along active faults, which are referenced in Figure 3.5-2 and Table 3.5-2. The highest potential for surface faulting is along existing fault traces that have had displacement in the last 11,000 years (Holocene Epoch).

Groundshaking

Groundshaking intensity varies depending on the overall earthquake magnitude, distance to the fault, focus of earthquake energy, and type of geologic materials underlying an area. Geologists and engineers attempt to predict earthquake ground acceleration at sites to improve the structural design of buildings so that the building can withstand earthquake motion and not collapse. A probabilistic seismic hazard assessment describes seismic hazard from earthquakes that geologists and seismologists agree could occur. The analysis takes into consideration the uncertainties in the size and location of earthquakes and the resulting ground motions that can affect a particular site. Given the presence of the known active faults listed in Table 3.5-2, the entire project area is susceptible to seismic groundshaking.

Liquefaction and Lateral Spreading

Liquefaction is the rapid loss of shear strength experienced in saturated, predominantly granular soils below the groundwater level during strong earthquake groundshaking and occurs due to an increase in pore water pressure (VT, 2013). Liquefaction-induced lateral spreading is defined as the finite, lateral displacement of gently sloping ground as a result of pore-pressure buildup or liquefaction in a shallow underlying deposit during an earthquake. The occurrence of this phenomenon is dependent on many complex factors, including the intensity and duration of groundshaking, particle-size distribution, and density of the soil.

The potential damaging effects of liquefaction include differential settlement, loss of ground support for foundations, ground cracking, heaving and cracking of structures due to sand boiling, and buckling of deep foundations due to ground settlement. Dynamic settlement (i.e., pronounced consolidation and settlement from seismic shaking) may also occur in loose, dry sands above the water table, resulting in settlement of and possible damage to overlying structures. In general, a relatively high potential for liquefaction exists in loose, sandy soils that are within 50 feet of the ground surface and are saturated (below the groundwater table). Lateral spreading can move blocks of soil, placing strain on buried pipelines that can lead to leaks or pipe failure. **Figure 3.5-3**, Liquefaction and Landslide Potential Map, shows areas susceptible to seismically induced liquefaction and landslides within the county.

Earthquake-Induced Settlement

Settlement of the ground surface can be accelerated and accentuated by earthquakes. During an earthquake, settlement can occur as a result of the relatively rapid rearrangement, compaction, and settling of subsurface materials (particularly loose, noncompacted, and variable sandy sediments). Settlement can occur both uniformly and differentially (i.e., where adjoining areas settle at different rates). Areas are susceptible to differential settlement if underlain by compressible sediments, such as poorly engineered artificial fill. Earthquake-induced settlement could occur in the event of an earthquake and is a potential seismic hazard discussed further in the Impact and Mitigations Measures section.

Seismically Induced Landslides

Landslides are defined as the movement of rock, debris, or earth masses down a slope. Landslides are a form of "mass wasting," which refers to any downslope movement of soil and rock under the direct influence of gravity (USGS, 2004). Landslide events include rock falls, topples, slides, spreads, and debris flows. Causes of landslides include rainfall, earthquakes, volcanic activity, groundwater changes, and alteration of a slope by man-made construction activities. Figure 3.5-3, Liquefaction and Landslide Potential Map shows areas susceptible to seismically induced liquefaction and landslides within the County.

LA County PEIR EWMP . 140474

Figure 3.5-3
Liquefaction and Landslide Potential Map

Geologic Hazards

Geologic hazards include land movement of problematic soils, including landslides and other slope failures, expansive soils, erosion, settlement and subsidence, and sinkholes. These geologic hazards are discussed below.

Landslides and Slope Failure

As discussed, ground failure is dependent on the slope and geology as well as the amount of rainfall, excavation, or seismic activities. A slope failure is a mass of rock, soil, and debris displaced down a slope by sliding, flowing, or falling. Steep slopes and downslope creep of surface materials characterize landslide-susceptible areas. The areas shown in Figure 3.5-3 that are susceptible to seismically induced landslides and slope failure would also be susceptible to movement from non-seismic causes, such as excavation of the toe of a landslide area or the introduction of excessive water to the head of the landslide area.

Expansive Soils

Expansive soils are clay-rich and subsequently subject to changes in volume with changes in moisture (NRCS, 2013). This results in the shrinking and swelling of expansive soils from changes in water content. Expansive soils can exert pressure on building foundations, “heaving” or lifting buildings during periods of high moisture and resulting in the settlement of buildings during periods of low moisture. They can also exhibit high amounts of pressure on building foundations, resulting in lateral movement. Techniques exist to reduce effects of expansive soils. Such techniques include prewetting of the soil, which allows for pre-expansion of the soil with the idea that further pressure would be minimized, and structural slabs, which provide extra reinforcement to resist movement and distress caused by pressure of underlying expansive soil.

Erosion

Erosion is the wearing away of soil and rock by processes such as mechanical or chemical weathering, mass wasting, and the action of waves, wind, and underground water (NCRS, 2001a, 2001b). Excessive soil erosion can eventually damage infrastructure such as pipelines, wellheads, building foundations, and roadways. In general, granular soils with relatively low cohesion and soils located on steep topography have a higher potential for erosion. In addition, soils erosion can be accelerated beyond natural rates in areas with depleted plant cover and degraded soil structure resulting from excessive disturbance or reduced organic matter input. During construction, exposed soils within the project area would be susceptible to erosion due to stormwater runoff during the rainy season.

Settlement and Subsidence

Settlement of the ground surface can occur under static forces (e.g., due to gravity or groundwater removal) but can also be accelerated and accentuated by earthquakes. As stated previously, during an earthquake, settlement can occur from rapid rearrangement, compaction, and settling of subsurface materials (particularly loose, noncompacted, and variable sandy sediments). Settlement can occur both uniformly and differentially (i.e., where adjoining areas settle at different rates). In addition, areas are susceptible to differential settlement if underlain by compressible sediments, such as poorly engineered artificial fill or poorly graded gravels. The sediments within the basins and valleys are typically alluvium comprised mostly of sand and silt. The potential for settlement would be higher in unconsolidated sediments and lower in consolidated or sediments reworked during development.

Subsidence is a form of settlement defined as the gradual settling or sudden sinking of the earth's surface due to subsurface movement of earth materials. Principle causes include either natural (tectonic movement) or human extraction activities, such as the removal of groundwater, oil, or gas. The extraction activities reduce the pore pressure, increase void spaces, and allow the underlying soils to compact.

Sinkholes

A sinkhole is an area of ground which has no natural external surface drainage; all water stays inside the sinkhole and rains into the subsurface. Some sinkholes form so slowly they are not noticed, but others form suddenly when a collapse occurs. Sinkholes can have a dramatic effect if they occur in an urban setting. Sinkhole occurrence within Los Angeles County is generally limited but depends on several characteristics, including frequency of drought, type and structure of parent material, changes in groundwater dispersal, and localized topographic conditions, which can directly cause or exacerbate sinkholes (USGS, 2007a).

Mineral Resources

Mineral resources include commercially viable oil and gas deposits, and nonfuel mineral resources deposits. Nonfuel mineral resources include metals such as gold, silver, iron, and copper; industrial metals such as boron compounds, rare-earth elements, clays, limestone, gypsum, salt, and dimension stone; and construction aggregate, including sand, gravel, and crushed stone. **Figure 3.5-4**, Mineral Resources Map, shows the mineral and oil and gas resources zones identified in the draft County General Plan (County of Los Angeles, 2014c).

California is the largest producer of sand and gravel in the nation and the greater Los Angeles area is the nation's leading producer for its geographical size. The County has large quantities of sand and gravel, which are located close to the market. Major sand and gravel extraction sites are located in the alluvial fans of the Big Tujunga Wash in the San Fernando Valley and in the San Gabriel River near Irwindale. Other extraction areas are located in northern Los Angeles County in other washes.

3.5.2 Regulatory Framework

State

Alquist-Priolo Earthquake Fault Zoning Act

The Alquist-Priolo Earthquake Fault Zoning Act was passed in 1972 to protect structures for human occupancy from the hazard of surface faulting (Bryant and Hart, 2007). In accordance with the Act, the State Geologist established regulatory zones—called earthquake fault zones—around the surface traces of active faults, and published maps showing these zones. Buildings for human occupancy[1] cannot be constructed across surface traces of faults that are determined to be active. Because many active faults are complex and consist of more than one branch that may experience ground-surface rupture, earthquake fault zones extend approximately 200 to 500 feet on either side of the mapped fault trace. Cities and counties must regulate certain development projects within the zones, which includes withholding permits until geologic investigations demonstrate that development sites are not threatened by future surface displacement. Surface fault rupture is not necessarily restricted within an Alquist-Priolo Zone. This applies to the project because structural Best Management Practices (BMPs) would be either prohibited within these fault zones or a geotechnical investigation would be required to develop design features to limit the impact from a seismic event.

Seismic Hazard Mapping Act

The Seismic Hazards Mapping Act was passed in 1990 following the Loma Prieta earthquake to reduce threats to public health and safety and to minimize property damage caused by earthquakes, strong ground shaking, liquefaction, landslides, or other hazards caused by earthquakes. This act requires the State Geologist to delineate various seismic hazard zones, and Cities, Counties, and other local permitting agencies to regulate certain development projects within these zones. Before a development permit is granted for a site within a seismic hazard zone, a geotechnical investigation must be conducted and appropriate mitigation measures incorporated into the project's design. For projects that would locate structures for human occupancy within designated Zones of Required Investigation, the Seismic Hazards Mapping Act requires project applicants to perform a site-specific geotechnical investigation to identify the potential site-specific seismic hazards and corrective measures, as appropriate, prior to receiving building permits. The CGS *Guidelines for Evaluating and Mitigating Seismic Hazards* (Special Publication 117A, CGS, 2008) provides guidance for evaluating and mitigating seismic hazards. The CGS is in the ongoing process of producing official maps based on USGS topographic quadrangles. This act applies to the program because structural BMPs would be either prohibited within these seismic hazard zones or a geotechnical investigation would be required to develop design features to limit the impact from a seismic event.

California Building Code

The California Building Code (CBC), which is codified in Title 24 of the California Code of Regulations, Part 2, was promulgated to safeguard the public health, safety, and general welfare

[1] A habitable building is any structure where human occupancy would exceed approximately 2,000 hours annually.

by establishing minimum standards related to structural strength, egress facilities, and general building stability. The purpose of the CBC is to regulate and control the design, construction, quality of materials, use/occupancy, location, and maintenance of all building and structures within its jurisdiction. Title 24 is administered by the California Building Standards Commission, which, by law, is responsible for coordinating all building standards. Under State law, all building standards must be centralized in Title 24 or they are not enforceable. The provisions of the CBC apply to the construction, alteration, movement, replacement, and demolition of every building or structure or any appurtenances connected or attached to such buildings or structures throughout California.

NPDES Construction General Permit

Construction associated with the proposed program would disturb more than one acre of land surface for centralized and regional structural BMPs (and possibly for those distributed structural BMPs larger than one acre), affecting the quality of stormwater discharges into waters of the United States. The proposed program would therefore be subject to the *NPDES General Permit for Stormwater Discharges Associated with Construction and Land Disturbance Activities* (Order 2009-0009-DWQ, NPDES No. CAS000002, Construction General Permit [CGP]), as amended by Order 2010-0014-DWQ and Order 2012-0006-DWQ). The CGP regulates discharges of pollutants in stormwater associated with construction activity to waters of the United States from construction sites that disturb one or more acres of land surface, or that are part of a common plan of development or sale that disturbs more than one acre of land surface.

The CGP requires the development and implementation of a Stormwater Pollution Prevention Plan (SWPPP) that includes specific BMPs designed to prevent pollutants from contacting stormwater and keep all products of erosion from moving off-site into receiving waters. The SWPPP BMPs are intended to protect surface water quality by preventing the off-site migration of eroded soil and construction-related pollutants from the construction area. The CGP and SWPPPs are described in more detail in Section 3.8, Hydrology and Water Quality.

Surface Mining and Reclamation Act of 1975

The State Surface Mining and Reclamation Act (SMARA), as amended, is the primary State law governing the conservation and development of mineral resources in California (Health and Safety Code, Division 2, Chapter 9, Section 2710, et seq.). Specifically, it mandates the development of mineral land classifications to help identify and protect mineral resources in areas within the State that are subject to urban expansion or other irreversible land uses that would preclude mineral extraction. After classification of mineral resource zones, SMARA provides for the designation of lands containing mineral deposits of regional or statewide significance, as discussed further below in the CGS section. In addition, SMARA was designed to provide guidelines for the proper reclamation of mineral lands. Local jurisdictions are required to enact specific procedures to guide mineral conservation and extraction at particular sites and to incorporate mineral resource management policies into their General Plans. SMARA applies to the program because structural BMPs would be either prohibited within these mineral resource areas or the local jurisdiction would be required to approve the placement of the structural BMP within the mineral resource zone.

California Geological Survey

Based on guidelines adopted by CGS, areas known as Mineral Resource Zones (MRZs) are classified according to the presence or absence of significant nonfuel mineral resources deposits. Nonfuel mineral resources include metals such as gold, silver, iron, and copper; industrial metals such as boron compounds, rare-earth elements, clays, limestone, gypsum, salt, and dimension stone; and construction aggregate including sand, gravel, and crushed stone. These classifications indicate the potential for a specific area to contain significant mineral resources.

The classification process involves the determination of Production-Consumption (P-C) Region boundaries, based on identification of active aggregate operations (Production) and the market area served (Consumption). The P-C regional boundaries are modified to include only those portions of the region that are urbanized or urbanizing and are classified for their aggregate content. An aggregate appraisal further evaluates the presence or absence of significant sand, gravel, or stone deposits that are suitable sources of aggregate. The classification of these mineral resources is a joint effort of the State and local governments. It is based on geologic factors and requires that the State Geologist classify the mineral resources area as one of the four MRZs, or Scientific Resource Zones (SZs) or Identified Resource Areas (IRAs), which are described as the following (County of Los Angeles, 2014c):

- MRZ-1: Areas where available geologic information indicates there is little or no likelihood for presence of significant mineral resources.
- MRZ-2: Areas where available geologic information indicates that significant measured or indicated resources are present or where adequate information indicates that significant mineral deposits are present or where it is judged that a high likelihood for their presence exists.
- MRZ-3: Areas where available geologic information indicates known or inferred mineral occurrences of undetermined mineral resource significance.
- MRZ-4: Areas of no known mineral occurrences where geologic information does not rule out the presence or absence of significant mineral resources.
- SZ Areas: Containing unique or rare occurrences of rocks, minerals, or fossils that are of outstanding scientific significance shall be classified in this zone.
- IRA Areas: County or State Division of Mines and Geology Identified Areas where adequate production and information indicates that significant minerals are present.

Much of the area within the MRZ sites in Los Angeles was developed with structures prior to the MRZ classification and, therefore, is unavailable for extraction.

Local

County of Los Angeles General Plan

A General Plan is a basic planning document that, alongside the zoning code, governs development in a city or county. The State requires each city and county to adopt a General Plan with seven mandatory elements: land use, open space, circulation, housing, noise, conservation, and safety, along with any number of optional elements as appropriate. The proposed Enhanced

Watershed Management Programs (EWMPs, or "program") would be subject to the local plans and policies of the areas in which they are located.

The County of Los Angeles is currently updating their General Plan from the element versions adopted in the 1980s and 1990s; the new comprehensive plan is expected to be complete by late 2014. Below are the relevant goals and policies from both the existing General Plan (County of Los Angeles, 1980, 1990) and the Draft General Plan 2035 (County of Los Angeles, 2014a) which relate to the EWMPs.

Existing General Plan – Conservation and Open Space Element, Adopted 1980

Goal – Conserve Natural Areas: The variety and stability of plant and animal communities requires the preservation of important natural habitats. These are threatened by land development and the resultant extension of roads through environmentally sensitive areas.

Policy 12: Protect watershed, stream, and riparian vegetation to minimize water pollution, soil erosion and sedimentation, maintain natural habitats, and aid in ground water recharge.

Goal – Protect Mineral Resources: In the past, valuable mineral resources have been lost when incompatible urban uses were moved into productive areas. These reserves must be protected, and potential sites identified. At the same time, mineral production must not be allowed top conflict seriously with the goals of environmental protection.

Policy 15: Protect and conserve existing mineral resources, evaluate the extent and value of additional deposits, and require future reclamation of depleted sites.

Goal – Protect Public Safety: Our society places high value on human life. Development in areas subject to fires, floods, seismic and geologic hazards can result in loss of life and property, and increased governmental costs. Steep sloping lands are particularly vulnerable to fire, landslide, mudslide and erosion hazards. Protection and proper management of lands subject to these hazards are needed.

Policy 21: Restrict urban development in areas subject to seismic and geologic hazards.

Policy 22: Restrict urban development in flood prone areas, and thus avoid major new flood control works. Maintain natural watershed processes by regulating development in tributary watersheds. Minimize increased runoff, erosion, and siltation of streambeds that would limit the uses of streams and water bodies for recreation and other beneficial water-rated uses.

Existing General Plan – Safety Element, Seismic Hazards, Adopted 1990

Goal: Minimize injury and loss of life, property damage, and the social, cultural, and economic impacts caused by earthquake hazards.

Policy 1: Encourage the use of non-urbanized segments of active fault zones for rural and open space purposes.

Policy 2: Review projects proposing new expansion and construction of new development, especially critical facilities, and encourage them to avoid localities exposed to high earthquake hazards through such techniques as cluster development and transfer of development rights.

Policy 3: Continue enforcement of stringent site investigations (such as seismic, geologic, and soils investigations) and implementation of adequate hazard mitigation measures for development projects in areas of high earthquake hazard, especially those involving critical facilities. Do not approve proposals and projects which cannot mitigate safety hazards to the satisfaction of responsible agencies.

Existing General Plan – Safety Element, Geologic Hazards, Adopted 1990

Goal: Protect public safety and minimize the social and economic impacts from geologic hazards.

Policy 8: Review proposals and projects proposing new development and expansion of existing development in areas susceptible to land sliding, debris flow, and rock falls and in areas where collapsible or expansive soils are a significant problem; and disapprove projects which cannot mitigate safety hazards to the satisfaction of responsible agencies.

Policy 9: Continue to improve and enforce stringent slope investigation and design standards, and to apply innovative hazard mitigation and maintenance plans for development in hillside areas.

Policy 10: Upgrade slope maintenance measures and improve emergency response capability in hillside areas.

Existing General Plan – Land Use Element, Adopted 1980

Goal: Conserve resources and enhance environmental quality.

Policy 26: Protect known mineral resource reserves (including sand and gravel) from encroachment of incompatible land uses.

Draft General Plan, 2014 – Conservation and Natural Resources Element

Goal – C/NR-5: Protected and useable local surface water resources. (Some of these policies also apply to this geology section)

Policy C/NR 5.2: Require compliance by all County departments with adopted Municipal Separate Storm Sewer System (MS4), General Construction, and point source NPDES permits.

Policy C/NR 5.4: Actively engage in implementing all approved Enhanced Watershed Management Programs/Watershed Management Programs and Coordinated Integrated Monitoring Programs/Integrated Monitoring Programs or other County-involved TMDL implementation and monitoring plans.

Policy C/NR 5.6: Minimize point and non-point source water pollution. (This applies to this geology section because this policy would include minimizing erosion that generates sediment)

Goal – C/NR-10: Locally available mineral resources to meet the needs of construction, transportation, and industry.

Policy C/NR 10.1: Protect MRZ-2s and access to MRZ-2s from development and discourage incompatible adjacent land uses.

Draft General Plan, 2014 – Safety Element

Goal S 1: An effective regulatory system that prevents or minimizes personal injury, loss of life and property damage due to seismic and geotechnical hazards.

Policy S 1.1: Discourage development in Seismic Hazard and Alquist-Priolo Earthquake Fault Zones.

Policy S 1.3: Require developments to mitigate geotechnical hazards, such as soil instability and landsliding, in Hillside Management Areas through siting and development standards.

City General Plans

The numerous cities encompassed by the EWMP area all have their own respective city General Plans, which may contain policies that address geology and minerals. As implementation of the individual structural BMP projects proceeds, specific policies and objectives pertaining to geology and minerals from applicable city General Plans would be identified and evaluated on a project-by-project basis during subsequent CEQA environmental processes.

County of Los Angeles Building Code Section 113

Section 113 prohibits the location of most structures for human occupancy across the traces of active faults, and lessens the impacts of fault rupture.

County of Los Angeles Low Impact Development Manual

- The County of Los Angeles (County) prepared the 2014 Low Impact Development Standards Manual (LID Standards) to comply with the requirements of the National Pollutant Discharge Elimination System (NPDES) Municipal Separate Storm Sewer System (MS4) Permit for stormwater and non-stormwater discharges from the MS4 within the coastal watersheds of Los Angeles County (CAS004001, Order No. R4-2012-0175), referred to as the 2012 MS4 Permit (County of Los Angeles, 2014b). The LID

Standards provide guidance for the implementation of stormwater quality control measures in new development and redevelopment projects in unincorporated areas of the County with the intention of improving water quality and mitigating potential water quality impacts from stormwater and non-stormwater discharges. The November 2013 LID Ordinance became effective December 5, 2013.

City of Los Angeles Low Impact Development Manual

In November 2011, the City of Los Angeles adopted the Stormwater Low Impact Development (LID) Ordinance #181899) with the stated purpose of:

- Requiring the use of LID standards and practices in future developments and redevelopments to encourage the beneficial use of rainwater and urban runoff
- Reducing stormwater/urban runoff while improving water quality
- Promoting rainwater harvesting
- Reducing offsite runoff and providing increased groundwater recharge
- Reducing erosion and hydrologic impacts downstream
- Enhancing the recreational and aesthetic values in our communities

The City institutionalized the use of LID techniques for development and redevelopment projects. Subsequent to the adoption of the Stormwater LID Ordinance, the City prepared the *Development Best Management Practices Handbook, Low Impact Development Manual,* dated June 2011, to describes the required BMPs (City of Los Angeles, 2011).

Other Cities LID

Various other cities within the County also have LID standards or guidance. The goals, objectives, and content of the LID document are similar to that of the County and City of Los Angeles, and are not referenced here.

3.5.3 Impact Analysis

The proposed program's potential impacts were assessed using the California Environmental Quality Act (CEQA) Guidelines Appendix G Checklist. This section discusses the key issue areas identified in the CEQA Guidelines with respect to the project's potential effect to geologic and mineral resources.

Thresholds of Significance

For the purposes of this PEIR and consistency with Appendix G of the CEQA Guidelines, the project would have a significant impact on geologic resources if it would:

- Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:

  - Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault;
  - Strong seismic groundshaking;
  - Seismic-related ground failure, including liquefaction; or
  - Landslides
- Result in substantial soil erosion or the loss of topsoil
- Be located on a geologic unit that is unstable or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse
- Be located on expansive soils, as defined in 24 CCR 1803.5.3 of the CBC (2013)[2]
- Have soils incapable of adequately supporting the use of a septic tank or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater

The project would have a significant impact on mineral resources if it would:

- Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state
- Result in the loss of availability of a locally important mineral resource recovery site delineated on a local General Plan, Specific Plan, or other land use plan

Project Impact Discussion

Exposure to Seismic-Related Hazards

Impact 3.5-1: The proposed program could locate new facilities in areas susceptible to seismic impacts such as (1) rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault, (2) strong seismic groundshaking, or (3) seismically induced liquefaction or landslides, which could expose people, structures, or habitat to potential risk of loss, damage, injury, or death.

Structural (Regional, Centralized, and Distributed) BMPs

The EWMP area lies in a region that is seismically active and includes numerous active faults. In the event of an earthquake, fault rupture and seismic groundshaking could be experienced in the project area, as is typical throughout Southern California. The seismic groundshaking could trigger seismically induced liquefaction, landslides, or other slope failure. As discussed in Section 3.5.1, *Environmental Setting*, and shown in Figure 3.5-2, 10 active faults are known within the project area. Facilities constructed on or within up to 500 feet of an active fault trace could be damaged by fault rupture. Seismic groundshaking and seismically induced liquefaction,

2 The updated CBC no longer cites the UBC Table 18-1-B for identifying expansive soils. The checklist in Appendix G of the CEQA Guidelines still refers to this out of date table. This PEIR uses the updated CBC section as defined in 24 CCR 1803.5.3 of the CBC (2013).

landslides, or other slope failure could result in structural damage to facilities, which in turn could affect operation of related systems. Regional and centralized BMPs with above-ground infrastructure components that could be seismically impacted include infiltration, bioretention, or detention basins with above ground berms or levees that form the basin. Subsurface infiltration, retention, or storage structures (e.g., trenches, galleries, and wells) and structures generally flush with the surrounding area (e.g., permeable pavement, swales, filter strips, and wetlands) would be less vulnerable to significant seismic damage, but could still be damaged during large earthquakes. Damage to these underground systems include structural damage to the underground vaults, connection to existing MS4, and underdrains that connect to the MS4. Centralized BMPs that consist of large diversion and treatment systems can also experience structural damage under seismic events.

Distributed structural BMPs would be smaller, site- or parcel-specific structures and would therefore be less vulnerable to seismic damage. Although distributed structural BMPs that include above-ground components (e.g., sides or levees to basins, planter boxes, rain barrels, water clarifiers) could be damaged by a seismic event, the resulting release of water would be smaller and less likely to cause significant damage. Damage to these underground systems includes structural damage to the underground vaults, connection to existing MS4, and underdrains that connect to the MS4. For all three structural BMPs, infiltration of water to the underlying soil can result in an increased potential for soil instability and liquefaction.

All of the proposed facilities would be uninhabitable. However, damage to facilities could result in threats to the safety of people in downslope areas or damage to other downslope facilities. To ensure impacts to public safety are minimized, prior to construction of each specific project, a design-level geotechnical investigation would be required. The geotechnical evaluation would identify the potential geologic and seismic hazards and would recommend site-specific design criteria to abate seismic hazards, such as special foundations and structural setbacks, and these recommendations would be incorporated into the design of individual proposed projects.

The geotechnical investigations would be conducted by a geotechnical engineer. Furthermore, project designs would be subject to the CBC design standards and local codes.[3] The California Professional Engineers Act (Building and Professions Code Sections 6700-6799), and the Codes of Professional Conduct, as administered by the California Board of Professional Engineers and Land Surveyors, provide the basis for regulating and enforcing engineering practice in California.

In addition, the County of Los Angeles LID Standards, as well as LID Standards for the various cities, require that all structural BMPs (regional, centralized, and distributed) that include ground-disturbance activities, regardless of size; conduct a site assessment; and identify design considerations. The site assessment specifically includes identifying the potential for fault rupture, seismic shaking, and seismically induced liquefaction and other ground failures. The

[3] A geotechnical engineer specializes in structural behavior of soil and rocks. Geotechnical engineers conduct soil investigations, determine soil and rock characteristics, provide input to structural engineers, and provide recommendations to address problematic conditions or soils.

design considerations must be prepared by a geotechnical engineer and must specifically include design features to minimize or avoid damage from fault rupture and seismic events.

It is likely that the structural elements of each proposed project would be subjected to a moderate to strong earthquake at least once during their operational life which could include surface displacement from fault rupture or seismic shaking. Completion of a comprehensive design-level geotechnical investigation, adherence to the current CBC, LID Standards, and local ordinances and laws regulating construction, and the application of proven seismic design criteria as standard engineering practice would ensure that structures are designed to withstand seismic events without sustaining substantial damage or collapsing. Therefore, this impact is considered less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural/Institutional BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities that are susceptible to seismic impacts. Consequently, there would be no new facilities that would place people or structures at risk to injury or damage due to fault rupture. Therefore, this impact would have no impact relative to fault rupture.

Mitigation Measures: None required

Significance Determination: No impact

Soil Erosion or Topsoil Loss

Impact 3.5-2: The proposed program could result in substantial soil erosion or the loss of topsoil.

Structural (Regional, Centralized, and Distributed) BMPs

Construction activities for proposed program facilities such as excavation and grading could result in soil erosion or loss of topsoil during rain or high-wind events. Erosion could damage facilities, pose risk to people, or damage habitat or improvements downslope of a proposed program, resulting in potentially significant impacts. However, each BMP type would generally serve to slow down or fully retain stormwater runoff. This would act to reduce erosion potential compared with existing conditions. Discharge points from centralized and distributed BMPs would be designed to minimize scour potential, and in any case improve scour potential from existing conditions.

To prevent erosion and runoff from construction sites, the CGP requires the preparation and implementation of a SWPPP that would include BMPs to control erosion and off-site sedimentation from construction sites. The required compliance with the SWPPP and implementation of erosion control BMPs would ensure that soil erosion and loss of topsoil would be minimized to levels considered less than significant.

Proposed projects that are smaller than one acre would be required to comply with the BMPs identified in the Los Angeles County MS4 Permit (RWQCB Order No. R4-2010-0175), which would implement minimum-control BMPs to provide erosion control and sediment control strategies for small construction sites (see Chapter 3.8, *Surface Hydrology and Water Quality*, for a more detailed explanation of the MS4 Permit.). Compliance with SWPPPs and runoff BMPs (will vary with the area of disturbance, construction vehicles used, site grade, and duration of project) would ensure less than significant erosion during construction.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural/Institutional BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no new facilities that would increase erosion or the loss of topsoil due to the construction of new facilities.

Mitigation Measures: None required

Significance Determination: No impact

Soil Stability

Impact 3.5-3: The proposed program could be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the program, and potentially result in on-site or off-site non-seismically induced geologic hazards such as landslides, lateral spreading, subsidence, collapse or sinkholes, settlement, or slope failure.

Structural (Regional, Centralized, and Distributed) BMPs

Non-seismically-induced geologic hazards such as landslides, lateral spreading, settlement, and slope failure can be caused by unstable soils. Infiltration of water into surficial soils can increase soil instability. Distributed structural BMPs would be smaller, site- or parcel-specific structures and would therefore be less vulnerable to geologic hazards. Although distributed structural BMPs that include above ground components (e.g., sides or levees to basins, planter boxes, rain barrels, water clarifiers) could be damaged by geologic hazards, the resulting release of water would be smaller and less likely to cause significant damage. The regional and centralized structural BMPs that include the construction of larger physical structures would be more susceptible to unstable soils.

Furthermore, infiltration could result in saturated soils, soil piping through preferential pathways, breakouts due to infiltrated water finding utility trenches and other preferential pathways, and raising the local groundwater levels such that infrastructure foundations and underground structures could be affected by unstable soils. Increased saturation of shallow soils could reduce the strength of the soils, resulting in an increased susceptibility to failure (e.g., lateral spreading, settlement, instability, soil piping, reduced or loss of shear strength). In addition, infiltrated water could become perched or find preferential pathways such as utility trenches and potentially inundate or destabilize subterranean structures and utilities, or breakout downstream and damage above ground structures. To ensure that structural BMPs are not undermined by unstable soils or impact adjacent infrastructure and buildings, **Mitigation Measure GEO-1** requires that each specific project would require a design-level geotechnical investigation. The geotechnical evaluation would identify the potential for geologic hazards and would recommend site-specific design criteria to abate geologic hazards, such as drainage barriers, lined trenches, continued monitoring of subsurface conditions, added site drainage, special foundations, and structural setbacks, and these recommendations would be incorporated into the design of individual proposed projects.

Implementing the design requirements in the CBC and local (County and city) ordinances and recommendations of geotechnical investigations would ensure that all structures are constructed in compliance with the applicable laws, regulations, and policies, including the LID Ordinances. Therefore, this impact is considered less than significant.

Mitigation Measures:

GEO-1: Prior to approval of infiltration BMPs, implementing agencies shall conduct a geotechnical investigation of each infiltration BMP site to evaluate infiltration suitability. If infiltration rates are sufficient to accommodate an infiltration BMP, the geotechnical investigation shall recommend design measures necessary to prevent excessive lateral spreading that could destabilize neighboring structures. Implementing agencies shall implement these measures in project designs.

Significance Determination: Less than significant (The application of this mitigation measure to specific BMP types and categories is identified in Table 3.5-3.)

Non-Structural/Institutional BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities that would be located on a geologic unit or soil that is unstable. Consequently, there would be no new facilities that would increase erosion or the loss of topsoil due to the construction of new facilities.

Mitigation Measures: None required

Significance Determination: No impact

Expansive Soils

Impact 3.5-4: The proposed program could be located on expansive soil as defined in 24 CCR 1803.5.3 of the California Building Code (2013), creating substantial risks to life or structures.

Structural (Regional, Centralized, and Distributed) BMPs

Soil expansion, also referred to as linear extensibility or shrink-swell, occurs in certain clayey soils that when subjected to repeated wetting and drying, undergo shrinking or swelling. As discussed in Section 3.5.1, *Environmental Setting*, some areas within the project area have expansive soil. Soil expansion can occur in expansive soils that have not been removed or properly conditioned. The differential ground movement that occurs through soil expansion could result in structural damage to facilities over the long term, which in turn could affect operation of related systems. Damage to the facilities could result in threats to the safety of people at or near the facilities.

All structural BMPs, regardless of size (regional, centralized, or distributed) would be susceptible to damage from soil expansion if placed on susceptible soil. Some distributed structural BMPs would be less or not susceptible (e.g., bioswales, planter boxes, flow-through treatment BMPs [debris booms/nets, end-of-pipe nets, floating trash booms]) because soil expansion beneath these BMPs, if any, would not result in significant damage.

Completion of a comprehensive design-level geotechnical investigation, implementing the design requirements in the CBC and local (County and city) ordinances, and ensuring that all structures are constructed in compliance with the applicable laws, regulations, and policies, including the LID Ordinances, would ensure that structural BMPs are constructed in a manner that avoids impacts from expansive soils. Therefore, this impact is considered less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural/Institutional BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Therefore, this impact would have no impact relative to expansive soils.

Mitigation Measures: None required

Significance Determination: Less than significant

On-Site Wastewater Treatment Systems

Impact 3.5-5: The proposed program could have soils incapable of adequately supporting the use of a septic tank or alternative wastewater treatment systems where sewers are not available for the disposal of wastewater.

Implementation of the proposed program would not include facilities that require the use of septic systems or alternate wastewater disposal systems where sewers are not available for the disposal of wastewater. Therefore, no impact would occur related to soil suitability for septic or alternative wastewater disposal systems.

Mitigation Measures: None required

Significance Determination: No impact

Mineral Resources

Impact 3.5-6: The proposed program could result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state or a locally important mineral resource recovery site delineated on a local General Plan, Specific Plan, or other land use plan.

Structural (Regional, Centralized, and Distributed) BMPs

The EWMP project area includes mineral resource areas in Los Angeles County that contain known or potentially productive petroleum fields, natural gas, construction aggregate, and mineral deposits. If the construction of a specific proposed program occurred within a mineral resources area, the access to or availability of that mineral resource could be restricted or eliminated.

Typical distributed structural BMPs would be constructed within areas that are already urbanized and disturbed, and would therefore not be available for mineral resource activities. Regional or centralized structural BMPs could be constructed in locations that are not already urbanized and are located within a designated MRZ, specifically an MRZ-2, an area with known mineral resources. Siting projects within designated MRZs could be conducted if the BMPs do not impede access to the mineral resources. In any case, siting large and small BMPs would need to comply with local and County General Plan zoning restrictions. Compliance with local General Plans and the County of Los Angeles General Plan would ensure that impacts to mineral resources would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural/Institutional BMPs

As discussed in Chapter 2.0, *Project Description*, Non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no new facilities that would affect mineral resources. Therefore, this impact would have no impact.

Mitigation Measures: None required

Significance Determination: Less than significant

Cumulative Impact Discussion

Structural (Regional, Centralized, and Distributed) BMPs

Although the EWMP area is located within a seismically active region, with a wide range of geologic and soil conditions, these conditions can vary greatly within a short distance, making the cumulative context for potential impacts one that is typically more localized. Consequently, most projects would have minimal potential to impact or be impacted by other projects. Impacts would be largely contained within the footprint of each individual proposed project.

Many of the distributed BMPs, as well as the larger-scale regional and central BMPs, would include infiltration as a primary component. Consequently, many infiltration projects could be implemented within each watershed. This would result in a significant amount of water infiltrated into the subsurface, which would saturate some shallow soils below the infiltration basins and raise groundwater levels. A general rise in groundwater levels due to stormwater retention and infiltration would provide water supply benefits to the region, but could also raise groundwater levels above current levels. A regional increase in the amount of infiltration added to subsoils throughout the urbanized areas where the structural BMPs will be installed may increase the potential for impacts to existing infrastructure and buildings. To ensure that structural BMPs are not undermined by unstable soils or impact adjacent infrastructure and buildings, each specific project would require a design-level geotechnical investigation. The geotechnical evaluation would identify the potential for geologic hazards and would recommend site-specific design criteria to abate geologic hazards, such as drainage barriers, lined trenches, continued monitoring of subsurface conditions, added site drainage, special foundations, and structural setbacks, and these recommendations would be incorporated into the design of individual proposed projects. Implementation of these requirements for a geotechnical investigation, assessment, and design recommendation for structural BMPs that include adding flows by infiltration and filtration to the subsurface should address the potential for cumulative impacts.

All the groundwater basins in Los Angeles County are actively used for multiple beneficial uses; most are designated as drinking water sources. The potential for groundwater levels to rise high enough to impact structural foundations and other support structures is low since the aquifers are generally over 100 feet below ground surface and are actively managed by overlying users. Furthermore, targeted pumping in areas with elevated groundwater levels would mitigate any soil stability issues. However, water levels may rise in local areas with limited extraction capabilities.

In addition, percolating water could become perched or find preferential pathways such as utility trenches and inundate underground utilities or structures. The cumulative effect of multiple infiltration projects could increase the severity of the perched or migrating water. However, Mitigation Measure GEO-1 would require that BMPs be designed to avoid infiltrating in areas with the potential for perched groundwater or migration. This would minimize the cumulative impact to regional infrastructure.

In addition, groundwater managers in each of the watersheds currently manage pumping effectively to prevent impacts to structural foundations resulting from groundwater mounding from existing recharge efforts. Under existing conditions, in areas with chronically high groundwater levels, dewatering operations are installed, and the water is beneficially used wherever possible. Implementation of **Mitigation Measure GEO-2** would require that the Implementing Agency notify groundwater managers of local infiltration projects to provide better coordination between stormwater retention and groundwater levels management. With this coordination, the potential contribution to cumulative effects to soil stability from elevated groundwater levels would be considered less than significant.

Significance Determination before Mitigation: Potentially significant

Mitigation Measures:

GEO-2: Prior to installing BMPs designed to recharge the local groundwater supplies, the Implementing Agency shall notify local groundwater managers, including the Upper Los Angeles River Area Water Master, the Water Replenishment District of Southern California, or the San Gabriel Water Master as well as local water producers such as local municipalities and water companies. The Implementing Agency shall coordinate BMP siting efforts with groundwater managers and producers to mitigate high groundwater levels while increasing local water supplies.

Significance Determination after Mitigation: Less than significant (The application of this mitigation measure to specific BMP types and categories is identified in Table 3.5-3.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no new facilities that would contribute to cumulative impacts.

Mitigation Measures: None required

Significance Determination: Less than significant

3.5.4 Summary of Impact Assessment

Table 3.5-3 shows a summary of the structural BMPs requiring mitigation.

TABLE 3.5-3
SUMMARY OF GEOLOGIC RESOURCE IMPACTS REQUIRING MITIGATION MEASURES

	Thresholds of Significance						
Structural BMPs	**Exposure to Seismic-Related Hazards**	**Soil Erosion or Topsoil Loss**	**Soil Stability**	**Expansive Soils**	**On-Site Wastewater Treatment Systems**	**Mineral Resources**	**Cumulative Impacts**
Applicable Mitigation Measures:	**None Required**	**None Required**	**GEO-1**	**None Required**	**None Required**	**None Required**	**GEO-2**
Regional BMPs							
Regional Detention and Infiltration	No	No	No	No	No	No	Yes
Regional Capture, Detention and Use	No	No	No	No	No	No	Yes
Centralized BMP							
Bioinfiltration	No	No	No	No	No	No	Yes

Source-Control Treatment BMPs (catch basin inserts/screens, hydrodynamic separators, gross solids removal devices)	No	No	No	No	No	No	Yes
Low-Flow Diversions	No	No	No	No	No	No	Yes

NOTE: These conclusions are based on typical BMP size and location.

3.6 Greenhouse Gas Emissions

This section provides a discussion of global climate change, existing regulations pertaining to global climate change, and potential greenhouse gas (GHG) emissions resulting from implementation of the proposed program. Impacts related to GHGs and climate change are analyzed and mitigation measures are provided for any potentially significant impacts. The methods of analyzing emissions described in this section are consistent with the recommendations of the South Coast Air Quality Management District (SCAQMD).

3.6.1 Environmental Setting

Affected Environment

This section presents a discussion of existing climate conditions, the current state of climate change science, and GHG emissions sources in California.

Climate

Climate is the accumulation of daily and seasonal weather events over a long period of time, whereas weather is defined as the condition of the atmosphere at any particular time and place (Ahrens, 2003). The proposed program is located in the County of Los Angeles within the Basin, which has a distinctive climate determined by its terrain and geographic location. The general region lies in the semipermanent high-pressure zone of the eastern Pacific, resulting in a mild climate tempered by cool sea breezes with light average wind speeds. The usually mild climate is interrupted occasionally by periods of extremely hot weather, winter storms, or Santa Ana winds.

Climate Change Overview

Various gases in the earth's atmosphere, classified as GHGs, play a critical role in determining its surface temperature. Solar radiation enters earth's atmosphere from space, and a portion of the radiation is absorbed by the earth's surface. Earth re-radiates this energy back toward space, but the properties of the radiation change from high-frequency solar radiation to lower-frequency infrared radiation. GHGs, which are transparent to solar radiation, are effective in absorbing infrared radiation. As a result, this radiation (that otherwise would have escaped back into space) is now retained in the atmosphere, and results in a warming of the atmosphere. This phenomenon, known as the greenhouse effect, is responsible for maintaining a habitable climate on earth. Without the greenhouse effect, the earth would not be able to support life as we know it.

Prominent GHGs contributing to the greenhouse effect are carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), chlorofluorocarbons (CFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6). Much of the scientific literature suggests that human-caused emissions of these GHGs in excess of natural ambient concentrations are responsible for intensifying the greenhouse effect and have led to a trend of unnatural warming of earth's climate, known as global climate change or global warming. While there is some debate regarding this issue, it is unlikely that global climate change of the past 50 years can be explained without contribution from human activities (IPCC, 2007).

Climate change is a global problem. GHGs are global pollutants, unlike criteria air pollutants and toxic air contaminants, which are pollutants of regional and local concern. Whereas pollutants with localized air quality effects have relatively short atmospheric lifetimes (about one day), GHGs have long atmospheric lifetimes (one year to several thousand years). GHGs persist in the atmosphere for long enough time periods to be dispersed around the globe. Although the exact lifetime of any particular GHG molecule is dependent on multiple variables and cannot be pinpointed, it is understood that more CO_2 is emitted into the atmosphere than is sequestered by ocean uptake, vegetation, and other forms of sequestration. Of the total annual human-caused CO_2 emissions, approximately 54 percent is sequestered through ocean uptake, uptake by northern hemisphere forest regrowth, and other terrestrial sinks within 1 year, whereas the remaining 46 percent of human-caused CO_2 emissions remains stored in the atmosphere (Seinfeld and Pandis, 1998).

Similarly, impacts of GHGs are borne globally, as opposed to localized air quality effects of criteria air pollutants and toxic air contaminants. The quantity of GHGs that it takes to ultimately result in climate change is not precisely known; however, it is clear that the quantity is enormous, and no single project would measurably contribute to a noticeable incremental change in the global average temperature, or to global, local, or micro climates. From the standpoint of the California Environmental Quality Act (CEQA), GHG impacts to global climate change are inherently cumulative.

Greenhouse Gas Emission Sources

According to much of the scientific literature on this topic, emissions of GHGs contributing to global climate change are attributable in large part to human activities associated with the transportation, industrial/manufacturing, utility, residential, commercial, and agricultural sectors. In California, the transportation sector is the largest emitter of GHGs, followed by electricity generation (CARB, 2014a). Emissions of CO_2 are by-products of fossil fuel combustion. CH_4, a highly potent GHG, results from off-gassing (the release of chemicals from nonmetallic substances under ambient or greater pressure conditions) and is largely associated with agricultural practices and landfills. N_2O is also largely attributable to agricultural practices and soil management. CO_2 sinks, or reservoirs, include vegetation and the ocean, which absorb CO_2 through sequestration and dissolution, respectively, and are two of the most common processes of CO_2 sequestration.

California is the 12th to 16th largest emitter of CO_2 in the world (CEC, 2006a). California produced 452 million gross metric tons of CO_2 equivalent (CO_2e) in 2010 (CARB, 2014a). CO_2e is a measurement used to account for the fact that different GHGs have different potential to retain infrared radiation in the atmosphere and contribute to the greenhouse effect. Expressing emissions in CO_2e takes the contributions to the greenhouse effect of all GHG emissions and converts them to the equivalent effect that would occur if only CO_2 were being emitted. This measurement, known as the global warming potential (GWP) of a GHG, is dependent on the lifetime, or persistence, of the gas molecule in the atmosphere. For example, as described in Appendix C, Calculation References, of the General Reporting Protocol of the California Climate Action Registry (CCAR, 2009), 1 ton of CH_4 has the same contribution to the greenhouse effect as approximately 21 tons of CO_2. Therefore, CH_4 is a much more potent GHG than CO_2.

Combustion of fossil fuel in the transportation sector was the single largest source of California's GHG emissions in 2012, accounting for 36 percent of total GHG emissions in the state (CARB, 2014a). This sector was followed by the electric power sector (including both in-state and out-of-state sources) (21 percent) and the industrial sector (19 percent) (CARB, 2014a).

3.6.2 Regulatory Framework

Federal

The federal Clean Air Act (CAA) requires the U.S. Environmental Protection Agency (USEPA) to define national ambient air quality standards to protect public health and welfare in the United States. The CAA does not specifically regulate GHG emissions; however, on April 2, 2007, the U.S. Supreme Court in *Massachusetts v. U.S. Environmental Protection Agency* determined that GHGs are pollutants that can be regulated under the CAA. Currently, there are no federal regulations that establish ambient air quality standards for GHGs.

On December 7, 2009, USEPA adopted its Proposed Endangerment and Cause or Contribute Findings for Greenhouse Gases under the CAA (Endangerment Finding). The Endangerment Finding is based on Section 202(a) of the CAA, which states that the USEPA Administrator should regulate and develop standards for "emission[s] of air pollution from any class or classes of new motor vehicles or new motor vehicle engines, which in [its] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare." The rule addresses Section 202(a) in two distinct findings. The first addresses whether the concentrations of the six key GHGs (CO_2, CH_4, N_2O, HFCs, PFCs, and SF_6) in the atmosphere threaten the public health and welfare of current and future generations. The second addresses whether the combined emissions of GHGs from new motor vehicles and motor vehicle engines contribute to atmospheric concentrations of GHGs and, therefore, contribute to the threat of climate change.

The USEPA Administrator determined that atmospheric concentrations of GHGs endanger the public health and welfare within the meaning of Section 202(a) of the CAA. The evidence supporting this finding consists of human activity resulting in "high atmospheric levels" of GHG emissions, which are likely responsible for increases in average temperatures and other climatic changes. Furthermore, the observed and projected results of climate change (e.g., higher likelihood of heat waves, wild fires, droughts, sea level rise, and higher intensity storms) are a threat to the public health and welfare. Therefore, GHGs were found to endanger the public health and welfare of current and future generations.

Specific GHG regulations that USEPA has adopted to-date are as follows:

> **40 CFR Part 98. Mandatory Reporting of Greenhouse Gases Rule.** This rule requires mandatory reporting of GHG emissions for facilities that emit more than 25,000 metric tons of CO_2e emissions per year (USEPA, 2011). Additionally, reporting of emissions is required for owners of SF_6- and PFC-insulated equipment when the total nameplate capacity of these insulating gases is above 17,280 pounds.

40 CFR Part 52. Proposed Prevention of Significant Deterioration and Title V Greenhouse Gas Tailoring Rule. USEPA recently mandated to apply Prevention of Significant Deterioration (PSD) requirements to facilities whose stationary source CO_2e emissions exceed 75,000 tons per year (USEPA, 2010).

The USEPA also recently released a proposed rule which would regulate GHG emissions from existing power plants across the nation. The proposed rule establishes state-by-state 2030 GHG goals.

State

The California Air Resources Board (CARB) is the agency responsible for coordination and oversight of state and local air pollution control programs in California. Various statewide and local initiatives to reduce the state's contribution to GHG emissions have raised awareness that, even though the various contributors to and consequences of global climate change are not yet fully understood, global climate change is under way, and there is a real potential for severe adverse environmental, social, and economic effects in the long term. Because every nation emits GHGs and therefore makes an incremental cumulative contribution to global climate change, cooperation on a global scale will be required to reduce the rate of GHG emissions to a level that can help to slow or stop the human-caused increase in average global temperatures and associated changes in climatic conditions.

There are currently no state regulations in California that establish ambient air quality standards for GHGs. However, California has passed laws directing CARB to develop actions to reduce GHG emissions, and several state legislative actions related to climate change and GHG emissions have come into play in the past decade.

Assembly Bill 1493 (Pavley)

In 2002, then-Governor Gray Davis signed Assembly Bill (AB) 1493. AB 1493 required that CARB develop and adopt, by January 1, 2005, regulations that achieve "the maximum feasible reduction of greenhouse gases emitted by passenger vehicles and light-duty trucks and other vehicles determined by CARB to be vehicles whose primary use is noncommercial personal transportation in the state."

To meet the requirements of AB 1493, in 2004 CARB approved amendments to the California Code of Regulations (CCR) adding GHG emissions standards to California's existing standards for motor vehicle emissions. Amendments to CCR Title 13, Sections 1900 and 1961 (13 CCR 1900, 1961), and adoption of Section 1961.1 (13 CCR 1961.1) require automobile manufacturers to meet fleet-average GHG emissions limits for all passenger cars, light-duty trucks within various weight criteria, and medium-duty passenger vehicle weight classes (i.e., any medium-duty vehicle with a gross vehicle weight rating less than 10,000 pounds that is designed primarily for the transportation of persons), beginning with the 2009 model year. For passenger cars and light-duty trucks with a loaded vehicle weight of 3,750 pounds or less, the GHG emission limits for the 2016 model year are approximately 37 percent lower than the limits for the first year of the regulations, the 2009 model year. For light-duty trucks with a loaded vehicle weight of 3,751 pounds to gross vehicle weight of 8,500 pounds, as well as medium-duty passenger vehicles, GHG emissions would be reduced approximately 24 percent between 2009 and 2016.

Executive Order S-03-05

Executive Order S-03-05, which was signed by Governor Arnold Schwarzenegger in 2005, proclaims that California is vulnerable to the impacts of climate change. It declares that increased temperatures could reduce the Sierra's snowpack, further exacerbate California's air quality problems, and potentially cause a rise in sea levels. To combat those concerns, the Executive Order established total GHG emission targets. Specifically, emissions were to be reduced to the 2000 level by 2010 and are to be reduced to the 1990 level by 2020, and to 80 percent below the 1990 level by 2050.

The Executive Order directed the Secretary of the California Environmental Protection Agency (CalEPA) to coordinate a multi-agency effort to reduce GHG emissions to the target levels. The Secretary will also submit biannual reports to the governor and state legislature describing progress made toward reaching the emission targets, impacts of global warming on California's resources, and mitigation and adaptation plans to combat these impacts. To comply with the Executive Order, the Secretary of CalEPA created the California Climate Action Team (CCAT), which is made up of members from various state agencies and commissions. CCAT released its first report in March 2006. The report proposed to achieve the targets by building on voluntary actions of California businesses, local government, and community actions, as well as through state incentive and regulatory programs.

Assembly Bill 32 (California Global Warming Solutions Act of 2006)

In September 2006, Governor Schwarzenegger signed the California Global Warming Solutions Act (AB 32; California Health and Safety Code Division 25.5, Sections 38500–38599). AB 32 establishes regulatory, reporting, and market mechanisms to achieve quantifiable reductions in GHG emissions and establishes a cap on statewide GHG emissions. AB 32 requires that statewide GHG emissions be reduced to 1990 levels by 2020. This reduction will be accomplished by enforcing a statewide cap on GHG emissions that will be phased in starting in 2012. To effectively implement the cap, AB 32 directs CARB to develop and implement regulations to reduce statewide GHG emissions from stationary sources.

Senate Bill 1368

Senate Bill (SB) 1368 is the companion bill of AB 32 and was signed by Governor Schwarzenegger in September 2006. SB 1368 required the California Public Utilities Commission (CPUC) to establish a GHG emission performance standard for baseload generation from investor-owned utilities. CPUC adopted a GHG Emissions Performance Standard in January 2007. The California Energy Commission (CEC) adopted consistent regulations for implementing and enforcing SB 1368 for the state's publicly owned utilities in August 2007. These standards cannot exceed the GHG emission rate from a baseload combined-cycle natural-gas-fired plant. The legislation further requires that all electricity provided to California, including imported electricity, must be generated from plants that meet the standards set by the CPUC and CEC.

Executive Order S-1-07

Executive Order S-1-07, which was signed by Governor Schwarzenegger in 2007, proclaims that the transportation sector is the main source of GHG emissions in California, generating more than 40 percent of statewide emissions. It establishes a goal to reduce the carbon intensity of transportation fuels sold in California by at least ten percent by 2020. This order also directed CARB to determine whether this Low Carbon Fuel Standard (LCFS) could be adopted as a discrete early-action measure as part of the effort to meet the mandates in AB 32.

On April 23, 2009, CARB approved the proposed regulation to implement the LCFS. The LCFS will reduce GHG emissions from the transportation sector in California by about 16 million metric tons (MMT) in 2020.

Senate Bill 97

SB 97, signed August 2007 (Chapter 185, Statutes of 2007; Public Resources Code Sections 21083.05 and 21097), acknowledges that climate change is a prominent environmental issue that requires analysis under CEQA. The bill directs the California Office of Planning and Research (OPR) to prepare, develop, and transmit to the California Natural Resources Agency, guidelines for the feasible mitigation of GHG emissions or the effects of GHG emissions, as required by CEQA, by July 1, 2009. The Natural Resources Agency was required to certify or adopt those guidelines by January 1, 2010. On April 13, 2009, OPR submitted to the Secretary for Natural Resources its proposed amendments to the CEQA Guidelines for GHG emissions, as required by SB 97. On February 16, 2010, the Office of Administrative Law approved the amendments, and filed them with the Secretary of State for inclusion in the CCR. The amendments became effective on March 18, 2010.

CARB Climate Change Scoping Plan

On December 11, 2008, CARB adopted its Scoping Plan, which functions as a roadmap of CARB's plans to achieve GHG reductions in California required by AB 32 through subsequently enacted regulations (CARB, 2008). CARB's Scoping Plan contains the main strategies California will implement to reduce CO_2e emissions by 169 MMT, or approximately 28.4 percent, from the state's projected 2020 emissions level of 596 MMT of CO_2e under a "business-as-usual" (BAU) scenario. In August 2011, the Scoping Plan was reapproved by the Board and includes the Final Supplement to the Scoping Plan Functional Equivalent Document. This document includes expanded analysis of project alternatives as well as updates the 2020 emission projections in light of the current economic forecasts. Considering the updated 2020 BAU estimate of 507 MMT CO_2e, a 16 percent reduction below the estimated BAU levels would be necessary to return to 1990 levels by 2020. The document also excludes one measure identified in the 2008 Scoping Plan that has been adopted and one measure that is no longer under consideration by CARB (CARB, 2011).

CARB's Scoping Plan calculates 2020 BAU emissions as the emissions that would be expected to occur in the absence of any GHG reduction measures. The 2020 BAU emissions estimate was derived by projecting emissions from a past baseline year using growth factors specific to each of the different economic sectors (transportation, electrical power, commercial and residential, industrial, etc.). CARB used 3-year average emissions, by sector, for 2002–2004 to forecast emissions to 2020. At the time CARB's Scoping Plan process was initiated, 2004 was the most recent year for which actual data was available. The measures described in CARB's Scoping Plan are intended to reduce the projected 2020 BAU levels to 1990 levels, as required by AB 32.

CARB's Scoping Plan also breaks down the amount of GHG emissions reductions CARB recommends for each emissions sector of the state's GHG inventory. CARB's Scoping Plan calls for the largest reductions in GHG emissions to be achieved by implementing the following measures and standards:

- Improved emissions standards for light-duty vehicles (estimated reductions of 31.7 MMT CO_2e)
- The LCFS (15.0 MMT CO_2e)
- Energy efficiency measures in buildings and appliances, and the widespread development of combined heat and power systems (26.3 MMT CO_2e)
- A renewable portfolio standard for electricity production (21.3 MMT CO_2e)

CARB has identified a GHG reduction target of 5 MMT (of the 174 MMT total) local land use changes (Table 2 of CARB's Plan), by implementation of Reduction Strategy T-3 regarding Regional Transportation-Related GHG Targets. Additional land use reductions may be achieved as SB 375 is implemented. CARB's Scoping Plan states that successful implementation of the plan relies on local governments' land use, planning, and urban growth decisions because local governments have primary authority to plan, zone, approve, and permit land development to accommodate population growth and the changing needs of their jurisdictions. CARB further acknowledges that decisions on how land is used will have large effects on the GHG emissions that will result from the transportation, housing, industry, forestry, water, agriculture, electricity, and natural gas emission sectors. CARB's Scoping Plan does not include any direct discussion about GHG emissions generated by construction activity.

Table 3.6-1 shows the Recommended Actions contained in Appendices C and E of CARB's Scoping Plan.

TABLE 3.6-1
RECOMMENDED ACTIONS FROM CARB CLIMATE CHANGE SCOPING PLAN

ID #	Sector	Strategy Name
T-1	Transportation	Pavley I and II – Light-Duty Vehicle GHG Standards
T-2	Transportation	LCFS (Discrete Early Action)
T-3	Transportation	Regional Transportation-Related GHG Targets
T-4	Transportation	Vehicle Efficiency Measures
T-5	Transportation	Ship Electrification at Ports (Discrete Early Action)
T-6	Transportation	Goods-movement Efficiency Measures
T-7	Transportation	Heavy-Duty Vehicle GHG Emission Reduction Measure – Aerodynamic Efficiency (Discrete Early Action)
T-8	Transportation	Medium- and Heavy-Duty Vehicle Hybridization
T-9	Transportation	High-Speed Rail

TABLE 3.6-1 (CONTINUED)
RECOMMENDED ACTIONS FROM CARB CLIMATE CHANGE SCOPING PLAN

ID #	Sector	Strategy Name
E-1	Electricity and Natural Gas	Increased Utility Energy efficiency programs More stringent Building and Appliance Standards
E-2	Electricity and Natural Gas	Increase Combined Heat and Power Use by 30,000GWh
E-3	Electricity and Natural Gas	Renewables Portfolio Standard
E-4	Electricity and Natural Gas	Million Solar Roofs
CR-1	Electricity and Natural Gas	Energy Efficiency
CR-2	Electricity and Natural Gas	Solar Water Heating
GB-1	Green Buildings	Green Buildings
W-1	Water	Water Use Efficiency
W-2	Water	Water Recycling
W-3	Water	Water System Energy Efficiency
W-4	Water	Reuse Urban Runoff
W-5	Water	Increase Renewable Energy Production
W-6	Water	Public Goods Charge (Water)
I-1	Industry	Energy Efficiency and Co-benefits Audits for Large Industrial Sources
I-2	Industry	Oil and Gas Extraction GHG Emission Reduction
I-3	Industry	GHG Leak Reduction from Oil and Gas Transmission
I-4	Industry	Refinery Flare Recovery Process Improvements
I-5	Industry	Removal of CH_4 Exemption from Existing Refinery Regulations
RW-1	Recycling and Waste Management	Landfill CH_4 Control (Discrete Early Action)
RW-2	Recycling and Waste Management	Additional Reductions in Landfill CH_4 – Capture Improvements
RW-3	Recycling and Waste Management	High Recycling/Zero Waste
F-1	Forestry	Sustainable Forest Target
H-1	High GWP Gases	Motor Vehicle Air Conditioning Systems (Discrete Early Action)
H-2	High GWP Gases	SF_6 Limits in Non-Utility and Non-Semiconductor Applications (Discrete Early Action)
H-3	High GWP Gases	Reduction in Perfluorocarbons in Semiconductor Manufacturing (Discrete Early Action)
H-4	High GWP Gases	Limit High GWP Use in Consumer Products (Discrete Early Action, Adopted June 2008)
H-5	High GWP Gases	High GWP Reductions from Mobile Sources
H-6	High GWP Gases	High GWP Reductions from Stationary Sources
H-7[a]	High GWP Gases	Mitigation Fee on High GWP Gases
A-1	Agriculture	CH_4 Capture at Large Dairies

[a] This original measure in the 2008 Scoping Plan was subsequently excluded by CARB in the Final Supplement to the Scoping Plan Functional Equivalent Document in 2011, as CARB staff concluded that implementation of this measure would not be feasible.

SOURCE: CARB, 2008.

As discussed previously, a draft Update to the initial Scoping Plan was developed by CARB in collaboration with the CCAT to address the requirement by AB 32 that the Scoping Plan be updated at least every 5 years. The draft Update to the initial Scoping Plan developed by CARB in collaboration with the CCAT was presented to CARB's Board for discussion at its February 20, 2014 meeting. The draft Update builds upon the initial Scoping Plan with new strategies and expanded measures, and identifies opportunities to leverage existing and new funds to drive GHG emission reductions through strategic planning and targeted program investments. The first update to the AB 32 Scoping Plan was approved on May 22, 2014, by CARB.

As part of the proposed update to the Scoping Plan, the emissions reductions required to meet the 2020 statewide GHG emissions limit were further adjusted. The primary reason for adjusting the 2020 statewide emissions limit was based on the fact that the original Scoping Plan relied on the Intergovernmental Panel on Climate Change (IPCC) 1996 Second Assessment Report (SAR) to assign the GWPs of greenhouse gases. Recently, in accordance the United Nations Framework Convention on Climate Change (UNFCCC), international climate agencies have agreed to begin using the scientifically updated GWP values in the IPCC's Fourth Assessment Report (AR4) that was released in 2007. Because CARB has begun to transition to the use of the AR4 100-year GWPs in its climate change programs, CARB recalculated the Scoping Plan's 1990 GHG emissions level with the AR4 GWPs (CARB, 2014b).

CEQA Guidelines Revisions

In 2007, the State Legislature passed SB 97, which required amendment of the CEQA Guidelines to incorporate analysis of, and mitigation for, GHG emissions from projects subject to CEQA. The California Natural Resources Agency adopted these amendments on December 30, 2009, and they took effect on March 18, 2010, after review by the Office of Administrative Law and filing with the Secretary of State for inclusion in the CCR.

The Guidelines revisions include a new section (Section 15064.4) that specifically addresses the potential significance of GHG emissions. Section 15064.4 calls for a "good-faith effort" to "describe, calculate or estimate" GHG emissions; Section 15064.4 further states that the analysis of the significance of any GHG impacts should include consideration of the extent to which the project would increase or reduce GHG emissions; exceed a locally applicable threshold of significance; and comply with "regulations or requirements adopted to implement a statewide, regional, or local plan for the reduction or mitigation of greenhouse gas emissions." The new Guidelines also state that a project may be found to have a less-than-significant impact on GHG emissions if it complies with an adopted plan that includes specific measures to sufficiently reduce GHG emissions (Section 15064(h)(3)). The Guidelines do not, however, require or recommend a specific analytical methodology or provide quantitative criteria for determining the significance of GHG emissions.

Local

SCAQMD

As an interim method for determining significance under CEQA until statewide significance thresholds are established, SCAQMD developed a draft tiered flowchart in 2008 for determining significance thresholds for GHGs for projects where SCAQMD is acting as the lead agency. The SCAQMD flowchart uses a tiered approach in which a proposed program is deemed to have a less-than-significant impact related to GHG emissions when any of the following conditions are met:

- GHG emissions are within GHG budgets in an approved regional plan.

- Incremental increases in GHG emissions due to the project are below the defined Significance Screening Levels, or mitigated to less than the Significance Screening Levels.
- Performance standards are met by incorporating project design features and/or implementing emission reduction measures.
- Carbon offsets are made to achieve target significance screening level.

County of Los Angeles General Plan

The 1980 County of Los Angeles General Plan does not address GHG emissions and climate change. However, the Conservation and Open Space Element contains policies that would contribute to the reduction of GHG emissions (County of Los Angeles, 1980). These are as follows:

Policy 1: Actively support strict air quality regulations for mobile and stationary sources, and continued research to improve air quality. Promote vanpooling, carpooling and improved public transportation.

Policy 2: Support the conservation of energy and encourage the development and utilization of new energy sources including geothermal, thermal waste, solar, wind and ocean-related sources.

Policy 3: Promote the use of solar energy to the maximum extent possible.

The Air Quality Element of the Draft 2014 County of Los Angeles General Plan summarizes air quality issues and outlines goals and policies that will improve air quality and reduce GHG emissions (County of Los Angeles, 2014a). The policies that are most relevant to GHG emissions include:

Policy AQ 1.2: Encourage the use of low or no volatile organic compound (VOC) emitting materials.

Policy AQ 3.1: Facilitate the implementation and maintenance of the Community Climate Action Plan to ensure that the County reaches its climate change and greenhouse gas emission reduction goals.

Policy AQ 3.2: Reduce energy consumption in County operations by 20 percent by 2015.

Policy AQ 3.3: Reduce water consumption in County operations.

Policy AQ 3.4: Participate in local, regional and state programs to reduce greenhouse gas emissions.

Policy AQ 3.5: Encourage maximum amounts of energy conservation in new development and municipal operations.

Policy AQ 3.6: Support and expand urban forest programs within the unincorporated areas.

County of Los Angeles Community Climate Action Plan

The County of Los Angeles released its Final Draft Community Climate Action Plan (CCAP) in July 2014, which serves to mitigate and avoid GHG emissions associated with community activities in unincorporated Los Angeles County. The CCAP addresses emissions from building energy, land use and transportation, water consumption, and waste generation. The measures and actions outlined in the CCAP ties together the County's existing climate change initiatives and provide a blueprint for a more sustainable future. Ultimately, the CCAP and associated GHG reduction measures will be incorporated into the Air Quality Element of the Los Angeles County General Plan 2035.

Specifically, the CCAP will identify emissions related to community activities, establish a GHG reduction target consistent with AB 32, and provide a roadmap for successfully implementing GHG reduction measures selected by the County. Based on the CCAP's estimated amount of GHG emissions generated by community activities in the County's unincorporated areas in 2010, it was determined that building energy use is the largest source of emissions (49 percent), followed by transportation emissions from on- and off-road vehicles (42 percent) and community waste generation (7 percent). The remaining GHG emissions sources are water conveyance and wastewater generation (2 percent), agriculture (0.4 percent), and stationary sources (0.02 percent). The CCAP comprises a variety of state and local actions to reduce GHG emissions within the unincorporated areas. The state actions considered in the CCAP include: the Renewables Portfolio Standard, Title 24 Standards for Commercial and Residential Buildings (Energy Efficiency and CALGreen), Pavley/Advanced Clean Cars (Vehicle Efficiency), the LCFS, and the California cap-and-trade program. These state actions generally do not require action from the County, but will result in local GHG reductions in the unincorporated areas. To supplement these statewide initiatives, the CCAP has identified 26 local actions to reduce GHG emissions in the unincorporated areas of the County. Specifically, these 26 local actions are grouped into five strategy areas: green building and energy; land use and transportation; water conservation and wastewater; waste reduction, reuse, and recycling; and land conservation and tree planting. Many of the local actions will also be implemented through General Plan policies or other County ordinances. These actions undertaken as part of the CCAP will result in important community co-benefits, including improved air quality, energy savings, and increased mobility, as well as enhancing the resiliency of the community in the face of changing climate conditions. Overall, the goal of the CCAP, which will be a component of the Los Angeles County General Plan, will be to reduce GHG emissions from community activities in the unincorporated areas of Los Angeles County in a manner that is consistent with statewide goals outlined under AB 32 (County of Los Angeles, 2014b). The Final Draft CCAP is anticipated to be adopted with the County's General Plan update.

City General Plans

The numerous cities encompassed by the Enhanced Watershed Management Program (EWMP) area all have their own respective city General Plans, some of which may contain policies that address GHG emissions and climate change. As implementation of the individual structural Best Management Practice (BMP) projects proceed, specific policies and objectives pertaining to GHG emissions and/or climate change from applicable city General Plans will be identified and evaluated on a project-by-project basis during subsequent CEQA environmental processes.

3.6.3 Impact Assessment

Thresholds of Significance

Based on Appendix G of the CEQA Guidelines, a project would have a significant effect on GHG emissions if it would:

- Generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment.
- Conflict with any applicable plan, policy, or regulation of an agency adopted for the purpose of reducing the emissions of GHGs.

As noted, the increased concentration of GHGs in the atmosphere has been linked to global warming, which can lead to climate change. Construction of the structural BMPs would incrementally contribute to GHG emissions along with past, present and future activities. As such, impacts of GHG emissions are analyzed here on a cumulative basis.

Currently, LACFCD has not adopted any thresholds for GHG emissions. Additionally, while SCAQMD has issued proposed standards and guidelines, there is no adopted state or local standard for determining the cumulative significance of the proposed program's GHG emissions on global climate change. In December 2008, SCAQMD adopted a 10,000 metric tons of CO_2 equivalents ($MTCO_2e$)/year for industrial facilities, but only with respect to projects where SCAQMD is the lead agency. Additionally, SCAQMD has proposed, but not adopted, a 3,000 MT/year CO_2e threshold for mixed use developments, a 3,500 MT/year CO_2e threshold for residential developments, and a 1,400 MT/year CO_2e threshold for commercial developments. As an alternative to the aforementioned proposed thresholds for residential, commercial, and mixed-use developments, SCAQMD has also recommended the use of a single numerical threshold of 3,000 $MTCO_2e$/year for all non-industrial projects. These draft threshold options are being evaluated through the GHG Thresholds Working Group and have not been adopted as of this writing (SCAQMD, 2010).

For the purposes of this analysis, because the BMPs (structural and non-structural) associated with the proposed program are not residential, commercial, mixed-use, or industrial projects, the most appropriate threshold that would apply to the proposed program would be, although not formally adopted, the 3,000 $MTCO_2e$/year criteria recommended by SCAQMD.

Program Impact Discussion

Program-Generated GHG Emissions

Impact 3.6-1: The proposed program could generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment.

Structural (Regional, Centralized, and Distributed) BMPs

The proposed program would primarily generate GHG emissions during construction of the proposed structural BMP projects in the EWMP areas. The amount of program-related construction that would occur on an annual basis cannot be determined with any certainty at this time. As such, it is expected that the construction activities for the structural BMPs in the EWMP areas would occur intermittently throughout the course of the program implementation period. Construction-related GHG emissions associated with each structural BMP development would be short-term in nature and limited to the period of time when construction activity is taking place for that particular development. Applying the same approach that was used for the program's air quality analysis in Section 3.2, *Air Quality*, of this PEIR, the maximum annual construction-related GHG emissions for the three structural BMP project types were estimated using the California Emissions Estimator Model (CalEEMod) based on general information provided for the structural BMP projects and CalEEMod default settings along with reasonable assumptions based on other similar types of projects (refer to Tables 3.2-4, 3.2-5, and 3.2-6 in Section 3.2, *Air Quality,* of this PEIR, for the modeling parameters used in CalEEMod for the representative distributed, centralized, and regional structural BMPs, respectively). **Tables 3.6-2**, **3.6-3** and **3.6-4** summarize the modeled worst-case annual GHG emissions that are estimated to occur for a representative distributed, centralized, and regional structural BMP project, respectively.

TABLE 3.6-2
ESTIMATED CONSTRUCTION-RELATED GREENHOUSE GAS EMISSIONS – PROPOSED DISTRIBUTED BMP PROJECT

Emission Source	Proposed Program Emissions CO_2e (MT/yr)
Construction	
Total	53.52
Construction (Amortized over 30 years)	1.78

NOTES: CO_2e= carbon dioxide equivalent; MT/yr = metric tons per year; see Appendix C for CalEEMod model outputs.

SOURCE: Modeling performed by ESA, 2013.

TABLE 3.6-3
ESTIMATED CONSTRUCTION-RELATED GREENHOUSE GAS EMISSIONS – PROPOSED CENTRALIZED BMP PROJECT

Emission Source	Proposed Program Emissions CO_2e (MT/yr)
Construction	
Total	335.33
Construction (Amortized over 30 years)	11.18

CO_2e= carbon dioxide equivalent;
MT/yr = metric tons per year;
see Appendix C for CalEEMod model outputs.

SOURCE: Modeling performed by ESA, 2013.

TABLE 3.6-4
ESTIMATED CONSTRUCTION-RELATED GREENHOUSE GAS EMISSIONS – PROPOSED REGIONAL BMP PROJECT

Emission Source	Proposed Program Emissions CO_2e (MT/yr)
Construction	
Total	2,227.89
Construction (Amortized over 30 years)	74.26

NOTES: CO_2e= carbon dioxide equivalent; MT/yr = metric tons per year; see Appendix C for CalEEMod model outputs.

SOURCE: Modeling performed by ESA, 2013.

As shown in Tables 3.6-2, 3.6-3, and 3.6-4, the total construction-related GHG emissions resulting from representative distributed, centralized, and regional structural BMP projects would be 53.52 $MTCO_2e$/year, 335.33 $MTCO_2e$/year, and 2,227.89 $MTCO_2e$/year, respectively. For construction GHG emissions, SCAQMD recommends that the total construction emissions for a project be amortized over 30 years and added to its operational emission estimates (SCAQMD, 2008). Based on the emissions presented in the tables above, when the highest annual GHG emissions for a representative regional structural BMP project (2,227.89 $MTCO_2e$/year) is amortized over 30 years, the resulting annual emissions would be 74.26 $MTCO_2$/year. Because this annual emissions amount only represents approximately 2.5 percent of the SCAQMD's recommended threshold of 3,000 $MTCO_2e$/year for non-industrial projects, the construction-related GHG emissions generated would be relatively minimal.

Additionally, although the number of pumps that may be installed for some of the centralized and regional structural BMPs is unknown at this juncture, it is not anticipated that the annual GHG emissions contribution from the operation of these pumps would, when added to the annual construction-related emissions at these applicable structural BMP sites, result in total GHG emissions that exceed 3,000 $MTCO_2e$/year at an individual BMP site. Furthermore, because the structural BMPs introduced into the EWMP areas under the program are not land use projects that would generate vehicle trips, GHG emissions would not be generated by motor vehicles traveling to and from the various structural BMP sites on a daily basis. As it is anticipated that only periodic worker trips to the structural BMP sites throughout the year would be required for inspection and maintenance activities, and the mobile GHG emissions generated by these worker trips would be negligible. Thus, because the total GHG emissions generated by the largest structural BMP projects (i.e., regional structural BMPs) under a worst-case scenario would not exceed the 3,000 $MTCO_2e$/year benchmark, impacts associated with GHG emissions generated by the structural BMPs in the EWMP areas under the proposed program would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts related to program-generated GHG emissions.

Mitigation Measures: None required

Significance Determination: No impact

Consistency with GHG Emissions Reduction Plans or Policies

Impact 3.6-2: The proposed program could conflict with any applicable plan, policy, or regulation of an agency adopted for the purpose of reducing the emissions of GHGs.

As discussed in the impact analysis, the GHG emissions generated by each of the structural BMPs associated with the proposed program would not exceed the SCAQMD's recommended threshold of 3,000 $MTCO_2e$ /year for non-industrial projects. The primary source of GHG emissions generated by the majority of the structural BMPs would occur only during construction, which would be temporary in nature. Additionally, as the structural BMPs are not land use projects, GHG emissions associated with mobile sources would only occur from periodic vehicle trips by workers to the structural BMP sites for inspection and maintenance purposes, which would not generate substantial emissions. The annual GHG emissions associated with the operation of pumps at some of the centralized and regional structural BMP sites would also be minimal relative to the GHG emissions generated during construction of these structural BMPs. Consequently, the implementation of these structural BMPs in the EWMP areas under the program would not generate substantial amounts of GHG emissions that would hinder the State's ability to achieve AB 32's goal of achieving 1990 levels of GHG emissions by 2020.

Consistency with CARB Scoping Plan

Out of the Recommended Actions contained in CARB's Scoping Plan (see Table 3.6-1), the actions that are most applicable to the proposed program would be Action W-4 (Reuse Urban Runoff), which aims to reduce urban runoff by capturing and treating the runoff. The program's BMPs would be implemented for this purpose, reducing and treating urban runoff throughout the County of Los Angeles to comply with the MS4 Permit. Implementation of the structural BMPs in the EWMP areas would serve as GHG emission reduction measures that are consistent with this recommended action from the Scoping Plan. Therefore, the program would not conflict with the CARB scoping plan, and this impact would be less than significant.

Consistency with County of Los Angeles Community Climate Action Plan

As discussed previously, the County released its Final Draft CCAP in July 2014 that serves to mitigate and avoid GHG emissions associated with community activities in unincorporated Los Angeles County. The CCAP establishes a GHG reduction target that is consistent with AB 32. As part of the CCAP, 26 local actions have been identified to reduce GHG emissions in the unincorporated areas of the County. In particular, Measure WAW-2 (Recycled Water Use, Water

Supply Improvement Programs, and Stormwater Runoff) from the CCAP specifically aims to promote recycled water use and policies to better manage stormwater to protect local groundwater supplies. A part of the goal for this measure is to manage stormwater and protect local groundwater supplies. A specific implementation step associated with this measure identified in the CCAP is to expand the Low Impact Development (LID) stormwater catchment to more facilities where feasible in the County. Thus, the structural BMPs that would be implemented as part of the proposed program would be consistent with this GHG reduction measure of the CCAP. Therefore, the program would not conflict with the County's CCAP, and this impact would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no conflicts with any applicable plan, policy, or regulation of an agency adopted for the purpose of reducing the emissions of GHGs.

Mitigation Measures: None required

Significance Determination: No impact

Cumulative Impact Discussion

As discussed previously, CEQA considers a project's impacts related to GHG emissions inherently cumulative. Therefore, the discussion presented above comprises the cumulative impact analysis related to global warming and climate change. As concluded, because the GHG emissions generated by the individual structural BMP projects in the EWMP areas would not exceed SCAQMD's recommended threshold of 3,000 MT CO_2e /year for non-industrial projects, the BMPs implemented under the proposed program would not result in substantial GHG emissions into the environment. Additionally, because the proposed BMPs under the program would serve to capture, treat, and manage stormwater runoff in the EWMP areas, the program would also be consistent with the applicable actions and measures of the CARB's Scoping Plan and County's CCAP, respectively. Overall, the proposed program would result in less than significant GHG and climate change cumulative impacts.

Mitigation Measures: None required

Significance Determination: Less than significant

3.6.3 Summary of Impact Assessment

Table 3.6-5 shows a summary of the structural BMPs requiring mitigation.

TABLE 3.6-5
SUMMARY OF GREENHOUSE GAS IMPACTS REQUIRING MITIGATION MEASURES

	Thresholds of Significance		
Structural BMPs	**GHG Emissions**	**Consistency with Plans**	**Cumulative Impacts**
Applicable Mitigation Measures:	**None Required**	**None Required**	**None Required**
Regional BMPs			
Regional Detention and Infiltration	No	No	No
Regional Capture, Detention and Use	No	No	No
Centralized BMP			
Bioinfiltration	No	No	No
Constructed Wetlands	No	No	No
Treatment/Low Flow Diversions	No	No	No
Creek, River, Estuary Restoration	No	No	No
Distributed BMPs			
Site Scale Detention	No	No	No
LID – Infiltration/Filtration BMPs – Porous Pavement, Green Streets, Bioswale/Filter Strips, downspout disconnects	No	No	No
LID – Green Infrastructure – Capture and Use – Cisterns, Rain Barrels, Green roofs, Planter Boxes	No	No	No
Flow through Treatment BMPs	No	No	No
Source Control Treatment BMPs (catch basin inserts/screens, hydrodynamic separators, gross solids removal devices)	No	No	No
Low Flow Diversions	No	No	No

NOTE: These conclusions are based on typical BMP size and location

3.7 Hazards and Hazardous Materials

Potential hazards addressed in this section include uses of hazardous materials during the construction and operation of the proposed program, hazardous materials in soil and groundwater from existing contaminated sites, and hazards related to schools, airports, emergency preparedness, and wildfires. Mitigation measures to reduce impacts to a less-than-significant level are identified, as needed.

3.7.1 Environmental Setting

Hazardous Materials and Hazardous Waste

A hazardous material is defined as any material that, because of quantity, concentration, or physical or chemical characteristics, poses a significant present or potential hazard to human health and safety or to the environment if released into the workplace or the environment (Health and Safety Code §25501(o)). The term "hazardous materials" refers to both hazardous substances and hazardous wastes. Under federal and state laws, any material, including wastes, may be considered hazardous if it is specifically listed by statute as such or if it is toxic (causes adverse human health effects), ignitable (has the ability to burn), corrosive (causes severe burns or damage to materials), or reactive (causes explosions or generates toxic gases).

Hazardous wastes are hazardous substances that no longer have practical use, such as materials that have been spent, discarded, discharged, spilled, contaminated, or are being stored until they can be disposed of properly (22 California Code of Regulations [CCR] Section 66261.10). Soil that is excavated from a site containing hazardous materials is a hazardous waste if it exceeds specific 22 CCR criteria. While hazardous substances are regulated by multiple agencies, as described in the Regulatory Framework below, cleanup requirements of hazardous wastes are determined on a case-by-case basis according to the agency with lead jurisdiction over the project.

Preschools, schools, daycare centers, nursing homes, and hospitals are considered sensitive receptors for hazardous material issues because children and the elderly are more susceptible than adults to the effects of many hazardous materials. There are numerous sensitive receptors located throughout the proposed EWMPs or "program" service area.

Urban Runoff

Within the EWMP area, much of the environment has been developed, resulting in large areas of impervious surfaces that include rooftops, highways and roads, and other hardscapes. Stormwater and urban runoff from these impervious surfaces tends to pick up trash, sediment, and other pollutants including (US EPA, 2003):

- Sediment
- Fuels, oil, grease, and chemicals from motor vehicles and mechanized equipment
- Fertilizers, pesticides and herbicides from landscaping and gardens

- Viruses, bacteria, and nutrients from pet waste and failing septic systems
- Road salts
- Heavy metals from roof shingles, motor vehicles, and other sources

Impacted stormwater and urban runoff that is then directed to a structural Best Management Practices (BMPs) to retain and filter or infiltrate the runoff may accumulate concentrations of chemicals in the upper soils and/or filter media such as petroleum hydrocarbons (fuels, oils, and greases), metals (copper, lead and zinc), polycyclic aromatic hydrocarbons (created as combustion byproducts of gasoline and other fossil fuels), bacteria, nutrients (nitrogen, phosphorus, nitrate, and organic nitrogen), and pesticides.

Hazardous Material Sites

Hazardous materials are currently stored and used at numerous facilities and locations within the EWMP area for a variety of purposes. Some facilities within the area that use or store hazardous materials or hazardous wastes may have experienced unauthorized releases into soil or groundwater, and these releases may or may not have been reported to the appropriate agency or agencies.

In California, regulatory databases listing hazardous materials sites provided by numerous federal, state, and local agencies are consolidated in the "Cortese List" pursuant to Government Code Section 65962.5. The Cortese List is located on the website of the California Environmental Protection Agency (Cal EPA; http://www.calepa.ca.gov/sitecleanup/corteselist/) and is a compilation of the following lists:

- List of Hazardous Waste and Substances sites from Department of Toxic Substances Control (DTSC) EnviroStor database
- List of Leaking Underground Storage Tank Sites by County and Fiscal Year from the State Water Resources Control Board (SWRCB) GeoTracker database
- List of solid waste disposal sites identified by SWRCB with waste constituents above hazardous waste levels outside the waste management unit
- List of "active" Cease and Desist Orders and Cleanup and Abatement Orders from the SWRCB[1]
- List of hazardous waste facilities subject to corrective action pursuant to Section 25187.5 of the Health and Safety Code, identified by DTSC and listed on their EnviroStor database

The five databases cited above identify sites with suspected and confirmed releases of hazardous materials to the subsurface soil and/or groundwater. The SWRCB GeoTracker database includes

[1] This list contains many Cease and Desist Orders and Cleanup and Abatement Orders that do NOT concern the discharge of wastes that are hazardous materials. Many of the listed orders concern, for example, discharges of domestic sewage, food processing wastes, or sediment that do not contain hazardous materials, but the Water Boards' database does not distinguish between these types of orders. See more at: http://www.calepa.ca.gov/sitecleanup/corteselist/default.htm#sthash.oSjMvSw7.dpuf

leaking underground storage tanks (LUSTs), permitted underground storage tanks (USTs), and Spills, Leaks, Investigations, and Cleanup Database (SLIC) sites. The DTSC EnviroStor database includes federal and state response sites; voluntary, school, and military cleanups and corrective actions; and permitted sites. The reporting and statuses of these sites change as identification, monitoring, and cleanup of hazardous materials sites progress. Typically, a listed site is considered to no longer be of concern once it has been demonstrated that existing site uses combined with the levels of identified contamination present no significant risk to human health or the environment.

The Los Angeles County Fire Department (LACFD) is the designated Los Angeles County Certified Unified Program Agency (LAC CUPA), described further in the Regulatory Framework. The LAC CUPA is responsible for the regulatory oversight of aboveground storage tanks (ASTs) and USTs, county hazardous materials and waste programs, and the California Accidental Release Prevention (CalARP) Program. The LAC CUPA would be the primary source of information regarding hazardous materials use and hazardous waste disposal for facilities that are at or near proposed program within the EWMP area.

The DTSC delegated corrective action oversight authority to LAC CUPA under Chapter 6.5 of Division 20 of California Health and Safety Code to implement corrective action under consent agreement at LAC CUPA facilities within its jurisdiction.

Schools

Schools are considered sensitive receptors for hazardous materials because children are more susceptible than adults to the effects of hazardous materials. There are over a thousand public and private schools, colleges, and universities within Los Angeles County. The proximity of a proposed project to day care centers would also need to be considered.

Airports

Aviation safety hazards can result if projects are sited on or in the vicinity of airports. Specifically, the land use compatibility plans at airports have land use restrictions, such as height, distracting light or glare, and attractants to wildlife, such as birds. The Federal Aviation Administration (FAA) Advisory Circular No: 150/5200-33B provides guidance on development projects affecting aircraft movement near hazardous wildlife attractants (FAA, 2007). The following list indicates the minimum separation criteria for specific aircraft types:

- Airports Serving Piston-Powered Aircraft: Airports that do not sell Jet-A fuel normally serve piston-powered aircraft (propeller-powered). General aviation airports typically serve piston-powered aircraft. However, there are exceptions. For example, the Santa Monica Airport is a general aviation airport but does serve turbine-powered aircraft. The FAA recommends a separation distance of 5,000 feet at these airports for hazardous wildlife attractants. This distance is to be maintained between an airport's air operations area (AOA) and the hazardous wildlife attractant.
- Airports Serving Turbine-Powered Aircraft: Airports selling Jet-A fuel normally serve turbine-powered aircraft (jet- or turbo-prop-powered). The FAA recommends a

separation distance of 10,000 feet at these airports for hazardous wildlife attractants. This distance is to be maintained between an airport's AOA and the hazardous wildlife attractant.

- Protection of Approach, Departure, and Circling Airspace: For all airports, the FAA recommends a distance of 5 statute miles between the farthest edges of the airport's AOA and the hazardous wildlife attractant if the attractant could cause hazardous wildlife movement into or across the approach or departure airspace.

Specific information of the types of aircraft using a particular airport, airport land use compatibility plans, and land use maps for airports within Los Angeles County is available at the Los Angeles County Airport Land Use Commission website at http://planning.lacounty.gov/aluc/airports.

Emergency Preparedness

Los Angeles County Office of Emergency Management (LAC OEM) is the designated lead agency for emergency response and coordinates the development, maintenance, and implementation of the Los Angeles County Operational Area Emergency Response Plan (http://lacoa.org/oaerp.htm). This Plan serves as a guide for the County's response to emergencies/disasters in the County.

Wildfires

Both the State of California and the County of Los Angeles Fire Department map the Fire Hazard Severity Zones (FHSZs) within Los Angeles County. The FHSZs are based on an evaluation of fire history, existing and potential fuel, flame length, blowing embers, terrain, weather, and the likelihood of buildings igniting (California Department of Forestry and Fire Protection, 2012). **Figure 3.7-1** presents the countywide FHSZ map for the state responsibility areas. **Figure 3.7-2** presents the countywide FHSZ map for the county responsibility areas. The very high FHSZ areas tend to be outside of the urban developed areas in areas with flammable vegetation, such as brush.

3.7.2 Regulatory Framework

Hazards and hazardous materials are subject to numerous federal, state, and local laws and regulations intended to protect health, safety, and the environment. The U.S. Environmental Protection Agency (USEPA), the California DTSC, RWQCB, and the County of Los Angeles are the primary agencies enforcing these regulations. Local regulatory agencies enforce many federal and state regulations through the CUPA program. In 1997, LACFD Health Hazardous Materials Division became the LAC CUPA for the Hazardous Waste Generator Program, the Hazardous Materials Release Response Plans and Inventory Program, the CalARP Program, and the Aboveground Storage Tank Program and the Underground Storage Tank Program in Los Angeles County.

Federal

Primary federal agencies with responsibility for hazardous materials management include the USEPA, Department of Labor (Federal Occupational Health and Safety Administration [OSHA]), and Department of Transportation (DOT). Major federal laws and issue areas include the following statutes (and regulations promulgated there under):

- Resources Conservation and Recovery Act (RCRA) 42 USC 6901 et seq. – RCRA is the principal law governing the management and disposal of hazardous materials. RCRA is considered a “cradle to grave” statute for hazardous wastes in that it addresses all aspects of hazardous materials from creation to disposal. Federal regulations for USTs derive from RCRA. RCRA applies to this program because RCRA is used to define hazardous materials.
- Emergency Planning and Community Right-to-Know Act (EPCRA from SARA Title III) – EPCRA improved community access to information regarding chemical hazards and facilitated the development of business chemical inventories and emergency response plans. EPCRA also established reporting obligations for facilities that store or manage specified chemicals. EPCRA applies to this program because the contractors that construct the structural BMPs will be required to prepare and implement written emergency response plans to properly manage hazardous materials during construction and respond to accidental spills.
- DOT Hazardous Materials Transportation Act (49 USC 5101) – DOT, in conjunction with the USEPA, is responsible for enforcement and implementation of federal laws and regulations pertaining to safe storage and transportation of hazardous materials. The Code of Federal Regulations (CFR) 49, 171–180, regulates the transportation of hazardous materials, types of material defined as hazardous, and the marking of vehicles transporting hazardous materials. This Act applies to this program because contractors will be required to comply with its storage and transportation requirements that would reduce the possibility of spills.
- The Federal Motor Carrier Safety Administration (49 CFR Part 382) – The Federal Motor Carrier Safety Administration, a part of the DOT, issues regulations concerning highway routing of hazardous materials, the hazardous materials endorsement for a commercial

driver's license, highway hazardous material safety permits, and financial responsibility requirements for motor carriers of hazardous materials. This Act applies to this program because contractors will be required to comply with its storage and transportation requirements that would reduce the possibility of spills.

- Occupational Safety and Health Administration (OSHA; 29 USC 15) – OSHA is the federal agency responsible for ensuring worker safety. These regulations provide standards for safe workplaces and work practices, including those relating to hazardous materials handling. OSHA applies to this program because contractors will be required to comply with its hazardous materials management and handling requirements that would reduce the possibility of spills.
- The FAA Advisory Circular No: 150/5200-33B – The FAA Advisory Circular provides guidance on development projects affecting aircraft movement near hazardous wildlife attractants (FAA, 2007). This Circular applies to this program because BMPs will be required to comply with its restrictions if at or near airports.

State

The primary State agencies with jurisdiction over hazardous chemical materials management are the DTSC and the RWQCB. Other State agencies involved in hazardous materials management are the Department of Industrial Relations (State OSHA implementation), State Office of Emergency Services (OES)—CalARP implementation, California Air Resources Board (CARB), California Department of Transportation (Caltrans), State Office of Environmental Health Hazard Assessment (OEHHA—Proposition 65 implementation) and California Integrated Waste Management Board (CIWMB). Hazardous materials management laws in California include the following statutes and regulations promulgated there under.

- Hazardous Waste Control Act (HWCA; California Health and Safety Code, Section 25100 et seq.) – The HWCA is the state equivalent of RCRA and regulates the generation, treatment, storage, and disposal of hazardous waste. This act implements the RCRA "cradle-to-grave" waste management system in California but is more stringent in its regulation of non-RCRA wastes, spent lubricating oil, small-quantity generators, transportation and permitting requirements, as well as in its penalties for violations. HWCA applies to this program because contractors will be required to comply with its hazardous waste requirements that would reduce the possibility of spills.
- California Hazardous Materials Release Response Plans and Inventory Law of 1985 (Business Plan Act) – The Business Plan Act requires preparation of hazardous materials business plans and disclosure of hazardous materials inventories, including an inventory of hazardous materials handled, plans showing where hazardous materials are stored, an emergency response plan, and provisions for employee training in safety and emergency response procedures (California Health and Safety Code, Division 20, Chapter 6.95, Article 1). Statewide, DTSC has primary regulatory responsibility for management of hazardous materials, with delegation of authority to local jurisdictions that enter into agreements with the state. Local agencies are responsible for administering these regulations.

Several state agencies regulate the transportation and use of hazardous materials to minimize potential risks to public health and safety, including CalEPA and the California Emergency Management Agency. The California Highway Patrol and Caltrans enforce regulations specifically related to the transport of hazardous materials. Together, these agencies determine container types used and license hazardous waste haulers for hazardous waste transportation on public roadways.

The Business Plan Act applies to this program because contractors will be required to comply with its handling, storage, and transportation requirements that would reduce the possibility of spills, and to prepare an emergency response plan to respond to accidental spills.

- California Division of Occupational Safety and Health (Cal/OSHA) – Cal/OSHA is responsible for developing and enforcing workplace safety standards and assuring worker safety in the handling and use of hazardous materials. Among other requirements, Cal/OSHA requires many entities to prepare injury and illness prevention plans and chemical hygiene plans, and provides specific regulations to limit exposure of construction workers to lead. OSHA applies to this program because contractors will be required to comply with its handling and use requirements that would reduce the possibility of spills, and to prepare an emergency response plan to respond to accidental spills.
- California Vehicle Code Section 38366 – The California Vehicle Code, Section 38366, requires spark-arresting equipment on vehicles that travel off-road. This code applies to the program because the vehicles that construct structural BMPs in off-road areas will be required to have spark-arresting equipment to reduce the risk of wildfires.

Local

Certified Unified Program Agency

In 1993, Senate Bill (SB) 1082 was passed by the State Legislature to streamline the permitting process for those businesses that use, store, or manufacture hazardous materials. The passage of SB 1082 provided for the designation of a CUPA that would be responsible for the permitting process and collection of fees. The CUPA would be responsible for implementing at the local level the Unified Program, which serves to consolidate, coordinate, and make consistent the administrative requirements, permits, inspections, and enforcement activities for the following environmental and emergency management programs:

- Hazardous Materials Release Response Plans and Inventories (Business Plans)
- California Accidental Release Prevention (CalARP) Program
- Underground Storage Tank Program
- Aboveground Petroleum Storage Act Requirements for Spill Prevention, Control and Countermeasure (SPCC) Plans
- Hazardous Waste Generator and On-Site Hazardous Waste Treatment (tiered permitting) Programs

- California Uniform Fire Code: Hazardous Material Management Plans and Hazardous Material Inventory Statements

The CUPA in Los Angeles County is the LACoFD. As such, the Department is given the primary regulatory responsibility for implementing and managing the above-listed programs.

Los Angeles County Operational Area Emergency Response Plan

In 1998, the County of Los Angeles adopted the Los Angeles County Operational Area Emergency Response Plan, which provides emergency planning for the Los Angeles County Operational Area, an area that includes the project area. The purpose of this plan is to increase cooperation and coordination between relevant government agencies and jurisdictions in order to increase efficiency and minimize losses in the event of an emergency or disaster within the Operational Area (County of Los Angeles 1998).

Los Angeles County Fire Department Wildfire Action Plan

In 2009, the LACFD adopted a Wildfire Action Plan, which contains guidelines that recommend fire prevention measures such as creating defensible space and completing fire-resistive retrofits in homes (LACFD 2009). In addition, this plan provides residents with information regarding emergency preparedness and planning in the event of a wildfire.

Los Angeles County General Plan

A General Plan is a basic planning document that, alongside the zoning code, governs development in a city or county. The State requires each city and county to adopt a General Plan with seven mandatory elements: land use, open space, circulation, housing, noise, conservation, and safety, along with any number of optional elements as appropriate. The proposed EWMPs would be subject to local plans and policies of the areas in which they are located.

The County of Los Angeles is currently updating their General Plan from the element versions adopted in the 1980s and 1990s; the new comprehensive plan is expected to be complete by late 2014. Below are the relevant goals and policies from both the existing General Plan (County of Los Angeles, 1980, 1990) and the Draft General Plan 2035 (County of Los Angeles, 2014a) which relate to the EWMP.

Existing General Plan – Safety Element, Adopted 1990

Goal: Reduce threats to public safety and protect property from wildland and urban fire hazards.

Policy 16: Continue to coordinate firefighting efforts with State, Federal and local agencies in fire hazard areas; and review and update mutual and automatic aid agreements between the County and other fire protection agencies.

Policy 19: Promote improved watershed management practices to reduce the risk of damaging runoff and debris movement into urban areas.

Goal: Reduce threats to public safety and protect property from hazardous materials.

Policy 20: Review proposed development projects involving the use or storage of hazardous materials, and disapprove proposals which cannot properly mitigate unacceptable threats to public health and safety to the satisfaction of responsible agencies.

Policy 21: Promote the safe transportation of hazardous materials.

Policy 22: Encourage businesses and organizations which store and us hazardous materials to improve management and transportation of such materials.

Policy 24: Encourage improved, timely communication between businesses and emergency response agencies regarding hazardous materials/waste incidents.

Draft General Plan, 2014 – Conservation and Natural Resources Element

Goal – C/NR-5: Protected and useable local surface water resources.

Policy C/NR 5.6: Minimize point and non-point source water pollution.

Goal – C/NR-6: Protected and usable local groundwater resources.

Policy C/NR 6.5: Prevent stormwater infiltration where inappropriate and unsafe, such as in areas with high seasonal groundwater, on hazardous slopes, within 100 feet of drinking water wells, and in contaminated soils.

County of Los Angeles Low Impact Development Manual

The County of Los Angeles (County) prepared the 2014 Low Impact Development Standards Manual (LID Standards) to comply with the requirements of the National Pollutant Discharge Elimination System (NPDES) Municipal Separate Storm Sewer System (MS4) Permit for stormwater and non-stormwater discharges from the MS4 within the coastal watersheds of Los Angeles County (CAS004001, Order No. R4-2012-0175), referred to as the 2012 MS4 Permit (County of Los Angeles, 2014b). The LID Standards provide guidance for the implementation of stormwater quality control measures in new development and redevelopment projects in unincorporated areas of the County with the intention of improving water quality and mitigating potential water quality impacts from stormwater and non-stormwater discharges.

The November 2013 LID Ordinance became effective December 5, 2013, and requires that all Designated, Non-Designated, street and road construction, and single family hillside home projects comply with Los Angeles County Code Title 12, Chapter 84. The LID Standards were prepared to complement and be consistent with the November 2013 LID Ordinance requirements.

The LID Standards address the following objectives and goals:

- Lessen the adverse impacts of stormwater runoff from development and urban runoff on natural drainage systems, receiving waters, and other water bodies;

- Minimize pollutant loadings from impervious surfaces by requiring development projects to incorporate properly-designed, technically-appropriate BMPs and other LID strategies; and
- Minimize erosion and other hydrologic impacts on natural drainage systems by requiring development projects to incorporate properly-designed, technically appropriate hydromodification control development principles and technologies.

City of Los Angeles Low Impact Development Manual

In November 2011, the City of Los Angeles adopted the Stormwater Low Impact Development (LID) Ordinance #181899) with the stated purpose of:

- Requiring the use of LID Standards and practices in future developments and redevelopments to encourage the beneficial use of rainwater and urban runoff
- Reducing stormwater/urban runoff while improving water quality
- Promoting rainwater harvesting
- Reducing off-site runoff and providing increased groundwater recharge
- Reducing erosion and hydrologic impacts downstream
- Enhancing the recreational and aesthetic values in our communities

The City institutionalized the use of LID techniques for development and redevelopment projects. Subsequent to the adoption of the Stormwater LID Ordinance, the City prepared the *Development Best Management Practices Handbook, Low Impact Development Manual,* dated June 2011, to describes the required BMPs (City of Los Angeles, 2011).

Other Cities LID

Various other cities within the County also have LID standards or guidance. The goals, objectives, and content of the LID document are similar to that of the County and City of Los Angeles, and are not referenced here.

City General Plans

The numerous cities encompassed by the EWMP area all have their own respective city General Plans, some of which may contain policies that address hazards and hazardous materials. As implementation of the individual structural BMP projects proceed, specific policies and objectives pertaining to hazards and hazardous materials from applicable city General Plans will be identified and evaluated on a project-by-project basis during subsequent CEQA environmental processes.

3.7.3 Impact Analysis

The proposed program's potential impacts were assessed using the CEQA Guidelines Appendix G Checklist. The following sections discuss the key issue areas identified in the CEQA Guidelines with respect to the program's potential hazard and hazardous material impacts.

Thresholds of Significance

Implementation of the proposed program may result in a potentially significant impact if any one of the following conditions would occur:

- Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials.
- Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment.
- Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school.
- Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would it create a significant hazard to the public or the environment.
- For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project result in a safety hazard for people residing or working in the project area.
- For a project within the vicinity of a private airstrip, would the project result in a safety hazard for people residing or working in the project area.
- Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan.
- Expose people or structures to a significant risk of loss, injury, or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands.

Project Impact Discussion

Routine Hazardous Materials Transport, Storage, Use, and Disposal and Accidental Release of Hazardous Materials Related to Construction and Maintenance

Impact 3.7-1: The proposed program would create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials or the accidental release during construction and maintenance activities.

Structural (Regional, Centralized, and Distributed) BMPs

Construction activities required for implementation of proposed program would potentially involve excavation, grading, drilling, trenching, and other ground-disturbing activities. Once constructed, the structural BMPs would require periodic maintenance activities such as channel clearing of sediment and vegetation maintenance that could include the use of chainsaws and weed- whackers that require fuel and oil. These anticipated construction and maintenance activities would likely require the transport, storage, use, and disposal of small amounts of hazardous materials, including fuels (e.g., gasoline, diesel), hydraulic fluids, oils and lubricants, paint, and other similarly related materials in varying quantities on each project site. The release of these materials could occur during routine transport, disposal, or use, and could potentially injure construction workers, contaminate soil, and/or affect habitats, surface water bodies, or groundwater. Impacts associated with release, although likely localized and short-term, could potentially create a significant hazard to the public or the environment.

The majority of BMPs are more likely to be smaller-scale, site- or parcel-specific distributed type BMPs that do not use chemicals for treatment. Distributed BMPs primarily use passive treatment techniques that capture stormwater and then reduce pollutant loads and stormwater volumes through containment, filtration, infiltration, and/or treatment techniques. Stormwater is directed to these BMPs and contained or stored to settle or filter out sediment and trash load (e.g., detention basins and ponds, debris booms and nets), and then allow the stormwater to infiltrate or filter through pervious surfaces that can be vegetated (e.g., bioswales, green streets, planter boxes, bioretention, bioswales, planter boxes, green streets).

The regional and centralized structural BMPs that include the construction of a smaller number of larger physical structures would use more equipment and materials, and could use larger volumes of potentially hazardous materials for longer periods of time. For example, low flow diversion structures may require chlorine treatment facilities rather than discharge to the sewer for treatment, in which case larger volumes of chlorine would be required to be stored on-site. However, the materials used would mostly be chemicals, fuels, oils, and lubricants, all of which are relatively common to store, transport, and handle. In the unlikely event of a spill, these petroleum products are relatively easy to clean up, treat, or biodegrade. Hazardous materials that are more difficult to treat, such as solvents and metals, would not be expected to be used or released in large quantities. Centralized structural BMPs that are treatment facilities may use treatment chemicals, such as chlorine depending on the treatment techniques (other options include ozone, ultraviolet, or electrocoagulation), and the structures may be painted. However, chlorination and dechlorination uses should consider proximity to residential areas for safety reasons, as well as access for chemical deliveries.

The implementing agency and construction contractor would be required to comply with all relevant and applicable federal, state, and local laws and regulations that pertain to the transport, storage, use, and disposal of hazardous materials and waste during construction of the proposed program. Because the implementing agency and its contractor would be required to comply with all relevant laws and regulations associated with the transport, storage, use, and disposal of hazardous materials and waste, the construction impacts would be less than significant.

Operation of proposed structural BMPs would generally require minimal to no transport, usage, or disposal of hazardous materials for activities such as maintaining detention basins, constructed wetlands, or infiltration galleries, which would require periodic transport and use of chemicals for purposes of operating equipment (e.g., weed-whackers), maintenance activities, and the transport of workers in vehicles. The implementing agency would be required to comply with all relevant and applicable federal, state, and local laws and regulations that pertain to the transport, storage, use, and disposal of hazardous materials and waste during operation of the proposed program.

Under the Unified Program, the CalARP Program requires facilities that use regulated substances to develop a Risk Management Plan (RMP). A RMP would be required for the proposed program that uses hazardous materials. The RMP would be kept on file with the LACFD, in addition to a Hazardous Materials Release Response Plan within a Hazardous Materials Business Plan (HMBP). Existing treatment plants that undergo expansion will require an updated RMP and HMBP to include new facilities and any associated hazardous material use, storage, or transport. These are public documents that reflect a facility's overall effort to manage and prevent risks associated with the storage, use, and/or processing of regulated substances.

The California Hazardous Materials Release Response Plans and Inventory Program (CCR Title 19, Division 2, Chapter 4) requires companies that store, use, and/or transport hazardous materials to prepare a HMBP that includes an inventory of hazardous substances and an Emergency Response Plan (ERP) to address emergencies such as accidental releases. For example, a contractor using fuels for chainsaws and weed-whackers to control vegetation at detention basins and infiltration galleries would be required to prepare and implement an HMBP and an ERP for their company activities. The ERP would include procedures for responding to accidental spills of fuels that might occur at any site they work at. The ERP would describe the cleanup procedures to be implemented in the event of an accidental release.

In addition, the transport of hazardous materials is regulated by Caltrans. Transporters of hazardous waste would be required to be certified by Caltrans. All hazardous materials would be tracked by Caltrans and delivery vehicles would be required to use roadways approved for transportation of hazardous materials and maintain the proper storage containers for hazardous materials.

Implementation of the RMP, HMBP, and ERP and compliance with existing regulations would reduce potential risks to the public and environment due to accidental release of hazardous materials to less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no new facilities that would require additional or new use of hazardous materials. While the non-structural BMPs would include a broad range of municipal practices such as street cleaning, landscape management, storm drain operation, and more, which does produce debris and trash for disposal, the materials collected are not considered hazardous waste or materials requiring hazardous waste disposal. Regular street sweeping is one of the most cost-effective non-structural BMPs used to remove sediment, metals, petroleum products, trash, and vegetation that accumulate on streets. Maintaining a regular street sweeping schedule reduces the buildup of trash on streets and prevents trash from entering catch basins and the storm drain system. The trash removed is disposed of in local landfills. Therefore, this program would have no impact relative to the routine use of hazardous materials.

Mitigation Measures: None required

Significance Determination: Less than significant

Accumulation of Potentially Hazardous Materials into BMPs

Impact 3.7-2: The proposed program could create a significant hazard to the public or the environment through the accumulation of potentially hazardous materials into BMPs.

Structural (Regional, Centralized, and Distributed) BMPs

The existing storm sewer systems convey stormwater and dry-weather flows to receiving waters that ultimately flow to the ocean. Operation of structural BMPs would not increase the potential for accidental releases of hazardous materials into the environment. Because of their function as water conveyance systems, the entire storm sewer system, as augmented by structural BMPs, would collect and retain sediment and chemicals from urban runoff, along with any accidental or illicit spills of hazardous materials. The introduction of hazardous materials into the storm sewer system could occur in large events as in a catastrophic spill, or could occur in small concentrations as in petroleum hydrocarbons and heavy metals picked up and carried by stormwater in urban runoff from the streets. Contaminants in the runoff water or as discrete concentrated spills could accumulate in the soils and vegetation of structural BMPs, as discussed below.

In the case of large spills that occur within the capture area of a BMP, regional BMPs would retain the spill and prevent any further contamination downstream since they would be designed to retain in-flow. Centralized BMPs, although generally designed to use flow-through or filter techniques, would still slow and retain much of the spill volume. Even distributed BMPs would slow and retain spills, although on a smaller scale. This retention would help to minimize impacts of large spills compared to existing conditions. Responding to major spills is the responsibility of local municipalities, usually led by the local fire department. Local jurisdictions prepare spill response plans that outline measures to contain and remediate spills of all kinds. The LAC OEM leads emergency response activities within Los Angeles County that would include responses to large hazardous spills. LAC OEM has prepared an Emergency Response Plan to coordinate response efforts. The responsibility for responding to and remediating spills would be similar to existing conditions.

All BMPs (regional, centralized, and distributed) would require cleanup following a spill event. Large spills could adversely affect the treatment systems including natural vegetation and filter matrices, including soil. Implementation of the BMPs would serve to add some protection against accidental or illicit spills compared with existing conditions. Cleanup of major spills would be coordinated through the LAC OEM in coordination with applicable regulations and regulatory agencies, specifically the RWQCB or the Department of Toxic Substance Control (DTSC).

In the case of small concentrations of contaminants either from small spills or the accumulation of contaminants from urban runoff, BMPs would collect and retain pollutants on site. Potential contaminants include typical urban runoff contaminants, such as fuels, oil and grease, pesticides, PCBs, PAHs, metals, and nutrients, as well as sediment that would clog filter media (e.g., soil) or reduce volume capacity of the receiving BMP. Over time, infiltration of stormwater runoff could increase contaminant loading in shallow soils and groundwater. Contaminants behave differently when filtered through native soils. Some contaminants (e.g., oil, grease, metals) adsorb onto surficial soils and remain within a few feet of the surface, while other more soluble contaminants (e.g., fuels, nitrate, and phosphate) may be entrained to deeper soils or migrate all the way to the groundwater. Over a long period of time, concentrations of these contaminants could increase resulting in contaminated soils and groundwater. Pretreatment of source water in areas with the potential for heavy contaminant loading would be implemented as a required design feature for regional and centralized BMPs to assist in reducing long-term loading. In addition, non-structural source control BMPs would help reduce contaminant loading over time. The LID Standards for the County of Los Angeles and the various cities participating in the EWMP provide protocols for designing regional and centralized BMPs that minimize the potential for contaminant loading. For example, the LID Manual requires a certain distance to groundwater to ensure that adequate soil filtration occurs prior to the percolating water reaching a drinking water aquifer.

Distributed BMPs, although on a smaller parcel or site scale, would also be designed to collect and treat stormwater to reduce the loading of the smaller amounts of contaminants transported by their relatively smaller receiving areas. This would reduce contaminant loading to receiving waters compared with existing conditions while capturing contaminants in filter media. The vegetation and microbial activity in soil would work to biodegrade the typical fuels, oil, and grease in local urban runoff.

To address the accumulation of contaminants in soil at BMPs, operations and maintenance plans for BMPs that might accumulate constituents in surface soils and media will be developed to include periodic removal and replacement of these potentially impacted surface materials to reduce the potential for long-term loading leading to hazardous concentrations in soils and groundwater. Implementation of **Mitigation Measure HAZ-1** would reduce the potential for impacts to less-than-significant levels.

Mitigation Measure:

HAZ-1: Implementing agencies shall prepare and implement maintenance practices that include periodic removal and replacement of surface soils and media that may accumulate constituents that could result in further migration of constituents to sub-soils and groundwater. A BMP Maintenance Plan shall be prepared by Implementing Agencies upon approval of the BMP projects ,that identifies the frequency and procedures for removal and/or replacement of accumulated debris, surface soils and/or media (to depth where constituent concentrations do not represent a hazardous conditions and/or have the potential to migrate further and impact groundwater) to avoid accumulation of hazardous concentrations and the potential to migrate further to sub-soils and groundwater. The BMP Maintenance Plan may consist of a general maintenance guideline that applies to several types of smaller distributed BMPs. For smaller distributed BMPs on private property, these plans may consist of a maintenance covenant that includes requirements to avoid the accumulation of hazardous concentrations in these BMPs that may impact underlying sub-soils and groundwater. Structural BMPs shall be designed to prevent migration of constituents that may impact groundwater.

Significance Determination: Less than significant with mitigation (The application of this mitigation measure to specific BMP types and categories are identified in Table 3.7-1.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. As a result, there would be no new facilities that would require additional or new use of hazardous materials. Therefore, this impact would have no impact relative to the accidental release of hazardous materials.

Mitigation Measures: None required

Significance Determination: Less than significant

Hazardous Materials near Schools

Impact 3.7-3: The proposed program could emit hazardous emissions or handle hazardous or acutely hazardous material, substances, or waste within one-quarter mile of an existing school.

Structural (Regional, Centralized, and Distributed) BMPs

BMPs may be installed throughout the watersheds. Some facilities may be installed within one-quarter mile of a school. Because construction and operation activities could potentially involve hazardous materials, the proposed program would have the potential to emit hazardous emissions or handle hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school. In addition, BMPs that are constructed on school properties may collect spills from off-site sources or accumulate contaminants from urban runoff in soil in the BMPs over time.

As discussed in Impact 3.7-1, individual BMP projects would be required to comply with regulations that would avoid or minimize the potential for releases of hazardous materials during the construction of the BMPs, in response to accidental spills either during the construction of the BMP, or as a result of the BMP collecting contaminants from an off-site spill. Air quality emissions are discussed in Section 3.2. Therefore, the potential impacts to nearby schools are considered less than significant.

As discussed in Impact 3.7-2, BMPs that use soil to filter contaminants from urban runoff may accumulate contaminants over time. Implementation of the Mitigation Measure HAZ-1 discussed above would reduce the potential for impacts to less than significant levels.

Mitigation Measure: HAZ-1

Significance Determination: Less than significant with mitigation (The application of this mitigation measure to specific BMP types and categories are identified in Table 3.7-1.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no new facilities that would require additional or new use of hazardous materials. Therefore, this impact would have no impact relative to schools.

Mitigation Measures: None required

Significance Determination: Less than significant

Hazardous Materials Sites

Impact 3.7-4: The proposed program could be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, could create a significant hazard to the public or the environment.

Structural (Regional, Centralized, and Distributed) BMPs

If a BMP were to be located on a hazardous materials site, construction workers could be exposed to hazardous materials during earth-moving activities. In addition, the earth-moving activities could mobilize hazardous materials to downslope or downgradient locations. If a BMP were to be located downslope or downgradient of a hazardous materials site, construction workers at the selected proposed project could be exposed to hazardous materials migrating from the nearby site. This could be considered a significant impact requiring mitigation.

As discussed in Section 3.7.1, information on the presence of known hazardous materials sites is provided within the databases that make up the Cortese List, which includes information on hazardous materials sites from five regulatory agency lists. In addition, the LACFD is the designated LAC CUPA and maintains a list of sites under its responsibility. Reviewing these lists would identify known hazardous materials sites. It is possible that a proposed project may be on an unknown hazardous materials site not yet included in the databases. Contaminated soil and/or groundwater could be encountered during excavation posing a health hazard to construction crews, the public, and the environment. Implementation of **Mitigation Measure HAZ-2** would reduce the potential impact to less than significant.

Mitigation Measure:

HAZ-2: Prior to the initiation of any construction requiring ground-disturbing activities in areas where hazardous material use or management may have occurred, the implementing agencies shall complete a Phase I Environmental Site Assessment (ESA) in accordance with American Society for Testing and Materials Standard E1527-13 for each construction site. Any recommended follow up sampling (Phase II activities) set forth in the Phase I ESA shall be implemented prior to construction. The results of Phase II studies, if necessary, shall be submitted to the local overseeing agency and any required remediation or further delineation of identified contamination shall be completed prior to commencement of construction.

Significance Determination: Less than significant with mitigation (The application of this mitigation measure to specific BMP types and categories are identified in Table 3.7-1.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no new facilities that would require additional or new use of hazardous materials. Therefore, this impact would have no impact relative to known hazardous materials sites.

Mitigation Measures: None required

Significance Determination: Less than significant

Hazards near Public or Private Airports and Airstrips

Impact 3.7-5: For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, for a project within the vicinity of a private airstrip, the project could result in a safety hazard for people residing or working in the project area.

Structural (Regional, Centralized, and Distributed) BMPs

Aviation safety hazards can result if projects are sited in the vicinity of airports. Specifically, the land use compatibility plans at airports have land use restrictions, such as height, distracting light or glare, and attraction of birds. The construction of an object high enough to intersect the flight path of aircraft would result in aircraft collision hazards and risks of death or injury to people in the aircraft and on the ground if the aircraft crashes. Similar hazards would be created if a proposed project were to result in distracting light or glare that could interfere with a pilot's ability to control the flight path of the aircraft, or if a proposed project were to create an attraction to wildlife, especially birds, that would pose hazards to aircraft.

The paved areas of airports (excluding the landing areas and taxiways, which have specific aircraft support requirements), and the undeveloped buffer zones around airports are potential sites for BMPs. Paved areas not used by aircraft could use permeable pavement and rainwater from buildings and paved areas could be routed to infiltration basins, bioswales, and subsurface infiltration galleries.

None of the proposed structural BMPs would result in the construction of structures of significant height or generating significant glare or distracting light. Larger regional or centralized BMPs, such as treatment facilities or larger aboveground detention basins would not be permitted within the landing and takeoff flight paths. However, some structural BMPs, such as detention basins that store water for a period of time or constructed wetlands that would increase or improve wildlife habitat, could be constructed on or near airports and could result in attracting wildlife. Deer and birds are known wildlife hazards to airports. If the proposed project is at or near an airport, this could increase hazards to aircraft from wildlife.

The FAA Advisory Circular No: 150/5200-33B provides specific guidance on development projects for new stormwater management facilities and artificial marshes. Implementation of **Mitigation Measure HAZ-3** for all BMPs that are within the airport land use plan area, regardless of whether the airport receives federal funding, would reduce the potential impact to less than significant.

Mitigation Measure:

HAZ-3: Implementing Agencies shall require that those BMPs that are within an airport land use plan area are compatible with criteria specified in FAA Advisory Circular No: 150/5200-33B (FAA, 2007). If the proposed BMP is within the minimum separation criteria, the Implementing Agency shall consult with the airport and collaboratively evaluate whether the potential increase in wildlife hazards can be mitigated.

Significance Determination: Less than significant with mitigation (The application of this mitigation measure to specific BMP types and categories are identified in Table 3.7-1.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no new facilities that would require additional or new use of hazardous materials. Therefore, this impact would have no impact relative to airports.

Mitigation Measures: None required

Significance Determination: Less than significant

Impact 3.7-6: The proposed program could impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan.

Structural (Regional, Centralized, and Distributed) BMPs

Construction activities associated with implementation of structural BMPs may include installations of pipelines or other infrastructure within roadway rights-of-way. These construction activities could potentially result in temporary lane or roadway closures or block access to roadways and driveways for emergency vehicles. Such construction-related impacts, although temporary, could potentially impair implementation of, or physically interfere with, an adopted emergency response plan or emergency evacuation plan. Impacts to access would be possible during the construction of larger scale regional or centralized BMPs, and less likely for the smaller-scale distributed BMPs.

Notification to emergency services providers would ensure that emergency responsiveness was not impaired. Once installed, the BMPs would have no effect on emergency response plans or evacuations plans.

Mitigation Measure: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no new facilities that would require additional or new use of hazardous materials. Therefore, this impact would have no impact relative to emergency response plans or emergency evacuation plans.

Mitigation Measures: None required

Significance Determination: Less than significant

Impact 3.7-7: The proposed program could expose people or structures to a significant risk of loss, injury, or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands.

Structural (Regional, Centralized, and Distributed) BMPs

The grading of unimproved areas could require the use of mechanized equipment with internal combustion engines. The equipment would include excavators, backhoes, drilling rigs, and support trucks. Parts of the engines and exhaust systems could get hot enough to ignite dry vegetation and cause a wildfire and expose people or structures to significant risk.

Most of the BMPs are likely to be distributed BMPs constructed within developed urban areas with no possibility for wildfires. However, some regional and centralized BMPs could be constructed in rural undeveloped areas. Larger-scale centralized BMP treatment facilities could be built in previously undeveloped areas, since the urban areas are largely built out.

As discussed in the Setting section, the CAL FIRE fire hazard severity zone maps identify areas within the EWMP with high and very high fire hazard severity categories. Structural BMPs conducted within these areas would have the added potential of causing wildfires. However, the requirements of the DOT and California Vehicle Code for spark arrester protection on vehicles would reduce the potential risk. Therefore, adherence to federal and state regulations would reduce the potential impacts from wildfires to less than significant. No mitigation measures would be required.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. As a result, there would be no new facilities that would have the potential to create a risk of wildfire. Therefore, this impact would have no impact relative to wildfires.

Mitigation Measures: None required

Significance Determination: Less than significant

Cumulative Impact Discussion

Structural (Regional, Centralized, and Distributed) BMPs

BMPs would be constructed throughout the watersheds. Most of the distributed BMPs would be small in scale and would not result in cumulatively significant impacts due to increased hazards from construction or operation. However, the combination of BMPs throughout the region would change the flow paths of stormwater and urban runoff that currently occurs in the region, resulting in the retention of pollutants generally within the soil of the BMPs that use soil for filtration and retention. Mitigation Measure HAZ-1 would reduce the potential for concentrations of these pollutants to result in localized hazardous conditions at individual BMP locations. Mitigation Measure HAZ-2 would mitigate the accumulation of contaminants in soil at BMPs. Cumulatively, throughout the region, the retention and treatment of pollutants within each watershed and the reduction of pollutant loading in waterways will substantially benefit water and sediment quality of the region's habitats, rivers, and beaches. Therefore, the project's potential contribution to cumulative effects on hazards and hazardous materials is considered beneficial.

Mitigation Measures: HAZ-1 and **HAZ-2**

Significance Determination: Less than significant with mitigation. (The application of this mitigation measure to specific BMP types and categories are identified in Table 3.7-1.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no new facilities that would contribute to cumulative impacts.

Mitigation Measures: None required

Significance Determination: Less than significant

TABLE 3.7-1
SUMMARY OF HAZARDS IMPACTS REQUIRING MITIGATION MEASURES

	Thresholds of Significance							
Structural BMPs	**Transport, use or disposal of hazardous materials**	**Accumulation of hazardous materials**	**Hazardous emissions near schools**	**Located on hazardous materials site**	**Vicinity of airport or airstrip**	**Impair implementation of emergency response plan**	**Exposure to wildland fires**	**Cumulative Impacts**
Applicable Mitigation Measures:	**None Required**	**HAZ-1**	**HAZ-1**	**HAZ-2**	**HAZ-3**	**None Required**	**None Required**	**HAZ-1 and HAZ-2**
Regional BMPs								
Regional Retention and Infiltration	No	Yes	Yes	Yes	Yes	No	No	Yes
Regional Capture, Detention and Use	No	Yes	Yes	Yes	Yes	No	No	Yes
Centralized BMP								
Bio-filtration	No	Yes	Yes	Yes	Yes	No	No	Yes
Constructed Wetlands	No	Yes	Yes	Yes	Yes	No	No	Yes
Treatment/Low-Flow Diversions	No	Yes	Yes	Yes	Yes	No	No	Yes
Creek, River, Estuary Restoration	No	Yes	Yes	Yes	Yes	No	No	Yes
Distributed BMPs								
Site-Scale Detention	No	Yes	Yes	Yes	Yes	No	No	Yes
LID – Infiltration/Filtration BMPs – Porous Pavement, Green Streets, Bioswale/Filter Strips, downspout disconnects	No	Yes	Yes	Yes	Yes	No	No	Yes
LID – Green Infrastructure – Capture and Use – Cisterns, Rain Barrels, Green roofs, Planter Boxes	No	Yes	Yes	Yes	Yes	No	No	Yes

RB-AR 8485

3.8 Hydrology and Water Quality

This section describes the existing hydrology and water quality conditions within the project area and evaluates whether the proposed program would result in significant hydrology or water quality impacts.

3.8.1 Environmental Setting

Surface Water

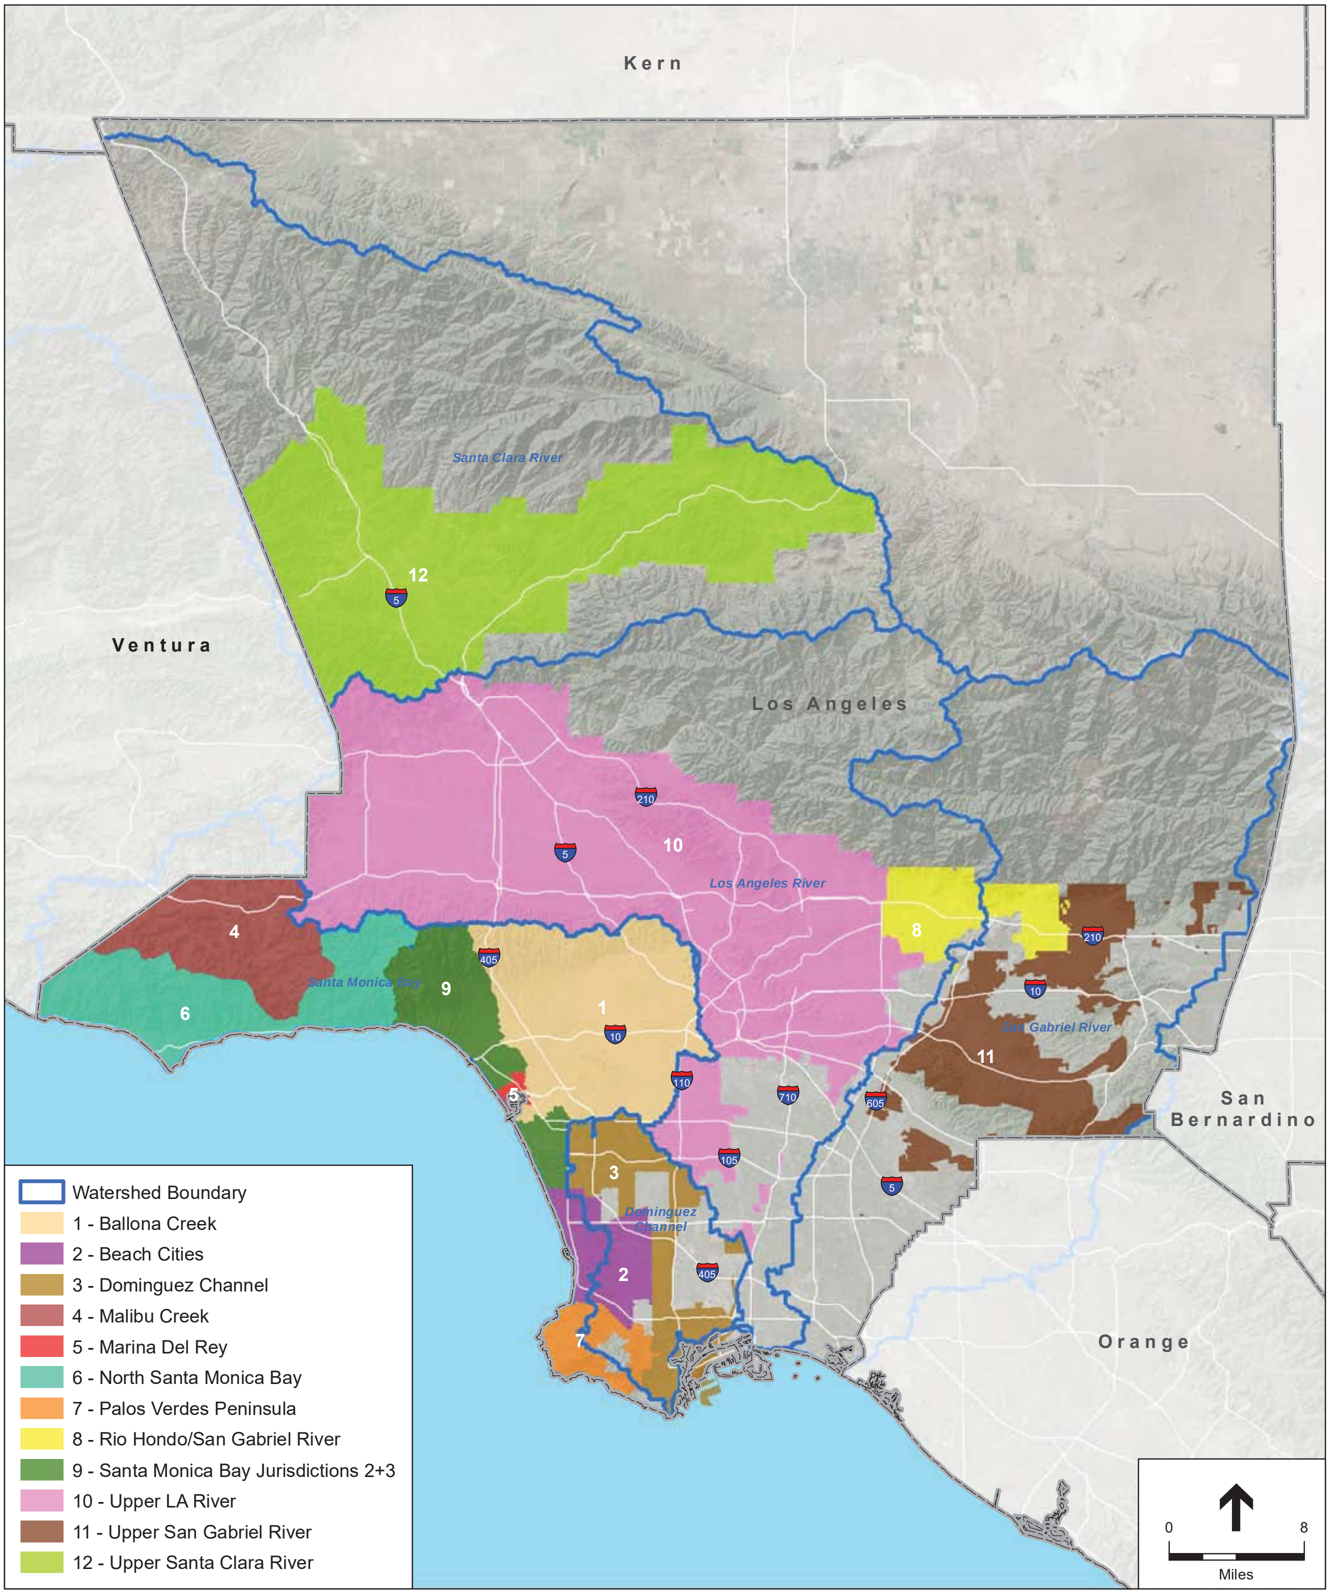
Climate and Precipitation

The 12 Enhanced Watershed Management Program (EWMP) Areas are located within Los Angeles County (County). The coastal mountains and plains within this region have a mediterranean climate with mild rainy winters and warm dry summers, while the inland slopes and basins tend to experience more extreme temperatures and less precipitation. These variations of climate within the region can be attributed to variable topography. Higher elevations generally receive more precipitation than nearby areas at lower elevations. Prevailing winds from the west and northwest carry moist air from the Pacific Ocean inland until it is forced upward by the Santa Monica, San Gabriel, or Santa Susanna Mountains. The resulting rainfall occurs mostly during discrete, episodic events between November and March.

Annual precipitation can vary significantly between drought and flood conditions; periodic and occasionally severe droughts and floods within the area are well-documented (LARWQCB, 1994), and the potential for extreme precipitation (maximum intensity of precipitation for periods of 12 hours or longer which might be expected at intervals of ten to 100 years) is greater in portions of the San Gabriel Mountains than practically anywhere else in the continental United States (WERC, 2014). Average annual rainfall within the Los Angeles Basin is approximately 14.5 inches, though local averages can vary considerably depending on location within the basin (WERC, 2012).

Los Angeles County Watersheds

As shown in **Figure 3.8-1**, the portion of Los Angeles County covered in this Program Environmental Impact Report (PEIR) is divided into distinct watersheds, including: the Los Angeles River, San Gabriel River, Rio Hondo, Santa Clara River north of the Santa Susana Mountains, Dominguez Channel, and coastal drainages stretching from Malibu to Palos Verdes, including Ballona Creek. The 12 EWMP areas were identified as portions of these greater watersheds that contain impaired water bodies needing structural Best Management Practices (BMPs) to comply with stormwater discharge permit requirements.



SOURCE: ESRI.

LA County PEIR EWMP . 140474

Figure 3.8-1
Watersheds and EWMP Groups

Los Angeles River

The 51-mile Los Angeles River stretches from its headwaters in the upper San Fernando Valley to its mouth in San Pedro Bay, draining the Santa Susana and San Gabriel Mountains and San Fernando Valley. Following several catastrophic and deadly floods in the early 1900s, the U.S. Army Corps of Engineers channelized and armored the river levees and numerous tributaries with concrete to mitigate future flooding concerns. The channelization of this stream, completed in the 1960s, ended ongoing flooding concerns and provided land for the construction of homes and businesses within the previous floodplain.

San Gabriel River

The San Gabriel River is bound by the San Gabriel Mountains to the north, San Bernardino to the east, Los Angeles River to the west, and Pacific Ocean to the south. The San Gabriel River flows 58 miles south until its confluence with the Pacific Ocean. Major tributaries to the San Gabriel River include Walnut Creek, San Jose Creek, Coyote Creek, and numerous storm drains entering from the 19 cities that the San Gabriel River passes through. Much of the channel above the Whitter Narrows is unlined. Storm flows are diverted from the riverbed into four different spreading grounds by dams for ground water recharge. The 10-mile segment below Whittier Narrows is a concrete-lined channel.

Rio Hondo

The Rio Hondo watershed is a subwatershed of the Los Angeles River watershed and is also linked to the adjacent San Gabriel River watershed. This link reflects both natural hydrologic processes and human intervention. Historically, the Los Angeles and San Gabriel Rivers were wide, shallow rivers consisting of a braided series of channels that would periodically intermingle following large storm events. Today, the rivers have been engineered into three channels created to bring water from the San Gabriel to the Rio Hondo, making the Rio Hondo serve as an outlet for the San Gabriel River.

Dominguez Channel

Named for the Juan Jose Dominguez family who owned a tract of 75,000 acres of land (Rancho San Pedro) from the Los Angeles River west to the Pacific Ocean in the late 1700s, the channel is a 15.7-mile-long waterway that drains a 110 square miles. The headwaters begin in Hawthorne and eventually empty into the East Basin of the Port of Los Angeles. Today, the Dominguez Channel watershed is 96 percent developed.

Santa Clara River

The Santa Clara River watershed encompasses approximately 1,030 square miles. The Upper Santa Clara River watershed is located primarily within both Ventura (243 square miles) and Los Angeles County (786 square miles), as well as a very small portion of Kern County. The Santa Clara River is one of the few natural river systems remaining in Southern California originating in the Angeles National Forest and flowing westward for approximately 84 miles to the Pacific Ocean. Throughout its length, the river crosses through farmland, undeveloped lands, and urban areas. The lower Santa Clara River watershed is located primarily within Ventura County and out of the study area for this project.

Coastal Drainages

All along the Los Angeles County coastline, distinct drainages flow from uplands to the ocean. In Malibu, these drainages within the Santa Monica Mountains are generally short, steep, and relatively natural channels. Malibu Creek drains a wide area that includes areas within and north of the Santa Monica Mountains. In the urbanized areas along Santa Monica Bay, the streams have been channelized.

Ballona Creek is a 9-mile-long waterway that drains the Santa Monica Mountains on the north and the Baldwin Hills on the south. Ballona Creek flows through Culver City until emptying into Santa Monica Bay between Marina del Rey and Playa del Rey. Following damaging flooding events, the Los Angeles County Flood Control District (LACFCD) concreted Ballona Creek and its tributaries during the 1930s. The Ballona Wetlands at the mouth of the creek are one of the last significant coastal wetland areas in Los Angeles County.

EWMP Groups

The proposed program has been divided into 12 EWMP Areas that have been organized by watershed groups that share comparable conditions. The key linkages that were used to distinguish the various EWMP groups were percentage of open space and urbanization, similar focus on the types and percentage of BMPs, and common hydrologic conditions. The following summaries are the general characteristics of the watersheds within the EWMP groups and the overall strategies for BMP implementation that reflect these characteristics. The 12 EWMPs are consolidated into six watershed areas that are grouped by similar watershed characteristics. This summary provides additional detail on the hydrologic features and strategies for the distribution and locations of potential and priority BMPs. Figures are referenced and provided for each of the six consolidated watershed areas and also provide hydrologic features and the locations and distribution of planned and priority regional/centralized BMPs. The priority BMPs are a subset of the planned BMPs and have been selected as priority projects based on a screening assessment of the planned projects. Priority projects will be implemented before additional planned projects. Distributed BMPs are planned to be implemented throughout the urbanized areas of the EWMPs. The following summaries of the six watershed areas also highlight the linkage between the BMP strategies with hydrologic conditions in these watersheds that provide a basis to assess potential environmental impacts presented in the assessment section.

1. **South Santa Monica Bay EWMP Watersheds (Figure 3.8-2)** (Marina del Rey, Ballona Creek, Beach Cites, South Santa Monica Bay Jurisdictional Group 2 and 3, and Peninsula Cities EWMP groups) – These watersheds are dominated by urbanized beach communities with high-density residential and commercial land uses throughout the watershed. Key BMP strategies in these watersheds are to address dry- and wet-weather flows that may impact beach water quality through bacteria loading. Other water quality priorities include trash, marine debris, metals, and toxics. The BMP strategy includes low-flow diversions (LFDs) to comply with dry-weather metals and bacteria Total Maximum Daily Loads (TMDLs). Although large regional and centralized retention and infiltration BMPs will be part of the pollutant load reduction strategy, the predominate structural BMP will be smaller distributed BMPs such as bioinfiltration, media filtration and flow-through BMPs located in street rights-of-way, parking lots, landscaped areas,

and as part of green streets and buildings. Due to the high ground water near the shore, capture and reuse regional projects or treatment BMP opportunities will be preferred. The receiving waters for the South Santa Monica Bay include the Pacific Ocean, the Ballona Creek, and the Marina del Rey Harbor. The Ballona Creek is channelized through the urbanized area of the Ballona Watershed. The Ballona Wetlands received muted tidal flow from Ballona Creek that is tidally influenced (see the photograph below).

Channelized Ballona Creek and Ballona Wetland

Marina del Rey EWMP – Because of the tidal influence of the marina to most of the watershed, regional projects will be located near the upstream end of the watershed, where groundwater depths are favorable. The tidally influenced areas will consist of mostly treatment distributed BMPs including bioinfiltration or tree wells.

Ballona Creek EWMP – Regional infiltration BMPs will be well distributed throughout the watershed and will be incorporated with distributed BMPs consisting mostly of treatment BMPs such as green streets. LFDs may also be pursued to comply with dry-weather TMDL requirements.

Beach Cities EWMP – The watershed includes a portion of the Beach Cities EWMP that drains to the Pacific Ocean. The Beach Cities will focus their efforts on regional projects near the outlet on the Beach similar to the Hermosa Beach Infiltration Trench or the Torrance infiltration basins. Where regional projects are infeasible, distributed projects such as green streets will be implemented.

Santa Monica Bay J2/3 – Many efforts have already been completed for the Santa Monica Bay J2/J3 watershed, including LFDs and reuse facilities. The group will investigate the possibility of more regional projects that are able to capture and reuse the flow. Remaining areas will be subject to distributed BMPs.

Peninsula Cities – The Peninsula Cities area (SMB J7) is mostly anti-degradation sites, so there will not be many control measures in this subwatershed.

2. **Northern Coastal EWMP Watersheds (Figure 3.8-3)** (Malibu Creek and North Santa Monica Bay Coastal Watershed EWMP groups) – These watersheds are characterized by lower-density development along the coast and the larger creeks with greater open space and park areas inland. There is increased development in the upper areas of the Malibu Creek watershed. Receiving waters in these watersheds are largely unlined and riparian corridors remain.

   Water quality priorities include bacteria, toxics, trash, and nutrients as well as benthic community impairments. Key BMP strategies are to address bacteria loading to the beaches and inland waters, but because of the lower development and largely decentralized infrastructure, LFDs are not the only strategy to address this priority issue. In addition to LFDs, larger centralized BMPs that include detention and infiltration and detention and filtration will be used for Municipal Separate Storm Sewer System (MS4) outfalls that are in close proximity to the receiving waters. Smaller distributed BMPs that include biofiltration, media filtration, green streets, and flow-through BMPs will be used in greater percentage than larger centralized BMPs and would be located in developed areas as retrofit BMPs.

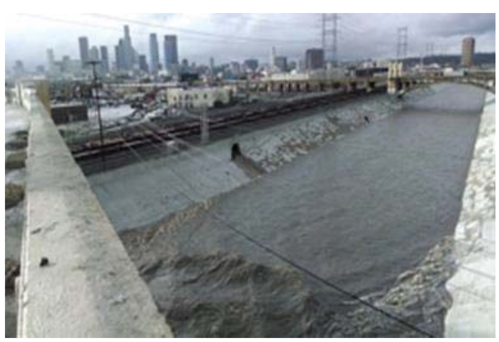
Marie Canyon Low-Flow Diversion – Malibu Creek

3. **Upper San Gabriel Watershed (Figure 3.8-4) –** This watershed is characterized by higher-density development in the lower watershed area and lower-density development and open space in the upper watersheds where the foothills to the San Gabriel Mountains begin. The priority pollutants in these watersheds include selenium in dry-weather flows and metals in storm flows in Coyote Creek. These watersheds are further differentiated by the importance of groundwater recharge basins that are supplied by a series of reservoirs further upstream in the mountains. The San Gabriel River is unlined in the upper watershed and conveys controlled non-storm and storm flows to recharge basins and downstream sections of the river.

Upper San Gabriel River

The BMP strategy in these watersheds focus more on regional and centralized retention and infiltration BMPs that take advantage of the favorable groundwater recharge characteristics of this area. These BMPs are located near or adjacent to the river. This watershed includes stream restoration that uses natural unlined tributaries and centralized bioinfiltration BMPs in parks and open spaces with favorable subsurface soils that promote higher infiltration rates. Distributed smaller BMPs are located in urbanized areas as retrofits in existing developments and streets.

4. **Upper Los Angeles River Watershed and Rio Hondo/San Gabriel Watershed (Figure 3.8-5)** – These watersheds traverse a large diverse area of the Los Angeles Basin with characteristics of Upper San Gabriel in the farthest upper reaches near the foothills, but, for most part, these watersheds are characterized by greater urbanization similar to the Ballona Creek watershed. The greater urbanization also results in additional priority pollutants compared to the Upper San Gabriel watershed and includes nutrients, trash, metals, bacteria, and sediment impacted by metals and organic compounds (DDT, PCBs, PAHs). The Rio Hondo/San Gabriel EWMP is characterized by increasing urbanization south of the foothills and industrial and commercial development along the I-210 corridor. The strategy for the locations and types of BMP is to use remaining available sites for retention and infiltration that takes advantage of the favorable infiltration rates of this area, including the existing groundwater recharge basins near the San Gabriel River.



Los Angeles River

The Los Angeles River is approximately 51 miles long, and five of six reaches lie within the Upper Los Angeles River EWMP. The natural hydrology of the Los Angeles River watershed has been altered by channelization and the construction of dams and flood control reservoirs. The Los Angeles River and many of its tributaries are lined with concrete for most or all of their length. Soft-bottom segments of the Los Angeles River occur where groundwater upwelling prevents armoring of the river bottom. Because of the greater extent and number of pollutant priorities, the BMP strategy in the Upper Los Angeles River watershed and Rio Hondo watershed includes well over a hundred planned regional and centralized retention and infiltration BMPs that take advantage of the favorable groundwater recharge characteristics in defined areas of the watershed. Also planned are centralized treatment wetlands and bioinfiltration BMPs in parks and open spaces with favorable subsurface soils that promote higher infiltration rates. The BMP strategy also includes distributed smaller BMPs located throughout the urbanized areas of the watershed as retrofits in existing developments and streets. LFDs to comply with dry-weather bacteria TMDLs will also be included.

5. **Dominguez Channel Watersheds (Figure 3.8-6)** (Dominguez Channel EWMP and Beach Cities EWMP– This watershed includes the Dominquez Channel EWMP and a portion of the Beach Cities EWMP that drains to Dominquez Channel. This watershed is differentiated by a larger area of industrial land use. Because of the high density of development and industrial land uses, large regional and centralized infiltration-type BMPs will be limited. The structural BMP strategy will be more LFDs, both large (centralized) and small (distributed), located at MS4 outfalls near the channelized Dominguez Chanel. The other BMP strategy is the use of smaller distributed BMPs that include the low-impact development (LID) type of BMPs, such as green streets and biofiltration BMPs. These distributed BMPs will be retrofit type BMPs that treat runoff from already developed properties and are located in street rights-of-way, parking lots, and limited open areas on public and private parcels. Distributed flow-through treatment BMPs will also be the other predominant BMP that will be retrofitted to the existing MS4 systems.

Dominquez Channel

6. **Upper Santa Clara River Watershed (Figure 3.8-7) –** The Santa Clara River watershed is distinctive in that it is predominantly open space—nearly 90 percent of the watershed is open space with approximately 88 percent being undeveloped. The watershed contains one of the last remaining natural rivers in Southern California. In years of significant rainfall, ephemeral springs and year-round flows exist in some tributaries and natural upstream areas. Flows in Santa Clara River reaches that pass through the EWMP area are predominantly stormwater runoff during wet-weather months and water reclamation plant effluent discharges in the drier months.

Upper Santa Clara River

Priority pollutants in this watershed are bacteria, nutrients, and chloride. In the source assessments for the nutrients TMDL and the chloride TMDL for the Santa Clara River, the storm drain system is not considered the primary source of these pollutants. Lake Elizabeth is also subject to a trash TMDL. The EWMP will evaluate potential MS4 nutrients and chlorides contributions and serve as the implementation plan for the bacteria TMDL. BMP strategies for this watershed are likely to include a focus more on regional and centralized detention and infiltration BMPs and less on filtration-type BMPs, which are not as effective at addressing bacteria.

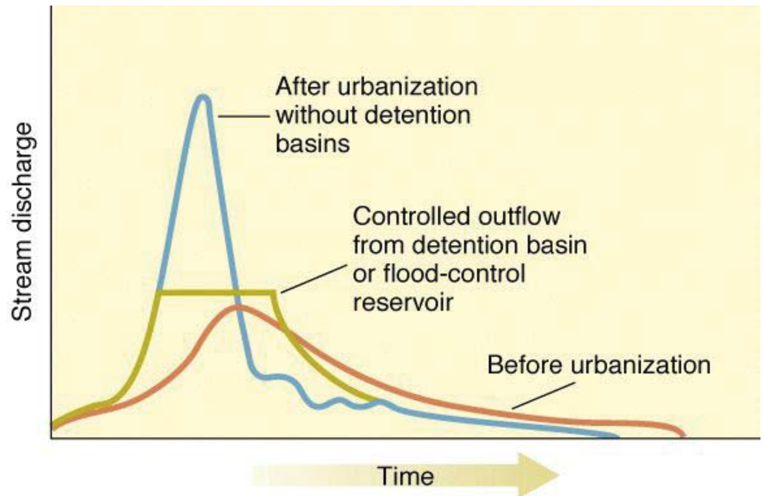
Effects of Urbanization on Streamflows

Prior to urbanization in the mid to late 1800s, surface water hydrology within the Los Angeles Basin was dominated by natural processes of watershed runoff and recharge. During the winter rainy season, runoff from the watershed would feed stream flows and recharge groundwater aquifers in the lower alluvial portions of the basin. As the intensity, frequency, and duration of winter rains decreased, stream flows would recede in response to decreased watershed runoff. In many locations, especially smaller streams, portions of streambeds would seasonally go dry (ephemeral), with surface flows only reestablished by the return of winter rains. In other streams, near-surface groundwater would maintain base flows throughout the summer, supporting wetland and floodplain habitats. During the summer, coastal streams would typically form freshwater-brackish lagoons at creek mouths behind sand berms built by summer wave action; these lagoons also supported seasonal aquatic habitats.

Pre-Development Hydrology is characterized by dry-weather flows fed by groundwater seepage fed by recharge during the rainy season. Some creeks and rivers are ephemeral and dry up in the dry season.

Most of the historic hydrologic processes have been fundamentally changed throughout the Los Angeles Basin due to urbanization. The replacement of native soils with largely impermeable surfaces such as concrete and asphalt has dramatically altered storm hydrographs (graph showing the flow rate in a stream or channel over the storm event) as shown in Figure 3.8-8, increasing runoff rates and flood volumes that have to be safely routed away from people, homes, businesses, and infrastructure. Floodplain and wetland habitats that formerly provided water quality treatment and groundwater recharge functions have been largely eliminated from the landscape, accelerating the transport of flows from higher to lower areas of the watersheds.

Figure 3.8-8 presents a comparison of the predevelopment and development conditions and impacts to hydrology. The effect that is shown in Figure 3.8-8 to the hydrograph from urbanization is called hydromodification. Hydromodification reduces base-flow (groundwater flow into streams) and increases peak discharge rates into streams and rivers. Figure 3.8-8 also shows the effect of the hydrograph when BMPs such as retention basin are implemented that capture urbanized storm flows and release these flows under reduced flows to return the hydrograph close to predevelopment conditions.

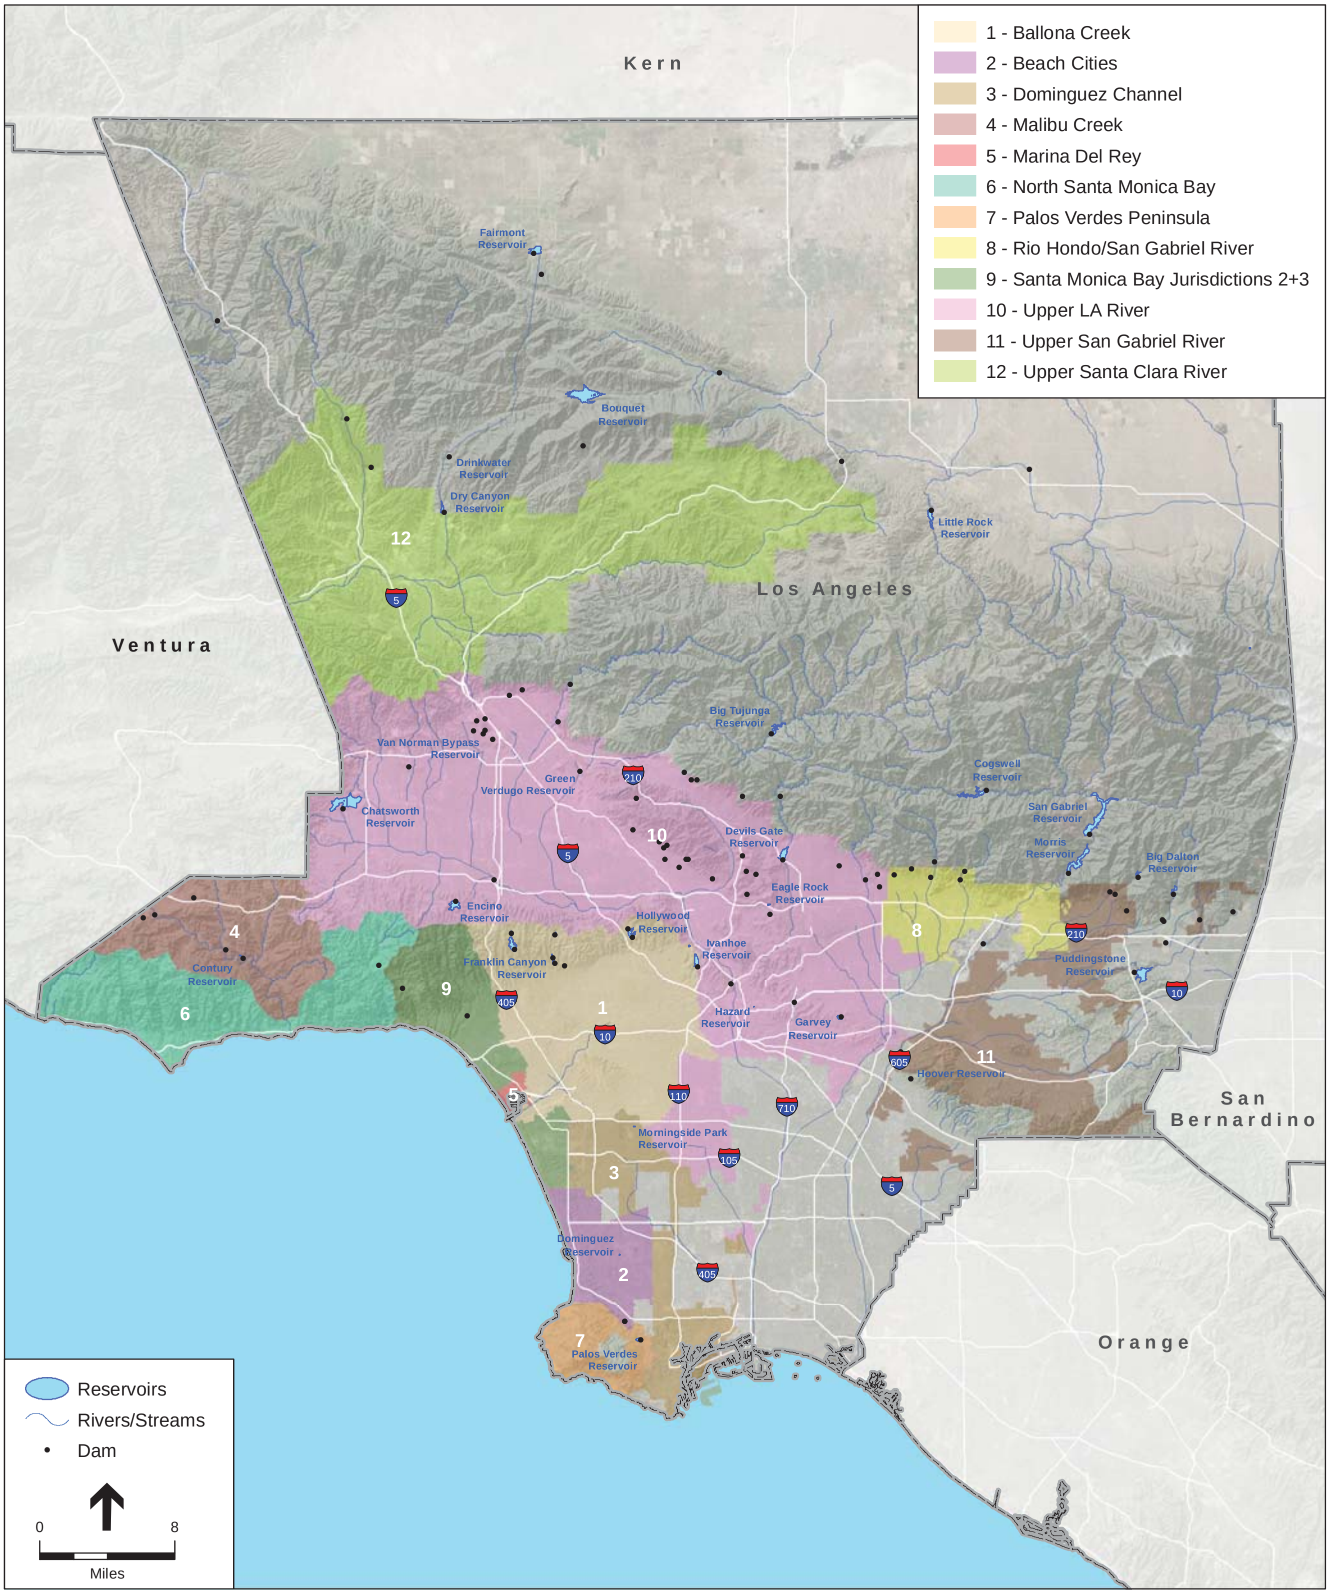


LA County PEIR EWMP . 140474

Figure 3.8-8
Effect of Urbanization on an Example Stream Hydrograph and Hydrograph after Implementation of Retention-Type BMP

In addition, urbanization can increase dry-weather flows in local streams that were historically ephemeral as a result of irrigation runoff and wastewater treatment plant discharges. Naturally occurring dry-weather flows in the San Gabriel River and Los Angeles River are also influenced by the management of upstream dams and reservoirs that impound flows from winter storm events and then distribute these flows to recharge basins and to treatment facilities as part of the water supply system. These flows are managed through periodic dam releases and downstream intake systems. **Figure 3.8-9** provides the locations of dams and reservoirs in the Los Angeles region.

Urban dry-weather flows from causes such as over-irrigation result in dry-weather flows in creeks and streams that historically are ephemeral.



SOURCE: ESRI; Los Angeles County GIS

LA County PEIR EWMP . 140474

Figure 3.8-9

System of Dams and Reservoirs in LA Basin

In the late 1990s, some Permittees along the Santa Monica Bay coast began to implement LFDs, which divert dry season flows from storm drains into the sanitary sewer system for treatment and disposal or reuse. Over 20 LFDs are currently in use within Los Angeles County; though most are along the SMB shorelineThe location of existing low flow diversions along the Santa Monica Bay coastline are shown on Figure 3.8-10. . Collectively, these LFDs divert a large volume of polluted urban runoff during each dry season, and they have proven to be one of the most effective tools for improving coastal water quality (LA Stormwater, 2014). The EWMPs include a suite of new LFDs and improvements to existing LFDs that will further increase the volume of dry-weather (and, in some cases, year-round) flows diverted for treatment. The installation/upgrades of these LFDs could potentially increase the amount of water available for recycling, reuse, and groundwater recharge.

Surface Water Quality

Surface water quality in Los Angeles is largely influenced by the intensive urban land uses of the region. Key sources of surface water contamination include landscape irrigation runoff conveying sediment, nutrients, pesticides, metals, oil and grease, and pathogens to receiving waters. Other dry-weather runoff from industrial activities can add organic compounds and petroleum hydrocarbons. The State Water Resources Control Board (SWRCB) has identified stream segments in each of the EWMP Areas that are considered impaired under the Clean Water Act (CWA) in the State Section 303d list. **Table 3.8-1** lists the major streams on the Section 303d list within the EWMP areas. A water body is placed on the State §303d list when the receiving water does not meet applicable water quality standards listed in the Basin Plan and determined not to be supporting the beneficial uses associated with the applicable water quality standard. Once placed on the State §303d list, the water body or segment is then subject to the development of a TMDL. Appendix F provides a list of the current TMDLs and the references to existing TMDL Implementation Plans.

TABLE 3.8-1
MAJOR IMPAIRED WATER BODIES IN THE STUDY AREA

Water Body/Reach Name	Pollutant/Stressor	Potential Source
Ballona Creek	Cadmium, Coliform Bacteria, Copper (dissolved), Cyanide, Lead, Selenium, Toxicity, Trash, Viruses (enteric), and Zinc	Unspecified or unknown point and nonpoint sources.
Dominguez Channel (lined portion above Vermont Avenue)	Ammonia, Copper, Diazinon, Indicator Bacteria, Lead, Toxicity, and Zinc	Unspecified or unknown point and nonpoint sources.
Dominguez Channel (unlined portion below Vermont Avenue)	Ammonia, Benthic Community Effects, Benzo(a)pyrene (3,4-Benzopyrene -7-d), Benzo[a]anthracene, Chlordane (tissue), Chrysene (C1-C4),Coliform Bacteria, DDT (tissue & sediment), Dieldrin (tissue), Lead (tissue), PCBs (Polychlorinated biphenyls), Phenanthrene, Pyrene, Sediment Toxicity, Zinc (sediment)	Unspecified or unknown point and nonpoint sources.
Los Angeles River (Reaches 1-6)	Ammonia, Cadmium, Coliform Bacteria, Copper (dissolved), Cyanide, Diazinon, Lead, Nutrients (algae), Oil, Trash, Zinc (dissolved), pH, and Selenium.	Urban Runoff, Unspecified or unknown point and nonpoint sources.

Water Body/Reach Name	Pollutant/Stressor	Potential Source
Malibu Creek	Benthic-Macroinvertabrate Bioassessments, Coliform Bacteria, Fish Barriers, Invasive Species, Nutrients (algae),Scum/Foam-unnatural, Sedimentation/Siltation, Selenium, Sulfates, Trash.	Urban Runoff, Unspecified or unknown point and nonpoint sources, Hydromodification, Waste Storage And Disposal, Recreation Areas And Activities, Groundwater Related, Atmospheric Deposition, Municipal Wastewater, and Agriculture
Rio Hondo (Reaches 1 and 2)	Coliform Bacteria, Copper, Lead, Toxicity, Trash, Zinc, pH, Cyanide	Urban Runoff, Unspecified or unknown point and nonpoint sources.
San Gabriel River (Reaches 1-3 and East Fork)	Coliform Bacteria, pH, Cyanide, Lead, Indicator Bacteria, Trash	Urban Runoff, Unspecified or unknown point and nonpoint sources
Santa Clara River (Reaches 1, 3, 5, 6, 7, and 11)	Toxicity, Ammonia, Chloride, Total Dissolved Solids (TDS), Coliform Bacteria, Iron, Chlorpyrifos, Copper, Diazinon, Boron, Specific Conductance, Sulfates.

Existing Stormwater Recharge

In Southern California's arid climate, stormwater is increasingly viewed as a critical component of the region's water supply. The nexus between stormwater and groundwater has been recognized since the early 20th century, when groundwater recharge facilities began to be constructed along the San Gabriel River and other basins (see Groundwater, below). According to the Metropolitan Water District, approximately 55 percent of water supplies in Southern California are imported; 45 percent are supplied by local groundwater basins that are recharged naturally from rainfall and through constructed recharge facilities (MWD, 2010). As described further in this section, stormwater recharge facilities currently augment local groundwater supplies in the region by an estimated 477,000 acre-feet per year (MWD, 2014). One of the primary goals of the EWMP program is to increase the amount of stormwater that is recharged into groundwater, particularly in portions of the Central Basin that experience a high degree of hydraulic connectivity between surface water and groundwater. Infiltration BMPs proposed within the EWMPs are expected to increase the rates and amounts of groundwater recharge—the degree to which these increase is dependent upon project-specific attributes such as size, location, and the size of the contributing watershed.

Groundwater

Groundwater Basins

Los Angeles County is located in the South Coast Hydrologic Region (HR), as described by the Department of Water Resources Groundwater Bulletin 118 (2003). The South Coast HR is divided into numerous smaller groundwater basins and subbasins; the two largest and most critical among them are the Central Basin and the West Coast Basin. **Figure 3.8-10** displays the boundaries of these basins.

LA County PEIR EWMP . 140474

Figure 3.8-10
Groundwater Basins within the EWMP Areas

The 140-square-mile West Coast Basin underlies much of the Beach Cities, Dominguez Channel, and Marina del Rey EWMP Areas. The 270-square-mile Central Basin underlies portions of the Los Angeles River, Upper San Gabriel, and SGR/Rio Hondo EWMP areas. The Central and West Coast Basins are characterized by aquifers that are generally confined by relatively impermeable clay layers over most of the area (DWR, 1961), with the exception of the Montebello and Los Angeles Forebays in the Central Basin.

Groundwater generally flows from east to west across the Main San Gabriel Basin, then southward into the Central Basin through the Montebello Forebay. Within all groundwater basins, groundwater flow directions are generally controlled by engineered recharge operations and groundwater pumping from the hundreds of wells distributed across the area (Shelton et al., 2001; Dawson et al., 2003). Stormwater recharge facilities currently augment local groundwater supplies in the region by an estimated 477,000 acre-feet per year (MWD, 2014). Due to the pumping depressions that exist in the Central and West Coast Basins, very little groundwater discharges or leaves the basins as subsurface outflow.

Recharge to the Central Basin occurs primarily by engineered recharge of stormwater, imported water, and reclaimed water along the upper reaches of the San Gabriel River and the Rio Hondo via the San Gabriel River Water Conservation System. This system is a series of dams, spreading grounds and instream recharge systems that facilitate groundwater recharge into the Main San Gabriel Basin and Montebello Forebay of the Central Basin. The system is comprised of four dams (Cogswell, San Gabriel, Morris, and Santa Fe) and three spreading grounds (San Gabriel Canyon, Sante Fe, and San Gabriel) on the San Gabriel River, as well as inflatable dams meant to pond water along the river's unlined stretch of the river. The system also includes one dam (Whittier Narrows) – and one spreading ground (Rio Hondo) along the Rio Hondo. Collectively, the Rio Hondo and San Gabriel River spreading grounds are referred to as the Montebello Forebay Spreading Grounds, or MFSG. Recycled water has been also delivered for recharge in the Montebello Forebay since 1962. Finally, the Central Basin includes one seawater intrusion barrier, the Alamitos Gap Seawater Intrusion Barrier (AGB), fed by treated imported water along with advanced water treatment recycled water.

Recharge to the West Coast Basin occurs primarily by injection of imported water and reclaimed water into wells of the seawater intrusion barrier and by underflow from the Central Basin. The Dominguez Channel Spreading Grounds (DGSG) are located along the Los Angeles River near the boundary between the West Coast and Central Basins. The sources of water for the spreading grounds are controlled flows from the Los Angeles River low-flow channel and uncontrolled flows from storm drains. The West Coast Basin includes two seawater intrusion barriers, the West Coast Basin Seawater Intrusion Barrier (WCBB) and Dominguez Gap Seawater Intrusion Barrier, also fed by treated imported water and advanced water treatment recycled water.

The EWMP areas overlie various groundwater basins as summarized in **Table 3.8-2**, most of which are adjudicated and managed by court-stipulated Watermasters. The Watermasters monitor groundwater production and participate in groundwater remediation programs.

TABLE 3.8-2
GROUNDWATER BASINS WITHIN THE EWMP AREAS

EWMP	Groundwater Basin	Adjudicated?	Watermaster
Ballona Creek	Santa Monica Basin Hollywood Basin Central Basin	No No Yes	None None CB

Groundwater Quality

In general, groundwater in the main producing aquifers of the West Coast and Central basins is of good quality. Localized areas of marginal to poor quality water exist, primarily at the basin margins where seawater intrusion occurred in the past and also in mostly shallow groundwater near environmental release sites. Groundwater has also been impacted by industrial activities that have introduced highly mobile man-made organic compounds such as solvents and fuel additives. These contaminated groundwater plumes are well documented. Areas of these contaminant plumes are designated to restrict recharge activities that may create an increased driver for contaminant migration.

Between the 1900s and 1950s, groundwater was an important factor in urbanization of the West Coast and Central basins. Excessive overpumping in the basins caused severe overdraft (i.e., lowered groundwater levels) and created a hydraulic gradient that resulted in seawater intrusion, which contaminated the coastal groundwater aquifers. To address this problem and halt the intrusion, three seawater intrusion barriers were constructed (discussed previously). While the water injection activities at the barriers were successful in halting further seawater intrusion, these efforts could not address the seawater that had already intruded into the Central and West Coast Basins before the barriers were constructed. These large plumes of saline water, referred to as “saline plumes,” are trapped inland of the injection wells, thereby degrading significant volumes of groundwater with high concentrations of chloride and total dissolved solids (TDS) and decreasing the ability of affected aquifers to provide groundwater storage.

Groundwater quality in the Central and West Coast Basins also reflects current and historical land uses. As a highly urban area, commercial and industrial activities have resulted in contamination due to leaking aboveground and underground storage tanks, leaking sewer and oil pipelines, spills, and illegal discharges. Many groundwater contamination plumes consist of priority contaminants such as petroleum fuels and additives (e.g., methyl tert-butyl ether), solvents (e.g., trichloroethylene and perchloroethylene), herbicides (e.g., atrazine, simazine, prometon), and other hazardous/toxic substances (e.g., arsenic, perchlorate). Groundwater contamination within the central, West Coast, and adjacent basins is discussed in depth in the California Groundwater Ambient Monitoring and Assessment's 2012 summary report (USGS and SWRCB, 2012). In general, contaminated plumes are typically found in shallow groundwater. However, as the aquifers and confining layers in these alluvial basins are typically interfingered,[1] the quality of groundwater in the deeper production aquifers is threatened by the migration of pollutants from the upper aquifers.

3.8.2 Regulatory Setting

Federal

Clean Water Act

The Federal Water Pollution Control Act (33 U.S.C. 1251 et. sec.) as amended by the Federal Water Pollution Control Act Amendments of 1972, also known as the CWA, states that the discharge of pollutants to waters of the United States from any point source is unlawful, unless the discharge is in compliance with a National Pollutant Discharge Elimination System (NPDES) permit. Amendments to the CWA added a section that established a framework for regulating municipal and industrial (M&I) stormwater discharges under the NPDES program. On November 16, 1990, the U.S. Environmental Protection Agency (USEPA) published final regulations, under the 1987 CWA Amendments, that establish application requirements for stormwater permits.

Clean Water Act Section 402

CWA Section 402 regulates discharges to surface waters of the United States through the NPDES program. In California, the USEPA authorizes the SWRCB to oversee the NPDES program through the Regional Water Quality Control Boards (RWQCBs). In September 2004, the RWQCB adopted Time Schedule Order No. R8-2004-0067, which requires the Sanitation District to achieve full secondary treatment by December 31, 2012. The Sanitation District has since carried out improvement projects of existing facilities and constructed new facilities to achieve secondary treatment standards by the year 2012 (RWQCB, 2004).

Stormwater discharges are also regulated under CWA Section 402.Construction activities disturbing one acre of land or greater must be covered under the SWRCB General Construction Activity Stormwater Permit. The permit requires preparation of a Stormwater Pollution

1 Interfinger means to grade or pass from one material (typically fine-grained) into another (typically coarse-grained) through a series of interpenetrating wedge-shaped layers. This can result in hydraulic connection between fine and coarse grounded layers.

Prevention Plan (SWPPP) for construction activities. A SWPPP prepared in compliance with the General Permit describes the site, erosion and sediment controls, runoff water quality monitoring, means of waste disposal, implementation of approved local plans, control of post-construction sediment and erosion control measures and maintenance responsibilities, and non-stormwater management controls. Dischargers are also required to inspect construction sites before and after storms to identify stormwater discharge from construction activity, and to identify and implement controls where necessary.

Clean Water Act Section 303(d)

Section 303(d) of the CWA requires that each state identify water bodies or segments of water bodies that are "impaired" (i.e., do not meet one or more of the water quality standards established by the state). These waters are identified in the Section 303(d) list as waters that are polluted and need further attention to support their beneficial uses. Once the water body or segment is listed, the state is required to establish TMDL for the pollutant. A TMDL is the maximum amount of a pollutant that a water body can receive and still meet the water quality standards. Typically, TMDL is the sum of the allowable loads of a single pollutant from all contributing point and nonpoint sources. On October 11, 2011, the USEPA approved a revised list of water quality limited segments (herein referred to as the 303(d) list) prepared by the RWQCB for California's 2008 through 2010. Table 3.8-1 summarizes the main impaired water bodies within the study area that are included on the RWQCB 2008 CWA Section 303(d) list that was revised on July 7, 2009.

Clean Water Act Section 401

Section 401 of the federal CWA requires that any activity, including the crossing of rivers or streams during road, pipeline, or transmission line construction, that might result in discharges of dredged or fill material into a state water body, be certified by the RWQCB. This certification ensures that the proposed activity does not violate state or federal water quality standards.

Clean Water Act Section 404

Wetlands are generally considered to be areas that are periodically or permanently inundated by surface water or groundwater, and support vegetation adapted to life in saturated soil. Wetlands are recognized as important features on a regional and national level due to their high inherent value to fish and wildlife, use as storage areas for storm and floodwaters, and water recharge, filtration, and purification functions. Technical standards for delineating wetlands have been developed by the ACOE which generally defines wetlands through consideration of three criteria: hydrology, soils, and vegetation. Under Section 404 of the CWA, the ACOE is responsible for regulating the discharge of dredged or fill material into waters of the United States. The term "waters of the United States" includes wetlands and non-wetland bodies of water that meet specific criteria as defined in the Code of Federal Regulations.

State

Porter-Cologne Water Quality Act

The Porter-Cologne Act (Division 7 of the California Water Code) provides the basis for water quality regulation within California and defines water quality objectives as the limits or levels of water constituents that are established for reasonable protection of beneficial uses. The SWRCB administers water rights, water pollution control, and water quality functions throughout the State, while the RWQCB conducts planning, permitting, and enforcement activities. The Porter-Cologne Act requires the RWQCB to establish water quality objectives, while acknowledging that water quality may be changed to some degree without unreasonably affecting beneficial uses. Beneficial uses, together with the corresponding water quality objectives, are defined as standards, per Federal regulations. Therefore, the regional plans form the regulatory standards for meeting State and federal requirements for water quality control. Changes in water quality are only allowed if the change is consistent with the maximum beneficial use designated by the State, does not unreasonably affect the present or anticipated beneficial uses, and does not result in water quality less than that prescribed in the water quality control plans.

California Ocean Plan

The SWRCB regulates water quality in the Pacific Ocean through regulatory standards and objectives outlined in the *Water Quality Control Plan, Ocean Waters of California* (commonly referred to the Ocean Plan) (SWRCB, 2012). The Ocean Plan identifies beneficial uses of ocean waters and provides water quality objectives that are protective of these uses. The plan provides objectives for bacteriological, physical, chemical, biological, and radioactive characteristics, as well as general requirements for the management of waste discharges to the Pacific Ocean. The USEPA relies upon the water quality objectives of the Ocean Plan for the purposes of regulating discharges from point sources that discharge into the Pacific (e.g. WWTP ocean outfalls) as well as the water quality of streams and channels that flow into the ocean.

In 1974, the SWRCB designated 34 regions along the coast of California as Areas of Special Biological Significance (ASBS) under Resolution Number 74-28 (SWRCB, 1974a). These ASBS are “areas designated by the SWRCB as ocean areas requiring protection of species or biological communities to the extent that alteration of natural water quality is undesirable” (SWRCB, 2012b). A portion of the Pacific off of the North Santa Monica Bay coastline from Laguna Point to Latigo Point offshore is designated as ASBS 24.

In March 2012, the SWRCB adopted the General Exception (SWRCB, 2012b), which exempts certain listed dischargers. The conditions in the General Exception are designed to protect beneficial uses of the receiving water, yet allow continuation of essential public services, such as flood control, slope stability, erosion prevention, maintenance of the natural hydrologic relationship between terrestrial and marine ecosystems, public health and safety, public recreation and coastal access, commercial and recreational fishing, navigation, and essential military operations (national security) (SWRCB, 2012b).

The General Exception designates the LACFCD, the City of Malibu and the California Department of Transportation (Caltrans) as dischargers to ASBS 24, and the California The General Exception authorizes these dischargers to discharge into ASBS 24, provided that it:

- Complies with the NPDES MS4 Permit.

- Includes an ASBS Compliance Plan that shall be included as part of the Permittees' primary policy, planning, and implementation documents for municipal NPDES Stormwater Permit compliance.

Proposed Trash Amendments to California Ocean Plan

The SWRCB has proposed to amend the California Ocean Plan and the forthcoming Inland Surface Waters, Enclosed Bays, and Estuaries Plan to address trash in waterways, including waterways regulated by the Los Angeles County MS4 (SWRCB, 2014). The proposed Trash Amendments would be incorporated into the MS4 Permit and:

- Establish a narrative water quality objective for trash.
- Establish a prohibition of discharge of trash.
- Provide implementation requirements for permitted stormwater dischargers and other discharges.
- Set a time schedule for compliance.
- Provide a framework for monitoring and reporting requirements.

A central element of the proposed Trash Amendments is a compliance approach that utilizes land use to target high trash generating areas (priority land uses), such as high-density residential, industrial, and commercial, mixed urban, and public transportation land uses. Within this land use- based approach, the SWRCB proposes two alternative compliance tracks (i.e., the Permittee must choose to comply with one of the tracks). Under Track 1, a Permittee could elect to install a network of full capture systems in the storm drains located in priority land uses for MS4s and the entire facility for IGP/CGP. Under Track 2, a Permittee could use any combination of controls (structural and/or institutional), as long as they can demonstrate that the combination of controls performs as well as Track 1. The SWRCB can extend this deadline by up to three years if Permittees implement regulatory source controls, such as product bans.

National Pollutant Discharge Elimination Program

The NPDES permit program is administered in the State of California by the RWQCBs, and was first established under the authority of the CWA to control water pollution by regulating point sources that discharge pollutants into waters of the United States. If discharges from industrial, municipal, and other facilities go directly to surface waters, those project applicants must obtain permits. An individual NPDES permit is specifically tailored to a facility. A general NPDES permit covers multiple facilities within a specific activity category such as construction activities. A general permit applies with same or similar conditions to all dischargers covered under the general permit.

General Dewatering Permit

The SWRCB also has issued General Waste Discharge Requirements (WDRs) under Order No. R8-2003-0061, NPDES No. CAG 998001 (Dewatering General Permit) governing non-stormwater construction-related discharges from activities such as dewatering, water line testing, and sprinkler system testing. The discharge requirements include provisions mandating notification, testing, and reporting of dewatering and testing-related discharges. The General

WDRs authorize such construction-related discharges so long as all conditions of the permit are fulfilled.

Construction General Permit

The Construction General Permit (CGP) requires the development and implementation of an SWPPP that includes specific BMPs designed to prevent pollutants from contacting stormwater and keep all products of erosion from moving off-site into receiving waters. The SWPPP BMPs are intended to protect surface water quality by preventing the off-site migration of eroded soil and construction-related pollutants from the construction area. Routine inspection of all BMPs is required under the provisions of the CGP. In addition, the SWPPP is required to contain a visual monitoring program, a chemical monitoring program for nonvisible pollutants, and a sediment monitoring plan if the site discharges directly to a water body listed on the 303(d) list for sediment.

In the project area, the CGP is implemented and enforced by the Los Angeles Regional Water Quality Control Board (LARWQCB), which administers the stormwater permitting program. Dischargers are required to electronically submit a Notice of Intent (NOI) and permit registration documents (PRDs) to obtain coverage under this CGP. Dischargers are responsible for notifying the LARWQCB of violations or incidents of noncompliance, as well as for submitting annual reports identifying deficiencies of the BMPs and how the deficiencies were corrected.

Municipal Stormwater Permitting (MS4)

The State’s Municipal Stormwater Permitting Program regulates stormwater discharges from Municipal Separate Storm Sewer Systems (MS4s). MS4 Permits were issued in two phases. Phase I was initiated in 1990, under which the RWQCBs adopted NPDES stormwater permits for medium (serving between 100,000 and 250,000 people) and large (serving more than 250,000 people) municipalities. As part of the Phase II, the SWRCB adopted a General Permit for small MS4s (serving less than 100,000 people) and non-traditional small MS4s including governmental facilities such as military bases, public campuses, and hospital complexes.

The Permittees’ 2012 MS4 Permit (Order No. R4-2012-0175; NPDES Permit No. CAS004001) requires Permittees to develop Enhanced Watershed Management Plans to ensure they are not causing or contributing to exceedances of water quality objectives or impairments of beneficial uses in the receiving waters of the Los Angeles region. The EWMPs are the subject of this PEIR.

Local Regulations

Los Angeles Regional Water Quality Control Plan

The preparation and adoption of water quality control plans (Basin Plans) is required by the California Water Code (Section 13240) and supported by the CWA. Section 303 of the CWA requires states to adopt water quality standards which “consist of the designated uses of the navigable waters involved and the water quality criteria for such waters based upon such uses.” According to Section 13050 of the California Water Code, Basin Plans consist of a designation or establishment for the waters within a specified area of beneficial uses to be protected, water quality objectives to protect those uses, and a program of implementation needed for achieving the objectives. Because beneficial uses, together with their corresponding water quality objectives, can be defined per Federal regulations as water quality standards, the Basin Plans are regulatory references for meeting the State and Federal requirements for water quality control. Beneficial uses for water bodies in the EWMP Areas are summarized in Appendix F.

County of Los Angeles Stormwater Pollution Control Requirements for Construction Activities

To comply with the Phase II General Construction Permit, the County of LA has established a set of BMPs with which all permitted construction activities on unincorporated county lands must comply. The BMPs, which are based on the state's Stormwater Best Management Practices Handbook (2003), are as follows:

- Eroded sediments and other pollutants must be retained on site and may not be transported from the site via sheetflow, swales, area drains, natural drainage courses or wind.
- Stockpiles of earth and other construction related materials must be protected from being transported from the site by the forces of wind or water.
- Fuels, oils, solvents and other toxic materials must be stored in accordance with their listing and are not to contaminate the soil and surface waters. All approved storage containers are to be protected from the weather. Spills must be cleaned up immediately and disposed of in a proper manner. Spills may not be washed into the drainage system.
- Non-stormwater runoff from equipment and vehicle washing and any other activity shall be contained at the project site.
- Excess or waste concrete may not be washed into the public way or any other drainage system. Provisions shall be made to retain concrete wastes on site until they can be disposed of as solid waste.
- Trash and construction related solid wastes must be deposited into a covered receptacle to prevent contamination of rainwater and dispersal by wind.
- Sediments and other materials may not be tracked from the site by vehicle traffic. The construction entrance roadways must be stabilized so as to inhibit sediments from being deposited into the public way. Accidental depositions must be swept up immediately and may not be washed down by rain or other means.
- Any slopes with disturbed soils or denuded of vegetation must be stabilized so as to inhibit erosion by wind and water.

The Los Angeles County Department of Public Works may identify and require additional BMPs, as appropriate.

City of Los Angeles Development Construction Model Program

The City of LA's Development Construction Model Program addresses NPDES Phase II requirements on construction sites within incorporated City lands. BMPs for construction (as well as source control and treatment) are detailed in the City's Reference Guide for Stormwater Best Practices (LADPW, 2000). The BMPs are consistent with those developed by the state and county, and include erosion and sedimentation control measures, site management practices, materials and waste management, and general preventive maintenance and inspection.

Stormwater Pollution Control Requirements for Other Cities in the County of Los Angeles

Other cities within the County also have stormwater pollution control requirements and associated BMPs; their content is similar to those described in this section for the County and City of Los Angeles.

County of Los Angeles Low Impact Development Manual

The County of Los Angeles (County) prepared the 2014 Low Impact Development Standards Manual (LID Standards Manual, County of Los Angeles, 2014b) to comply with the requirements of the 2012 MS4 Permit. The LID Standards Manual provides guidance for the implementation of stormwater quality control measures in new development and redevelopment projects in unincorporated areas of the County with the intention of improving water quality and mitigating potential water quality impacts from stormwater and non-stormwater discharges.

The LID Standards Manual addresses the following objectives and goals:

- Lessen the adverse impacts of stormwater runoff from development and urban runoff on natural drainage systems, receiving waters, and other water bodies.
- Minimize pollutant loadings from impervious surfaces by requiring development projects to incorporate properly-designed, technically-appropriate BMPs and other LID strategies.
- Minimize erosion and other hydrologic impacts on natural drainage systems by requiring development projects to incorporate properly-designed, technically appropriate hydromodification control development principles and technologies.

City of Los Angeles Low Impact Development Manual

In November 2011, the City of Los Angeles adopted the Stormwater Low Impact Development Ordinance #181899 with the stated purpose of:

- Requiring the use of LID standards and practices in future developments and redevelopments to encourage the beneficial use of rainwater and urban runoff
- Reducing stormwater/urban runoff while improving water quality
- Promoting rainwater harvesting
- Reducing off-site runoff and providing increased groundwater recharge
- Reducing erosion and hydrologic impacts downstream
- Enhancing the recreational and aesthetic values in our communities

The City of Los Angeles institutionalized the use of LID techniques for development and redevelopment projects. Subsequent to the adoption of the Stormwater LID Ordinance, the City prepared the *Development Best Management Practices Handbook, Low Impact Development Manual,* dated June 2011, to describes the required BMPs (City of Los Angeles, 2011).

Low Impact Development Manuals for Other Cities in the County of Los Angeles

Some of the other cities within the County also have LID ordinances and manuals. Their content is similar to the LID manuals described in this section for the County and City of Los Angeles.

City General Plans

The numerous cities encompassed by the EWMP project area all have their own respective city General Plans, some of which may contain policies that address water quality and hydrology. As implementation of the individual structural BMP projects proceed, specific policies and objectives pertaining to water quality and hydrology from applicable city General Plans will be identified and evaluated on a project-by-project basis during subsequent California Environmental Quality Act (CEQA) environmental processes.

3.8.3 Impact Analysis

The proposed project's potential impacts were assessed using the California Environmental Quality Act (CEQA) Guidelines Appendix G Checklist. The following sections discuss the key issue areas identified in the CEQA Guidelines with respect to the project's potential hydrology and water quality impacts.

Thresholds of Significance

For the purposes of this PEIR and consistency with Appendix G of the CEQA Guidelines, applicable local plans, and agency and professional standards, the project would have a significant impact on aesthetic resources if it would:

- Violate any water quality standards or waste discharge requirements.
- Otherwise substantially degrade water quality.
- Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted).
- Substantially alter the existing drainage pattern of a site or area through the alteration of the course of a stream or river, or by other means, in a manner that would result in substantial erosion or siltation on- or off-site.
- Substantially alter the existing drainage pattern of a site or area through the alteration of the course of a stream or river or, by other means, substantially increase the rate or amount of surface runoff in a manner that would result in flooding on- or off-site.
- Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff.

- Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other authoritative flood hazard delineation map.
- Place within a 100-year flood hazard area structures that would impede or redirect flood flows.
- Expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam.
- Expose people or structures to a significant risk of loss, injury, or death involving inundation by seiche, tsunami, or mudflow.

Program Impact Discussion

Water Quality Standards, Waste Discharge Requirements, and Further Degradation of Water Quality

Impact 3.8-1: The proposed project would violate water quality standards or waste discharge requirements or further degrade water quality.

Structural (Regional, Centralized, and Distributed) BMPs

Construction

Construction, demolition, and renovation activities associated with the installation of some BMPs, particularly larger centralized and regional BMPs, could lead to ground disturbance and polluted runoff. However, as described above, the NPDES CGP requires that any actions that disturb an acre or more of ground must develop an SWPPP to prevent the transport of polluted runoff. SWPPPs will most likely be necessary for the construction of regional and centralized BMPs, particularly those that are larger, multi-benefit projects such as greenway redevelopments. Projects under an acre in size, which will include most distributed BMPs, must comply with NPDES Phase II requirements and incorporate construction BMPs mandated by the jurisdiction within which the project falls. Compliance with the CGP would ensure that the construction of BMPs would have no temporary or permanent impact to water quality.

Operation

The structural BMPs are designed to reduce the transport of pollutants in stormwater, thereby helping Permittees improve water quality. The EWMP structural BMPs that have stormwater retention and infiltration as a function are designed to reverse the impacts from urbanization on the natural hydrograph and water quality. The widespread implementation of distributed BMPs with these functions in urban areas of all the EWMP groups will significantly reduce stormwater flow volumes and pollutant loading to creeks and rivers. The increased infiltration of stormwater from the widespread implementation of these projects will have the effect of increasing recharge to the groundwater, reducing peak storm flows and altering the hydrograph toward more natural conditions. By retaining stormwater flows and either infiltrating or releasing these flows closer to the natural conditions, the stream hydrographs will be less impacted by the urbanization. The increase in infiltration of stormwater from these BMPs will also raise groundwater levels and increase groundwater seepage to creeks and rivers following storm events. Runoff reduction measures and LFDs under the EWMP will significantly reduce dry-weather “nuisance” flows that have altered formerly ephemeral systems to perennial creeks and streams.

Distributed BMPs, although on a smaller parcel or site scale, would also be designed to collect and treat stormwater to reduce the loading of the smaller amounts of contaminants transported by their relatively smaller receiving areas. This would reduce contaminant loading to receiving waters compared with existing conditions while capturing contaminants in filter media. The vegetation and microbial activity in soil would work to biodegrade the typical fuels, oil, and grease in local urban runoff.

As discussed in the Project Description (Section 2.0), the identification of water quality priorities is required in Section VI.C.5.a of the MS4 permit as part of EWMP development. Appendix F provides a listing of the water quality priorities for each EWMP. As highlighted in this prioritization process, pollutants under a TMDL have higher priority and will be addressed under the timelines defined in the TMDLs. This highlights that the EWMP is a continuation of water quality improvement efforts by the Permittees under existing TMDLs through adopted TMDL Implementation Plans. BMP types that are assessed in this PEIR therefore include BMPs under various stages of implementation and planning to meet TMDL waste load allocations.

Once constructed, the structural BMPs would provide source control treatment of stormwater runoff prior to discharge to receiving waters whether on a site-specific (distributed structural BMPs), local (centralized structural BMPs), or regional (regional structural BMPs) basis. These structural BMPs would provide improved water quality through infiltration and treatment (e.g., filtration, settling, sedimentation, sorption, straining, and biological or chemical transformations) that would minimize the off-site transport of typical urban runoff pollutants. Implementation of the proposed BMPs would have no adverse impacts to surface water quality.

Mitigation Measures: None required

Significance Determination: Less than significant impact

Non-Structural (Institutional) BMPs

Non-structural BMPs policies, actions, and activities intended to prevent pollutants from entering stormwater runoff, thus eliminating the source of the pollutants. These BMPs would not involve any earthwork disturbance or construction activities, and similar to the Structural BMPs, once implemented, would aid in minimizing off-site discharge of urban runoff pollutants. As a result, they would have no adverse impact on water quality standards or waste discharge requirements.

Mitigation Measures: None required

Significance Determination: No impact

Groundwater

Impact 3.8-2: The proposed project would result in higher groundwater levels and could potentially affect groundwater quality.

Structural (Regional, Centralized, and Distributed) BMPs

Water Levels

Regional BMPs would recharge stormwater into the groundwater basin and could raise local groundwater levels following major storm events. Distributed infiltration BMPs would typically be too small to have a measureable effect on local groundwater levels. Groundwater basins in southern Los Angeles County are adjudicated and managed for beneficial uses. Increased capture of stormwater is a key element to integrated water supply planning in Southern California. The increased water supplies captured by the infiltration basins through the EWMP areas would be a beneficial impact of the projects.

In areas with shallow groundwater tables or impermeable soils, recharge could result in mounding that affects subsurface infrastructure such as building or bridge foundations. This would be a potential impact of regional BMPs that recharge large volumes of captured stormwater, but could also occur for distributed BMPs in areas with limited permeability. For example, the EWMP Areas of Malibu Creek, Northern Santa Monica Bay, and Palos Verdes are located in areas where no significant groundwater basin occurs. In addition, the West Coast Basin consists of a series of aquitards near the surface that prevent surface water percolation into the productive aquifers. Infiltration BMPs in these areas would result in shallow infiltration followed by lateral movement and seepage to nearby areas that could include creek cuts, areas of lower elevation, or basements and underground vaults. **Mitigation Measure HYDRO-1** requires Permittees to evaluate the suitability of BMP locations for groundwater recharge. Infiltration BMPs would not be suitable in areas of low permeability where subsurface structures could be adversely affected by groundwater mounding.

Groundwater Quality

Infiltration of stormwater runoff could increase contaminant loading in shallow soils and groundwater. Some contaminants found in stormwater runoff (e.g., oil, grease, metals) adsorb onto surficial soils and remain within a few feet of the surface, while other more soluble contaminants (e.g., fuels, nitrate, phosphate) may be entrained to deeper soils or migrate all the way to the groundwater. Over a long period of time, concentrations of these contaminants could increase resulting in contaminated soils and groundwater. Pre-treatment of source water in areas with the potential for heavy contaminant loading would be implemented as a required design feature for regional and centralized BMPs to assist in reducing long-term loading. In addition, non-structural source control BMPs would help reduce contaminant loading over time. The LID standards for the County of Los Angeles and the various cities participating in the EWMP provide protocols for designing regional and centralized BMPs that minimize the potential for contaminant loading. Compliance with these protocols and implementation of **Mitigation Measure HYDRO-2** which would require the implementing agencies to evaluate the need for pretreatment at each infiltration BMP, impacts to groundwater quality would be less than significant.

Proposed projects that recharge the shallow aquifers have the potential to mobilize shallow contamination and alter groundwater flow directions. Within the urbanized areas of the County, legacy groundwater contamination is prevalent resulting from overlying uses such as industrial operations and underground storage of fuels. A few major contamination areas have rendered the groundwater basins unusable for potable uses. In particular, groundwater contamination plumes exist in the southeast corner of the San Fernando Groundwater Basin, the Main San Gabriel Basin, and the East Subbasin in Santa Clarita. Each of these areas are undergoing remedial actions to improve groundwater quality.

The infiltration of large volumes of water in certain areas could modify these existing contaminant plumes. If these infiltration facilities were located over contaminated groundwater plumes, groundwater flow patterns could be modified such that contaminated groundwater migrates into areas that are not currently contaminated or pushed away from existing treatment systems. **Mitigation Measure HYDRO-3** would require that infiltration BMPs would be required to evaluate site conditions and the existence of contaminated groundwater plumes during planning stages prior to construction of infiltration galleries, trenches, and basins.

Mitigation Measures:

HYDRO-1: Prior to approving an infiltration BMP, the Permittee shall conduct an evaluation of the suitability of the BMP location. Appropriate infiltration BMP sites should avoid areas with low permeability where recharge could adversely affect neighboring subsurface infrastructure.

HYDRO-2: Prior to approving an infiltration BMP, the Permittee shall identify pretreatment technologies, type, and depth of filtration media; depth to groundwater; and other design considerations necessary to prevent contaminants from impacting groundwater quality. The design shall consider stormwater quality data within the BMP's collection area to assess the need and type of treatment and filtration controls. Local design manuals and ordinances requiring minimum separation distance to groundwater shall also be met as part of the design.

HYDRO-3: Prior to the installation of an infiltration BMP, the Permittee shall conduct a database review for contaminated groundwater sites within a quarter mile of the proposed infiltration facility. The Permittee shall identify whether any contaminated groundwater plumes are present and whether coordination with the local and state environmental protection overseeing agency and responsible party is warranted prior to final design of infiltration facility.

Significance Determination: Less than significant with mitigation (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.8-3.)

Non-Structural (Institutional) BMPs

Non-structural BMPs policies, actions, and activities are primarily intended to prevent pollutants from entering stormwater runoff, thus eliminating the source of the pollutants. However, within Planning and Land Use Programs, there would be encouragement for implementation of LID strategies which not only improve water quality but also include on-site infiltration which can increase groundwater levels. Most non-structural institutional BMPs are implemented to meet

Minimum Control Measure (MCM) requirements in the MS4 permit. As discussed above, increased infiltration from local LID drainage features are not as likely to result in substantive increases in groundwater levels and therefore would have a less than significant impact on groundwater supplies.

Mitigation Measures: None required

Significance Determination: Less than significant

Drainage Pattern Alteration Resulting in Erosion or Siltation

Impact 3.8-3: The proposed project could substantially alter the existing drainage pattern of a site or area through the alteration of the course of a stream or river, or by other means, in a manner that would result in substantial erosion or siltation on- or off-site.

Structural (Regional, Centralized, and Distributed) BMPs

The proposed structural BMPs would be designed to minimize off-site discharge of urban runoff pollutants including siltation and sedimentation. Many of the structural BMPs would include on-site infiltration of stormwater runoff which would also be effective in minimizing erosion or transport of sedimentation into receiving waters. Through increased infiltration prior to discharge into receiving waters, flows within existing streams or rivers would receive reduced stormwater flow volumes thereby decreasing flow energies. As a result, the potential for erosion or siltation within existing streams or rivers would be reduced and the potential impact less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

Non-structural BMPs policies, actions, and activities are primarily intended to prevent pollutants from entering stormwater runoff largely through the use of drainage features that either infiltrate or detain stormwater runoff on-site. Drainage patterns would change through implementation of these non-structural institutional BMPs that are implemented to meet Minimum Control Measure (MCM) requirements in the MS4 permit. MCMs are considered a subset of institutional BMPs. These BMPs are not constructed, but within Planning and Land Use policies there would be encouragement for implementation of LID strategies which include on-site infiltration and/or detaining peak flows that would minimize off-site flows as well as the potential for erosion and off-site siltation. As discussed previously, increased infiltration from local LID drainage features minimize the potential for erosion and therefore there would be a less than significant impact related to erosion and siltation.

Mitigation Measures: None required

Significance Determination: Less than significant

Drainage Pattern Alteration Resulting in Flooding

Impact 3.8-4: The project could substantially alter the existing drainage pattern of a site or area through the alteration of the course of a stream or river or, by other means, substantially increase the rate or amount of surface runoff in a manner that would result in flooding on- or off-site.

Structural (Regional, Centralized, and Distributed) BMPs

The proposed structural BMPs include features that would increase stormwater retention and encourage on-site infiltration to reverse the impacts from urbanization on the natural hydrograph. The widespread implementation of distributed BMPs with these functions in urban areas of all the EWMP groups will significantly reduce stormwater flow volumes especially during peak storm flow events as indicated by the figure shown in Impact 3.8-3. Larger retention and infiltration regional and centralized BMPs will also have a beneficial effect on regional hydrology through delayed discharge to avoid the spike in peak flows currently experienced. By retaining stormwater flows and either infiltrating or releasing these flows closer to the natural hydrograph, the change in drainage patterns would result in reduced peak flows and as a result a reduced potential for flooding on- or off-site. Therefore, the potential impact would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

Non-structural BMPs policies, actions, and activities are primarily intended to prevent pollutants from entering stormwater runoff and include drainage features that infiltrate or detain stormwater runoff on-site. Drainage patterns would change through implementation of these non-structural institutional BMPs, however implementation of LID strategies which include on-site infiltration that would minimize off-site flows as well as the potential for erosion and off-site siltation. As discussed above, increased infiltration from local LID drainage features are minimize the potential for erosion and therefore would be a *less than significant impact*.

Mitigation Measures: None required

Significance Determination: Less than significant

Stormwater Drainage Systems

Impact 3.8-5: The proposed project could create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff.

Structural (Regional, Centralized, and Distributed) BMPs

The proposed structural BMPs whether regional, centralized or distributed would have an overall effect of reducing off-site stormwater flows through on-site infiltration and detention. As a result of having a net effect of reducing stormwater runoff volumes, there would be a less-than-significant effect on the capacity of existing or planned stormwater drainage systems. The structural BMPs would also provide improvements to water quality of receiving waters as that is the primary purpose of these BMPs and have proven effective in reducing potential sources of polluted runoff for a less than significant impact.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

The non-structural BMPs would similarly provide the policies, actions, and activities to encourage the use of drainage features that either infiltrate or detain stormwater runoff on-site. Drainage patterns would change through implementation of these non-structural institutional BMPs but would be designed to improve water quality and reduce stormwater flow volumes. Therefore, the potential impact to the capacity of drainage systems would be less than significant as well as the potential to provide additional sources of polluted runoff.

Mitigation Measures: None required

Significance Determination: Less than significant

Flood Hazards: Housing

Impact 3.8-6: The project could place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other authoritative flood hazard delineation map.

Structural (Regional, Centralized, and Distributed) BMPs

The proposed structural BMPs would not include the construction of any housing and therefore there would be no impact related to placement of housing in a flood hazard area.

Mitigation Measures: None required

Significance Determination: No impact

Non-Structural (Institutional) BMPs

Similar to above, the non-structural BMPs would not include the construction of any housing and therefore there would be no impact related to placement of housing in a flood hazard area.

Mitigation Measures: None required

Significance Determination: No impact

Flood Hazards: Structures

Impact 3.8-7: The project could place within a 100-year flood hazard area structures that would impede or redirect flood flows.

Structural (Regional, Centralized, and Distributed) BMPs

In general, the majority of the structural BMPs would consist of either features with a very low profile in terms of having any effect on flood flows (e.g., drainage swales, infiltration trenches, galleries, ponds, planter boxes and pervious pavement) or features that are subterranean (e.g., cisterns, detention basins, dry wells). However, structural BMPs could include above ground detention basins. Above ground detention basins would be required to adhere to any local flood zone construction permitting requirements such that they would not be impede or redirect flood flows. As a result, the impact of structural BMPs would *be less than significant*.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

Non-structural BMPs would not include the construction of any structures and therefore there would be no impact related to impeding or redirecting flood flows.

Mitigation Measures: None required

Significance Determination: No impact

Flood Hazards: Levee or Dam Failure

Impact 3.8-8: The proposed project could expose structures to a significant risk of loss, including flooding as a result of the failure of a levee or dam.

Structural (Regional, Centralized, and Distributed) BMPs

The majority of the structural BMPs would consist of features with a very low profile and would be designed to aid in the conveyance of runoff and high flows. Structural BMPs could also include above ground detention basins. Above ground detention basins would not be staffed and not likely to be susceptible to substantive damage in the event of a catastrophic failure of a levee or dam based on the general characteristics of how above ground detention basins are constructed. As a result, the impact of structural BMPs would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

Non-structural BMPs would not include the construction of any structures and therefore there would be no impact related to failure of a levee or dam.

Mitigation Measures: None required

Significance Determination: No Impact

Tsunami, Seiche or Mudflow

Impact 3.8-9: The proposed project could place structures in areas subject to inundation by seiche, tsunami, or mudflow.

Structural (Regional, Centralized, and Distributed) BMPs

The project area includes coastal areas and areas that are adjacent to enclosed bodies of water that could be subject to seiche, tsunami, or mudflow. As described above the majority of these BMP facilities consist of either subterranean improvements or low profile features that are generally not considered susceptible to substantive damage from these hazards. Larger above ground improvements such as centralized or regional detention basins, could be located in areas that are within seiche, tsunami, or mudflow hazard areas. However, these structures would not be staffed and any potential damage that they might incur would likely be relatively easily repaired. As a result, the potential impact to structures subject to inundation by seiche, tsunami, or mudflow would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

Non-structural BMPs would not include the construction of any structures and therefore there would be no impact related to inundation by seiche, tsunami, or mudflow.

Mitigation Measures: None required

Significance Determination: No impact

Cumulative Impact Discussion

Structural (Regional, Centralized, and Distributed) BMPs

The EWMPs span numerous watersheds within Los Angeles County. Implementation of the proposed structural BMPs, together with past, present, and other reasonably foreseeable future projects across the different watersheds of the region would result in improved stormwater quality and reduced non storm flows. As BMPs are incrementally installed, the Los Angeles region will experience reduced dry-weather runoff, a more natural hydrology, and improved receiving water quality. In addition, new infiltration projects will incrementally augment groundwater drinking water supplies. Although the increased infiltration projects may increase pollutant loads to groundwater aquifers, pretreatment systems coupled with regional groundwater management lead by the local Watermasters will ensure that the beneficial uses of groundwater basins are not significantly impaired. Implementation of the EWMPs will beneficially impact local surface water quality and groundwater supplies.

Mitigation Measures: None required

Significance Determination: Less than significant

3.8.4 Summary of Impact Assessment

Table 3.8-3 on the following page shows a summary of the structural BMPs requiring mitigation.

TABLE 3.8-3
SUMMARY OF HYDROLOGICAL RESOURCE IMPACTS REQUIRING MITIGATION MEASURES

	Thresholds of Significance

NOTE: These conclusions are based on typical size and locations of BMPs.

3.9 Land Use and Agriculture

This section describes and discusses existing land uses and agricultural resources that may be affected by the proposed program in the Enhanced Watershed Management Program (EWMP) areas of Los Angeles County (County) and considers the compatibility of the proposed program with relevant land use plans and policies. The analysis identifies potential impacts that may result from implementing the proposed program and evaluates their significance. Applicable plans and policies related to land use and agriculture are presented and potential impacts and mitigation measures, if needed, are identified.

3.9.1 Environmental Setting

Regional Setting

The proposed program is located in Los Angeles County, which covers an area of about 4,083 square miles and comprises 88 cities and approximately 2,650 square miles of unincorporated areas. The majority of the County is highly urbanized and consists of several cities, communities and unincorporated areas. The proposed projects are located in multiple jurisdictions of Los Angeles County; these include Los Angeles County Flood Control District (LACFCD), the County of Los Angeles, and the following cities: Los Angeles, Beverly Hills, Culver City, Inglewood, Santa Monica, West Hollywood, Hawthorne, El Segundo, Lomita, Baldwin Park, Covina, Glendora, Industry, La Puente, Malibu, Calabasas, Agoura Hills, Westlake Village, Hidden Hills, Santa Clarita, Rancho Palos Verdes, Palos Verdes Estates, Rolling Hills Estates, Redondo Beach, Hermosa Beach, Torrance, Manhattan Beach, Arcadia, Azusa, Bradbury, Duarte, Monrovia, Sierra Madre, Alhambra, Burbank, Glendale, Hidden Hills, La Cañada Flintridge, Montebello, Monterey Park, Pasadena, Rosemead, San Gabriel, San Marino, South Pasadena, and Temple City (see Figure 1-1). Each of these jurisdictions have independent planning documents that guide the development of urban, agricultural, and other land uses within their jurisdictional boundaries.

Existing Land Use Characterization

Land uses within the County are widely varied and include open space, residential, commercial, mixed-use, public and semi-public, and industrial land uses. The proposed program would be located in various watersheds across Los Angeles County that span multiple jurisdictions with varying land use regulations. The existing land uses within each watershed are summarized in this section by EWMP group and are based upon information from the Southern California Association of Government (SCAG) and the EWMP Work Plans. The EWMP agencies have no jurisdiction over the land that is owned by the State of California (i.e., California Department of Fish and Wildlife, the State Lands Commission, and the California Department of Transportation) or the U.S. Government.

Ballona Creek

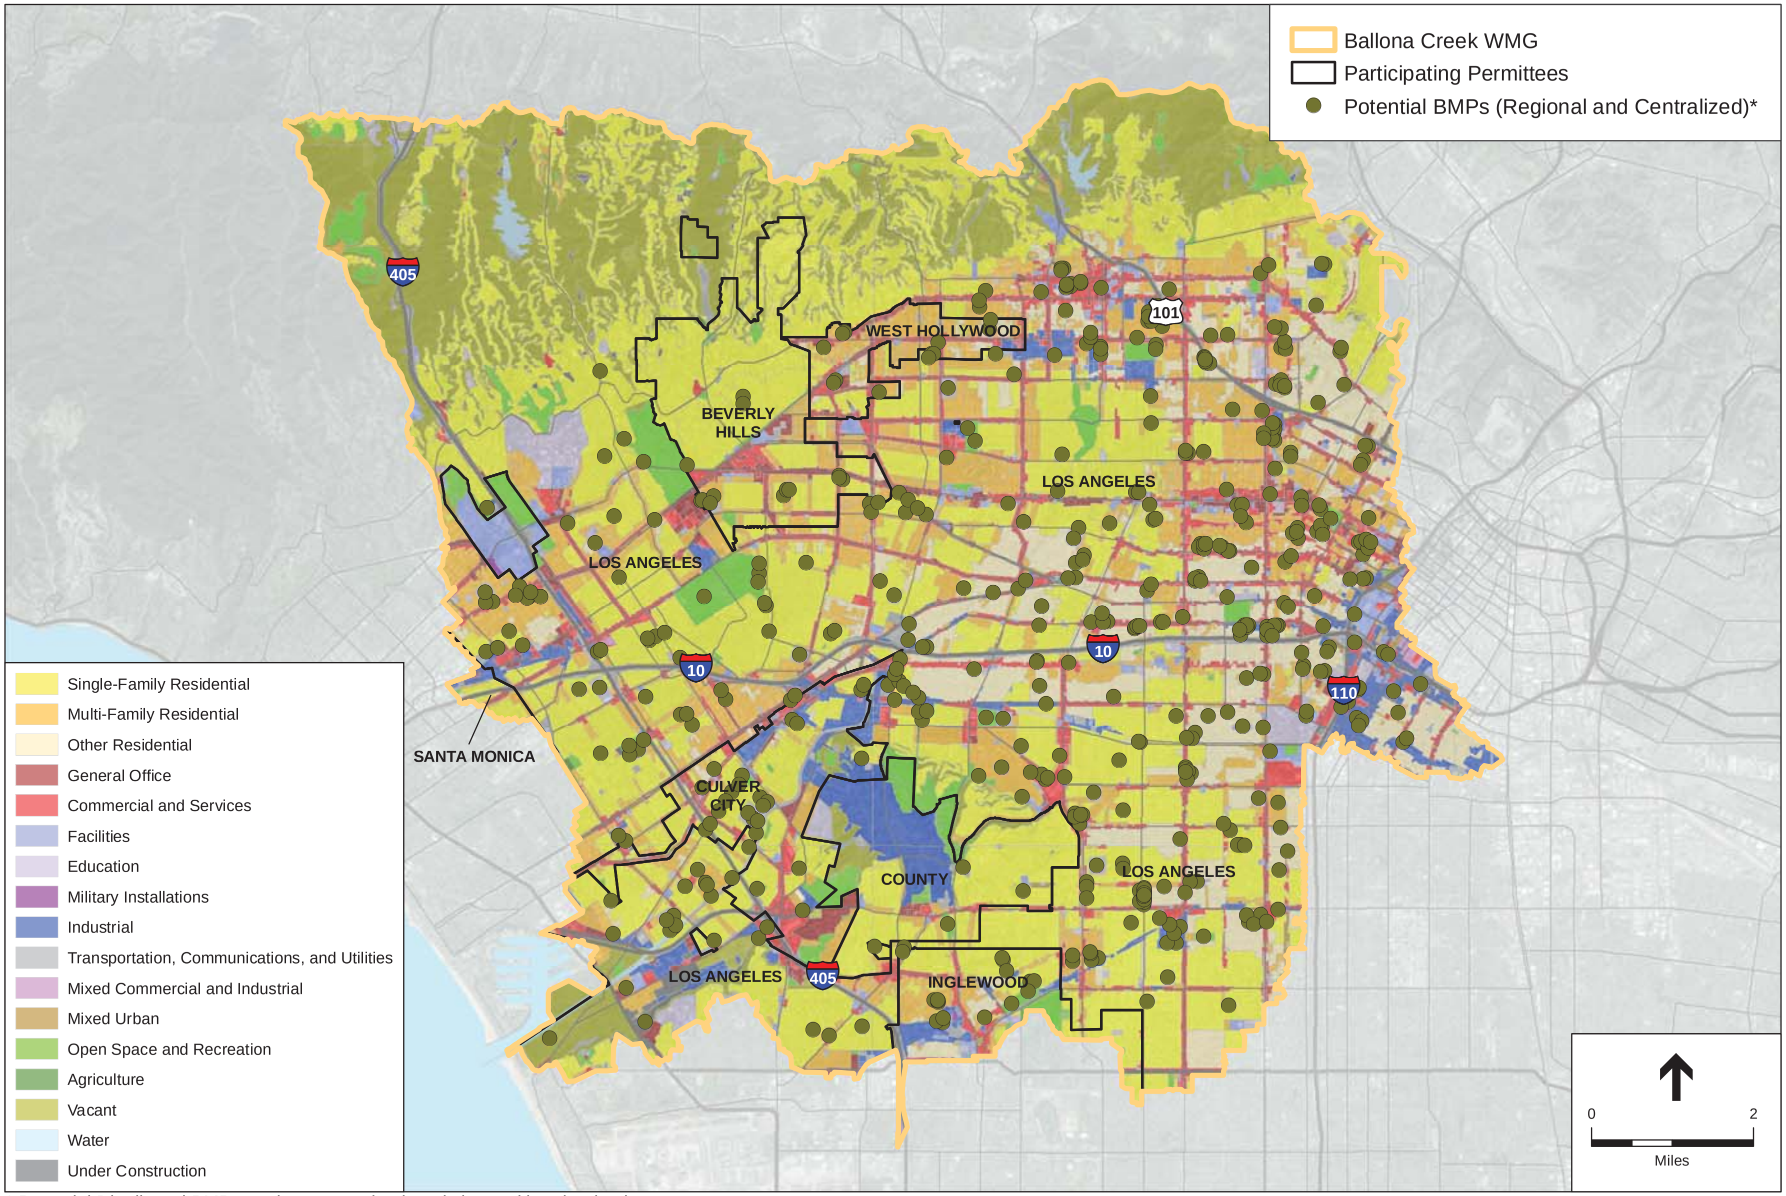
The Ballona Creek EWMP area covers the Ballona Creek Watershed. The Permittees within this EWMP are: the Cities of Beverly Hills, West Hollywood, Los Angeles, Inglewood, Culver City, Santa Monica; the County of Los Angeles; and LACFCD. The Ballona Creek Watershed comprises the cities of Beverly Hills, Culver City, and West Hollywood and parts of Inglewood, Los Angeles and Santa Monica as well as small unincorporated areas of Los Angeles County. Collectively, the Municipal Separate Stormwater Sewer Systems (MS4) Permittees in the Ballona Creek Watershed have jurisdiction over 123 square miles or 96 percent of the total watershed area. A breakdown of areas by MS4 Permittees is provided in **Table 3.9-1**.

TABLE 3.9-1
BALLONA CREEK WATERSHED LAND AREA DISTRIBUTION

Agency	Land Area (Acres)	Percent of EWMP Area
City of Los Angeles	65,272.89	83.21%
County of Los Angeles	3,164.76	4.03%
City of Beverly Hills	3,618.95	4.61%
City of Culver City	3,125.00	3.98%
City of Inglewood	1,907.72	2.43%
City of West Hollywood	1,135.00	1.45%
City of Santa Monica	217.31	0.28%
Total	**78,441.63**	**100.00%**

SOURCE: Ballona Creek EWMP Work Plan, 2014.

The population in the Ballona Creek Watershed is approximately 1.6 million people (LADPW, 2004). The predominant land use in the Ballona Creek Watershed is residential, representing 63.7 percent of the total land area, including multi-family residential uses covering 18 percent of the area. Although open space areas represent 16.7 percent, this category may include parks and other open areas not generally open to the public, including vacant land and golf courses (LADPW, 2004). Commercial, public, light industrial, other urban and unknown land uses represents 19.6 percent of the total land area. **Figure 3.9-1** shows land uses in the Ballona Creek Watershed and the location of planned and priority regional/centralized Best Management Practices (BMPs). The location of distributed BMPs would be throughout the urbanized areas of the watershed.



* Potential Distributed BMP not shown - predominantly located in urbanized areas

Beach Cities

The Beach Cities EWMP area covers portions of two watersheds: Santa Monica Bay Watershed (Jurisdictional Group [JG] 5 and JG6) and the Dominguez Channel Watershed. The Permittees within this EWMP are: the Cities of Redondo Beach, Manhattan Beach, Hermosa Beach, and Torrance; and the LACFCD. **Figure 3.9-2** shows land uses in the Beach Cities EWMP area and the location of planned and priority regional/centralized BMPs. The location of distributed BMPs would be throughout the urbanized areas of the watershed.

The western portion of the Beach Cities EWMP area consists of approximately 7,840 acres of land that drains to Santa Monica Bay. This accounts for 38.4 percent of the total Beach Cities Watershed Management Group area, and includes portions of the cities of Manhattan Beach, Redondo Beach, and Torrance and the entirety of the City of Hermosa Beach.

The northeastern portion of the Beach Cities EWMP area is tributary to Dominguez Channel (including the Torrance Carson Channel) and comprises approximately 7,380 acres of land. This watershed accounts for 36.1 percent of the total Beach Cities EWMP area, and includes portions of the cities of Manhattan Beach, Redondo Beach, and Torrance. Storm drains from the Cities of Manhattan Beach and Redondo Beach drain through the City of Lawndale before discharging to Dominguez Channel. Torrance's MS4 discharges directly to the Dominguez Channel and Torrance Carson Channel (Torrance Lateral).

The southeastern portion of the Beach Cities EWMP area is tributary to Machado Lake (including Wilmington Drain) and comprises approximately 5,182 acres of land. This watershed accounts for 25.5 percent of the total Beach Cities EWMP area. All but 1.2 acres (0.02 percent) of this area is within the City of Torrance. The City of Redondo Beach owns the remainder of the area, though no Redondo Beach catch basins or MS4 are tributary to Machado Lake. LACFCD is not responsible for land within the Beach Cities EWMP area, but does own and maintain infrastructure within all three watersheds. A breakdown of areas by MS4 Permittee is provided in **Table 3.9-2**.

TABLE 3.9-2
BEACH CITIES WATERSHED LAND AREA DISTRIBUTION

Agency	SMB Watershed (acres)	Dominguez Channel Watershed (acres)	Machado Lake Watershed (acres)	Total EWMP Area (acres)	Percent of EWMP Area
Redondo Beach	2,614	1,217	1	3,832	19%
Manhattan Beach	2,078	350	-	2,428	12%
Hermosa Beach	832	-	-	832	4%
City of Torrance	2,314	5,812	5,181	13,307	65%
Total	**7,837**	**7,379**	**5,182**	**20,399**	**100%**

Dominguez Channel

The Dominguez Channel EWMP area covers portions of the Dominguez Channel Watershed and the Machado Lake and the Los Angeles/Long Beach Harbor subwatersheds. The Dominguez Channel EWMP addresses approximately 36,410 acres, or 47.45 percent of the total 133-square-mile watershed. The Permittees within this EWMP are: the Cities of El Segundo, Hawthorne, Inglewood, Lomita, and Los Angeles; the County of Los Angeles; and the LACFCD. A breakdown of areas by MS4 Permittee and other agencies is provided in **Table 3.9-3**. **Figure 3.9-3** shows land use in the Dominguez Channel EWMP area and the location of planned and priority regional/centralized BMPs. The location of distributed BMPs would be throughout the urbanized areas of the watershed. **Table 3.9-4** provides the land use breakdown within the Dominguez Channel EWMP.

Malibu Creek

The Malibu Creek Watershed EWMP area covers the majority of the Malibu Creek Watershed. The Permittees within this EWMP are: the Cities of Agoura Hills, Calabasas, Hidden Hills, and Westlake Village; the County of Los Angeles; and the LACFCD.

Malibu Creek Watershed land uses are 81 percent vacant, 11 percent residential, 2 percent open space and recreation, 2 percent commercial and public, 1 percent transportation and utilities, and 1percent mixed-use (LADPW, 2005a). The Malibu Creek Watershed EWMP area is approximately 32,992 acres, which is approximately 46.7 percent of the total area in the Malibu Creek Watershed. A breakdown of areas by MS4 Permittee and other agencies is provided in **Table 3.9-5**. **Figure 3.9-4** shows land use in the Malibu Creek Watershed EWMP area and the location of planned and priority regional/centralized BMPs. The location of distributed BMPs would be throughout the urbanized areas of the watershed.

Marina del Rey

The Marina del Rey EWMP area covers the Marina del Rey Watershed. The Permittees within this EWMP are: the Cities of Los Angeles and Culver City; the County of Los Angeles; and LACFCD.

Land uses within the Marina del Rey Watershed are 52 percent residential, 46 percent commercial and 2 percent open space (LADPW, 2014a). A breakdown of areas by MS4 Permittee and other agencies is provided in **Table 3.9-6**. **Figure 3.9-5** shows land use in the Marina del Rey Watershed EWMP area and the location of planned and priority regional/centralized BMPs. The location of distributed BMPs would be throughout the urbanized areas of the watershed. **Table 3.9-7** provides the land use breakdown within the Marina del Rey Watershed.

North Santa Monica Bay

The North Santa Monica Bay EWMP area covers the north region of the Santa Monica Bay Watershed (JG1 and JG4 and a portion of JG9) within the city of Malibu's borders. The Permittees within this EWMP are: the City of Malibu; County of Los Angeles; and LACFCD. The North Santa Monica Bay EWMP area encompasses 55,121 acres. The North Santa Monica Bay EWMP area is over 93 percent vacant land. The EWMP Group land use breakdowns by JG and watershed are shown in **Table 3.9-8**. **Figure 3.9-6** shows land uses in the North Santa Monica Bay EWMP area and the location of planned and priority regional/centralized BMPs. The location of distributed BMPs would be throughout the urbanized areas of the watershed.

Peninsula Cities

The Peninsula Cities EWMP area covers most of the Santa Monica Bay Watershed JG7, the Los Angeles/Long Beach Harbor Watershed, and the Machado Lake Watershed. The Permittees within this EWMP are: the Cities of Rancho Palos Verdes, Palos Verdes Estates, and Rolling Hills Estates; the County of Los Angeles; and LACFCD.

The Santa Monica Bay Watershed accounts for 63 percent (14.2 square miles) of the total Peninsula watershed management group area, and includes portions of the cities of Palos Verdes Estates, Rancho Palos Verdes, and Rolling Hills Estates. The Los Angeles Harbor subwatershed accounts for 15 percent (3.4 square miles) of the total Peninsula watershed management group area, and includes portions of the cities of Rancho Palos Verdes and Rolling Hills Estates. The Machado Lake subwatershed accounts for 22 percent (4.9 square miles) of the total Peninsula watershed management group area, and includes portions of the cities of Palos Verdes Estates, Rancho Palos Verdes, and Rolling Hills Estates and the County of Los Angeles. **Table 3.9-9** provides the Peninsula EWMP area identified by watershed and agency. **Figure 3.9-7** shows land uses in the Palos Verdes Peninsula EWMP area and the location of planned and priority regional/centralized BMPs. The location of distributed BMPs would be throughout the urbanized areas of the watershed.

Rio Hondo/San Gabriel River

The Rio Hondo/San Gabriel River EWMP area covers portions of the Los Angeles and San Gabriel River watersheds. The Permittees within this EWMP are: the Cities of Arcadia, Azusa, Bradbury, Duarte, Monrovia, and Sierra Madre; the County of Los Angeles; and LACFCD.

Table 3.9-10 provides the size and percentage of each participating member's jurisdiction within the group and the percent contribution to the Los Angeles River and/or San Gabriel River Watersheds. The area included in the Rio Hondo/San Gabriel River EWMP encompasses approximately 41 square miles of predominately residential and open space land use and excludes areas in the Angeles National Forest. Of the total Los Angeles River and San Gabriel River Watershed areas, the Rio Hondo/San Gabriel River EWMP members have jurisdiction over 4 and 3 percent of the total watersheds, respectively. **Table 3.9-11** depicts the watershed land use categories within the Rio Hondo/San Gabriel River EWMP area. **Figure 3.9-8** shows land uses in the Rio Hondo/ San Gabriel River EWMP area and the location of planned and priority regional/centralized BMPs. The location of distributed BMPs will be throughout the urbanized areas of the watershed.

Figure 3.9-8

Land Uses in the Rio Hondo / San Gabriel River Watershed Management Group

Santa Monica Bay Jurisdictional Groups 2 & 3

The Santa Monica Bay EWMP area covers the central region of the Santa Monica Bay Watershed (JG2 and JG3) and includes the urbanized Dockweiler and Santa Monica subwatersheds, as well as natural open space located in the Castle Rock, Pulga Canyon, Temescal Canyon, and Santa Monica Canyon subwatersheds. The Permittees within this EWMP include the Cities of Los Angeles, Santa Monica, and El Segundo; the County of Los Angeles; and LACFCD.

The Santa Monica Bay EWMP Group area covers 34,362 acres. Approximately 49 percent of the Santa Monica Bay EWMP Group area is open space, and approximately 93 percent of the open space is located the northern subwatersheds and approximately 7 percent is located in the Dockweiler subwatershed. Approximately 67 percent of the Santa Monica Bay EWMP Group area is pervious according to geographic information system (GIS) data from the Los Angeles County Department of Public Works, the large majority of which comes from the northern-most subwatersheds of Castle Rock, Pulga Canyon, Temescal Canyon, and Santa Monica Canyon. **Table 3.9-12** provides the size and percentage of each participating member's jurisdiction within the watershed. **Figure 3.9-9** shows land uses in the Santa Monica Bay EWMP area and the location of planned and priority regional/centralized BMPs. The location of distributed BMPs would be throughout the urbanized areas of the watershed.

Upper Los Angeles River

The Upper Los Angeles River EWMP area covers the upper reaches of the Los Angeles River Watershed. The Permittees within this EWMP are: the Cities of Alhambra, Burbank, Calabasas, Glendale, Hidden Hills, La Cañada Flintridge, Los Angeles, Montebello, Monterey Park, Pasadena, Rosemead, San Gabriel, San Marino, South Pasadena, and Temple City; the County of Los Angeles; and LACFCD.

The area included in the Upper Los Angeles River Watershed EWMP is approximately 479 square miles, or 57.43 percent of the total watershed area. **Table 3.9-13** provides the size and percentage of each participating member's jurisdiction within the watershed. **Figure 3.9-10** shows land uses in the Upper Los Angeles River EWMP area and the location of planned and priority regional/centralized BMPs. The location of distributed BMPs would be throughout the urbanized areas of the watershed.

City of Glendora	9,307	13.5%
City of Industry	7,647	11.1%
City of La Puente	2,207	3.2%
Los Angeles County	40,812	59.4%

SOURCE: Upper San Gabriel River EMWP Work Plan, 2014.

Upper Santa Clara River

The Upper Santa Clara River EWMP area covers approximately 121,423 acres the Upper Santa Clara River Watershed. The Permittees within this EWMP are the City of Santa Clarita; the County of Los Angeles; and LACFCD.

Land uses within the Santa Clara River Watershed include residential, commercial, agricultural and undeveloped land (LADPW, 2014b). Within the 500-year river flood plain, the most prevalent land use is open space (62 percent), followed by agriculture (29 percent). The remaining land uses can be considered developed and/or urbanized and make up less than 10 percent of the total (LADPW, 2005b). Of the total watershed area, the City of Santa Clarita and County of Los Angeles have jurisdiction over 46 percent of the land area. **Table 3.9-15** provides the size and percentage of each participating member's jurisdiction within the watershed. **Figure 3.9-12** shows land uses in the Upper Santa Clara River Watershed EWMP area.

Habitat Conservation Plan

There is one adopted habitat conservation plan area within the EWMP watershed areas: the Palos Verdes Peninsula Natural Communities Conservation Plan (NCCP)/Habitat Conservation Plan (HCP). The Palos Verdes Peninsula NCCP/HCP is within the Palos Verdes Peninsula EWMP area. The Palos Verdes Peninsula NCCP/HCP covers the city of Rancho Palos Verdes, which is approximately 8,600 acres. The Rancho Palos Verdes City Council adopted the NCCP/HCP in 2004.

The City of Rancho Palos Verdes NCCP Subarea Plan (Subarea Plan) was prepared to maximize benefits to wildlife and vegetation communities while accommodating appropriate economic development within the city and region pursuant to the requirements of the NCCP Act and Section 10(a) of the Endangered Species Act (URS, 2004). The Subarea Plan provides for the comprehensive management and conservation of multiple species. The subarea is unique in that it contains healthy concentrations of coastal sage scrub habitat (approximately 1,000 acres) and a number of coastal sage scrub species that are not found in other Southern California coastal sage scrub communities.

Agriculture

The County of Los Angeles contains very little agricultural or forest land, as the majority of the land is urbanized. The watersheds in the northwestern corner of the County along the coast contain land designated as Farmland of Local Potential by the California Department of Conservation. This type of land is primarily located in the North Santa Monica Bay Coastal and the Malibu Creek Watersheds, with some located within the Upper Los Angeles River Watershed and the Upper Santa Clara River Watershed. The Upper Santa Clara River Watershed, covering the northwestern and northernmost borders of the County, contains large areas of Grazing Land and Farmland of Local Potential, and tiny pockets of Prime Farmland, Farmland of Statewide Importance, and Unique Farmland.

The only Williamson Act contracts in effect in Los Angeles County are for land on Santa Catalina Island (Los Angeles County, 2014), which is not located within the EWMP group areas.

To the north of the Los Angeles River EWMP group is the Angeles National Forest, which offers outdoor activities such as hiking trails, campgrounds, and picnic areas. Angeles National Forest covers approximately 1,024 square miles just outside of the highly urbanized cities of Los Angeles County. While it is very close, it is not inside the Los Angeles River EWMP group boundary.

3.9.2 Regulatory Setting

State

California Coastal Commission

The California Coastal Commission (CCC) is a state agency that works in conjunction with local cities and counties to plan and regulate the use of land and water in the coastal zone. The coastal zone covers the entire shoreline of California and varies in width depending on the region. The CCC regulates development activities in the coastal zone. The CCC was established by the California Coastal Act of 1976. Local Coastal Programs (LCPs) are approved by the CCC to allow local jurisdictions to guide development in the coastal zone. LCPs require a Coastal Development Permit (CDP) for development in the coastal zone.

Southern California Association of Governments Regional Comprehensive Plan

SCAG is the federally mandated Metropolitan Planning Organization representing six counties: Los Angeles, Imperial, Orange, Riverside, San Bernardino, and Ventura. The SCAG Regional Comprehensive Plan addresses important regional issues such as housing, traffic/transportation, water, and air quality and serves as an advisory planning document to support and encourage local agencies in their planning efforts.

California Farmland Mapping and Monitoring Program

The California Department of Conservation, under the Division of Land Resource Protection, has established the Farmland Mapping and Monitoring Program. The Farmland Mapping and Monitoring Program monitors the conversion of the state's farmland to and from agricultural use and reports on the amount of land converted from agricultural to non-agricultural use. The Farmland Mapping and Monitoring Program maintains an inventory of state agricultural land and updates its "Important Farmland Series Maps" every 2 years (California Department of Conservation, 2007). Important farmlands are divided into the following five categories on Farmland Mapping and Monitoring Program maps based on their suitability for agriculture:

- **Prime Farmland.** Prime Farmland is land with the best combination of physical and chemical characteristics able to sustain long-term production of agricultural crops. This land has produced irrigated crops at some time within the four years prior to the mapping date.
- **Farmland of Statewide Importance.** Farmland of Statewide Importance is land that meets the criteria for Prime Farmland but with minor shortcomings such as greater slopes or lesser soil moisture capacity.
- **Unique Farmland.** Unique Farmland has even lesser quality soils and produces the state's leading agricultural crops. This land is usually irrigated but also includes non-irrigated orchards and vineyards.

- **Farmland of Local Importance.** Farmland of Local Importance is land that is important to the local agricultural economy as determined by each county's board of supervisors and a local advisory committee.
- **Grazing Land.** Grazing Land is land on which the existing vegetation is suited to the grazing of livestock.

Local

County of Los Angeles Low Impact Development Manual

The County of Los Angeles (County) prepared the 2014 Low Impact Development Standards Manual (LID Standards) to comply with the requirements of the National Pollutant Discharge Elimination System (NPDES) MS4 Permit for stormwater and non-stormwater discharges from the MS4 within the coastal watersheds of Los Angeles County (CAS004001, Order No. R4-2012-0175), referred to as the 2012 MS4 Permit (County of Los Angeles, 2014b). The LID Standards provide guidance for the implementation of stormwater quality control measures in new development and redevelopment projects in unincorporated areas of the County with the intention of improving water quality and mitigating potential water quality impacts from stormwater and non-stormwater discharges. The November 2013 LID Ordinance became effective December 5, 2013.

City of Los Angeles Low Impact Development Manual

In November 2011, the City of Los Angeles adopted the Stormwater Low Impact Development (LID) Ordinance #181899) with the stated purpose of:

- Requiring the use of LID standards and practices in future developments and redevelopments to encourage the beneficial use of rainwater and urban runoff
- Reducing stormwater/urban runoff while improving water quality
- Promoting rainwater harvesting
- Reducing offsite runoff and providing increased groundwater recharge
- Reducing erosion and hydrologic impacts downstream
- Enhancing the recreational and aesthetic values in our communities

The City of Los Angeles institutionalized the use of LID techniques for development and redevelopment projects. Subsequent to the adoption of the Stormwater LID Ordinance, the City prepared the *Development Best Management Practices Handbook, Low Impact Development Manual,* dated June 2011, to describe the required BMPs (City of Los Angeles, 2011).

Other Cities LID

Various other cities within the County also have LID standards or guidance. The goals, objectives, and content of the LID document are similar to that of the County and City of Los Angeles, and are not referenced here.

County of Los Angeles General Plan

A General Plan is a basic planning document that, alongside the zoning code, governs development in a city or county. The State requires each city and county to adopt a General Plan with seven mandatory elements: land use, open space, circulation, housing, noise, conservation, and safety, along with any number of optional elements as appropriate. The proposed EWMPs would be subject to local plans and policies of the areas in which they are located. Because this is a high-level assessment of projects spanning the entire County, this Program Environmental Impact Report (PEIR) will only discuss County-level goals and policies relating to the overall program.

The County of Los Angeles is currently updating their General Plan from the version adopted in 1980; the new comprehensive plan is expected to be complete by late 2014. Below are land use and agriculture goals and policies from both the existing General Plan and the Draft General Plan 2035 (as of August 2014) which relate to the proposed program.

Existing General Plan, Adopted 1980

Goal – Conserve Resources and Enhance Environmental Quality: Increasing pressures for urban expansion into outlying areas of significant ecological and scenic resources require that effective measures be taken to conserve and enhance our most valuable natural assets.

Policy 20: Establish land use controls that afford effective protection for significant ecological and habitat resources, and lands of major scenic value.

Policy 21: Protect identified Potential Agricultural Preserves by discouraging inappropriate land division and allowing only use types and intensities compatible with agriculture.

Policy 22: In non-urban areas outside of Potential Agricultural Preserves, encourage the retention and expansion of agriculture by promoting compatible land use arrangements and providing technical assistance to involved farming interests.

Policy 23: In urban areas, encourage the retention of economically viable agricultural production, e.g., high value crops such as strawberries, cut flowers, nursery stock, etc., through the identification and mitigation of significant adverse impacts resulting from adjacent new development.

Goal – Improve the Land Use Decision-Making Process: The manner in which land use decisions are made must address cumulative social, economic and environmental effects, and ensure opportunity for citizen participation.

Policy 29: Improve the land use decision-making process by closely monitoring and evaluating the cumulative impacts of individual projects and by modernizing development regulations

Goal – Improve Inter-Agency Coordination in Land Use Planning: There is a growing need to more effectively coordinate the land use planning activities of local, regional, State, and federal agencies in Los Angeles County.

Policy 30: Promote improved interjurisdictional coordination of land use policy matters between the County, cities, adjacent counties, special districts, and regional and subregional agencies.

Policy 31: Ensure that cities have a voice in land use decisions within their adopted spheres of influence.

Draft General Plan, Drafted 2014

Goal LU 2: Community-based planning efforts that implement the General Plan and incorporate public input, and regional and community level collaboration.

Policy LU 2.8: Coordinate with the Los Angeles County Department of Public Works and other infrastructure providers to analyze and assess infrastructure improvements that are necessary for plan implementation.

Goal LU 8: Well-designed and healthy places that support a diversity of built environments.

Policy LU 8.2: Design development adjacent to natural features in a sensitive manner to complement the natural environment.

Policy LU 8.4: Promote environmentally sensitive and sustainable design.

Goal M-7: Transportation networks that minimizes negative impacts to the environment and communities.

Policy M 7.1: Encourage the use of natural systems to treat stormwater and rainwater runoff.

Policy M 7.2: Minimize roadway runoff through the use of permeable surface materials, such as porous asphalt and concrete materials, wherever feasible.

Goal C/NR-5: Protected and useable local surface water resources.

Policy C/NR 5.1: Support the LID philosophy, which seeks to plan and design public and private development with hydrologic sensitivity, including limits to straightening and channelizing natural flow paths, removal of vegetative cover, compaction of soils, and distribution of naturalistic BMPs at regional, neighborhood, and parcel-level scales.

Policy C/NR 5.2: Require compliance by all County departments with adopted Municipal Separate Storm Sewer System (MS4), General Construction, and point source NPDES permits.

Policy C/NR 5.3: Actively engage with stakeholders in the formulation and implementation of surface water preservation and restoration plans, including plans to improve impaired surface water bodies by retrofitting tributary watersheds with LID types of BMPs.

Policy C/NR 5.4: Actively engage in implementing all approved Enhanced Watershed Management Programs/Watershed Management Programs and Coordinated Integrated Monitoring Programs/Integrated Monitoring Programs or other County-involved TMDL implementation and monitoring plans.

Policy C/NR 5.6: Minimize point and non-point source water pollution.

Policy C/NR 5.7: Actively support the design of new and retrofit of existing infrastructure to accommodate watershed protection goals, such as roadway, railway, bridge, and other—particularly—tributary street and greenway interface points with channelized waterways.

Goal C/NR-6: Protected and usable local groundwater resources.

Policy C/NR 6.1: Support the LID philosophy, which incorporates distributed, post-construction parcel-level stormwater infiltration as part of new development.

Policy C/NR 6.2: Protect natural groundwater recharge areas and regional spreading grounds.

Policy C/NR 6.3: Actively engage in stakeholder efforts to disperse rainwater and stormwater infiltration BMPs at regional, neighborhood, infrastructure, and parcel-level scales.

Policy C/NR 6.5: Prevent stormwater infiltration where inappropriate and unsafe, such as in areas with high seasonal groundwater, on hazardous slopes, within 100 feet of drinking water wells, and in contaminated soils.

Goal C/NR 7: Protected and healthy watersheds.

Policy C/NR 7.1: Support the LID philosophy, which mimics the natural hydrologic cycle using undeveloped conditions as a base, in public and private land use planning and development design.

Policy C/NR 7.2: Support the preservation, restoration and strategic acquisition of open space to preserve natural streams, drainage paths, wetlands, and rivers, which are necessary for the healthy function of watersheds.

Policy C/NR 7.3: Actively engage with stakeholders to incorporate the LID philosophy in the preparation and implementation of watershed and river master plans, ecosystem restoration projects, and other related natural resource conservation aims, and support the implementation of existing efforts, including Watershed Management Programs and Enhanced Watershed Management Programs.

Policy C/NR 7.4: Promote the development of multi-use regional facilities for stormwater quality improvement, groundwater recharge, detention/attenuation, flood management, retaining non-stormwater runoff, and other compatible uses..

City General Plans

The numerous cities encompassed by the EWMP area all have their own respective city General Plans, which may contain policies that address land use and agriculture. As implementation of the individual structural BMP projects proceed, specific policies and objectives pertaining to land use and agriculture from applicable city General Plans will be identified and evaluated on a project-by-project basis during subsequent CEQA environmental processes.

3.9.3 Impact Assessment

The proposed program's potential impacts have been assessed using the CEQA Guidelines Appendix G Checklist. The following sections discuss the key issue areas identified in the CEQA Guidelines with respect to the program's potential effect to agricultural resources and land use.

Threshold of Significance

For the purposes of this PEIR and consistency with Appendix G of the CEQA Guidelines, the program would have a significant impact on land uses if it would:

- Physically divide an established community.
- Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect.
- Conflict with any applicable habitat conservation plan or natural community conservation plan.

The program would have a significant impact on agriculture land uses if it would:

- Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Resources Agency, to non-agricultural use.
- Conflict with existing zoning for agricultural use, or a Williamson Act contract.
- Conflict with existing zoning for, or cause rezoning of, forest land (as defined in Public Resources Code section 12220(g)), timberland (as defined by Public Resources Code section 4526), or timberland zoned Timberland Production (as defined by Government Code section 51104(g)).
- Result in the loss of forest land or conversion of forest land to non-forest use.

- Involve other changes in the existing environment which, due to their location or nature, could result in conversion of Farmland, to non-agricultural use or conversion of forest land to non-forest use.

The significance determination for the above-listed impact thresholds is based on both short-term and long-term impacts of project implementation.

Project Impact Discussion

Division of an Established Community

Impact 3.9-1: The proposed program could physically divide an established community.

Structural (Regional, Centralized, and Distributed) BMPs

Distributed BMPs are most likely to be implemented in high-density urban, commercial, industrial, and transportation areas where they would either replace or improve upon existing stormwater infrastructure. These types of BMPs are generally “retrofit” type projects that replace existing impervious surfaces with pervious surfaces such as bioinfiltration cells, bioswales, porous pavement, and filter strips that tie into existing stormwater management systems. These projects may also augment the existing stormwater management systems with additional inlet screens, filter media systems, sediment removal systems, and diversions to sanitary sewer lines. Ground disturbance for distributed BMPs is typically less than 1 to 2 acres in extent, but may extend in some limited applications up to 5 acres where space is available, generally on municipally owned lands such as parks and schools, which would not divide a community.

Centralized structural BMPs collect, store, treat, and filter stormwater from multiple parcels and much larger drainage areas. Like centralized BMPs, regional BMPs can be implemented in a broad range of land use types, from high-density urban to open space, and can have multiple benefits (habitat, recreation, aesthetics, etc.). Centralized and regional structural BMPs require greater footprints for construction and implementation. However, the installation of these larger BMPs would not physically divide an established community as they would be implemented primarily on existing sidewalks, streets, parks, and city-owned lands. The BMPs would augment the physical structure of established communities, blending in as part of the existing landscape; enhancing water quality of existing communities. Additionally, much of the implementation would consist of the retrofitting of already-established stormwater infrastructure, and would not physically divide an established community. No impact would occur.

Mitigation Measures: None required

Significance Determination: No impact

Non-Structural (Institutional) BMPs

The non-structural BMPs associated with the proposed program would not consist of structural components; these BMPs would include programs, actions, and activities to eliminate pollutants from stormwater runoff, none of which would contribute to the physical division of a community. Therefore, non-structural BMPs would not have a physical impact on the built environment.

Mitigation Measures: None required

Significance Determination: No impact

Land Use Plan, Policy or Regulation Confliction

Impact 3.9-2: The proposed program could conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the program (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect.

Structural (Regional, Centralized, and Distributed) BMPs

Structural BMPs would be located throughout Los Angeles County, spanning multiple jurisdictions within varying land uses. Each BMP would be subject to land use zoning and General Plan designations adopted by the local municipality or the County. Implementing agencies will identify appropriate locations based on the local zoning codes. Some BMPs may require easements, conditional use permits, variances, or General Plan amendments. Approval by local jurisdictions of these land use conditions would ensure consistency with local plans. The structural BMPs associated with the proposed program would complement the Los Angeles County's LID Ordinance that became effective December 5, 2013. The LID Standards provide guidance for the implementation of stormwater quality control measures in new development and redevelopment projects in unincorporated areas of the County with the intention of improving water quality and mitigating potential water quality impacts from stormwater and non-stormwater discharges. The proposed EWMP Program would implement LID techniques throughout the urbanized landscape via the implementation of distributed BMPs, as such; the implementation of structural BMPs would support implementation of the County's LID Ordinance.

The structural BMPs associated with the proposed program would complement the Los Angeles County's land use goals and policies for the built environment including conserving resources and enhancing environmental quality (goal from 1980 General Plan), creating well-designed and healthy places that support a diversity of built environments (Goal LU 8), supporting transportation networks that minimize negative impacts to the environment and communities, which includes encouraging the use of natural systems to treat stormwater runoff, and minimizing roadway runoff through the use of permeable surface materials wherever feasible, protecting local surface water resources (Goal C/NR 5), protecting local groundwater sources (Goal C/NR 6), and creating protected and healthy watersheds (Goal C/NR 7). These goals would be supported by the proposed project because they would not change land uses and would implement BMPs to support protection of important water resources in a way that would minimize the impact of the land use on the environment. The proposed water conservation and water quality projects included as part of the proposed program would align with the County LID standards, which call for projects to mimic naturally occurring runoff conditions, as best as possible.

RB-AR 8562

Implementation of BMPs to enhance water quality in the region would not conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project adopted for the purpose of avoiding or mitigating an environmental effect.

Mitigation Measures: None required

Significance Determination: No impact

Non-Structural (Institutional) BMPs

Non-structural BMPs associated with the proposed program include policies, actions and activities intended to prevent pollutants from entering stormwater runoff, thus eliminating the sources of the pollutants. The non-structural BMPs would not physically change the built environment, and would implement further policies and actions to protect stormwater runoff from pollution.

Mitigation Measures: None required

Significance Determination: No impact

Habitat Conservation Plan Or Natural Community Conservation Plan Confliction

Impact 3.9-3: The proposed program could conflict with any applicable habitat conservation plan or natural community conservation plan.

Structural (Regional, Centralized, and Distributed) BMPs

Only one HCP/NCCP has been adopted within the EWMP areas. The City of Rancho Palos Verdes NCCP Subarea Plan (Subarea Plan) was prepared to maximize benefits to wildlife and vegetation communities while accommodating appropriate economic development within the city and region pursuant to the requirements of the NCCP Act and Section 10(a) of the ESA (URS, 2004). The BMPs would be located primarily in high-density urban, commercial, industrial, and transportation areas, where they would either replace or improve upon existing stormwater infrastructure. BMPs proposed within the HCP/NCCP would be required to comply with the adopted plan. This would include avoiding impacts to coastal sage scrub habitat. The goals of the EWMP and the HCP are consistent and conflicts would be avoided through site placement, BMP type, and City of Rancho Palos Verde approval.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

The non-structural BMPs associated with the proposed program are program- and policy-based and do not involve physical structures, so they would not introduce any physical impacts to the built environment. The project areas is located primarily in developed areas of Los Angeles

County, and would not take place within an HCP, NCCP, or any other conservation plan-covered area. There would be no impact.

Mitigation Measures: None required

Significance Determination: No impact

Agricultural and Forestry Resources

Impact 3.9-4: The proposed program could convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Resources Agency, to non-agricultural use. The proposed program could involve other changes in the existing environment which, due to their location or nature, could result in conversion of agricultural land to non-agricultural use or conversion of forest land to non-forest use.

Structural (Regional, Centralized, and Distributed) BMPs

Only small areas of Designated Prime, Unique and Important Farmlands exist within the EWMP area, limited to the Santa Clara and Malibu Watersheds. The structural BMPs associated with the proposed program would not convert any Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to non-agricultural uses because the BMPs would be located primarily in high-density urban, commercial, industrial, and transportation areas where they would either replace or improve upon existing stormwater infrastructure. The construction of structural BMPs would primarily focus on the retrofitting of existing infrastructure, and would be located on existing streets, sidewalks, and parks. The larger regional and centralized projects would be located in parks and open space areas that may be adjacent to or on farmland. However, none of the BMPs would replace designated Prime, Unique, or Important Farmland. There would be no impact to farmland.

Mitigation Measures: None required

Significance Determination: No impact

Non-Structural (Institutional) BMPs

Non-structural BMPs would consist of policies and programs that would not be physically constructed and would not involve or contribute to the conversion of agricultural land to non-agricultural uses. There would be no impact.

Mitigation Measures: None required

Significance Determination: No impact

Existing Agricultural Zoning or Williamson Act Contract Confliction

Impact 3.9-5: The proposed program could conflict with existing zoning for agricultural use, or a Williamson Act contract.

Structural (Regional, Centralized, and Distributed) BMPs

The structural BMPs associated with the proposed program would be constructed on urbanized land primarily on streets, sidewalks, and in parks or other city-owned lands, and would therefore not conflict with existing land zoned for agricultural use. There are no Williamson Act contracts within the project area. As a result, there would be no impacts to existing agricultural zoning or land under the Williamson Act contract.

Mitigation Measures: None required

Significance Determination: No impact

Non-Structural (Institutional) BMPs

The non-structural BMPs associated with the proposed program would not require any physical construction and would be implemented in primarily urbanized areas; therefore, they would have no impact on agriculturally-zoned land. There are no Williamson Act contracts within the project area.

Mitigation Measures: None required

Significance Determination: No impact

Forest Land Confliction

Impact 3.9-6: The proposed program could conflict with existing zoning for, or cause rezoning of, forest land (as defined in Public Resources Code section 12220(g)), timberland (as defined by Public Resources Code section 4526), or timberland zoned Timberland Production (as defined by Government Code section 51104(g)). The proposed program could result in the loss of forest land or conversion of forest land to non-forest use.

Structural (Regional, Centralized, and Distributed) BMPs

The structural BMPs associated with the proposed program would not conflict with existing zoning for, or cause rezoning of, forest land, timberland, or timberland zoned Timberland Production, and would not result in the loss of forest land or conversion of forest land to non-forest land because there is no land within the EWMP groups zoned as forest land or timberland. The structural BMPs would be constructed and implemented primarily on urbanized land primarily on streets, sidewalks, and in parks or other city-owned lands, and would therefore have no impact on forest land, timberland, or timberland zoned Timberland Production.

Mitigation Measures: None required

Significance Determination: No impact

Non-Structural (Institutional) BMPs

The non-structural BMPs associated with the proposed program would not involve any physical construction and would not conflict with existing zoning for, or cause rezoning of, forest land, timberland, or timberland zoned Timberland Production. Implementation of the non-structural BMPs would not result in the loss of forest land or conversion of forest land to non-forest use.

Mitigation Measures: None required

Significance Determination: No impact

Cumulative Impact Discussion

Structural (Regional, Centralized, and Distributed) BMPs

No land use planning impacts have been identified in this analysis as a result of the structural BMPs associated with the proposed program because the EWMPs would be implemented in already established urban areas. BMP locations would be required to be consistent with local zoning and General Plan designations. Furthermore, the BMPs would be supportive of LID Ordinance goals and objectives. The incremental effect on cumulative land use and planning during construction and operation of the proposed program would be less than significant. Therefore, the contribution is not cumulatively considerable and would not result in a cumulative impact on land use and planning. Furthermore, the proposed program would not impact agricultural and forest lands since structural BMPs would be implemented largely in urbanized areas and focus on improving existing facilities. Therefore, the contribution is not cumulatively considerable and would not result in a cumulative impact on agricultural resources.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

No land use planning impacts have been identified in this analysis as a result of the non-structural BMPs associated with the proposed EWMPs because there is no physical construction associated with these BMPs. The non-structural BMPs will consist of policies, actions, and activities to help prevent pollutants from entering stormwater runoff. They will likely provide improvements to existing land uses because their primary goal will be to improve water quality. One major purpose of the non-structural BMPs is to meet Minimum Control Measure (MCM) requirements in the MS4 Permit. Therefore, the proposed program is not cumulatively considerable and would not result in a cumulative impact on land use and planning. Furthermore, the proposed program would not impact agricultural and forest lands since there would be no physical construction associated with these BMPs. Therefore, the non-structural BMPs are not cumulatively considerable and would not result in a cumulative impact on agricultural resources.

Mitigation Measures: None required

Significance Determination: Less than significant

3.9.4 Summary of Impact Assessment

Table 3.9-16 shows a summary of the structural BMPs requiring mitigation.

TABLE 3.9-16
SUMMARY OF LAND USE AND AGRICULTURE IMPACTS REQUIRING MITIGATION MEASURES

RB-AR 8568

3.10 Noise

This section evaluates the potential for noise and groundborne vibration impacts to result from implementation of the proposed Enhanced Watershed Management Program (EWMP). This includes the potential for the proposed program to result in impacts associated with a substantial temporary and/or permanent increase in ambient noise levels in the vicinity of the proposed program; exposure of people in the vicinity of the proposed program to excessive noise and groundborne vibration levels; and whether this exposure is in excess of applicable, established standards in the EWMP areas of Los Angeles County (County). Mitigation measures to reduce potential noise and vibration impacts are identified, where warranted.

3.10.1 Principles of Noise and Vibration

Noise Principles and Descriptors

Noise is generally defined as unwanted sound, traveling in the form of waves from a source and exerting a sound pressure level (referred to as sound level) that is measured in decibels (dB), which is the standard unit of sound amplitude measurement. The dB scale is a logarithmic scale that describes the physical intensity of the pressure vibrations that make up any sound, with 0 dB corresponding roughly to the threshold of human hearing and 120 to 140 dB corresponding to the threshold of pain. Pressure waves traveling through air exert a force registered by the human ear as sound.

Sound pressure fluctuations can be measured in units of hertz (Hz), which correspond to the frequency of a particular sound. Typically, sound does not consist of a single frequency, but rather a broad band of frequencies varying in levels of magnitude. When all the audible frequencies of a sound are measured, a sound spectrum is plotted consisting of a range of frequency spanning 20 to 20,000 Hz. The sound pressure level, therefore, constitutes the additive force exerted by a sound corresponding to the sound frequency/sound power level spectrum.

The typical human ear is not equally sensitive to all frequencies of the audible sound spectrum. As a consequence, when assessing potential noise impacts, sound is measured using an electronic filter that deemphasizes the frequencies below 1,000 Hz and above 5,000 Hz in a manner corresponding to the human ear’s decreased sensitivity to extremely low and extremely high frequencies. This method of frequency weighting is referred to as A-weighting and is expressed in units of A-weighted decibels (dBA). A-weighting follows an international standard methodology of frequency deemphasis and is typically applied to community noise measurements. Some representative noise sources and their corresponding A-weighted noise levels are shown in **Figure 3.10-1**.

LA County PEIR EWMP . 140474

Figure 3.10-1
Effects of Noise on People

RB-AR 8570

Noise Exposure and Community Noise

An individual's noise exposure is a measure of noise over a period of time. A noise level is a measure of noise at a given instant in time. The noise levels presented in Figure 3.10-1 are representative of measured noise at a given instant in time; however, they rarely persist consistently over a long period of time. Rather, community noise varies continuously over a period of time with respect to the contributing sound sources of the community noise environment. Community noise is primarily the product of many distant noise sources, which constitute a relatively stable background noise exposure, with the individual contributors unidentifiable. The background noise level changes throughout a typical day, but does so gradually, corresponding with the addition and subtraction of distant noise sources such as traffic. What makes community noise constantly variable throughout a day, besides the slowly changing background noise, is the addition of short duration, single-event noise sources (e.g., aircraft flyovers, motor vehicles, sirens), which are readily identifiable to the individual.

These successive additions of sound to the community noise environment change the community noise level from instant to instant, thus requiring that noise exposure be measured over a period of time to legitimately characterize a community noise environment and evaluate cumulative noise impacts. This time-varying characteristic of environmental noise is described using statistical noise descriptors. The most frequently used noise descriptors are summarized below:

L_{eq}: The L_{eq}, or equivalent sound level, is used to describe noise over a specified period of time in terms of a single numerical value; the L_{eq} of a time-varying signal and that of a steady signal are the same if they deliver the same acoustic energy over a given time. The L_{eq} may also be referred to as the average sound level.

L_{max}: The maximum, instantaneous noise level experienced during a given period of time.

L_{min}: The minimum, instantaneous noise level experienced during a given period of time.

L_{50}: The noise level that is equaled or exceeded 50 percent of the specified time period. The L_{50} represents the median sound level.

L_{90}: The noise level that is equaled or exceeded 90 percent of the specified time period. The L_{90} is generally considered to be representing the background or ambient level of a noise environment.

L_{dn}: Also termed the day-night average noise level (DNL), the L_{dn} is the average A-weighted noise level during a 24-hour day, obtained after an addition of 10 dBA to measured noise levels between the hours of 10:00 P.M. and 7:00 A.M. to account nighttime noise sensitivity.

CNEL: CNEL, or Community Noise Equivalent Level, is the average A-weighted noise level during a 24-hour day that is obtained after an addition of 5 dBA to measured noise levels between the hours of 7:00 P.M. and 10:00 P.M. and after an addition of 10 dBA to noise levels between the hours of 10:00 P.M. and 7:00 A.M. to account for noise sensitivity in the evening and nighttime, respectively.

Effects of Noise on People

Noise is generally loud, unpleasant, unexpected, or undesired sound that is typically associated with human activity that is a nuisance or disruptive. The effects of noise on people can be placed into four general categories:

- Subjective effects (e.g., dissatisfaction, annoyance)
- Interference effects (e.g., communication, sleep, and learning interference)
- Physiological effects (e.g., startle response)
- Physical effects (e.g., hearing loss)

Although exposure to high noise levels has been demonstrated to cause physical and physiological effects, the principal human responses to typical environmental noise exposure are related to subjective effects and interference with activities. Interference effects of environmental noise refer to those effects that interrupt daily activities and include interference with human communication activities, such as normal conversations, watching television, telephone conversations, and interference with sleep. Sleep interference effects can include both awakening and arousal to a lesser state of sleep. With regard to the subjective effects, the responses of individuals to similar noise events are diverse and are influenced by many factors, including the type of noise, the perceived importance of the noise, the appropriateness of the noise to the setting, the duration of the noise, the time of day and the type of activity during which the noise occurs, and individual noise sensitivity.

Overall, there is no completely satisfactory way to measure the subjective effects of noise, or the corresponding reactions of annoyance and dissatisfaction on people. A wide variation in individual thresholds of annoyance exists, and different tolerances to noise tend to develop based on an individual’s past experiences with noise. Thus, an important way of predicting a human reaction to a new noise environment is the way it compares to the existing environment to which one has adapted (i.e., comparison to the ambient noise environment). In general, the more a new noise level exceeds the previously existing ambient noise level, the less acceptable the new noise level will be judged by those hearing it. With regard to increases in A-weighted noise level, the following relationships generally occur:

- Except in carefully controlled laboratory experiments, a change of 1 dBA cannot be perceived.
- Outside of the laboratory, a 3 dBA change in noise levels is considered to be a barely perceivable difference.
- A change in noise levels of 5 dBA is considered to be a readily perceivable difference.
- A change in noise levels of 10 dBA is subjectively heard as doubling of the perceived loudness.

These relationships occur in part because of the logarithmic nature of sound and the decibel system. The human ear perceives sound in a nonlinear fashion; hence, the decibel scale was developed.

Because the decibel scale is based on logarithms, two noise sources do not combine in a simple additive fashion, but rather logarithmically. For example, if two identical noise sources produce noise levels of 50 dBA, the combined sound level would be 53 dBA, not 100 dBA.

Noise Attenuation

Stationary point sources of noise, including stationary mobile sources such as idling vehicles, attenuate (lessen) at a rate between 6 dBA for hard sites and 7.5 dBA for soft sites for each doubling of distance from the reference measurement. Hard sites are those with a reflective surface between the source and the receiver, such as asphalt or concrete surfaces or smooth bodies of water. No excess ground attenuation is assumed for hard sites and the change in noise levels with distance (drop-off rate) is simply the geometric spreading of the noise from the source. Soft sites have an absorptive ground surface such as soft dirt, grass, or scattered bushes and trees. In addition to geometric spreading, an excess ground attenuation value of 1.5 dBA (per doubling distance) is normally assumed for soft sites. Line sources (such as traffic noise from vehicles) attenuate at a rate between 3 dBA for hard sites and 4.5 dBA for soft sites for each doubling of distance from the reference measurement (Caltrans, 1998).

Fundamentals of Vibration

As described in the Federal Transit Administration's (FTA's) *Transit Noise and Vibration Impact Assessment* (FTA, 2006), groundborne vibration can be a serious concern for nearby neighbors of a transit system route or maintenance facility, causing buildings to shake and rumbling sounds to be heard. In contrast to airborne noise, groundborne vibration is not a common environmental problem. It is unusual for vibration from sources such as buses and trucks to be perceptible, even in locations close to major roads. Some common sources of groundborne vibration are trains, buses on rough roads, and construction activities such as blasting, pile-driving, and operation of heavy earthmoving equipment.

There are several different methods that are used to quantify vibration. The peak particle velocity (PPV) is defined as the maximum instantaneous peak of the vibration signal. The PPV is most frequently used to describe vibration impacts to buildings. The root mean square (RMS) amplitude is most frequently used to describe the effect of vibration on the human body. The RMS amplitude is defined as the average of the squared amplitude of the signal. Decibel notation (VdB) is commonly used to measure RMS. The relationship of PPV to RMS velocity is expressed in terms of the "crest factor," defined as the ratio of the PPV amplitude to the RMS amplitude. PPV is typically a factor of 1.7 to 6 times greater than RMS vibration velocity (FTA, 2006). The decibel notation acts to compress the range of numbers required to describe vibration. Typically, groundborne vibration generated by man-made activities attenuates rapidly with distance from the source of the vibration. Sensitive receptors for vibration include structures (especially older masonry structures), people (especially residents, the elderly, and sick), and vibration-sensitive equipment.

The effects of groundborne vibration include movement of the building floors, rattling of windows, shaking of items on shelves or hanging on walls, and rumbling sounds. In extreme cases, the vibration can cause damage to buildings. Building damage is not a factor for most projects, with the occasional exception of blasting and pile-driving during construction. Annoyance from vibration often occurs when the vibration levels exceed the threshold of perception by only a small margin. A vibration level that causes annoyance will be well below the damage threshold for normal buildings. The FTA measure of the threshold of architectural damage for conventional sensitive structures is 0.2 in/sec PPV (FTA, 2006).

In residential areas, the background vibration velocity level is usually around 50 VdB (approximately 0.0013 in/sec PPV). This level is well below the vibration velocity level threshold of perception for humans, which is approximately 65 VdB. A vibration velocity level of 75 VdB is considered to be the approximate dividing line between barely perceptible and distinctly perceptible levels for many people (FTA, 2006).

3.10.2 Environmental Setting

Existing Noise Sources

As the EWMP areas are located throughout Los Angeles County, existing noise levels in the EWMP areas would consist of various noise sources typically associated with highly urbanized environments. These noise sources commonly include, but are not limited to, traffic, construction work, commercial operations, human activities, emergency vehicles, aircraft overflights, etc. Of these sources, transportation-related noise associated with vehicular traffic is generally the constant, dominating noise source that comprises an urban environment's ambient noise levels. Vehicular traffic creates noise on roads and highways in residential, commercial, industrial, and mixed-use areas. Aside from vehicular traffic on roadways, other transportation-related noise sources include rail/urban transit systems and airports, which are also located throughout the County. Noise generated by stationary sources in an urban environment are generally associated with heating, ventilating, and air conditioning (HVAC) equipment for residential and commercial uses as well as other similar and larger mechanical stationary equipment for industrial uses. The use of larger-capacity stationary mechanical equipment by industrial uses generally results in higher noise levels in industrial-zoned areas when compared with residential or retail areas.

Existing Groundborne Vibration Levels

Aside from periodic construction work that may occur throughout the County where the EWMP areas are located, other sources of groundborne vibration in the County include heavy-duty vehicular travel (e.g., refuse trucks, delivery trucks, and transit buses) on local roadways. Trucks and buses traveling at a distance of 50 feet typically generate groundborne vibration velocity levels of around 63 VdB (approximately 0.006 in/sec PPV), and these levels could reach 72 VdB (approximately 0.016 in/sec PPV) where trucks pass over bumps in the road (FTA, 2006). In terms of PPV levels, a heavy-duty vehicle traveling at a distance of 50 feet can result in a vibration level of approximately 0.001 inch per second.

Sensitive Receptors

Noise-sensitive receptors are locations where people reside or where the presence of unwanted sound could adversely affect or disrupt the types of activities associated with the land use at the location. Land uses such as residences, hotels, schools, rest homes, libraries, churches, and hospitals are generally more sensitive to noise than commercial and industrial land uses. As such, these types of land uses are considered to be noise-sensitive receptors. Given that the majority of the County is highly urbanized with a variety of land use types (e.g., open space, residential, commercial, mixed-use, public and semi-public, and industrial uses), and that the proposed program would be located in various watersheds across the County that span multiple jurisdictions, existing noise-sensitive uses such as residences, schools, guest lodging, hospitals, churches, parks, etc. would be located within and in proximity to the EWMP areas. As described in Section 3.9, *Land Use and Agriculture,* of this Program Environmental Impact Report (PEIR), many of the EWMP areas, including Ballona Creek, Beach Cities, Dominguez Channel, and Marina del Rey, have residential uses as the predominant land use.

3.10.3 Regulatory Setting

Federal

Federal Noise Standards

There are no federal noise standards that directly regulate environmental noise related to the construction or operation of the proposed program. With regard to noise exposure and workers, the Office of Safety and Health Administration (OSHA) regulations safeguard the hearing of workers exposed to occupational noise. Federal regulations also establish noise limits for medium and heavy trucks (more than 4.5 tons, gross vehicle weight rating) under 40 Code of Federal Regulations (CFR), Part 205, Subpart B. The federal truck pass-by noise standard is 80 dBA at 15 meters from the vehicle pathway centerline. These controls are implemented through regulatory controls on truck manufacturers.

Federal Transit Authority Vibration Standards

The FTA has adopted vibration standards that are used to evaluate potential building damage impacts related to construction activities. The vibration damage criteria adopted by the FTA are shown in **Table 3.10-1**.

TABLE 3.10-1
CONSTRUCTION VIBRATION DAMAGE CRITERIA

Building Category	PPV (in/sec)
I. Reinforced concrete, steel or timber (no plaster)	0.5
II. Engineered concrete and masonry (no plaster)	0.3
III. Non-engineered timber and masonry buildings	0.2
IV. Buildings extremely susceptible to vibration damage	0.12

SOURCE: FTA, 2006.

In addition, the FTA has also adopted standards associated with human annoyance for groundborne vibration impacts for the following three land-use categories: Vibration Category 1 – High Sensitivity, Vibration Category 2 – Residential, and Vibration Category 3 – Institutional.

The FTA defines Category 1 as buildings where vibration would interfere with operations within the building, including vibration-sensitive research and manufacturing facilities, hospitals with vibration-sensitive equipment, and university research operations. Vibration-sensitive equipment includes, but is not limited to, electron microscopes, high-resolution lithographic equipment, and normal optical microscopes. Category 2 refers to all residential land uses and any buildings where people sleep, such as hotels and hospitals. Category 3 refers to institutional land uses such as schools, churches, other institutions, and quiet offices that do not have vibration-sensitive equipment, but still have the potential for activity interference.

Under conditions where there are an infrequent number of events per day, the FTA has established thresholds of 65 VdB for Category 1 buildings, 80 VdB for Category 2 buildings, and 83 VdB for Category 3 buildings.[1] Under conditions where there are an occasional number of events per day, the FTA has established thresholds of 65 VdB for Category 1 buildings, 75 VdB for Category 2 buildings, and 78 VdB for Category 3 buildings.[2] No thresholds have been adopted or recommended for commercial and office uses.

State

California Department of Health Services Noise Standards

The California Department of Health Services (DHS) has established guidelines for evaluating the compatibility of various land uses as a function of community noise exposure. These guidelines for land use and noise exposure compatibility are shown in **Table 3.10-2**. In addition, Section 65302(f) of the California Government Code requires each county and city in the State to prepare and adopt a comprehensive long-range general plan for its physical development, with Section 65302(g) requiring a noise element to be included in the general plan. The noise element must: (1) identify and appraise noise problems in the community; (2) recognize Office of Noise Control guidelines; and (3) analyze and quantify current and projected noise levels.

The State of California also establishes noise limits for vehicles licensed to operate on public roads. For heavy trucks, the State pass-by standard is consistent with the federal limit of 80 dBA. The State pass-by standard for light trucks and passenger cars (less than 4.5 tons, gross vehicle rating) is also 80 dBA at 15 meters from the centerline. These standards are implemented through controls on vehicle manufacturers and by legal sanction of vehicle operators by state and local law enforcement officials.

1 "Infrequent events" is defined by the FTA as being fewer than 30 vibration events of the same kind per day.
2 "Occasional events" is defined by the FTA as between 30 and 70 vibration events of the same source per day.

TABLE 3.10-2
COMMUNITY NOISE EXPOSURE (L_{dn} OR CNEL)

Land Use	Normally Acceptable[a]	Conditionally Acceptable[b]	Normally Unacceptable[c]	Clearly Unacceptable[d]
Single-family, Duplex, Mobile Homes	50 - 60	55 - 70	70 - 75	above 75
Multi-Family Homes	50 - 65	60 - 70	70 - 75	above 75
Schools, Libraries, Churches, Hospitals, Nursing Homes	50 - 70	60 - 70	70 - 80	above 80
Transient Lodging – Motels, Hotels	50 - 65	60 - 70	70 - 80	above 75
Auditoriums, Concert Halls, Amphitheaters	---	50 - 70	---	above 70
Sports Arena, Outdoor Spectator Sports	---	50 - 75	---	above 75
Playgrounds, Neighborhood Parks	50 - 70	---	67 - 75	above 75
Golf Courses, Riding Stables, Water Recreation, Cemeteries	50 - 75	---	70 - 80	above 80
Office Buildings, Business and Professional Commercial	50 - 70	67 - 77	above 75	---
Industrial, Manufacturing, Utilities, Agriculture	50 - 75	70 - 80	above 75	---

[a] Normally Acceptable: Specified land use is satisfactory, based upon the assumption that any buildings involved are of normal conventional construction without any special noise insulation requirements.

[b] Conditionally Acceptable: New construction or development should be undertaken only after a detailed analysis of the noise reduction requirements is made and needed noise insulation features included in the design. Conventional construction, but with closed windows and fresh air supply systems or air conditioning will normally suffice.

[c] Normally Unacceptable: New construction or development should generally be discouraged. If new construction or development does proceed, a detailed analysis of the noise reduction requirements must be made and needed noise insulation features included in the design.

[d] Clearly Unacceptable: New construction or development should generally not be undertaken.

SOURCE: Office of Planning and Research, State of California Genera Plan Guidelines, October 2003 (in coordination with the California Department of Health Services).

State Vibration Standards

There are no state vibration standards applicable to the proposed program. Moreover, according to the California Department of Transportation's (Caltrans') *Transportation and Construction Vibration Guidance Manual* (2013), there are no official Caltrans standards for vibration. However, this manual provides guidelines for assessing vibration damage potential to various types of buildings, ranging from 0.08 to 0.12 in/sec PPV for extremely fragile historic buildings, ruins, and ancient monuments to 0.50 to 2.0 in/sec PPV for modern industrial/commercial buildings. The vibration criteria for structural damage and human annoyance established in Caltrans' *Transportation and Construction Vibration Guidance Manual* (2013) are shown in **Tables 3.10-3** and **3.10-4**, respectively.

TABLE 3.10-3
CALTRANS VIBRATION DAMAGE POTENTIAL THRESHOLD CRITERIA

	Maximum PPV (in/sec)	
Structure and Condition	**Transient Sources**	**Continuous/Frequent Intermittent Sources**
Extremely fragile historic buildings, ruins, ancient monuments	0.12	0.08
Fragile buildings	0.2	0.1
Historic and some old buildings	0.5	0.25
Older residential structures	0.5	0.3
New residential structures	1.0	0.5
Modern industrial/commercial buildings	2.0	0.5

NOTE: Transient sources create a single isolated vibration event, such as blasting or drop balls. Continuous/frequent intermittent sources include impact pile-drivers, pogo-stick compactors, crack and-seat equipment, vibratory pile drivers, and vibratory compaction equipment.

SOURCE: Caltrans, Transportation and Construction Vibration Guidance Manual, September 2013.

TABLE 3.10-4
CALTRANS VIBRATION ANNOYANCE POTENTIAL CRITERIA

	Maximum PPV (in/sec)	
Structure and Condition	**Transient Sources**	**Continuous/Frequent Intermittent Sources**
Barely perceptible	0.04	0.01
Distinctly perceptible	0.25	0.04
Strongly perceptible	0.9	0.10
Severe	2.0	0.4

NOTE: Transient sources create a single isolated vibration event, such as blasting or drop balls. Continuous/frequent intermittent sources include impact pile-drivers, pogo-stick compactors, crack and-seat equipment, vibratory pile drivers, and vibratory compaction equipment.

SOURCE: Caltrans, Transportation and Construction Vibration Guidance Manual, September 2013.

Local

County of Los Angeles General Plan Noise Element

The California Government Code Section 65302(g) requires that a noise element be included in the General Plan of each county and city in the state. The Noise Element of the County of Los Angeles General Plan was established as a planning tool to develop strategies and action programs that address the multitude of noise sources and issues throughout the County. The noise guidelines used by the County are based on the community noise compatibility guidelines established by the State of California DHS (refer to Table 3.10-2), as described above. Specific regulations that implement these guidelines are set forth in the Los Angeles County Municipal Code as discussed below.

County of Los Angeles Municipal Code

Chapter 12.08, Noise Control, of the County of Los Angeles Municipal Code serves as the Noise Ordinance for the County and establishes noise standards to control unnecessary, excessive, and annoying noise and vibration in the County. Within Chapter 12.08 of the Los Angeles County Code, Section 12.08.380 assigned the following noise zones for receptor properties in the County:

1. Noise Zone 1 – Noise-sensitive areas
2. Noise Zone 2 – Residential properties
3. Noise Zone 3 – Commercial properties
4. Noise Zone 4 – Industrial properties

With respect to operational noise, Section 12.08.390 of the Noise Ordinance established exterior noise levels that should be applied to all receptor properties within a designated noise zone in the County. These exterior noise levels are shown in **Table 3.10-5**.

TABLE 3.10-5
COUNTY OF LOS ANGELES EXTERIOR NOISE STANDARDS BY NOISE ZONES

Noise Zone	Designated Noise Zone Land Use (Receptor Property)	Time Interval	Exterior Noise Level (dBA)
I	Noise-sensitive area	Anytime	45
II	Residential properties	10:00 P.M. to 7:00 A.M. (nighttime)	45
		7:00 A.M. to 10:00 P.M. (daytime)	50
III	Commercial properties	10:00 P.M. to 7:00 A.M. (nighttime)	55
		7:00 A.M. to 10:00 P.M. (daytime)	60
IV	Industrial properties	Anytime	70

SOURCE: County of Los Angeles Ordinance No. 11743, Section 12.08.390.

The exterior noise levels shown in Table 3.10-5 are meant to be further applied as noise standards based on the duration of the noise; i.e., the louder the noise, the shorter the time it is allowed to last. The Noise Ordinance uses a number of noise metrics to define the permissible noise levels. These metrics include L_{50}, L_{25}, $L_{8.3}$, $L_{1.7}$, and L_{max}, and are based upon a 1-hour timeframe which indicates exceedances of 50, 25, 8.3, and 1.7 percent of the time, plus the maximum sound level during that time period. The following noise standards should be applied to the exterior noise levels provided in Table 3.10-5:

- Standard No. 1 shall be the exterior noise level that may not be exceeded for a cumulative period of more than 30 minutes in any hour. Standard No. 1 shall be the applicable noise level from Table 3.10-5; or, if the ambient L_{50} exceeds the forgoing level, then the ambient L_{50} becomes the exterior noise level for Standard No. 1.

- Standard No. 2 shall be the exterior noise level that may not be exceeded for a cumulative period of more than 15 minutes in any hour. Standard No. 2 shall be the applicable noise level from Table 3.10-5 plus 5 dB(A); or, if the ambient L_{25} exceeds the forgoing level, then the ambient L_{25} becomes the exterior noise level for Standard No. 2.
- Standard No. 3 shall be the exterior noise level that may not be exceeded for a cumulative period of more than 5 minutes in any hour. Standard No. 3 shall be the applicable noise level from Table 3.10-5 plus 20 dB(A); or, if the ambient $L_{8.3}$ exceeds the forgoing level, then the ambient $L_{8.3}$ becomes the exterior noise level for Standard No. 3.
- Standard No. 4 shall be the exterior noise level that may not be exceeded for a cumulative period of more than one minute in any hour. Standard No. 4 shall be the applicable noise level from Table 3.10-5 plus 15 dB(A); or, if the ambient $L_{1.7}$ exceeds the forgoing level, then the ambient $L_{1.7}$ becomes the exterior noise level for Standard No. 4.
- Standard No. 5 shall be the exterior noise level that may not be exceeded for any period of time. Standard No. 5 shall be the applicable noise level from Table 3.10-5 plus 20 dB(A); or, if the ambient L_0 exceeds the forgoing level, then the ambient L_0 becomes the exterior noise level for Standard No. 5.

Section 12.08.400 of the Noise Ordinance also established interior noise standards for dwelling units in the County based on the allowable interior noise levels shown in **Table 3.10-6**.

TABLE 3.10-6
COUNTY OF LOS ANGELES INTERIOR NOISE STANDARDS FOR DWELLING UNITS

Noise Zone	Designated Land Use	Time Interval	Allowable Interior Noise Level (dBA)
All	Multifamily	10:00 P.M. to 7:00 A.M.	40
	Residential	7:00 A.M. to 10:00 P.M.	45

SOURCE: County of Los Angeles Ordinance No. 11743, Section 12.08.400.

As indicated in Section 12.08.400, no person is allowed to operate or cause to be operated within a dwelling unit any source of sound, or allow the creation of any noise, that causes the noise level when measured inside a neighboring receiving dwelling unit to exceed the following standards:

- Standard No. 1. The applicable interior noise level from Table 3.10-6 for cumulative period of more than 5 minutes in any hour.
- Standard No. 2. The applicable interior noise level from Table 3.10-6 plus 5 dB(A) for a cumulative period of more than 1 minute in any hour.
- Standard No. 3. The applicable interior noise level from Table 3.10-6 plus 10 dB(A) or the maximum measured ambient noise level for any period of time.

With respect to construction noise in the County, Section 12.08.440 of the Noise Ordinance prohibits the operation of any tools or equipment used between weekday hours of 7:00 P.M. and 7:00 A.M., or at any time on Sundays or holidays, that will create a noise disturbance across a residential or commercial real-property line. The only exceptions would be emergency work or public safety projects (Section 12.08.0570, part 5, exemption H, Public Health and Safety Activities) or by variance issued by the health officer. Additionally, both the working hours and maximum levels of equipment and activity noise that are allowable from both mobile and stationary equipment in the County are defined by land use and shown in **Table 3.10-7**.

TABLE 3.10-7
COUNTY OF LOS ANGELES CONSTRUCTION NOISE STANDARDS

Allowable Work Dates & Hours	Residential Structures					
	Single-Family		Multi-Family		Semi-Residential/Commercial	
	Mobile Equipment [a]	Stationary Equipment [b]	Mobile Equipment [a]	Stationary Equipment [b]	Mobile Equipment [a]	Stationary Equipment [b]
Daily 7:00 A.M. to 8:00 P.M.[c]	75 dBA	60 dBA	80 dBA	65 dBA	85 dBA	70 dBA
Daily 8:00 P.M. to 7:00 A.M.[d]	60 dBA	50 dBA	64 dBA	55 dBA	70 dBA	60 dBA
	Business Structures					
Daily[d]	85 dBA					

[a] Represents maximum noise levels for nonscheduled, intermittent, short-term operation (less than 10 days).
[b] Represents maximum noise level for repetitively scheduled and relatively long-term operation (periods of 10 days or more).
[c] Exception for Sundays and legal holidays.
[d] Includes all day Sunday and legal holidays.

SOURCE: County of Los Angeles Ordinance No. 11743, Section 12.08.440.

County of Los Angeles Groundborne Vibration Regulation

With respect to vibration, the County Noise Ordinance identifies a presumed perception threshold of 0.01 inches per second over the range of 1 to 100 hertz . Section 12.08.560 of the County Noise Ordinance prohibits the operation of any device that creates vibration above the vibration perception threshold of any individual at or beyond the property boundary of the source if on private property, or at 150 feet (46 meters) from the source if on a public space or public right-of-way.

City General Plans and Municipal Codes

The EWMP areas associated with the proposed program are located in multiple jurisdictions of Los Angeles County, which aside from the County also includes 46 cities. Each of these cities has their own independent General Plan and municipal code that regulates noise levels from various sources within their jurisdictional boundaries. Given that a project-level analysis for each structural BMP proposed in the EWMPs is beyond the scope of this PEIR, an extensive listing of the noise policies and regulations of each of the participating Permittees is not provided in this PEIR.

3.10.4 Impact Assessment

The proposed program's potential impacts have been assessed using the California Environmental Quality Act (CEQA) Guidelines Appendix G Checklist. The following sections discuss the key issue areas identified in the CEQA Guidelines with respect to the proposed program's potential effect due to noise and vibration.

Thresholds of Significance

For the purposes of this PEIR and consistency with Appendix G of the CEQA Guidelines, the proposed program would have a significant noise impact if it would:

- Result in exposure of persons to, or generation of, noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies.
- Result in exposure of persons to, or generation of, excessive groundborne vibration or groundborne noise levels.
- Result in a substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project.
- Result in a substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project.
- For a project located within an airport land use plan area, or, where such a plan has not been adopted, in an area within 2 miles of a public airport or public use airport, expose people residing or working in the area to excessive noise levels.
- For a project located in the vicinity of a private airstrip, expose people residing or working in the project area to excessive noise levels.

Program Impact Discussion

Noise Levels Standard Exceedance

Impact 3.10-1: The proposed program could result in exposure of persons to, or generation of, noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies.

Structural (Regional, Centralized, and Distributed) BMPs

Construction

Implementation of the proposed program would involve the installation of structural control measures that would be constructed as BMPs to reduce the impact of stormwater and non-stormwater on receiving water quality within the EWMP areas. Construction of the various structural BMPs proposed in the EWMP is anticipated to occur intermittently over the program implementation period. The proposed locations of individual BMPs are subject to change throughout the EWMP planning process. Definitive construction equipment lists, material lists, construction methods, construction schedules, and workforce details would be developed in the future as specific structural BMP projects are finalized according to the EWMPs.

The construction noise impacts associated with each individual structural BMP project would be short-term in nature and limited to the period of time when construction activity is taking place for that particular project. Construction activity noise levels at and near each structural BMP construction site would fluctuate depending on the particular type, number, and duration of usage of various pieces of construction equipment. Generally, development at each BMP construction site may require the use of heavy construction equipment for activities such as site preparation, grading and excavation, and the physical development of the structural BMP. Development activities could also involve the use of smaller power tools, generators, and other sources of noise. During each stage of development for each individual structural BMP project, there would be a different mix of equipment operating and noise levels would vary based on the amount and type of equipment in operation and the location of the activity.

The USEPA has compiled data for outdoor noise levels for typical construction activities. These data are presented in **Table 3.10-8**. The noise levels shown in Table 3.10-8 represent composite noise levels associated with typical construction activities, which take into account both the number of pieces and spacing of heavy construction equipment that are typically used during each phase of construction. These noise levels would diminish rapidly with distance from the construction site at a rate of approximately 6 dBA per doubling of distance. For example, a noise level of 84 dBA L_{eq} measured at 50 feet from the noise source to the receptor would reduce to 78 dBA L_{eq} at 100 feet from the source to the receptor, and reduce by another 6 dBA L_{eq} to 72 dBA L_{eq} at 200 feet from the source to the receptor. **Table 3.10-9** shows the typical maximum and average noise levels produced by various types of construction equipment.

TABLE 3.10-8
TYPICAL OUTDOOR CONSTRUCTION NOISE LEVELS

Construction Phase	Noise Level (dBA, $_{Leq}$)[a]
Ground Clearing	84
Excavation	89
Foundations	78
Erection	85
Finishing	89

[a] Average noise levels correspond to a distance of 50 feet from the noisiest piece of equipment associated with a given phase of construction and 200 feet from the rest of the equipment associated with that phase.

Welder/Torch	74	70

[a] The average noise levels for the construction equipment at 50 feet were calculated from the maximum noise levels using the usage factors for each piece of equipment provided in the FHWA's RCNM.

SOURCE: FHWA, 2006.

As shown in Table 3.10-8, excavation activities can typically generate noise levels of 89 dBA L_{eq} at 50 feet from the construction noise source. Given the urbanized environment of many of the EWMP areas, many of the structural BMP projects would be constructed in proximity or adjacent to existing land uses, including those that are noise-sensitive uses. The construction activities for each structural BMP project would temporarily expose their respective existing off-site surrounding land uses to increased noise levels while construction activities are ongoing. This would be most applicable to the distributed BMPs, which are most likely to be implemented in high-density urban, commercial, industrial, and transportation areas where they will either replace or improve upon existing stormwater infrastructure. While the larger centralized and regional structural BMP projects (which require a larger footprint than the distributed BMPs) would occur mostly in existing open space areas that may have greater buffer distances to nearby surrounding land uses, there may still be incidences where a proposed centralized or regional structural BMP site could be located directly adjacent to an existing noise-sensitive land use. Where a proposed structural BMP site is located adjacent or in proximity to existing land uses, the construction activities at the structural BMP site would expose these off-site land uses to increased temporary and intermittent noise levels that are substantially greater than existing ambient noise levels in the area.

While construction noise levels may be exempt from the noise regulations of most of the implementing agencies, there may also be instances where some of the implementing agencies have their own established numerical noise standard for construction noise levels, such as the County of Los Angeles, City of Los Angeles, and the City of El Segundo. Although it is generally anticipated that construction of the structural BMPs would comply with such construction noise standards, there may be scenarios where these local numerical noise standards could potentially be exceeded. As a result, under these conditions, construction noise impacts would be potentially significant.

Mitigation Measure NOISE-1 would reduce construction noise impacts, requiring construction activities to be conducted in accordance with the applicable local noise regulations and standards, the implementation of noise reduction devices and techniques during construction activities, and advance notification to the surrounding noise-sensitive receptors of a structural BMP site about upcoming construction activities and their hours of operation. This would serve to reduce the construction-related noise levels at nearby receptors to the maximum extent feasible. However, as discussed previously, for implementing agencies that have established numerical noise standards for construction activities, there may be circumstances where the construction activities for a particular structural BMP project may exceed established thresholds. . Because of the possibility that certain structural BMP projects may exceed noise levels established by their respective local jurisdictions, this impact would be significant and unavoidable.

Operation

As discussed previously, the majority of the distributed, centralized, and regional structural BMPs would operate passively in the sense that they would not require the use of mechanized stationary equipment for their operation; however, it is anticipated that some of the centralized and regional structural BMPs would require the use of irrigation pump stations and associated components to divert the collected stormwater. At these structural BMP sites, operational noise levels would result from operation of the pumps and associated components. However, as a stationary noise source, the pumping equipment used at a structural BMP site would be required to comply with the applicable exterior noise standards and/or regulations established by the implementing agency that has jurisdiction over the site. Additionally, it is anticipated that many of the irrigation pumps would be located belowground and all other noise-producing components (e.g., generators) would be enclosed. As such, the noise levels generated by on-site pumps and associated components at structural BMP sites associated with the project would not exceed or violate noise standards and regulations established by implementing agencies in the EWMP areas. **Mitigation Measure NOISE-2** would be implemented to ensure that the operational noise levels occurring at structural

BMP sites that employ stationary mechanized equipment would be required to adhere and comply with the local noise standards established by the responsible implementing agency. Thus, with implementation of Mitigation Measure NOISE-2, operational noise impacts would be less than significant.

Mitigation Measures:

NOISE-1: The implementing agencies shall implement the following measures during construction as needed:

- Include design measures necessary to reduce the construction noise levels to where feasible. These measures may include noise barriers, curtains, or shields.
- Place noise-generating construction activities (e.g., operation of compressors and generators, cement mixing, general truck idling) as far as possible from the nearest noise-sensitive land uses.
- Locate stationary construction noise sources as far from adjacent noise-sensitive receptors as possible.
- If construction is to occur near a school, the construction contractor shall coordinate the with school administration in order to limit disturbance to the campus. Efforts to limit construction activities to non-school days shall be encouraged.
- For the centralized and regional BMP projects located adjacent to noise-sensitive land uses, identify a liaison for these off-site sensitive receptors, such as residents and property owners, to contact with concerns regarding construction noise and vibration. The liaison's telephone number(s) shall be prominently displayed at construction locations.
- For the centralized and regional BMP projects located adjacent to noise-sensitive land uses, notify in writing all landowners and occupants of properties adjacent to the construction area of the anticipated construction schedule at least 2 weeks prior to groundbreaking.

NOISE-2: All structural BMPs that employ mechanized stationary equipment that generate noise levels shall comply with the applicable noise standards established by the implementing agency with jurisdiction over the structural BMP site. The equipment shall be designed with noise-attenuating features (e.g., enclosures) and/or located at areas (e.g., belowground) where nearby noise-sensitive land uses would not be exposed to a perceptible noise increase in their noise environment.

Significance Determination: Significant and unavoidable with mitigation for construction; less than significant with mitigation for operations. (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.10-11.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts related to construction noise.

Mitigation Measures: None required

Significance Determination: No impact

Groundborne Vibration

Impact 3.10-2: The proposed program could result in exposure of persons to, or generation of, excessive groundborne vibration.

Structural (Regional, Centralized, and Distributed) BMPs

Construction of many of the structural BMP projects would include activities such as site preparation, grading, and excavation, which would have the potential to generate low levels of groundborne vibration. Persons residing and working in an area located in proximity to a structural BMP site could be exposed to some degree of groundborne vibration or groundborne noise levels related to construction activities. Ground vibrations from construction activities only rarely reach the levels that can damage structures, but they can be perceived in the audible range and be felt in buildings very close to a construction site.

Construction activities for the various structural BMP projects would have the potential to impact their respective nearby land uses. Given the urbanized environment of the County, the potential exists for construction of a structural BMP project, especially the distributed structural BMPs that would most likely be implemented in existing high-density areas, to be located within 25 feet of an adjacent noise-sensitive land use. Consequently, existing off-site receptors that are located immediately adjacent to these structural BMP sites could be exposed to some degree of groundborne vibration. The various PPV and RMS velocity (in VdB) levels for the types of construction equipment that could operate during the construction of the structural BMP projects are identified in **Table 3.10-10**. Based on the information presented in Table 3.10-11, vibration velocities could reach as high as approximately 0.089-inch-per-second PPV at 25 feet from the operation of a large bulldozer. This corresponds to an RMS velocity level (in VdB) of 87 VdB at 25 feet from the large bulldozer.

For the types of construction methods required to construct the various structural BMPs, vibration levels at nearby sensitive receptors would not approach the Caltrans damage thresholds presented in Table 3.10-3. Although some vibration may be experienced locally, vibration-related impacts from implementation of structural BMPs would be less than significant.

TABLE 3.10-10
VIBRATION VELOCITIES FOR CONSTRUCTION EQUIPMENT

Construction Equipment	PPV at 25 feet (inches/second)	RMS at 25 feet (VdB)
Large Bulldozer	0.089	87
Loaded Trucks	0.076	86
Jackhammer	0.035	79
Small Bulldozer	0.003	58

SOURCE: FTA, 2006.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts related to groundborne vibration or noise.

Mitigation Measures: None required

Significance Determination: No impact

Permanent Ambient Noise Levels Increase

Impact 3.10-3: The proposed program could result in a substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project.

Structural (Regional, Centralized, and Distributed) BMPs

Given that the majority of the distributed, centralized, and regional structural BMPs would operate in a passive manner (i.e., would not require the use of mechanized stationary equipment) after their construction, no operational noise levels would be generated by these structural BMPs. However, it is anticipated that that some of the centralized and regional structural BMPs would require the use of irrigation pump stations and associated components to divert the collected stormwater. At these structural BMP sites, noise levels generated from the long-term operation of the pumps and associated components could result in increased noise levels in the surrounding noise environment. However, as discussed under Impact 3.10-1, the pumping equipment used at a structural BMP site would be required to comply with the applicable exterior noise standards and/or regulations established by the implementing agency that has jurisdiction over the site. In addition, many of the irrigation pumps would primarily be located belowground and all other noise-producing components (e.g., generators) would be enclosed. Furthermore, with implementation of **Mitigation Measure NOISE-1**,which would require the stationary mechanized equipment employed at each structural BMP site to comply with the local noise standards established by the responsible implementing agency with jurisdiction over the site, and for the equipment to be designed and located in a manner such that neighboring sensitive land uses would not be exposed to a perceptible noise increase in their environment (**Mitigation Measure NOISE-2)**, this impact would be less than significant.

Mitigation Measures: Implementation of **Mitigation Measures NOISE-1** and **NOISE-2**

Significance Determination: Less than significant with mitigation (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.10-11.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the operation of new facilities. Consequently, there would be no impacts related to a substantial permanent increase in ambient noise levels resulting from implementation of the non-structural BMPs.

Mitigation Measures: None required

Significance Determination: No impact

Temporary Ambient Noise Levels Increase

Impact 3.10-4: The proposed program could result in a substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project.

Structural (Regional, Centralized, and Distributed) BMPs

During construction of the distributed, centralized, and regional structural BMPs, temporary or periodic increases in noise levels in and around each structural BMP site would result from the operation of construction equipment. As discussed in Impact 3.10-1, the construction activities for each individual structural BMP project would expose their respective nearby existing land uses to increased noise levels. Where a structural BMP site is located within 25 feet of an existing noise-sensitive land use, the resulting construction noise levels at that existing land use could reach as high as 95 dBA L_{eq} during excavation activities, which would result in a substantial noise increase over existing ambient noise levels at that existing land use. Although implementation of **Mitigation Measure NOISE-1** would reduce construction noise levels associated with the proposed program to the maximum extent feasible, under circumstances where future structural BMP sites are located immediately adjacent to existing sensitive land uses, the noise impacts related to a substantial temporary or periodic increase in ambient noise levels above levels existing without the structural BMPs would remain significant. Therefore, this impact for the proposed program would be significant and unavoidable. The identification of a significant and unavoidable program-level impact in this PEIR for the proposed program, however, does not preclude the finding of future less-than-significant impacts for individual structural BMP projects.

Mitigation Measures: Implementation of **Mitigation Measure NOISE-1**

Significance Determination: Significant and unavoidable with mitigation (The application of this mitigation measure to specific BMP types and categories are identified in Table 3.10-11.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts related to a substantial temporary or periodic increase in ambient noise levels resulting from implementation of the non-structural BMPs.

Mitigation Measures: None required

Significance Determination: No impact

Exposure of Excessive Airport Noise Levels

Impact 3.10-5: For a project located within an airport land use plan area, or, where such a plan has not been adopted, in an area within 2 miles of a public airport or public use airport, implementation of the proposed program could expose people residing or working in the area to excessive noise levels.

Structural (Regional, Centralized, and Distributed) BMPs

The Distributed, Centralized, and Regional structural BMPs that would be implemented as part of the proposed program would serve to reduce the impact of stormwater and non-stormwater on receiving water quality and address the water quality priorities as defined by the MS4 Permit. While some of these structural BMPs could potentially occur at paved areas of airports (excluding the landing areas and taxiways, which have specific aircraft support requirements) and the undeveloped buffer zones around airports, no permanent residents or workers would be introduced to these areas under the proposed program. While maintenance and inspection of the structural BMPs would occur, these activities would only occur periodically and would be minimal during project operations. Therefore the proposed program would not introduce permanent future residents or workers to the structural BMP areas and as such would not expose persons to excessive airport-related noise levels. Exposure to airport noise would be a less than significant impact.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts related to the exposure of people to excessive noise levels associated with a public airport or public use airport.

Mitigation Measures: None required

Significance Determination: No impact

Exposure of Persons to Excessive Private Airstrip Noise Levels

Impact 3.10-6: For a project located in the vicinity of a private airstrip, the proposed program could expose people residing or working in the project area to excessive noise levels.

Structural (Regional, Centralized, and Distributed) BMPs

As discussed under Impact 3.10-5 above, the proposed program would not introduce permanent future residents or workers to the structural BMP areas. Thus, while future structural BMP sites could be located in the vicinity of private airstrips, no persons would be exposed to excessive airstrip-related noise levels. Exposure to airstrip-related noise would be a less than significant impact.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts related to the exposure of people to excessive noise levels associated with a private airstrip.

Mitigation Measures: None required

Significance Determination: No impact

Cumulative Impact Discussion

Structural (Regional, Centralized, and Distributed) BMPs

Noise and vibration are both defined as localized phenomena that significantly reduce in magnitude as distance from the source increases. The structural BMPs associated with the proposed program would be constructed in multiple jurisdictions of Los Angeles County, which aside from the County also includes 46 cities and LACFCD. As such, these structural BMP projects would be generally spread over a large geographic area within the County. These structural BMPs in combination with other current and planned projects in the County would result in an increase in construction-related noise levels, which would temporarily increase the ambient noise levels of the existing noise environment in areas where a construction project would occur. This would result in significant and unavoidable impacts for construction, but less than significant for operation.

Mitigation Measures: Implementation of **Mitigation Measures NOISE-1** and **NOISE-2**

Significance Determination: Significant and unavoidable with mitigation for construction; Less than significant for operation. (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.10-11.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no new facilities that would contribute to cumulative noise impacts. As such, no impacts related to cumulative noise would occur.

Mitigation Measures: None required

Significance Determination: No impact

Summary of Impact Assessment

Table 3.10-11 shows a summary of the structural BMPs requiring mitigation.

TABLE 3.10-11
SUMMARY OF NOISE IMPACTS REQUIRING MITIGATION MEASURES

	Thresholds of Significance				
Regional BMPs	**Exceed Noise Standards**	**Vibration**	**Ambient Noise**	**Exposure to Airport Noise**	**Cumulative Impacts**
Applicable Mitigation Measures:	**NOISE-1; NOISE-2**	**None Required**	**NOISE-1**	**None Required**	**NOISE-1; NOISE-2**
Regional Detention and Infiltration	Yes	Yes	Yes	No	Yes
Regional Capture, Detention and Use	Yes	Yes	Yes	No	Yes

Low Flow Diversions	No	No	No	No	No

NOTE: These conclusions are based on typical size and function of BMPs.

3.11 Population and Housing and Environmental Justice

This section examines the existing population, housing, and employment conditions in Los Angeles County (County) as a whole. Data presented in this section was obtained from two U.S. Census Bureau data sets: 2010 census files and 2008–2012 American Community Survey (ACS) 5-year estimates. According to Section 15382 of the California Environmental Quality Act (CEQA) Guidelines, "An economic or social change by itself shall not be considered a significant impact on the environment." Socioeconomic characteristics should be considered in an Environmental Impact Report (EIR) only to the extent that they create adverse impacts on the physical environment.

3.11.1 Environmental Setting

Population

The proposed program is located in Los Angeles County, which has a population of approximately 10,017,068 people (U.S. Census Bureau, 2013). Like much of the Southern California region, Los Angeles County has experienced a population increase over the past decade. Between 2000 and 2012, the County experienced a growth rate of 3.8 percent, roughly two and a half times below the rest of the Southern California Association of Governments (SCAG) Region (10.4 percent) (SCAG, 2013). The County's population is estimated to grow to 11,353,000 by 2035 (SCAG, 2012).

Demographics

According to the 2008–2012 ACS 5-year estimates data, the racial breakdown of Los Angeles County's population is as follows:

- 27.8 percent White
- 47.7 percent Hispanic or Latino of any race
- 13.7 percent Asian
- 8.2 percent Black/African American
- 0.2 percent American Indian and Alaska Native
- 0.2 percent Native Hawaiian and Other Pacific Islander
- 2.2 percent Other (two or more races; some other race)

The general distribution of demographics around the County based on 2010 census data shows that the Hispanic and Black/African American populations are most highly concentrated within the center of the County's coastal basin, with the Black/African American population most highly concentrated within the cities of Baldwin Hills, Inglewood, Compton, and Carson. White populations within the County are most concentrated along the coastal western County boundary from Malibu down to Palos Verdes and along the coastal southern County boundary from Long Beach to Los Alamitos. The White populations are also concentrated along the Santa Monica Mountains and northern County limits, interspersed with mainly Hispanic and Asian populations in the central San Fernando Valley. Concentrations of the Asian populations exist around South San Gabriel and North El Monte, as well as around mid-city Los Angeles, Westwood, Torrance, and Norwalk (Cable, 2013).

Income

In the County of Los Angeles, the median household income is $56,241 according to the 2008-2012 ACS 5-Year Estimates data. Between the years of 2000 and 2012, the median household income for the County increased by an average of $11,691 annually. Median household income levels vary widely by census tract throughout the County, with lower-income tracts primarily located in central, east, and south Los Angeles. Other lower-income census tracts lie in the northern edges of the County, including some in the cities of Palmdale and Lancaster.

The median household annual income for all cities/Permittees included in the 12 EWMP areas ranges from $41,538 in the City of Industry to over $250,000 in the City of Hidden Hills. This represents over a $200,000 range in the EWMP areas. The cities'/Permittees' median household income is $75,350, which is almost $20,000 higher than the County median household income level.

TABLE 3.11-1
2014 LOS ANGELES COUNTY AREA MEDIAN HOUSEHOLD INCOME CLASSIFICATION IN U.S. DOLLARS

	2 persons in household	3 persons in household	4 persons in household
Extremely low income	20,500	23,050	25,600
Very low income	34,200	38,450	42,700
Low Income*	54,650	61,500	68,300
Median Income	51,850	58,300	64,800
Moderate Income	62,200	70,000	77,750

*Low income exceeding median income is an anomaly just for LA County due to HUD historical high cost adjustments to median. Household lower-income figures are derived based on very-low income figures not adjusted by HUD to account for any exceptions.

SOURCE: California Department of Community Development, 2014

Median household income varies greatly throughout Los Angeles neighborhoods. "High" median household income levels are concentrated mostly along the western boundary of the County along the coast and in Santa Clarita bordering Ventura County. These areas include the majority of the Upper Santa Clara River, Malibu Creek, North Santa Monica Bay, Beach Cities, and Palos Verdes Peninsula EWMP areas, along with parts of the Santa Monica Bay Jurisdictions 2 and 3 and the Ballona Creek EWMP areas. "Low" median household income areas are concentrated in the southern center of the County, and include parts of the Upper Los Angeles River, Ballona Creek, and Dominguez Channel EWMP areas. "Medium" median household income areas are more evenly interspersed throughout the County (Los Angeles Times, 2014).

Housing

There are approximately 3,441,416 housing units in Los Angeles County, with an average household size of 3.19 for owner-occupied units and 2.84 for renter-occupied units (U.S. Census Bureau, 2008–2012). As for housing tenure, 47.3 percent of County units are owner-occupied and 52.7 percent are renter-occupied units. The County homeowner vacancy rate is 1.7 percent and the rental vacancy rate is 4.5 percent; these vacancy rates are much lower than the national rates (2.3 percent of homeowners and 7.5 percent of rentals). Vacancy rates are an indicator of housing market balance in the County, where high vacancy rates demonstrate low demand and/or high prices, and low vacancy rates demonstrates high demand and/or low prices in the housing market. The County's vacancy rates are relatively low compared to the national level, indicating a relatively high demand for housing in the region.

3.11.2 Regulatory Setting

Federal

Executive Order 12898 outlines federal actions to address environmental justice in minority populations and low-income populations. Executive Order 12898 states that agencies shall identify and address disproportionately high and adverse human health or environmental effects on minority and low-income populations. A new working group was created to develop strategies for programs and policies regarding minority and low-income populations to: promote enforcement of all health and environmental statutes, improve research and data collection in relation to health and environment, identify different patterns of consumption of natural resources, and ensure greater public participation.

Local

County of Los Angeles General Plan

A General Plan is a basic planning document that, alongside the zoning code, governs development in a city or county. The State requires each city and county to adopt a General Plan with seven mandatory elements: land use, open space, circulation, housing, noise, conservation, and safety, along with any number of optional elements as appropriate. The proposed EWMPs would be subject to the local plans and policies of the areas in which they are located. Because this Program Environmental Impact Report (PEIR) is a high-level assessment of projects spanning the entire County, it will discuss only the County-level goals and policies relating to the overall program.

Housing Element (2014–2021)

The Housing Element is a required section of the General Plan, and serves to address the existing and projected housing needs of a city or county, including their share of the regional housing need. State law requires each local government agency to update their Housing Element every 5 years, and submit it to the State Department of Housing and Community Development for review. Los Angeles County's Housing Element was updated most recently in early 2014 for the 2014–2021 planning period. This policy guide analyzes the housing needs of the unincorporated areas of the County, and its primary focus is to ensure decent, safe, sanitary, and affordable housing for current and future residents in those areas. The following are the goals and policies from the Los Angeles County Housing Element that relate to the proposed program.

Goal 5: Neighborhoods that protect the health, safety, and welfare of the community, and enhance public and private efforts to maintain, reinvest in, and upgrade the existing housing supply.

Policy 5.2: Maintain adequate neighborhood infrastructure, community facilities, and services as a means of sustaining the overall livability of neighborhoods.

Goal 6: An adequate supply of housing preserved and maintained in sound condition, and located within safe and decent neighborhoods.

Policy 6.4: Maintain and improve community facilities, public housing services, and infrastructure, where necessary, to enhance the vitality of older, low income neighborhoods.

City General Plans

The EWMP areas associated with the proposed program are located in multiple jurisdictions of Los Angeles County, which, aside from the County, also includes 46 cities. Each of these cities has their own independent General Plan and municipal code that regulates housing. Given that a project-level analysis for each structural Best Management Practice (BMP) proposed in the EWMPs is beyond the scope of this PEIR, an extensive listing of the housing policies and regulations of each of the participating Permittees is not provided in this PEIR.

3.11.3 Impacts Assessment

Thresholds of Significance

For the purposes of this PEIR and consistency with Appendix G of the CEQA Guidelines, the project would have a significant impact on population and housing if it would:

- Induce substantial population growth in an area, either directly (for example, by proposing new homes and businesses) or indirectly (for example, through extension of roads or other infrastructure).
- Displace substantial numbers of existing housing, necessitating the construction of replacement housing elsewhere.
- Displace substantial numbers of people, necessitating the construction of replacement housing elsewhere.

Implementation of the proposed project may result in a potentially significant impact to environmental justice if the projects would:

- Affect the health or environment of minority or low-income populations disproportionately.

Program Impact Discussion

Impact 3.11-1: Implementation of the proposed program could induce substantial population growth in an area, either directly (for example, by proposing new homes and businesses) or indirectly (for example, through extension of roads or other infrastructure).

Structural (Regional, Centralized, and Distributed) BMPs

The structural BMPs associated with the proposed program would be installed to treat existing water quality impairments and would not induce population growth in the EWMP areas, either directly or indirectly. The structural BMPs are not habitable structures and would not provide new homes or businesses. In addition, the structural BMPs would generally be located within existing urbanized areas that do not have structural BMPs to treat existing runoff; the implementation of structural BMPs within existing stormwater infrastructure would not indirectly induce growth as the BMPs do not provide growth opportunities, as occurs with the extension of roads or other infrastructure. The construction work force anticipated to support implementation of the proposed projects would be drawn from the local Los Angeles region workforce and would not require housing. Because of the relatively short construction durations (typically less than one year) of the various types of structural BMPs and large available construction workforce in the Los Angeles Region, it is assumed that construction workers would not have to travel far or add traffic to roads outside of the vicinity of the project sites.

In addition, while one of the main goals of the EWMP is to increase infiltration and potentially increase recharge of stormwater into the groundwater basin, the amount of water potentially recharged would not be enough to indirectly support population growth. This potential additional recharge would contribute to local water supplies, but would not alter population demographics. Therefore, there would be no impact on population growth, either directly or indirectly.

Mitigation Measures: None required

Significance Determination: No impact

Non-Structural (Institutional) BMPs

Non-structural BMPs consist of policies, actions, and activities aimed at preventing pollutants from entering stormwater runoff; therefore, no physical impacts would occur in the EWMP areas. Non-structural BMPs would not include any direct or indirect population growth-inducing measures. There would be no impact.

Mitigation Measures: None required

Significance Determination: No impact

Impact 3.11-2: Implementation of the proposed program could displace substantial numbers of existing housing, necessitating the construction of replacement housing elsewhere.

Structural (Regional, Centralized, and Distributed) BMPs

The proposed program and implementation of associated structural BMPs would not impact existing housing or necessitate construction of additional or replacement housing elsewhere. Structural BMPs may be constructed on private parcels, but would not displace existing housing or necessitate replacement housing elsewise. Although a property owner may decide to modify the structures on their property, that a structural BMP would not displace existing housing.

Distributed BMPs are most likely to be implemented in high-density urban, commercial, industrial, and transportation areas where they would either replace or improve upon existing stormwater infrastructure. These types of BMPs are generally "retrofit" type projects that replace existing impervious surfaces with pervious surfaces such as bioinfiltration cells, bioswales, porous pavement, and filter strips that tie into existing stormwater management systems. These projects may also augment the existing stormwater management systems with additional inlet screens, filter media systems, sediment removal systems, and diversions to sanitary sewer lines. Ground disturbance for distributed BMPs is typically less than 1 to 2 acres in extent, but may extend in some limited applications up to 5 acres where space is available. Any new construction would be implemented along sidewalks and streets, in parks, and on publicly owned lands and would have no direct impact on existing homes. If projects are implemented in residential areas or streets, the projects would likely provide an improvement to the community in terms of aesthetic appearance.

Mitigation Measures: None required

Significance Determination: No impact

Non-Structural (Institutional) BMPs

The implementation of non-structural BMPs would not displace housing, as they do not involve structural elements and would not have a direct physical impact on the environment, as no construction or maintenance activities would be required. There would be no impact.

Mitigation Measures: None required

Significance Determination: No impact

Impact 3.11-3: Implementation of the proposed program could displace substantial numbers of people, necessitating the construction of replacement housing elsewhere.

Structural (Regional, Centralized, and Distributed) BMPs

The currently planned program and implementation of associated structural BMPs would not displace any housing or people. Structural BMPs would generally be implemented along sidewalks and streets, in parks, and on publicly owned lands and would have no direct impact on existing homes or residents. Future regional and centralized structural BMPs under the EWMP may include private property, schools, and universities. These potential future structural BMPs are not anticipated to result in displacement of existing housing.

RB-AR 8599

Mitigation Measures: None required

Significance Determination: No impact

Non-Structural (Institutional) BMPs

The implementation of non-structural BMPs would not displace any people, as they do not consist of structural improvements that would have a physical impact on the environment. No construction or maintenance activities would be required. There would be no impact.

Mitigation Measures: None required

Significance Determination: No impact

Impact 3.11-4: Implementation of the proposed program could affect the health or environment of minority or low-income populations disproportionately.

Structural (Regional, Centralized, and Distributed) BMPs

Structural BMPs would be located throughout the County and cities based on water quality priorities and site suitability, factors of which include space, soil type, proximity/connectivity to other BMPs, etc. Structural BMPs are not expected to be concentrated in any one area or city in particular within the EWMP areas. The structural BMPs are expected to be located on public lands (e.g., schools, parks, sidewalks, and road rights-of-way) throughout the EWMP areas and would be designed to capture, convey, and/or filter stormwater and surface runoff. The structural BMPs would treat surface water runoff in a manner that would not result in human contact with surface flows that are potentially harmful to health. Structural BMPs would not disproportionately affect the health or environment of minority or low-income populations. Impacts would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant impact

Non-Structural (Institutional) BMPs

Similar to structural BMPs, non-structural BMPs are expected to be implemented throughout the County area, with no concentration in any area in particular. Non-structural BMPs would consist of policies and measures taken to prevent surface water pollution, and by their non-structural and preventative nature are not expected to introduce a threat to the environmental or public health, much less a disproportionate threat to minority or low-income populations. Street sweeping is a non-structural BMP that requires temporary parking restrictions to allow for effective collection and removal of debris and sediment from the streets. Curb parking spaces tend to be used more in higher-density, predominantly rental communities. Prior to implementation of increased street sweeping activities to improve effectiveness of these measures, the impact on street parking would be assessed and frequency of restriction on street parking assessed to avoid impacts to these communities that rely more heavily on street parking for residences and small businesses. Impacts would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant impact

Cumulative Impact Discussion

Structural (Regional, Centralized, and Distributed) BMPs

The proposed program would involve implementation of structural BMPs that would capture and/or infiltrate, filter, divert, or treat stormwater runoff. Structural BMPs would result in the improvement of existing stormwater infrastructure and stormwater quality, and would therefore not result in a direct or indirect increase in population or housing. Structural BMPs would be installed along sidewalks and streets and in other public areas, and would not displace existing people or housing. There would be no impacts to population and housing; therefore, there would be no cumulative impacts to population and housing.

Mitigation Measures: None required

Significance Determination: No impact

Non-Structural (Institutional) BMPs

Non-structural BMPs consist of policies, actions, and activities aimed at preventing pollutants from entering stormwater runoff; there would not be physical impact to the environment. Non-structural BMPs would not include any direct or indirect population growth-inducing measures, and would not displace existing people or housing. There would be no impacts to population and housing; therefore, there would be no cumulative impacts to population and housing.

Mitigation Measures: None required

Significance Determination: No impact

3.11.4 Summary of Impact Assessment

Table 3.11-2 shows a summary of the structural BMPs requiring mitigation.

TABLE 3.11-2
SUMMARY OF POPULATION AND HOUSING IMPACTS REQUIRING MITIGATION MEASURES

	Thresholds of Significance				
Structural BMPs	**Population Growth**	**Displaced Housing**	**Displaced Population**	**Disproportionate Impact on Minority Populations**	**Cumulative Impacts**
Applicable Mitigation Measures:	**None Required**	**None Required**	**None Required**	**None Required**	**None Required**
Regional BMPs					
Regional Retention and Infiltration	No	No	No	No	No

Low-Flow Diversions	No	No	No	No	No

NOTE: These conclusions are based on typical size and function of BMPs.

3.12 Public Services and Recreation

This section addresses potential impacts on public services and recreational resources that could occur as a result of implementation of the proposed program. The public services addressed in this section include law enforcement services, fire protection services, and schools.

3.12.1 Environmental Setting

Public Services

Fire Protection

The Los Angeles County Fire Department (LACFD) serves unincorporated areas as well as many of the cities within the County; 21 of these cities are participating Permittees within the Enhanced Watershed Management Program (EWMP) areas. These cities include Hawthorne, West Hollywood, Malibu, Palos Verdes Estates, Rancho Palos Verdes, Rolling Hills Estates, Azusa, Bradbury, Duarte, Calabasas, Hidden Hills, La Canada Flintridge, Rosemead, San Gabriel, Temple City, Baldwin Park, Covina, Glendora, Industry, La Puente, and Santa Clarita (LACFD, 2013). LACFD employs approximately four thousand emergency personnel and works out of 170 fire stations across the County. In addition to fire suppression, the LACFD also provides fire prevention services, emergency medical services, hazardous materials services, and urban search and rescue services.

LACFD is organized into three different emergency operations bureaus, the North, Central, and East Regional Operations Bureau. The North Regional Operations Bureau includes 43 fire stations serving communities in the Antelope and Santa Clarita Valleys. The Central Regional Operations Bureau includes 51 fire stations serving communities in the central Los Angeles portions of the County. It also includes the Lifeguard Division based in Venice, which helps protect millions of annual visitors along 74 miles of the Pacific Coast. The East Regional Operations Bureau includes 76 fire stations servicing communities within the east side of the County (LACFD, 2013).

Under a mutual-aid pact covering federal forestlands, responsibility for nonstructural fires within the National Forest belongs to the U.S. Forest Service (USFS), while LACFD has the primary mission of suppressing structure fires. In addition, they have an automatic-aid agreement that allows the closest municipality to provide an initial response to fires that may occur in a part of another municipality. The LACFD has several standards to maintain adequate fire protection within their service area (Los Angeles County, 2014). The current standards for response times are:

- 5 minutes or less for response times for urban areas
- 8 minutes or less for suburban areas
- 12 minutes or less for rural areas

LACFD has designated lands in Los Angeles County with regard to their potential for wildland fires. These designations, determined by the County Forester, are based on an area's accessibility, amount and type of vegetative cover, water availability, and topography. LACFD uses three wildland fire hazard designations: Moderate Fire Hazard, High Fire Hazard, and Very High Fire Hazard. Areas in Los Angeles County that are not designated within a fire hazard zone are not considered to be subject to wildland fire hazards (Los Angeles County, 2014).

The following 26 EWMP participating Permittees run city-owned fire departments: Beverly Hills, Culver City, Inglewood, Santa Monica, Hermosa Beach, Manhattan Beach, Redondo Beach, Torrance, El Segundo, Agoura Hills, Westlake Village, Culver City, Malibu, Arcadia, Monrovia, Sierra Madre, Alhambra, Burbank, Glendale, Los Angeles, Montebello, Monterey Park, Pasadena, Rosemead, San Marino, and South Pasadena, (LACFD, 2013).

Police Protection

The Los Angeles County Sheriff's Department (LASD) provides law enforcement services to more than one million people living within 90 unincorporated communities and to more than four million residents living within 40 contract cities. In addition, LASD provides law enforcement services to nine community colleges, Metro, and 48 Superior Courts (Los Angeles County, 2014). LASD comprises 11 divisions, including 3 patrol divisions and the Office of Homeland Security. In addition to proactive enforcement of criminal laws, the LASD also provides investigative, traffic enforcement, accident investigation, and community education functions.

Cities within the EWMP areas that contract with LASD for their police services include West Hollywood, Agoura Hills, Calabasas, Hidden Hills, Malibu, Westlake Village, Rancho Palos Verdes, Rolling Hills Estates, Rolling Hills. Duarte, Bradbury, Monrovia, Santa Clarita, Industry, La Puente, Glendora, Covina, Baldwin Park, Temple City, East Pasadena, Rosemead, La Canada Flintridge, Hidden Hills, and Calabasas. LASD staff has indicated that an officer-to-population ratio of 1 officer to every 1,000 residents provides the desired level of service for its service area (Los Angeles County, 2014). The LASD also has established an optimal service response time of 10 minutes or less for emergency response incidents (a crime that is presently occurring and is a life-or-death situation), 20 minutes or less for priority response incidents (a crime or incident that is currently occurring but is not a life-or-death situation), and 60 minutes or less for routine response incidents (a crime that has already occurred and is not a life-or-death situation). These response times represent the range of time required to handle a service call, which is measured from the time a call is received until the time a patrol car arrives at the incident scene. Response time is variable, particularly because the nearest responding patrol car may be located anywhere within the station's patrol area and may not necessarily respond directly from the station itself (Los Angeles County, 2014).

Nineteen cities within the EWMP areas run their own city police departments; these cities are Beverly Hills, El Segundo, Culver City, Inglewood, Santa Monica, Los Angeles, Hermosa Beach, Manhattan Beach, Torrance, Hawthorne, Arcadia, San Marino, South Pasadena, San Gabriel, Burbank, Monterey Park, Montebello, Glendale, and Alhambra.

Schools

Within the County there are more than two thousand public schools (not including colleges) that serve over 1.5 million students. The County's role in developing and managing educational facilities and programs is limited. However, the Los Angeles County Office of Education (LACOE) serves as a regional education agency and an intermediary between the local school districts and the California Department of Education. LACOE supports 80 public school districts and numerous other educational agencies within the County (LACOE, 2014). The largest public school district in the County is Los Angeles Unified School District (LAUSD), which has a service area of over 720 square miles and includes the City of Los Angeles, 31 smaller municipalities, and unincorporated areas. LAUSD has more than nine hundred schools and 640,000 students (LAUSD, 2014). There are several other smaller school districts in the EWMP study area. **Table 3.12-1** lists the school districts in each EWMP area. **Figure 3.12-1** shows the schools located throughout the EWMP areas, distinguishing between elementary schools, middle schools, high schools, and colleges; other schools such as pre-schools, colleges, and other types of education facilities are not shown.

Figure 3.12-1

Public School Locations

Parks and Recreational Resources

The County of Los Angeles Department of Parks and Recreation owns, operates, and maintains nearly 174 parks and recreational facilities (LADPR, 2014). The local park system encompasses approximately 609 total acres, and includes community parks (10 to 20 acres in size), neighborhood parks (3 to 10 acres in size), pocket parks (less than 3 acres in size), and park nodes (small pieces of open space that provide breaks to the urban landscape). Local parks serve neighborhoods within a maximum of a 2-mile radius of the park. The regional park system makes up 68,986 acres and includes regional parks (greater than 100 acres), community regional parks (20 to 100 acres), and special-use facilities (single-use facilities serving greater recreational or cultural needs). The parks in the regional park system provide service for areas within a 20- to 25-mile radius. Other recreational facilities available to County residents include trails, multi-benefit parks, school sites, city parks and facilities, private recreational facilities, and greenways (Los Angeles County, 2014).

The County goal for the provision of parkland is 4 acres of local parkland per 1,000 residents of the population in the unincorporated areas, and 6 acres of regional parkland per 1,000 residents of the total population of Los Angeles County (Los Angeles County, 2014). Section 21.24.340 of the County Code has a standard of 3 acres of local and 5 acres of regional parkland per 1,000 residents.

According to County estimates, there are currently a total of 1,066,414 people living in the unincorporated areas. This means that for every 1,000 residents there are a total of approximately 0.57 acres of local parkland, resulting in a local parkland deficit; the current acreage of available local parkland does not meet the County's goal for recreational facilities (Los Angeles County, 2014). In addition to the 609 acres of local parkland, there is a total of 68,986 acres of regional parkland in Los Angeles County at this time. For every 1,000 residents in Los Angeles County, there is a total of approximately 7 acres of regional parkland. There is a surplus of regional parkland, which exceeds the County's goal for regional parkland (Los Angeles County, 2014). **Figure 3.12-2** shows the County parks present within the EWMP areas.

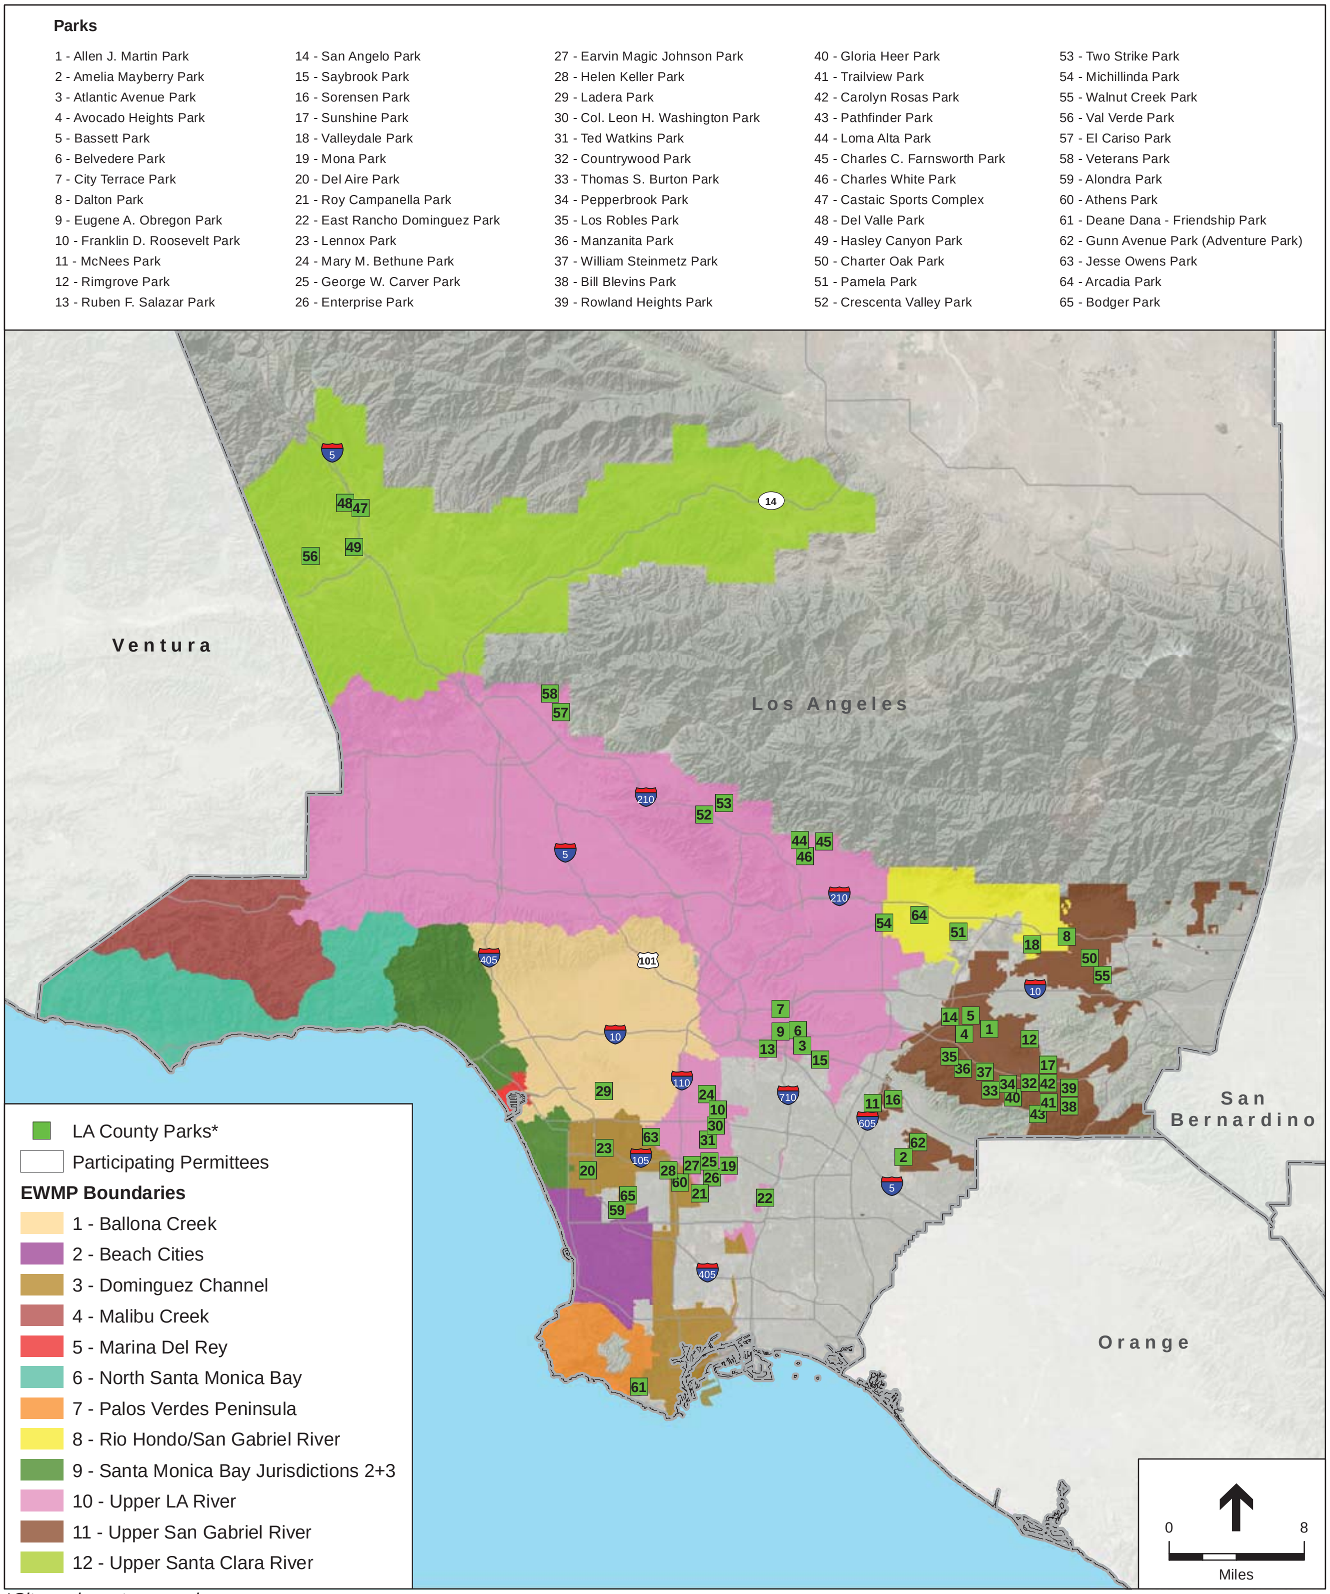
Many of the cities/Permittees within the EWMP areas have city-owned and -operated parks. Given that a project-level analysis for each structural Best Management Practice (BMP) proposed in the EWMPs is beyond the scope of this Program Environmental Impact Report (PEIR), an extensive listing of each of the participating Permittees' parklands is not provided in this PEIR.

3.12.2 Regulatory Setting

Local

Los Angeles County General Plan

State law requires every city and county to include an Open Space Element in their General Plan. Both the existing and draft County of Los Angeles General Plan include a Parks and Recreation Element that discusses recreational facilities available within the County boundaries, and goals and policies addressing the growing and diverse recreation needs of the region. The following are the parks and recreation goals and policies.



City parks not mapped

SOURCE: ESRI.

LA County PEIR EWMP . 140474

Figure 3.12-2
County Park Locations

Existing General Plan 1980

Goal: Provide Outdoor Recreation Areas.

Policy 27: Provide low intensity outdoor recreation in areas of scenic and ecological value compatible with protection of these natural resources.

Policy 28: Develop local parks in urban areas as part of urban revitalization projects, wherever possible.

Draft General Plan 2035

Goal P/R 1: Enhanced active and passive park and recreation opportunities for all users.

Policy P/R 1.4: Promote efficiency by building on existing recreation programs.

Policy P/R 1.5: Ensure that County parks and recreational facilities are clean, safe, inviting, usable and accessible.

Goal P/R 2: Enhanced multi-agency collaboration to leverage resources.

Policy P/R 2.5: Support the development of multi-benefit parks and open spaces through collaborative efforts among entities such as cities, the County, state, and federal agencies, private groups, schools, private landowners, and other organizations.

State law also requires the inclusion of a Safety Element that addresses environmental hazards and other safety concerns and aims to reduce the potential risk of death, injury, and economic damage resulting from natural and man-made hazards. The following presents the goals and policies in the existing and draft County of Los Angeles General Plan Safety Element.

Existing General Plan 1980

Goal: Strengthen County short-term emergency response and long-term recovery capability.

Policy 27: Strengthen the capability of County agencies to effectively respond to earthquake and non-earthquake induced emergencies.

Policy 28: Upgrade regional heavy rescue capability including mobilization operations and resource management.

Policy 29: Encourage critical facilities to maintain and regularly update emergency response plans identifying safety procedures, disaster control capabilities, and evacuation procedures such as drills and exercises.

Policy 30: Upgrade interagency and multijurisdictional communications, planning and decision making to ensure efficient and integrated emergency response capability.

Policy 31: Promote improved cooperation with nonprofit and private sector emergency response organizations.

Policy 35: Strengthen emergency communication systems and improve cooperation between the media and emergency response agencies.

Goal: Continue to promote research on and mapping of natural and urban hazards: and improve safety information systems for planning, emergency response management and hazard mitigation.

Policy 37: Encourage research that will lead to the detailed mapping of ground response (microzonation) of Los Angeles County.

Draft General Plan 2035

Goal S 3: An effective regulatory system that prevents or minimizes personal injury, loss of life, and property damage due to fire hazards.

Policy S 3.9: Adopt by reference the County of Los Angeles Fire Department Strategic Fire Plan, as amended.

Goal S 4: Effective County emergency response management capabilities.

Policy S 4.1: Ensure that residents are protected from the public health consequences of natural or man-made disasters through increased readiness and response capabilities, risk communication, and the dissemination of public information.

Policy S 4.2: Support County emergency providers in reaching their response time goals.

Policy S 4.3: Coordinate with other County and public agencies, such as transportation agencies and health care providers on emergency planning and response activities, and evacuation planning.

Policy S 4.5: Ensure that there are adequate resources, such as sheriff and fire services, for emergency response.

Los Angeles County Strategic Fire Plan

LACFD provides fire, safety, and emergency medical services to the unincorporated areas, as well as to several cities in the County. Their strategic plan is updated yearly and includes department goals and policies the department implements to ensure safety of residents and to carry out the County’s public safety mission.

City General Plans and Municipal Codes

The EWMP areas associated with the proposed program are located in multiple jurisdictions of Los Angeles County, which, aside from the County, also includes 46 cities. Each of these cities has their own independent General Plan and municipal code that regulates public service levels and recreation resources within their jurisdictional boundaries. Given that a project-level analysis for each structural BMP proposed in the EWMPs is beyond the scope of this PEIR, an extensive listing of the public service and recreation policies and goals of each of the participating Permittees is not provided in this PEIR.

3.12.3 Impact Assessment

The proposed program's potential impacts were assessed using the California Environmental Quality Act (CEQA) Guidelines Appendix G Checklist. The following sections discuss the key issue areas identified in the CEQA Guidelines with respect to the proposed program's potential effects on public services and recreational resources.

Thresholds of Significance

For the purposes of this PEIR and consistency with Appendix G of the CEQA Guidelines, the project would have a significant impact on public services if the project would:

- Result in substantial adverse physical impacts associated with the provision of, or the need for, new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for any of the following public services:
    - Fire protection
    - Police protection
    - Schools
    - Parks
    - Other public facilities

Implementation of the proposed project may result in a potentially significant impact to recreational resources if the projects would:

- Increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated.
- Include recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment.

Program Impact Discussion

Fire Protection Services

Impact 3.12-1: The proposed program could result in substantial adverse physical impacts associated with the provision of, or the need for, new or physically altered governmental fire protection facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for fire protection services.

Structural (Regional, Centralized, and Distributed) BMPs

Distributed BMPs are most likely to be implemented in high-density urban, commercial, industrial, and transportation areas where they would either replace or improve upon existing stormwater infrastructure. These types of BMPs are generally "retrofit"-type projects that replace existing impervious surfaces with pervious surfaces such as bioinfiltration cells, bioswales, porous pavement, and filter strips that tie into existing stormwater management systems. These projects may also augment the existing stormwater management systems with additional inlet screens, filter media systems, sediment removal systems, and diversions to sanitary sewer lines. Ground disturbance for distributed BMPs is typically less than 1 to 2 acres in extent, but may extend in some limited applications up to 5 acres where space is available. Centralized structural BMPs use similar elements to the types of BMPs used in distributed structural BMPs, but also collect, store, treat, and filter stormwater from multiple parcels and much larger drainage areas. Like centralized BMPs, regional BMPs can be implemented in a broad range of land use types, from high-density urban to open space, and can have multiple benefits (habitat, recreation, aesthetics, etc.). Centralized and regional structural BMPs require greater footprints for construction and implementation. Regional and centralized BMPs have similar construction methods.

The structural BMPs associated with the proposed program would be installed to treat existing water quality impairments and would not contribute to an increased need for fire protection services. The structural BMPs are not habitable structures, would not be constructed with flammable materials, and would not require fire protection services. Because of the relative scale of these infrastructure improvements, the construction of the various structural BMPs are not expected to result in the need for new or physically altered fire protection facilities. However, construction of new structural BMPs in streets, sidewalks, parkland, or other facilities (these may include public service facilities such as police stations, fire stations, and municipal maintenance yards) within existing high-density urban, commercial, industrial, and transportation areas, as well as associated staging areas, could temporarily disrupt the provision of fire services, resulting in potentially significant impacts. Implementation of **Mitigation Measure PS-1** (construction noticing) would reduce potential impacts to a less-than-significant level.

Mitigation Measure:

PS-1: The Permittee implementing the EWMP project shall provide reasonable advance notification to service providers such as fire, police, and emergency medical services as well as to local businesses, homeowners, and other residents adjacent to and within areas potentially affected by the proposed EWMP project about the nature, extent, and duration of construction activities. Interim updates should be provided to inform them of the status of the construction activities.

Significance Determination: Less than significant with mitigation (The application of this mitigation measure to specific BMP types and categories are identified in Table 3.12-2.)

Non-Structural (Institutional) BMPs

The non-structural BMPs associated with the proposed program would consist of standards and policies related to development and maintenance activities in mostly urban areas. The non-structural BMPs would not contribute to an increase in population within the project area, and would therefore not result in the need for new or physically altered fire protection facilities. There would be no impact.

Mitigation Measures: None required

Significance Determination: No impact

Police Protection Services

Impact 3.12-2: The proposed program could result in substantial adverse physical impacts associated with the provision of, or the need for, new or physically altered governmental police protection facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for police protection services.

Structural (Regional, Centralized, and Distributed) BMPs

The structural BMPs associated with the proposed program would not contribute to an increase in population requiring police protection services. The structural BMPs are not habitable structures; they include mostly unobtrusive structures such as bioswales, pervious pavement, and bioretention areas and are not expected to be of a nature that would require police protection services. Larger-size regional and centralized BMPs could be located in public open spaces such as parks and large parking lots, but would not result in an increased need for police services. Centralized BMPs may include larger-scale diversion and treatment systems that may require added security systems to protect operating systems. These added security systems will be part of the design process and operation and maintenance of these facilities. The structural BMPs would therefore not result in the need for new or physically altered police protection facilities, as there would be no increase in the demand for police protection services.

Mitigation Measure: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

Consisting of standards and activities designed to protect surface water quality, the non-structural BMPs associated with the proposed program are not expected to result in substantial increases of criminal activity and would not result in the need for new or physically altered police protection facilities. There would be no impact.

Mitigation Measures: None required

Significance Determination: No impact

Schools

Impact 3.12-3: The proposed program could result in substantial adverse physical impacts associated with the provision of, or the need for, new or physically altered schools, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for schools.

Structural (Regional, Centralized, and Distributed) BMPs

The structural BMPs associated with the proposed program would consist of structures such as bioinfiltration cells, bioswales, porous pavement and filter strips, low-flow diversions, detention ponds, treatment wetlands, and stream/creek restoration projects; it would not increase the population in the project area, so it would not generate additional students. However, some of the structural BMPs may be installed on school facilities, on or under large grassy fields typically found on school sites. Large open space areas that can be found on school sites offer potential opportunities for infiltration and recharge areas. Such impacts would be analyzed on a site-specific basis as projects are brought forward and will be reviewed under a subsequent CEQA process. However, because of the short construction period of the types of structural BMPs under consideration, construction activities would not be anticipated to significantly affect the operation of existing school facilities such that new or physically altered facilities would be required. In addition, the long-term operation of the structural BMPs would not likely affect the operation of existing school facilities because of the relatively small scale and design of these structural BMPs. Impacts would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

The non-structural BMPs would consist of standards and activities designed to protect surface water quality, and would not increase population within the project area. Therefore, these BMPs would not result in the need for new or physically altered school facilities. There would be no impact.

Mitigation Measures: None required

Significance Determination: No impact

Increased Use of Recreational Facilities

Impact 3.12-4: The proposed program could increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated.

Structural (Regional, Centralized, and Distributed) BMPs

The structural BMPs would not contribute to an increase in population and an associated increase in existing recreational facilities that could result in physical deterioration of existing facilities.

Some of the structural BMPs associated with the proposed program are anticipated to be located on existing parkland, as these open space areas offer ample area for potential subsurface spreading and infiltration. During the construction of such infrastructure, certain parts of selected parks and recreational facilities would temporarily be removed from service. Bike lanes and other linear recreational resources may also be affected by construction activities. Therefore, the construction of structural BMPs could temporarily limit the usage of the parks on which they are located, thereby potentially temporarily increasing the use at adjacent parks. Such temporary limits on access to parks and recreational resources may create increased demand on other parks and recreational resources within the EWMP area.

Once constructed, the structural BMPs would be in-ground or compatible with open space uses. The structural BMPs would operate passively and consist of mostly unobtrusive structures such as bioinfiltration cells, bioswales, porous pavement and filter strips, low-flow diversions, detention ponds, treatment wetlands, and stream/creek restoration projects. Construction periods for each BMP are expected to be relatively short, typically several months to a year. Because the construction will be temporary, the physical deterioration of park and recreational facilities to which recreational activities were diverted would not be substantial. The structural BMPs operated as part of the proposed program would be compatible with recreational and park-set activities; therefore, no impacts would occur during operation. Thus, construction and operation of structural BMPs would not increase the use of adjacent recreational facilities in such a way that would physically deteriorate them.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

The non-structural BMPs associated with the proposed program would include programs that would lead to the establishment of various standards and/or physical maintenance activities, such as street sweeping. These BMPs would be preventative of water quality degradation and would not directly result in population growth or displace any existing recreational resources that would thereby result in the increased use of neighborhood or regional recreational resources. Therefore, they would not result in physical deterioration of existing facilities. There would be no impact.

Mitigation Measures: None required

Significance Determination: No impact

Inclusion of Recreational Facilities

Impact 3.12-5: The proposed program could include recreational facilities or require the construction or expansion of recreational facilities which might have an adverse physical effect on the environment.

Structural (Regional, Centralized, and Distributed) BMPs

The structural BMPs associated with the proposed program would not require the construction or expansion of recreational facilities, although some BMPs may be located within existing parks or would create new public park space. Implementation of these BMPs would not increase the population and would therefore not create a need for the construction of new or expansion of existing recreational facilities. The structural BMPs constructed and operated as part of the proposed program, if it is approved, would be located on existing recreational facilities and would be compatible with recreational uses during operation. Therefore, the BMPs would not impact parkland in such a way that would require its expansion or the creation of new parkland. Impacts would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

The non-structural BMPs associated with the proposed program would not include recreational facilities. Non-structural BMPs would consist of programs and policies that would include development guidelines and activities designed to prevent surface water quality degradation, and would not specifically result in the construction of new or expansion of existing recreational facilities. There would be no impact.

Mitigation Measures: None required

Significance Determination: No impact

Cumulative Impact Discussion

Structural (Regional, Centralized, and Distributed) BMPs

BMPs would be constructed throughout the watersheds. None of the facilities individually or cumulatively would increase population; require additional police, fire, or emergency services; or result in construction of new schools. Most of the distributed BMPs would be small in scale and would not result in cumulatively significant impacts to public services. Similarly, the larger regional and centralized BMPs would not result in cumulatively significant impacts to public services, but may instead provide multiple benefits by increasing public open space in urban areas. Therefore, the program's potential contribution to cumulative effects on public services and recreation is considered less than significant.

Mitigation Measures: Mitigation Measure **PS-1** (The application of this mitigation measure to specific BMP types and categories is identified in Table 3.12-2.)

Significance Determination: Less than significant with mitigation

Non-Structural (Institutional) BMPs

The non-structural BMPs associated with the proposed program would not result in impacts to public services or recreational facilities, as these BMPs will not consist of any physical construction. There would be no impact.

Mitigation Measures: None required

Significance Determination: No impact

3.12.4 Summary of Impact Assessment

Table 3.12-2 shows a summary of the structural BMPs requiring mitigation.

TABLE 3.12-2
SUMMARY OF PUBLIC SERVICES AND RECREATION IMPACTS REQUIRING MITIGATION MEASURES

	Thresholds of Significance					
Structural BMPs	**Adverse physical impacts due to new or altered fire protection facilities**	**Adverse physical impacts due to new or altered police facilities**	**Adverse physical impacts due to new or altered schools**	**Increased use of recreational facilities**	**Construction of recreational facilities**	**Cumulative Impacts**
Applicable Mitigation Measures:	**PS-1**	**None Required**	**None Required**	**None Required**	**None Required**	**PS-1**
Regional BMPs						
Regional Retention and Infiltration	Yes	No	No	No	No	Yes
Regional Capture, Detention and Use	Yes	No	No	No	No	Yes
Centralized BMP						
Biofiltration	Yes	No	No	No	No	Yes
Constructed Wetlands	Yes	No	No	No	No	Yes
Treatment/Low-Flow Diversions	Yes	No	No	No	No	Yes
Creek, River, Estuary Restoration	Yes	No	No	No	No	Yes
Distributed BMPs						
Site Scale Detention	Yes	No	No	No	No	Yes
LID – Infiltration/Filtration BMPs – Porous Pavement, Green Streets, Bioswale/Filter Strips, downspout disconnects	Yes	No	No	No	No	Yes
LID – Green Infrastructure – Capture and Use – Cisterns, Rain Barrels, Green roofs, Planter Boxes	Yes	No	No	No	No	Yes
Flow-through Treatment BMPs	Yes	No	No	No	No	Yes
Source Control Treatment BMPs (catch basin inserts/screens, hydrodynamic separators, gross solids removal devices)	Yes	No	No	No	No	Yes
Low-Flow Diversions	Yes	No	No	No	No	Yes

NOTE: These conclusions are based on typical size and function of BMPs.

3.13 Transportation and Circulation

This section discusses the setting, regulatory framework, and impacts and mitigation measures regarding traffic and transportation services in the Enhanced Watershed Management Program (EWMP) areas. Temporary impacts related to construction of Best Management Practices (BMPs) have been identified and analyzed throughout the section.

3.13.1 Environmental Setting

Regional and Local Roadways

The network of regional and local roadways in the potentially affected areas of the EWMP areas consists of interstate freeways (e.g., I-405, I-710, and I-210), state highways (e.g., State Route [SR] 1, and SR 60), and numerous local roads that are under the jurisdiction of a particular city or Los Angeles County Department of Public Works. Local roads provide access to the individual project work sites and also provide a connection between local land uses and major thoroughfares.

Public Transportation

Public transit service is provided by various agencies in the study area; for example, the Los Angeles County Metro, Torrance Transit, and the Los Angeles Department of Transportation Transit Service. Buses serve local and regional needs for public transportation with varying frequencies.

Bicycle and Pedestrian Transportation

The regional network of bicycle facilities includes a variety of Class I (bicycle paths), Class II (bicycle lanes, striped in roads), and Class III (bicycle routes without striping) bikeways within the cities and communities in the EWMP study areas. Pedestrian facilities consist of sidewalks and intersection crosswalks in built-up areas.

Truck Routes

Cities often develop a truck route plan, which designates truck routes to provide contractors with the preferred travel roadways to and from connecting local roadways. For example, the cities of Torrance and Los Angeles have such plans. Los Angeles County has a similar system of truck routes for unincorporated areas.

3.13.2 Regulatory Setting

State

California Department of Transportation

The California Department of Transportation (Caltrans) is responsible for planning, designing, constructing, operating, and maintaining all state highway and interstate freeway systems. As a result, any change to the state roadway system requires an Encroachment Permit from Caltrans.

Caltrans' construction practices require temporary traffic control planning "during any time the normal function of a roadway is suspended" (Caltrans, 2012). In addition, Caltrans has the discretionary authority to issue special permits for the movement of vehicles/loads exceeding statutory limitations on the size, weight, and loading of vehicles contained in Division 15 of the California Vehicle Code. Requests for such special permits require the completion of an application for a Transportation Permit. The California Highway Patrol is notified about transportation of oversize/overweight loads. In addition to maintaining highways, and general regulations and laws dealing with licensing, traffic signage, and other noncommercial driver requirements, state laws and regulations also govern motor carriers on roadways within the state.

Local

County and City Land Use Regulations and Ordinances

Local regulations and ordinances vary widely in the program area. Traffic-related policies included in General Plans typically concern traffic resulting from project operation rather than project construction. However, some local jurisdictions incorporate restrictions to their General Plans that pertain to construction activities in or through their jurisdictional areas, such as assigning truck traffic routes or requiring the development of Traffic Control Plans.

3.13.3 Impact Assessment

Approach and Methods

This section assesses the transportation impacts that could result from the implementation of the proposed structural and non-structural BMPs. Because of the geographic scale of the program area and the range of actions that fall within the scope of the proposed program, this impact assessment was conducted at a programmatic level. Assumptions regarding the types of transport and the types of roads used to haul materials were used to assess the overall significance of program impacts. In determining the level of significance, the assessment assumed that the implementation of the proposed BMPs would comply with relevant federal, state, and local laws, regulations, ordinances, and guidance. It is assumed that supplemental project-level analysis of transportation-related impacts (e.g., traffic safety analysis of heavy vehicles traveling on, and turning onto and off of, local roads) would be required for site-specific structural BMPs prior to commencement of construction activity.

Thresholds of Significance

The California Environmental Quality Act (CEQA) defines a significant effect on the environment as a substantial, or potentially substantial, adverse change in the physical conditions of the area affected by a project. An impact related to transportation would be considered significant if it would result in any of the following, which are from Appendix G of the CEQA Guidelines:

- Conflict with an applicable plan, ordinance or policy establishing measures of effectiveness for the performance of the circulation system, taking into account all modes of transportation including mass transit and non-motorized travel and relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit.

- Conflict with an applicable congestion management program, including, but not limited to level of service standards and travel demand measures, or other standards established by the county congestion management agency for designated roads or highways.
- Result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks.
- Substantially increase hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g. farm equipment).
- Result in inadequate emergency access.
- Conflict with adopted policies, plans or programs regarding public transit, bicycle, or pedestrian facilities, or otherwise decrease the performance or safety of such facilities.

The following discussion of environmental impacts is limited to those potential impacts that could result in some level of potentially significant environmental change, as defined by CEQA. The project site is located in the County of Los Angeles, which has established level-of-service standards and a congestion management program that are intended to monitor and address long-term traffic impacts resulting from future development, but do not apply to temporary impacts associated with construction projects (bullet 2 in the list of guidelines). In addition, implementation of the proposed program would not affect air traffic patterns of airports in the program area (bullet 3 above). Also, implementation of the proposed program would not directly or indirectly eliminate existing or planned alternative transportation corridors or facilities (bicycle paths, lanes, bus turnouts, etc.), include changes in policies or programs that support alternative transportation, or construct facilities in locations in which future alternative transportation facilities are planned (bullet 6 in the list of guidelines). Therefore, no impact would occur under these three categories, and these categories are not discussed further within this section.

Program Impact Discussion

Effects on Performance of the Traffic Circulation System

Impact 3.13-1: The proposed program could intermittently and temporarily increase traffic levels and traffic delays due to vehicle trips generated by construction workers and construction vehicles on area roadways.

Structural (Regional, Centralized, and Distributed) BMPs

Implementation of the proposed program would involve the installation of structural control measures that would be constructed as BMPs to reduce the impact of stormwater and non-stormwater on receiving water quality within the EWMP areas. The construction activities for the proposed distributed, centralized, and regional structural BMPs would generally require similar processes such as removal of existing aboveground and/or surface materials, ground disturbance (e.g., site preparation and grading), and construction of the structural control measure. The intensity and nature of the construction activity required for the different structural BMPs would vary, and the number of vehicle trips generated by that activity would similarly vary. A general description of the anticipated construction activities that would be required for each of the various types of distributed, centralized, and regional structural BMPs are provided in Chapter 2.0, *Project Description*, of this Program Environmental Impact Report (PEIR). Construction activities of the various structural BMPs proposed in the EWMPs are anticipated to occur intermittently in the future, and would be subject to change, as the EWMPs are also planning documents that will be revised periodically to reflect new data, further modeling, emerging technologies, and results of BMP assessments. As such, the proposed locations of individual BMPs are subject to change throughout the EWMP process. Definitive construction equipment lists, material lists, construction methods, construction schedules, and workforce details would be developed in the future as specific structural BMP projects are finalized according to the EWMPs.

Vehicle trips would be generated primarily by construction workers commuting to and from the BMP work sites, and by trucks hauling materials and equipment to and from the sites. Construction equipment would be delivered to and removed from each site as needed. The construction traffic impacts associated with each individual structural BMP project would be short-term in nature and limited to the period of time when construction activity is taking place for that particular project. The primary off-site impacts resulting from the movement of construction trucks would include a short-term and intermittent lessening of roadway capacities due to the slower movements and larger turning radii of the trucks compared to passenger vehicles. Drivers could experience delays if they were traveling behind a heavy truck. The added traffic would be most apparent on the local roadways serving the facility sites. Although project-related traffic would be temporary, supplemental project-level analysis of potential site-specific impacts could determine that addition of project-generated traffic would be considered substantial in relation to traffic flow conditions on local roadways. For this program-level assessment, this impact is considered potentially significant.

To reduce the potential construction traffic impacts associated with the structural BMP projects, **Mitigation Measure TRAF-1** would be implemented; it would require all construction activities to be conducted in accordance with an approved construction traffic control plan. This would serve to reduce the construction-related traffic impacts to the maximum extent feasible. Thus, through the environmental review and development permit process, subsequent project-specific analysis by implementing agencies would be needed to determine specific required elements of the traffic control plans.

Mitigation Measures:

TRAF-1: For projects that may affect traffic, implementing agencies shall require that contractors prepare a construction traffic control plan. Elements of the plan should include, but are not necessarily limited to, the following:

- Develop circulation and detour plans to minimize impacts to local street circulation. Use haul routes minimizing truck traffic on local roadways to the extent possible.
- To the extent feasible, and as needed to avoid adverse impacts on traffic flow, schedule truck trips outside of peak morning and evening commute hours.

- Install traffic control devices as specified in Caltrans' Manual of Traffic Controls for Construction and Maintenance Work Zones where needed to maintain safe driving conditions. Use flaggers and/or signage to safely direct traffic through construction work zones.

- Coordinate with facility owners or administrators of sensitive land uses such as police and fire stations, hospitals, and schools. Provide advance notification to the facility owner or operator of the timing, location, and duration of construction activities.

Significance Determination: Less than significant with mitigation (The application of this mitigation measure to specific BMP types and categories are identified in Table 3.13-1.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts related to transportation and traffic.

Mitigation Measures: None required

Significance Determination: No impact

Traffic Safety Hazards

Impact 3.13-2: Construction of the proposed program could potentially cause traffic safety hazards for vehicles, bicyclists, and pedestrians on public roadways, and could increase traffic hazards due to possible road wear.

Structural (Regional, Centralized, and Distributed) BMPs

The construction activities for the proposed distributed, centralized, and regional structural BMPs would not alter the physical configuration of the existing roadway network serving the area, and would not introduce unsafe design features. Impacts would be less than significant...

Curb and traffic flow designs would be subject to the design requirements imposed by local Departments of Traffic. Freeways, major arterials, and collectors are designed to accommodate a mix of vehicle types, including heavy trucks needed for temporary construction activities; therefore, impacts to traffic safety would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts related to transportation and traffic.

Mitigation Measures: None required

Significance Determination: No impact

Inadequate Emergency Access

Impact 3.13-3: The proposed program could result in inadequate emergency access during construction.

Structural (Regional, Centralized, and Distributed) BMPs

Construction trucks generated by the individual structural BMP projects would interact with other vehicles on project area roadways, including emergency vehicles, but would not alter the physical configuration of the existing roadway network serving the area. As such, while individual emergency vehicles could be slowed if travelling behind a slow-moving truck, per vehicle code requirements, vehicles must yield to emergency vehicles using a siren and red lights. Lane closures would be subject to local Departments of Traffic requiring coordination with emergency providers. This potential impact is considered to be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant impact

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no impacts related to transportation and traffic.

Mitigation Measures: None required

Significance Determination: No impact

Cumulative Impact Discussion

Impact 3.13-4: Construction of the proposed program could contribute to cumulative impacts to traffic and transportation (traffic congestion, traffic safety, and emergency vehicle access).

Structural (Regional, Centralized, and Distributed) BMPs

The geographic scope of potential cumulative traffic impacts includes access routes to regional and local roadways used for haul routes and construction equipment/vehicle access throughout the project area. Given the dispersion of individual structural BMP project construction vehicle trips over the study area, and the fact that the trips would occur over the course of each workday, the project-related traffic on any one roadway during any hour of the day would not be substantial, and the contribution to cumulative traffic conditions would be less than significant.

However, constructing the structural BMPs could result in intermittent and temporary traffic-related impacts in the cumulative context. Traffic impacts include temporary increases in traffic congestion and increased potential for traffic safety hazards. The project has the potential to contribute to potentially significant cumulative construction-related impacts as a result of (1) cumulative projects (such as land development projects) that generate increased traffic at the same time on the same roads as would the proposed program, causing increased congestion and delays; and (2) infrastructure projects in roads that would be used by project construction workers and trucks, which could delay project-generated vehicles past the work zones of those other projects.

The structural BMPs associated with the proposed program would be constructed in multiple jurisdictions of Los Angeles County, which aside from the County also includes 46 cities and LACFCD. As such, these structural BMP projects would be generally spread over a large geographic area within the County. These structural BMPs, in combination with other current and planned projects in the County, would result in an increase in construction-related traffic levels, which would temporarily increase the levels of congestion on roadways in areas where a construction project would occur. However, each construction project occurring in the multiple municipalities of the County would be subject to the applicable regulations (e.g., traffic control plans) established by their respective municipalities. Nonetheless, temporary increases in traffic would occur as a result of construction activities under the proposed program along with other related project construction activities in the County. Where a related project is located in proximity to a structural BMP site and is constructed concurrently with the structural BMP, the combined construction traffic levels could have a cumulative effect on nearby roadways. Thus, under circumstances where these simultaneous construction activities would occur in proximity to roads with existing congestion, the cumulative traffic impacts related to a substantial temporary or periodic increase in ambient traffic levels could be cumulatively considerable.

However, with implementation of traffic control plans for each project that has the potential to increase traffic, including circulation and detour plans, traffic control devices, and scheduling (to the extent feasible) truck trips outside of peak morning and evening commute hours (as identified in **Mitigation Measure TRAF-1**) the project's contribution to the cumulative impacts from construction would be minimal. Once constructed, no impacts to traffic would result. Therefore, the contribution of structural BMPs to cumulative traffic conditions is less than significant.

Mitigation Measures: Implementation of **Mitigation Measure TRAF-1**

Significance Determination: Less than significant with mitigation (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.13-1.)

Non-Structural (Institutional) BMPs

As discussed in Chapter 2.0, *Project Description*, non-structural/institutional BMPs do not include the construction of new facilities. Consequently, there would be no cumulative impacts related to transportation and traffic.

Mitigation Measures: None required

Significance Determination: No impact

3.13.4 Summary of Impact Assessment

Table 3.13-1 shows a summary of the structural BMPs requiring mitigation.

**TABLE 3.13-1
SUMMARY OF TRANSPORTATION AND CIRCULATION IMPACTS REQUIRING MITIGATION MEASURES**

	Thresholds of Significance			
Structural BMPs	**Traffic Circulation**	**Traffic Safety**	**Emergency Access**	**Cumulative Impacts**
Applicable Mitigation Measures:	**TRAF-1**	**None Required**	**None Required**	**TRAF-1**
Regional BMPs				
Regional Detention and Infiltration	Yes	No	No	Yes
Regional Capture, Detention and Use	Yes	No	No	Yes
Centralized BMPs				
Bioinfiltration	Yes	No	No	Yes
Constructed Wetlands	No	No	No	No
Treatment/Low-Flow Diversions	No	No	No	No
Creek, River, Estuary Restoration	No	No	No	No
Distributed BMPs				
Site Scale Detention	No	No	No	No
LID – Infiltration/Filtration BMPs – Porous Pavement, Green Streets, Bioswale/Filter Strips, downspout disconnects	No	No	No	No
LID – Green Infrastructure – Capture and Use – Cisterns, Rain Barrels, Green roofs, Planter Boxes	No	No	No	No
Flow-through Treatment BMPs	No	No	No	No
Source Control Treatment BMPs (catch basin inserts/screens, hydrodynamic separators, gross solids removal devices)	No	No	No	No
Low-Flow Diversions	No	No	No	No

NOTE: These conclusions are based on typical size of BMPs and the need for hauling materials off-site during construction.

3.14 Utilities, Service Systems, and Energy

This section discusses existing utilities and service systems in the County of Los Angeles, presents the associated regulatory framework, and provides an analysis of potential impacts to utilities and service systems that would result from implementation of the proposed program. Public utilities and utility systems in the program area include: water, wastewater, stormwater, solid waste, and energy. The following discussion describes existing utilities and service systems in the program area.

3.14.1 Environmental Setting

Water Agencies

Several water agencies participate in delivering water from its source to retail customers and households in Los Angeles County. Water supplies include local surface and groundwater, imported surface water, captured and recharged stormwater, and recycled water. The California Department of Water Resources operates and maintains the State Water Project that imports water from the Sacramento River Delta to Southern California. The Metropolitan Water District (Metropolitan) buys imported State Water Project water, imports water from the Colorado River through the Colorado River Aqueduct, and wholesales water to its member agencies. Other water wholesalers in Los Angeles County include the Central Basin Municipal Water District, West Basin Municipal Water District, Upper San Gabriel Valley Municipal Water District, Castaic Lake Water Agency, Las Virgenes Municipal Water District, Three Valleys Municipal Water District, and Antelope Valley–East Kern Water Agency. Water wholesalers provide water to retail customers; some are agencies of cities or counties, some are private companies, and some are special districts. There are several water purveyors that supply water to the Enhanced Watershed Management Program (EWMP) areas of Los Angeles County (Los Angeles County, 2014), as listed in **Table 3.14-1**.

According to Metropolitan, approximately 55 percent of water supplies in Southern California are imported, and 45 percent are supplied by local groundwater basins that are recharged naturally from rainfall and through constructed recharge facilities (MWD, 2010). Local supplies fluctuate in response to variations in rainfall. Stormwater recharge facilities currently augment local groundwater supplies in the region by an estimated 477,000 acre-feet per year (MWD, 2014). Studies have estimated about 1 million acre-feet per year of stormwater in the region is not captured (MWD, 2014). The largest stormwater detention and recharge facilities in Los Angeles County are located along the San Gabriel River in the City of Pico Rivera. These facilities, shown in **Figure 3.14-1, Water Recharge Facilities**, were constructed in the 1930s when the river levees were significantly improved. These groundwater recharge facilities are also used to recharge recycled water conveyed from the Los Coyote Hills Treatment Plant.

TABLE 3.14-1
EWMP AREA WATER PURVEYORS

Group Name	Permittees Involved	Water Agency
Ballona Creek	Beverly Hills, Culver City, Inglewood, Los Angeles, Santa Monica, West Hollywood, Los Angeles County, LACFCD	Beverly Hills Public Works; Central Basin Municipal Water District; West Basin Municipal Water District; Santa Monica Public Works; LADWP
Beach Cities Watershed Management Group	Hermosa Beach, Manhattan Beach, Redondo Beach, Torrance, LACFCD	West Basin Municipal Water District; Torrance Public Works
Dominguez Channel Watershed Management Group	El Segundo, Hawthorne, Inglewood, Los Angeles, Lomita, Los Angeles County, LACFCD	West Basin Municipal Water District; LADWP
Malibu Creek Watershed	Agoura Hills, Calabasas, Hidden Hills, Westlake Village, Los Angeles County, LACFCD	Las Virgenes Municipal Water District
Marina Del Rey	Culver City, Los Angeles, Los Angeles County, LACFCD	West Basin Municipal Water District; LADWP
North Santa Monica Bay Coastal Watersheds	Los Angeles County, Malibu, LACFCD	West Basin Municipal Water District; Los Angeles County Waterworks Districts
Palos Verdes Peninsula EWMP Agencies	Palos Verdes Estates, Rancho Palos Verdes, Rolling Hills Estates, Los Angeles County, LACFCD	West Basin Municipal Water District
Rio Hondo/San Gabriel River Water Quality Group	Arcadia, Azusa, Bradbury, Duarte, Monrovia, Los Angeles County, Sierra Madre, LACFCD	Three Valleys Municipal Water District; Upper San Gabriel Valley Municipal Water District
Santa Monica Bay Watershed Jurisdictions 2 and 3	Los Angeles, El Segundo, Santa Monica, Los Angeles County, LACFCD	West Basin Municipal Water District; LADWP; Santa Monica Public Works
Upper Los Angeles River Watershed	Alhambra, Burbank, Calabasas, Glendale, Hidden Hills, La Canada Flintridge, Los Angeles, Montebello, Monterey Park, Pasadena, Rosemead, San Gabriel, San Marino, South Pasadena, Temple City, Los Angeles County, LACFCD	Alhambra Public Works Department; Burbank Water and Power; Foothill Municipal Water District; Glendale Water and Power; Crescenta Valley Water District; Las Virgenes Municipal Water District; LADWP; Central Basin Municipal Water District; Upper San Gabriel Valley Municipal Water District; California-American Water Company

Water Recharge Facilities

Wastewater

Several wastewater agencies participate in providing wastewater collection and treatment for the EWMP areas. The EWMP areas fall within the Sanitation Districts of Los Angeles County, the City of Los Angeles Bureau of Sanitation, and Las Virgenes Municipal Water District wastewater system service areas.

The Sanitation Districts are a partnership of 24 independent special districts that serve the wastewater and solid waste management needs of approximately 5.5 million people in Los Angeles County (County). The Sanitation Districts' service area covers approximately 824 square miles and encompasses 78 cities and unincorporated territory within the County. Within the Sanitation Districts' service area, there are approximately 9,500 miles of sewers that are owned and operated by the cities and County that are tributary to the Sanitation Districts' wastewater collection system. The Sanitation Districts own, operate, and maintain approximately 1,400 miles of sewers, ranging from 8 to 144 inches in diameter, that convey approximately 500 million gallons per day of wastewater to 11 wastewater treatment plants. Included in the Sanitation Districts' wastewater collection system are 48 active pumping plants located throughout the County. In the interest of promoting better health and safety protection for those who engage in water contact activities in coastal areas bordered by the Sanitation Districts service area, the Sanitation Districts have consented, where justified, to accept the diversion of dry-weather urban runoff into the sewer system. The agencies responsible for the stormwater collection system are required to obtain permits from the Sanitation Districts, install equipment to remove gross solids, provide the means for measuring flow, and pay appropriate fees.

The City of Los Angeles Bureau of Sanitation provides wastewater treatment to the City of Los Angeles, as well as several unincorporated areas next to the City of Los Angeles. The Bureau of Sanitation operates and maintains its own wastewater collection and treatment systems with over 6,500 miles of sewers that serve more than four million residential and business customers in Los Angeles and 29 contracting cities and agencies. These sewers are connected to the City of Los Angeles' four wastewater and water reclamation plants that process an average of 550 million gallons of wastewater each day of the year. The City of Los Angeles Department of Public Works have implemented several low-flow diversion systems along the coast that divert urban dry-weather runoff and other types of non-stormwater from the storm drain system into the sewer system for treatment by the City of Los Angeles Hyperion Sewer Treatment Plant. Some of the low-flow diversion systems are being upgraded and, to convey the increased diverted stormwater flows from the low-flow diversion systems to the Hyperion Treatment Plant, the Coastal Interceptor Relief Sewer (CIRS) was constructed to provide additional capacity to the existing sewer system.

Las Virgenes Municipal Water District and the Triunfo Sanitation District (that serves a portion of Ventura County) share a service area in the Malibu Creek watershed. The Tapia Water Reclamation Facility and the Rancho Las Virgenes Composting Facility are owned by the Las Virgenes – Triunfo Joint Powers Authority and operated by Las Virgenes Municipal Water District personnel.

Table 3.14-2 lists the major municipal wastewater treatment plants in the EWMP areas. Each of these facilities provides treatment for daily wastewater flows and is designed with augmented hydraulic capacity to receive and discharge peak flows that enter the system during storm events.

TABLE 3.14-2
EWMP AREA WASTEWATER TREATMENT PLANTS

Water Reclamation Plants (WRP)	Rated Capacity (mgd)	Average Daily Flow 2013 (mgd)
Hyperion	450	362
Joint Water Pollution Control Plant (JWPCP)	400	264
La Cañada WRP	0.2	0.1
Los Angeles/Glendale WRP	20	20
Long Beach WRP	25	17
Los Coyotes WRP	37.5	21
Saugus WRP	6.2	5.2
San Jose Creek WRP	100	63
Tapia WRF	16	9.5
Tillman WRP	80	67
Whittier Narrows WRP	15	8.6
Valencia WRP	21.6	15.7

mgd = million gallons per day

Stormwater

The Los Angeles County Flood Control District (LACFCD) encompasses more than 3,000 square miles, 85 cities, and approximately 2.1 million land parcels. It includes the vast majority of drainage infrastructure within incorporated and unincorporated areas in every watershed, including 500 miles of open channel, 2,800 miles of underground storm drains, and an estimated 120,000 catch basins. In addition to the County maintaining regional storm drain structures, many of the cities within the EWMP study areas maintain storm drains within their respective city boundaries.

A low-flow diversion is a structural system that diverts potentially polluted, dry-weather flow to be treated, usually at a sewage treatment plant, before being discharged into the ocean. Several coastal cities have installed low-flow diversion systems that divert dry-weather flows to local treatment plants. For example, the City of Santa Monica operates the Santa Monica Urban Runoff Recycling Facility (SMURRF), which treats dry-weather runoff water (from excessive irrigation, spills, construction sites, pool draining, car washing, the washing down of paved areas, and some initial wet-weather runoff) prior to discharging to the ocean. An average of 500,000 gallons per day (gpd) of urban runoff generated in parts of the cities of Santa Monica and Los Angeles is treated by conventional and advanced treatment systems at the SMURRF. The runoff water is diverted from the City of Santa Monica's two main storm drains (Pier, Pico-Kenter) into the SMURRF and treated to remove pollutants such as trash, sediment, oil, grease, and pathogens (Santa Monica, 2014). In addition, LACFCD owns and operates 20 low-flow diversions in the Santa Monica Bay coast which divert low flows to the sanitary sewer system; these low-flow diversions also capture trash and floating debris in a trash well (LACFCD, 2013).

Solid Waste Management

Trash discarded on land frequently makes its way into streams, creeks, rivers, and eventually the ocean as rain storms wash it into gutters and storm drains. Types of trash generated by human activity that frequently pollute waterways include cigarette butts, paper, fast food containers, plastic grocery bags, cans and bottles, used diapers, construction site debris, industrial preproduction plastic pellets, old tires, appliances, and more. Trash is a significant pollutant of California's waters that adversely affects beneficial uses, including but not limited to uses that support aquatic life, wildlife, and public health (SWRCB, 2014).

The EWMP areas are served by various landfills and recycling centers operated by cities, the County, and private facility operators. Sanitation Districts of Los Angeles County (LACSD) serves the solid waste management needs of a large portion of Los Angeles County with several landfills, recycle centers, materials recovery/transfer facilities, and energy recovery facilities (LACSD, 2014). The two operational landfill sites are the Calabasas Landfill, located near Agoura Hills, and the Scholl Canyon Landfill, located in the Glendale. Other solid waste collection facilities operated by LACSD include the Puente Hills Materials Recovery Facility, the Downey Area Recycling and Transfer Facility, South Gate Transfer Station, the Commerce Refuse-to-Energy Facility, and the Southeast Resource and Recovery Facility. The City of Los Angeles Bureau of Sanitation collects refuse, recyclables, yard trimmings, and other bulky items from more than 750,000 homes and operates the Central LA Recycling and Transfer Station, which temporarily stores refuse and transports it to the nearest landfill. The City of Los Angeles has closed its five landfills and now uses Sunshine Canyon landfill for refuse disposal. Many of the participating cities within the EWMP study areas contract with landfills outside of Los Angeles County for disposal.

Energy

In 2012, the County of Los Angeles used 69,277.09 million kilowatt-hours (kWh) (CEC, 2014). Southern California Edison (SCE) provides electricity for the majority of the County. The Los Angeles Department of Water and Power provides over 23 million megawatt-hours (MWh) for the 1.4 million customers in the City of Los Angeles and Owens Valley (LADWP, 2013). LADWP is the third largest California electric utility in terms of consumption, behind Pacific Gas & Electric and SCE (LADWP, 2013). Both LADWP and SCE continue to increase efforts to use additional renewable energy resources. Local, state, and federal mandates require levels of renewable energy as a percentage of electricity sales. Senate Bill (SB) 2 (1X) set renewable energy targets of 20 percent for years 2011–2013, 25 percent by 2016, and 33 percent by 2020 and thereafter.

3.14.2 Regulatory Setting

State

California Health and Safety Code

The California Health and Safety Code, Division 104, Part 12, Chapter 5, Article 2, Section 116815, requires all pipes carrying recycled water to be colored purple or wrapped in purple tape. This requirement stems from a concern in cross contamination and potential public health risks similar to those discussed for Title 17 (Public Health) of the California Code of Regulations. It is also discussed in the California Health Laws Related to Recycled Water (the Purple Book).

Protection of Underground Infrastructure

The California Government Code Section 4216-4216.9 "Protection of Underground Infrastructure" requires an excavator to contact a regional notification center (e.g., Underground Services Alert or Dig Alert) at least two days prior to excavation of any subsurface installations. Any utility provider seeking to begin a project that could damage underground infrastructure can call Underground Service Alert, the regional notification center for Southern California, which would in turn notify the utilities of potentially buried lines within 1,000 feet of the project excavation. Representatives of the utilities are then required to mark the specific location of their facilities within the work area prior to the start of excavation activities in the area.

California Integrated Waste Management Act of 1989

The California Integrated Waste Management Act of 1989 (Public Resources Code, Division 30) enacted through AB 939 emphasizes conservation of natural resources through reduction, recycling, and reuse of solid waste. AB 939 requires that all cities and counties divert 25 percent of solid waste streams from landfills by 1995 and 50 percent by 2000. In accordance with AB 939, each local agency must submit an annual report to the California Integrated Waste Management Board summarizing its progress in diverting disposed of solid waste.

2005 California Energy Action Plan II

The California Energy Commission's California Energy Action Plan II is the state's principal energy planning and policy document. The plan identifies state-wide energy goals, describes a coordinated implementation plan for state energy policies, and identifies specific action areas to ensure that California's energy is adequate, affordable, technologically advanced, and environmentally sound. In accordance with this plan, the first priority actions to address California's increasing energy demands are energy efficiency and demand response (i.e., reduction of customer energy usage during peak periods in order to address system reliability and support the best use of energy infrastructure). Additional priorities include the use of renewable sources of power and distributed generation (i.e., the use of relatively small power plants near or at centers of high demand). To the extent that these actions are unable to satisfy the increasing energy and capacity needs, clean and efficient fossil-fired generation is supported.

The Energy Action Plan II includes the following energy efficiency action specific to water supply systems:

- Identify opportunities and support programs to reduce electricity demand related to the water supply system during peak hours and opportunities to reduce the energy needed to operate water conveyance and treatment systems.

California Urban Water Management Planning Act of 1983

Section 10610 of the California Water Code establishes the Urban Water Management Planning Act. The act states that every publicly and privately owned urban water service provider that serves 3,000 or more customers or that supplies over 3,000 acre-feet of water annually is required to prepare an Urban Water Management Plan (UWMP) every 5 years. The goal of an UWMP is to ensure a reliable level of water service sufficient to meet the needs of customers during normal, dry, and multiple dry years.

NPDES Construction General Permit

Construction associated with the proposed program would disturb more than one acre of land surface for centralized and regional structural Best Management Practices (BMPs) (and possibly for those distributed structural BMPs larger than one acre), affecting the quality of stormwater discharges into waters of the United States. The proposed program would therefore be subject to the National Pollutant Discharge Elimination System (NPDES) General Permit for Stormwater Discharges Associated with Construction and Land Disturbance Activities (Order 2009-0009-DWQ, NPDES No. CAS000002, Construction General Permit [CGP]), as amended by Order 2010-0014-DWQ and Order 2012-0006-DWQ). The CGP regulates discharges of pollutants in stormwater associated with construction activity to waters of the United States from construction sites that disturb one or more acres of land surface, or that are part of a common plan of development or sale that disturbs more than one acre of land surface.

The CGP requires the development and implementation of a Stormwater Pollution Prevention Plan (SWPPP) that includes specific BMPs designed to prevent pollutants from contacting stormwater and keep all products of erosion from moving off-site into receiving waters. The SWPPP BMPs are intended to protect surface water quality by preventing the off-site migration of eroded soil and construction-related pollutants from the construction area. The CGP and SWPPPs are described in more detail in Section 3.8, *Hydrology and Water Quality*.

Statewide Water Quality Control Plans for Trash

The State Water Board proposes to adopt Amendments to Statewide Water Quality Control Plans to Control Trash (Trash Amendments) to the *California Ocean Plan* and the forthcoming *Inland Surface Waters, Enclosed Bays, and Estuaries Plan*. The proposed Trash Amendments will include six elements: (1) water quality objective, (2) prohibition of discharge, (3) implementation provisions, (4) time schedule, (5) time extension option for State Water Board consideration, and

(6) monitoring and reporting requirements. The project objective for the proposed Trash Amendments is to provide statewide consistency for the State Water Board's regulatory approach to protect aquatic life and public health beneficial uses, and reduce environmental issues associated with trash in state waters, while focusing limited resources on high-trash-generating areas (SWRCB, 2014).

Local

Los Angeles County Municipal Separate Storm Sewer System Permit

The current Municipal Separate Storm Sewer System (MS4) Permit for Los Angeles County (Order No. R4-2012-0175) became effective December 28, 2012 and contains requirements that are necessary to improve efforts to reduce the discharge of pollutants in stormwater runoff to the maximum extent practicable and achieve water quality standards.

Illicit Connections and Illicit Discharge Elimination Program

The MS4 Permit requires Permittees to continue to implement an Illicit Connection and Illicit Discharge (IC/ID) Program to detect, investigate, and eliminate IC/IDs to its MS4. Each Permittee must have adequate legal authority to prohibit IC/IDs to the MS4 and enable enforcement capabilities to eliminate the source of IC/IDs. The IC/ID Program includes at least the following major program components:

a) An up-to-date map of the MS4 facilities
b) Procedures for conducting source investigations for IC/IDs
c) Procedures for eliminating the source of IC/IDs
d) Procedures for public reporting of IDs
e) Spill response plan
f) IC/IDs education and training for staff

Enhanced Watershed Management Programs

The MS4 Permit allows Permittees the flexibility to develop EWMPs to implement the requirements of the Permit on a watershed scale through customized strategies, control measures, and BMPs. Participation in an EWMP is voluntary and allows a Permittee to address the highest watershed priorities, including complying with the requirements of Receiving Water Limitations and Total Maximum Daily Load Provisions. Customized strategies, control measures, and BMPs will be implemented on a watershed basis, where applicable, through each Permittee's stormwater management program and/or collectively by all participating Permittees through an EWMP. An EWMP comprehensively evaluates opportunities, within the participating Permittees' collective jurisdictional area in a Watershed Management Area, for collaboration among Permittees and other partners on multi-benefit regional projects that, wherever feasible, retain (i) all non-stormwater runoff and (ii) all stormwater runoff from the 85th percentile, 24-hour storm event for the drainage areas tributary to the projects, while also achieving other benefits including flood control and water supply, among others. An EWMP shall ensure that existing requirements to comply with technology-based effluent limitations and core requirements (e.g., including elimination of nonstormwater discharges of pollutants through the MS4, and controls to reduce the discharge of pollutants in stormwater to the maximum extent practicable) are not delayed.

County of Los Angeles Low Impact Development Manual

The County of Los Angeles prepared the 2014 Low Impact Development Standards Manual (LID Standards) to comply with the requirements of the NPDES MS4 Permit for stormwater and non-stormwater discharges from the MS4 within the coastal watersheds of Los Angeles County (CAS004001, Order No. R4-2012-0175), referred to as the 2012 MS4 Permit. The LID Standards provide guidance for the implementation of stormwater quality control measures in new development and redevelopment projects in unincorporated areas of the County with the intention of improving water quality and mitigating potential water quality impacts from stormwater and non-stormwater discharges. The November 2013 LID Ordinance became effective December 5, 2013.

City of Los Angeles Low Impact Development Manual

In November 2011, the City of Los Angeles adopted the Stormwater Low Impact Development (LID) Ordinance #181899 with the stated purpose of:

- Requiring the use of LID standards and practices in future developments and redevelopments to encourage the beneficial use of rainwater and urban runoff
- Reducing stormwater/urban runoff while improving water quality
- Promoting rainwater harvesting
- Reducing offsite runoff and providing increased groundwater recharge
- Reducing erosion and hydrologic impacts downstream
- Enhancing the recreational and aesthetic values in our communities

The City of Los Angeles institutionalized the use of LID techniques for development and redevelopment projects. Subsequent to the adoption of the Stormwater LID Ordinance, the City prepared the *Development Best Management Practices Handbook, Low Impact Development Manual,* dated June 2011, which describes the required BMPs (City of Los Angeles, 2011).

Other Cities LID

Various other cities within the County also have LID standards or guidance. The goals, objectives, and content of the LID document are similar to that of the County and City of Los Angeles and are not referenced here.

Los Angeles County Construction and Demolition Debris Recycling and Reuse Program

On January 1, 2011, Los Angeles County adopted the Green Building Standards Code, which sets forth recycling requirements for construction and demolition projects in the unincorporated areas of Los Angeles County. These requirements apply to any project requiring a construction, demolition or grading permit. According to the requirements, nonresidential construction projects consisting of commercial, industrial, or retail structures, as well as all tenant improvements, irrespective of the square footage, must recycle a minimum of 65 percent of the debris generated by weight (Los Angeles County, 2014).

Los Angeles County General Plan

The County of Los Angeles is currently updating their 1980 General Plan; the new comprehensive General Plan was expected to be adopted by late 2014, but is still pending approval. The following are utilities and service systems goals and policies relating to the proposed program from the existing General Plan's Water and Waste Management Element, and the Draft General Plan 2035 (as of September 2014) Public Services and Facilities Element.

Existing General Plan 1980:

Goal – Reduce Service Deficiencies: Major deficiencies include the lack of water in aquifers and the shortage of solid waste landfill capacity. Technological advancements may reduce reliance on landfills.

Goal – Reduce Detrimental Impacts on Natural and Man Made Environments: Adverse effects on the natural, social and man-made environment arising from water and waste management development must be anticipated and mitigated where they cannot be avoided.

Draft General Plan 2014:

Goal PS/F 1: A coordinated, reliable, and equitable network of public facilities that preserves resources, ensures public health and safety, and keeps pace with planned development.

Goal PS/F 3: Increased local water supplies through the use of new technologies.

Policy PS/F 3.1: Increase the supply of water through the development of new sources, such as recycled water, gray water, and rainwater harvesting.

Policy PS/F 3.2: Support the increased production, distribution and use of recycled water, gray water, and rainwater harvesting to provide for groundwater recharge, seawater intrusion barrier injection, irrigation, industrial processes and other beneficial uses.

Goal PS/F 4: Reliable sewer and urban runoff conveyance treatment systems.

Policy PS/F 4.1: Encourage the planning and continued development of efficient countywide sewer conveyance treatment systems.

Goal PS/F 5: Adequate disposal capacity and minimal waste and pollution.

Policy PS/F 5.1: Maintain an efficient, safe and responsive waste management system that reduces waste while protecting the health and safety of the public.

Goal PS/F 6: A County with adequate public utilities.

Policy PS/F 6.1: Ensure efficient and cost-effective utilities that serve existing and future needs.

City General Plans

The numerous cities encompassed by the EWMP area all have their own respective city General Plans, some of which may contain policies that address public utilities. As implementation of the individual structural BMP projects proceed, specific policies and objectives pertaining to public utilities from applicable city General Plans will be identified and evaluated on a project-by-project basis during subsequent California Environmental Quality Act (CEQA) environmental processes.

3.14.3 Impact Assessment

The proposed program's potential impacts have been assessed using the CEQA Guidelines Appendix G Checklist. The following sections discuss the key issue areas identified in the CEQA Guidelines with respect to the program's potential effect to utilities and service systems.

Thresholds of Significance

For the purposes of this Program Environmental Impact Report (PEIR) and consistency with Appendix G of the CEQA Guidelines, applicable local plans, and agency and professional standards, the proposed program would have a significant effect on utilities and service systems if it would:

- Exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board (RWQCB).
- Require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects.
- Require or result in the construction of new stormwater drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects.
- Have sufficient water supplies available to serve the project from existing entitlements and resources, or would require new or expanded water supply resources or entitlements.
- Result in a determination (by the wastewater treatment provider that serves or may serve the project) that it has inadequate capacity to serve the project's projected demand in addition to the provider's existing commitments.
- Be served by a landfill with insufficient permitted capacity to accommodate the project solid waste disposal needs.
- Not comply with federal, state, and local statutes and regulations related to solid waste.

- Cause a substantial increase in overall or per capita energy consumption or cause wasteful or unnecessary consumption of energy.
- Require construction of new sources of energy supplies or additional energy infrastructure capacity, the construction of which could cause significant environmental effects.
- Conflict with applicable energy efficiency policies or standards.

Program Impact Discussion

Wastewater Treatment

Impact 3.14-1: Implementation of the proposed program could exceed wastewater treatment requirements of the applicable RWQCB or result in the construction of new treatment facilities or expansion of existing facilities if the wastewater treatment provider has inadequate capacity to serve the proposed program.

Structural (Regional, Centralized, and Distributed) BMPs

The proposed program would involve the construction of structural BMPs intended to treat stormwater and non-stormwater runoff. The structural BMPs that fall under this category include green infrastructure/LID, of which there are many subtypes, including bioretention and biofiltration, permeable pavement, and bioswales, flow-through treatment BMPs, source-control BMPs, infiltration BMPs, capture-and-use BMPs, bioinfiltration BMPs, treatment facilities and low-flow diversions, constructed wetlands, and other multi-benefit flood management projects.

The implementation of the proposed program would comply with the MS4 Permit issued by the RWQCB. Existing discharge permits for individual facilities such as publically owned treatment works, or for general actions such as construction and industrial activities, would not be affected by the implementation of proposed structural BMPs. Each Permittee would be required to comply with existing discharge permit limitations, as is the case under existing conditions. Implementation of facilities meant to improve water quality and meet water quality objectives of the MS4 Permit would be consistent with RWQCB discharge requirements. (See Section 3.8.4, *Hydrology and Water Quality*, for a discussion on construction-related water quality impacts.)

The construction of structural BMPs would vary significantly based on the location, size, and configuration of the BMP. Construction methods may include removal or retrofitting of above-ground infrastructure or local soils in relatively compact areas, requiring the hauling of demolished material. Excavation may be necessary for subsurface structure installations such as dry/wet wells, underdrain, flow-through treatment BMPs, infiltration BMPs, capture-and-use BMPs, and treatment facilities. However, many of these structural BMPs would have a relatively small footprint of a few acres or much less. Some of the centralized BMPs would require larger areas of excavation for installation of infiltration and detention basins and other subsurface facilities and may be a few acres to several tens of acres.

Most structural BMPs would be constructed in developed areas, including parking lots, roads, or sidewalks, and would not require new treatment facilities or expansion of existing facilities. Treatment provided by most of the structural BMPs would be from soil infiltration. However, some BMPs, in particular low-flow diversion systems, would be designed to convey dry-weather flows to a newly constructed treatment system, or to an existing wastewater treatment facility. Some of these facilities would be small and constructed in close proximity to the water course. The implementing agency would be required to evaluate the location of these facilities to ensure compatible land uses, but otherwise these new treatment facilities would be constructed as part of the water quality improvement project.

Other low-flow diversion systems would divert dry-weather flows to existing wastewater treatment plants. As part of the design for these types of projects, the implementing agency would be required to evaluate the available dry-weather capacity of the existing treatment facility and to evaluate whether the additional flow could be accommodated within the existing system and under the existing discharge requirements. The wastewater treatment provider would be a lead agency in evaluating impacts to their facility. If additional capacity is required, or additional treatment processes are required to meet discharge limitations, the implementing agency would evaluate these elements as part of the proposed low-flow diversion project. Implementation of these low-flow diversion projects would require the cooperation and approval of the wastewater treatment provider under the discharge permit limitations.

The operational purpose of the structural BMPs associated with the proposed EWMPs is to meet the surface water treatment requirements of the Los Angeles RWQCB for stormwater and non-stormwater discharges. The main functions of the structural BMPs would be to infiltrate, treat, and store runoff to help reduce the impact of stormwater and non-stormwater discharges on receiving water quality, which would not produce wastewater during operation. Therefore, the structural BMPs would be designed to meet wastewater treatment requirements of the RWQCB permit. Impacts would be less than significant.

Construction requiring ground disturbance could encounter buried utilities including wastewater conveyance infrastructure. As part of the project design, Implementing Agencies would be required to identify the potential for underground utilities and determine whether they would need to be relocated to accommodate the BMP. As standard construction practices require, Implementing Agencies would conduct an underground utility search prior to excavation and would coordinate with utility providers in advance to ensure no disruption in services to the utility customers. Impacts to wastewater infrastructure would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

The non-structural BMPs associated with the proposed program would include programs and policies that would entail development guidelines and activities designed to prevent surface water quality degradation. Examples include construction stormwater management programs, municipal pollutant reduction programs, IC/ID detection programs, smart growth planning and LID practices, and public education programs. These BMPs would not increase local populations and would not contribute to an increased generation of wastewater exceeding wastewater treatment requirements of the RWQCB. Consequently, the structural BMPs would not require construction or the expansion of any water or wastewater treatment facilities. There would be no impact.

Mitigation Measures: None required

Significance Determination: No impact

Stormwater Facilities

Impact 3.14-2: The proposed program could require or result in the construction of new stormwater drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects.

Structural (Regional, Centralized, and Distributed) BMPs

The proposed program consists of improvements to existing storm drainage facilities as well as new storm drain facilities within the EWMP program areas. New facilities proposed would likely be installed within existing sidewalks, streets, parks, municipally owned lands, or drainage easements. Storm drainage capacity would be verified during design as applicable, and temporary retention facilities may be used until such time as adequate downstream storm drainage facilities are constructed and operational. This PEIR contains an analysis on the potential environmental effects that might result from the installation of storm drainage facilities identified in the proposed EWMPs. No additional analysis is required under this impact discussion.

Mitigation Measures: None required

Significance Determination: Less than significant

Non-Structural (Institutional) BMPs

The non-structural BMPs associated with the proposed EWMPs would involve policies, actions, and activities and would not require construction of new stormwater drainage facilities or expansion of existing facilities. There would be no impact.

Mitigation Measures: None required

Significance Determination: No impact

Water Supply

Impact 3.14-3: The proposed program could require new or expanded water supply resources or entitlements or require or result in the construction of new water facilities or expansion of existing facilities, the construction of which could cause significant environmental effects.

Structural (Regional, Centralized, and Distributed) BMPs

Implementation of the EWMPs would not increase water demands. Construction of the majority of the structural BMPs would require some minor water usage for dust control and concrete washout activities. However, the construction periods for BMPs are expected to be relatively short, lasting several months to a year. Therefore, water demand during construction is not expected to be substantial enough to require new or expanded water supply resources. Some of the BMPs would augment local water supplies through enhanced stormwater recharge. Impacts to the existing water supplies are anticipated to be beneficial as a result of the stormwater and non-stormwater runoff infiltration and conservation BMPs implemented across the EWMP areas. No adverse impacts related to new or expanded water supply resources or entitlements would occur.

Construction requiring ground disturbance could encounter buried utilities including water supply infrastructure. As part of the project design, Implementing Agencies would be required to identify the potential for underground utilities and determine whether they would need to be relocated to accommodate the BMP. As standard construction practices require, Implementing Agencies would conduct an underground utility search prior to excavation and would coordinate with utility providers in advance to ensure no disruption in services to the utility customers. Impacts to water supply infrastructure would be less than significant.

Local surface water contributes little to the regional water supply; local agriculture relies mostly on groundwater and imported water. Throughout Los Angeles County, stormwater flows are captured for recharge by LACFCD where suitable detention and infiltration facilities are available. These captured flows augment groundwater supplies, but are not directly diverted for beneficial uses such as drinking water. Dry-weather flows are also captured in some areas for groundwater recharge. Construction of BMPs to detain stormwater and dry-weather flows may reduce flows downstream, thereby reducing access to beneficial uses downstream. Under California law, the State Water Resources Control Board (SWRCB), Division of Water Rights, is responsible for issuing appropriation permits pursuant to Division 2, Part 2 of the California Water Code. The SWRCB maintains a list of water diversion rights issued since the 1920s in Los Angeles County (http://www.waterboards.ca.gov/waterrights/board_decisions/adopted_orders/decisions/county.shtml). If installation of BMPs (detention, infiltration, and low-flow diversions) would reduce water available to downstream diverters such that their water rights would be impinged, this would be a significant impact of the Program. However, much of the existing diversion permits for Los Angeles County involve streams that are fed by groundwater seepage. These flows, to the extent they still remain, would not be adversely affected by the installation of BMPs since they are fed by natural sources.

The urbanization of the County has resulted in channelization of many drainages that are owned and managed by LACFCD. In areas with natural unimproved streams, such as in the Santa Clara River watershed and Malibu watershed where surface water diversions may be more common, stormwater flows are conveyed downstream quickly. Any detention of storm flows upstream would not substantially reduce storm flows downstream or significantly impede access to storm flow. Dry-weather flows in coastal streams and foothills are largely fed by groundwater seepage or wastewater discharges. These flows would not be affected by infiltration BMPs. However, implementation of **Mitigation Measure UTIL-1** would ensure that downstream water rights would not be affected by upstream diversions.

Mitigation Measure:

UTIL-1: Prior to approval of BMPs, implementing agencies shall evaluate the potential for impacts to downstream beneficial uses, including surface water rights. Implementing agencies shall not approve BMPs that result in preventing access to previously appropriated surface water downstream.

Significance Determination: Less than significant (The application of this mitigation measure to specific BMP types and categories are identified in Table 3.14-3.)

Non-Structural (Institutional) BMPs

The non-structural BMPs associated with the proposed program would include programs and policies that would entail development guidelines and activities designed to prevent surface water quality degradation; they would not increase water demand. Some non-structural BMPs would result in water conservation of existing water sources. For example, the Malibu Creek EWMP would implement the Citywide Smart Irrigation Control System, which calls for the installation of a smart irrigation control system using evapotranspiration technology. This system would be put into place at all City of Calabasas-owned facilities, street medians, and parkways. Replacement of irrigation controllers is projected to reduce irrigation runoff that is associated with overwatering of landscaped areas. The City uses 66,431 gallons of water on annual basis for landscape irrigation. It is anticipated that with the new system, the City would save between 13,300 to 16,600 gallons of water, which also translates to approximately 5,000 to 7,000 gallons of reduction in runoff. Therefore, they would not require new or expanded water supply resources or entitlements.

Mitigation Measures: None required

Significance Determination: No impact

Solid Waste

Impact 3.14-4: The proposed program could be served by a landfill with insufficient permitted capacity to accommodate the project solid waste disposal needs or the project could not comply with federal, state, and local statutes and regulations related to solid waste.

Structural (Regional, Centralized, and Distributed) BMPs

Construction activities associated with the structural BMPs would include excavation and demolition of some existing infrastructure, which would produce solid waste requiring disposal in the nearest landfill. The largest potential source of solid waste during construction would be excavated soil. While it is expected that most clean soil would be recycled, reused offsite, or stockpiled and reused as backfill, this analysis assumes that a portion of soil would be disposed in landfills. The exact quantity of waste materials to be disposed of in nearby landfills (which includes construction debris, demolition materials, and excavation spoils) would not be known until each project undergoes a detailed evaluation as part of separate, project-level CEQA review. Recycling and reuse of construction and demolition material has been shown to considerably reduce the amount of debris sent to landfills. The County of Los Angeles and many participating cities have construction and demolition debris recycling and reuse programs. According the

County of Los Angeles, except under unusual circumstances, it is feasible to recycle or reuse at least 50 percent or construction and demolition debris (RWQCB, 2008). Development of a waste management or recycling plan (**Mitigation Measure UTIL-2**) would reduce this impact.

Some of the EWMPs, including the Dominguez Channel EWMP and the Upper Santa Clara River EWMP, are required to implement trash Total Maximum Daily Limits (TMDLs) and associated trash removal structural BMPs. Two types of source-control BMPs for trash are illustrated in Section 2.0, *Project Description*: catch basin inserts, which use nets, screens, fabric, or similar filtration media to separate sediment and gross solids from stormwater, and hydrodynamic separators, which use screens, baffles, or vertical flow to separate sediment and gross solids from stormwater.

The Upper Santa Clara River EWMP plans to implement trash removal BMPs for 79 storm drains in a commercial/industrial park (County of Los Angeles) and 110 storm drain inlets in a commercial/industrial park (City of Santa Clarita). The Dominguez Channel EWMP plan primarily proposes the installation of catch opening screen covers and inserts in those structures found in the Santa Monica Bay, Machado Lake, and Dominguez Channel watersheds of the City of Los Angeles. The catch basin opening screen covers are coarse screens that are installed in the catch basin openings and prevent trash from entering the City storm drain system. Each catch basin opening screen cover has a self-opening device activated by a predetermined street gutter flow to disengage its locking mechanism. The catch basin inserts are perforated screens that are installed inside the catch basin in front of the outlet pipe of the catch basin.

The EPA-approved Trash TMDLs for the EWMP areas require annual determination of trash discharges. The TMDLs also require compliance monitoring calculations of the Trash Daily Generation Rate. These monitoring efforts allow permitting agencies to track and monitor the amounts being sent to landfills. The volume of trash removed from the regional waterways is small when compared to daily trash collection and disposal quantities in the highly urbanized Los Angeles County. The new trash collection would be accommodated with existing and planned trash disposal facilities. Based on landfill capacity in the Los Angeles region, there appears to be ample availability to receive trash that would be collected as part of compliance with the Malibu Creek and Machado Lake Trash TMDLs (RWQCB, 2007; 2008). Impacts related to insufficient permitted landfill capacity from implementation of the proposed program is anticipated be less than significant.

The program would comply with all federal, state, and local statutes and regulations related to solid waste, including the Los Angeles County Construction and Demolition Debris Recycling and Reuse Program. Impacts regarding noncompliance solid waste regulations would be less than significant.

Mitigation Measure:

UTIL-2: Implementing agencies shall encourage construction contractors to recycle construction materials and divert inert solids (asphalt, brick, concrete, dirt, fines, rock, sand, soil, and stone) from disposal in a landfill, where feasible. Implementing agencies shall incentivize construction contractors with waste minimization goals in bid specifications where feasible.

Significance Determination: Less than significant (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.14-3.)

Non-Structural (Institutional) BMPs

The non-structural BMPs associated with the proposed EWMPs would not involve the construction of new facilities that would generate a new solid waste disposal need. However, the non-structural BMPs would include a broad range of municipal practices such as street cleaning, landscape management, storm drain operation, and more, which produce debris and trash for disposal. Regular street sweeping is one of the most cost-effective non-structural BMPs used to remove sediment, metals, petroleum products, trash, and vegetation that accumulate on streets. Maintaining a regular street sweeping schedule reduces the buildup of trash on streets and prevents trash from entering catch basins and the storm drain system. Street sweeping can also improve the appearance of roadways and urban areas. Based on the existing and planned trash disposal and recycling facilities available to the Los Angeles region, the additional solid waste would not exceed disposal capacity or require additional disposal facilities. As a result, impacts related to insufficient permitted landfill capacity would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Energy

Impact 3.14-5: Construction and operation of the proposed program would require additional energy use that could result in wasteful consumption, affect local and regional energy supplies, or conflict with applicable energy efficiency policies or standards.

Structural (Regional, Centralized, and Distributed) BMPs

Construction of BMPs would require use of non-renewable energy in the form of gasoline and diesel to power construction equipment. However, use of this fuel for construction would not be at such a large scale that it could be seen as wasteful or as affecting local or regional energy supplies. Impacts to energy supplies for construction would be less than significant.

Construction requiring ground disturbance could encounter buried or overhead utilities including electric or gas conveyance infrastructure. As part of the project design, Implementing Agencies would be required to identify the potential for underground utilities and determine whether they would need to be relocated to accommodate the BMP. As standard construction practices require, Implementing Agencies would conduct an underground utility search prior to excavation and would coordinate with utility providers in advance to ensure no disruption in services to the utility customers. Impacts to electric or gas infrastructure would be less than significant.

Some of the centralized and regional structural BMPs may require the installation of pump stations and ancillary components that would be electrically powered. Operation of the proposed pump station facilities would require new connections to the local electrical transmission system. Plans for the pump station facilities have not been finalized, and thus the energy requirements for operation of the proposed pump stations have not been determined. Operation of the pump stations may be variable in response to seasonal fluctuations.

Energy for the pump stations would be provided by LADWP and SCE. Electricity is generated and made available to Southern California from generating facilities and transmission lines located throughout the western United States. LADWP and SCE would be responsible for delivering the energy needed for the proposed structural BMPs. The proposed program would include implementation of energy efficient equipment, such as pumps and lighting, which would minimize the energy requirements of the proposed pump stations. The use of energy anticipated for the proposed program is minor when compared to the County-wide use of electricity. In addition, the proposed program would be supporting water conservation efforts and water quality requirements of the MS4 Permit, which would not result in wasteful consumption, affect local and regional energy supplies, or conflict with applicable energy efficiency policies or standards. Impacts to energy supplies for operation would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

Cumulative Impact Discussion

Structural (Regional, Centralized, and Distributed) BMPs

Structural BMPS constructed to treat, infiltrate, and/or store stormwater and non-stormwater throughout the watershed would not generate wastewater or require wastewater treatment. However, low-flow diversion BMPs would install localized treatment facilities or use existing wastewater treatment systems to treat and discharge dry-weather flows. Use of these treatment systems throughout the region would result in cumulatively improved water quality and local impacts during construction, but would not result in adverse cumulative impacts from operation or construction. Cumulative impacts would be less than significant.

The proposed program consists of improvements to existing storm drainage facilities as well as new storm drain facilities within the EWMP program areas. This PEIR contains an analysis on the potential environmental effects that might result from the installation of storm drainage facilities identified in the proposed EWMPs. Cumulative impacts to storm drain facilities would be less than significant.

Impacts to the existing water supplies are anticipated to be beneficial as a result of the stormwater and non-stormwater runoff infiltration and conservation BMPs implemented across the EWMP areas. **Mitigation Measure UTIL-1** would require that implementing agencies evaluate impacts to downstream beneficial uses, including surface water rights prior to BMP approval. No adverse cumulative impacts related to new or expanded water supply resources or entitlements would occur.

Construction and operation of the structural BMPs would generate solid waste; however, landfills serving the program area are expected to have sufficient capacity to accommodate the amount of waste generated. Development of a waste management or recycling plan (**Mitigation Measure UTIL-2**) would reduce this impact. Disposal of the solid waste generated during construction and operation would comply with all pertinent regulations and statutes. All other projects implemented in the area would also be required to comply with federal, state, and local solid waste regulations and statutes. Cumulative impacts would be less than significant.

The use of energy anticipated for the proposed program is minor when compared to the County-wide use of electricity. The proposed program would use energy-efficient equipment and would not result in wasteful consumption. Cumulative impacts would be less than significant.

Mitigation Measures: Implement **Mitigation Measure UTIL-1** and **Mitigation Measure UTIL-2**

Significance Determination: Less than significant (The application of these mitigation measures to specific BMP types and categories are identified in Table 3.14-3.)

Non-Structural (Institutional) BMPs

The non-structural BMPs associated with the proposed program would generally have no impact on utilities and service systems. The non-structural BMPs would not require construction and would not require water or wastewater treatment or expanded water supply sources. However, the non-structural BMPs would include street cleaning, landscape management, and storm drain operation, which produce debris and trash for disposal. Based on landfill capacity for the Los Angeles region, there appears to be ample availability to receive trash that would be collected with street cleaning throughout the EWMPs in addition to all other projects implemented in the program area. As a result, cumulative impacts related to insufficient permitted landfill capacity would be less than significant.

Mitigation Measures: None required

Significance Determination: Less than significant

3.14.4 Summary of Impact Assessment

Table 3.14-3 shows a summary of the structural BMPs requiring mitigation.

TABLE 3.14-3
SUMMARY OF UTILITIES AND SERVICE SYSTEM IMPACTS REQUIRING MITIGATION MEASURES

	Thresholds of Significance

Low flow diversions	No	No	No	Yes	No	Yes

NOTE: These conclusions are based on typical need for excavation, generation of construction debris, and trash collection

CHAPTER 4
Cumulative Impacts

4.1 Introduction

This chapter presents CEQA requirements for cumulative impact analysis and analyzes the potential for the proposed program to have significant cumulative effects when combined with other past, present, and reasonably foreseeable future projects in each resource area's cumulative geographic scope. This section provides the requirements for cumulative impact analysis. Cumulative impacts for the proposed program when combined with other reasonable and foreseeable future projects in the area are organized by resource topic and analyzed below.

CEQA Guidelines Section 15130(a) requires that an EIR discuss the cumulative impacts of a project when the project's incremental effect is "cumulatively considerable," meaning that the project's incremental effects are considerable when viewed in connection with the effects of past, current, and probable future projects. A consideration of actions included as part of a cumulative impact scenario can vary by geographic extent, time frame, and scale. They are defined according to environmental resource issues and the specific significance level associated with potential impacts. *CEQA Guidelines* 15130(b) requires that discussions of cumulative impacts reflect the severity of the impacts and their likelihood of occurrence. The *CEQA Guidelines* note that the cumulative impacts discussion does not need to provide as much detail as is provided in the analysis of project-only impacts and should be guided by the standards of practicality and reasonableness and focus on the cumulative impact to which the identified other projects contribute rather than the attributes of other projects which do not contribute to the cumulative impacts.

CEQA Analysis Requirements

CEQA requires that an EIR assess the cumulative impacts of a project with respect to past, current, and probable future projects within the region. *CEQA Guidelines* (Section 15355) define cumulative effects as "two or more individual effects that, when considered together, are considerable or which compound or increase other environmental impacts. The cumulative impact from several projects result from the incremental impacts of the proposed program when added to other closely related, and reasonably foreseeable, future projects." Pertinent guidance for cumulative impact analysis is given in Section 15130 of the *CEQA Guidelines*:

- An EIR shall discuss cumulative impacts of a project when the project's incremental effect is "cumulatively considerable", (i.e., the incremental effects of an individual project are considerable when viewed in connection with the effects of past projects, the effects of current projects, and the effects of probable future projects, (including those outside the control of the lead agency, if necessary).

- An EIR should not discuss impacts that do not result in part from the project evaluated in the EIR.
- A project's contribution is less than cumulatively considerable, and thus not significant, if the project is required to implement or fund its fair share of a mitigation measure or measures designed to alleviate the cumulative impact.
- The discussion of impact severity and likelihood of occurrence need not be as detailed as for effects attributable to the project alone.

In addition, the *CEQA Guidelines* Section 15130(b) allows for the use of two alternatives methods to determine the scope of projects for the cumulative impact analysis:

- List Method - A list of past, present, and probable future projects producing related or cumulative impacts, including, if necessary, those projects outside the control of the agency.
- Regional Growth Projections Method - A summary of projects contained in an adopted general plan or related planning document or in a prior environmental document which has been adopted or certified, which described or evaluated regional or area wide conditions contributing to the cumulative impact (Section 15130).

The analysis of cumulative effects in this PEIR utilizes a combination of the list and regional growth projections methods and focuses on the effects of concurrent construction and operation of the proposed EWMP projects along with the regional growth anticipated in each of the following Participating Permittee's jurisdictional areas: LACFCD, County of Los Angeles, and the following 46 cities: Los Angeles, Beverly Hills, Culver City, Inglewood, Santa Monica, West Hollywood, Hawthorne, El Segundo, Lomita, Baldwin Park, Covina, Glendora, Industry, La Puente, Malibu, Calabasas, Agoura Hills, Westlake Village, Hidden Hills, Santa Clarita, Rancho Palos Verdes, Palos Verdes Estates, Rolling Hills Estates, Redondo Beach, Hermosa Beach, Torrance, Manhattan Beach, Arcadia, Azusa, Bradbury, Duarte, Monrovia, Sierra Madre, Alhambra, Burbank, Glendale, Hidden Hills, La Cañada Flintridge, Montebello, Monterey Park, Pasadena, Rosemead, San Gabriel, San Marino, South Pasadena, and Temple City (refer to Figure 2-1).

Each of these jurisdictions have independent planning documents that guide the development of urban, agricultural and other land uses within their jurisdictional boundaries.

4.2 Related Projects

Geographic Scope

Cumulative impacts are assessed for related projects within a similar geographic area. This geographic area may vary, depending upon the issue area discussed and the geographic extent of the potential impact. For example the geographic area associated with construction noise impacts is limited to areas directly adjacent to construction sites, whereas the geographic area that is affected by construction-related air emissions may include the larger air basin. Construction impacts associated with increased noise, dust, erosion, and access limitations tend to be localized but could be exacerbated if other development or improvement projects are occurring within the same or adjacent locations as the proposed program.

Geographically, the proposed program is located in the Los Angeles basin. For the purposes of this analysis, the PEIR considered planned EWMP projects within the service area of LACFCD and all participating permittees, along with the adopted general plans or related planning documents for the EWMP areas, when evaluating potential cumulative impacts due to construction and operation of the proposed program. The planned EWMP projects are listed in **Table 4-1**, shown on **Figure 4-1**, Planned EWMP Projects and detailed further in Section 2.0, *Project Description*.

Project Timing

In addition to the geographic scope, cumulative impacts also take into consideration the timing of related projects relative to the proposed program. The implementation schedule is particularly important for construction-related impacts; for a group of projects to generate cumulative construction impacts, they must be temporally as well as spatially proximate. The EWMP projects that will be included in the proposed EWMPs along with other reasonably foreseeable future projects in the EWMP areas may or may not occur simultaneously. However, this analysis assumes some the EWMP projects and other local projects would be implemented concurrently, between 2015 and 2035.

Type of Projects Considered

As described throughout Chapter 3 of this PEIR, the impacts associated with implementation of the proposed program include both short-term, temporary construction-related impacts and long-term impacts related to program operation.

Cumulative Construction Impacts

Cumulative effects could result when considering the effects of the proposed program in combination with the effects of other construction projects in the area. For this PEIR, the analysis of cumulative construction impacts assumes that throughout the EWMP areas, planned future development projects will be on-going simultaneously with the proposed program, including other local major residential construction, small-scale construction project, and projects that have not yet been identified.

Cumulative Operational Impacts

Cumulative effects could result when considering the effects of the proposed program in combination with the effects of operating other projects in the EWMP areas.

TABLE 4-1
EWMP PROJECTS

Map Number	Project Name	BMP Type	Project Sponsor	Project Implementation
6	Phase IV Trash TMDL Implementation	Distributed	Dominguez Channel	Installation of CB covers began the Summer of 2013.
3	Citywide Smart Irrigation Control System	Distributed	Malibu Creek	Unknown
5	Wildlife Road Storm Drain Improvements	Distributed	North Santa Monica Bay Coastal Watersheds	Construction was scheduled to begin March 2014 and continue through August 2014
2	Model Equestrian Center	Distributed	Palos Verdes Peninsula	Completion anticipated June 2015
4	Brandon Street and Green Street Improvements Project	Distributed	Upper LA River	Construction Spring 2014 to Fall 2014
7	Avocado Heights Multiuse Trail Project	Distributed	Upper San Gabriel River	Constructed
1	Trash removal BMPs	Distributed	Upper Santa Clara River	Planned Implementation Date July 2015
13	Phase II of the Mar Vista Recreation Center Stormwater BMP Project	Centralized	Ballona Creek	Phase II is expected to be completed by December 2014.
16	Manhattan Beach Greenbelt Infiltration System	Centralized	Beach Cities WMG	The project construction was completed February 19, 2013.
18	Oxford Basin Multi-Use Enhancement Project	Centralized	Marina Del Rey	LACFCD anticipates the project to commence construction by the end of this year or early 2015.
12	Lindero Parkway Improvements	Centralized	Malibu Creek	Construction of the proposed improvements is expected to commence either Spring 2015 or early Summer 2015.
14	Broad Beach Biofiltration Project	Centralized	North Santa Monica Bay Coastal Watersheds	June 2014 (Completion of Construction)
19	San Ramon Canyon Stormwater Flood Reduction Project	Centralized	Palos Verdes Peninsula	Anticipated to be completed June 2015.
11	Monrovia Station Square/Transit Village Multi-Benefit Park and Greenway Project	Centralized	Rio Honda - San Gabriel River	Planned Implementation Date Spring 2015.
17	Metro Gold Line Infiltration Project	Centralized	Rio Honda - San Gabriel River	Planned Implementation Date Spring 2016.
15	Penmar Water Quality Improvement Project (Phase I and Phase II)	Centralized	Santa Monica Bay Jurisdictions 2+3	Phase II – expected completion by Spring 2015.
10	Humboldt Greenway Project	Centralized	Upper LA River	Under Construction
8A-8C	Torrance Stormwater Basin Recharge and Enhancement Project	Regional	Beach Cities WMG	Construction was scheduled for Spring 2014.
9	Malibu Legacy Park Pump Station Improvements	Regional	North Santa Monica Bay Coastal Watersheds	Anticipated to be completed June 2015.

Figure 4-1
Planned EWMP Projects

4.3 Plan Consistency

General Plans

Construction of structural BMPs and adoption of non-structural BMPs would occur throughout each of the EWMP areas, encompassing 84 cities and large areas of unincorporated Los Angeles County. Each city has adopted land use plans and zoning codes covering development within their jurisdictions. Many cities including the City of Los Angeles have adopted LID ordinances that promote new development of storm flow retention and water quality BMPs. Each implementing agency would be required to evaluate the consistency of each BMP with local zoning codes. Compliance with city codes for placement of BMPs would ensure that the cumulative impact of installing multiple BMPs throughout the County would not conflict with local plans and policies.

The Los Angeles County General Plan includes land use designations covering development throughout the County. Section 3.9 Land Use and Agriculture provides a list of goals and policies in the Los Angeles County General Plan that promote storm water quality infrastructure. The installation of multiple BMPs throughout the County would be consistent with the County General Plan goals promoting LID infrastructure and improved storm water quality. Section 3.3 Biological Resources identifies the regional conservation planning efforts throughout the County including critical habitat, significant ecological areas, habitat conservation planning areas, and regional, state and federal parks. The goals of enhanced water quality and a more natural hydrology encouraged by the proposed program are consistent with the habitat conservation goals of each of these plans. Furthermore, the Permit describes the Watershed Management Program optional compliance approach as providing more opportunities for multi-benefit projects that would encourage goals of recreation and habitat value creation as part of the BMP. The proposed program would be consistent with regional General Plan goals and policies.

Resource Management Plans

In addition to the municipalities and County, resource management agencies mitigate cumulative effects of development on the environment. Several regional agencies including SCAQMD, Water Replenishment District, LARWQCB, Department of Toxic Substances Control, wildlife agencies, Coastal Conservancy, Coastal Commission, National Parks, National Forest Service, Santa Monica Mountains Conservancy, and Metropolitan Water District of Southern California manage resources cumulatively impacted by regional development. Each of these resource managers prepare resource management plans to mitigate potentially significant cumulative impacts. Consistency with these management plans minimizes impacts to cumulative impacts. **Table 4-2** lists major resource management agencies and identifies where consistency with resource management plans is discussed in the PEIR. The proposed program would be consistent with regional resource management plans.

TABLE 4-2
KEY REGIONAL RESOURCE MANAGEMENT AND/OR PROTECTION AGENCIES

Agency	Management Plan	Where Discussed in PEIR
SCAQMD	Air Quality Management Plan	Section 3.2
Water Replenishment District	Groundwater Basins Master Plan	Section 3.8
RWQCB	Basin Plan	Section 3.8
Department of Toxics Substances Control	CUPA	Section 3.7
Wildlife agencies (CDFW, USFWS, NMFS)	Critical Habitat Designations, NCCP/HCPs	Section 3.3
Coastal Conservancy and Coastal Commission	Ocean Plan	Section 3.8
National Parks and Forest Service	Forest and Parks Plans	Section 3.9
Santa Monica Mountains Conservancy	Santa Monica Mountains Comprehensive Plan	Section 3.3

4.4 Cumulative Impacts and Mitigation Measures

For some impact issue areas (i.e., air quality, traffic, and water supply), the cumulative setting is defined by specific regional boundaries (air basin, regional roadway network, etc.) or projected regional or area-wide conditions, contributing to cumulative impacts. For the remaining impact issue areas, the cumulative setting is based on development anticipated within the vicinity of the EWMP project. The impact analysis in Chapter 3 includes a discussion of cumulative impacts for each resource area. **Table 4-3** summarizes the conclusions of the cumulative analysis in Chapter 3. As shown in the table, implementation of the BMPs would result in cumulative significant impacts to air quality, cultural resources, and noise.

TABLE 4-3
SUMMARY OF CUMULATIVE IMPACT ANALYSIS

Issue Area	Significance Determination
Aesthetics (Cumulative)	LSM
Air Quality (Cumulative)	**SU**
Biological Resources (Cumulative)	LSM

CHAPTER 5
Growth-Inducement Potential

This chapter analyzes the growth-inducement potential and associated secondary effects of growth impacts of the proposed program, as required by the California Environmental Quality Act (CEQA).

5.1 CEQA Requirements

The CEQA Guidelines require that an Environmental Impact Report (EIR) evaluate the growth-inducing impacts of a proposed action (Section 15126.2[d]). A growth-inducing impact is defined by the CEQA Guidelines as:

> [Discuss the way in which a proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth (a major expansion of a wastewater treatment plant might, for example, allow for more construction in service areas). Increases in the population may tax existing community service facilities, requiring construction of new facilities that could cause significant environmental effects. Also discuss the characteristic of some projects which may encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment.

A project can have direct and/or indirect growth-inducement potential. Direct growth inducement would result if a project involved construction of new housing. A project can have indirect growth-inducement potential if it would establish substantial new permanent employment opportunities (e.g., commercial, industrial, or governmental enterprises) or if it would involve a substantial construction effort with substantial short-term employment opportunities and indirectly stimulate the need for additional housing and services to support the new employment demand. Similarly, under CEQA, a project would indirectly induce growth if it would remove an obstacle to additional growth and development, such as removing a constraint on a required public service. An example of this indirect effect would be the expansion of a wastewater treatment plant, which might allow for more development in service areas. Under CEQA, growth is not considered necessarily detrimental or beneficial.

Based on the CEQA definition above, assessing the growth-inducement potential of the proposed program involves answering the question: "Would implementation of the proposed program directly or indirectly support economic expansion, population growth, or residential construction?" Stormwater is typically not one of the chief public services needed to support urban development; however, water supply is needed to support urban development. Additional water supply would play a role in supporting additional growth in the Enhanced Watershed Management Program (EWMP) areas, but it would not be the single impetus to such growth. In addition, factors such as the General Plans and policies of the cities and Los Angeles County (County) and/or the availability of wastewater disposal capacity, public schools, and transportation services also influence business and residential or population growth in the EWMP areas. Economic factors, in particular, greatly affect development rates and locations.

5.2 Methodology

Growth inducement may result in adverse impacts if the growth is not consistent with the land use plans and growth management plans and policies for the area affected. Local land use plans provide for land use development patterns and growth policies that allow for the orderly expansion of urban development supported by adequate urban public services, such as water supply, roadway infrastructure, sewer service, and solid waste service. A project that would induce "disorderly" growth that is in conflict with local land use plans could indirectly cause additional adverse environmental impacts and impacts to other public services. Thus, it is important to assess the degree to which the growth accommodated by a project would or would not be consistent with applicable land use plans.

To determine direct growth-inducement potential, the proposed program was evaluated to verify whether an increase in population or employment, or the construction of new housing would occur as a direct or indirect result of the program. If either of these scenarios occurred, the proposed program could result in direct growth-inducement within the EWMP areas.

5.3 Growth-Inducement Potential and Significant and Irreversible Effects

The proposed program intends to improve stormwater quality through implementation of both structural and non-structural Best Management Practices (BMPs), with the goal of complying with the requirements of the National Pollutant Discharge Elimination System (NPDES) Municipal Separate Storm Sewer System (MS4) Permit to reduce the impact of stormwater and non-stormwater on receiving water quality within the EWMP areas. Structural BMPs would include BMPs categorized as distributed, centralized, or regional. Distributed structural BMPs treat runoff close to the source and are typically implemented at a single- or few-parcel level. Centralized structural BMPs treat runoff from multiple parcels. Regional structural BMPs are larger in scale, and are meant to retain and/or treat the 85th percentile storm over 24 hours from a contributing area. The major functions of these three types of structural BMPs are infiltration, treatment, and storage; they may be used individually or in combination with one another. Although there would be construction involved, the structural BMPs would largely be implemented in urbanized areas including streets, sidewalks, parking lots, and parks.

The proposed program is not a land use project and its implementation would not introduce new residential or commercial buildings or any other growth-inducing land uses. The structural BMPs would augment the physical structure of established communities, blending in as part of the existing landscape and enhancing the water quality of existing communities. As a result, the proposed program would not induce population growth.

The proposed program would expand stormwater capture abilities, increasing groundwater recharge and improving the quality of stormwater runoff into receiving waters in the Los Angeles region. The program would not include construction of residential or commercial buildings and thus would not increase the demand for or require new public services and utilities facilities (including water supply, fire protection and other emergency services, public education, and parks and recreation facilities). The nature of the proposed program is to increase stormwater recharge and improve stormwater quality; such activities would not result in increased economic activity or population growth in the EWMP areas. And the amount of water recharged as part of the proposed program is anticipated to support existing water supply needs and reduce dependence on imported water supplies.

The non-structural BMPs associated with the proposed program consist of policies, actions, and activities intended to prevent pollutants from entering stormwater runoff, thus eliminating the source of the pollutants. Examples include irrigation control, covered trash receptacles, replacement of brake pads and lead in wheel weights, pet waste cleanup stations, street sweeping, catch basin cleaning, and downspout disconnect programs, all aiming to prevent and/or reduce runoff and/or pollution close to the source. These BMPs would not include construction activities and would not result in direct or indirect growth-inducement within the EWMP areas.

5.4 Secondary Effects of Growth

Implementation of the proposed program would not result in a direct or indirect increase in population or employment. The proposed program itself, therefore, is not growth-inducing and would not induce secondary effects of growth. While one of the main goals of the EWMPs is to increase infiltration and potentially increase recharge of stormwater into the groundwater basin, the amount of water potentially recharged would not be enough to indirectly support population growth and is intended to support existing water supply needs. This potential additional recharge would contribute to local water supply needs but would not alter population demographics. Therefore, there would be no secondary effects of growth.

5.5 Significant Irreversible Environmental Changes

CEQA Guidelines 21100(b) (2) and 15126.2(b) require that any significant effect on the environment that would be irreversible if the project is implemented must be identified. A project would generally result in a significant irreversible impact if:

- Primary and secondary impacts (such as roadway improvements that provide access to previously inaccessible areas, etc.) would commit future generations to similar uses.
- The project would involve a large commitment of nonrenewable resources.

- The project would involve uses in which irreversible damage could result from any potential environmental accidents associated with the project.

In accordance with Section 21100(b)(2)(B) of CEQA and Sections 15126(c) and 15126.2(c) of the CEQA Guidelines, the purpose of this section is to identify significant irreversible environmental changes that would be caused by implementation of the proposed program. Construction and operational impacts associated with implementation of the program would result in an irretrievable and irreversible commitment of natural resources through the use of fossil fuels and construction materials. Operation of the program would incrementally increase power consumption associated with stormwater BMPs requiring pump stations. The program's incremental increased use of these resources, however, would not significantly increase the overall commitment of resources associated with stormwater and would in fact increase conservation of other valuable resources. The proposed program would involve only minor incremental use of nonrenewable resources and would locate facilities primarily on lands already developed. Furthermore, since the implementing agencies would implement the mitigation measures identified in this Program Environmental Impact Report in concert with other ongoing stewardship and watershed protection activities, implementation of the proposed program would not result in significant irreversible environmental changes. When completed, the proposed program would provide a high level of water quality protection as well as increase water conservation throughout the EWMP areas.

CHAPTER 6
Alternatives Analysis

6.1 Introduction

According to the California Environmental Quality Act (CEQA) Guidelines, an Environmental Impact Report (EIR) must describe a reasonable range of alternatives to a proposed project that could feasibly attain most of the basic project objectives, and would avoid or substantially lessen any of the proposed project's significant environmental effects. This alternatives analysis summarizes the alternatives screening process conducted to identify feasible alternatives to the proposed Enhanced Watershed Management Programs (EWMPs). Information to select an "environmentally superior alternative," which may be the proposed program, is also provided in this chapter.

Section 15126.6(f) of the CEQA Guidelines provides direction on the required alternatives analysis:

> "The range of alternatives required in an EIR is governed by a 'rule of reason' that requires the EIR to set forth only those alternatives necessary to permit a reasoned choice. The alternatives shall be limited to ones that would avoid or substantially lessen any of the significant effects of the project. Of those alternatives, the EIR need examine in detail only the ones that the lead agency determines could feasibly attain most of the basic objectives of the project. The range of feasible alternatives shall be selected and discussed in a manner to foster meaningful public participation and informed decision making."

An EIR need not consider every conceivable alternative to a project. Rather, the alternatives must be limited to ones that meet the project objectives, are feasible, and would avoid or substantially lessen at least one of the significant environmental effects of the project. "Feasible" means capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, legal, social, and technological factors. Section 15126.6(b) of the CEQA Guidelines states that an EIR:

> "... must identify ways to mitigate or avoid the significant effects that a project may have on the environment, the discussion of alternatives shall focus on alternatives to the project or its location which are capable of avoiding or substantially lessening any significant effects of the project, even if these alternatives would impede to some degree the attainment of the project objectives, or could be more costly."

Section 15126.6 (d) of the CEQA Guidelines provides further guidance on the extent of alternatives analysis required:

> "The EIR shall include sufficient information about each alternative to allow meaningful evaluation, analysis, and comparison with the proposed project. A matrix displaying the major characteristics and significant environmental effects of each alternative may be used to summarize the comparison. If an alternative would cause one or more significant effects in addition to those that would be caused by the project as proposed, the significant effects of the alternative shall be discussed, but in less detail than the significant effects of the project as proposed."

The EIR must briefly describe the rationale for selection and rejection of alternatives and the information the Lead Agency relied on when making the selection. It also should identify any alternatives considered but rejected as infeasible by the lead agency during the scoping process and briefly explain the reasons for the exclusion. Alternatives may be eliminated from detailed consideration in the EIR if they fail to meet most of the project objectives, are infeasible, or do not avoid any significant environmental effects.

Section 15126.6(e)(1) of the CEQA Guidelines also requires that the "no project" alternative be addressed in this analysis. The purpose of evaluating the "no project" alternative is to allow decision-makers to compare the potential consequences of the proposed program with the consequences that would occur without implementation of the proposed program.

Finally, an EIR must identify the environmentally superior alternative. The "no project" alternative may be environmentally superior to the proposed program based on the minimization or avoidance of physical environmental impacts. However, the "no project" alternative must also achieve the project objectives in order to be selected as the environmentally superior alternative. CEQA Guidelines Section 15126.6(e)(1) requires that if the environmentally superior alternative is the "no project" alternative, the EIR shall identify an environmentally superior alternative among other alternatives.

6.2 Review of Proposed Program Goals and Objectives

The alternatives presented in this chapter were analyzed for their abilities to reduce significant program impacts and meet the objectives of the proposed program, which are:

- To collaborate among agencies (Permittee jurisdictions) across the watershed to promote more cost-effective and multi-beneficial water quality improvement projects to comply with the Municipal Separate Storm Sewer System (MS4) Permit.
- To develop watershed-wide Enhanced Watershed Management Programs (EWMPs) that would, once implemented, remove or reduce pollutants from dry- and wet-weather urban runoff in a cost-effective manner.
- To reduce the impact of stormwater and non-stormwater on receiving water quality.

6.3 Review of Significant Environmental Impacts

CEQA Guidelines Sections 21100(b) (2) and 15126.2(b) require that any significant and unavoidable effect on the environment must be identified. In addition, CEQA Guidelines 15093(a) allows the decision-making agency to determine if the benefits of a proposed project outweigh the unavoidable adverse environmental impacts of implementing the project. The Lead Agency can approve a project with unavoidable adverse impacts if it prepares and adopts a "Statement of Overriding Considerations" setting forth the specific reasons for making such a judgment. Unavoidable adverse impacts identified in this Program Environmental Impact Report (PEIR) are discussed in this section. For each of the unavoidable adverse impacts, the Los Angeles County Flood Control District (LACFCD) must prepare and adopt a Statement of Overriding Considerations if the program is approved.

Chapters 3 and 4 provide analyses of potentially significant impacts that could result from implementation of the proposed program. **Table 6-1** identifies the potentially significant and unavoidable impacts associated with implementation of the proposed program. The range of alternatives required to be evaluated in an EIR is limited to those alternatives that would avoid or substantially lessen any significant effects of the proposed program and could feasibly attain most of the program objectives.

6.4 Program-Level Alternatives Analysis

In accordance with the CEQA "rule of reason," an EIR is required to consider a range of alternatives that permit a reasoned choice and that are "limited to ones that would avoid or substantially lessen any of the significant effects of the project" (CEQA Guidelines Section 15126.6(f)). The Lead Agency conducted an alternatives screening process to identify feasible alternatives to the proposed program. The screening process for identifying viable alternatives included consideration of the following criteria:

- Ability to meet the program objectives
- Ability to reduce significant environmental effects of the proposed program
- Economic and engineering feasibility

Based on these criteria, the Lead Agency has identified the following alternatives:

- No Program Alternative
- Non-Structural Best Management Practices (BMPs) Only Program Alternative
- Distributed Structural BMPs Only Program Alternative (no centralized and regional)

TABLE 6-1
SUMMARY OF PROGRAM IMPACT ANALYSIS

Issue Area	Significance Determination
Aesthetics	LSM
Air Quality (Construction)	**SU**
Air Quality (Operation)	LTS
Air Quality (Cumulative Construction)	**SU**
Biological Resources (Direct and Cumulative)	LSM
Cultural Resources	**SU**
Cultural Resources (Cumulative)	**SU**
Geology and Soils/Mineral Resources (Direct and Cumulative)	LSM
Greenhouse Gas Emissions	LTS
Hazards and Hazardous Materials (Direct and Cumulative)	LSM
Hydrology and Water Quality (Direct and Cumulative)	LSM
Land Use and Planning/Agriculture (Direct and Cumulative)	LTS
Noise (Construction)	**SU**
Noise (Operation)	LTS
Noise (Cumulative)	**SU**
Population and Housing and Environmental Justice (Direct and Cumulative)	LTS
Public Services/Recreation (Direct and Cumulative)	LTS
Traffic and Transportation (Direct and Cumulative)	LSM
Utilities and Service Systems (Direct and Cumulative)	LSM
Growth Inducement (Direct/Indirect)	LTS

LTS = Less than Significant
LSM = Less than Significant with Mitigation
SU = Significant and Unavoidable

6.4.1 No Program Alternative

The CEQA Guidelines require an analysis of the specific alternative of "no project" (CEQA Guidelines, Section 15126.6). Specifically, the CEQA Guidelines state that "[t]he purpose of describing and analyzing a 'no project' alternative is to allow decision makers to compare the impacts of approving the proposed project with the impacts of not approving the proposed project." The "no project" alternative is not necessarily the same as the baseline used to determine the environmental impacts of the proposed program. The analysis of the no project alternative includes the existing baseline environmental conditions as well as "what would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with available infrastructure and community services" (CEQA Guidelines, Section 15126.6 (e)(2)). The analysis of impacts related to the no project alternative includes projecting what would reasonably be expected to occur "in the foreseeable future if the project were not approved."

The No Program Alternative (please note: for the sake of this EWMP, this PEIR will use the term "No Program Alternative") would result in the non-implementation of the EWMP approach allowed in the MS4 Permit. Although this would not necessarily result in noncompliance with MS4 Permit since preparation of the EWMPs is an optional compliance method, each Permittee would be required to reach water quality objectives for MS4 discharges on their own, with no clear compliance strategy. The collaborative approach outlined in the MS4 Permit would not be available to each Permittee. Under the No Project Alternative, each Permittee would construct BMPs necessary to achieve compliance, some of which would be similar to the proposed alternative. This includes the construction of distributed, centralized, and regional BMPs necessary to achieve local discharge compliance.

Ability to Meet Program Objectives

The No Program Alternative would not meet the EWMP objective to collaborate among agencies across the watershed to promote more cost-effective and multi-beneficial water quality improvement projects, but it would meet the other objectives to remove or reduce pollutants from dry- and wet-weather urban runoff and reduce the impact of stormwater and non-stormwater on receiving water quality through implementation of structural and non-structural BMPs.

The No Project Alternative would not necessarily avoid the potential environmental impacts that would occur as a result of implementing the EWMPs, as compliance with the MS4 Permit is still required. However, to achieve compliance with the MS4 Permit, each of the BMPs would need to be installed rapidly to avoid permit violations. There would be less coordination within each watershed, which could result in inefficient or redundant BMPs based on municipal boundaries rather than watershed boundaries. Potential impacts of this alternative are discussed in the following pages.

Aesthetics

Under the No Project Alternative, each Permittee would implement BMPs within their jurisdictions that would result in aesthetic modifications similar to the proposed alternative. The impacts to aesthetics throughout the watershed would be site specific, similar to the proposed alternative. [Similar impacts]

Air Quality

Air emissions resulting from the construction of BMPs under the No Project Alternative would be similar to the proposed alternative since both alternatives would require installation of similar types of BMPs requiring similar types of construction methods. However, because the programs would need to be installed rapidly and because more BMPs would likely be required as a result of the inefficiencies of municipal boundaries, slightly more construction emissions would result. [Slightly greater impacts]

Biological Resources

Impacts to biological resources would be similar to the proposed alternative. The potential impacts to biological resources throughout the watershed would be site specific, but the BMP locations would be similar to those identified under the proposed alternative. [Similar impacts]

Cultural Resources

Impacts to cultural resources would be similar to the proposed alternative. The potential impacts to cultural resources throughout the watershed would be site specific, but the BMP locations would be similar to those identified under the proposed alternative. [Similar impacts]

Geology and Soils/Mineral Resources

Impacts to geological and mineral resources would be similar to the proposed alternative since impacts would be site specific and within similar locations. [Similar impacts]

Greenhouse Gases

Construction of the BMPs would result in only minor greenhouse gas (GHG) emissions. GHG emissions would be similar to the proposed alternative since similar BMPs would be constructed. In terms of the cumulative impact to global climate change, the impact would be similar to the proposed alternative. [Similar impacts]

Hazards and Hazardous Waste

Impacts to hazards and hazardous waste would be similar to the proposed alternative since impacts would be site specific and within similar locations. Localized subsurface contamination could be affected by any of the BMP types and individual projects would be subject to similar preconstruction evaluations to assess suitability of the location. [Similar impacts]

Hydrology and Water Quality

Achieving water quality objectives required in the MS4 Permit immediately would be difficult under the No Program Alternative since the permit does not allow for an installation grace period outside of the EWMP. The potential for noncompliance with the MS4 Permit under this alternative would result in a significant impact compared to that of the proposed alternative. [Greater impacts]

Land Use Planning/Agriculture

Impacts to land use would be similar to the proposed alternative since impacts would be site specific and within similar locations. [Similar impacts]

Noise

Noise resulting from the construction of BMPs under the No Project Alternative would be similar to the proposed alternative since both alternatives would require installation of similar types of BMPs requiring similar types of construction methods in similar locations. [Similar impact]

Population and Housing
