The approach mandated by section 402(p)(2) is fully consistent with the intent and requirements of Section 319 of the WQA of 1987. Section 319 was enacted to require States to prevent and control nonpoint source pollution.

Under section 319 States are required to submit Nonpoint Source Assessment Reports identifying State waters which, without additional control of nonpoint sources of pollution, cannot be expected to attain or maintain designated uses. States were also required to prepare and submit for EPA approval a statewide management program for controlling nonpoint source water pollution to navigable waters within the State and improving the quality of such waters to levels sufficient for attaining or maintaining applicable water quality standards or goals. Furthermore, the State program submittal was to identify specific best management practices and measures which the state proposes to implement, in the first four years after program submission, to reduce pollutant loadings from identified nonpoint sources to levels required to achieve the stated water quality objectives.

Although the State nonpoint source programs are not enforceable under Federal law, States were encouraged to adopt both regulatory and non-regulatory approaches under State and local law. Section 319(b)(2)(B) specifies that a combination of "non-regulatory or regulatory programs for enforcement, technical assistance, financial assistance, education, training, technology transfer, and demonstration projects" may be used, as necessary, to achieve implementation of the best management practices or measures identified in the section 319 submittal.

To date, all States have approved section 319 assessments and approved management programs. EPA has awarded approximately $38 million in FY90 funds, $51 million in FY91 funds, and is in the process of awarding $52.5 million in FY92 funds to assist States in implementing the section 319 programs. EPA expects that State nonpoint source management programs will be revised and refined periodically in response to re-evaluated priorities and new strategies and technologies.

Numerous States and local governments have implemented regulations and enforceable policies to control nonpoint source pollution. States such as Delaware and Florida as well as local governments such as the Lower Colorado River Authority are aggressively pursuing storm water management goals through numerical treatment standards for new development. Many States and local governments have enforceable erosion and sediment control regulations. On a broader scale, nonpoint source pollution is being addressed at the watershed level by programs such as those being implemented by the State of Wisconsin and the Puget Sound Water Quality Authority and the states which are parties to the International Agreement on the Great Lakes. A number of individual States and local communities have adopted legislation or regulations like Maryland's Critical Areas Bill which limits development and/or

VOL 12 4482

R0037791

requires special management practices in areas surrounding water resources of special concern. California has also recently created Storm water management districts to better address the control of nonpoint source pollution.

A further development in the area of Federally-mandated nonpoint source management occurred in 1990 with the enactment of section 6217 of the Coastal Zone Act Reauthorization Amendments (CZARA). Section 6217 provides that States with approved coastal zone management programs must develop and submit to EPA and NOAA for approval a coastal nonpoint pollution control program. Failure to submit an approvable program will result in the loss of Federal grants under both the Coastal Zone Management Act and section 319 of the CWA. State nonpoint pollution control programs must also include enforceable policies and mechanisms which ensure implementation of the management measures throughout the coastal management area. Management measures as defined in section 6217(g)(5) are: "Economically achievable measures for the control of the addition of pollutants from existing and new categories and classes of nonpoint sources of pollution, which reflect the greatest degree of pollutant reduction achievable through the application of the best available nonpoint pollution control practices, technologies, processes, siting criteria, operating methods, or other alternatives."

The section 6217(g) guidance was issued for public comment in May, 1991. Final guidance is expected by October, 1992. The technology-based approach used in the guidance provides State Officials flexibility to meet the management measures using best management practices identified in the guidance or other methods and strategies which achieve equivalent or higher levels of pollutant control. If the technology-based approach fails to achieve and maintain applicable water quality standards and protect designated uses, additional management measures are required under CZARA section 6217(b)(3). Congress mandated a technology-based approach founded on technical and economic achievability under the rationale that neither States nor EPA have the money, time, or other resources to create and implement a program which depends on establishing cause and effect linkages between particular land use activities and specific water quality problems. Nonpoint sources addressed in the proposed guidance include: urban runoff from both developing and developed areas, roads, highways and bridges, agriculture, forestry, marinas, hydromodification, dams and levees.

C. Current (Phase I) Storm Water Permitting Program

EPA promulgated permit application regulations for Phase I storm water discharges on November 16, 1990 (55 FR 47990). The November 16, 1990 regulations established the scope of the Phase I storm water program by defining two major classes of storm water discharges identified under section 402(p)(2)(B), (C), and (D) of the CWA: Storm water discharges associated with industrial activity,[2] and discharges from municipal separate storm sewer systems (MS4s) serving a population of 100,000 or more.[3] In addition, the November 16, 1990 regulations established permit application requirements, including deadlines for these two classes of discharges (for a summary of Phase I see appendix A).

The November 16, 1990 regulations defined municipal separate storm sewer system serving a population of 100,000 or more to include municipal separate storm sewers within the boundaries of 173 incorporated cities, and within unincorporated portions of 47 counties that were identified as having populations of 100,000 or more in unincorporated, urbanized portions of the county.[4] In addition, the regulations allowed for additional municipal separate storm sewers to be designated by the Director of the NPDES program as being part of a large or medium MS4. The November 16, 1990 regulations establish comprehensive two part permit applications for discharges from large or medium MS4s. The permit application requirements for large and medium MS4s, among other things, require municipal applicants to propose municipal storm water management programs to control pollutants to the maximum extent practicable and to effectively prohibit non-storm water discharges to the MS4.[5]

The November 16, 1990 regulations also defined the term "storm water discharges associated with industrial activity" to include 11 categories of industrial facilities (see 40 CFR 122.26(b)(14)). The November 16, 1990 regulations establish two sets of application requirements for storm water discharges associated with industrial activity: Individual applications and group applications. In addition, the notice recognizes a third set of application procedures for storm water discharges associated with industrial activity referred to as "notice of intent" (NOI) requirements associated with general permits.

The Phase I storm water program takes two very different approaches to defining the roles of EPA and authorized NPDES States in controlling pollutants in storm water discharges. With respect to permits for large and medium MS4s, the efforts of the NPDES permitting authority (EPA or an authorized NPDES State) are directed to ensuring that municipalities develop and implement storm water management programs to control pollutants to the maximum extent practicable. Municipal programs address the control of pollutants in storm water from all areas within the boundaries of the MS4 that discharge to the system, including privately-owned lands, as well as modifying municipal activities (e.g. road deicing and maintenance, flood control efforts, maintenance of municipal lands, etc.) to address storm water quality concerns. The Agency has defined the role of municipalities under this program in a flexible manner that allows local governments to assist in defining priority pollutant sources within the municipality, and to develop and implement appropriate controls for such discharges. With respect to permits for storm water discharges associated with industrial activity, the NPDES permitting authority has a more direct role in regulating facilities.[6]

While today's request for comments focuses on developing Phase II of the storm water program, readers may find that a brief summary of progress to date

---

[2] On June 4, 1992 the United States Court of Appeals for the Ninth Circuit found that EPA's rational for exempting construction sites of less than five acres and certain uncontaminated storm water discharges from light industrial facilities from Phase I of the storm water program to be invalid and has remanded these exemptions for further proceedings (see *Natural Resources Defense Council versus EPA* No. 91–70176).

[3] Consistent with Section 402(p)(2) of the CWA, the November 16, 1990 regulations address two subclasses of municipal separate storm sewer systems serving a population of 100,000 or more. Large municipal separate storm sewer systems are defined as systems serving a population of 250,000 or more (see 40 CFR 122.26(b)(4)). Medium municipal separate storm sewer systems are defined as systems serving a population of 100,000 or more, but less than 250,000 (see 40 CFR 122.26(b)(7)).

[4] See appendices F, G, H, and I to 40 CFR part 122.

[5] See 40 CFR 122.26(d)(2)(iv).

[6] NPDES permits for discharges from large and medium MS4s will establish municipal responsibilities for assisting EPA and authorized NPDES States in implementing controls to reduce pollutants in storm water discharges associated with industrial activity which discharge through large and medium MS4s. A more detailed description of the role of municipalities in addressing industrial storm water sources under this Federal/State/Municipal partnership, is provided at 56 FR 40972 (August 16, 1991).

VOL 12

4483

in implementing the first phase of the program would be helpful. Part of current implementation activities include outreach efforts and two rulemakings discussed in more detail below which are specifically designed to provide more flexibility and minimize regulatory and administrative burdens where possible.

As discussed above, the November 1990 storm water rule provided for three different options for storm water discharges associated with industrial activity to seek coverage under the program: individual, group, and general permit applications. Since November 1990, there has been a great deal of activity as EPA and the States have worked with the regulated community to provide guidance and implement the program. The Agency has established a four tier risk-based storm water permitting strategy which emphasizes the use of general permits (April 2, 1992, (57 FR 11394)). As part of the strategy, EPA called for the development of State storm water management programs to track permit issuance, provide for prioritization of risk, and create baselines against which to assess environmental results. As part of the same rule, the Agency extended the deadline for Part 2 of group applications until October 1, 1992, and also deferred regulation of storm water discharges from industrial activities owned or operated by municipalities with a population under 100,000 until Phase 2 of the program, pursuant to section 1068(c) of the Intermodal Surface Transportation Efficiency Act of 1991. In providing for greater flexibility, reduced burdens, extended deadlines, and deferred regulation, this recent storm water rulemaking addresses many of the goals underlying the President's January 28, 1992 request to review existing regulations.

Since November 1990, the Agency has received over 1,200 Part I group applications representing more than 60,000 facilities. EPA is currently processing these applications. Final decisions have been reached on over 1,000 to date. Approximately 75% have been approved, 20% withdrawn or determined not to be covered, and 5% denied. Part I group applications were due on September 30, 1991. Part II sampling information from approved groups is due on October 1, 1992.

At the same time that EPA has been receiving and processing group applications, States have been actively moving to provide for storm water general permit issuance. When the storm water application rules were issued in November 1990, only 17 out of 39 States authorized to administer the NPDES program were also approved to issue NPDES general permits. Since then, an additional 16 States have requested and received Federal approval to issue general permits. Over two thirds of the States that now have general permit authority are presently developing specific general permits to cover storm water discharges.

For the 12 States without NPDES authority, EPA is in the process of issuing storm water general permits that rely heavily upon industrial facilities developing and implementing their own storm water pollution prevention plans.

As part of the four tier risk-based permitting strategy referred to above and discussed in more detail in the Agency's April 2, 1992 notice, EPA believes that the majority of storm water discharges associated with industrial activities should be covered by general permits. The Agency urges all authorized NPDES States without general permit approval to obtain NPDES general permit authority.[7] EPA places a high priority on this effort and is providing direct technical guidance and assistance to support States both in obtaining general permit approval and in developing specific general storm water permits.

With regard to guidance, training, and outreach, EPA has undertaken a number of efforts to provide technical assistance and also to get public input on ways to streamline the existing program. In the area of guidance, EPA has published and distributed thousands of municipal and industrial permit application manuals in addition to numerous summaries, fact sheets and work shop materials over the past eighteen months. The Agency has issued additional guidance on storm water sampling, pollution prevention plan development, and storm water best management practices (BMPs), and is developing guidance for part 2 municipal applications. A list of EPA technical guidance, summaries, and storm water fact sheets can be obtained by calling the Agency's storm water hotline at (703) 821-4823.

In the area of training and outreach, EPA staff has participated in over 60 workshops and presentations throughout the country, training permitting authorities and educating the regulated community. For example, EPA Regions held fourteen public hearings to receive public comment on the Agency's proposed general permits in August and September of 1991. EPA held an additional 26 storm water workshops across the country this summer and would welcome hearing from groups or organizations interested in receiving workshop materials for further in-house or local training.

While EPA recognizes the importance of ongoing training and outreach efforts to provide information on the storm water program, the Agency also regards these activities as an effective mechanism for getting feedback on the program and identifying areas for further improvement. The new guidance documents referred to above and presently being developed reflect input from States and the regulated community on high priority areas requiring clarification and further technical assistance.

In addition to these activities, EPA has recently completed a study, in conjunction with the Rensselaerville Institute, to obtain direct public input and develop recommendations for streamlining the program and making it more effective. This study has two objectives. The first is to develop recommendations to streamline program implementation under existing regulations and legislation (Phase I). The second is to develop cost-effective options for addressing risks from storm water sources not currently required to be permitted that could potentially be addressed under Phase II of the storm water program.

Under the first objective, the Rensselaerville Institute sponsored 8 focus groups across the country with members representing state and local government, the regulated community, and environmental interests for uninterrupted full day discussions on ways to improve the storm water program. Five key issues were raised by all groups: (1) Groups felt that EPA has not been very clear about the intended goals of the regulations and should communicate storm water risks, objectives, and requirements more clearly to the general public as well as the regulated community, (2) participants noted that the cost of program implementation is significantly higher than original EPA estimates and there is great concern regarding the real costs of the program and of achieving compliance, (3) there was consensus that EPA and States must accelerate general permit issuance and focus on general permits to achieve efficient implementation of the program, (4) participants felt that technical outreach should be targeted at the State and local level as opposed to the national level and should provide better guidance on the regulations and how to implement

[7] Currently, DE, IA, KS, MI, NV, NY, OH, SC, VT and the Virgin Islands have authorized NPDES programs, but do not have general permit authority.

VOL 12

4484

them, and (5) groups noted that coverage under certain industrial storm water categories should be clarified.[8] EPA agrees with these recommendations and is taking steps, some of which are outlined above, to follow up in each of these areas.

The second objective of the Rensselaerville study, consistent with the purpose of today's notice, is to get as much input as possible on different options for identifying and addressing those Phase II storm water discharges not regulated under the current program. Under the study, however, the mechanism for encouraging feedback was more targeted and interactive. The Rensselaerville Institute has obtained input from national experts (representing permitting authorities, the environmental community, and regulated interests) and then followed up with a series of 3 expert discussion forums that were open to the public in June.

The public meetings were held in Denver, San Francisco and Washington, DC. Attendees were divided into task teams and asked to develop their own strategy for addressing Phase II sources. There were 16 task teams: Five each at the Denver and San Francisco meetings, and six in Washington, DC. They were given a strategy template to guide them in their discussion, but were not confined to the template in developing their strategies and recommendations.

Each team considered and then presented the option they had developed over a four hour period. There were common strategy characteristics mentioned across groups within meetings and also across meetings. The recommendations of the focus groups covered four specific areas: Targeting strategies, controls that should be put in place, timetable, and the role of EPA in Phase II. The recommendations made by focus groups regarding the first three areas are discussed below along with the options presented for comment.

With regard to the role of EPA, participants identified the areas of responsibility they felt it would be appropriate for EPA to assume under Phase II. Their recommendations can be classified by four common themes: (1) Teams felt that EPA should provide technical assistance, information dissemination, and do any research necessary as a part of Phase II, (2) participants suggested that EPA should provide funding for research or demonstration projects, but not for program implementation; (3) groups stressed that EPA should set broad guidelines for the program, but allow State and local governments to determine the level of specificity needed to effectively implement the program; and (4) teams felt that EPA should be responsible for training regulators in the program.

II. Today's Notice

A. Purpose and Intent

CWA sections 402(p)(5) and (6) require EPA to identify storm water discharges not covered under Phase I which should be regulated to protect water quality.[9] The purpose of this notice is to solicit public comment on ways to implement the second phase of the storm water permitting program for sources and activities not regulated under the existing program. EPA is seeking comments on approaches for meeting CWA Phase II storm water requirements while at the same time minimizing the economic impacts and regulatory and administrative burdens associated with additional Phase II storm water controls. There are a number of ways to identify additional categories of storm water activities for further controls and EPA requests comment on the alternatives listed below as well as on any other approaches that may not be identified in today's notice.

B. Alternative Approaches

EPA is interested in comments from the general public, state and local government, the regulated community and environmental groups on each of the options outlined below. The goal of the CWA is to restore and maintain the chemical, physical, and biological integrity of the Nation's waters. In practice, programs implemented under the Clean Water Act have two basic goals: To reduce pollutant loadings to the environment and to require more stringent controls where necessary to assure attainment of State water quality standards and designated uses. These goals are compatible. However, the specific regulatory strategy and pollution reduction alternatives to be chosen for addressing Phase II storm water discharges could have a large impact on the size of the regulated universe and regulatory burden associated with the program.

To generate discussion and input from commenters, today's notice discusses several alternative approaches for controlling storm water discharges from currently unregulated sources under Phase II of the storm water program. A number of different control strategies, with variations in scope and timing, are outlined below. They range from comprehensive permitting of all municipal, light industrial, and commercial activities that generate storm water runoff to little or no NPDES permitting of Phase II sources.

A major distinction between several of the options listed below is whether Phase II efforts should focus on developing requirements for targeted municipalities to develop source controls and management programs for storm water discharges within their jurisdictions (for example, see options (b) and (c) below) or whether Phase II should, instead, focus on point source discharges of storm water without reference to the municipality in which they may be located. Under the first approach, EPA would develop NPDES requirements that required targeted municipalities to develop and implement storm water management programs which address storm water discharges within their jurisdiction [10] to the maximum extent practicable. This approach would allow for flexibility based on local factors, but could lead to varying levels of control from one area to another. EPA requests comments on the ability of municipalities to effectively regulate storm water discharges. In addition, the Agency requests comment on appropriate funding mechanisms for municipal programs, in particular the feasibility of implementing storm water utilities, which are currently being used in more than 100 communities nationwide.[11]

To facilitate comment and analysis, the following discussion is organized in terms of three issues: Targeting, control strategies, and deadlines. Each of these areas overlap and any final decision must reflect choices from each group. However, the objective is to solicit input

[8] The regulatory definition of storm water discharge associated with industrial activity identifies 11 categories of industrial facilities (see 40 CFR 122.26(b)(14)). In particular, category viii (certain transportation facilities) and category xi (certain manufacturing facilities with materials and/or materials handling equipment exposed to precipitation) were identified as needing clarification.

[9] Section 502(14) of the CWA excludes agricultural storm water runoff from the definition of point source. Section 402(1)(2) prohibits EPA from requiring an NPDES permit for certain "uncontaminated" storm water discharges from mining sites and oil and gas operations. EPA cannot regulate these discharges under section 402(p)(6) of the CWA.

[10] One issue that needs to be resolved is whether targeted municipalities should be responsible for controlling all priority storm water discharges within their jurisdiction or only those that discharge directly to the MS4.

[11] For more information see "Storm Water Utilities: Innovative Financing for Storm Water Management", EPA, Water Policy Branch, OPPE, 1992.

VOL 12

4485

on three basic questions. First, what should be covered under Phase II, that is, what additional municipal separate storm sewer systems, municipal industrial activities, commercial, light industrial, retail, or residential activities not presently covered under Phase I of the storm water program should be targeted or identified as needing additional controls? Second, what control strategies should be developed and implemented to address these Phase II activities? Third, what deadlines or time frames should apply in implementing Phase II of the storm water program?

In addressing each of these questions, commenters are requested not only to provide their views on appropriate alternatives (including approaches that may not be included in this notice), but also where possible detailed rationales and additional data or other information which address the practical, administrative and legal feasibility and/or the environmental benefits, of a particular option. In addition, each of the approaches presented could be combined with others to achieve specific environmental objectives. For example, dischargers of specific pollutants in particular water bodies could be targeted for permits or more stringent controls. Along with input on individual options EPA requests comments on possible combinations or other approaches not outlined above. Commenters are also asked to address the roles and responsibilities of Federal, State and local governments under various approaches, particularly with respect to: (1) Identifying approaches that target MS4s in currently unregulated municipal areas as needing permits, and (2) approaches that identify classes of individual facilities (e.g. commercial or retail facilities) as needing permits.

The Agency also requests input on what type of information should be used in identifying sources to be covered and whether commenters believe there is presently sufficient information or monitoring data at the state and local level to expeditiously implement a particular option listed below. If on a national or regional basis there are not sufficient data, the next question to be addressed is whether a comprehensive monitoring and data gathering effort is warranted to assure effective implementation of one approach over another. In other words, there may be a trade off between: (1) Near term general targeting approaches combined with flexible control strategies based on information currently available, and (2) a heavier reliance on longer term specific geographic, watershed, or water body related targeting mechanisms which may require more comprehensive data gathering efforts on both a facility and stream reach basis.

1. Targeting

(a) Seek amendments to the CWA to eliminate Phase II and use designation authority to bring additional sources under Phase I. Section 402(p)(2)(E) presently provides that EPA or a State may designate non-industrial storm water discharges and discharges from MS4s other than those serving a population of 100,000 or more for control under Phase I where the discharge contributes to water quality violations or is a significant contributor of pollutants to waters of the U.S. Some commenters may conclude that the remaining unregulated discharges of storm water (associated with smaller municipalities, commercial activities, and some retail or residential activities) constitute, on the whole, a negligible source of environmental risks, relative to the discharges already regulated.

Under this option, Congress would amend the CWA to eliminate section 402(p)(6) (Phase II requirements) as a part of the NPDES program and expand use of the existing designation authority under 402(p)(2)(E) to designate individual or classes of storm water activities on a category, watershed, stream reach, loadings, or other basis for specific regulation under existing Phase I requirements. Under this option, those storm water activities not designated for Phase I controls could be addressed by an alternative means, possibly under the State nonpoint source management programs funded under section 319 of the CWA or coastal nonpoint pollution control programs developed pursuant to section 6217 of the CZARA. The Agency requests comments on: (1) Whether State programs funded under Section 319 can better ensure appropriate control of diffuse pollutant sources and: (2) whether heavier reliance on State nonpoint source programs to address Phase II storm water point source discharges would have adverse impacts on States' program resources and the ability of States to address agricultural sources. The selective nature of this designation option could reduce the potential economic impact on the economy and small entities. However, using 402(p)(2)(E) may be viewed by some commenters as a reactive approach which does not recognize the advantages of prevention of storm water pollution problems over remediation of these problems after they have been identified. This approach may also increase the administrative burden on States and local government to identify and undertake the necessary administrative process to include additional storm water activity under Phase I.

(b) Identify targeted MS4s as needing an NPDES permit under section 402(p)(6) of the CWA. The Phase I MS4 program currently only applies to municipal separate storm sewer systems serving a population of 100,000 or more. EPA has defined the scope of these Phase I requirements to specifically identify 173 incorporated cities with a population of 100,000 or more and 47 counties with a population of 100,000 or more in unincorporated, urbanized areas.[12] In general, this approach focuses on core cities of large metropolitan areas, but with the exceptions of 47 counties addressed, does not address urban fringes or suburban areas in large metropolitan areas, urbanized areas without large core cities, or smaller isolated cities or population centers.[13] EPA requests comments on factors that should be considered when evaluating options for addressing Phase II MS4s.[14]

---

[12] The 220 cities and counties addressed by these definitions have a combined population of over 87.8 million people under the 1980 Census. However, a significant percentage of the population of the 220 municipalities are served by combined sewers (not addressed by the storm water program), which are found primarily in areas of older development.

[13] The 1980 Census indicates that 87.3 million people lived in areas designated as urbanized areas but outside of incorporated cities with a population of 100,000 or more. Portions of over 3,400 incorporated cities, towns and villages, 800 counties and about 1,300 minor civil divisions (unincorporated towns and townships) are in Phase II municipalities that are part of urbanized areas.

[14] EPA outlined seven factors it considered when defining the scope of large and medium MS4s (see December 7, 1988 (53 FR 49444), and November 16, 1990 (55 FR 48038)). These factors included: the advantages of developing system-wide storm water management programs for municipal systems; the inter-jurisdictional complexities associated with municipal governments; the fact that many municipal storm water programs have traditionally focused on water quantity concerns, and have not evaluated water quality concerns; the geographic basis necessary for planning comprehensive management programs to reduce pollutants in discharges from MS4s; the geographic basis necessary to provide flexibility to target controls on areas where water quality impacts associated with discharges from MS4s are the greatest and to provide an opportunity to develop cost effective controls; the need to establish a reasonable number of permits; Congressional intent to allow the development of jurisdiction-wide, comprehensive storm water programs with priorities given to the most heavily populated areas of the country. The Agency requests comment on which of these factors should be considered in identifying Phase II MS4 sources.

VOL 12

4486

The Agency also requests comment on the advantages of municipalities associated with urbanized areas coordinating storm water management efforts on a regional basis. The Agency notes that a number of municipalities have developed regional administrative approaches to flood control management.[15] Regional administrative approaches appear to provide opportunities for municipalities to lower overall administrative burdens, consolidate efforts to study or evaluate approaches, and adequately plan cost-effective approaches to consider and address the needs of all represented municipalities. The Agency requests input on how it could or should encourage the development and use of regional approaches to storm water management under the NPDES program. Specifically, EPA requests comments on the following targeting options as well as any that may not be included in this notice.

(i) *Focus on population.* Expand coverage to address additional municipalities based on population. Following the Phase I approach, coverage of municipalities could be expanded by lowering the minimum population requirement across the board or by designating additional municipalities or municipal systems by name. EPA requests comments on the appropriate role of county governments and appropriate ways to characterize the population of counties under this approach.[16] This approach controls more sources of storm water, but imposes regulatory burdens on additional municipal entities.

(ii) *Focus on population density.* Alternatively, EPA could focus on the population density of metropolitan areas instead of the population within a particular municipality or municipal system, and require permits for discharges from municipal separate storm sewers in areas of a specified density. Urban storm water runoff is related to the density of urban development, the increase in impervious areas, and the reduction in the area of recharge and infiltration zones. EPA requests comment on the use of urbanized areas designed by the Bureau of Census as a tool for characterizing population density and development patterns.[17]

(iii) *Focus on population growth.* Focussing on population growth in addition to, or in place of, population density might be an additional consideration in implementing this option.[18] Studies have shown that it is much more cost effective to develop measures to prevent or reduce pollutants in storm water during new development than it is to correct these problems later on.[19] In addition, appropriate storm water measures for new development can prevent or minimize irreversible degradation to surface waters. This approach might serve to minimize the impact of small and lightly-developed population centers, but it would still increase the burden on a number of municipalities not presently regulated under Phase I.

(c) *Continued reliance on Phase I MS4s to control Phase II sources which discharge through their system.* Under this approach, EPA would generally not designate additional individual sources (such as commercial and light industrial sources) which discharge through a large or medium MS4 as needing their own NPDES permit. Instead, EPA would continue to rely on municipalities to identify priority storm water discharges and develop appropriate controls for those discharges as part of requirements to develop and implement municipal storm water management programs. This option addresses some currently unregulated sources, allows for flexibility and consideration of local factors, and avoids duplicative regulation at the local, national and State level. This approach also relies on existing institutional frameworks of municipalities[20] as well as the institutional framework that EPA envisions municipalities will develop pursuant to NPDES requirements.[21] However, it imposes additional administrative and regulatory costs on local governments and may result in varying levels of control among municipal programs. The Agency requests comment on whether municipalities are in the best position (with assistance from EPA and authorized NPDES States through technical guidance) to identify priority sources which discharge through their MS4, or whether EPA should attempt to designate such additional sources as needing an NPDES permit. The Agency also requests comments on the appropriate funding mechanisms for MS4s (e.g. storm water utilities, various fees, general revenues, etc.), and opportunities for municipalities to modify existing functions to address storm water concerns.

(d) *Identify additional Phase II activities other than MS4s based on comparative loadings.* EPA could use available information (such as case studies and other research) to prioritize Phase II sources in terms of their relative pollutant loadings as well as the type and nature of those loadings. On this basis the Agency could issue regulations to target those general activities which contribute the highest loadings of pollutants to receiving waters as needing an NPDES permit. This option is consistent with the technology-based approach reflected in the existing CWA. It would provide more comprehensive coverage and clarify the program. It would also avoid expensive and time consuming debates regarding the specific causal relationship between a particular storm water discharge and site by site specific receiving water quality impact. However, it would impose further administrative and analytical burdens in terms of gathering additional loadings information on a national basis. This approach may also result in including

---

[15] For more information see: William A. Macaitis, "Regional Storm Water Management Trends", and: L. Scott Tucker, "Current Programs and Practices in Storm Water Management", Water and the City: the Next Century, Public Works Historical Society, 1991.

[16] The 1990 Census indicates that 447 counties have a population of 100,000 or more. The current definitions of large and medium MS4 address 47 of these counties not already covered by Phase I of the program.

[17] The Bureau of Census defines urbanized areas comprised of a central city (or cities) with a surrounding closely settled area. The population of the entire urbanized area must be greater than 50,000 people, and the closely settled area outside the city, the urban fringe, must have a population density generally greater than 1,000 persons per square mile (just over 1.5 persons per acre) to be included. The Bureau of Census defined 396 urbanized areas in the United States based on the 1990 Census. These urbanized areas have a combined population of 158.3 million, or 63.6 percent of the nation's total population. However, these areas only account for 1.5 to 2 percent of the land surface of the country.

[18] Most Urban growth occurs in urban fringe areas outside of large core cities. For example, between 1970 and 1980, the population in those parts of Census designated urbanized areas that are outside of incorporated cities with a population of 100,000 or more increased by 18.9 million. During this same time period, the population of incorporated cities with a population of 100,000 or more (Phase I cities) increased by only 0.6 million, with the population of many of these cities decreasing.

[19] For example, see "Results from the Nationwide Urban Runoff Program, Vol 1—Final Report", EPA, 1983.

[20] Examples of municipal functions that can be adapted to provide for consideration of storm water concerns include oversight of new development, fire safety inspections, pretreatment program implementation, flood control activities, management of municipal lands and activities, and maintenance of public roads.

[21] The NPDES regulatory framework for permits for large and medium MS4s envision that municipalities will be required to develop and implement storm water management programs to reduce pollutants in non-storm water discharges (e.g. illicit connections and improper dumping); storm water from residential and commercial areas; storm water discharges from industrial activities; and storm water discharges from construction activities.

VOL 12

4487

more sources than necessary due to differences in loadings and existing storm water controls, both structural and non-structural, across similar activities. The regulatory burden would be determined in large part by the overall control strategy chosen to implement this approach.

This approach differs from those outlined under options (b) and (c) in that it relies on direct permitting by EPA and authorized NPDES States rather than requiring municipalities to develop programs to address sources. The Agency requests comments on which sources of pollutants are better addressed by specific NPDES permit requirements rather than through municipal storm water management programs required pursuant to NPDES permits for MS4s. For example, activities generally located in rural areas such as feedlots, orchards, and golf courses most likely are not suited for control through municipal storm water management programs required under permits for MS4s. Although large feedlots (those subject to effluent limitations guidelines) presently are covered under Phase I, smaller feedlots represent a significant source of pollutants such as suspended solids, BOD, and nutrients such as nitrates and phosphates. In addition, storm water discharges from commercial activities such as greenhouses, nurseries, and golf courses might be more effectively controlled under a separate NPDES permit requirement than through a MS4 program. As another example, many commenters from all levels of State and local government have expressed concern about municipalities being required to control pollutants from State highways (see November 16, 1990 (55 FR 48041)).

(e) Geographic targeting. EPA could regulate Phase II storm water activities on a watershed, waterbody, or regional basis to protect water quality, control water quality problems and attain designated uses in specific areas. EPA could:

(i) Designate additional municipal and individual sources for permitting in specific areas. A key aspect of this approach would be developing a list of waters that are not meeting designated uses due to pollution from storm water runoff (from section 305(b) reports or from the section 304(l) list of waters) or where sensitive waters or outstanding national resource waters need special protection. This approach could help to achieve water quality goals and would avoid imposing a burden on other dischargers, but would not be uniformly applied on a national basis. This option is also reactive in nature, and overlooks the advantages of prevention over remediation. The availability of technical information and water quality data limitations and the administrative and regulatory burden associated with collecting and analyzing additional data would have to be carefully considered in evaluating the feasibility of this approach.

(ii) Designate additional sources for permitting or special requirements within rainfall zones. The nature of storm water problems varies between areas with frequent rainfall, where storm water flows are high with continual pollutant loadings, and areas with low or seasonal rainfall, where intermittent flows carry highly concentrated loadings of pollutants accumulated during dry weather which result in high shock loadings to receiving waters. This option would recognize these regional variations and tailor regulatory requirements for Phase II discharges (monitoring, best management practices, reporting) to the local nature of rain events. However, immediate environmental benefits could be delayed due to the inexact nature of rainfall zones and the scarcity of comprehensive information upon which to base regulatory requirements.

(f) Establish requirements for State storm water management programs. Under this approach, EPA could develop requirements for State storm water management programs under section 402(p)(6) for the CWA which would require States to identify additional classes of storm water discharges for control. This approach may offer the advantages of additional flexibility for States to target sources based on State specific factors (climate, water resources, development patterns) and provide additional flexibility in the type of administrative program developed. However, the disadvantages of this approach include the need for generating additional resources at the State level at a time when State capacity is also strained, and possible disparities in programs in different States. Such disparities could make it hard for a State to develop an aggressive program when neighboring States have lesser requirements. Further, this approach may create additional burdens on EPA to provide adequate oversight of the State programs. EPA also requests comments on the appropriate role of EPA in reviewing State plans or developing minimum requirements for State plans and how that role should change, if at all, for States without authorized NPDES programs. The Agency requests comments on appropriate criteria for evaluating the adequacy of State programs, and appropriate procedures for periodic review and evaluation of such programs. EPA also requests comments on whether this approach could be harmonized with the requirements of section 402(p)(6) for EPA to take the lead in developing management practices and controls for Phase II sources, or whether this approach might also require statutory change.

(g) Rensselaerville focus groups. There were several common themes recognized by the focus groups with regard to identifying potential sources to be included in Phase II.

(i) Groups suggested that targeting be done on a watershed basis, with information gathered as a part of Phase I used to help identify sensitive watersheds. It was noted that this type of targeting approach may require intergovernmental agreements for effective implementation.

(ii) Teams emphasized that the focus of Phase II should be on "bad actors", i.e. those sources that are known to cause significant water quality problems. Sources identified by team members included: Gas/auto service industries, transportation, highway systems, land use development and agricultural sources. There was a consensus among groups that facilities not contributing to impairment of water quality should be able to gain an exemption from controls, permits, fees, and implementation of BMP's. Teams concluded that SIC categories are an ineffective way to designate covered sources and that targeting should be done based on the degree of risk that a given facility poses, due to possible differences between facilities in any one industry.

(iii) Focus groups recommended that small municipalities be included in Phase II but with simplified application requirements. Participants felt that municipalities impacting watersheds of concern or those connected to larger MS4s should be targeted.

(iv) Participants in the study felt that EPA should hold off on selecting sources for Phase II until the Agency has carefully looked at the date gathered during Phase I. It was noted that numerous sources of information are available which could help determine targeting priorities, for example, 305(b) reports, information from Phase I program sources, NURP, and the first Report to Congress.

VOL 12

4488

VOL 12

2. Control Strategies

The current Phase I storm water program for industrial sources is implemented through the NPDES program with a heavy emphasis on the use of general NPDES permits which require the implementation of best management practices including development of site specific pollution prevention plans. Phase I requirements for large and medium MS4s focus on system-wide permits which require the development and implementation of municipal storm water management programs.

Regardless of how additional Phase II storm water activities are identified—whether they are designated under 402(p)(2)(E), comprehensively covered, or selectively targeted for further controls, a key issue on which EPA requests comment is what are the appropriate tools or control strategies to put in place which assure pollutant loading reductions and water quality improvement?

(a) Continued reliance on NPDES program. One option is the continued reliance on individual or general NPDES permits for individual sources, and system-wide permits for MS4s. Developing or processing specific application forms for and issuing individual permits for all Phase II sources may well be the most resource intensive of any control approach. Consistent with EPA's four tier Phase I permitting strategy for industrial storm water sources, individual permits may be most appropriate in those case specific situations where a particularly difficult or complex discharge situation needs to be addressed. By contrast, input from the public and regulated community to date suggests that heavy reliance on general permits may well be a very effective alternative within the NPDES system. EPA solicits comments on whether continued reliance on NPDES permitting as the overall control strategy for Phase II is the most appropriate approach. An extensive State and national administrative NPDES infrastructure already exists and is being relied upon for Phase I and reliance on the general permit is increasingly favored as an appropriate storm water control strategy. However, the capacity of the current system with its existing resources to accommodate a significant number of additional permittees has already been called into question for Phase I. A very real issue exists as to whether the permitting Agencies have the resources to address more than a limited number of additional Phase II permittees.

(b) Continued reliance on nonpoint source program. Another approach includes continued reliance on the State nonpoint source programs under section 319 of the CWA and future reliance on programs under section 6217 of the CZARA in coastal areas to control Phase II storm water sources not explicitly addressed or designated under Phase I.

The structure, organization, and working relationship within EPA and State offices for the section 319 program are established and proven successful. The States have taken the lead under section 319 to develop assessments of storm water/nonprofit source impacts and management programs to implement controls. EPA has approved all States assessments, 44 complete management programs, and portions of all the remaining State management programs. The States management programs typically include continued problem assessments and monitoring, voluntary control measures, mandatory control measures established under State and local authorities, State funding assistance, public outreach, technical assistance, enforcement, targeting of priority waters, and coordination with other Federal and State programs and agencies. Therefore, the section 319 program's potential ability to control Phase II sources is high. Also, section 319 programs are founded on a watershed planning and pollution prevention/source reduction approach which may be an effective vehicle to provide program and technical assistance to State and local governments.

In addition, the new CZARA program provides an excellent tool to address Phase II sources in the coastal zone in a comprehensive manner. EPA emphasizes that the goals of the NPDES and CZARA programs are complementary. Many of the techniques and practices used to control urban runoff are equally applicable to both programs. While different legal authorities and geographic coverage may apply to specific sources. States have the option to implement CZARA section 6217(g) management measures throughout the coastal zone, as long as NPDES requirements are met for those entities subject to NPDES requirements. States outside of the coastal zone may also voluntarily incorporate the management measures appropriate to particular sources or specific problems into the State's CWA section 319 program.

(c) Mandatory performance standards, guidelines, management practices and/or treatment requirements. An alternative option might also be to develop a set of mandatory national Phase II control guidelines that apply directly to Phase II storm water activities without a permit. The national pretreatment categorical effluent guidelines is an example of this approach. Permits by rule or general permits without application or reporting requirements are a similar concept. A variation on this approach might include the development of minimum categories or classes of BMP's or pollution prevention approaches with a requirement that elements from each class be chosen and implemented on a facility or system specific basis. At one level, this approach would appear to reduce the regulatory and administrative burden associated with submission of Phase II storm water applications. However, as a technical matter, it may be extremely difficult to develop one national rule that appropriately addresses all Phase II storm water activities. Developing such a rule may take a significant amount of time and may also entail substantial monitoring and data collection. A further issue upon which EPA solicits comment is whether a national rule would be the most effective approach given that many members of the Phase II universe may not be familiar with national regulations and may not even be aware that such requirements apply to them. EPA recognizes that implementation of control strategies other than NPDES permitting would probably require statutory change and requests comments on what changes would be appropriate.

(d) Rensselaerville focus groups. Focus groups identified several common themes with regard to controls that should be put in place for Phase II:

(i) Focus groups recommended that if a permitting process is to be continued for Phase II sources, NPDES general permits should be used, and the focus should be on the implementation of effective BMP's. Participants felt that permits should be simpler, less costly, and that EPA should make absolutely clear to applicants what information is required through the use of checklists of inclusion, a menu of potential BMP's, and other documents to assist permitees. The team members again stressed that exemptions from permitting should be available for sources not contributing to water quality problems.

(ii) The teams concluded that education is often overlooked and that it should be a primary component of any Phase II program. Team members felt that education is important for all audiences and that local level education

4489

R0037798

for the public and affected industry is critical to the success of the program.

(iii) There was an agreement among teams that there should be more emphasis on voluntary programs, perhaps similar to those under the 319 nonpoint source program. Groups also suggested that for facilities that have contact with storm water, there should be limited additional governmental intervention, but rather an emphasis on pollution prevention incentives, BMP's, and specific pollution prevention techniques. Participants stressed that pollution prevention should be emphasized, particularly with new development. Some suggested prevention methods included: recycling storm water, good housekeeping practices, plantings to minimize runoff, street sweeping of work areas on a daily basis, storm water collection methods, coverage of storage areas, changing manufacturing processes to minimize pollutants and better controls of air emissions.

(iv) Groups felt that there should be correlation between the severity of the problem and the degree of controls required and that fines and fee structures could be used as "carrot-stick" measures to aid implementation.

3. Deadlines

Section 402(p) presently provides that the current prohibition against permitting Phase II sources expires on October 1, 1992. EPA solicits comment on the possible options for alternative deadlines for Phase II permit application requirements and statutory revisions of the CWA. One option is for Congress to extend the current October 1, 1992 deadline for Phase II sources. Under this option, EPA requests comment on what the new Phase II date should be and why one particular extension is more appropriate than another. For example, one possible date might be October 1, 1995, to allow one year for additional data gathering and public input on appropriate Phase II sources and control strategies and then two additional years to propose and finalize Phase II regulations.

Another strategy might be to adopt a phased set of Phase II deadlines with high priority storm water sources covered first and lower risk sources addressed at a later date.

A third approach follows option 1 under Targeting; that is, to eliminate the Phase II deadlines and follow option 1 or direct EPA to follow some other option.

Focus group recommendations from the Rensselaerville study suggested that a minimum of 2–3 years is needed to prepare for Phase II, with at least a year dedicated to looking at data gained from Phase I of the storm water program and other documents such as the first Report to Congress. Participants also felt that the effectiveness of presently used BMP's needs to be looked at to determine variations in effectiveness between different geographic locations and pollutants.

III. Request for Comments

EPA is requesting comments on all aspects of the Phase II storm water permitting program. EPA is soliciting general comments on environmental objectives and economic impacts, as well as specific recommendations and implementation advice on each of the options outlined above. Based on comments received and the results of the two studies required under CWA section 402(p)(5), EPA may propose a rule under section 402(p)(6) or solicit additional comments on options again when more data becomes available. In addition, EPA welcomes data or information from ongoing studies that support specific comments or recommendations.

A. General Issues for Comment

Based on the discussion above and the President's memorandum on reducing the burden of government regulation, EPA requests comment on the advantages and disadvantages of each option outlined above as well as any other potential approaches in terms of the following factors.

1. How well does the approach perform with respect to the environmental goals of protecting water quality, reducing pollutant loadings, and achieving designated uses in impaired waters? EPA requests comment on which of these approaches most lends itself to the documentation and establishment of environmental baselines and identification of appropriate environmental indicators against which to evaluate progress. EPA specifically solicits input on appropriate environmental indicators in connection with any of the approaches outlined above or identified by a commenter.

2. Does the option balance the need for regulation to protect/improve the environment with the desire to minimize the regulatory burden and maximize the cost effectiveness of the approach?

3. Does the option help to reduce the regulatory burden on potential permittee, while still maintaining environmental benefits?

4. Does the option help to reduce the administrative burden on Federal, State and local government, so that resources are used to address important environmental problems efficiently?

5. To what extent does the option support or provide an incentive or additional flexibility for implementing pollution prevention and other innovative permit approaches?

6. Does the option allow or encourage the use of market incentives or trading to promote greater or more effective loadings reductions and water quality improvements?

7. What is the impact of the proposed approach on small businesses [12] and communities?

8. does the option allow consideration of the issue of affordability as a factor in determining which Phase II sources should be controlled? For example, some data indicates that average per capita income in suburban fringe areas is substantially higher than in core cities. Does the option allow this to be factored in when identifying high priority groups or selecting appropriate control strategies?

EPA requests specific implementation recommendations based on the respondent's general evaluation of the options outlined above. EPA also seeks detailed comments on how the option will be implemented and ways to refine the respondent's preferred approach. For example, address issues of affordability, cost effectiveness and possible funding mechanisms and sources, in addition to providing case examples where available of successful State or local implementation of a preferred option. Respondents should also consider the need for statutory changes or rulemaking to implement recommended approaches.

B. Current Classification of Regulated Discharges

The current regulatory framework of Phase I is summarized in appendix A. This information may help respondents to understand which types of municipalities and commercial and light industrial activities are not currently regulated under Phase I of the program. Sources exempted from Phase II and some sources potentially covered under Phase II are summarized in appendix B.

IV. Review and Analysis Requirements

Various reviews and analyses are required to assess the economic or paperwork impact of new rulemaking activities under Executive Order 12291, the Paperwork Reduction Act (44 U.S.C. 3501, et. seq.), and the Regulatory Flexibility Act (5 U.S.C. 601, et. seq.).

[12] With respect to impacts on municipalities, the agency requests comments on options municipalities have for generating the revenue required to run such programs.

VOL 12

4490

R0037799

These assessments are not necessary for this notice, which merely requests comments on ways to reduce the regulatory burden of potential future rulemaking.

Dated: September 1, 1992.

Martha G. Prothro,

Acting Assistant Administrator.

Appendix A. Facilities Covered in Phase 1

1. Industrial Facilities

EPA has defined the term "storm water discharge associated with industrial activity" in a comprehensive manner to address over 100,000 facilities. All storm water discharges associated with industrial activity that discharge directly to waters of the United States or through municipal separate storm sewer systems are required to obtain NPDES permits, including those which discharge through systems located in municipalities with populations of less than 100,000. Discharges of storm water to a combined sewer system or to a Publicly Owned Treatment Works (POTW) are excluded. Facilities with storm water discharges associated with industrial activity include: manufacturing/industrial facilities; construction operations disturbing five or more acres; hazardous waste treatment, storage, or disposal facilities; landfills; certain sewage treatment plants; recycling facilities; powerplants; mining operations; some oil and gas operations; airports; and certain other transportation facilities. Operators of industrial facilities that are Federally, State or municipally owned or operated (with the exception of certain facilities owned or operated by a municipality of less than 100,000 people [1] that meet the description of the facilities listed in 122.26(b)(14) (i)–(xi), described below, must also submit applications.

SUMMARY OF INDUSTRIAL ACTIVITIES COVERED UNDER PHASE I OF THE STORM WATER PROGRAM

40 CFR 122.26(b)(14) Subpart	
(i)	Facilities subject to storm water effluent limitations guidelines, new source performance standards, or toxic pollutants effluent standards under 40 CFR, Subchapter N (except facilities which are exempt under category (xi)).
(ii)	Facilities classified as
	SIC 24 (except 2434)—Lumber and wood products.
	SIC 26 (except 265 and 267)—Paper and allied products.
	SIC 28 (except 283 and 285)—Chemicals and allied products.
	SIC 29—Petroleum and coal products.
	SIC 311—Leather tanning and finishing.
	SIC 32 (except 323)—Stone, clay and glass products.
	SIC 33—Primary metal industries.
	SIC 3441—Fabricated structural metal.
	SIC 373—Ship and boat building and repairing.
(iii)	Facilities classified as:
	SIC 10—Metal mining.
	SIC 11—Anthracite mining.
	SIC 12—Coal mining.
	SIC 13—Oil and gas extraction.
	SIC 14—Nonmetallic minerals, except fuels.
(iv)	Hazardous waste treatment, storage, or disposal facilities, including those that are operating under interim status or a permit under Subtitle C of the Resource Conservation and Recovery Act (RCRA).
(v)	Landfills, land application sites, and open dumps that receive or have received any industrial wastes including those that are subject to regulation under subtitle D or RCRA.
(vi)	Facilities involved in the recycling of material, including metal scrapyards, battery reclaimers, salvage yards, and automobile junkyards, including but limited to those classified as.
	SIC 5015—Motor vehicle parts, used.
	SIC 5093—Scrap and waste materials.
(vii)	Steam electric power generating facilities, including coal handling sites.
(viii)	Transportation facilities covered by the following SIC codes which have vehicle maintenance (including vehicle rehabilitation, mechanical repairs, painting, fueling, and lubrication), equipment cleaning operations, or airport de-icing operations, or which are otherwise listed in another category, are included.
	SIC 40—Railroad transportation.
	SIC 41—Local and suburban transit.
	SIC 42 (except 4221-25)—Motor freight and warehousing.
	SIC 43—U.S. Postal Service.
	SIC 44—Water transportation.
	SIC 45—Transportation by air.
	SIC 5171—Petroleum bulk stations and terminals.
(ix)	Treatment works treating domestic sewage or any other sewage sludge or wastewater treatment device or system, used in the storage, treatment, recycling, and reclamation of municipal or domestic sewage, including lands dedicated to the disposal of the sewage sludge that are located within the confines of the facility, with a design flow of 1.0 Million Gallons per Day (MGD) or more, or required to have an approved pretreatment program under 40 CFR Part 403. Not included are farm lands, domestic gardens, or lands used for sludge management where sludge is beneficially reused and which are not physically located in the confines of the facility, or areas that are in compliance with Section 405 of the CWA.
(x)	Construction activity including clearing, grading, and excavation activities except operations that result in the disturbance of less than 5 acres of total land area which are not part of a larger common plan of development or sale[1].
(xi)	Facilities under the following SICs [which are not otherwise included in categories (ii)–(x)], including only storm water discharges where material handling equipment or activities, raw materials, intermediate products, final products, waste materials, byproducts, or industrial machinery are exposed to storm water[1].
	SIC 20—Food and kindred products.
	SIC 21—Tobacco products.
	SIC 22—Textile mill products.

[1] In the Intermodal Surface Transportation Efficiency Act of 1991, Congress provided that industrial activities owned or operated by municipalities with a population of less than 100,000 be placed into Phase II of the storm water program with the exception of airports, power plants and uncontrolled sanitary landfills.

VOL 12

4491

SUMMARY OF INDUSTRIAL ACTIVITIES COVERED UNDER PHASE I OF THE STORM WATER PROGRAM—Continued

40 CFR 122.26(b)(14) Subpart	
	SIC 23—Apparel and other textile products
	SIC 2434—Wood kitchen cabinets
	SIC 25—Furniture and fixtures
	SIC 265—Paperboard containers and boxes
	SIC 267—Converted paper and paper board products (except containers and boxes)
	SIC 27—Printing and publishing
	SIC 283—Drugs
	SIC 285—Paints, varnishes, lacquer, enamels
	SIC 30—Rubber and misc. plastics products
	SIC 31—(except 311)—Leather and leather products
	SIC 323—Products of purchased glass
	SIC 34 (except 3441)—Fabricated metal products
	SIC 35—Industrial machinery and equipment, except electrical
	SIC 36—Electronic and other electric equipment
	SIC 37 (except 373)—Transportation equipment
	SIC 38—Instruments and related products
	SIC 39—Miscellaneous manufacturing industries
	SIC 4221—Farm products warehousing and storage
	SIC 4222—Refrigerated warehousing and storage
	SIC 4225—General warehousing and storage

[1] On June 4, 1992 the United States Court of Appeals for the Ninth Circuit found that EPA's rational for exempting construction sites of less than five acres and certain uncontaminated storm water discharges from category xi light industrial facilities from Phase I of the storm water program to be invalid and has remanded these exemptions for further proceedings (see *Natural Resources Defense Council v. EPA* No. 91-70176).

Source: FEDERAL REGISTER, Vol. 55, No. 222, p. 48065, November 16, 1990

2. Municipal Facilities

"Municipal separate storm sewer" is defined as any conveyance or system of conveyances that is owned or operated by a State or local government entity designed for collecting and conveying storm water which is not part of a Publicly Owned Treatment Works. The application requirements do not apply to discharges from combined sewers (systems designed as both a sanitary sewer and a storm sewer). Municipal separate storm sewer systems that are addressed by the November 16, 1990 regulations include storm sewers located in one of 173 cities with a population of 100,000 or more; located in one of the 47 counties identified by EPA as having large populations in unincorporated, urbanized areas; and systems that are designated by the Director based on consideration of the location of the discharge with respect to waters of the United States, the size of the discharge, the quantity and nature of the pollutants discharged to waters of the United States, and other relevant factors. These are named in Appendices F–L of the November 16, 1990, regulation.

INDUSTRIAL AND MUNICIPAL PERMIT APPLICATION DEADLINES

Type of Application	Deadline	
● Individual	October 1, 1992	
● Group	Part 1	Part 2
All industrial activities except those owned or operated by a municipality with a population of less than 250,000	September 30, 1991	October 1, 1992
Industrial activities owned or operated by a municipality with a population of 100,000 to 250,000	May 18, 1992	May 17, 1993
● General Permit NOI	Deadline established in the general permit, but no later than October 1, 1992 for existing sources.	
	Part 1	Part 2
Large Municipalities	November 18, 1991	November 16, 1992
Medium Municipalities	May 18, 1992	May 17, 1993

Appendix B. Potential Universe of Phase II Dischargers

Phase II potentially includes all point source discharges of storm water to waters of the United States (including Municipal Separate Storm Sewer Systems) that are not regulated under Phase I of the storm water program (See Appendix A). The following table illustrates those types of operations which have been statutorily exempted from both Phase I and Phase II of the NPDES storm water program along with a general list of potential Phase II sources:

Statutory / Regulatory exemptions:	● Non Point Source Silviculture Activities. ● Agricultural Runoff and Irrigation Return Flows. ● Uncontaminated discharges from Mining, Oil and Gas Operations.
General categories of sources	● All municipalities with populations less than 100,000.

VOL 12

4492

- All industrial activities not regulated under Phase I (including those owned/operated by municipalities under 100,000 [illegible] farms, auxiliary facilities [illegible])
- Commercial activities with industrial components (gas stations, dry cleaners)
- Construction activities involving less than 5 acres [1]
- Large parking lots (shopping malls, stadiums)
- Residential property
- Recreational areas (ski areas, golf courses, amusement parks)
- Livestock facilities (stables, feedlots not addressed by Phase I regulations [2], etc.)
- Greenhouses, nurseries

[1] On June 4, 1992 the United States Court of Appeals for the Ninth Circuit found that EPA's rationale for exempting construction sites of less than five acres from Phase I of the storm water program to be invalid and has remanded the exemption for further proceedings (see *Natural Resources Defense Council v. EPA* No. 91-70176).

[2] Feedlots, as a class of facilities, have been associated with high loadings of pollutants such as suspended solids, BOD, and nutrients such as nitrogen and phosphorus, and could be an example of a targeting approach based on high loadings.

ACKNOWLEDGEMENTS

We are most grateful for direction and guidance for this project provided by the Office of Wastewater Enforcement and Compliance, Michael B. Cook, Director; James Horne, Project Officer.

We also acknowledge the efforts of those persons who participated in the focus groups, the expert surveys, the public forums, and the "design team" session. The thoughtfulness of opinions and insights voiced is impressive.

We are encouraged by the willingness of people with very different perspectives to not only listen carefully to each other but to seek common ground. The prospects for collaborative work are strong.

EXECUTIVE SUMMARY

In December 1991, the Deputy Administrator of the U.S. Environmental Protection Agency (EPA) asked the Office of Water to undertake a research project with two objectives: 1) identify ways to improve and streamline the existing storm water regulatory program implemented by the agency under Section 402 (p) (2) of the Clean Water Act: and 2) define and annotate options for controlling sources of storm water runoff designed for Phase II of this same section.

In response to this request, the Office of Wastewater Enforcement and Compliance (OWEC) engaged The Rensselaerville Institute to develop a two-part project to gather and integrate diverse opinion and insight on ways to improve the efficiency and effectiveness of the existing Phase I program and the best possible response for the Phase II program designed to cover remaining storm water sources and problems.

Part I of the project was conducted during February and March, 1992 when six focus groups were held around the U.S. to gain user feedback on how the current regulations and implementation procedures could be improved and streamlined. These groups, which included representation by both public- and private-sector permittees as well as regulatory agencies, private consulting firms, industry, and environmental interests, identified numerous ways EPA and others could address permitting and compliance procedures seen as difficult or problematic.

Part II of the project began with an Expert Survey of 32 persons highly knowledgeable in storm water and its control who represented different perspectives (academic/research, state/local government, commercial development, environmental advocacy, and consultant/engineering) and different geographic areas. Experts were asked to respond to a set of options for targeting and controlling sources and to suggest additional alternatives as well. Insights on voluntary measures that have proven effective in storm water control were solicited through a separate survey of five experts in nonpoint program approaches.

Based on the results of these surveys, three public meetings were announced in the Federal Register and held in Denver, San Francisco and Washington, DC during June, 1992. Those attending were divided into teams and asked to define their own preferred strategies for a Phase II program response, including definition of sources to be regulated, the preferred method of control (permit-based or other) and their sense of both timetable and the role EPA should play.

Finally, a small group of insightful individuals representing diverse viewpoints from both point source and nonpoint source programs was convened for a strategy design meeting for the purpose of adding greater depth and breadth to one or more Phase II approaches identified in the public meetings. From this group, a ten-point strategy was created, as well as a series of recommendations to EPA on developing the second phase of the storm water program.

This Executive Summary presents the findings from each of these activities in summary form. More complete recommendations are contained in the body of Volume I. The project data base is contained in Volume II.

Summary of Findings on Improving Phase I of the Storm Water Program

Forty individuals participated in focus groups held in Atlanta, GA; Hartford, CT; Chicago, IL; Washington, DC; Seattle, WA; and Phoenix, AZ. Together, the participants included all identified viewpoints and separable interests--including EPA regional staff, state and local government officials, engineering consultants, environmental advocates, and representatives of corporations included in Phase I permitting.

Participants responded to a set of questions which probed for opinion and insight on such matters as the unclear aspects of the Phase I regulations, additional steps that should be taken to simplify the process and help permittees to achieve compliance, and the relative merits of individual and group permits. In addition to participant responses to core questions, the afternoon of each session was used to further elaborate problems and solutions of interest to participants in an informative format.

While many issues raised were location- or source-specific, some spanned geographic and demographic boundaries. Eight issues common across all focus groups were identified as key areas to be clarified and/or modified to improve program implementation:

1. EPA has not been clear about the intended goals of the regulations. A stronger sense of the relative importance of storm water in the framework of environmental risk is needed, as is clarity about short range and long term targets. There is a difference, for example between clean water standards and stream health standards. It is clear that there are storm water permits. It is not clear how the permits reflect a coherent program.

2. The expense of program implementation is significantly higher than EPA has estimated. There is great concern over what the program's real costs have been in terms of dollars and manpower costs of preparing a permit application, and the anticipated costs of achieving compliance. A broader concern: municipalities now beleaguered by resource shortfalls cannot reasonably afford the combined costs of compliance with all environmental regulations.

3. The administrative complexity of the program is enormous at the federal, state and local levels, and has quickly outpaced the availability of resources and manpower needed to carry it out. In some cases, field staff have been

VOL 12

4501

pulled in simply to process the paperwork involved.

4. Clarification is needed on the roles and expectations EPA has for itself, states and permittees. What is clear to everyone is that EPA does not have the capacity to administer and enforce the program alone. This cannot be seen as an EPA program administered in a "command and control" style totally from Washington. It must involve active participation, not simply passive compliance, from all levels involved.

5. More technical support for the program is needed. Expanded information explaining the regulations and how to implement them is especially needed. Also, there should be less "national level" support and more focus on regional conditions. Much of the content of storm water workshops held at EPA headquarters is irrelevant to any given participant.

6. States need EPA to either clarify how to interpret unclear points of the regulations, or allow them the latitude to make the interpretations themselves. One unclear area is the inconsistencies and inequalities created by use of industrial SIC codes in such areas as transportation. Another murky area is the group application process.

7. EPA should consider consolidating programs in order to address water pollution in an efficient and cost-effective manner. A watershed approach is preferable to current practices of separating problems by media.

8. General permits are "the way to go" and EPA should continue to focus on and accelerate efforts in this direction.

Many focus group members made a point of indicating their pleasure with the focus group format used and the ways in which EPA had 1) encouraged interaction and customer insight and 2) listened carefully to their advice. A complete report on focus group responses and conclusions is contained in the body of this publication.

Summary of Findings on Designing Phase II of the Storm Water Program

Expert Survey

The second part of the Rensselaerville project began with a survey of a select group of 32 point source storm water program experts from across the country. The purpose was to solicit opinions on ways to implement the second phase of the storm water program. Five perspectives were represented: academic/research; commercial development; consultant engineering/legal; environmental advocacy; and state/local government. A first mail-back survey round gained opinion and consensus on relevant issues and

VOL 12

4502

options for addressing Phase II sources. Data from the first set of returned surveys were analyzed and given back to participants in a second survey round, which refined positions and created more options for Phase II consideration.

To ensure inclusion of all critical perspectives, five nonpoint source program experts were asked to provide feedback, with emphasis on potential voluntary approaches for addressing Phase II sources.

While approaches recommended differed by profession and geography, these common targeting themes emerged for identifying whom to include in Phase II:

- develop a geographically-based phasing plan by watershed impairment/severity of threat;
- determine selection criteria for pollution sources and use these to identify municipalities that should participate;
- do pilot projects first, evaluate, and then develop and implement a strategy;
- encourage and fund comprehensive basin research and planning to guide targeting;
- require Phase II industries to be covered under Phase I general permits;
- develop national guidelines, and leave selection of sites and methods to state discretion;
- require smaller communities (< 100,000) to apply for permits only when their storm water contributes a significant pollution problem;
- designate problem areas, establish permit requirements for municipals regardless of population, and allow municipals to exclusively regulate industries; and
- initiate a focused dialogue with key stakeholders (applies to both targeting and controls).

Common themes expressed for control strategies included:

- build a Best Management Practices (BMPs) menu that can be used by states to implement and verify progress;

- require localities to select from a list of BMPs the ones most appropriate for their needs and apply industry-specific BMPs nationwide with allowance for state/local officials to modify;

- provide nationwide public education and community-wide public education on the need for storm water control;

- establish national or industry-specific minimum practices for controlling storm water;

- implement good housekeeping and source reduction practices;

- require routine certification and audit of storm water pollution plans and practices;

- establish industry-specific and watershed-specific BMPs; and

- establish BMPs required nationwide and strictly enforce. Require facilities to further treat storm water discharges where BMPs are not effective.

The strongest additional factor in nonpoint survey responses was the degree of emphasis placed on education at all levels, including the general public, local and state officials, and local businesses and industry. Education was seen as the key to making voluntary approaches effective. Voluntary compliance, in turn, was then advanced as highly cost effective.

Respondents feel that EPA must be the "stick" that would fall--with permit requirements, fines, etc.--if a storm water source does not voluntarily take action and achieve certain minimum goals. But limited manpower and financial resources form a rationale for not addressing Phase II with the costly conventional federal mandates of Phase I.

Public Meetings

Three meetings were conducted to gain public responses to options for targeting and controlling Phase II sources. They were held in Denver, CO; San Francisco, CA; and Washington, DC during June, 1992. At each meeting, three experts selected from the Expert Survey process presented their ideas on a regulating strategy for the moratorium sources. Participants were then divided into small task teams, and given the charge of devising their own strategies for targeting and controlling Phase II sources. A strategy template was provided to guide group consideration of three key issues: 1) who should be covered under Phase II; 2) what controls are needed; 3) over what timeframe the program should be implemented. At the end of each public meeting, the task teams presented their options to other participants for discussion.

VOL 12

4504

Common strategy characteristics emerged, in many cases paralleling those apparent in the expert survey. For targeting:

- Targeting should be done by watershed. Information gathered from Phase I should help identify sensitive watersheds. This may require intergovernmental agreements.

- The focus should be on "bad actors", i.e., those that are known problem sources. The ones most frequently identified were: gas/auto service industries, transportation, highway systems, land use development and agricultural sources. There needs to be the ability for facilities not contributing impairment of water to gain an exemption from permits, fees, implementation of BMPs. Categories are an ineffective way to designate covered sources - should be done by the degree of risk a given facility poses, because it may not be a whole industry, but rather individual facilities.

- Small municipalities should be included, but they should have a much simpler application process. Or, only small municipalities where a storm water problem is identified should there be required action.

- EPA should defer on selecting targeted sources until the agency has carefully looked at the data gathered during Phase I. Numerous sources of information are available which would help determine targeting priorities, e.g., information gathered through 305b reports, information from Phase I program sources, the NURP study.

For needed and desirable controls, these themes emerged:

- If a permitting process is to be continued for point sources, NPDES general permits should be used, and focus should be on implementing Best Management Practices (BMPs). Permits should be simpler, and much less costly. EPA should make clearer to the applicant what information is required, e.g. provide the permittee with a "checklist of inclusions" for the application, develop a menu of BMPs. Permit exemptions should be granted to those targeted sources who offer no contribution to the problem.

- Education should be seen not as an "add-on", but rather as a primary tool for effective control. Locally implemented education for public and industry is especially important; the premise is that information and conviction born of education will encourage many to take the needed preventive and remedial steps.

- More emphasis should be placed on voluntary programs, e.g., 319 nonpoint

VOL 12

4505

source-like programs. For facilities with contact with storm water, there should be little or no government intervention, but rather emphasis on pollution prevention incentives, BMPs, and measures of pollution prevention.

Pollution prevention programs should be emphasized, particularly with new development. Some suggested prevention methods included: recycling storm water, "good housekeeping" practices, plantings to minimize runoff, street sweeping of work areas on a daily basis, storm water collection methods, coverage of storage areas, changing manufacturing processes to minimize pollutants, and improvement of air emissions.

- Closer correlation should exist between the severity of the problem and the degree of controls required. Fines and fee structures could be used as "carrot-stick" measures.

- BMPs should be required based upon the specific pollutant problem. EPA should develop a menu of BMPs to assist businesses in determining the appropriate BMP for their problem.

In terms of a timetable for phasing in Phase II, two widespread opinions emerged:

- A minimum of two years is needed to prepare for Phase II, with at least a year dedicated to looking at data gained from Phase I of the storm water program. Effectiveness of presently used BMPs needs to be studied to determine differences in effectiveness between geographic locations and pollutants.

- Whatever the period established for phase-in, it should not begin until promulgation of the regulations.

A final question in the strategy template: "**For whatever strategy is chosen, what could EPA do to make the decision-making process for Phase II more responsive?**" generated responses focused on some common themes:

- Coordinate information dissemination, e.g., set up regional clearinghouses offering such program information as general permit writing, effective applications of BMPs, and examples of successful efforts from programs around the country.

- Provide funding not for program implementation but for needed research, e.g., on BMP effectiveness, and for demonstration projects.

- Set broad guidelines for the program and establish minimum standards, and then allow state and local regulatory agencies determine how to achieve them.

- Develop and implement training programs for regulators, including regional and state, on the program. These people are the ones who will be the informational source for the regulated community, and need to know the details of the program.

As with the focus groups the participants in the public meetings felt positive about the format used. A mail-back survey returned by more than 30% of meeting participants showed that they strongly favored this interactive process over what they perceived as the conventional practice of a stream of public comments that encouraged adversarial positioning and boredom for those listening. Comments of attendees included:

- "The opportunity to formulate an entire strategy to deal with this issue was very useful;"
- "I obtained a better point of view of government's problems and felt that government representatives also obtained a better point of view of industry's problems;"
- "Result was a much less confrontational and much more problem-solving atmosphere;" and
- "It was a valuable way to address drafting of regulations, allowing the regulated community to feel a part of the process."

The body of this report contains a further elaboration of the process and the ways in which it might be used by the EPA in other communication and outreach efforts.

Design Team Meeting

A meeting of seven point and non-point storm water program experts, all of whom were survey respondents, and selected EPA staff was convened in Washington DC on September 17-18, 1992. The purpose was to gain the experts' varied insights on development of the Phase II storm water program and to build a strategy, or multiple strategies, for addressing Phase II sources.

Many discussions were specific to certain types of activity--not only municipal or industrial, but to specific kinds and levels of enterprise. Others focused on regional differences--for example the strong distinctions from places that are uniformly wet, uniformly dry, or highly volatile in hydrological terms. Still others found differentiation in scale--such as the difference in impact a regulation would have on a city as compared to a small town. These distinct findings are contained in the full report which follows in this volume.

A broader set of ten recommendations emerged for the major Phase II challenge which generally transcend such differences. They include:

1. **It is possible and desirable to identify priority target areas for which there is widespread consensus concerning their contribution to water pollution.** These areas begin with new development and redevelopment--both residential and commercial. They also include transportation corridors, dense existing development and automotive services.

2. **EPA needs to communicate more clearly and regularly with everyone impacted by the storm water regulations.** The priority focus should be less on the amount of communication and more on different kinds of communication.

3. **EPA could improve program effectiveness, efficiency and cost control in Phase II by "starting small".** The concept of regional and even local prototypes is a way of getting proposed new Phase II frameworks into the hands of users in prompt fashion to build and refine based on early use.

4. **Selectivity in data collection and monitoring is essential.** At present, some data collection frameworks consume tremendous time and money only to yield bad or useless data or murky or disputed conclusions. At other times, very simple actions taken with known consequences require simple verification, not extensive measuring.

5. **More customer differentiation is also needed.** At present the mind-set appears to be that one size fits all. While giving the appearance of equity, this concept actually creates strong inequalities. The same programs and regulations that befit a large corporation or municipality are simply not equitable for smaller enterprise and communities, for example.

6. **While the ultimate goal is water quality standards, this is very difficult to achieve and/or to measure in the short term.** Therefore, while retaining water quality standards as the ultimate goal, EPA should be focusing on best management practices, and in particular those that reflect preventive and non-structural solutions.

7. **The most functional unit of both analysis and intervention is the watershed.** Most people in our samples for opinion and recommendation strongly suggested the watershed approach--not only on the macro level (e.g., Chesapeake Bay) but the micro-level as well.

VOL 12

4508

8. **EPA's role is to offer technical support and direction more than program funding or even full guidelines for state and local implementation.** In particular, building useful data bases and collection methodologies not only on water quality but on practices to achieve it is critical. Such practices should include education, given that prevention and voluntary compliance are much less costly than litigation.

9. **A collaborative approach to developing effective solutions is possible.** The interactive elements of this project are one reflection of the ability of those with strikingly different perspectives (ranging from strong environmental protection to a focus on economic development) to work cooperatively.

10. **Agriculture's absence from the storm water program is notable and regrettable.** In many regions, agriculture (which includes livestock as well as crops) is a primary contributor to surface water pollution. Permitting or in other ways controlling the transport of agricultural products introduces intervention too late.

The remainder of Volume I amplifies these findings and presents the rationales and key data points which underlie them. Volume II includes the complete data base, including all instruments used to collect and analyze information.

VOL 12

4509

PART I: IMPROVING PHASE I OF THE STORM WATER PROGRAM

In December, 1991, the Deputy Administrator of the U.S. Environmental Protection Agency asked the Office of Water to undertake a project that would achieve two results: first, identify ways to improve and streamline the existing storm water regulatory program currently being implemented by the agency; and second, develop options for controlling sources of storm water runoff not currently required to be permitted under Section 402(p)(2) of the Clean Water Act.

In response to this request, the Office of Wastewater Enforcement and Compliance (OWEC), working with The Rensselaerville Institute, developed a two-part project. This section addresses the outcomes from Part I, which focused on identifying improvements to the existing regulatory program.

VOL 12 4511

Description

As the first part of The Rensselaerville Institute's project to help EPA assess the effectiveness and efficiency of the existing Storm Water Program, focus groups were held in diverse regions of the country to gain feedback on how the regulations promulgated on November 16, 1990 could be streamlined and improved. Six such meetings comprising representatives from state, municipal, private industrial and environmental groups were conducted between February 24 - March 2, 1992.

A total of 40 individuals participated in the focus groups, which were held in Atlanta, GA; Hartford, CT; Chicago, IL; Washington, DC; Seattle, WA; and Phoenix, AZ. The format for each meeting was the same: participants provided feedback on eleven questions developed by EPA and Institute staff. The questions:

1. **Which aspects of the storm water regulations are least clear?**

2. **What additional steps would be helpful in assisting permittees achieve compliance in the allotted timeframe? Who should take those steps?**

3. **Exactly what kinds of guidance and information are needed to help people implement the program? How would you prioritize these listed storm water program activities in terms of their usefulness?**

4. **Is there a need for EPA to do more national workshops on the storm water regulations? What about regional or local workshops? On which subjects?**

5. **What support should states, as opposed to EPA or other organizations, be expected to provide to their "universe" of permittees? What resources do they need in order to provide those supports?**

6. **If you had to name three ways to streamline the permitting process, what would they be?**

7. **What could EPA do to encourage those states without general permit authority to get it? What steps are needed to get general permits out? What simple, short-term grassroots efforts can associations and trade groups take to help this effort, and how could EPA support those efforts?**

8. **What outreach efforts to explain to permittees what they have to do to comply with the regulations have been most effective to date? Are there informational pieces that EPA could prepare that would best help these efforts?**

9. What are the techniques, methods or strategies you would recommend to help permittees achieve water quality standards? In what timeframe should permittees be required to comply with WQS?

10. Given that construction activities are most often local in nature and temporary in duration, do you have suggestions about how EPA could more effectively regulate such activities?

11. What suggestions would you offer in terms of the most efficient way to enforce EPA existing regulation requirements, both application requirements and substantive permitting requirements?

Responses to question #6 were revisited in the afternoon of each session, when participants were asked to further define their recommendations, indicate who they felt should be responsible for initiating the changes, and list the initial steps they would take.

Response summaries were drafted following each meeting and sent to participants for additions and modifications. Their changes were incorporated into their respective reports. This overall report summarizes, interprets, and analyzes group discussions and conclusions.

Focus Group Findings

Despite the many issues surrounding implementation of the regulations, the consensus of all focus groups, including industrial representatives, was that storm water control is needed and appropriate. There was general agreement that storm water is a significant contributor to water pollution. Some felt that a regulatory program was appropriate to address the problem. A number of participants expressed that, overall, the storm water program is significantly more rational and easier to deal with than other EPA water programs, for example, the wetlands program.

Yet the storm water regulations still inspire much confusion and frustration. There is frustration with EPA, as well. Many felt there was a lack of consideration given to their inputs by the agency prior to promulgation of the regulations, and some thought that EPA had been unresponsive to questions and concerns voiced since the regulations went into effect. When pressed, however, most admitted that they perceived this to be an endemic or generic problem of government. For a few, this perception will not be changed. However, most were impressed that EPA was now willing to actually look at the storm water program and solicit input from those dealing with the regulations on how they could be improved or streamlined.

Reservation was voiced, however, that EPA would do nothing with the recommendations generated from these focus groups. Their concern was that the results would have as little impact on EPA's decision-making and responsiveness as had previous efforts to make their opinions known.

It is critical, therefore, that EPA identify those procedural changes made in response to the recommendations, and make them known both to focus group participants specifically and to the permitted and regulatory communities in general.

The range of concerns voiced was large, and differed between geographic regions and the representational make-up of the group. Each group raised issues that were quite specific to themselves or their region, e.g., New York City was concerned about the effects of tidal flow and backwater as they relate to water quality; Utah and other arid and semi-arid states were concerned about sampling procedures when there was scarce rainfall; Seattle felt that the regulations did not allow its storm water program to build on earlier work; general contractors do not understand why concrete mixing requires a separate permit even though it is done on the construction site, etc. The specificity of concerns for each group is reflected in the individual summary reports, which are included in Volume II.

Some issues and concerns identified, however, spanned geographic and demographic boundaries. They were raised across groups as key areas in need of clarification and/or modification. There were seven broad areas identified where members felt efforts should be made to improve and streamline the storm water regulations.

1. **Permittees and regulatory agencies feel that the EPA has not been clear about the intended goals of the regulations. A view of the "bigger picture" is wanted.**

   While group members agree that storm water is a contributory factor to water pollution, there does not seem to be an understanding of what EPA hopes to achieve with the regulations promulgated in November 1990. A frequently heard comment was that "the big picture" is missing. Participants felt that EPA has not been clear about how these regulations will accomplish the goal of achieving clean water, and in what timeframe. This has hampered efforts to comply because many do not understand what they should be setting as performance targets.

   One participant said, "What is a clean urban stream?" The point: participants were not sure what goals they need to attain to comply with the regulations and protect themselves from being sued or fined for non-attainment. Almost all participants felt that water quality standards were useful as the ultimate goal toward which to work, but were unachievable in a two- or three-year period. When asked what they felt would be a reasonable timeframe, estimates ranged from five to thirty years, with a few participants indicating that, given the large number of pollutant sources impacting on a given water body, achievement of water quality standards through the storm water program alone is a strong improbability. One participant stated that the scientific community's perspective is, "...there is no way water quality

VOL 12

standards can be achieved with known storm water technologies"; it will take further research and development of BMPs before water quality standards could be achieved.

It was clear that members need more guidance about where the program is headed. Participants want EPA to be more explicit about what should be achieved in terms of improvement of water quality in the timeframes that have been given and with the technologies that are presently available.

Group members were aware that environmental advocacy groups will bring pressure on EPA to hold to established numerical water quality standards, and that reducing or replacing them is not likely a viable option. As one representative from an environmental advocacy organization stated regarding water quality standards, "...(they are) the heart of the Clean Water Act." Participants felt, however, that EPA needs to explicitly acknowledge that cleaning up the waters of the U.S. is a long-term effort that requires federal, state and local governments to work in partnership with permittees rather than through "command and control" relationships. Permittees fear being sued for non-compliance when in fact they are making the best efforts possible.

Permittees and regulatory agencies want EPA to provide them the time and support they need to design and implement storm water programs that make sense in terms of effectiveness and cost. They feel that EPA, by not clearly stating goals, has hampered efforts to deal with the problem; permittees are not sure which approaches to take because they don't know what they have to achieve. They want the guidance and information necessary to implement the most appropriate measures available for their discharges, and the time to evaluate those efforts. As one group member observed, "...What is needed is a longer period (than the permit period) to do BMPs - and then monitor their effectiveness. Where necessary, go back and change things. It's an evolutionary process. This is not a quick tech fix! EPA is creating more problems than answers. October 1 should not be 1992, it should be 1995."

If EPA is to achieve success with the program, it needs to address confusion over program goals and timeframes. The agency needs to be explicit about what it expects industrial and municipal permittees to accomplish in the first permit period, what they expect them to achieve in the longer term, and what they anticipate the impact of the storm water program to be on overall water quality.

2. **The cost of program implementation is significantly higher than EPA estimates. There is great concern over what the program's real costs have been in terms of dollars and manpower.**

A great concern of focus group members was the excessive cost of preparing a

VOL 12

4514

permit application, and the anticipated costs of achieving compliance. A number of state representatives indicated that implementation of their state program took, in terms of staff time alone, more than all other water programs combined - without the concomitant added federal dollars that those programs provided. That EPA has provided minimum federal dollars for the program is a major issue. Municipalities and industries were concerned with the significant additional costs of manpower and technology needed for both application and compliance. One focus group participant brought for discussion a study done by the School of Public and Environmental Affairs at Indiana University. The study has identified that the actual mean cost for Part 1 of the municipal application process for 59 cities exceeded by <u>six times</u> the EPA-estimated costs of the program [Gebhardt & Lindsey (1992), "NPDES Requirements for Municipal Separate Storm Sewer Systems: Costs and Concerns"].

That EPA has set aside some monies to assist in program development is not commonly known information. There was confusion among a number of focus group members about the availability and applicability of grant monies, e.g. 104(b) funds, that <u>are</u> dedicated to implementation of the program. For example, within the same focus group, one person said that they had applied for and received the funds to help prepare their application; another member replied that they were told that the monies could <u>not</u> be used for that purpose. Members of some groups were unaware that the funds were available at all. This indicates that communication from EPA has been inadequate in letting eligible groups know that there are some, albeit limited, dollars available to help them in setting up their programs, and that there has been inconsistent communication about the guidelines for use of those funds. Further, every person who indicated knowledge of the money also noted that the funds available were minuscule in comparison to what was needed to actually get their programs up and running.

Some states have developed the necessary revenue-gathering mechanisms to fund their storm water program. One state representative indicated that, by charging permit fees, they have been able to hire six staff people for the program. A few other state representatives indicated that storm water utilities had been successful in helping to raise the funds necessary for program operations. A significant number, however, contend that their state does not have the funds to implement the program, nor do they have a system devised to raise these funds. Therefore, wholehearted efforts are not being made to respond to the regulations. Further, some states have implied that they do not consider storm water a priority, and therefore are not willing to devote any portion of their budget to the program. This latter point creates a significant problem for the thousands of permittees in such a state that are then without a critical support system to provide them guidance and technical assistance.

The storm water field in general is perplexed that EPA could promulgate these regulations without at least providing "seed monies" to assist the application process and help states set up their own revenue-generating systems. To some, the message EPA sent by not providing funds is that the agency itself is not invested in the program. If EPA plans to continue to regulate storm water without providing financial assistance, one way it could assist permittees is to provide guidance and examples of successful fund raising systems that some states have devised, e.g., storm water utilities.

3. **The administration of the program is enormous. Clarification is needed on the roles and expectations EPA has for itself, states and permittees.**

Much of the controversy surrounding the regulations arises from unclear delineation of the roles, responsibilities and authority of each level. What is clear to everyone is that EPA alone does not have the capacity to administer and enforce the program. Therefore, much responsibility must fall on state and municipal levels. However, the regulations do not delineate the responsibilities of each level. Group members were clear that they want EPA to be more decisive and explicit about what is expected of states and municipalities in terms of administration and enforcement, and the areas where they will be allowed authority and flexibility in decision-making.

Some state and local governments have not waited for EPA to define their roles. The regulatory deadlines were powerful motivators for them to move forward without such guidance. Thus, frequently heard was states' hesitancy to discuss with EPA what they were doing programmatically, because they were afraid they might not be doing it "right", i.e. in accord with what EPA wants done. They were concerned about asking EPA for clarity they feared the agency might take away their assumed authority since it had not been specifically assigned in the first place. A number of state representatives admitted that they interpret the regulations in their own way rather than wait for EPA to provide interpretation. As one state representative put it, "...we looked at the regs as guidance rather than rules. We do it our own way. We are not sure if it is appropriate, (so) I have concerns asking for guidance from EPA because they may take away our latitude to make our own judgments."

The vagueness in assignment of responsibility and authority has clearly hampered program implementation. It may have been the intention of EPA to be less specific so that other entities would make their own interpretations, but they clearly do not feel comfortable assuming responsibility or authority. Many have been frustrated by the agency's lack of response when trying to gain clarity of the regulations. For example, one trade association representative stated that, in order to inform his membership about the regulations, he wanted to publish in their trade newsletter an article that outlined their members' responsibilities under them. To ensure that his interpretation was in accord with EPA's, he submitted the article to

VOL 12

EPA for review. In his words, "I waited a month, and when EPA did not respond, I went ahead and printed it. They [EPA] didn't like that."

Some state representatives said that they were unwilling to help industrial people make decisions on whether they are covered by the regulations, because they do not want to be held accountable when EPA has not specifically given states the authority to make interpretations of the SIC codes. Participants felt that the states are more likely than EPA to know the specifics of the industries in their boundaries, and also to know which ones are high-risk pollutant sources. But states do not feel that EPA has given them the authority to use that knowledge to make their own judgments on whether an industry is covered or not.

Industries also feel unsure about their responsibilities under the regulations, and are turning to the states for guidance. The regulations are unclear, for example, about what level of program implementation is expected in a given timeframe. As one state representative put it, "...there needs to be some guidance from EPA to the <u>states</u> on what (industries) need to do!"

States feel they have more knowledge of the industrial risks within their boundaries, and know what is needed to bring those risks into compliance. A number of focus group members cited the uselessness of having EPA develop requirements and guidance for <u>any</u> given industry when it did not <u>understand</u> specific industries. They felt it far more effective for EPA to work <u>with</u> industrial representatives when developing materials to ensure clarity and correctness. This would likely create the added benefit of gaining industry's commitment to achieving certain results.

Given the magnitude of these regulations, the lack of funding available to support implementation, the fiscal constraints under which all levels of government are operating, and the limited staff at each level, working in partnership with states and permittees rather than through a "command and control" relationship could get the program in place more quickly and maximize its effectiveness. EPA needs to determine each government level's responsibilities, be explicit about what decisions and flexibility can be allowed, and be clear about what <u>results</u> are expected from each level of government if given the authority to interpret certain aspects of the regulations.

4. **More supporting information for the program is needed, and dissemination of that information needs to be improved.**

Information supplementary to the regulations, explaining them and providing explicit information on how to implement them, was cited as a critical need that had only partially been met. All focus group members gave feedback on those pieces of EPA-generated information they thought was useful, what they felt was not helpful, and what other information they desired or felt was needed. They also addressed the regulations themselves as a source of information.

a. Written Documents

Written information EPA has provided to supplement the regulations, such as guidance documents and supportive materials, received overall good reviews. Numerous participants stated that both the Industrial and Municipal Permit Application Guidances were helpful.

The primary problem with much of the written guidance and information is that it is coming out too late to be useful. A number of participants indicated that a model general permit would have been helpful, but that they were at the point of writing their own, so for them it was too late. Often group members' suggestions for specific informational documents were accompanied by the caveat that it was needed now, e.g., permit writers guidance; Model Permits for MS4s: a BMP manual; Construction Activity Guidance.

Not everyone wants to receive new information at this point in the program. A number of participants said, "Don't do anything...We have a track: anything that would confuse that would be a problem. Even clarification. We have an idea for what we want to do and if guidance comes out now, it might conflict with what we want to do."

One person commented that EPA should prepare guidance documents so that they can be released concurrently with promulgation of the regulations. This would avoid not having them ready in a useful timeframe. A number of participants felt that EPA should be more willing to release information in draft form if the final document is going to be late. EPA should make preparing information for Phase II of the program a priority; the timeliness of delivery is a reflection of the program's credibility and of EPA's commitment to the program. It is clear that those who have gone forth without the support of written guidance are going to be highly resistant to any input by EPA that would require them to modify what has already been done.

Dissemination of EPA documents has been inconsistent. Regions vary in their thoroughness of distribution. One group member said, "...EPA needs to be better at getting this stuff to us. I often have somebody walk into the office with something that has been out for three months that I have not seen." This frustration was echoed in a number of the focus groups. EPA needs to publish a list of available documents which people can request either in writing or through the Hotline.

VOL 12

4518

b. Verbal Communications

The Storm Water Hotline received mixed reviews from group members. The primary response was that it effectively addressed very basic questions, but that the program had advanced quickly to the point where more technical information was needed. Trust in the ability of those answering the phones to address complex issues was low. However, this is not an unusual response to Hotlines; often callers complain that information given is inadequate, inconsistent, or not appropriate to the situation of the caller.

Some focus group members stated they were pleased with the response they had gotten from the Hotline. Some indicated that they were relieved just to have someone to call for program information. Others felt it was a good way to confirm their "hunches". Overall, given the size of the program and the number of phone calls that have been received, the perception of the Hotline is relatively positive.

Some alternative roles were suggested for the Hotline. Members stated that it could be used as an information clearinghouse, having available a list of sources that callers could turn to for more technical information. One person suggested that operators have lists of experts in categories to whom they could refer callers for more information.

One frustration voiced was that reaching EPA staff people was a problem. This has created for some the perception that EPA headquarters staff are unapproachable. On the practical side, however, responding to all the phone calls they receive would tie up all available staff for the duration of the program; headquarters staff would do nothing but answer phone calls. Yet it is important to recognize that this problem influences people's perception of EPA's commitment to the program. Perhaps with EPA's attention to the more substantive items listed in this report, e.g., getting documentation out in a more timely manner and with more thorough dissemination, etc., this perception will self-correct.

c. Workshops and Presentations

All groups felt that workshops of national scope were no longer needed, because the issues being dealt with were now more technically specific to certain industries or areas. The consensus was that state and local workshops, providing industry-specific guidance and information on water pollution control, were most needed. Most felt that such workshops should be sponsored and planned by trade associations and other membership associations like APWA, WEF, ASIWPCA, etc. rather than EPA. They did feel that EPA should be a speaker at the programs, and be willing to help address the federal perspectives in response to local concerns.

A main concern of group members, from coast to coast, is reaching those

VOL 12

4519

industries who are covered by the regulations: many businesses covered under the regulations do not know that they must apply for a permit. Trade associations were recommended as one of the best ways to get to the harder-to-reach permittees (usually referred to as "Mom-and-Pops"), but even they are limited to those businesses who are members. Group members mentioned other avenues through which they have tried to reach these businesses, such as direct mailings to municipalities and working through Chambers of Commerce. None have been completely effective. Most members said that this was not solely EPA's responsibility, but also one of states, local governments and trade associations as well. EPA could support this effort by suggesting methods for reaching these businesses, and contacts at the national level that could be helpful, e.g., Small Business Administration.

d. <u>The Regulations as Information</u>

The Federal Register notice of the regulations was considered by participants to be a key source of information about the program. Numerous comments were made about its inability to convey needed information clearly and concisely. Length, layout, language and accessibility were identified as deterrents for many "laypeople" to comprehend them.

One member said the length was approximately 127 pages too long; he felt it should have been three pages, with a focus on what the regulations will do to reduce water pollution. Many felt that the regulations were not user-friendly because of the language used, which they referred to as "legalese". One person remarked, "What is needed is an English version of the regs!" The citations were claimed to be confusing, and some felt substantive requirements were "buried" in the wrong section, e.g., important permitted industrial activities were in the Definitions section, and municipal requirements were scattered throughout rather than placed in a "Municipals" section. Another noted that the three-column format was difficult to read for most not used to the Federal Register format.

Many noted that the Federal Register is a publication that may be picked up by <u>some</u> large businesses, but would rarely find its way into the smaller ones. Given the widespread impact of the regulations, there is valid concern that EPA views the Federal Register as a primary method to "get the word out." They felt this was not a good assumption, since circulation of the Federal Register is very limited, leaving the vast majority of those industries covered by the regulations unaware that they are affected.

There is need for a more clearly stated version of the storm water regulations. Trade associations have done a great deal to try to reduce the regulations to laymen's terms for their members. But when supplemental guidance documents, which are more reader-friendly than the regulations, are not quickly forthcoming

VOL 12

4520

and the regulations provide the only source of information, confusion is inevitable.

5. **The regulations lack clarity on a number of key aspects. State authorities need EPA to either clarify these points of the regulations, or they need EPA to allow them the latitude to make the interpretations themselves.**

During each focus group, members discussed many particular points of the regulations that they had found unclear. These varied from group to group, depending on the perspectives represented. As one would guess, points that to a municipal person lacked clarity were often different than issues of concern to an industrial representative. For example, industrial representatives spoke of confusion with deadlines as a result of the Surface Transportation Act amendments, how to pick the appropriate permit to apply for, and how industries connected to municipal sewer systems should deal with the regulations. Municipal representatives, on the other hand, mentioned specific sampling and field screening methods, the definition of Maximum Extent Practicable, what to do about application sampling requirements in the face of drought conditions, and how to classify industrial parks as issues that lacked clarity. Further, participants felt there were some aspects where there was room for interpretation. Important to them was knowing where they would have latitude to <u>make</u> interpretations.

Presented here are the areas <u>commonly identified</u> as in need of clarification by EPA.

a. Who is covered under the Industrial SIC codes:

Every group questioned EPA's use of the Standard Industrial Classification codes to determine which industries should be included under the regulations. The consensus was that these codes, which are economic indicators, are inappropriate for regulations that deal with environmental issues. Their use has caused a great deal of confusion as various industries try to apply them to their "primary" activities. Businesses don't know how to use them to determine if they are included under the regulations - and regulatory agencies are <u>very</u> reluctant to make that call for them given the "downside" of either decision. Group members indicated that the Transportation category (#8) and the category of Exposure (#11) were the most problematic and inconsistent.

One state representative said that trying to get businesses past this first decision point had consumed most of the manpower in their office. They were receiving 80-90 phone calls a day <u>just</u> on that question; they had to hire a "temp" to respond to these phone calls and refer callers either to an EPA field office or a consultant. Another group member said that they did one informational mailing to businesses in their county, and were flooded with 7,000 phone calls; they did not know how to respond to callers, so they ended up hiring a consultant to handle the questions.

One comment from a member in the Phoenix group accurately represents the feeling expressed across focus groups: "It is virtually impossible to determine who needs a permit...You are not looking at the runoff quality with the SIC codes. I do not know of an existing code that looks at runoff, and that ought to be the basis of the code (used for these regulations)."

EPA needs to clarify how these codes are to be used. As one member stated, "OMB decided to use the SIC codes for other than they were intended. EPA (therefore) must define how to use it; this needs research and an environmental interpretation done." EPA also needs to be explicit about states' liability if their interpretations of coverage are different from what EPA's would have been. One group member suggested that EPA put together a brief (1-2 page) guidance summary to help industries decide whether they are covered, and also to develop descriptive categories of industries covered. EPA needs to define the minimum criteria for coverage to help regulatory agencies and industries determine their status, and then give latitude to states to use Best Professional Judgment when making decisions to include or exclude a given industry.

b. Exposure:

The category of "exposure" was cited by all groups as one of the two most difficult to determine. Members requested that EPA allow regulatory agencies to use Best Professional Judgment in determining which industries should be covered. Examples were mentioned, included the artist doing metal sculptures (all his activities took place indoors), and the farmer trucking potatoes to the potato chip factory (he was advised to cover his load with a tarp). As one member stated, decisions on whether an industry falls under the exposure category need to be determined on a case-by-case basis, and may require a site visit for a final decision to be made. Members did feel this category was "good" because it is the only one that is risk-based, yet "bad" primarily because exposure is "fuzzy".

EPA needs to allow states to develop their own definition and criteria for exposure, reach agreement with them, and be comfortable with the possibility that states may be different. The enormous number of covered industries under the category would otherwise exhaust EPA's resources to deal with it.

c. **The group application process:**

Focus group members feel that the group application process has created significant confusion among permittees: there is no such thing as a group permit, yet there are large numbers of industries that participated in a group application still under the impression that they will be covered by a group permit. As a number of participants stated, "(those who applied for one) think group applications mean group permits. And that is not the case."

One industrial member voiced their frustration: "Industry feels that the group application was misrepresented. (We thought,) this looks good; we can band together, demonstrate our likeness, devise sampling techniques, and regulate accordingly. Then we heard that you don't get a group permit; you get sent to the next tier down - the state. And the state then decides what you get... This has discouraged us from being proactive, forward thinking, because the rules keep changing in mid-stream."

Some members thought the group application was a useful process. One stated, "The group application process will get the best information at the least cost. It is the best research process because you can control it. For example, the textile industry: consultants will get together with them to determine how sampling and BMPs will be done. It provides a source of comparison within industry."

EPA needs to let participating industries know what the process is about, what the next steps will be for them after application review, and where there will be extended timeframes for them to submit a NOI under a general permit or an individual permit application.

6. **EPA needs to consider consolidating programs in order to address water pollution in an efficient and cost-effective manner.**

All groups suggested that EPA look at consolidating the different water programs for greater cost-efficiency and effectiveness. Rather than looking at it by different water source, e.g., storm water, wastewater, wetlands, etc., limited federal resources could be applied on a prioritized basis by watershed. Group members felt that this approach would eliminate redundant efforts across programs, allow dollars to be spent by risk priority rather than through separate program allocation, and have a more profound effect on reducing water pollution.

The perception is that present programs are more interested in "bean counting"; that is, keeping their present funding levels at the expense of the environment. One group member said, "Avoid bean counting...Transfer the funds to where it makes sense. Some water bodies have five different funding streams. (EPA) should look at one water body, and look at point and non-point factors. See if we can pull the program together to yield an environmentally efficient program that brings all this together. This would form a prototype of pollution elimination by integration of programs." Another suggested the development of a "water pollution block grant."

In no group was there a concrete discussion on how EPA would accomplish this at a federal level, although many thought that a start would be to get people from each of the programs to "sit down together in the same room" to discuss ways of working together toward the same goals. State representatives were aware of program separation at their level, and cited the different funding streams - with some programs having far more than others - available for each one. It is clear that most would like to see a strategy in place that allows monies to be allocated based upon watershed priority. This ability to be able to shift funds between programs many felt would have eased the financial burden of getting their storm water programs up and running.

7. **EPA should continue to focus on general permits in order to get the program implemented as efficiently as possible.**

One of the most-mentioned ways of reducing regulatory burden was the use of general permits to cover as many industries as possible. Many state participants voiced frustration at EPA's slowness in getting a model general permit out, and some remarked on their slowness in reviewing state applications for general permit authority. One indicated that it had taken their state nine months for approval. Yet groups were unanimous that general permits are an excellent way to streamline the program.

Participants felt that states should **want** permit authority; as one member put it, "...they should want control over their own destiny." States that have not applied for general permit authority, such as New York, are seen by permit applicants as unhelpful. One voiced frustration that his state DEC office could not provide assistance when he needed it, because the state had chosen to "ignore" the regulations; he has looked to the regional EPA office for assistance, even though he was not sure that was the "right" route for him to go. Another state representative said that her state wants authority because "they could then issue more permits, cover more people. It's revenue-producing, and the dollars would come into (our) department."

Many participants predicted that states without general permit authority will be overwhelmed by the number of individual permits. They felt that EPA, as well as state and national trade associations, should make states aware of the consequences of not having general permit authority. One suggestion often heard was to get trade associations involved in lobbying state legislatures to put pressure

VOL 12

4524

on their state government. Some members recommended that EPA also put pressure on states to apply for permit authority by using a carrot-stick approach: assist them to apply, but withhold program monies from non-delegated states. Others suggested that the carrot be dollars, such as the 106 monies, used as an incentive. Participants felt that getting most industries into the program under a general permit umbrella would establish a baseline for the program so that a tiered approach could be used to identify and deal with pollutant sources.

It was evident from comments that some state representatives would like to see a model general permit. They are looking for guidance in developing their own, and models--either EPA-generated or state-generated--would obviously assist states in drafting their own. Critical to this effort is that this assistance be made available as quickly as possible.

There is a common thread across these seven issues. That thread is the need for more and clearer communication, from use of terminology and language more familiar to the "layperson", to explicit guidance on fund raising approaches to support program implementation.

In many organizations, "improved communication" is cited as a sought-after end, but it is often set forth without identification of the means by which to achieve it. With this project, EPA addressed the means by asking the "experts"--those people at the regional, state and local levels who have to ensure that the regulations are implemented--where communication has faltered and what is needed to address the problem. It will be the continued involvement of these people in working on solutions that will ensure successful achievement of the end.

VOL 12

4526

PART II: DESIGNING PHASE II OF THE STORM WATER PROGRAM

The second part of The Rensselaerville Institute project was conducted during April-September 1992. It consisted of three distinct efforts: a survey of point source and nonpoint source program experts to gain their insights on the development of a strategy for Phase II of the storm water program; three public meetings to gain citizen advice on key elements that should be considered for the Phase II program; and facilitation of a "design team" effort with selected experts to generate a detailed strategy to guide EPA in planning and implementing Phase II of the storm water program.

For each effort, the focus was on three elements: **targeting** (which sources shall be included and by what categories); **control** (e.g., should permits be used or another strategy developed); and **timetable** (with what schedule and over what period of time should Phase II be implemented, particularly with regard to the October 1, 1992 deadline established in the Clean Water Act amendment).

This report profiles project activities, then summarizes the findings from each of them. The reader is referred to the supporting documentation in Volume II of this report for the database compiled during this project, including analysis and comments from the Expert Survey.

Expert Survey

Part II of the project began with survey input from a select group of 32 storm water experts from throughout the country. Five perspectives were represented: academic/research; commercial development; consultant engineering/legal; environmental advocacy; and state/local government. A Delphi-type survey approach was used to obtain initial opinion and consensus on relevant issues and options for addressing Phase II sources.

Two survey rounds were conducted with point source program experts. The instruments presented respondents with a series of potential targeting and control strategies along with timing options. Survey participants were asked to identify the strengths and weaknesses as well as steps and resources needed to implement each option and were also given the chance to suggest an alternative strategy to the ones presented.

Five nonpoint program experts received one survey designed to capture more specific information on voluntary approaches for achieving program success. They were asked to provide the same level of detail for their preferred strategy as point source experts. Please see Volume II of this report for survey transcripts and analyses.

Survey Findings

Respondents were asked to identify, from a list of 18 potential sources, which sources they felt to be the top five that "must be" regulated in Phase II. In descending order with frequency of response in parentheses, the sources identified were:

1. "Some industrial activities not covered under Phase I because of anomalies in the SIC codes." (24)

2. "Suburban areas of large metro areas outside city boundaries." (20)

3. "Some commercial activities with industrial components." (18)

4. "Large retail complexes." (15)

5. "State highway systems." (13)

The themes that characterized the designation of these sources as the top five included: 1) contribution to pollution load; 2) risk posed; 3) administrative efficiency of control; and 4) cost-effectiveness of control.

Respondents were presented with specific strategies for targeting and controlling Phase II storm water sources. They were asked to assign a level of desirability and feasibility to each. The scale used ranged from "1" (least desirable, least feasible) to "7" (most

VOL 12

4527

desirable, most feasible).

The three targeting strategies, and ratings and comments they received, are listed below.

Responses to Strategy I were spread across the scale: 39% of respondents felt it was "very desirable" and 36% rated it "not desirable". The same response pattern was given to feasibility: 21% rated it highly feasible while 29% rated it not feasible. That strategy was:

Strategy I: "Eliminate Phase II as a separate part of the storm water program and expand the current designation authority under Section 402 (p)(2)(e)."*

> *** 402(p)(2)(e): A discharge for which the Administrator or the State, as the case may be, determines that the storm water discharge contributes to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States.**

Some of the comments made by experts regarding this strategy included:

- "Gives the Administrator too much authority."
- "This approach provides the greatest flexibility and provides time so that we can learn from current programs."
- "Not feasible...unfortunately, the science is often not good enough to pinpoint culprits; the database...is weak; it is difficult to single out one of many candidate polluters."
- "Allows resources to be focused strictly on problem sources from the Phase II universe."
- "Arbitrary and capricious interpretation of intent of Congress."
- "Very desirable and feasible. It makes sense to target programs to areas that contribute to water quality standard violations and are significant contributors of pollutants."

Responses to Strategy I were the most mixed. While some saw it desirable because sources covered would be more selective and limited and therefore the program would require less resources and administration to implement, others did not support it because they were unsure what criteria would be used for targeting sources, and were concerned about the types of information used in decision-making as well as the experience of those making the decisions.

Most respondents felt that Strategy II would be costly, complex and unwieldy, and resemble Phase I in terms of its drain on resources and manpower. Some respondents felt it would expand the number of groups opposing storm water regulations.

Strategy II: "Cover all remaining point source storm water discharges under existing Phase I requirements."

This strategy received a mean rating for desirability of 2.25 and a mean rating of feasibility of 2.43.

Some of the comments regarding this strategy included:

- "Inadequate resources would pose a major implementation problem."
- "Ill advised and will be increasingly costly. There is no need to promulgate new regulations that we know will not be enforced."
- "Would be an administrative nightmare."
- "Too broad with respect to potential benefits."

Strategy III was seen by a majority of respondents to be the most equitable and rational of the three choices, as well as the most scientifically based. Concern that political pressures might sway the development of targeting criteria was expressed by some respondents. That strategy is:

Strategy III: "Apply Phase II controls selectively (e.g. on the basis of such factors as population density, pollutant loadings, or geographic targeting, or others you find to be appropriate)."

This strategy received a mean rating for desirability of 4.64 and a mean rating of feasibility of 3.75. It was rated the most desirable and feasible of the three suggested strategies.

Some expert comments on this strategy were:

- "Best of all worlds - reasonably objective."
- "Strategy III is the most desirable of the three strategies because it maximizes efficiency, effectiveness, and the flexibility to address water pollution problems based on site-specific factors, especially risk."
- "Sound on a technical basis, but probably requires too many resources, particularly information needed to do intelligent targeting."

VOL 12

4529

- "Desirable - this focuses scarce resources on likely and easily identifiable problem areas. Feasible - the factors (e.g. population density) are easily identifiable."

In the second round of surveys, respondents were asked to recommend a fourth strategy if they did not support one of the three suggested by EPA. Most frequently mentioned was a strategy that was **a combination of Strategies I and III.**

Four control strategies were presented to respondents for similar ratings of desirability and feasibility. These strategies were:

1. **"Mandatory reliance on general permits."**
2. **"Direct regulation under a national Phase II guideline, which may well require a national rulemaking by EPA."**
3. **"Requiring direct regulation of Phase II municipalities under 100,000 and requiring them to develop necessary controls for priority sources discharging into the municipal storm water system."**
4. **"Control under the nonpoint source program authorized under Section 319 of the Clean Water Act."**

Desirability ratings for the first three strategies were approximately the same: respondents felt that they were "somewhat" desirable. The fourth strategy was rated as slightly less desirable. The greatest feasibility was assigned to Strategy 1. The least feasible strategy, in the respondents' opinions, was Strategy 4.

In the second survey round, respondents were asked to describe implementation of their preferred strategy. When asked what minimum control strategies they would use, the following methods were mentioned:

- a menu or roster of BMPs from which could be selected the most appropriate approaches for the industry or watershed;
- public education;
- erosion and sediment control methods;
- "good housekeeping" and source reduction/elimination methods;
- establishment of national minimum standards;
- elimination of illicit connections;

- emphasis on pollution prevention.

Few respondents saw the implementation of Phase II to be a short-term process. Most suggested a phase-in approach over a period of five to ten years. During this time, BMPs could be tested for effectiveness and cost-benefit in terms of reducing and eliminating storm water pollutant problems, and programs could establish solid components of education, training and technical assistance.

<u>Nonpoint Source Perspectives</u>

Nonpoint program experts also favored Strategy III: "Apply Phase II controls selectively..." for targeting Phase II sources, with a mean rating of <u>4.0</u> on Desirability. The ratings ranged, however, from "1" (not desirable) to "6" (very desirable). Some of the comments included:

- "Is inequitable. Establishes economic hardships for those required to participate. Only strength is less administrative burden."
- "Would be easy to identify sources that fall under criteria. Could be preventive since you are not waiting for a problem to happen."
- "Excellent in theory, but would require a lot of data for prioritization, and would create confusion for some period of time."

The survey instrument used for nonpoint program experts was a modified version of the point source expert survey that included a fourth EPA-suggestedtargeting strategy for consideration. It was:

Strategy IV: "Target and address problems and significant storm water sources and pollutant loadings by using Section 319 and CZARA programs."

Respondents' mean ratings of the strategy were <u>3.2</u> for desirability and <u>2.8</u> for feasibility. Comments included:

- "These programs lack real regulatory teeth. CZARA 6217 applies only to coastal regions. They just aren't aggressive enough."
- "Section 319 is broader than NPDES and has more technical experience with BMPs. CZARA 6217 results in specification by EPA of management measures, in effect setting standards and providing impetus to explore alternatives."
- "Since only limited 319 funds are available, it would be difficult to get much done."

- "This is an important piece of a multifaceted approach, but not adequate alone."

Respondents were given the same control strategies for consideration as the point source program experts. Of the four, #3: "Requiring direct regulation of Phase II municipalities under 100,000..." was most favored, with a mean rating of 5.2 for desirability and 3.8 for feasibility. This control strategy was the only one to receive ratings higher than "5" for either desirability or feasibility.

The majority of respondents were opposed to extending the October 1, 1992 deadline. The reasons given included:

- "The longer we wait to address the problem, the more costly, less technically capable and less environmentally effective the solution will be. There are more opportunities today, especially in less populated areas, than tomorrow to solve and prevent problems."

- "Storm water-related use impairment is a serious problem. Currently, there is little being done to remediate existing problems and no assurance that problems related to new development will be prevented. It is clear that the voluntary approach is not adequate."

- "Things aren't getting better. Forum and impetus are already in place - capitalize on it."

Many of the recommendations made by point source program experts for targeting and controlling storm water sources were echoed by nonpoint survey respondents. Some of the targeting similarities include:

- selection of Strategy III: "Apply Phase II controls selectively..." as the most desirable of EPA-suggested strategies. The most mentioned reasons for preference were ease of identifying targeted sources, and the more efficient use of resources;

- target by watershed impairment/threat severity;

- conduct pilot projects first, evaluate, and then develop and implement a strategy;

- develop minimum national guidelines, and leave selection of sites and methods to state discretion;

- initiate a focused dialogue with key stakeholders (for both targeting and controls).

Some of the similarities in preferred control strategies included:

- build a BMP menu that can be used to implement and verify progress: allow selection of most appropriate BMPs based on industry and watershed;
- provide public education on need for storm water control;
- provide national criteria with flexibility for local implementation of most appropriate controls;
- develop baseline control standards for all new development.

One primary difference between point and nonpoint respondents was the application of the "stick" by EPA, with the "stick" being the requirement of permits for those sources that did not achieve significant movement toward program goals via voluntary efforts within a reasonable timeframe. As one nonpoint respondent phrased it, EPA should keep permit requirements as the "gorilla in the closet" to be used as needed when voluntary efforts were not adequate for the problem.

A number of nonpoint respondents indicated that the 319 and CZARA 6217 programs do not have the "teeth" they need to ensure compliance. Most feel that a combination of programs is needed for successful achievement of water quality goals.

EPA STORM WATER PUBLIC MEETINGS

Description of the Meeting Format:

Three public meetings were conducted to gain citizen suggestions on options for targeting and controlling Phase II sources. These meetings were held in Denver, CO; San Francisco, CA; and Washington, DC. Approximately 200 people attended the three meetings.

At each meeting, three experts selected from the survey process presented their ideas on a regulating strategy for the moratorium sources. Following their presentations, attendees were divided into small task teams with an assigned facilitator, and given the charge of devising their own strategies for targeting and controlling Phase II sources. The strategy template provided to guide group consideration of key issues is presented below. During the latter half of the meeting, each task team presented their option to the other attendees for discussion.

Teams were asked to consider these issues:

1. Targeting (What light industrial, commercial, retail, residential, or other areas or other areas do you include in Phase II?)

2. Control (Do you use continued reliance on the existing NPDES permitting process or something else such as nonpoint source programs, selected permitting based on risk, geographic targeting, etc.?)

3. Timetable (How would you phase in the major components of the strategy and over what timeframe? Do you suggest full implementation on October 1, 1992 [as stated in CWA] or do you recommend a different set of deadlines and why?)

4. Key steps to implement (Please indicate up to five critical, major steps to take in implementing your strategy and the timetable for each.)

5. How will costs of your strategy be distributed over key players and how will costs be understood and controlled?

6. What measures of performance will you use and how will you verify the environmental results? (Do you rely on numerical measures and quantitative pollution indices or other factors?)

7. Strategy Strengths (Name four key strengths of your strategy which, in your judgement, make it preferable over alternative strategies.)

8. Strategy Vulnerabilities (Name four most critical points at which your strategy is most vulnerable to failure or shortfall in implementation.)

9. For whatever strategy is chosen, what could EPA do to make the decision-making process for Phase II more responsive?

Meeting Findings:

A total of sixteen task teams presented their strategies for Phase II of the storm water program. The individual task team strategy outlines offered a diversity of approaches for designing, implementing, monitoring, and funding Phase II of the storm water program. Individual strategies presented a large range of methods for targeting and controlling sources, and many different timeframes over which the program could be phased in.

Despite the different representations, experiences and expertise, there were points of congruence between many of the proposed strategies. Common strategy characteristics across task teams included the following:

1. **Targeting:**

a. Targeting should be done by watershed. Information gathered from Phase I should help identify sensitive watersheds. May require intergovernmental agreements.

b. The focus should be on "bad actors", i.e. those that are known problem sources. The ones most frequently identified were: gas/auto service industries, transportation, highway systems, land development and agricultural sources. There needs to be the ability for facilities not contributing impairment of water to gain an exemption from permits, fees, implementation of BMPs. Categories are an ineffective way to designate covered sources. Selection should be done by the degree of risk a given facility poses rather than categorical inclusion.

c. Small municipalities should have a much simpler application process, or have the opportunity to be excluded if they do not contribute to the pollution problem. In addition to impact on a watershed, proximity to larger municipalities should be considered as well.

d. EPA should defer on selecting targeted sources until the agency has carefully looked at the data gathered during Phase I. Numerous sources of information are available which would help determine targeting priorities, e.g. information gathered through 305b reports, information from Phase I program sources, NURP.

2. **Controls:**

a. If a permitting process is to be continued for point sources, NPDES general permits should be used, and focus should be on BMPs. Permits should be simpler, and much less costly. EPA should make clearer to the applicant what information is required, e.g. checklist of inclusions, menu of BMPs. Exemptions should be available for non-contributors.

b. Education should be a primary form of control. It is important at all levels and for all audiences, yet is often overlooked or underrated.

c. There should be more emphasis on voluntary programs, e.g. the "319" nonpoint source program. For facilities with contact with storm water, there should be little or no more government intervention, but rather emphasis on pollution prevention incentives, BMPs, and practical measures of pollution prevention.

Pollution prevention programs should be emphasized, particularly with new development. Some suggested prevention methods include: recycling storm water, good housekeeping practices, plantings to minimize runoff, street sweeping of work areas on a daily basis, storm water collection methods, coverage of storage areas, changing manufacturing processes to minimize pollutants, improvement of air emissions.

d. BMPs should be required based upon the specific pollutant problem and strategies known to be effective in its mitigation or elimination. The focus must be a known connection between solution and its effect on the problem. BMPs must also recognize financial constraints, providing actions that are relatively higher in terms of cost-effectiveness.

3. **Timetable:**

a. A minimum of two years is needed to prepare for Phase II, with at least a year dedicated to looking at data gained from Phase I of the storm water program. Effectiveness of presently used BMPs needs to be looked at to determine differences in effectiveness between geographic locations and pollutants.

b. Whatever the period established for phase-in, it should not begin <u>until</u> promulgation of the regulations.

4. **Role of EPA Headquarters.**

a. Research, information dissemination, technical assistance.
EPA should also provide focus within these areas. Also, the current efforts are too diffuse, and imply a complexity that makes applications seem difficult and formidable.

b. Funding, not for program implementation, but for research.
Two areas of research requested are water basin pollution control and determination of effectiveness of BMPs. The majority of participants recognize that EPA does not have the fiscal resources to fund programs. What they <u>do</u> want from EPA is guidance in establishing fund raising mechanisms, such as storm water utilities.

c. Establishing broad guidelines for the program within which local flexibility is allowed and encouraged.
Flexibility, at the same time, does not provide an excuse for inaction or postponement. Rather, it recognizes that different actions and action sequences are appropriate to different contexts and conditions.

d. Responsibility for training regulators in the storm water program.

Until those administering the program are well equipped to enable action, effective responses will be difficult.

Please see Volume II of this report for copies of the individual strategies developed at each of the public meetings.

<u>Reflections on Meeting Format</u>

A presumption shared by EPA and the contractor, The Rensselaerville Institute, was that the conventional format for public hearings and meetings is of limited value in engaging citizens or of making the critical transition from criticism to advice on how best to do things. Given this belief, a different format was devised that proved quite different from the typical approach of lectures by experts and/or testimonies read to the record by concerned citizens.

In the interactive approach used, participants were advised that they would be asked to form into task teams to first listen to experts offer their insights, then to develop, as a team, a preferred strategy for responding to Phase II of the storm water program. Each team comprised a cross-section of those attending--including where there are possible strong environmental, industrial, and local government perspectives.

In all three meetings, participants accepted the format and energetically engaged in the task of constructing a preferred solution. This included the session held in Washington, D.C. where participants from major interest groups were in the habit of providing critical feedback and criticism more than engaging in a positive design process.

To gauge participant responses to the different public meeting format, a mail-back questionnaire was used inviting comments by the some two hundred participants in the three public meetings. Approximately 35% of those attending completed the survey. They were first asked to comment on their assessment of the more traditional public hearing format. Most held a clear and consistent view of the traditional approach as focusing primarily on prepared statements. Where dialogue was included, it was seen as argumentative and contentious. The general conclusions:

- opinions are solicited for the record and to insure the perception of public participation but not to provide genuine input. The sense is not of active government listening.

- primary participants are those with strong convictions and often special interests; they are not a representative sampling of public opinion and tend to run the gamut of extreme perspectives on a given issue.

- sessions tend to become adversarial or at best argumentative. No mechanism for cooperation is available and differences tend to get magnified, not resolved.

- the focus is on the problem much more than on ideas for resolving it. On the one hand this attracts critics more than implementors. On the other, it provides little guidance to people who full well know the problem and are looking for ways to deal with it.

Participants were much more positive about the format used. Among the sentiments voiced:

1. Participants had a full chance to participate--not only to be heard but to be directly engaged in finding solutions.

   "It was a valuable way to address the drafting of regulations--allowing the regulated community to feel part of the process";

   "Encouraged the regulated community to get involved and feel involved";

   "Participants felt that EPA was actually listening and dialoguing."

2. The process was genuinely two-way, allowing both EPA staff and those effected to better understand each other.

   "It made you appreciate the USEPA's tough job of satisfying the concerns of many people while protecting the environment";

   "Felt it draws out better data";

   "Actually got to interact one on one with industry and government and consultant representatives. Obtained a better point of view of government's problems and felt that government representatives also obtained a better point of view of industry's problems."

3. The format created an atmosphere for cooperation and even for collaboration among people with very different viewpoints.

   "The meeting went a long way towards promoting the creative thinking, open discussion, and presentation of ideas";

   "Group discussion is a fine vehicle to provide input as well as learning tool. It forces you to think through participation, rather than just simply sitting and trying to absorb by osmosis.";

"Small diverse groups allowed ideas to be evaluated fairly and fostered "brainstorming" and allowed ideas to be developed to better fit broad based objectives."

The positive elements of the meeting extended beyond the effective communication of opinion and position to EPA to broader understandings of issues, complexities, and solutions. Indeed, the sessions seemed as influential in creating new insights as in communicating old ones.

Respondents suggested two primary ways to improve the format for future uses. The first is the need for more detailed advance preparation--in part, needed to change the mind-set and expectations which people tend to have for a traditional public hearing or meeting. The second suggestion: minimize expert presentations, even when used in the "pump-priming" mode employed in this session. Trust the process and get right to the participants.

When asked if they would advise the EPA to use this kind of interactive task-focussed approach with other meetings designed to get public input, over 90% said "Yes." Two persons indicated that it depends on the issue and only two indicated that they preferred to remain more passive.

THE "DESIGN TEAM" MEETING

Meeting Description:

A meeting of seven point and non-point storm water program experts, all of whom were survey respondents, and selected EPA staff was convened in Washington, D.C. on September 17-18, 1992. The purpose was to gain the experts' insights on development of Phase II storm water regulations, and the intended outcome was to build a strategy, or multiple strategies, for regulating Phase II sources.

Participants included:

Mr. Gail Boyd
Woodward-Clyde Consultants, Portland, Oregon

Ms. Diane Cameron
Natural Resources Defense Council, Washington, D.C.

Mr. Dennis Dreher
Northeastern Illinois Planning Commission

Mr. Tom Mumley
San Francisco Bay Regional Water Quality Control Board

Mr. Earl Shaver
State of Delaware Department of Natural Resources and Environmental Control

Ms. Coleen Sullins
State of North Carolina Division of Environmental Management

The participants selected were deemed, by their peers nationwide and EPA, insightful and highly articulate exponents of all major viewpoints on the storm water program.

Also in attendance were these key people from U.S. EPA:

Mr. Michael Cook, Director
U.S. EPA, Office of Wastewater Enforcement and Compliance

Mr. Geoffrey Grubbs, Director
Assessment and Watershed Protection Div.
U.S. EPA, Office of Wetlands, Oceans and Watersheds

Mr. James Horne, Special Assistant to the Director
U.S. EPA, Office of Wastewater Enforcement and Compliance

Mr. Ephraim King, Chief
NPDES Program Branch, Permits Div.
U.S. EPA, Office of Wastewater Enforcement and Compliance

Mr. Jack Lehman, Deputy Director
U.S. EPA, Office of Wastewater Enforcement and Compliance

Session Findings:

1. Development of a ten-point outline describing a potential strategy for Phase II of the storm water program.

Consistent with the overall purpose of the meeting, participants identified ten core elements that they feel constitute a potential strategy for Phase II of the storm water program. These elements are:

A. Objective: To get certain BMPs, ordinances and education programs into place over a 10-15 year period. Progress would be measured by getting these elements into place, with direction toward water quality standards and beneficial uses over a longer period of time. EPA would work with all states to help them develop Phase II programs.

B. Priorities: EPA would set these. They would include: the sources listed by the group, using a watershed approach where feasible, focusing first on those local governments with the size and capability to get going.

C. Education/outreach/technical assistance: these are all critical components of a successful program.

E. Mandatory Interim Milestones: EPA needs to determine interim milestones state programs need to meet which would show they are on track.

F. Financial Plan: states/local governments need to develop plans for financing the program.

G. Guidance: guidance is needed on BMPs and local ordinances. These would be generated at the federal level, and states could adapt/modify as needed.

H. "Default" system: local governments would take the lead with their programs, but there would be a built-in default system where the states or EPA would take over with more stringent controls if the locals fail to meet requirements.

I. Permit issuance: for high priority categories, could issue permits that allow flexibility or some alternative mechanism at state's option. Permits might be just for high priority categories; would include site design performance standards.

J. Phasing: there would be a schedule for issuing permits to key municipalities: high priority to low (e.g. coordinate by watershed); high flexibility to "getting tough" with recalcitrant localities. These would be based on inspections, on-site reviews.

K. Monitoring: this would be the difficult part of the program because of cost. Need is to be able to design something useful. The system might be "tiered" - highest to lowest priority; or "strategic" - focused only on gathering what we really need to know.

2. Sources to be targeted in Phase II.

The participants identified a number of specific unregulated pollutant sources that need to be targeted in Phase II of the storm water program. An approach recommended by some of the participants for controlling these sources is a "whole basin approach", which would focus attention and resources on activities impacting the water quality of a given watershed.

The group identified approximately 40 pollutant sources that they believe need to be included in Phase II of the storm water program. The sources identified include the following:

New Development/Redevelopment (commercial and residential)
Transportation Corridors
Dense Existing Development (commercial and residential)
Automotive Services
Federal facilities/military facilities
Feedlots (including dairy)
Failing septic systems
All incorporated places with less than 100,000
Non-urbanized watersheds yet to be determined
Parts of watersheds where land use is in a state of flux
Dry cleaning shops
Parking lots
Some forest operations
Nurseries/orchards
Recreational areas (e.g., stadiums, golf courses)
Landfills
Office parks
Grain elevators
Concrete cutting sites
Commercial pesticides
Landscaping industry
Car washes
Mobile washing units
Equipment maintenance
Boat yards
Tank farms
Shopping malls
Restaurants
Airports
Janitorial services
On-site solid waste (collection, hauling, transfer stations)
Atmospheric deposition
Cemeteries
Commercial strips
Wood stoves
Marine ports
Animal waste
Warehouses/storage facilities
Exterior building maintenance
Bridge maintenance

Members of the group suggested that rather than use the Phase I approach of including sources by category into the regulations, regulatory staff time and resources should be allocated on a water basin approach, i.e., target a watershed, identify impacting activities and their location within the watershed, and determine a set of criteria to deal with the problems impairing the watershed. This would allow limited resources to have maximum impact.

3. Source priorities.

After listing the range of sources that they felt should be included in the Phase II program, participants voted for what they considered to be the top priority sources, i.e. those sources that EPA should address immediately and diligently. The top sources selected are listed below, in order of decreasing number of votes received. All sources were selected by at least 50% of the participants. The sources identified as top priority for addressing in this order:

A. New Development/Redevelopment (commercial and residential)

B. Transportation Corridors

C. Dense Existing Development (commercial and residential)

D. Automotive Services

E. Federal facilities/military facilities

F. Feedlots (including dairy)

G. Failing septic systems

4. Lessons from a case study.

One participant presented an outline of the basic components of the Puget Sound Water Quality Management program. The program is a multifaceted approach toward the achievement of improved water quality which heavily emphasizes voluntary measures in its implementation strategy.

The program includes minimum BMP standards for all jurisdictions with additional water quality treatment BMPs, guidance and requirements for higher risk storm water dischargers. Key facets include: vigorous technical assistance, education, state financial support, education and support for storm water utility development, highway runoff regulations, a full nonpoint watershed management program, storm water operation and maintenance requirements, source controls, and local control and flexibility.

The program is being phased in over several years. It is a combination of mandatory requirements, technical guidance and voluntary compliance. There are specialized focus areas, such as shellfish protection districts and conservation districts. There is a coordination effort with individual and general permittees in the Puget Sound area.

The program views its strengths to be greater local flexibility and acceptance of requirements, a strong sense of teamwork between all levels, better water quality results, and better targeting and use of limited resources than if they were regulated by NPDES. They view the NPDES program as the "gorilla in the closet" that can be brought to bear if and when a source does not meet minimum standards and requirements.

5. Principles for Phase II.

Participants discussed the basic principles they believed should drive the Phase II program at the national level. For the program to be successful, it would require that the following pieces be put into place:

A. Require that people gather documentation of information regarding dischargers' activities and accomplishments and provide outsiders with that documentation;

B. Formally define gaps where additional information and understanding is needed. There needs to be an incentive to close these gaps;

C. Support (with encouragement and incentives) efforts that will close these gaps, and advance the state of the art and/or provide a technically sound basis for the programs' requirements;

D. Actively encourage a broad spectrum of understanding and involvement (the general public, community leaders, service groups, environmental groups) via educational programs and materials;

E. Strategically identify "good" guys and "bad" guys in the regulated community;

F. Provide clear guidance regarding programmatic and physical actions that are required/expected. Actively seek out evidence that people know <u>what</u> to do, and provide technical training to be sure that people know <u>how to do</u> what is required (technical transfer);

G. Require relevant/credible/useful monitoring only. Don't waste people's time/money/energy running data collection programs that yield bad or irrelevant data.

6. State suggestions of what EPA needs to consider in developing the Phase II program.

A sub-group of participants from state regulatory agencies met, and set forth a list of suggestions for EPA to consider in developing Phase II. The following recommendations were made:

A. EPA needs to provide states with the minimum program requirements they must achieve, and then allow states flexibility on how they will do it. The components must include:

- requirements/BMP standards for new development
- education/technical assistance
- control requirements for illicit connections/dumping
- developing state-specific priorities

B. EPA should require states to adopt regulations that specify program components that must be included;

C. To assure program funding, EPA needs to require that state and local governments set up funding mechanisms, e.g. storm water utilities, permit fees, etc.;

D. EPA needs to compile and disseminate technical information that would support programs, e.g. set up a national or regional clearinghouse of information on storm water plans being implemented, BMP-specific information and materials, etc.;

E. EPA needs to compile a national BMP manual that would assist members of the regulated community in determining and implementing appropriate BMPs to address their storm water problems. EPA needs to recognize, however, that BMP application will differ between regions, e.g. climatic differences will require different approaches;

F. EPA needs to require that states develop and implement education, technical assistance, and training programs; EPA also needs to hold the states responsible for effectiveness of these programs, and require permitting in the event that these measures do not work;

G. EPA needs to maintain the right to require permits in a reasonable amount of time (e.g. 2-3 years) if a state's program is not meeting federally determined requirements;

H. EPA needs to determine what short and long term goals they wish the

VOL 12

4545

storm water program to achieve.

7. Identification of problem areas and needs of the regulated community in dealing with the storm water program.

Participants were asked to identify what their "hot buttons" were, i.e. elements or considerations that EPA might include in the Phase II program which would cause major problems for them, or those which if not considered by EPA would create needs for the regulated community.

The list of "hot buttons" include the following:

A. Penalizing those who have already solved their problems by requiring permits.

B. Liability for water quality standards, sediment standards, and resource damage clean-up in the first round.

C. Failure to provide technical transfer - permittees need to know what to do and how to do it.

D. Failure to promulgate revised and simplified NPDES regulations that get around the complicated approval process.

E. Possible backlash from local governments if they are held responsible for instances of independent commercial activity that they cannot address or control when they don't know about it.

F. Lack of research on BMP effectiveness from a watershed perspective. There is inadequate federal/state money to look at BMPs because monitoring is so expensive.

G. Possibility of EPA not basing the program on permits (except in cases where the state can show that it can reach goals alternatively).

H. The inherent substantial risk of tremendous backlash that would affect people's livelihoods, i.e. failure to try to sell the program to regulators and public, including the NPDES permit process.

I. Prevention v. wetlands - determining how to prevent storm water problems while protecting wetlands.

J. Not addressing the roadblocks created by the regulations themselves. The system is so complicated, it now takes two generations for permits to get

VOL 12

4546

to goals.

K. Lack of federal monetary assistance. Some states may be reluctant to develop adequate programs without it.

L. Not getting rid of the acronyms in the regulatory language. No one understands what EPA is saying.

M. Concern that mainstream design is end-of-pipe treatment. This is not prevention! CZARA is on a better track.

N. Allowing states to cut monitoring activities first. They need to be encouraged to not eliminate that element disproportionately from their budget.

O. Need to figure out how to sell the program - to get through to OMB and top levels of state governments exactly what it is going to take to get the program into place.

P. Not identifying funding incentives and disincentives.

Q. Not giving praise for progress.

Additional Advice

Additional suggestions for development of the Phase II program were generated by the group during the two-day meeting. Included in those recommendations are the following:

1. **EPA needs to revisit and revise the terminology used in the regulations.**

- the problems are often with the common words, e.g. runoff, storm water, nonpoint source, point source. EPA staff have attached certain meanings to words that are not conveyed to the regulated community, so there is inherent danger that people are not talking about the same thing. Words need to have clear and referenced meanings.

- the enormous number of acronyms used by EPA creates significant comprehension problems for regulatees. The regulations need to be written with fewer acronyms, and all communications need to be sensitive to the level of use.

2. **EPA needs to clearly define the goals of the program.**

- all levels of feedback (focus group, survey, and meeting results) generated during The Rensselaerville Institute project have pointed out that the regulated community does not understand what EPA is trying to achieve with the storm water program. Assumption of what the goal is ranges from achievement of set water quality numerical limits to returning a water body to its original uses.

Confusion over the goals causes confusion for regulatees in terms of selecting the tools that need to be used to reach them. EPA needs to determine what the federal purpose is with regard to the storm water regulations given the reality of limitations of presently available methods and resources for preventing and treating storm water pollution.

3. **Citizen involvement can play an important role in achieving program goals. EPA, states and local governments need to promote citizen education and enforcement authority.**

Participants gave numerous examples of how citizens could play an active role in implementing and monitoring pollution reduction efforts. Given the limited resources of federal, state and local governments, voluntary citizen involvement can support successful program outcomes, including enforcement. Education of citizens at different levels, e.g. qualitative vs. quantitative monitoring, stream health vs. compliance monitoring, etc. would be needed. Guidance manuals can be developed to guide public education.

General Recommendations

The ten summary recommendations stated at the conclusion of the Executive Summary are here amplified to reflect the discussions and insights generated in this project. While not all persons involved agree with each observation and recommendation, these are advanced as having widespread support.

1. **It is possible and desirable to identify priority target areas for which there is widespread consensus concerning their contribution to water pollution.**

   These areas begin with new development and redevelopment--both residential and commercial. They also include transportation corridors, dense existing development and automotive services. Further, the priority of these target sources is relative to the watershed upon which they are impacting.

   Strategically, approaches that focus on a small number of priorities based on relative risk will show stronger results than one that initially targets a broad set of sources in Phase II. Also, it much more cost-effective to identify and pursue the "bad actors" (eg. those contributing toxicity as opposed to sediments or turbidity) as a priority, then get to those adding incremental pollution through routine activity.

2. **EPA needs to communicate more clearly and regularly with everyone impacted by the storm water regulations.**

The priority focus should be less on the amount of communication and more on different kinds of communication. Specifically, communications should be:

- more interactive--the examples of the focus groups and public meetings used in this project are often cited as productive formats for future citizen input;

- more localized to contexts--as in more regional workshops and fewer national ones. This means communications less inclined to reflect the national complexity of the program and more inclined toward addressing the specific information and guidance needs of the local person involved in a specific and delimited way. It also means less "canned" content and more consultative dialogue;

- less laden with acronyms and technical language that confuse and irritate many of the people who are the true "customers" of the program, and who are required to carry out the federal mandate. Along with this, more attention should be paid to finding and marketing simplicities rather than complexities.

3. **EPA could improve program effectiveness, efficiency and cost control in Phase II by "starting small".**

The concept of regional and even local prototypes was advanced by many people as a way of getting proposed new Phase II frameworks into the hands of users in prompt fashion to build and refine based on early use. This was generally seen as preferable to the comprehensive approach in which new programs are developed fully and then introduced comprehensively at a point when modification is difficult and expensive.

Related to prototypes is the case study--in which an analytical eye is turned to current programs that demonstrate one or more strategies or best practices for storm water implementation. An example is the Puget Sound model, with its focus on the tangible and cost-saving values of voluntary compliance by small businesses (a summary of this approach is contained in Volume 2).

The use of a small scale plays to the strength of regional differences as well as the reality that an equal stress on comprehensive large programs may so paralyze states and localities that nothing is done expeditiously.

4. **Selectivity in data collection and monitoring is essential.**

At present, some data collection frameworks consume tremendous time and money only to yield bad or useless data or murky or disputed conclusions. More attention should be paid as to what constitutes "good science" and activities that may show the appearance of effective activity but in reality be consuming scarce resources to no clear gain. This also relates to the adage, "what you measure is what you will get." While the tendency is to see monitoring and assessment as questions of methodology, they must first be viewed as questions of substance. What are we trying to measure and at what level of detail and accuracy?

Not all measuring and assessment need be arcane. In development projects, for example, the use of hay bales is known to contain overflows. No great study of cause or effect is needed. And if there is floating oil on a body of water, we can start by verifying that it is there--a useful step even if we do not "measure" its amount. At the same time, other kinds of assessment are meaningless without extensive (and expensive) levels of detail and analysis.

A related point is that documentation of discharger activity and accomplishment is as critical as scientific study of water conditions.

5. **More customer differentiation is also needed.**

At present the mind-set appears to be that one size fits all. While giving the appearance of equity, this concept actually creates strong inequalities. The same programs and regulations that befit a large corporation or municipality are simply not equitable for smaller enterprise and communities, for example. More broadly, some specific operations within a given source category contribute significant pollution; others contribute none. Some way to either make the initial process much less costly or to more quickly separate out those who do not need continuing attention must be found.

One form of general differentiation is between those who are causing a problem by clearly inappropriate activity (the "bad actors") and those contributing to storm water pollution by standard and at times inadvertent practice.

6. **While the ultimate goal is water quality standards, this is very difficult to achieve and/or to measure in the short term.**

While retaining water quality standards as the ultimate goal, EPA should be focusing on best management practices, and in particular those that reflect preventive and non-structural solutions. An example is stronger standards and technologies for storm water control in new residential and commercial construction. In many instances, the correlation is clear between the management practice and the consequences for cleaner water.

The codification and communication of best management practices applies not only to those targeted and controlled but to state and local actors implementing storm water programs. For example, a set of "carrots and sticks" known to promote voluntary compliance is just as critical to disseminate as a new approach to storm retention ponds in a sub-division.

While BMPs are set in place, interim milestones for water quality are also critical--and feasible--as a way of measuring progress. The transition from progress by practice to achievement by water quality measure must begin now.

7. **The most functional unit of both analysis and intervention is the watershed.** Most people in our samples for opinion and recommendation strongly suggested the watershed approach--not only on the macro level (e.g., Chesapeake Bay) but the micro-level as well. In particular, this means looking at stream quality issues beginning at the headwaters for early contributions and alterations. Most felt that functional differentiation of pollutant sources is not really meaningful in terms of either regulation or effective change at the watershed level.

8. **EPA's role is to offer technical support and direction more than program funding or even full guidelines for state and local implementation.** In particular, building useful data bases and collection methodologies not only on water quality but on practices to achieve it is critical. Also key are training and support programs and development of effective dissemination networks. In all EPA roles, the need is to recognize both regional differences and the need for a multi-faceted set of strategies, tools, approaches, solutions.

   Another EPA function is to focus on the connection between best management practices and long term consequences for water quality. While those who introduce them are in the best position to refine BMP's, they often do not have the tools to verify a correlation (let alone a causal connection) to water quality. This is an important EPA function.

9. **A collaborative approach to developing effective solutions is possible.** The interactive elements of this project are one reflection of the ability of those with strikingly different perspectives (ranging from strong environmental protection to a focus on economic development) to work cooperatively. If adversarial and polemical dynamics can be set aside, the gains are far greater.

   Collaboration must begin within EPA itself, where there is a tendency for those focussing on permits and "harder" tools of compliance and those focussing on education and "softer" elements of prevention to not fully connect with each other. In reality, there is a strong common theme from the need to see the storm water program as a way of enabling local communities and industries to change their behaviors to help the environment in ways that will directly benefit them as well as

VOL 12 4551

all other citizens.

10. **Agriculture activities should be included more directly in the storm water program.**

In many regions, agriculture (which includes livestock as well as crops) is a primary contributor to surface water pollution. While the present NPDES program requires permitting of the transport of agricultural products, this brings intervention too late. The critical first steps of agricultural activities, e.g. soil preparation, growing, and harvesting, must be included.

Beyond this reality is the signal sent that for whatever set of reasons, some interests are exempt from a program in which they clearly belong.

EPA GROUP INVOLVEMENT PROJECT

CONDUCTED BY: THE RENSSELAERVILLE INSTITUTE

REPORT SUBMITTED: SEPTEMBER 14, 1993

VOL 12

4555

EPA GROUP INVOLVEMENT PROJECT

Introduction

In early 1993, The Rensselaerville Institute undertook a project designed to gain various groups' involvement in development of Phase II of the Storm Water program. Working with the U.S. EPA Office of Wastewater Enforcement and Compliance, The Institute implemented an approach whereby groups and people with interest in the Storm Water program became actively involved in identifying and discussing a series of program design options.

A series of meetings were held in Dallas, TX; Washington, DC; Chicago, IL; and Falls Church, VA. Approximately 150 people participated in the meetings.

This report describes project implementation and the method utilized, highlights the results of the project, and provides a set of recommendations for program development.

Project Implementation

One of the first steps of the project was to craft a number of options to describe how the Phase II program could be organized and implemented. At a Phase II Options Identification Meeting held in January 1993, 14 different options for target and control of Phase II storm water discharges were outlined. From the original 14, seven options were developed; each designated certain program responsibilities and authority between federal, state and local entities.

These seven options were used as the basis for focusing team work at each of the meetings. Briefly, the presented options were:

1. **State Target Selection - Non-NPDES Control.**

   Phase II sources would be targeted by the states, using information from 305(b), 303(d) and 304(l) reports to target sources in watersheds where storm water is a significant source of impairment. Individual States would be able to select from a mix of controls to attain water quality standards. There would be no provision for Federal oversight of State control options.

2. Eliminate Phase II; Expand Phase I Designation Authority.

This option would eliminate Phase II of the storm water program. NPDES permitting authorities would retain designation authority to target and control any high risk sources of concern under Phase I of the program. The remainder of Phase II sources would be prioritized and controlled by States through existing non-NPDES control strategies.

3. NPDES Permits for Federally Selected Municipalities Not Covered Under Phase I.

Under this option, EPA would target urbanized areas and emerging growth area portions of municipalities and counties. NPDES permits would be issued to selected municipalities/counties and would require the implementation of a storm water management program through which the municipality would control commercial/industrial/residential sources within their jurisdiction.

4. Tiered Federal and State Target Selection - Tiered NPDES and Non-NPDES Control.

The first tier of high risk sources would be selected on a national basis with this option. Potential targets would include categories of facilities or activities, and urbanized and associated developing area portions of municipalities and counties. Additional sources may be selected by individual States based on information available to the State, including watershed data generated through 305(b) reports as well as 303(d) and 304(l) information. First tier high risk sources would be controlled through NPDES permits (State/EPA). Second tier sources would be controlled through a range of control measures under State discretion.

5. Federal Target Selection - Non-NPDES Control.

With this option, high risk sources would be Federally selected. Potential targets include categories of facilities or activities and municipalities located in urbanized and associated developing areas. Individual States would select their own control mechanisms for all Federally selected sources. There would be no provision for Federal oversight of State control mechanisms.

6. State Target Selection Consistent with Federal Criteria - State NPDES or non-NPDES Control.

EPA would develop selection criteria for sources (criteria would include watershed targeting and reliance on 305(b) reports as well as 303(d) and 304(1) lists as appropriate). States would identify high risk activities using these criteria. Potential targets would include categories of facilities or activities, urbanized and associated developing area portions of municipalities and counties, and sources located in affected watersheds. The State may implement either point or non-point source control measures as they see fit. Federal oversight would be exercised; sub-options would provide for different oversight schemes.

7. Federal Target Selection - NPDES Control.

With this option, high risk sources would be selected at the Federal level. Potential targets would include categories of facilities or activities, and urbanized and associated developing are portions of municipalities and counties. All sources identified would be controlled through NPDES permits.

At each of the three public meetings held, participants were presented the above list of options, and were provided the opportunity to ask clarifying questions about each one. For their first task, they were asked to identify strengths and weaknesses of each option in terms of targeting, control and timing strategies, and decide what changes if any they would make in the option to improve it. Participants were also given the opportunity to create their own option(s) for consideration.

The second task for participants at each public meeting was to list the key components that they felt should be included in a Phase II program for it to be successful, and to identify actions that EPA should avoid taking because the actions would have major detrimental effects on program success.

Participants were divided into small working teams of 6-8 people. Each team appointed one person to record group responses to each of the tasks. Following each task, teams reported out to the rest of the group.

Individual meeting reports of team responses to the options are appended to this Executive Summary. The list of options for the first meeting was slightly different than the list used for the remaining meetings in both order of option presentation and wording. The list was modified for two reasons: 1) there was a sense that, because the options were presented from most to least Federal control, people in the first two meetings may have been

VOL 12

4557

unintentionally drawn to 'middle of the road' options; and 2) initially, one option explicitly included a watershed approach, and therefore people may have felt that it was the only option that could incorporate it, even though the other options in no way excluded using the approach. Thus, participants in the second two meetings received the options in a different order and with explicit reference to the watershed approach given in a number of option descriptions.

Two final 'expert meetings' was held in Chicago, IL and Falls Church, VA, where national storm water experts convened to review the options and suggest overall criteria for selecting a Phase II option.

Project Results

Task I: Identifying Strengths and Weaknesses of Options

At each public meeting, individual teams presented their responses to each of the options listed above. The responses of all teams for all meetings were compiled for this report. The responses of any individual team can be found, by meeting, in the appendix. Below, in discussion of various favored options, a sampling of responses across teams and meetings is presented.

Option Responses:

Across the board, meeting participants identified Option #6, 'State Target Selection Consistent with Federal Criteria - State NPDES or non-NPDES Control' and Option #4, 'Tiered Federal and State Target Selection - Tiered NPDES and Non-NPDES Control' as their most favored options.

Option #6, which would have States target high risk sources based upon Federally established criteria for selection and would include Federal oversight of State programs, was seen to provide the consistency needed nationwide for target selection while still allowing states the flexibility needed to control sources and identify high-risk polluters. This option was seen as easily incorporating a watershed approach, and including both point and non-point sources. Some of the strengths identified for Option #6 included:

- uniformity of selection criteria of sources among States;
- removal of the burden on States to develop selection criteria of their own;
- the flexibility to allow non-point source controls;
- giving States, who are closer to the problems and issues, more input into the decision-making process;

VOL 12

4558

- giving States more latitude to develop programs which meet their own needs and high risks;
- establishing a partnership model between EPA and States, not a command-and-control model.

Some of the weaknesses that participants associated with Option #6 included:

- the probability that there would be inconsistencies between States on requirements;
- that it does not protect unimpaired waters, because the focus is on remediation not prevention;
- the potential for disagreement between State and Federal levels on the criteria established. The State may differ in the prioritization of pollutant sources;
- that Federal criteria may not be applicable to the State because of geographic, industrial, or other unique characteristics;
- a State may not have the resources to handle the program;
- the potential for State and local disagreement over controls used;
- that it could penalize progressive States that have already taken the initiative to develop a program, only to have EPA set criteria that don't "mesh" with their progress;
- the possibility that industries with multiple facilities in different States would have to deal with differences in requirements, timing, etc.

Option #4 was identified by participants as the next most favored option. According to that option, EPA would identify the first tier of high risk sources, and then the States would target additional sources as appropriate. The EPA-targeted sources would be permitted by EPA or delegated States, and then the States would have the latitude to use a range of control strategies for additional identified sources. Some of the strengths that teams listed for Option #4 included:

- would allow for quickly addressing severe problems, so the State would have more time to deal effectively with other problem sources they identified;
- provides more options for compliance in its latitude for control strategies;
- allows States more discretion and time to identify and prioritize sources;
- provides a potential advantage for industries to keep themselves clean enough so that they are not targeted for (State-selected) Tier II. This option might act as an incentive to get industries to focus on pollution prevention;

- offers the ability to incorporate less resource-intensive controls to lesser risk sources such as 404-type permits;
- Tier I allows non-contributors out of the system (since EPA would be targeting only determined high risk sources);
- seems to be more equitable than Phase I targeting and control strategies.
- permitting provides a clear point of control, i.e. the "gorilla in the closet".

Some of the weaknesses that teams associated with Option #4 included:

- the time and expense of performing risk assessments, which the States would need to do in order to target Tier II sources;
- promotes 'buck-passing' of responsibility between Federal and State levels;
- the possibility that it would create inconsistencies among States for targeting and controlling industrial categories (high risk sources);
- EPA/State coordination could be difficult, which could prolong the time it would take to implement this option;
- the potential inconsistencies that could occur for States regulating interstate waters, e.g. Chesapeake Bay.
- EPA may not have adequate information to screen and identify high risk sources on a national basis.

There did not seem to be a consistent "worst choice" option among meetings. However, among teams at the Dallas meeting, one option - Option #7, in which high risk sources would be selected at the Federal level and controlled through NPDES permits - stood out as unfavorable for six out of eight teams. Their common reason was that the Federal level would be the primary decision-maker in this option. Across all meetings, teams favored options that promoted a system of shared decision-making and responsibility reflecting the need for a partnership between Federal and State entities.

In one of the Washington public meetings, two options - option #5, in which high-risk sources would be Federally selected, with no provision for Federal oversight of control mechanisms; and Option #1, in which States would select sources and controls, with no provision for Federal oversight - were deemed the <u>least</u> favorable. In terms of Option #5, participants did not see the federal "teeth" that they felt would be needed to enforce the program. Many people across meetings felt that if there was not "the gorilla in the closet", i.e. the threat of EPA enforcement of the regulations after incentives were tried and failed, the program would not work.

VOL 12

4560

Sentiment was similar regarding Option #1, and again centered around the sense that some States would do very little if the Federal government were not driving them.

It was quite apparent that, while involved groups do not want a standard command and control situation with every aspect of the program dictated at the Federal level, they still see a need and role for Federal regulatory enforcement as a motivator to get States and the regulated community to implement effective storm water programs.

VOL 12

Task II: Contributors to Program Success

The purpose of Task II was to have participants identify the critical factors that would help to ensure a successful storm water program, no matter which option or combination of options was selected. Teams were asked to identify the essential and basic components of a program that they believed would be required for the program to be successful. Further, they were asked to advise EPA on what the agency needed to avoid doing in order to further ensure successful program outcomes.

A summary of team responses to each of these tasks is presented below.

Task II a: Key Components for Program Success

Teams were asked to identify and list what they believed to be the key components of a successful storm water program. Responses to this task differed between group representation (e.g. State government, local government, etc.) and geographic region. There were, however, common components listed by teams across meetings. The first four items were mentioned by more than half of all work teams; the remainder were mentioned by 25-50% of the teams. The items teams identified as key to a successful program included: (in parentheses are comments made by some of the individual teams re: the item)

4561

1. Public education and awareness programs (e.g. through trade associations, at schools, use of various media - everybody needs to be educated);

2. Training for regulators and the regulated community (e.g. for States, regions, permit writers, permittees; periodic regional/national meetings; hands-on training for municipalities and industry; dialogue and feedback between EPA, States and locals; technical assistance);

3. Timely guidances (get guidances out ahead of time as regulations are passed; provide guidance on technology transfer and innovative technology; include case studies and a data clearinghouse);

4. Determination of what lessons were learned from Phase I of the program, and mechanisms for Phase II that will allow tracking and assessment of the program within reasonable timeframes. A key factor is to allow enough time for an adequate review process of Phase I to see how Phase II could build on and expand those efforts;

5. Clear regulations (e.g. straightforward as possible; user friendly, clarity of coverage/applicability; clarity in criteria; be more specific in naming industrial activities covered under the regulations);

6. Use of a Watershed approach to implement the program;

7. National guidelines for the program (e.g. identify measurable goals for regulated sources, standards, designated use impairments, mechanisms for oversight, long range planning; recognize cost and implementation of compliance; provide realistic measures of success);

8. A phased-in approach for the Phase II program (e.g. reasonable time schedule, long-term phase-in). The most common timeframe mentioned by teams was 3-5 years for program implementation;

9. Pollution prevention incentives (send out guidance on pollution prevention to potentially regulated facilities now; offer exemptions; reduce requirements as an incentive for successful use; possibly provide a menu of programs on pollution prevention plans from which entities can pick and choose);

10. Program flexibility (e.g. to change deadlines based on hydrological flow; to implement and use elements of a watershed approach to bring in stakeholders and implement a program).

Approximately half the teams noted that there need to be some dedicated funding sources available to States, local government and permittees to assist in successful implementation of these program components. Teams felt that EPA should either provide funds or provide guidance on how States and local governments could implement fund-generating systems, e.g. storm water utilities. Team suggestions included: funding could first be made available through congressional appropriation to EPA to help programs start, and then programs could generate on-going funds through permit

VOL 12

4562

fees; EPA should make available federal grants and loans to States, locals and permittees.

Task II b: EPA Actions that would be a Barrier to Program Success

Teams were asked to identify and list those actions that EPA should avoid taking lest those actions prevent programs from being successful. The actions most frequently mentioned include:

1. Unnecessary/unusable program requirements, including excessive monitoring, unrealistic BMPs and compliance criteria, cost-prohibitive Best Management Practices;
2. Fully developing requirements before pilot testing various proposed components of the program to catch inconsistencies, problems, etc. In other words, do small scale testing of program elements and use knowledge gained from those pilot tests to refine the regulations before they are put into effect;
3. Unrealistic deadlines and goals;
4. Implementing program regulations without providing dedicated program funding;
5. Promulgating the requirements without providing written guidances and technical assistance concurrent to doing so.

Criteria for Selecting A Phase II Option

The final meetings brought together storm water experts from across the country to develop an option in detail for the Phase II program. One of the products from those meetings was a developed set of criteria on which to base option selection.

Those criteria are that the program:

1. Does not rely solely on the actions of just one player. The program needs to include multiple levels: EPA, States, targeted municipalities and industries. For example, the Federal government should not be designer and decision-maker, educator, enforcer and funder. The program needs a balance of players across levels, each with a clearly defined role. Also, there needs to be a clear avenue for intervention at the Federal level if States or municipalities fail to implement the program, i.e. "the gorilla in the closet".

VOL 12 4563

2. Provides clear guidance and unambiguous targeting categories and words (e.g., words like "sufficient" should be avoided, at least if there is no way to define what they mean in a given context). Simplicity and clarity should be favored; words that are ambiguous or hazy should be avoided. The regulations must be clear to the regulated community in terms of goals, objectives and implementation if EPA is to gain "buy-in" from them.

3. Provides the resources (not only dollars, but people as well) or suggests how they can be obtained for that option. The program needs to be clear on who pays for what, e.g. Federal, State, local, permittee.

4. Is flexible, especially in recognizing regional and local differences, not only in terms of storm water pollutant loadings but also in terms of their environmental impact. For example, even if all gas stations put out an equal volume of pollution, the environmental impact may vary depending on location. Or as another example, recognition of the vast differences between States, such as mid-Atlantic compared to Southwest, which would mean a vast difference in what they need in terms of a storm water program.

5. Needs to be nationally consistent in the underlying methodology used, i.e. consistent national guidelines, identified goals, measures of success, etc. while at the same time recognizing regional differences and allowing flexibility to implement a program that best addresses the particular characteristics of local problems.

6. Emphasizes the need for program responsibility and authority that is "pushed" down to a local level. The sense of some of the participants in this meeting was that the best understanding of the problem and how to deal with it is the people closest to the problem who have to deal with it, i.e. local problem/local government and groups. Note: People representing local government at the meetings were extremely concerned about the lack of resources and technical expertise that might be found at the local level in many situations. The need for adequate funding was again identified as a critical issue, and some suggested that utility districts would be the only real way to fund the program unless the cost is low enough that it could be covered in a regular budget. The group agreed as a whole that resources and technical expertise not withstanding, this program must be accepted and supported at the local level if it is to be successful.

VOL 12

4564

7. Provides the opportunity to integrate other water issues and concerns--e.g., groundwater. For example, restriction on certain BMPs affects groundwater impacts. The methodology used should allow integration with groundwater, habitat, and other water programs. It needs to integrate or be compatible with other sections of the Clean Water Act, e.g. right now 402 causes 401 and 404 compliance problems.

8. Needs to build on and tie to Phase I, where much work was done and where momentum has been established. A lull now means the need for a new start up - right now the energy level is high and awareness of the storm water program has been growing, so EPA needs to tap into that forward movement. If EPA waits too long in getting Phase II out, inertia will set in, and it will take much more energy and effort to get it in place. And the talented people will go on to something else (208 was given as an example).

Other key areas of expert discussion around Phase II program considerations included:

1. **EPA needs to recognize the potential gaps between "best efforts" and performance standards.** On the one hand, we have a variety of ways of characterizing best efforts: Best Management Practices (BMP's) and Maximum Extent Practicable (MEP) are examples. These are inputs, presumed to influence water quality. On the other hand, we have water quality standards that are outcomes. One question: what do we do if people follow BMP's and water quality does not improve to the standards we set? What if the "maximum extent practicable" is deemed in place and we still have an outcome shortfall?

2. **Two distinct structural premises are in play.** One is of a national program which is administered by the States. In this view, EPA provides mandates, and supports state and local efforts to reach them. The other premise is more decentralized. It is seen as a set of State programs and initiatives which share a national performance target. In at least some respects, the structural premise held suggests different programmatic approaches in such areas as desired and allowable variability among states and localities.

3. **Much wisdom about storm water controls are not readily generalizable.** BMP's in the residential development field, for example, were said, by some experts, to hold true for a scale of 5 - 50 acres. And many watersheds for which solutions are designed are actually very small. It is hard to "scale up" answers.

VOL 12

4565

4. **Program "champions" are often a factor in program success.** One expert observed, and others agreed, that the individuals involved in storm water programs were as much a reason for high program performance as was the program plan. We should be careful to allow for this factor in the emphasis on rules, procedures, and even workplans.

5. **Pollution prevention should be emphasized.** While often anecdotal, a variety of examples were offered of situations in which preventive steps solved a water quality problem. These examples, like the Puget Sound program discussed in our earlier report, were generally focused and interactive. They did not rely on the spread of information alone to prompt changes in behavior.

6. **EPA needs to allow State and local flexibility to address priorities as they have identified them.** The theme of selectivity combined often with local flexibility. e.g., in some areas, a little more grease has a tremendous negative impact on the environment. In others, it does not. Selectivity on targeting is also clear, e.g., that BMP's on new land development (commercial as well as residential) would pay high dividends vs. other generalized targets.

7. **Several equity or fairness issues emerge and persist.** One concerns those sources targeted. If a discharger has done everything in their permit -- all the BMP's are in place -- and the water is still dirty, is he or she liable? Another is the distinction between larger organizations (corporate or municipal) with resources to handle permits and processes and much smaller ones which lack that capacity. To what extent is the same rule as "fair" for the small town as for the big city?

8. **The Federal role in the program to establish a partnership with States, and be an enabler rather than an enforcer.** Participants felt that EPA's responsibilities would be to develop national goals and guidelines, set national selection criteria, establish a selection methodology, and develop a universal methodology for selecting controls that would allow programs to choose alternatives based upon their needs, e.g. regional and local differences. Participants felt strongly that Federal oversight is a necessary component to ensure that States do implement programs, i.e. be the "gorilla in the closet". However, in a partnership capacity, participants felt EPA should first be ready to provide support and technical assistance rather than punitive measures to programs that were not meeting standards despite best efforts.

4567

APPENDIX J

SUMMARY OF PHASE II COMMENTS

Organization of Phase II Comments

I. Targeting

A. General Targeting Approaches for Both Municipalities and Industries

	Yes	No
■ Examine Phase I data before selecting Phase II sources. **[1.g.iv]**	52	0
■ Amend CWA and eliminate Phase II/ cover additional sources under Phase I **[1.a]**	28	7
■ Establish requirements for State storm water programs to identify additional sources. **[1.f]**	18	5

■ **Examine Phase I data before selecting Phase II sources. [1.g.iv]**

The majority of the commenters (52 commenters) agree that a close examination of Phase I is essential before launching into Phase II. Many of these commenters also stressed that EPA should complete the Reports to Congress, as specified under section 402(p)(2)(5) of the CWA. Such an examination would allow EPA to evaluate whether the current approach is achieving the intended goals, or whether another approach to storm water permitting would be more effective. As discussed in detail later, commenters expressed a number of concerns about the storm water program, including 1) the high cost associated permit compliance and program administration; 2) the ineffectiveness and inequity of "blanket coverage" of particular industrial activities that do not pollute while other "bad polluters" remain unregulated; and 3) a general uncertainty about the goals of the storm water program and whether, in fact, these goals are being achieved under current program.

■ **Amend CWA and eliminate Phase II by covering additional sources under Phase I; administer through NPDES or section 319 (NPS) or section 6217 (CZARA). [1.a]**

To address these problems associated with Phase I, commenters indicate that a change in how facilities are targeted is necessary. Of the 91 commenters, approximately a third (28) favor amending the CWA to eliminate Phase II of the storm water program and to bring additional sources under Phase I. As far as regulating these Phase II sources under Phase I, the majority of commenters prefer a continued reliance on the NPDES program as opposed to State non-point source programs (funded under Section 319 of the CWA and/or section 6217 of the CZARA). While commenters support continued reliance on NPDES, they overwhelmingly agreed that Phase II

VOL 12

4568

sources should not be targeted by EPA headquarters but rather by State and/or local entities.

These commenters argue that by eliminating Phase II and bringing additional sources under Phase I, the problems associated with Phase I storm water permitting will be most effectively addressed. In particular, by designating facilities under section 402(p)(2)(E), States can target those industrial activities that are impacting sensitive watersheds and/or posing the greatest environmental risk. One State agency notes EPA should "maintain national data for determining environmental risk, establish priorities for additional activities to be covered under a storm water permit, and coordinate compliance, enforcement and educational information among the States."

The majority of commenters believe that designation authority in the hands of the State would be the most cost-effective targeting approach. However, other commenters express concern over shrinking State budgets and indicate that additional funding would be needed, particularly if the program were administered under section 319.

Those commenters opposing the elimination of Phase II (7 commenters) argue that for reasons of equity Phase II sources should be subject to the same requirements as Phase I. The concern is that State designation of Phase II sources may result in inconsistencies throughout the country. One municipality argues that in order to effectively protect water quality, smaller municipalities should be required to develop the same storm water management programs as the medium and large municipalities were required to under Phase I.

- **Establish requirements for State storm water programs to identify additional sources. [1.f]**

18 commenters out of 91 commenters favor the targeting option whereby EPA would establish Phase II requirements for State NPDES storm water programs to identify additional sources. 5 oppose this option.

Those supporting this option believe that States and local entities (not EPA) should be identifying additional sources for Phase II permitting, adding that EPA should somehow direct the States and municipalities to develop programs appropriate to their unique requirements and monitor the progress of these programs. As far as EPA's exact role in this process, some commenters assert that EPA should establish baseline effluent limitations for particular industries and then establish control measures for these industries. Other commenters believe that such determinations should be made by the State, with EPA maintaining its important role as an information and guidance clearinghouse. One State agency writes that "minimum criteria in the area of funding levels and educational requirements seems appropriate." These commenters indicate that this approach is preferable as it establishes consistent criteria for the development of State storm water programs.

B. Options for Targeting Phase II Industrial Sources

	Yes	No
■ Geographic Targeting: Designate additional individual sources in watersheds of concern (those not meeting designated water uses) and in specific rainfall zones [1.e/1.g.i]	48	5
■ Focus on high-risk polluters and exempt facilities that don't pollute. [1.d/1.g.ii]	39	3
■ Rely on Phase I MS4s to target industrial sources that discharge through their system. [1.c]	9	11

■ **Geographic Targeting: Designate additional individual sources in watersheds of concern (those not meeting designated water uses) and in specific rainfall zones. [1.e./1.g.i]**

Almost half of the 91 commenters (45 commenters) support targeting sensitive watersheds, i.e., those that have high pollutant loadings and/or those not meeting designated uses. These commenters argue that such an approach is the most cost-effective way to improve the quality of the Nation's water. (Please note that within this category, more commenters support permitting watersheds under the NPDES program than under State nonpoint source programs). Commenters suggested that this approach should be coupled with identifying the industry "bad actors" within watersheds of concern. (Identification of "bad actors" is discussed in the following section).

A number of commenters believe that watersheds should be prioritized based on criteria such as threats to high quality resources or significant degradation. One industry offered the following suggestions for a watershed strategy: "1) Conduct a survey of receiving watersheds and rank them based upon their designated uses and level of contamination; 2) Identify and prioritize major sources of pollutant loadings; 3) Analyze the control measures to control these pollutant sources and prioritize them based on cost effectiveness." Some commenters stress the importance of developing national criteria for evaluating watersheds so as to avoid inconsistencies among different regions.

In terms of evaluating watersheds, commenters suggest using the following CWA mechanisms: Section 303(d) which prioritizes a ranking of waters, section 305(b) which describes water quality of all navigable waters in the State, section 319 watershed listings, and section 304(l) which lists waters not expected to meet water quality standards. Some commenters suggest that sampling data from Phase I cities be used to generate regionalized watershed loading criteria.

Regarding costs, a number of commenters agree that targeting watersheds would be more cost-effective for both industries and States than current targeting strategies. However, some States express concern over the cost of gathering watershed-specific information in a timely manner. One State argues that "entirely too much effort would need to be invested to determine what waters have been negatively impacted by storm water runoff. Using the lists from 305(b) reports is not sufficient nor acceptable."

As far as designating specific sources by rainfall zone, there was some scattered support for this measure. However, most commenters agreed that it could be difficult and costly to generate timely, meaningful data that could justify variances or special conditions between regions.

- **Focus on high-risk polluters and exempt facilities that don't pollute. [1.d/1.g.ii]**

Nearly half of the commenters (39 commenters) supported targeting high-risk industrial polluters. Only three commenters opposed the option. As discussed above, many commenters believe that targeting of "bad actors" should be linked to the targeting of sensitive watersheds.

In general, commenters feel that the Phase I targeting of industries based on SIC codes was not cost-effective. In addition, many commenters believe that a number of the big industrial polluters were not included under Phase I of the storm water program. Commenters unanimously agree that bad actors who are contributing to water quality degradation should be targeted for Phase II permitting, while those "good actors" who don't pollute should be exempted. This approach, commenters say, would reduce the regulatory burden on all those facilities that are not contributing to water quality problems.

One State agency stressed that determinations of "bad actors" must be done on a State or local basis, not by EPA. "Controlling activities that are specifically designated by EPA could be a significant waste of time and resources if a particular jurisdiction has other activities that contribute to higher pollutant loads." This commenter suggested using data gleaned from municipal applications to determine Regional water quality information.

As far a which particular "bad actors" should be targeted under Phase II, commenters suggested the following industries: gas/auto service, State highways, large parking lots (malls), tank farms, commercial activities with industrial components, and construction activities of less than five acres. Please note, however, that a number of trade organizations representing the above industries submitted lengthy comments outlining why their industries do not pose environmental risks.

Those commenters opposing the option (3 commenters) claim that focusing on "bad actors" is a reactive strategy rather than a preventative one. Further, one commenter argues that using impairment would be imprudent as States (after more than a decade) still have not completed inventories of their waters. The commenter further states that agricultural runoff and irrigation return flows, which are exempted under the CWA, constitute some of the worst pollution in the country. One commenter suggests the continued use of SIC codes but with exemptions provided for those who have proven that they don't pollute.

- **Rely on Phase I MS4s to target industrial sources that discharge through their system. [1.c]**

11 commenters opposed the targeting option whereby Phase I MS4s would target industrial sources discharging through their systems; 9 commenters supported the option.

Those commenters opposing this option feel that the burden of regulating Phase II industrial dischargers would be too great, and that this role rightfully belongs to the State. Further, commenters believe that water quality problems are not confined to individual municipalities, but rather they span entire watersheds. These commenters argue that standards would not be uniform--or efforts might not be coordinated--between different municipalities and, therefore, regulation through State or EPA would be more equitable. Municipalities indicate a willingness to assist States in targeting Phase II sources, for example, by providing a list of potentially high-risk industries. Commenters supporting this option believe that because Phase I municipalities already have their storm water management plans in place, they are the most appropriate entity to identify additional sources under Phase II.

VOL 12

4573

C. Options for Targeting Phase II Municipalities

	Yes	No
■ Identify MS4s based on population, population density, and or population growth. [1.b]	20	20
■ Geographic Targeting: Designate additional municipal sources impacting watersheds of concern (those not meeting designated water uses) and in specific rainfall zones [1.e/1.g.i]	48	5
■ Permit small municipalities but establish simplified application requirements. [1.g.iii]	15	1

- **Identify MS4s based on population, population density, and/or population growth. [1.b]**

Commenters are split evenly (20 in favor, 20 against) Phase II MS4s being targeted on the basis of population, population density and/or population growth.

Commenters in support of this approach argue that municipalities having particularly dense populations and those experiencing intense population growth due to new development should be of primary concern under Phase II of the storm water program. One commenter also notes that MS4s could be targeted on the basis of watershed population. At any rate, numerous commenters agree that effective Phase II storm water programs must be coordinated on a regional basis [perhaps in conjunction with those already established under Phase I]. This would allow for the development/implementation of regional policies and regional BMPs, and would facilitate addressing specific issues such as land use, structural controls and construction activities. As discussed later, the majority of commenters supporting this approach also advocate the establishment of simplified permit application requirements.

The majority of the comments opposing this option are from small municipalities. Approximately half of these commenters believe that municipal storm water management should be conducted on a watershed basis rather than by determining population density and/or growth. The other half opposes Phase II regulation of small municipalities altogether. "Phase II regulations will have a very significant impact on municipal budgets if implemented similar to Phase I," 11 municipalities wrote. "These will entail increased staff levels, testing, consulting fees and other costs which are unduly burdensome, particularly where there is no Phase I documentation to show that environmental quality is enhanced." Of primary concern among municipal commenters is the astronomical cost associated with completing municipal storm water permit applications. They argue that funds do not exist to implement the storm water program and that political pressures would prevent them from securing storm water utilities.

- **Geographic Targeting: Designate municipalities impacting watersheds of concern (those not meeting designated water uses) and in specific rainfall zones. [1.e./1.g.i]**

As discussed under the "Industrial Targeting" section, nearly half of the 91 commenters (45 commenters) support targeting sensitive watersheds, i.e., those that have high pollutant loadings and/or those not meeting designated uses. While targeting these watersheds can help identify significant industrial polluters, many commenters also believe that this approach is useful in identifying MS4s for storm water permitting.

These commenters argue that since watersheds are oftentimes a patchwork of rural, suburban and urban lands comprised of incorporated and unincorporated areas, storm water permits should apply to the jurisdiction as a whole, not just to individual municipalities within the watershed. Commenters note that in watersheds of concern, all Phase II municipalities could become co-permittees with Phase I municipalities. Where it is determined that watersheds are not polluted, Phase II municipalities would not be required to obtain a storm water permit. This option provides opportunities for municipalities to reduce administrative burdens, consolidate efforts to study or evaluate approaches, and greatly reduce costs of program development and implementation. Although a great deal of regional coordination would be required, commenters believe that such an approach would yield the greatest environmental benefit.

(Please refer to the "Industrial Targeting" section for a summary of options for targeting on a watershed basis).

- **Permit small municipalities but establish simplified application requirements. [1.g.iii]**

15 commenters support the idea of permitting small municipalities but establishing simplified application requirements. Arguing that Phase I municipal permit application requirements (particularly Part 2 requirements) were burdensome and overly costly, these commenters suggest that Phase II municipalities be covered under a simplified general permit that requires a storm water management plan and flexible watershed-specific monitoring requirements. One commenter suggests the following components of a Phase II municipal program: 1) *Sediment and Erosion Control*:

VOL 12

4574

R0037883

Applicants incorporate erosion control into the development review and local permitting process; 2) *Storm Water Quality Control*: Applicants incorporate storm water BMPs into the municipal development review and approval process and into municipal operations; and 3) *Illicit Discharges*: Applicant prohibits illicit connections and improper dumping, he/she develops a spill prevention and response plan.

II. Control Strategies

A. General Control Strategies for Both Municipalities and Industries

	Yes	No
■ Continue to rely on NPDES programs; use NPDES general permits that focus on BMPs. [2.a/2.d.I]	32	4
■ Rely on nonpoint source programs administered under section 319 of the CWA and section 6217 of CZARA. [2.b]	20	3
■ Establish mandatory national Phase II performance standards without a permit. [2.c]	14	10

■ **Continue to rely on NPDES programs; use NPDES general permits that focus on BMPs [2.a.]**

Approximately 32 commenters favor the continued use of NPDES programs to regulate storm water discharges. 19 commenters prefer reliance on State nonpoint source programs under section 319. Most commenters state that it would be inefficient to discontinue the current program, and, as one commenter notes, displacing the NPDES program would "create a significant amount of confusion among authorized NPDES States and the regulated community." Additionally, the NPDES storm water permit program is in the initial stages of development and results may not be realized for at least two years. The majority of the commenters who support reliance on the NPDES program encourage use of general permits, for an "emphasis on the development of effective programs, not on lengthy and expensive application processes." Most commenters believe that BMPs are a more effective control strategy and a better allocation of resources than monitoring and numeric effluent limitations. BMPs utilized should be those which proved cost effective for Phase I sources.

- **Rely on nonpoint source programs administered under section 319 of the CWA and section 6217 of CZARA. [2.b.]**

Approximately 21 commenters favor the use of State nonpoint source programs and/or section 6127 of CZARA to regulate Phase II storm water discharges. Many of these commenters assert that storm water runoff is a nonpoint source rather than a point source and therefore should be regulated under section 319. Moreover, State nonpoint source programs are already developed and utilizing them would lessen the repetition of water quality programs. Several commenters emphasize, however, that if State nonpoint source programs were expanded to include storm water runoff, additional funding would be essential. Those commenters that supported the use of section 319 see it beneficial in that the program encourages flexibility through voluntary control measures, pollution prevention, and watershed planning. Several commenters express some trepidation that nonpoint sources may be moved under the NPDES program, and assert that nonpoint sources should continue to be covered under section 319, not NPDES.

- **Establish mandatory national Phase II control strategies without requiring a permit. [2.c.]**

Commenters are fairly divided on whether EPA should establish national control strategies for Phase II sources. Various statements from the 12 commenters who support mandatory guidelines indicate that this approach would be cost-effective and would alleviate the administrative burdens of permit applications. A few commenters also state that, in order to be most effective, the guidelines and management practices should be industry-specific. A model that is mentioned by several commenters is the Puget Sound Water Quality Management Plan and the Washington State Department of Ecology's Stormwater manual for the Puget Sound Basin. These commenters suggest that all States adopt a similar storm water management plan which would be required to at least meet a national standard; all municipalities within the State would have to adhere to the plan.

11 of the commenters who address this control strategy oppose mandatory national control guidelines for Phase II activities. Several commenters believe it would be difficult to effectively notify and educate the general population concerning the details of such a program. Other commenters express concern that the diversity in climate and topography throughout the country requires more flexibility than national standards would provide.

B. Key Elements of a Control Strategy

		Yes	No
■	Focus on education for public and affected industry. [2.d.ii]	18	0
■	Emphasize pollution prevention incentives and BMPs, particularly for new development. [2.d.iii]	17	0
■	Establish correlation between severity of pollution and controls required, using fines to aid implementation. [2.d.iv]	3	0

- **Focus on education for public and affected industry. [2.d.ii]**

  14 commenters state that education needs to be a primary focus of the Phase II program. One commenter notes that EPA should "keep it simple," particularly on issues on coverage, since Phase II dischargers may be smaller and less familiar with environmental regulations than Phase I dischargers. Commenters unanimously stress the importance of public education and outreach. They urge that EPA/States 1) distribute guidance documents and fact sheets prior to implementing the rule, 2) provide examples of pollution prevention programs, 3) conduct workshops, 4) prepare video presentations for distribution, and 5) launch public education campaigns geared towards explaining water quality problems associated with storm water.

- **Emphasize pollution prevention incentives and BMPs, particularly for new development. [2.d.iii]**

  14 commenters support an emphasis on voluntary pollution prevention programs. This approach is favored because of its cost-effectiveness, flexibility, and reduction in regulatory burden. Additionally, several commenters indicate that it would establish a 'partnership' between the regulated community and regulatory agencies by encouraging dialogue and guidance concerning pollution prevention techniques. One State notes that the voluntary measures in its nonpoint source program have proven very successful in improving water quality, and that similar practices could be implemented for storm water runoff. The State recommends, however, that voluntary approaches be used in conjunction with mandatory approaches and that "provisions be included for requirements placed on 'bad actors' if cooperation is not attained through the voluntary programs." Numerous commenters point out that education would need to be far-reaching if the voluntary programs were implemented.

VOL 12

4577

- **Establish correlation between severity of pollution and controls required, using fines to aid implementation. [2.d.iv.]**

Only 3 commenters address this control strategy, and all 3 support a correlation between severity of pollution and controls required. One commenter writes that, "market based incentives structured to incorporate true economic externalities associated with pollution can be a valuable tool in helping society balance economic growth and levels of pollution." Another commenter notes that State agencies should administer the fine/implementation system, as States can adjust their controls based on the types of pollutant sources and sensitivity of the watersheds in a particular region.

III. Deadlines

A. Options for Program Deadlines [3]

	Yes	No
■ October 1, 1995 or later	12	
■ Prioritize sources; establish phased deadlines	3	
■ Eliminate Phase II; no deadlines	1	
■ Pending thorough review of Phase I	20	
■ H.R. 6167 deadlines satisfactory	3	
■ Before October 1, 1994	3	

Commenters unanimously feel that Phase II should not be implemented until a thorough review of Phase I has been completed. A number of these commenters indicated that Phase II regulations should not be published before October 1, 1995.

VOL 12

4578

VOL 12

IV. Costs/Regulatory Burden

A. Issues associated with costs and regulatory burden

■	Balancing the need to protect the environment with the cost-effectiveness of the program [III.A.2]
■	Examining the impacts of the storm water program on small businesses and communities [III.A.7]
■	Assessing the regulatory burden on permittees and regulators [III.A.3/III.A.4]

General Cost/Benefit Concerns

Nearly a third of the commenters (26 commenters) express concern over the costs associated with implementing the storm water program, and whether these costs justify the need to protect the environment.

Municipalities, in particular, voice concern over the costs associated with completing municipal permit applications and implementing storm water management programs. One commenter argues that while cities across the nation have spent over $1 trillion dollars to implementing the program, water quality is not significantly improving because of upstream discharges not regulated under the CWA. This commenter further states that since urban runoff affects only 11% of river impairment and 29% of lake impairment, the price tag of implementing storm water management programs is not justified. (Please note that a number of commenters question EPA's methodology in 305(b) reports as it pertains to assessing "designated uses" for waterbodies).

Comments indicate that across the board--among cities, small business owners, and trade associations--the storm water program is viewed as a major financial burden on communities and industries. Of particular concern for cities (and especially small cities) is the number of growing number of projects/regulations that need to be supported by shrinking municipal budgets. Generating a storm water utility to support the program has proven politically difficult in a number of cities. On the industrial side of the program, there are equally as many concerns over costs and benefits. In particular, commenters argue that a number of small industries which pose little risk to the environment were required to apply for a storm water permit under Phase I, while "higher risk" industries such as oil and gas, agriculture, and retail gasoline facilities were not covered by the rule. A number of small industries claim that sampling is cost-prohibitive and that the quantitative data generated are oftentimes inaccurate/meaningless. Regarding Phase II, one construction operator

4579

argues that inclusion of construction operations under 5 acres would render these small-scale activities cost-prohibitive.

Strategies for Phase II

In closing, commenters offer the following suggestions for maximizing cost-effectiveness and environmental benefit under Phase II:

- Phase I of the storm water program must be thoroughly assessed in terms of dollars spent and environmental benefits gained before launching into Phase II.
- EPA and/or States must incorporate a more realistic benefit/cost analysis of Phase II, particularly for the municipal side of the program.
- Under Phase II, emphasize storm water management and pollution prevention rather than sample gathering and analysis. (A number of the quantitative requirements under Part 2 of the municipal permit application were viewed as unnecessary and overly costly)
- EPA and States should use data generated from Phase I of the program so as to make Phase II more cost-effective and environmentally beneficial.
- Rely more heavily on State or local entities for storm water program administration.

V. General Concerns/Issues Related to the Storm Water Program [4]

■ Lack of adequate outreach/public education/timely guidance during Phase I resulted in confusion about: • Which facilities are subject to regulation (use of SIC codes viewed as confusing, inappropriate) • The types of permit application options available • Deadlines • The relationship between the industrial and municipal programs • The overall relevance of the program
■ Confusion resulted from different requirements in different States (i.e., those with approved NPDES programs and those without) particularly in regards to the group application process.

- **Lack of adequate outreach/public education/timely guidance during Phase I resulted in confusion over a number of issues, including:**

  Use of SIC codes. A number of commenters indicated that there was widespread confusion during Phase I over which facilities were subject to regulation. In particular, the use of SIC codes to determine regulatory status was viewed as confusing. Multiple activities commonly occur at a single facility and people were frequently unclear as to how they are classified under the SIC code system. Due to this excessive confusion, commenters generally feel that SIC codes are an ineffective way of targeting facilities for regulation under the storm water program.

  Application Options. Commenters complained that the storm water permit application options were not spelled out clearly in the beginning of the program. In particular, some expressed anger over the group application process. One commenter notes that while the group application option seemed preferable a year ago, it became clear that this option was problematic given that certain States are not accepting group applications as legal coverage. In addition, a number of group applicants would have opted for coverage under the general permit had that option been available in the first place. Commenters resented that it was oftentimes necessary to hire expensive consultants simply to understand the regulations and stay informed of their application options.

  Deadlines. Commenters indicate that there was confusion surrounding permit application deadlines. In the future, this could be alleviated by improved outreach and public education.

The relationship between the industrial and municipal programs. One commenter recommends separating municipalities and industries into two distinct rules so as to avoid confusion over the differences between the two programs.

The "Big Picture" of the storm water program. As discussed throughout this report, commenters seem frustrated over the fact that huge costs are being incurred to implement the storm water program without a clear indication that environmental benefits are being achieved. Commenters write that it essential for EPA to step up public education and outreach efforts in the future.

- **Confusion resulted from different requirements in different States (i.e., those with approved NPDES programs and those without) particularly in regards to the group application process.**

Numerous commenters state that the conflicting time frames between States and EPA in developing and issuing the permits created enormous confusion for the regulated community. As discussed above, this situation was particularly frustrating members of group applications.

APPENDIX K

SELECTED MANAGEMENT MEASURES DEVELOPED UNDER SECTION 6217 OF CZARA

4583

SELECTED MANAGEMENT MEASURES DEVELOPED UNDER SECTION 6217 OF CZARA[1]

MANAGEMENT MEASURES FOR URBAN AREAS (Chapter 4 of CZARA guidance)

I. INTRODUCTION

II. URBAN RUNOFF

A. New Development Management Measure

(1) By design or performance:

(a) After construction has been completed and the site is permanently stabilized, reduce the average annual total suspended solid (TSS) loadings by 80 percent. For the purposes of this measure, an 80 percent TSS reduction is to be determined on an average annual basis,[2] or

(b) Reduce the postdevelopment loadings of TSS so that the average annual TSS loadings are no greater than predevelopment loadings, and

(2) To the extent practicable, maintain postdevelopment peak runoff rate and average volume at levels that are similar to predevelopment levels.

Sound watershed management requires that both structural and nonstructural measures be employed to mitigate the adverse impacts of storm water. Nonstructural Management Measures for new development (B&C) can be effectively used in conjunction with this Management Measure reduce both the short-and long-term costs of meeting the treatment goals of this management measure.

B. Watershed Protection Management Measure

Develop a watershed protection program to:

(1) Avoid conversion, to the extent practicable, of areas that are particularly susceptible to erosion and sediment loss;

[1] See "Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters," January 1993, U.S. EPA, 840-B-92-002.

[2] Based on the average annual TSS loadings from all storms less than or equal to the 2-year/24-hour storm. TSS loadings from storms greater than the 2-year/24-hour storm are not expected to be included in the calculation of the average annual TSS loadings.

(2) Preserve areas that provide important water quality benefits and/or are necessary to maintain riparian and aquatic biota; and

(3) Site development, including roads, highways, and bridges, to protect to the extent practicable the natural integrity of waterbodies and natural drainage systems.

C. Site Development Management Measure

Plan, design, and develop sites to:

(1) Protect areas that provide important water quality benefits and/or are particularly susceptible to erosion and sediment loss;

(2) Limit increases of impervious areas, except where necessary;

(3) Limit land disturbance activities such as clearing and grading, and cut and fill to reduce erosion and sediment loss; and

(4) Limit disturbance of natural drainage features and vegetation.

III. CONSTRUCTION ACTIVITIES

A. Construction Site Erosion and Sediment Control Management Measure

(1) Reduce erosion and, to the extent practicable, retain sediment onsite during and after construction, and

(2) Prior to land disturbance, prepare and implement an approved erosion and sediment control plan or similar administrative document that contains erosion and sediment control provisions.

B. Construction Site Chemical Control Management Measure

(1) Limit application, generation, and migration of toxic substances;

(2) Ensure the proper storage and disposal of toxic materials; and

(3) Apply nutrients at rates necessary to establish and maintain vegetation without causing significant nutrient runoff to surface waters.

VOL 12

4585

IV. EXISTING DEVELOPMENT

A. Existing Development Management Measure

Develop and implement watershed management programs to reduce runoff pollutant concentrations and volumes from existing development:

(1) Identify priority local and/or regional watershed pollutant reduction opportunities, e.g., improvements to existing urban runoff control structures;

(2) Contain a schedule for implementing appropriate controls;

(3) Limit destruction of natural conveyance systems; and

(4) Where appropriate, preserve, enhance, or establish buffers along surface waterbodies and their tributaries.

V. ONSITE DISPOSAL SYSTEMS

A. New Onsite Disposal Systems Management Measures

(1) Ensure that new Onsite Disposal Systems (OSDS) are located, designed, installed, operated, inspected, and maintained to prevent the discharge of pollutants to the surface of the ground and to the extent practicable reduce the discharge of pollutants into ground waters that are closely hydrologically connected to surface waters. Where necessary to meet these objectives: (a) discourage the installation of garbage disposals to reduce hydraulic and nutrient loadings; and (b) where low-volume plumbing fixtures have not bee installed in new developments or redevelopments, reduce total hydraulic loadings to the OSDS by 25 percent. Implement OSDS inspection schedules for preconstruction, construction, and postconstruction.

(2) Direct placement of OSDS away from unsuitable areas. Where OSDS placement is unsuitable areas is not practicable, ensure that the OSDS is designed or sited at a density so as not to adversely affect surface waters or ground water that is closely hydrologically connected to surface water. Unsuitable areas include, but are not limited to, areas with poorly or excessively drained soils; areas with shallow water tables or areas with high seasonal water table; areas overlaying fractured bedrock that drain directly to ground water; areas within floodplains; or areas where nutrient and/or pathogen concentrations in the effluent cannot be sufficiently treated or reduced before the effluent reaches sensitive waterbodies;

(3) Establish protective setbacks from surface waters, wetlands, and floodplains for conventional as well as alternative OSDS. The lateral setbacks should be based on soil type, slope, hydrologic factors, and type of OSDS. Where uniform protective

setbacks cannot be achieved, site development with OSDS so as not to adversely affect waterbodies and/or contribute to a public health nuisance;

(4) Establish protective separation distances between OSDS system components and groundwater which is closely hydrologically connected to surface waters. The separation distances should be based on soil type, distance to ground water, hydrologic factors, and type of OSDS;

(5) Where conditions indicate that nitrogen-limited surface waters may be adversely affected by excess nitrogen loadings from ground water, require the installation of OSDS that reduce total nitrogen loadings by 50 percent to ground water that is closely hydrologically connected to surface water.

B. Operating Onsite Disposal Systems Management Measure

(1) Establish and implement policies and systems to ensure that existing OSDS are operated and maintained to prevent the discharge of pollutants to the surface of the ground and to the extent practicable reduce the discharge of pollutants into ground waters that are closely hydrologically connected to surface waters. Where necessary to meet these objectives encourage the reduced use of garbage disposals, encourage the use of low-volume plumbing fixtures, and reduce total phosphorus loadings to the OSDS by 15 percent (if the use of low-level phosphate detergents has not been required or widely adopted by OSDS users). Establish and implement policies that require an OSDS to be repaired, replace, or modified where the OSDS fails, or threatens or impairs surface waters;

(2) Inspect OSDS at a frequency adequate to ascertain whether OSDS are failing;

(3) Consider replacing or upgrading OSDS to treat influent so that total nitrogen loadings in the effluent are reduced by 50 percent. This provision applies only:

(a) where conditions indicate that nitrogen-limited surface waters may be adversely affected by significant ground water nitrogen loadings from OSDS, and

(o) where nitrogen loadings from OSDS are delivered to ground water that is closely hydrologically connected to surface water.

VI. POLLUTION PREVENTION

A. Pollution Prevention Management Measure

Implement pollution prevention and education programs to reduce nonpoint source pollutants generated from the following activities, where applicable:

VOL 12

4587

- The improper storage, use, and disposal of household hazardous chemicals, including automobile fluids, pesticides, paints, solvents, etc.;
- Lawn and garden activities, including the application and disposal of lawn and garden care products, and the improper disposal of leaves and yard trimmings;
- Turf management on golf courses, parks, and recreational areas;
- Improper operation and maintenance of onsite disposal systems;
- Discharge of pollutants into storm drains including floatable, waste oil, and litter;
- Commercial activities including parking lots, gas stations, and other entities not under NPDES purview, and
- Improper disposal of pet excrement.

VII. ROADS, HIGHWAYS, AND BRIDGES

A. Management Measure for Planning, Siting, and Developing Roads and Highways

Plan, site, and develop roads and highways to:

(1) Protect areas that provide important water quality benefits or are particularly susceptible to erosion or sediment loss;

(2) Limit land disturbance such as clearing and grading and cut and fill to reduce erosion and sediment loss; and

(3) Limit disturbance of natural drainage features and vegetation.

B. Management Measure for Bridges

Site, design, and maintain bridge structures so that sensitive and valuable aquatic ecosystems and areas providing important water quality benefits are protected from adverse effects.

C. Management Measure for Construction Projects

(1) Reduce erosion and, to the extent practicable, retain sediment onsite during and after construction and

(2) Prior to land disturbance, prepare and implement an approved erosion control plan or similar administrative document that contains erosion and sediment control provisions.

D. Management Measure for Construction Site Chemical Control

(1) Limit the application, generation, and migration of toxic substance;

(2) Ensure the proper storage and disposal of toxic materials; and

(3) Apply nutrients at rates necessary to establish and maintain vegetation without causing significant nutrient runoff to surface water.

E. Management Measure for Operation and Maintenance

Incorporate pollution prevention procedures into the operation and maintenance of roads, highways, and bridges to reduce pollutant loadings to surface waters.

F. Management Measure for Road, Highway, and Bridge Runoff Systems

Develop and implement runoff management systems for existing roads, highways, and bridges to reduce runoff pollutant concentrations and volumes entering surface waters.

(1) Identify priority and watershed pollutant reduction opportunities (e.g., improvements to existing urban runoff control structures; and

(2) Establish schedules for implementing appropriate controls.

MANAGEMENT MEASURES FOR ANIMAL FEEDLOTS (Chapter 2.II.B of CZARA guidance)

B1. Management Measures for Facility Wastewater and Runoff from Confined Animal Facility Management (Large Units not subject to NPDES permit requirements)

Limit the discharge from the confined animal facility to surface waters by:

(1) Storing both the facility wastewater and the runoff from confined animal facilities that is caused by storms up to and including a 25-year, 24-hour frequency storm. Storage structures should:

(a) Have an earthen lining or plastic membrane lining, or
(b) Be constructed with concrete, or
(c) Be a storage tank;

and

(2) Managing stored runoff and accumulated solids from the facility through an appropriate waste utilization system.

B2. Management Measures for Facility Wastewater and Runoff from Confined Animal Facility Management (Small Units not subject to NPDES permit requirements)

Design and implement systems that collect solids, reduce contaminant concentrations, and reduce runoff to minimize the discharge of contaminants in both facility wastewater and in runoff that is caused by storms up to and including a 25-year, 24-hour frequency storm. Implement these systems to substantially reduce significant increases in pollutant loadings to ground water.

Manage stored runoff and accumulated solids from the facility through an appropriate waste utilization system.

STORM WATER PROGRAMS

ISSUE:

How should CWA storm water requirements be revised to strengthen and facilitate implementation of storm water controls?

BACKGROUND:

States report that approximately 30 percent of remaining surface water quality impairment is attributable to storm water discharges. Significant sources of storm water discharges include urban runoff, industrial activity, construction, and resource extraction (mining). For example, in urban areas, loadings from storm water runoff for heavy metals, sediment, bacteria, polycyclic aromatic hydrocarbons (PAHs), acidity, and floatables are higher than those from POTWs.

To address these environmental risks, Congress established in 1987 a two-phased storm water program under CWA §402(p). Phase I applies to municipal storm sewer systems serving a population over 100,000, as well as storm water discharges associated with industrial activity.

In November of 1990, EPA issued regulations that identified 220 municipalities whose separate storm sewer systems are subject to Phase I of the NPDES program. States and EPA have designated an additional 550 municipalities as part of the Phase I program. The Agency estimates that the Phase I municipalities have a population of over 90 million people (about 36 percent of the total U.S. population). EPA and authorized States have received comprehensive permit applications from many of the municipalities, and are in the process of developing and issuing permits for these dischargers.

In addition, the Phase I regulations established regulation of over 100,000 industrial facilities in eleven categories, including manufacturing, mining, waste management, construction, and transportation. Permits for storm water discharges from Phase I industries generally were required to be issued by October 1, 1993. The Ninth Circuit struck down EPA's exemption from Phase I regulations of construction sites under 5 acres and light industrial activities "with no exposure" to rain water.

Phase II applies to all remaining light industrial, commercial, retail, and residential facilities with storm water discharges that are not in Phase I. Preliminary estimates indicate that millions of facilities are not addressed by Phase I. Phase II is potentially ten times larger in scope than Phase I, and could address a large number of municipalities without significant urban populations. EPA was required to issue Phase II regulations by October 1, 1993, which would designate classes of Phase II storm water discharges to be regulated to protect water quality. Phase II sources are required to obtain a permit by October 1, 1994. EPA did not meet the October 1993 deadline for Phase II regulations.

Municipal Compliance with Standards

Municipal separate storm sewer systems (or "MS4"--those municipal systems that are covered by the storm water program) have stated that it is both technologically and financially impossible to establish treatment or management practices that can ensure that urban storm water runoff complies with water quality standards. They have indicated that it is highly uncertain whether feasible storm water control measures (source controls, traditional structural controls, and best management practices) will ensure that storm water discharges will meet water quality standards. They further argue that the only other alternative, collecting and treating essentially all of the storm water from widespread urbanized areas, would be infeasible and result in significant destruction of urban streams and wetlands.

Under the existing CWA, §402(p)(3)(B)(iii), a statutory standard exists that NPDES storm water discharge permits issued to municipal separate storm sewer systems require controls to reduce the discharge of pollutants in storm water to the "maximum extent practicable" (MEP). The statutory standard can include management practices, control techniques, and system design and engineering methods and other such provisions that the Administrator or State determines are necessary for the control of such pollutants. Because of the lack of a more specific definition of the statutory standard of MEP, municipalities, permitting authorities, and members of the public are uncertain as to the extent of storm water control requirements a municipality must implement in its storm water management program.

Provisions for Facilities with No Exposure

EPA attempted to exempt from storm water control requirements certain industrial facilities that had no exposure of materials, equipment, or wastes to storm water. However, this exemption of facilities without storm water exposure was overturned by the Ninth Circuit. Such an exemption, if reinstated through legislation, would create a strong incentive for facilities to implement pollution prevention. It would simultaneously accomplish environmental objectives (reducing pollutants in storm water) and greatly reduce administrative burdens for EPA, States, and industries.

Deadline Extensions for Phase II

EPA is presently required to issue Phase II regulations designating sources for permitting and establishing deadlines by October 1, 1993. In the absence of new regulations, Phase II sources are required to have permits after October 1, 1994. Given the scope and complexity of Phase II, EPA was unable to meet the October 1, 1993 regulatory deadline. Furthermore, EPA and authorized States will not be able to issue permits to all Phase II sources by October 1, 1994. This may expose unpermitted dischargers, including many small municipalities or commercial enterprises posing small risks, to litigation for discharging without a permit. In addition, potential Phase II municipalities need additional time to develop the financial capabilities and institutional frameworks needed to comply with storm water requirements.

Phase II Storm Water Requirements

Phase II regulations must be reasonable in scope and establish a workable program that will focus on sources of storm water discharges that pose the highest risk. The Bureau of Census has designated 396 urbanized areas which represent the most widespread and dense urban development. These urbanized areas occupy less than 2 percent of the total land area of the United States but contain 165 million people, or about 65 percent of the total population of the United States. In addition, most new development occurs in or adjacent to these urbanized areas. Between 1980 and 1990, over 75 percent of the national increase in population occurred in these urbanized areas. However, over 5,000 municipal entities in urbanized areas are not in Phase I of the NPDES storm water program.

Authorize Municipalities to Directly Regulate Storm Water Facilities Within Their Jurisdiction

Under current CWA provisions, the storm water program requires permits for industrial activities even if they are discharging to municipal separate storm sewer systems which also must obtain storm water permits. Municipalities argue that this is redundant and inefficient, and also undercuts their effectiveness in directly dealing with an industrial facility.

Inactive and Abandoned Mines

It is estimated that there are in the range of 400,000 or more inactive and abandoned mine sites (IAMs) on Federal lands. The environmental damages posed by these sites can vary significantly. While many sites are relatively benign, releases from other sites result in significant environmental degradation, even decades after active operations have ceased. A major administrative challenge is to (1) prioritize these sites that cause environmental problems so that the United States can address them in a rational environmentally protective manner, and (2) effectively protect water resource quality by addressing these sites according to the prioritized order. Another major challenge is to target control measures so as to achieve the greatest improvement in environmental quality for the limited Federal resources that may be available. Although the estimates of total costs of mitigating water resource quality impacts from IAMs vary significantly, they range into the many tens of billions of dollars without such cost-effective, risk-based prioritization.

A significant number of IAMs on Federal lands are believed to have point source discharges of pollutants, as defined under current statute and regulation, to waters of the United States subject to regulation under the NPDES permit program. Given the large number of IAMs and the costs of mitigating sites causing environmental impacts, there is a need for a phased, cost-effective, risk-based prioritized approach to mitigating these sources.

RECOMMENDATIONS:

The Administration recommends that the CWA be amended to do the following--

<u>Municipal Compliance with Standards</u>

- Establish a phased permit compliance approach that requires best management practices in first-round municipal storm water permits, and through improved best management practices in second-round permits, where necessary, to move towards compliance with water quality standards. In later permits, compliance with water quality standards will occur using water quality based effluent limits, where necessary. This would give EPA and municipalities additional time to evaluate the technical feasibility of establishing numeric effluent limits to meet water quality standards and give States time to develop specific water quality standards appropriate for storm water discharges, if necessary.

- The Administration supports clarifying authority under section 402(p)(3)(B) concerning "maximum extent practicable" (MEP). In contrast to best available technology economically achievable (BAT) and best conventional pollutant control technology (BCT) that are applicable for storm water discharges associated with industrial activities, under MEP, storm water management programs can be implemented in a site-specific and flexible manner to address the storm water management concerns in the municipality. It should be made clear that MEP allows for the consideration of different factors including: (1) the severity of the impairment caused by the source, (2) the effectiveness of alternative approaches at reducing storm water discharges, and (3) the cost of control measures. Under MEP, a storm water management program can target controls based on differences in the type and size of sources, climate, geography, and water quality concerns. Based on a statutory clarification, EPA will then issue guidance on the best methods by which to implement MEP in NPDES permits.

- The Administration supports encouraging States to review and revise their designated uses and water quality standards implementation procedures, as they develop water quality-based permits, to reflect the episodic nature of storm water runoff, the varying loadings during storm water events, and the potential resilience of natural ecosystems to some infrequent, temporary incremental loadings.

Provisions for Facilities with No Exposure

- Authorize EPA to exempt from individual storm water permitting requirements facilities that can certify that there is no nor will be exposure of industrial or other activities or significant materials to rain water and snow melt. This change would ensure that several hundred thousand low-risk facilities are not subject to NPDES requirements, allowing allocation of resources to more critical areas. This would also effectively create incentives for facilities to eliminate contamination of storm water.

Deadline Extensions for Phase II

- Extend the Phase II deadline for EPA issue to regulations to October 1, 1997. Also, extend the deadline to obtain a permit to October 1, 1999. These extensions are necessary to allow EPA to work with States and municipalities in developing workable, effective regulations. Extending the deadline for permits would give municipalities an opportunity to begin to build institutional frameworks and provide the funding necessary to implement storm water management programs. It would also allow permits to be issued to Phase II municipalities at the same time Phase I permits are expiring. This will promote regional and watershed-wide permitting by allowing different municipalities to be co-applicants and coordinate their storm water programs.

Phase II Storm Water Requirements

- Focus Phase II requirements on system-wide permits for municipal separate storm sewer systems in Census-designated urbanized areas with a population of 50,000 or more.

- Target storm water management programs for municipal separate storm water systems (MS4) in the 138 Phase II urbanized areas associated with a Phase I permitted MS4 to address, at a minimum, non-storm water discharges into storm sewers and storm water runoff from growth and development and significant redevelopment. The CWA should encourage NPDES permitting authorities as part of a watershed approach to implement a more comprehensive municipal storm water management program where appropriate based on water quality impairments or other factors for the MS4s in these urbanized areas. In the remaining 258 Phase II urbanized areas, storm water management programs would be required which focus only on controlling non-storm water discharges into storm sewers and storm water runoff from growth and development and significant redevelopment activities.

- Under Phase II for those MS4s required to implement a storm water management program targeted to growth, development and significant redevelopment and illicit connections, the municipal program will control those Phase II storm water sources, including discharges from construction of less than 5 acres, which are part of growth, development, and significant redevelopment activities and may address, where appropriate, subject to the MEP standard, those Phase II sources causing water quality impairment. For those municipal separate storm sewer systems required by the NPDES permitting authority to implement a more comprehensive storm water management program, Phase II light industrial, commercial, retail, and institutional storm water sources would be addressed through the program under the municipality's NPDES storm water permit, which meets the MEP standard. Phase II sources not addressed through a municipal program would not be covered by the NDPES program.

- Do not directly regulate Phase II light industrial, commercial, retail, and institutional storm water discharges, and municipalities outside of Census-designated urbanized areas under the NPDES program, unless otherwise designated by the permitting authority for inclusion in the NPDES program under §402(p)(2)(E) of the CWA. (EPA does not expect that this designation process would be used, except in highly-unusual circumstances, to require an NPDES permit for a typical homeowner.) Rather, such discharges could be addressed by NPS program, if they were a targeted source.

<u>Authorize Municipalities to Directly Phase I Industrial Regulate Storm Water Facilities Within Their Jurisdiction Under the NPDES Program</u>

- Allow EPA and authorized States to authorize municipalities to establish programs for Phase I industrial storm water permit issuance and controls, where it has the appropriate authority, and is willing to commit to implement Federal requirements. EPA does not envision Federal funding to be available to municipalities to perform this function. This recommendation is similar to the industrial pretreatment program currently authorized under the CWA. As in the industrial pretreatment program, storm water permits and controls that are issued by municipalities in an EPA-approved program would be Federally enforceable.

<u>Inactive and Abandoned Mines</u>

- The Administration recommends that the CWA be amended to make the following changes to the NPDES permitting program to target control measures so as to achieve the greatest improvement in environmental quality for the limited Federal resources available for inactive and abandoned mine sites (IAMs) without an operator present:

- The Administration supports clarifying authority to issue NPDES permits on a State-wide basis for IAMs within resource management units (e.g., one permit per State for the National Forest Service, National Park System, Bureau of Land Management, or Fish and Wildlife Service resource areas). This would allow Federal land managers to establish State-wide priorities based on impairment or threats to water resource quality and the most effective use of the available resources. Such priorities could allow some sites not to be controlled or be subject to relatively less stringent controls.

- The Administration supports an amendment to substitute, for existing technology-based requirements under the NPDES program for IAMs on Federal lands, the authority for Federal land managers to identify water resource quality that is threatened or impaired by IAMs and to implement targeted controls for such sites, similar to existing authority for permits for municipal separate storm sewer systems contained in section 402(p)(3)(B).

- The Administration further supports allowing, in general, no more than up to ten years to meet appropriate water quality standards within a resource management unit, as defined in the language above, from the date of issuance of an NPDES permit to the Federal land manager. The Federal land manager would be expected during this period to 1) strive to achieve water quality standards as expeditiously as possible, 2) continue to assess the water resource quality impacts of IAMs where they are currently unknown, and 3) continue to implement targeted controls for those sites causing impairments or threats once identified. This provision should not apply to IAMs which were permitted under the NPDES program prior to the date of enactment.

- The Administration supports encouraging States to review and revise their designated uses and water quality standards implementation procedures, as they develop water quality-based permits, to reflect the episodic nature of storm water runoff, the varying loadings during storm water events, and the potential resilience of natural ecosystems to some infrequent, temporary incremental loadings.

PRESIDENT CLINTON'S CLEAN WATER INITIATIVE:

Analysis of Benefits and Costs

4600

Recycled/Recyclable
Printed with Soy/Canola Ink on paper that contains at least 50% recycled fiber

4.0 Storm Water

EPA's current Phase I storm water program requires NPDES permits of cities and counties with municipal separate storm sewer systems (MS4s) serving populations of 100,000 or more and "storm water discharges associated with significant industrial activity." The Phase II program, currently suspended due to a Congressional moratorium, could require permits for all private sources of storm water (commercial, industrial, retail, and institutional) and all MS4s serving all populations that have the potential to affect water quality. In the Initiative, EPA has addressed the potentially high costs of the Phase II program while still providing protection from private sources and additional MS4s.

The "worse case" scenario for storm water permitting reflects the most inclusive option of all potential options that EPA would consider in proposing rules for the types of facilities covered under Phase II. If EPA were to propose regulations for permitting Phase II facilities, EPA may propose to cover only a portion of these facilities, based on consideration of costs incurred and environmental benefits gained. EPA could propose regulations covering the same facilities to the same extent as suggested in the Initiative.

The Initiative's Phase II program will focus on system-wide permits for MS4s in Census-designated urbanized areas--i.e., areas with a population of 50,000 or more and a population density of 1,000 persons per square mile. The Census Bureau has identified 396 such urbanized areas nationwide. Phase II MS4s will be required to implement storm water management programs that are subject to a "maximum extent practicable" (MEP) standard. These programs will, at a minimum, address: (1) nonstorm water discharges to their systems (i.e., illicit connections) and (2) storm water runoff from growth and development and significant redevelopment activities (including discharges from construction of less than 5 acres) and, where appropriate, those Phase II sources causing water quality impairment.

Where the NPDES authority deems it necessary, MS4s in the 138 urbanized areas associated with a Phase I permitted MS4 may be required to have a more comprehensive storm water management program (consistent with the Phase I storm water requirements). The comprehensive storm water management programs would cover Phase II light industrial, commercial, retail, and institutional storm water sources under a municipality's storm water permit. The NPDES program would not cover Phase II sources not addressed through a municipal program. Such discharges could be addressed by the NPS program if they were a targeted source.

4.1 Private Sources

Under a stringent interpretation of the CWA, the current Phase I program is estimated to cost industrial permittees $3.99 billion per year, while Phase II under a similarly stringent interpretation could cost as much as $16.23 billion in annual costs.

VOL 12

4601

To account for the uncertainty in estimating the potential costs, EPA has developed ranges. These ranges account for variations in both the number of sources affected and the costs incurred. The Initiative's Phase II plan would reduce these impacts on commercial, service, and institutional facilities considerably, imposing costs of between $0.34 billion and $1.67 billion per year, as follows:

	Low	High
10,000 facilities x $22,340/facility	$0.22 billion	
28,000 facilities x $34,700/facility		$0.97 billion
96,000 facilities x $630/facility	$0.06 billion	
269,000 facilities x $1,885/facility		$0.51 billion
100,000 sites x $630/site	$0.06 billion	
100,000 sites x $1,885/site		$0.19 billion
TOTAL	**$0.34 billion**	**$1.67 billion**

From a universe of 1.1 million significant sources, EPA has identified 100,000 that are similar to Phase I industrial sources while the remaining 1.0 million are retail, commercial, and institutional. Of the 100,000 industrial sources, approximately 60 percent or 60,000 have no storm water exposure. Of the remaining 40,000 sources, EPA has assumed that municipalities will require between 25 and 70 percent of the facilities to install storm water controls. To further account for the uncertainty inherent in projecting costs, EPA has used $22,340 per facility at the low end and $34,700 per facility at the high end of the estimated cost to comply (EPA, 1994c). The total cost for industrial look-a-likes is estimated to be between $0.22 billion and $0.97 billion per year.

Of the remaining 1.0 million sources, 60 percent are located in urbanized areas and may be addressed under storm water management programs for the urbanized areas. As above, 36 percent, or 216,000 sources, are estimated to have no storm water exposure. Of the remaining 384,000 sources, or 64 percent, the low-end number of facilities (96,000 sources or 25 percent) could incur costs as low as $630 per facility, while the high-end number of facilities (269,000 sources or 70 percent) could incur costs as high as $1,884 per facility.

In addition, 40 percent of the private sources that are not covered by a municipal program would be covered by the NPS program. Under the NPS program, only the sites located in impaired watersheds would need controls. EPA believes roughly 25 percent of these sites are in impaired watersheds. At a range of $630 and $1,885 per site and 100,000 sites, the annual costs will be between $0.06 billion and $0.19 billion.

Based on these estimates, the Initiative's total cost on private sources is between $0.34 billion and $1.67 billion. Compared to EPA's best interpretation of current law and assuming that the moratorium will expire, the Initiative will avoid costs (or yield a cost savings) of between $14.6 billion and $15.9 billion.

The Initiative may also result in potential cost savings for those facilities currently or soon to be permitted under the existing storm water Phase I regulations. About 60 percent of existing permitted industrial sources and 100 percent of potentially permitted light industrial sources will not require NPDES permits under the Initiative's provisions. In addition, small (less than 5 acre) construction sites will be considered Phase II sources, and this would result in additional cost savings of $70 million per year. As a result, additional cost savings to private sources from Phase I requirements will be between $1.1 billion and $1.6 billion.

The above estimates are derived in EPA, 1994c, and are summarized here. Based on a stringent interpretation of the current law, the overall cost savings (or costs avoided) to private sources from these provisions would be in the range of $15.7 billion and $17.5 billion, as shown in Table 21.

4.2 Municipalities

Costs for the current Phase I program for municipal sources are estimated at between $1.6 billion and $2.6 billion annually, based on a covered population of 69.3 million people and per person costs of between $23.91 and $37.00 per person.[8]

If the Phase II moratorium expires, EPA could be required to promulgate regulations covering an additional population of at least 74.1 million people (25.3 million in 138 urbanized areas associated with Phase I MS4s, 29 million in 258 additional urbanized areas between the population of 50,000 and 100,000, and potentially 19.8 million in other MS4s). EPA's best interpretation of the current law is that it would not include these additional 28 million in other MS4s. Using the same unit costs ($23.91 to $37.00), the existing Phase II program could cost between $1.8 and $2.7 billion per year.

To account for the uncertainty of the impact in terms of the number of municipalities affected and the costs incurred, EPA has estimated a range of costs for the Phase II provision in the Initiative. The following estimates are derived in EPA, 1994c, and are summarized here. About 25.3 million people live in 138 urbanized areas (UAs) with growth and development and illicit discharge. Costs range from a low of $15.33 per capita to a high of $23.72 per capita. The range of total costs for these urbanized areas is between $0.39 billion and $0.60 billion. Next, EPA assumed that between 25 and 70 percent of the population in these UAs will be covered by a comprehensive program based in part on the percentage of impaired urban waters. The population affected will be between 6.33 million and 17.7 million. The additional cost of

[8] Population estimates for the municipal storm water costs are from the draft "Report to Congress on Storm Water Dischargers Not Regulated Under Phase I of the NPDES Storm Water Program" (EPA, 1993d). Average costs are from the draft EPA report "Review of Program Costs in Part 2 NPDES Municipal Storm Water Permit Applications" (EPA, 1993c).

a comprehensive plan above the cost of addressing growth and development and illicit discharges will be in the range of $8.58 and $13.28 per capita. The total cost of the comprehensive coverage will vary from a low of $0.05 billion to a high of $0.24 billion.

EPA identified 29 million people in another 258 UAs who will be affected by the Phase II provisions. The cost of compliance will vary from $15.33 per capita to $23.72 per capita. The total cost of this coverage will be in the range of $0.44 billion and $0.69 billion. The final element of this cost on municipalities is the cost of addressing private sources and industrial look-a-likes that impact water quality in areas without the comprehensive program and in areas with combine sewers. At a per capita cost of $2.00, EPA estimates that about 75.7 million people will incur $0.15 billion. At a per capita cost of $5.00, the upper-end cost would be $0.38 billion.

	Low	High
25.3 million population x $15.33 per capita	$0.39 billion	
25.3 million population x $23.72 per capita		$0.60 billion
6.33 million population x $8.58 per capita	$0.05 billion	
17.7 million population x $13.28 per capita		$0.24 billion
29.0 million population x $15.33 per capita	$0.44 billion	
29.0 million population x $23.72 per capita		$0.69 billion
75.7 million population x $2.00 per capita	$0.15 billion	
75.7 million population x $5.00 per capita		$0.38 billion
TOTAL	**$1.03 billion**	**$1.91 billion**

The total cost to the municipalities of the proposed Phase II requirements is between $1.03 billion and $1.91 billion, as shown in Table 20.

Compared with the cost of Phase II requirements under a stringent interpretation of the current law, total savings to municipalities will be between $755 million and $850 million per year.

4.3 State Water Programs

The impacts of the Phase II storm water provisions on states have not been estimated but are expected to be minimal.

4.4 Federal Agencies

Additional costs of the storm water provisions on federal agencies will total $19 million per year. EPA will account for $2 million per year of this cost, and DOI will account for $17 million per year.

4.5 Benefits[9]

The benefits of storm water control as proposed in the Initiative are based on numerous case studies and are summarized as follows:

- 75 to 80 percent reduced loadings in urbanized areas prior to and during development,
- 15 to 25 percent reduced loadings in areas already developed,
- Greater environmental protection at lower cost,
- Improved water resource quality, habitat, and aquatic life; reduced flooding; improved recreational opportunities; increased commercial fishing; improved human health; and increased employment.

(Note that more cost-effective and institutionally feasible prevention and management methods are available for new development than for areas that have already been developed.)

Case Studies[10]

Bellevue, Washington (see longer summary in Appendix B)

Bellevue has a population of nearly 87,000 and covers a 30-square mile area that contains five lakes and over 50 miles of open streams. The city established a storm water utility in 1974 to maintain a hydrologic balance, prevent property damage, and protect water quality.

The city requires newly developing areas to include on-site storm water management that provides protection for 24-hour, 100-year storm events.

Examples of program benefits:

- Flood control. One of the most successful aspects of the program is flood control, which relies on eight remote-controlled regional detention basins along major stream corridors to monitor rainfall, stream flow, and water levels. This helps ensure that flood gates control peak flows. Small detention basins reduce peak flow rates up to 60 percent, providing flood and stream-bank erosion control and protecting stream-side property.

---

[9] See also the EPA (1994e) background paper "CWA Benefits of Storm Water Controls," January 1994.

[10] Costs for these case studies were not available and hence are not included here.

– Reduced property damage. As a result of storm water controls over the previous 10 years, property damages were avoided during a 100-year storm in January 1986.

– Reduced pollutant loadings. Runoff concentrations of lead and total solids were reduced by 10 to 25 percent through biannual cleaning of storm drainage inlet pumps and catch basins; oxygen demanding substances, nutrients, and zinc concentrations were reduced by 5 to 10 percent. Conventional street-sweeping operations reduced toxic loadings by 5 to 10 percent. Installation and maintenance of oil/water separators reduced floatables in the drainage system.

– Reduced illegal dumping. Dumping of motor oil and debris in storm drains was significantly reduced through increasing public awareness of storm water issues and volunteer stenciling of storm drains. A recent survey indicates that 85 percent of area residents dispose of used oil at a recycling facility.

– Increased recreational opportunities. Clean-up of Mercer Slough (a 325-acre wetland) along with stream and wildlife enhancement of the park resulted in increased canoeing on the slough and increased visitation to the park's trails.

Murray City, Utah

Murray City (population 31,000) worked with the Utah Department of Transportation (DOT) to develop a storm water control system for runoff from a 4.5-mile stretch of highway in conjunction with the construction of an 18-hole, 135-acre municipal golf course.

Storm water runoff from the highway and subsurface waters is collected and routed through a series of streams and wetlands into four ponds on the golf course.

Examples of program benefits:

– Reduction in pollutant loadings. The pond system removes approximately 90 percent of the sediment, oil and grease, and dissolved materials from the highway runoff.

– Flood control. The system successfully handled the runoff from two 25-year storms.

– Savings in irrigation water costs. The detention ponds provide 7 acres of flood retention area and created nearly 11 acres of wetlands. The ponds also provide water to irrigate the golf course, which saves nearly $80,000 per year in watering costs.

– Savings in highway construction costs. Because runoff was diverted to irrigate the golf course, DOT saved $300,000 in land acquisition and storm water piping costs by eliminating the need to construct a separate storm water discharge system for the highway.

Orlando, Florida

The city of Orlando (population 160,000) receives over 50 inches of rain annually, over half of which converts to storm water runoff and flows into the city's 83 lakes. One example of a project to manage storm water is the creation of the Greenwood Urban Wetland, which consists of several ponds in a series.

Examples of program benefits:

- Increased property values. Overall, whenever Orlando constructs a storm water control lake, property values in that area increase.

- A savings was realized in construction of the Greenwood Urban Storm Water Control Wetland with the sale of fill dirt that was excavated ($5/cubic yard).

- Creation of a natural park. The Greenwood Urban Wetland created a natural park atmosphere (with footbridges, walking paths, picnic areas, and opportunities for observing wetland wildlife) in an urbanized area.

- Irrigation and drinking water supply. Cleansed storm water is used to irrigate the upland areas of the park, which conserves the drinking water supply.

Santa Clara Valley, California

Santa Clara Valley has a municipal storm water permit covering 15 co-permittees (14 municipal entities and one water control district). Three of the municipalities have populations over 100,000, four are between 50,000 and 100,000, and seven are less than 50,000.

Transportation activities have been identified as potentially the most significant source of storm water pollutants. Copper and zinc have been identified as significant contaminants in the storm water runoff into south San Francisco Bay. These metal are carried by suspended particles. Brake pad dust is believed to be a major source of the copper.

Examples of program benefits:

- Significant reduction in copper loadings. Street sweeping activities clean 19,000 miles per month and have prevented 2,500 pounds of copper and 46,000 cubic yards of material throughout the area from entering storm sewers.

- Reduction in floatables. Cleaning 34,000 catch basins has removed 1,000 cubic

VOL 12

4607

yards of material. Inspection and cleaning of 160 miles of conveyances has removed 400 cubic yards of material.

-- Identification of illegal dumping activities. The co-permittees identified 867 cases of illegal dumping, of which 700 have been resolved.

Tulsa, Oklahoma

The city of Tulsa (population 367,000) has been recognized as having an effective storm water management program. EPA recently issued a draft municipal storm water permit for Tulsa.

Discharges from Tulsa's storm sewer collection system were identified as a source of pollutant loadings in the Zinc Lake portion of the Arkansas River. The storm sewer's discharges showed a high concentration of bacteria.

Examples of program benefits:

-- Removal of suspended solids. Tulsa estimates that its construction site storm water controls average 70 percent effectiveness in removing total suspended solids from storm water runoff. In addition, the city estimates that its street sweeping and structural operation and maintenance reduce suspended solids by up to 50 percent; metals by up to 10 percent; total solids and lead by 10 to 25 percent; and oxygen demanding substances, nutrients, and zinc by 5 to 10 percent.

-- Improved Water Quality in the Arkansas River. The city identified 35 illicit storm sewer connections drained into Zinc Lake and the Arkansas River. Tulsa removed these discharges from the storm sewer system and states that water resource quality has improved as a result.

APPENDIX B

STORM AND SURFACE WATER UTILITY
BELLEVUE, WASHINGTON

Bellevue, Washington, is a suburban community located in the Puget Sound area east of Lake Washington in the Seattle metropolitan area. The city experienced substantial population growth during the last 30 years and particularly rapid growth over the last 20 years. When Bellevue incorporated as a city in 1953, the population was approximately 6,000 and the city limits covered five square miles. By 1990, Bellevue had grown to a population of 86,000 and an area that covered 30 square miles, making it the fourth largest city in Washington State. Recent estimates indicate that the watershed is over 90 percent developed, primarily with residential units and commercial and light industrial uses.

Rapid growth and development created storm water runoff problems in most of the natural streams draining the area. The city's 30-square mile area contains over 50 miles of open streams and five lakes. Much of the average annual rainfall of 42 inches is carried by existing streams into the following receiving waters: Kelsey Creek, Meydenbauer Bay and the Lake Washington East Channel, Yarrow Bay on Lake Washington, Lake Sammamish, and Coal Creek. Of these, Lake Washington is considered the primary receiving water body. The types of storm water runoff problems documented in the Bellevue area include increased flooding and streambank erosion; property damage; stream sedimentation/siltation; diminished salmon runs; water quality degradation by discharges of nutrients, heavy metals, pesticides, and oil; and illicit connections.

In response to citizen concerns about environmental degradation caused by storm water runoff, the city of Bellevue established a storm water utility in 1974. The mission of Bellevue's Storm and Surface Water Utility (SSWU) is to manage the storm and surface water system in Bellevue, to maintain a hydrologic balance, to prevent property damage, and to protect water quality for the safety and enjoyment of citizens and the preservation and enhancement of wildlife habitat.

STORM AND SURFACE WATER UTILITY PROGRAMS

When first established, Bellevue's utility focused on examining various solutions to control flooding and preserve waterways. The utility selected an "open stream concept" using streams as the main conveyance system for storm water runoff. This system uses regional, in-stream flood control facilities to attenuate peak flows for older development. The utility also manages the municipal storm drainage system. In addition, regulations require developers to provide erosion and sedimentation controls at all construction sites and on-site storm water controls for new development. With successful flood control systems in place, the focus has recently shifted to water quality controls, including requirements mandated by the federal Clean Water Act. For the most part, SSWU's comprehensive effort to solve storm water quality problems is preventive in nature, but the utility also recognizes the need for retrofitting and new capital improvements for treatment.

Management of Bellevue's storm drainage system and open streams involves five major programs: a capital improvement program, operations and maintenance, water quality control, public education, and administration. Activities conducted under each of the major programs are summarized below.

- **Capital improvement program.** SSWU's capital improvement program (CIP) involves planning, design, property acquisition, flood control construction, water quality treatment, and stream enhancement projects. The utility constructed a series of 11 in-stream flood control facilities (detention basins) within the Bellevue stream system to provide protection for the 24-hour, 100-year storm event. SSWU also improves stream passages for carrying capacity, stability, wildlife habitat, and migratory fish passage.

- **Operations and maintenance.** The operations and maintenance (O&M) program involves those functions typically associated with urban drainage, such as repair and minor replacement of SSWU's structural facilities. Bellevue's O&M program also includes operation of structures for flood control, including a telemetry control system for structures and an emergency storm response program, a drainage system inventory, and advice to private citizens on private drainage concerns.

- **Water quality control.** Activities conducted for water control include drainage system cleaning, routine monitoring of receiving waters, investigative monitoring of pollution events and sources, emergency response for water pollution events, coordination with other water quality control agencies, participation in lake restoration studies and projects, a private maintenance inspection program, and a streams enhancement program.

- **Public education.** SSWU's public education efforts focus on available services and the environment. Specific activities include articles in local publications about SSWU services and the effects of human practices on the environment, the Stream Team Program (includes a water quality newsletter, workshops, and citizen activities), City Hall's "Mini Salmon Hatchery" and annual salmon release, storm drain stenciling projects, and a business water quality program.

- **Administration.** Administrative programs for SSWU include financial management, rate administration, comprehensive drainage planning, general administration, and support for the City Council and Storm and Surface Water Advisory Commission. SSWU assures quality control of utility services by tracking all service requests through an automated Customer Action Request system.

UTILITY FINANCING

The city decided that the most equitable system of drainage service charges entails basing changes on the estimated amount of runoff that individual properties contribute to the surface water system. All properties are classified according to their intensity of development. Each classification is assigned a rate (per 2,000 square feet of property area), with current rates set as follows: undeveloped ($0.17), light development ($0.99), moderate development ($1.23), heavy development ($1.83), and very heavy development ($2.46). Wetlands are also a class; however, wetlands are not charged due to their value in water quantity and quality control. The classification combined with the total square footage of the property determines the service charge, which is billed every two months.

Revenues grew slowly until rates were raised to fund the adopted Capital Improvement Program, which was initiated by issuance of $10 million in revenue bonds. Three major rate increases occurred in 1980 (70 percent), 1982 (90 percent), and 1986 (35 percent), and subsequent rate increases have remained in the single-digit category largely to cover inflation. Although the majority of SSWU revenue is from service charges, other revenue sources include clearing and grading permit fees, general facilities charges, and interest on fund accounts. Revenues from the utility service charges and these other sources cover the full costs of Bellevue's storm and surface water management program.

Single-family customers make up 92 percent of the 24,000 accounts and contribute 45 percent of the revenue. An average single-family household pays $16.44 every two months ($98 per year) for 10,000 to 12,000 square feet of property with a typical home. Tax-exempt properties are not exempt from the utility charges. (Washington State highways and Bellevue streets are the SSWU's two biggest ratepayers.)

BENEFITS OF THE STORM AND SURFACE WATER PROGRAM

One of the most successful of SSWU's programs is flood control, and several different approaches to managing storm water discharges are achieving water quality improvements. In addition, Bellevue's reputation as a well-planned, environmentally sensitive city is enhanced through SSWU programs that preserve the city's numerous streams.

Reductions in Peak Flows

- Bellevue's use of the natural stream system to manage storm water preserves the environment and reduces costs. Bellevue's storm water management activities to address flooding and stream erosion problems range from four to ten times less costly than traditional storm sewer improvements.

- Small detention basins (detention times of 30 minutes or less) reduced peak flow rates by up to 60 percent, providing flood and streambank erosion control that protects streamside property.

- With a computerized remote control system, maximum flood protection along major stream corridors is achieved through eight regional detention basins. The remote control system monitors rainfall, stream flow, and water levels to ensure optimal operation of flood gates to control peak flows.

- During a 100-year storm experienced by the Bellevue area in January 1986, property damages occurred only where planned improvements were not yet constructed. Capital improvements totalling $15 million and constructed over the previous 10 years reduced flooding and streambank erosion, thereby avoiding property damages.

- Calls for emergency service during storm events continue to decrease, indicating that SSWU's flood control system has significantly reduced hazards to life and property.

Reductions in Pollutant Loadings/Discharges

- Runoff concentrations of lead and total solids were reduced by between 10 to 25 percent over a two-year period through biannual cleaning of storm drainage inlet sumps and catch basins. Chemical oxygen demand (COD), nutrient, and zinc concentrations were reduced by between 5 to 10 percent over a two-year period.

- Toxic loadings were reduced by between 5 and 10 percent by conventional street-sweeping operations.

- Introduction of floatables to the drainage system was reduced by the installation and maintenance of oil/water separators, some of which have the capability of reducing oil and grease during oil spill events to levels generally associated with background levels in urban storm water.

- Dumping of motor oil and debris in storm drains was significantly reduced by increasing public awareness of storm water issues through SSWU's Stream Team Program and volunteer stenciling of storm drains. A recent survey indicates that 85 percent of area residents dispose of used oil at a recycling facility.

- Dumping of motor oil and household chemicals was also reduced through SSWU's Oil Recycling and Hazardous Waste Program. SSWU collected 2,100 gallons of petroleum products at a recycling event in October 1993.

- Total solids in urban runoff originating from residential yards were reduced by increasing public awareness of practices such as pet waste and litter control.

- A wide variety of local businesses work with SSWU water quality staff to prevent storm water pollution at the source through an innovative program called Business

Partners for Clean Water.

Protection or Restoration of Ecological Resources

- Volunteers have planted thousands of native trees and shrubs along 10 miles of Bellevue's open streams to shade stream waters and enhance fish habitat. Other stream enhancement projects conducted through the Stream Team Program have reduced streambank erosion which also lowered water temperatures and provided shade to enhance fish habitat.

- Kelsey Creek's salmon fishery was enhanced through installation of regional detention basins that help mitigate peak flows and habitat improvements from streambank revegetation projects. Previously, this salmon fishery was limited and unhealthy because of high peak flows from urban runoff that altered the stream channel and carried pollutants.

- Anadramous fish populations are enhanced because SSWU's flood control system is designed to provide maximum flood protection with minimum impact on fisheries and fish migration. During salmon spawning season, flood control gates remain open until significant heavy rainfall occurs.

- Sensitive areas (floodplains, wetlands, and steep slopes) are protected through the city's Natural Determinants Regulations, which prohibit development of designated areas, including 740 acres of wetlands.

- The city is restoring Phantom and Larsen Lakes in partnership with the Washington Department of Ecology. Restoration measures for Phantom Lake over a two-year period reduced annual internal phosphorus loading to the lake by approximately 75 percent and reduced annual external phosphorus loading by 39 to 54 percent. The trophic status of Phantom Lake improved substantially after implementation of restoration measures, although it remains a eutrophic lake.

- Ecological and aesthetic features of the natural environment are preserved through regulation of new development under city codes and a Comprehensive Plan to reflect the philosophy that development should be integrated naturally with the environment and preserve rather than overcome natural features.

Recreation Activity

- Kelsey Creek, a natural water channel that was developed to convey storm water from the city of Bellevue to Lake Washington, provides recreational opportunities such as canoeing, birdwatching, and hiking.

- Cleanup of Mercer Slough (a 325-acre wetland), along with stream and wildlife enhancement in Mercer Slough Nature Park, resulted in increased canoeing on the slough and increased visitation to the park's interpretive trail.

- Phantom and Larsen Lakes furnish recreational opportunities such as fishing and educational opportunities for school children, who visit the lakes for environmental education projects.

Economic Activity

- Clean water in Bellevue and the surrounding Puget Sound area is important for drinking, food sources, recreation, and industry.

NPDES STORM WATER SAMPLING GUIDANCE DOCUMENT

1. INTRODUCTION

The 1972 Federal Water Pollution Control Act [(FWPCA), also referred to as the Clean Water Act (CWA)] prohibits the discharge of any pollutant to waters of the U.S. from a point source unless the discharge is authorized by a National Pollutant Discharge Elimination System (NPDES) permit. Efforts to improve water quality under the NPDES program have focused traditionally on reducing pollutants in industrial process wastewater discharges and from municipal sewage treatment plants. Past efforts to address storm water discharges, in particular through the NPDES program, have generally been limited to certain industrial categories, using effluent limitations for storm water as a permit condition.

Recognizing the need for more comprehensive control of storm waters discharges, Congress amended the CWA in 1987 and established a two-phase program. In Phase I, Congress required the U.S. Environmental Protection Agency (EPA) to establish NPDES requirements for certain classes of storm water discharges.

4621

- A storm water discharge for which a permit has been issued prior to February 4, 1987
- A storm water discharge associated with industrial activity
- A storm water discharge from a municipal separate storm sewer system serving a population of 250,000 or more (large system)
- A storm water discharge from a municipal separate storm sewer system serving a population of 100,000 or more, but less than 250,000 (medium system)
- A discharge for which the Administrator or the State determines that the storm water discharge contributes to a violation of a water quality standard or is a significant contributor of pollutants to the waters of the United States.

To implement these requirements, EPA published on November 16, 1990 (55 Fed. Reg. 47990), permit application requirements that include storm water sampling. EPA and the States will subsequently issue NPDES storm water permits based on these applications, and many of these permits will require storm water sampling. Congress intended for EPA to address all other point source discharges of storm water in Phase II of the program.

1.1 PURPOSE OF THIS MANUAL

This manual is for operators of facilities that discharge storm water associated with industrial activity and operators of large and medium municipal separate storm sewer systems. Storm water sampling is sometimes difficult due to the unpredictability of storm events and the variable nature of storm water discharges. This manual is primarily designed to assist operators/owners in planning for and fulfilling the NPDES storm water discharge sampling requirements for permit applications as well as for other storm water sampling needs.

It is assumed that applicants already have a basic understanding of the storm water permit application requirements. This document is designed to supplement existing storm water application guidance by focusing on the technical aspects of sampling. Since many industrial storm water permits and all municipal storm water permits will require regular storm water sampling, many of the concepts in this guidance may be applicable to sampling requirements contained in NPDES storm water permits.

The information in this manual pertains specifically to individual industrial storm water applications, group storm water applications (Part 2), and municipal Part 2 storm water permit applications for storm water discharges. For information on other storm water application requirements for industrial facilities and large and medium municipal separate storm sewer systems, see EPA's Guidance Manual for the Preparation of NPDES Permit Applications for Storm Water Discharges Associated with Industrial Activity (EPA-505/8-91-002, April 1991), and EPA's Guidance Manual for the Preparation of Part 1 of the NPDES Permit Applications for Discharges from Municipal Separate Storm Sewer Systems (EPA-505/8-91-003A, April 1991), respectively. These manuals can be requested by calling the Storm Water Hotline [(703) 821-4823] or the National Technical Information Service (NTIS) [(703) 487-4650]. Additional background documents for further information are listed in Technical Appendix D.

1.2 ORGANIZATION OF THIS MANUAL

This manual explains the basic requirements of storm water sampling and provides procedural guidance on sampling for permit applications. Chapter 2 discusses background information (i.e., a

VOL 12

4622

summary of permit application requirements, who must sample, when and where to sample, and staffing considerations). Chapter 3 presents the fundamentals of sampling (i.e., types of sampling, obtaining flow data, handling samples, and sending them to the laboratory). Chapter 4 presents analytical considerations, including the storm water pollutants that must be analyzed under the regulations. Chapter 5 discusses regulatory flexibility with respect to storm water sampling, and Chapter 6 includes health and safety considerations.

Technical Appendices provide information as follows:

- Technical Appendix A—Forms 2F and 1
- Technical Appendix B—NOAA Weather Radio Information
- Technical Appendix C—Required Containers, Preservation Techniques, Holding Times and 40 Code of Federal Regulations (CFR) Part 136
- Technical Appendix D—References
- Technical Appendix E—Glossary
- Technical Appendix F—Acronyms.

VOL 12

4624

2. BACKGROUND FOR STORM WATER SAMPLING

This chapter presents background information, definitions, and a description of the fundamentals of sampling. Specifically, it covers the following areas:

- The benefits of sampling
- A summary of storm water application regulations
- Who must sample
- When sampling is required
- Where to sample
- Staffing considerations

In response to the 1987 Water Quality Act amendments to the CWA, EPA published the storm water final rule on November 16, 1990. In this rule, EPA established the initial scope of the storm water program by defining the phrase "storm water discharge associated with industrial activity" in terms of 11 categories of industrial activity and the phrase "large and medium municipal separate storm sewer systems" to include municipal systems serving a population greater than 100,000. These terms are discussed in greater detail in Section 2.6, "Who Must Sample."

In addition to defining the initial scope of the storm water program, the final rule established permit application requirements, including requirements for storm water sampling. Sampling data gathered for the application will be used to characterize storm water discharges, and will serve as a basis for establishing requirements in NPDES storm water permits. It is important to note that the applicant must report data that are representative of the storm water discharge, and that the intentional misrepresentation of discharge characteristics is unlawful.

2.1 BENEFITS OF SAMPLING

Data that characterize storm water discharges are valuable to permitting authorities and permittees for several reasons. First, storm water sampling provides a means for evaluating the environmental risk of the storm water discharge by identifying the types and amounts of pollutants present. Evaluating these data helps to determine the relative potential for the storm water discharge to contribute to water quality impacts or water quality standard violations. And, storm water sampling

VOL 12

4625

data can be used to identify potential sources of pollutants. These sources can then be either eliminated or controlled more specifically by the permit.

2.2 INDUSTRIAL FACILITY APPLICATION REQUIREMENTS

The storm water permit application regulations provide operators of facilities (including those owned by the government) that have storm water discharges associated with industrial activity with three application options: (1) submit an individual application; (2) participate in a group application (a two-part application); or (3) submit a Notice of Intent (NOI) to be covered by a general permit where general permits are available. This guidance focuses on sampling requirements for individual applications and Part 2 of group applications. Sampling data generally will not be required for an NOI, however, the general permit may require sampling during the term of the permit. State permitting authorities may also require sampling information for an NOI at their discretion, and should, therefore, be consulted prior to submittal.

Industrial facilities submitting individual applications must submit sampling data on a completed application Form 2F (entitled "Application for Permit to Discharge Storm Water Discharges Associated with Industrial Activity"). Facilities selected to be part of the sampling subgroup for a group application must submit sampling data with Part 2 of the application. Members of the sampling subgroup must complete only the quantitative data portions of Form 2F, including Sections VII, VIII, IX, and the certification in Section X. Exhibit 2-1 details the types of information required for each section of Form 2F. Exhibit 2-2 describes what sampling information must be provided in Part 2 of the group application. It should be noted that States may require the use of different forms and submittal of additional documentation.

Form 1 must also be submitted with Form 2F by applicants submitting individual permit applications. General information about the facility is provided on Form 1 (i.e., addresses, operators, etc.); it does not request sampling data. Forms 1 and 2F are reproduced in Technical Appendix A.

Facilities with unpermitted combined discharges of storm water and process or nonprocess wastewater must submit Form 2C or 2E, respectively, in addition to Forms 1 and 2F. Facilities with storm water discharges combined with new sources or new discharges of process wastewater must submit Form 2D as well as Forms 1 and 2F.

EXHIBIT [illegible] REQUIREMENTS

Section	Requirement
2F-I	Outfall location(s), including longitude and latitude and receiving water(s)
2F-II	Facility improvements which may affect the discharges described in the application
2F-III	Site drainage map
2F-IVA	Estimates of impervious area within each outfall drainage area
2F-IVB	A narrative description of pollutant sources (i.e., onsite materials which may come in contact with storm water runoff)
2F-IVC	Location and description of existing structural and nonstructural pollutant control measures
2F-VA	Certification that outfalls have been tested or evaluated for non-storm water discharges
2F-VB	Description of method used for testing/evaluating presence of non-storm water discharges
2F-VI	History of significant leaks or spills of toxic or hazardous pollutants at the facility within the last 3 years
2F-VII	Discharge characterization for all required pollutants
2F-VIII	Statement of whether biological testing for acute or chronic toxicity was performed and list of pollutants it was performed for
2F-IX	Information on contract laboratories or consulting firms
2F-X	Certification that information supplied is accurate and complete

Note: See Form 2F and the instructions for more detail on application requirements.

2.3 MUNICIPALITIES' APPLICATION REQUIREMENTS

Operators of large and medium municipal separate storm sewer systems are required to submit a two-part application. Both parts contain sampling requirements: Part 1 requires information characterizing discharges from the separate storm sewer system, including field screening sample data for identifying illicit/illegal connections; Part 2 requires sampling at representative locations and estimates of pollutant loadings for those sites. These sampling data are to be used to design a long-term storm water monitoring plan that will be implemented during the term of the permit. The sampling data that must be submitted in Parts 1 and 2 of municipal applications are listed in Exhibit 2-3. There is no standard application form for municipalities.

Quantitative Testing Data

- For groups with 4 to 20 members, 50 percent of the facilities must submit data; for groups with 21 to 99 members, a minimum of 10 dischargers must submit quantitative data; for groups with 100 to 1,000 members, a minimum of 10 percent of the facilities must submit data; for groups with greater than 1,000 members, no more than 100 facilities must submit data; there must be 2 dischargers from each precipitation zone in which 10 or more members of the group are located, or 1 discharger from each precipitation zone in which 9 or fewer members are located.
- Sampling and analysis requirements are described in 40 Code of Federal Regulations (CFR) 122.26(c)(1)(i)(E) and 40 CFR 122.21(g)(7). Pollutants to be analyzed depend on the type(s) of industries applying as a group.
- Sampling subgroup must provide all quantitative discharge information required in Form 2F Sections VII-IX plus the certification in Section X.
- The group application sampling subgroup must collect grab samples during the first 30 minutes of the storm event and flow-weighted composite samples as required in 40 CFR 122.21(g)(7).

2.4 APPLICATION SUBMITTAL DEADLINES

Deadlines for submitting permit applications and associated sampling requirements are presented in Exhibit 2-4 for individual and group industrial applications and for municipal applications.

2.5 WHERE TO SUBMIT APPLICATIONS

Storm water discharge permit applications are generally submitted directly to the permit-issuing authority. The appropriate authority is the State, where the State has been granted the authority to issue NPDES permits, or the EPA Regional office, where the State does not have NPDES authorization. Exhibit 2-5 indicates which States have approved NPDES permitting programs. It also provides contact names and addresses where applications should be submitted for each State or EPA Regional Office (depending on who the permitting authority is in each case). It should be noted, however, that both parts of a group application must instead be submitted to EPA Headquarters. Group applications must be sent to: Director, Office of Wastewater Enforcement and Compliance, Attention Mr. William Swietlik, U.S. EPA, EN-336, 401 M Street, SW, Washington, DC 20640.

[illegible]

Part 1

- Monthly mean rainfall and snowfall estimates
- Existing quantitative data on the depth and quality of storm water discharges
- A list of receiving water bodies and existing information concerning known water quality impacts
- Field screening analysis for illicit connections and illegal dumping
- Identification of representative outfalls for further sampling in Part 2

Part 2

- Quantitative data from 5 to 10 representative locations in approved sampling plans
- Estimates of the annual pollutant load and event mean concentration (EMC) of system discharges
- Proposed schedule to provide estimates of seasonal pollutant loads and the EMC for certain detected constituents in a representative storm event during the term of the permit
- Proposed monitoring program for representative data collection during the term of the permit

Applications submitted by industrial facilities must be certified by a responsible corporate officer as described in 40 CFR 122.22 (e.g., president, secretary, treasurer, vice president of the corporation in charge of a principal business function). Applications submitted by municipalities must be certified by a principal executive officer or ranking elected official as described in 40 CFR 122.22.

2.6 WHO MUST SAMPLE

Operators of facilities that have storm water discharges associated with industrial activity and operators of large and medium municipalities are required to conduct storm water sampling as part of their NPDES permit applications. Specifically, the following types of industries and municipalities must sample storm water discharges:

VOL 12

4629

R0037938

[illegible]

	Date	Sampling Requirement
Industrial*		
Individual	October 1, 1992	Sampling data due
Group • Part 1 • Part 2	September 30, 1991 October 1, 1992	Sampling subgroup identified Sampling data due
Municipal		
Large Municipalities • Part 1 • Part 2	November 18, 1991 November 16, 1992	Illicit connection screening due and identification of sampling points Effluent characterization due Monitoring management program identified
Medium Municipalities • Part 1 • Part 2	May 18, 1992 May 17, 1993	Illicit connection screening due and identification of sampling points Effluent characterization due Monitoring management program identified

*NOI under a general permit is due on October 1, 1992 or the date specified in the permit, whichever comes first.

- Storm Water Discharges Associated With Industrial Activities - Under Phase I, the storm water permit application regulations identify, by Standard Industrial Classification (SIC) code and narrative description, 11 categories of facilities considered to be "engaging in industrial activity" for the purposes of storm water permit application requirements. Those facilities included in 40 CFR 122.26(b)(14)(i) through (xi) of the storm water permit application regulations with storm water point source discharges to waters of the U.S. or separate storm sewers and those designated under Section 402(p)(2)(E) of the CWA are required to apply for storm water permit coverage by October 1, 1992. Industrial facilities include those that are Federally, State, or municipally owned or operated. Exhibit 2-6 lists these industrial facilities. The Transportation Act of 1991 provides an exemption from storm water permitting requirements for certain industrial activities owned or operated by municipalities with a population of less than 100,000. Such municipalities must submit storm water discharge permit applications for only airports, power plants, and uncontrolled sanitary landfills that they own or operate, unless a permit is otherwise required by the permitting authority.

- Municipal Separate Storm Sewer Systems - Under Phase I, those municipalities with separate storm sewer systems serving 100,000 people or more are required to submit an application for discharges from the system. (Only the part of the population served by municipal separate storm sewers is to be included in the 100,000 count, not the part served by combined sewers.) Regulated municipalities are listed in Appendices F through I in the November 16, 1990, final rule or have been designated by their permitting authority.

2.7 WHEN SAMPLING IS REQUIRED

Industrial individual and group applicants must include sampling data from at least one representative storm event. Operators of large or medium municipal separate storm sewer systems must submit sampling data from three different representative storm events. How to determine "representativeness" and other considerations for when to sample are presented below.

2.7.1 STORM EVENT CRITERIA

Storm water discharge permit application requirements establish specific criteria for the type of storm event that must be sampled:

- The depth of the storm must be greater than 0.1 inch accumulation
- The storm must be preceded by at least 72 hours of dry weather
- Where feasible, the depth of rain and duration of the event should not vary by more than 50 percent from the average depth and duration.

[illegible]

40 CFR 122.26(b)(14) Subpart	Description
(i)	Facilities subject to storm water effluent limitations guidelines, new source performance standards, or toxic pollutants effluent standards under 40 CFR, Subchapter N [except facilities which are exempt under category (xi)].
(ii)	Facilities classified as: SIC 24 (except 2434) ...... Lumber and Wood Products SIC 26 (except 265 and 267) . Paper and Allied Products SIC 28 (except 283 and 285) . Chemicals and Allied Products SIC 29 .... Petroleum and Coal Products SIC 311 .... Leather Tanning and Finishing SIC 32 (except 323) ...... Stone, Clay and Glass Products SIC 33 .... Primary Metal Industries SIC 3441 .... Fabricated Structural Metal SIC 373 .... Ship and Boat Building and Repairing
(iii)	Facilities classified as SIC 10 through 14, including active or inactive mining operations and oil and gas exploration, production, processing, or treatment operations, or transmission facilities that discharge storm water contaminated by contact with, or that has come into contact with, any overburden, raw material, intermediate products, finished products, byproducts, or waste products located on the site of such operations. SIC 10 .... Metal Mining SIC 11 .... Anthracite Mining SIC 12 .... Coal Mining SIC 13 .... Oil and Gas Extraction SIC 14 .... Nonmetallic Minerals, except Fuels
(iv)	Hazardous waste treatment, storage, or disposal facilities, including those that are operating under interim status or a permit under Subtitle C of the Resource Conservation and Recovery Act (RCRA).
(v)	Landfills, land application sites, and open dumps that receive or have received any industrial wastes including those that are subject to regulation under subtitle D or RCRA.
(vi)	Facilities involved in the recycling of material, including metal scrapyards, battery reclaimers, salvage yards, and automobile junkyards, including but limited to those classified as: SIC 5015 .... Motor Vehicle Parts, Used SIC 5093 .... Scrap and Waste Materials
(vii)	Steam electric power generating facilities, including coal handling sites.
(viii)	Transportation facilities which have vehicle maintenance shops, equipment cleaning operations, or airport de-icing operations. Only those portions of the facility that are either involved in vehicle maintenance (including vehicle rehabilitation, mechanical repairs, painting, fuelling, and lubrication), equipment cleaning operations, or airport de-icing operations, or which are otherwise listed in another category, are included. SIC 40 .... Railroad Transportation SIC 41 .... Local and Suburban Transit SIC 42 (except 4221-25) .... Motor Freight and Warehousing SIC 43 .... U.S. Postal Service SIC 44 .... Water Transportation SIC 45 .... Transportation by Air SIC 5171 .... Petroleum Bulk Stations and Terminals

*On June 11, 1992, the U.S. Court of Appeals for the Ninth Circuit remanded the exemption for construction sites of less than five acres in category (x) and for manufacturing facilities in category (xi) which do not have materials or activities exposed to storm water to the EPA for further rulemaking. (Nos. 90-70671 & 91-70200).

VOL 12

4638

These criteria were established to: (1) ensure that adequate flow would be discharged; (2) allow some build-up of pollutants during the dry weather intervals; and (3) ensure that the storm would be "representative," (i.e., typical for the area in terms of intensity, depth, and duration).

Collection of samples during a storm event meeting these criteria ensures that the resulting data will accurately portray the most common conditions for each site. However, the permitting authority is authorized to approve modifications of this definition (especially for applicants in arid areas where there are few representative events). Section 5.1 of Chapter 5 discusses general protocol for requesting modifications to application requirements, including the definition of "representative storm."

In determining whether a storm is representative, there are two important steps to take. First, data on local weather patterns should be collected and analyzed to determine the range of representative storms for a particular area. Second, these results should be compared to measurements of duration, intensity, and depth to ensure that the storm to be sampled fits the representativeness criteria.

2.7.2 OBTAINING RAINFALL DATA

Several sources provide accurate local weather information for both: (1) determining what a representative storm event is for a particular area; and (2) assessing expected storm events to determine whether a predicted rainfall will be "representative," and thus, meet the requirements for storm water sampling. The National Oceanic and Atmospheric Administration (NOAA) National Climatic Data Center's (NCDC's) Climate Services Branch is responsible for collecting precipitation data. Data on hourly, daily, and monthly precipitation for each measuring station (with latitude and longitude) are available to the public on computer diskette, microfiche, or hard copy. Orders can be placed by calling (704) 259-0682, by fax at (704) 259-0876, or by writing to NCDC, Climate Services Branch, The Federal Building, Asheville, North Carolina 28071-2733.

The National Weather Service (NWS) of NOAA can also provide information on historic, current, and future weather conditions. Local NWS telephone numbers can be obtained from the NWS Public Affairs Office at (301) 713-0622. Telephone numbers are also usually in local phone directory listings under "National Weather Service" or "Weather." In addition, NOAA runs the NOAA NWS

Weather Radio, which provides continuous broadcasts of the most current weather information. This broadcast can be accessed with a radio that has a weather band feature. Approximately 90 percent of the United States population is within listening range of the 380 NWS stations. Technical Appendix B presents additional information on NOAA Weather Radio, including radio frequencies for specific locations and a listing of weather band radio manufacturers. Telephone recordings of weather conditions are also provided by most NWS offices.

Cable TV weather stations and local airports can also provide weather information. Weather information provided by the local newspaper or TV stations should be used only if more accurate data (as described above) are unavailable, since weather forecasts can change drastically within several hours.

Someone should be designated at the facility to follow current weather conditions by listening to NOAA Weather Radio, calling the local NWS offices, and watching cable TV weather news. Exhibit 2-7 presents a storm water sampling decision chart for mobilizing field personnel for a probable storm event.

Annual rainfall statistics can also be used to evaluate representativeness of storm events. For example, Exhibit 2-8 presents fifteen rain zones in the United States and related storm event statistics. (These rain zones are not those shown in 40 CFR Part 122 Appendix E.) To determine typical values of annual storm events for a particular facility, identify the zone in which the facility is located. The tabulated information lists the annual average number of storms and precipitation as well as the average duration, intensity, and depth of independent storm events for each zone. Care must be taken, however, in using annual rainfall statistics for determining representativeness of storm events, since the annual rainfall statistic may not be representative of seasonal rainfall events. If rainfall data is available at or close to a particular facility, it is preferable to use this data for determining average storm event statistics.

Rainfall data tabulated from NOAA precipitation data indicate for Alaska (not shown in Exhibit 2-8) that average storm events last from 14 to 24 hours in duration and are 0.6 to 1.05 inches in depth. Average storm event data for Hawaii are 9 to 11 hours in duration and from 0.6 to 1.6 inches in depth.

VOL 12
4642

The NWS should be consulted for proper procedures for collecting and interpolating rainfall data if the applicant elects to collect the data rather than use existing data.

2.7.3 DETERMINING REPRESENTATIVENESS

An example of how to determine whether a rainfall event varies by more than 50 percent (i.e., is not representative) is shown in Exhibit 2-9.

[illegible] RAINFALL

Event Type	Duration (hrs.)	Depth (in.)
Average event	5.2	0.43
50 percent average event	2.6	0.22
150 percent average event	7.8	0.65

Once the information on an average duration and depth storm event is obtained for a specific location, multiply these numbers by 0.5 to get the 50 percent average event numbers and multiply by 1.5 to get the 150 percent average event numbers.

A representative storm in both duration and depth for a specific area will fall between the shaded numbers above (i.e., between 2.6 and 7.8 hours in duration and 0.22 and 0.65 inches in depth).

Snowmelt creates runoff which may result in point source discharges very similar to that from other storm events. Pollutants accumulate in snow, and when a thaw occurs, the pollutants will be discharged to receiving waters much like during a rain storm event. Snowmelt may be sampled as long as the applicant works closely with the permitting authority to determine the proper sampling strategy, i.e., sampling procedures, techniques, and pollutant analyses.

For snowmelt, the sampling strategy should be developed depending on the drainage area being monitored for storm flow. The strategy should consider (1) snow removal or clearing practices, e.g., direct dumping into water bodies, plowing, and the creation of snow mounds (whether in a line along a roadway or in piles on parking lots, etc.), and (2) the melting process.

It is also important to consider what happens to snowmounds as they melt and evaporate, which can alter the pollutant concentration in the resulting runoff. In addition, pollutants from the surrounding air and pavement can build up on snow mound surfaces in a crust or cake-like manner eventually leaving a residue (including previously dissolved solids that become a remaining solids residue) which is later left to be washed off by rainfall, manual flushing or other mechanisms.

The sampling of snow mounds, undisturbed snow itself, and hard pack requires a carefully thought out strategy. Given the complexities associated with snowmelt sampling, applicants should have proposed sampling strategies reviewed by the permitting authority before attempting to conduct sampling.

2.7.4 LOGISTICAL PROBLEMS WITH WHEN TO SAMPLE

Applicants may encounter weather conditions that may not meet minimum "representative" storm criteria; these conditions may prevent adequate collection of storm water samples prior to application submission deadlines. For instance, sampling may be problematic in parts of the country that experience drought or near-drought conditions or areas that are under adverse weather conditions such as freezing and flooding. Events with false starts and events with stop/start rains can also cause problems. Solutions for sampling under these circumstances are discussed below.

Where the timing of storm event sampling poses a problem, it may be appropriate for the applicant to petition the permitting authority for a sampling protocol/procedure modification either prior to sampling or after sampling is conducted (if the storm event is not acceptable). When the applicant requests a sampling protocol/procedure modification, a narrative justification should be attached. This justification should be certified by a corporate official (for industrial facilities) or the principle executive officer or ranking official (for municipalities), as per 40 CFR 122.22. Section 5.1 of Chapter 5 discusses protocol/procedure modifications.

<u>Arid Areas</u>

For arid or drought-stricken areas where a storm event does not occur prior to the time the applicant must sample and submit data with the application form, the applicant should submit the application, complete to the extent possible, with a detailed explanation of why sampling data are not provided and an appraisal of when sampling will be conducted. This explanation must be certified by the appropriate party (as described above). The applicant should also contact the permitting authority air and pavement can build up on snow mound surfaces in a crust or cake-like manner eventually leaving a residue (including previously dissolved solids that become a remaining solids residue) which is later left to be washed off by rainfall, manual flushing or other mechanisms.

The sampling of snow mounds, undisturbed snow itself, and hard pack requires a carefully thought out strategy. Given the complexities associated with snowmelt sampling, applicants should have proposed sampling strategies reviewed by the permitting authority before attempting to conduct sampling.

2.7.4 LOGISTICAL PROBLEMS WITH WHEN TO SAMPLE

Applicants may encounter weather conditions that may not meet minimum "representative" storm criteria; these conditions may prevent adequate collection of storm water samples prior to application submission deadlines. For instance, sampling may be problematic in parts of the country that experience drought or near-drought conditions or areas that are under adverse weather conditions such as freezing and flooding. Events with false starts and events with stop/start rains can also cause problems. Solutions for sampling under these circumstances are discussed below.

Where the timing of storm event sampling poses a problem, it may be appropriate for the applicant to petition the permitting authority for a sampling protocol/procedure modification either prior to sampling or after sampling is conducted (if the storm event is not acceptable). When the applicant requests a sampling protocol/procedure modification, a narrative justification should be attached. This justification should be certified by a corporate official (for industrial facilities) or the principle executive officer or ranking official (for municipalities), as per 40 CFR 122.22. Section 5.1 of Chapter 5 discusses protocol/procedure modifications.

<u>Arid Areas</u>

For arid or drought-stricken areas where a storm event does not occur prior to the time the applicant must sample and submit data with the application form, the applicant should submit the application, complete to the extent possible, with a detailed explanation of why sampling data are not provided and an appraisal of when sampling will be conducted. This explanation must be certified by the appropriate party (as described above). The applicant should also contact the permitting authority

VOL 12

4545

for further direction. Where the applicant can anticipate such problems, approval for an extension to submit sampling data should be acquired prior to the deadline.

Adverse Weather Conditions

The applicant should never conduct storm water sampling during unsafe conditions. It is likely that, in areas that experience flooding, lightening storms, high winds, etc., another representative storm event will occur for which sampling conditions will be much safer. (For further information on safety issues, see Chapter 6.) If no other storm event occurs, the applicant should submit a justification as to why the event was not sampled. This information should be certified by the appropriate official.

False Starts and Stop/Start Rains

False start and stop/start rains can also cause problems. False starts may occur when weather conditions are unpredictable and it appears that a storm event may be representative, collection begins, and then the rain stops before an adequate sample volume is obtained. (Necessary sample volumes are discussed in Section 3.6.) Some latitude may be given for the 0.1-inch rainfall requirement as long as the sample volume is adequate; the permitting authority may accept the results with applicant justification and certification. Again, see Chapter 5 for information on requesting protocol/procedure modifications to storm water sampling requirements.

During stop/start rains (those in which rainfall is intermittent), samples should be taken until an adequate sample volume is obtained. Exhibit 2-10 summarizes logistical problems of storm water sampling and presents solutions to the problems identified.

2.7.5 WHEN INDUSTRIAL FACILITIES MUST SAMPLE

Industrial applicants must generally collect two types of storm water samples: (1) grab samples collected during the first 30 minutes of discharge; and (2) flow-weighted composite samples collected during the first 3 hours of discharge (or the entire discharge, if it is less than 3 hours). Information from both types of samples is critical to fully evaluate the types and concentrations of pollutants present in the storm water discharge.

VOL 12

4646

VOL 12

EXHIBIT 2-10. LOGISTICAL PROBLEMS OF STORM WATER SAMPLING	
Problem:	Arid/drought areas
Solution:	Submit a petition requesting a modification to the protocol if problems are anticipated and, if it is approved, submit the application without sampling data by the application due date with a certified explanation. Provide sampling data to the permitting authority as soon as possible.
Problem:	Adverse weather conditions such as freezing, flooding, winds, tornadoes, electrical storms, and gully washes
Solution:	Sample another, less hazardous event or submit a certified justification of why the event was not sampled. Provide sampling data to the permitting authority as soon as possible.
Problem:	False starts
Solution:	Discard the sample if the volume is inadequate. If the volume is adequate, submit the sampling data with a certified explanation that the sample is from a non-representative event. Continue to monitor weather conditions and attempt to resample as soon as possible.
Problem:	Stop/start rains
Solution:	Continue to sample in case the storm event turns out to be representative and adequate sample volumes are obtained. If sample volumes are inadequate, continue to monitor weather conditions and attempt to resample as soon as possible.

4647

The grab samples taken during the first 30 minutes of a storm event will generally contain higher concentrations of pollutants, since they pick up pollutants that have accumulated on drainage surfaces since the last storm event.

Composite samples characterize the average quality of the entire storm water discharge. Flow-weighted composite samples provide for the most accurate determination of mass load. The flow-weighted composite sample must be taken for either the first 3 hours or for the entire discharge (if the event is less than 3 hours long). Additional information on how to collect grab and composite samples is presented in Sections 3.3 and 3.4, respectively.

Industrial applicants are required at a minimum to sample only one storm event. However, if samples from more than one storm are analyzed and the results are representative of the discharge, the data representing each event must be reported. The facility must provide a description of each storm event tested. The average of all values within the last year must be determined and the concentration, mass, and total number of storm events sampled must be reported on Form 2F. Furthermore, sampling should be conducted during normal operating procedures (day or night), and, not when the facility has been closed for a period of time.

Industrial applicants must certify, as a separate requirement, that all outfalls have been tested or evaluated to determine whether non-storm water discharges are present (e.g., process wastewater, sanitary wastes, cooling water, or rinse water) or whether illegal/illicit connections are occurring in the system. This testing should be conducted during dry weather to avoid any flows of storm water through the conveyance.

A checklist that can be used to conduct dry weather evaluations is provided in Exhibit 2-11. A narrative description of the method used to conduct dry weather evaluations and the date and the drainage points must be included in Section V.A of Form 2F. This statement must be certified by the appropriate party as described in Section 2.7.4.

A dry weather visual inspection is the simplest way to screen for illicit discharges. If one or more of the items on the checklist in Exhibit 2-11 are answered affirmatively, or if there are other reasons to believe that illicit connections exist, more detailed investigations (such as dye tests, smoke tests, evaluation of piping designs, and TV line monitoring) may be necessary. Dye testing involves releasing fluorescent, nontoxic dye into the suspected source of non-storm water, (e.g., a drain, sink, toilet, or pipe) and checking to see whether the dye shows up in the storm water outfall. Smoke testing involves pumping smoke into a storm sewer and viewing the facility to see if smoke escapes through unknown openings or storm sewer inlets. The presence of smoke indicates that storm water may enter the sewer through these openings or inlets. However, smoke testing may prove ineffective at finding non-storm water discharges to separate storm sewers. Smoke passage may be blocked due to line traps that are intended to block sewer gas.

TV line monitoring is a technique whereby a small video camera is placed in the storm sewer and a video image of the sewer is viewed on a monitor at the surface to identify illicit connections. The camera can be moved through the sewer by remote control. For more information on smoke and dye testing and TV line monitoring, consult EPA's Guidance Manual for the Preparation of NPDES

EXHIBIT 2-1[illegible] CHECKLIST FOR CONDUCTING DRY WEATHER EVALUATIONS

1. Date of inspection: ____________
2. Facility name and address: ____________
3. Date of last rain event: ____________
4. Inspector name: ____________
5. Type of outfall

☐ Concrete ☐ Pipe ☐ Grassed ☐ Rock ☐ Other ____________

6. Is there visible flow from the pipe? ☐ Yes ☐ No
If yes, check all that apply. If no, go to number 7.

☐ Colored water (describe) ____________ ☐ Oily sheen
☐ Odor* (describe) ____________ ☐ Sludge present
☐ Murky ☐ Clear water
☐ Floating objects (describe) ____________ ☐ Stains on conveyance
☐ Absence of plant life surrounding conveyance ☐ Notable difference in plant life surrounding conveyance
☐ Scum ☐ Suds ☐ Other: ____________

*e.g., rotten eggs, earthy, chemical, chlorine, soap, putrescence, gasoline, musty, etc.

Estimate the flow either visually or by describing the width, height, and shape of the conveyance and the approximate percentage of the conveyance where flow is present or the approximate depth of the flow. Describe your estimate.

7. Is there standing water present? ☐ Yes ☐ No
If yes, check all that apply. If no, go to number 8.

☐ Colored water (describe) ____________ ☐ Oily sheen
☐ Odor* (describe) ____________ ☐ Sludge present
☐ Murky ☐ Clear water
☐ Floating objects (describe) ____________ ☐ Stains on conveyance
☐ Absence of plant life surrounding conveyance ☐ Notable difference in plant life surrounding conveyance
☐ Suds ☐ Scum ☐ Other: ____________
☐ Absence of plant life surrounding conveyance

*e.g., rotten eggs, earthy, chemical, chlorine, soap, putrescence, gasoline, musty, etc.

8. From the inspection locations, can you see any unusual piping or ditches that drain to the storm water conveyance? ☐ Yes ☐ No
9. Is there any overland flow visible from the discharge location? ☐ Yes ☐ No
10. Are there dead animals present? ☐ Yes ☐ No

VOL 12

4649

R0037958

Permit Applications for Storm Water Discharges Associated with Industrial Activity (EPA-505/8-91-002, April 1991).

A problem with the dry weather evaluation process is that the presence of a dry weather/non-storm water discharge may be caused by infiltration of ground or surface waters through cracks in the storm water drainage system. In this situation, all other possible sources of the non-storm water discharge should be examined and ruled out. If no sources are found, the physical structure of the conveyance system should be inspected for deterioration.

The applicant should make every attempt to halt non-storm water discharges to the storm sewer system unless the discharge is covered by an NPDES permit. If it is not feasible to halt the discharge of non-storm water to the storm sewer system, and the discharge is not authorized by a process wastewater or storm water permit, the applicant must submit either Form 2C (for a process water discharge) or Form 2E (for a nonprocess water discharge), and check with state officials to see if alternate forms are required.

2.7.6 WHEN MUNICIPAL FACILITIES MUST SAMPLE

Municipal applicants are required to conduct sampling for both Parts 1 and 2 of their applications. In Part 1, municipalities must conduct a field screening analysis to detect illicit connections and illegal dumping into their storm sewer system. Where flow is observed during dry weather, two grab samples must be collected during a 24-hour period with a minimum of 4 hours between samples. These samples must be analyzed for pH, total chlorine, total copper, total phenol, and detergents (surfactants). Note that these are dry weather samples, rather than storm water samples. EPA's Guidance Manual for the Preparation of Part 1 of the NPDES Permit Applications for Discharges from Municipal Separate Storm Sewer Systems presents a description of conducting field screening sampling and provides a data sheet.

For Part 2 of the application, municipalities must submit grab (for certain pollutants) and flow-weighted sampling data from selected sites (5 to 10 outfalls) for 3 representative storm events at least 1 month apart. The flow-weighted composite sample must be taken for either the entire discharge or the first 3 hours (if the event lasts longer than 3 hours). Municipal facilities are not required to collect grab samples within the first 30 minutes of a storm event.

VOL 12

4650

R0037959

VOL 12

In addition to submitting quantitative data for the application, municipalities must also develop programs for future sampling activities that specify sampling locations, frequency, pollutants to be analyzed, and sampling equipment. Where necessary (as determined by the municipality or if required by the permitting authority), responsibilities may also include monitoring industries connected to the municipality's storm sewers for compliance with their facility-specific NPDES permits. Refer to EPA's Guidance Manual for the Preparation of Part 1 of the NPDES Permit Applications for Discharges from Municipal Separate Storm Sewer Systems for information on how to develop municipal sampling programs.

2.7.7 USE OF HISTORICAL DATA

Data from storm water samples analyzed in the past can be submitted with applications in lieu of new sampling data if:

- All data requirements in Form 2F are met
- Sampling was performed no longer than 3 years prior to submission of the permit application
- All water quality data are representative of the present discharge.

4651

The historical data may be unacceptable if there have been significant changes since the time of that storm event in production level, raw materials, processes, or final products. Significant changes which may also impact storm water runoff include construction or installation of treatment or sedimentation/erosion control devices, buildings, roadways, or parking lots. Applicants should assess any such changes to determine whether they altered storm water runoff since the time of the storm event chosen for use in the permit application. Historical data can be used only in applications. Historical data cannot be used for fulfilling permit requirements.

2.8 WHERE TO SAMPLE STORM WATER DISCHARGES

Storm water samples should be taken at a storm water point source. A "point source" is defined as any discernible, confined, and discrete conveyance, including (but not limited to) any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, landfill leachate collection system, vessel, or other floating craft from which pollutants are or may be discharged (as per 40 CFR 122.2). Included in the definition of storm water "point sources" is storm water from an industrial facility that enters, and is discharged through, a municipal separate storm sewer. In short, most storm water discharges can be defined as "point source" discharges, since they ultimately flow into some kind of conveyance (e.g., a channel or swale).

2.8.1 INDUSTRIAL FACILITIES

Industrial applicants submitting individual applications must collect and analyze a grab sample taken within the first 30 minutes of the storm event and flow-weighted composite samples from each of the industrial storm water "point source" outfalls identified on the site drainage map submitted for Section III of Form 2F. Applicants submitting quantitative data for Part 2 of the group application must also collect samples for each outfall discharging storm water associated with industrial activity. All outfalls should be sampled during the same representative storm event if possible. If this is not feasible, outfalls may be sampled during different representative storm events upon approval by the permitting authority. Descriptions of each storm event and which outfalls were sampled during each event must be included in the application. Storm water runoff from employee parking lots, administration buildings, and landscaped areas that is not mixed with storm water associated with industrial activity, or storm water discharges to municipal sanitary sewers, do not need to be sampled.

<u>Outfalls With Substantially Identical Effluents—Industrial Facilities</u>

If an applicant has two or more outfalls with "substantially identical effluents," the facility may petition the permitting authority to sample and analyze only one of the identical outfalls and submit the results as representative of the other. "Substantially identical effluents" are defined as discharges from drainage areas undergoing similar activities where the discharges are expected to be of similar quantity and quality, and indistinguishable in expected composition. Chapter 5 presents an example of a petition for substantially identical effluents and discusses this process in more detail.

2.8.2 MUNICIPALITIES

Large and medium municipalities are required to sample storm water discharges from 5 to 10 outfalls or field screening points that were proposed in Part 1 of the application. The final decision on the number and location of sampling points will be determined by the permitting authority and will depend on site-specific conditions such as land use or drainage area and results of data collected during the field screening analysis process for Part 1 of the application.

2.8.3 LOGISTICS OF WHERE TO SAMPLE

The ideal sampling location would be the lowest point in the drainage area where a conveyance discharges storm water to waters of the U.S. or to a municipal separate storm sewer system. A sample point also should be easily accessible on foot in a location that will not cause hazardous sampling conditions. Ideally, the sampling site should be on the applicant's property or within the municipality's easement; if not, the field personnel should obtain permission from the owner of the property where the discharge outfall is located. Typical sampling locations may include the discharge at the end of a pipe, a ditch, or a channel.

However, logistical problems with sample locations may arise (e.g., nonpoint discharges, inaccessibility of discharge point, etc.). Logistical problems with sample locations and suggested solutions are described in Exhibit 2-12. In many cases, it may be necessary to locate a sampling point further upstream of the discharge point (e.g., in a manhole or inlet). If the storm water at a selected location is not representative of a facility's total runoff, the facility may have to sample at several locations to best characterize the total runoff from the site. In situations where discharge points are difficult to sample for various reasons, the applicant should take the best sample possible and explain the conditions in the application. A discussion on sampling at retention ponds appears in Section 3.1.2.

2.9 STAFFING CONSIDERATIONS

Staffing needs for sampling must be determined by the applicant. Factors in making the determination include the number of sample locations, the size of the area to be sampled, how far apart the locations are, the type of sampling required, the technique to be used, the number of samples to be taken (depending on how many parameters must be analyzed), and safety considerations.

Training sampling personnel is important to the success of storm water discharge characterization. Training can be done using this manual. Sampling conducted by untrained personnel may result in

EXHIBIT 2-12 SOLUTIONS TO SAMPLE LOCATION PROBLEMS

Problem:	Sampling where storm water commingles with process or non-process water
Solution:	Attempt to sample the storm water discharge before it mixes with the non-storm water discharge. If this is impossible, sample the discharge both during dry and wet weather and present both sets of data to the permitting authority. This will provide an indication of the contribution of pollutants from each source.
Problem:	Numerous small point discharges
Solution:	Impound channel or join together flow by building a weir or digging a ditch to collect discharge at a low point for sampling purposes. This artificial collection point should be lined with plastic to prevent infiltration and/or high levels of sediment. Or, sample at several locations to represent total site runoff.
Problem:	Inaccessible discharge point [examples include underwater discharges or unreachable discharges (e.g., out of a cliff)]
Solution:	Go up the pipe to sample (i.e., to the nearest manhole or inspection point). If these are not available, tap into the pipe or sample at several locations to best represent total site runoff.
Problem:	Managing multiple sampling sites to collect grab samples during the first 30 minutes (industrial facilities only)
Solution:	Have a sampling crew ready for mobilization when forecasts indicate that a representative storm will occur or sample several different representative events. Also, for most parameters, automatic samplers may be used to collect samples within the first 30 minutes triggered by the amount of rainfall, the depth of flow, flow volume or time.
Problem:	Commingling of parking lot runoff with discharge associated with industrial activity
Solution:	The combined runoff must be sampled at the discharge point as near as possible to the receiving water or the parking lot drain inlet if there is one.
Problem:	Sampling in manholes
Solution:	Sample in manholes only when necessary. See Chapter 6 for safety information. Sampling in manholes requires training on confined space entry.
Problem:	Runon from other property
Solution:	If possible, estimate the volume of offsite runon contributions and offsite runon sources of pollutants to perform a mass balance calculation. Include this information in the permit application. If this estimation is not possible, provide a narrative discussion of the upstream site (e.g., is it developed, if so the type of facility, the types of pollutants that may be present on the site, etc.).

data that is unrepresentative of the facility's storm water discharge. This data might be rejected by the permitting authority, who would then require another sampling effort.

3. FUNDAMENTALS OF SAMPLING

Because of the variable nature of storm water flows during a rainfall event and different analytical considerations for certain pollutants, the storm water regulations establish specific requirements for sample collection techniques. The quality of storm water discharges and logistical needs for sampling will be different for industrial applicants and municipal applicants. Therefore, specific sampling requirements vary. After a brief review of sampling fundamentals and special sampling requirements for storm water permit applications, the following sections are intended to teach applicants how to sample to meet these requirements.

The applicant should carefully plan his/her sampling strategy prior to the actual sampling event, e.g., walk the site to determine appropriate sampling locations, become familiarized with local rainfall patterns, train sampling staff in procedures and safety, consult with laboratory, and collect supplies.

3.1 TYPES AND TECHNIQUES OF SAMPLING

There are three basic aspects of sampling:

- Sample type (i.e., grab versus composite)
- Sample technique (i.e., manual versus automatic)
- Flow measurement methods.

These topics will be discussed in relation to requirements of an NPDES storm water discharge permit application. Once these aspects are addressed, step-by-step instructions on sampling procedures are presented. The sections below define and describe the types of storm water samples that must be collected and methods or techniques for collecting them. In addition, special sampling requirements for certain pollutants are discussed.

3.1.1 SAMPLE TYPE VERSUS SAMPLE TECHNIQUE

It is important to understand the difference between sample type and technique. "Sample type" refers to the kind of sample that must be collected -- either a grab or a composite. "Sample technique" refers to the method by which a grab or composite sample is actually collected -- either manually or by automatic sampler. A generalized relationship between sample type and sample technique is presented in Exhibit 3-1. Sections 3.1.2 and 3.1.3 further explain the significance of these terms as they relate to storm water sampling requirements.

EXHIBIT 3-1. SAMPLE TYPE VS. SAMPLE TECHNIQUE

Sample Type	Sample Technique
Grab	Manual Automatic sampling system
Composite	Manual with manual compositing Automatic system or automatic sampling with manual compositing

3.1.2 SAMPLE TYPE: GRAB AND COMPOSITE SAMPLES

To comply with storm water application requirements, the sample type (grab or composite) must be collected in accordance with 40 CFR 122.21(g)(7) and 40 CFR Part 136. The storm water application requirements clearly specify which pollutants must be analyzed by grab sample, and which by composite sample. Although the requirements in 40 CFR 122.21(g)(7) do not explicitly specify either manual or automatic sampling techniques, the approved analytical methods contained in 40 CFR Part 136 direct that grab samples must be collected manually for certain pollutants. Sections 3.3 and 3.4 clarify which pollutants must be grabbed, which ones must be grabbed manually, and which ones must be flow-weighted composites.

The two types of storm water samples required by the regulations, grab and composite samples, are described below.

VOL 12

4658

VOL 12

Grab Samples

A grab sample is a discrete, individual sample taken within a short period of time (usually less than 15 minutes). Analysis of grab samples characterizes the quality of a storm water discharge at a given time of the discharge.

Composite Samples

A composite sample is a mixed or combined sample that is formed by combining a series of individual and discrete samples of specific volumes at specified intervals. Although these intervals can be time-weighted or flow-weighted, the storm water regulations require the collection of flow-weighted composite samples. This means that discrete aliquots, or samples, are collected and combined in proportion to flow rather than time. Composite samples characterize the quality of a storm water discharge over a longer period of time, such as the duration of a storm event.

Application Requirements

Both types of samples must be collected and analyzed for storm water discharge permit applications. Grab samples must be collected for the following conditions:

- For storm water discharges associated with industrial activity, a grab sample must be obtained during the first 30 minutes of a discharge. This requirement is in addition to the composite sampling requirements. These samples are intended to characterize the maximum concentration of a pollutant that may occur in the discharge and/or may indicate intermingling of non-storm water discharges.

- For storm water discharges from large and medium municipal separate storm sewers, grab samples are required for Part 1 of the application if a discharge is noted during dry weather field screening. Two grab samples must be collected during a 24-hour period with a minimum of 4 hours between samples. These samples are intended to assist in the identification of illicit connections or illegal dumping. In Part 2, grab samples may be required for the analysis of certain pollutants for which municipalities are required to sample.

Flow-weighted composite samples must be collected during the first 3 hours of discharge or the entire discharge (if it is less than 3 hours) for both industrial and municipal applicants.

4659

Pollutant-specific Requirements

The regulations at 40 CFR 122.21(g)(7) identify certain pollutants for which grab sampling is required:

- Monitoring by grab sample must be conducted for pH, temperature, cyanide, total phenols, residual chlorine, oil and grease (O&G), fecal coliform, and fecal streptococcus. Composite samples are not appropriate for these parameters due to their tendency to transform to different substances or change in concentration after a short period of time. Such transformations may be particularly likely in the presence of other reactive pollutants.

Sampling At Retention Ponds

Retention ponds with greater than a 24-hour holding time for a representative storm event may be sampled by grab sample. Composite sampling is not necessary. The rationale for this is that, because the water is held for at least 24 hours, a thorough mixing occurs within the pond. Therefore, a single grab sample of the effluent from the discharge point of the pond accurately represents a composite of the storm water contained in the pond. If the pond does not thoroughly mix the discharge, thereby compositing the sample, then a regular grab and composite sample should be taken at the inflow to the pond. Since each pond may vary in its capability to "composite" a sample, applicants must carefully evaluate whether the pond is thoroughly mixing the discharge. Such factors as pond design and maintenance are important in making this evaluation. Poor pond design, for example, where the outfall and inflow points are too closely situated, may cause short-circuiting and inadequate mixing. In addition, poor maintenance may lead to excessive re-suspension of any deposited silt and sediment during heavy inflows. Because of factors such as these, the applicant should determine the best location to sample the pond (e.g., at the outfall, at the outfall structure, in the pond) to ensure that a representative composite sample is taken. If adequate compositing is not occurring within the pond, the applicant should conduct routine grab and flow-weighted composite sampling.

A grab sample <u>and</u> a flow-weighted sample must be taken for storm water discharges collected in holding ponds with less than a 24-hour retention period. The applicant must sample the discharge in the same manner as for any storm water discharge [as described in 40 CFR 122.21(g)(7)]. In effect, the applicant must take one grab sample within the first 30 minutes of discharge, or as soon as possible. The applicant must also collect a flow-weighted composite sample for at least the first 3 hours of the discharge, or for the event's entire duration (if it is less than 3 hours). The flow-weighted composite sample may be taken using a continuous sampler or as a combination of at least three sample aliquots taken during each hour of the discharge, with a minimum of 15 minutes between each aliquot. If the applicant does not know what retention period the pond is designed for, the design engineer of the pond should be consulted.

3.1.3 SAMPLE TECHNIQUE: MANUAL VERSUS AUTOMATIC SAMPLING

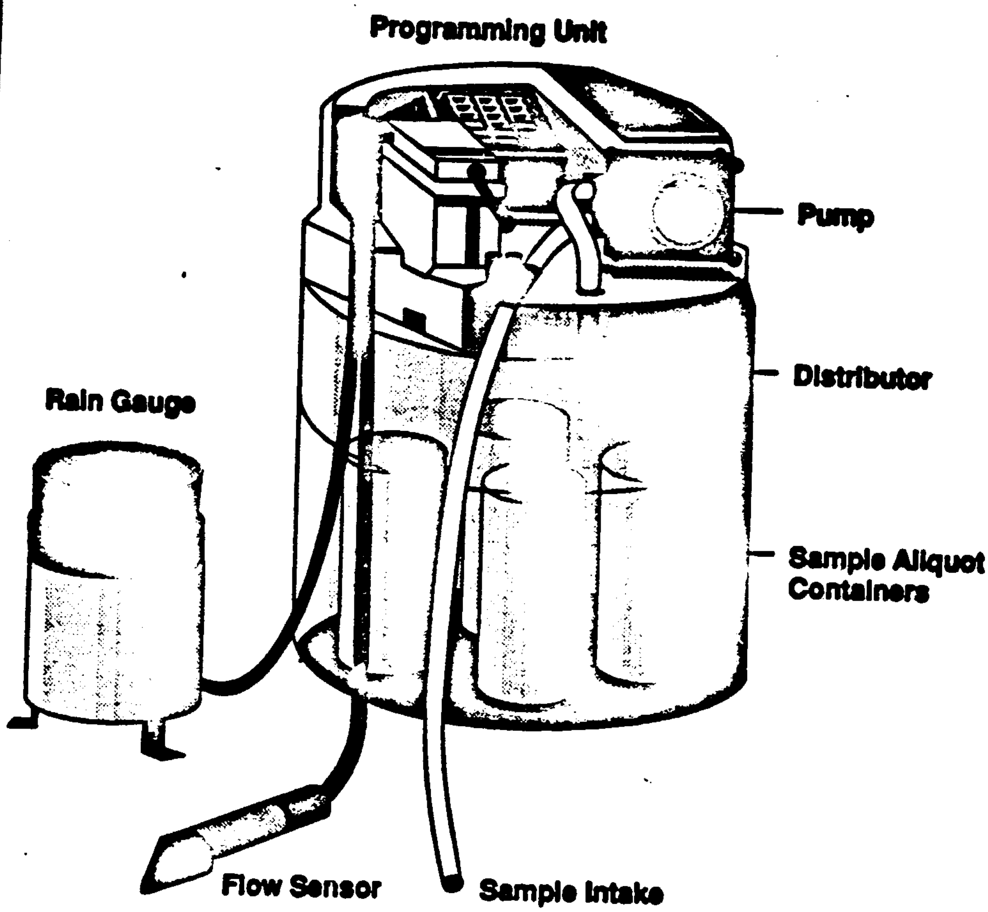
As previously discussed, manual and automatic sampling techniques are methods by which both grab and composite samples can be collected. Manual samples are simply samples collected by hand. Automatic samplers are powered devices that collect samples according to preprogrammed criteria. A typical automatic sampler configuration is shown in Exhibit 3-2.

For most pollutants, either manual or automatic sample collection will conform with 40 CFR Part 136. However, one case in which automatic samplers cannot be used is for the collection of volatile organic compound (VOC) samples because VOCs will likely volatilize as a result of agitation during automatic sampler collection. Samples collected for VOC analysis should be filled until a reverse meniscus is found over the top of the collection bottle and capped immediately to leave no air space. Automatic samplers do not perform this function. Special requirements for VOC sampling are discussed in Section 3.5.2.

Although both collection techniques are available, several other pollutants may not be amenable to collection by an automatic sampler, for example fecal streptococcus, fecal coliform and chlorine have very short holding times (i.e., 6 hours), pH and temperature need to be analyzed immediately and oil and grease requires teflon coated equipment to prevent adherence to the sampling equipment.

Other restrictions on sample collection techniques (such as container type and preservation) should be determined by consulting the approved analytical methods listed in 40 CFR Part 136. Section 3.5 and Technical Appendix C provide additional information on sample handling, holding times, and preservation methods.

EXHIBIT 3-2 AUTOMATIC SAMPLER



Manual and automatic techniques have advantages and disadvantages that the applicant should consider in relation to the sampling program. The main advantage of manual sampling is that it can be less costly than purchasing or renting automatic samplers. Automatic samplers, however, can be often more convenient. Exhibit 3-3 presents a matrix of advantages and disadvantages associated with each technique. Ultimately, the best technique to use will depend on each applicant's situation.

3.2 OBTAINING FLOW DATA

In addition to collecting samples of storm water discharges, applicants must collect data characterizing the flow rate and flow volume for each storm water discharge sampled. Flow rate is the quantity of storm water discharged from an outfall per unit of time. Total flow is a measure of the total volume of storm water runoff discharged during a rain event. Flow rates and volumes can either be measured specifically or can be estimated (based on rainfall measurements, velocities, and depth of flows). To collect flow-weighted composite samples, flow rate data is necessary to combine proportional volumes of individually collected aliquots. Applicants must also report the mass of pollutants contained in storm water discharges (see Section 3.2.5). To determine mass loadings of pollutants, applicants must measure both discharge flow rate and pollutant concentration. This section presents methods for obtaining flow data.

3.2.1 MEASURING FLOW RATES

Flow rates for storm water discharges are most accurately measured using either primary or secondary flow measurement devices. Facilities should use these devices to characterize their discharge as precisely as possible. Where flow measurement devices are not already installed, portable devices should be considered. There are many permanent and portable types of flow measurement devices available. This discussion is limited to the most common flow measurement devices. To purchase flow measurement devices and rain gauges, pertinent engineering journals can be consulted for equipment vendor listings. Proper analysis of site discharge conditions must be conducted prior to purchase and installment of flow measurement devices.

<u>Primary Flow Measurement Devices</u>

A primary flow measurement device is a man-made flow control structure which, when inserted into an open channel, creates a geometric relationship between the depth of the flow and the rate of the

VOL 12

4663

EXHIBIT [illegible]. COMPARISON OF MANUAL AND AUTOMATIC SAMPLING TECHNIQUES

Sample Method	Advantages	Disadvantages
Manual Grabs	• Appropriate for all pollutants • Minimum equipment required	• Labor-intensive • Environment possibly dangerous to field personnel • May be difficult to get personnel and equipment to the storm water outfall within the 30 minute requirement • Possible human error
Manual Flow-Weighted Composites (multiple grabs)	• Appropriate for all pollutants • Minimum equipment required	• Labor-intensive • Environment possibly dangerous to field personnel • Human error may have significant impact on sample representativeness • Requires flow measurements taken during sampling
Automatic Grabs	• Minimizes labor requirements • Low risk of human error • Reduced personnel exposure to unsafe conditions • Sampling may be triggered remotely or initiated according to present conditions	• Samples collected for O&G may not be representative • Automatic samplers cannot properly collect samples for VOCs analysis • Costly if numerous sampling sites require the purchase of equipment • Requires equipment installation and maintenance • Requires operator training • May not be appropriate for pH and temperature • May not be appropriate for parameters with short holding times (e.g., fecal streptococcus, fecal coliform, chlorine) • Cross-contamination of aliquot if tubing/bottles not washed
Automatic Flow-Weighted Composites	• Minimizes labor requirements • Low risk of human error • Reduced personnel exposure to unsafe conditions • May eliminate the need for manual compositing of aliquots • Sampling may be triggered remotely or initiated according to on-site conditions	• Not acceptable for VOCs sampling • Costly if numerous sampling sites require the purchase of equipment • Requires equipment installation and maintenance, may malfunction • Requires initial operator training • Requires accurate flow measurement equipment tied to sampler • Cross-contamination of aliquot if tubing/bottles not washed

VOL 12

4664

flow. The depth of the flow, referred to as the head (H), can then be measured at the respective reference point/area with a ruler or other staff gauge. When substituted into a formula, which mathematically describes the relationship between depth and discharge for the primary devices, the head measurement can be used to calculate a flow rate (Q). The most common primary flow measurement devices are weirs and flumes. Weirs and flumes are flow structures designed to provide a known, repeatable relationship between flow and depth.

Weirs

Weirs consist of a crest located across the width of an open channel (at a right angle to the direction of the flow). The flow of water is impeded, causing water to overflow the crest. Diagrams and formulas of some typically found weirs are provided in Exhibit 3-4. Weirs are inexpensive and particularly valuable in measuring flow in natural or man-made swales because they are easily installed in irregularly shaped channels.

Weirs can only provide accurate flow measurements when head measurements are appropriately taken. When flow exceeds the capacity of the weir and water overtops the weir crest, flow depth actually diminishes as the water approaches the weir, as shown in Exhibit 3-5. Therefore, measuring the depth at the weir crest will result in an inaccurate measurement of the actual head. Under these circumstances, the head should be measured upstream, at a point determined by the type of weir and the estimated amount of flow. A staff gauge can be installed at a nonturbulent point upstream of the weir crest to provide accurate and convenient measurements.

Flumes

Flumes are structures which force water through a narrow channel. They consist of a converging section, a throat, and a diverging section. Exhibit 3-6 portrays the most common type of flume, the Parshall flume, and also provides formulas for calculating appropriate flow rates.

Parshall flumes have fixed specifications relating to geometric shape. They vary only in throat width. Due to these geometric constraints, Parshall flumes may be expensive to install. They are typically used in permanent flow measurement points and are most commonly placed in concrete-lined channels. However, Parshall flumes can also be used in temporary points. Parshall flumes provide accurate measurements for a relatively wide range of flow rates. The flow rate through the Parshall flume (see Exhibit 3-6) is calculated from the depth (H_a) of flow measured in the converging

section of the flume. The exact location of the depth measurement depends on the specific design of the Parshall flume. Exhibit 3-6 indicates the equations used to calculate flow rate through a typical Parshall flume. These equations are accurate only when the submergence ratio (H_b/H_a) is greater than 0.7. The manufacturers' information should be consulted for the flow rate equation and measuring points for a specific Parshall flume.

Palmer-Bowlus flumes, shown in Exhibit 3-7, are also used at some facilities. Palmer-Bowlus flumes are designed to be installed in an existing circular channel (such as a manhole channel) and are available as portable measurement devices. While Palmer-Bowlus flumes are inexpensive, self cleaning, and easy to install, they can only measure flow rates accurately over a narrow range of flow.

The flow from a Palmer-Bowlus flume is calculated using the height between the floor of the flume portion and the water level, not the total head of the water level. Head measurements are taken at

a distance from the throat equal to one half the width of the flume. The dimensions of a Palmer-Bowlus flume have been standardized in a generic sense, but the flume shape may vary. Therefore, there are no formulas that can be applied to all Palmer-Bowlus flumes. Device-specific head-flow relationships for each device should be obtained from the manufacturer.

There are a number of other, less common, flow measurement devices available which will not be discussed (see Appendix D for additional references).

Secondary Flow Measurement Devices

Secondary flow measurement devices are automated forms of flow rate and volume measurement. Typically, a secondary device is used in conjunction with a primary device to automatically measure the flow depth or head. This value is then processed, using established mathematical relationships to relate the depth measurement to a corresponding flow rate. The device also may have the capacity to convert this flow rate to a volume. Secondary flow measurement devices include floats, ultrasonic transducers, pressure transducers, and bubblers. The output of the secondary device is transmitted to a display, recorder, and/or totalizer to provide flow rate and volume information. The user manuals for these devices should be consulted for proper usage.

Evaluation of Flow Measurement Devices

To ensure accurate results, facilities should evaluate, via visual observation and routine checks, the design, installation, and operation of flow measurement devices. When evaluating design, select a device which:

- Is accurate over the entire range of expected flow rates
- Can be installed in the channel to be monitored
- Is appropriate to the sampling location (i.e., power setup, submersible, etc.).

When evaluating the installation of flow measurement devices, ensure that:

- There are no leaks and/or bypasses of flow around the measuring device
- The primary device is level and squarely installed
- The secondary device is calibrated.

When evaluating the operation of flow measurement devices, look for:

- Excessive flows which submerge the measuring device
- Flows outside the accuracy range of the device
- Leaks and/or bypasses around the measuring device

VOL 12

- Turbulent flow through the measuring device
- Corrosion, scaling, or solids accumulation within the measuring device
- Obstructions to the measuring device
- Use of the correct factor or formula to convert head readings to actual flow rate.

Other than ensuring appropriate design and installation, accuracy checks are difficult to accomplish for primary flow measurement devices. Secondary flow measurement devices, on the other hand, may require evaluation of design, installation, and calibration. Applicants should examine the secondary recording devices and their readouts after installation to ensure that they are operating properly. Unusual fluctuations or breaks in flow indicate operational or design flaws.

3.2.2 ESTIMATING FLOW RATES

There are a variety of techniques for estimating flow rates. These methods are not as accurate as the methods described in Section 3.2.1 above, but are suitable for those discharges where primary or secondary devices are not practical or economically feasible. Each of the following methods is suitable for certain types of flow situations, as indicated. For each, the procedure for collecting flow rate data will be given along with a sample calculation.

4671

Float Methods

Float methods can be used for any discharge where the flow is exposed and/or easily accessible. It is particularly useful for overland flows, gutter flows, and open drain or channel flows. The flow rate is calculated in each of the float methods by estimating the velocity of the flow and the cross-sectional area of the discharge and using the standard flow rate equation:

$$\textit{Flow Rate (cfm)} = \textit{Velocity (ft/min)} \times \textit{Area (ft}^2\textit{)}$$

The velocity is estimated by measuring the time it takes a float to travel between two points (point A and point B) along the flow path. For most accurate results, the two points should be at least 5 feet apart. The cross-sectional area is estimated by measuring the depth of the water and the width of the flow, and multiplying the depth by the width. This assumes a uniform cross-section in the flow path and a geometric cross-section shape. The float method can also be used for any accessible pipe or ditch where the movement of the float can be traced downstream for at least 5 feet. Subsurface storm water flows can be measured with the float method where there are two accessible manholes.

If the flow is overland, the water will need to be directed into a narrow channel or ditch so that the measurements can be taken. The initial preparation for this method requires that a shallow channel or ditch be dug that is 6 feet long or longer and 4 to 12 inches wide. The channel or ditch should be shallow enough to easily obtain flow depths but should be deep enough to carry the flow that will be diverted to it. Boards or other barriers should be placed on the ground above the channel (so that the flow is diverted into the channel) and along the edges of the channel or ditch (flush with the ground surface so that flow does not seep under them).

The procedure for measuring the flow rate by the float method involves measuring the length of the channel between chosen points A and B (which must be 5 feet apart or more). The depth of the water at point B, in the middle of the channel, must be determined, and the width of the water flow must be measured at point B. A float is then placed in the water and timed as it moves from point A to point B. Exhibit 3-8 provides an example of estimating the flow rate using the float method.

For runoff flows from many directions into a drain in a low or flat area where ponding is evident, the float method can also be used. The total flow rate is calculated by measuring flow rates for several points into the drain and adding these values together. Exhibit 3-9 provides an example of estimating the flow rate using the float method in this situation.

<u>Bucket and Stopwatch Method</u>

The bucket and stopwatch method of estimating flow rate is the easiest of all the flow rate estimation procedures. However, it can only be used under certain conditions. The flow or discharge to be measured must be flowing from a small pipe or ditch, and it must be free-flowing. In other words,

EXHIBIT [illegible] EXAMPLE CALCULATION OF FLOAT METHOD FOR UNIMPEDED OPEN CHANNEL FLOW

3	40	5.0	0.20	0.29	0.5	3.6
4	60	5.0	0.21	0.33	0.5	3.9
5	80	5.0	0.18	0.29	0.5	4.0
6	100	5.0	0.17	0.25	0.5	3.7
7	120	5.0	0.17	0.12	0.5	1.8
8	140	5.0	0.16	0.12	0.5	1.9
9	160	5.0	0.18	0.12	0.5	1.7

Step 2: Place a float in the water flow at point A and time it as it moves from point A to point B. Record the time in minutes. See column D.

Step 3: Measure the depth of the water and the width of the flow at point B. See columns E and F.

Step 4: Calculate the flow rate for each sample time using the common flow rate formula. See column G.

Formulas:

$$\textit{Velocity } (V) = \frac{\text{Length from A to B}}{\text{Time of Travel}}$$

$$\textit{Area } (A) = \textit{Water Depth} \times \textit{Width of Flow}$$

$$\textit{Flow Rate } (Q) = (V) \times (A)$$

Example: For Sample 1

$$V = \frac{5.0\ ft}{0.17\ min} = 29.4\ ft/min$$

$$A = 0.12\ ft \times 0.5\ ft = 0.06\ ft^2$$

$$Q = 29.4\ ft/min \times 0.06\ ft^2 = 1.8\ cfm$$

EXHIBIT [illegible] EXAMPLE CALCULATION OF FLOAT METHOD FOR ESTIMATING DRAIN FLOWRATES

Step 1: When each sample or aliquot is taken, record the data for the time the sample was taken. Measure the outer perimeter or edge of the drain where the water flows in. See columns B and C.

Step 2: Designate three evenly spaced points surrounding the drain approximately 3 to 5 feet from the drain. These points will be referred to as points A, B, and C. Record the distance from each point to the edge of the drain. See column D.

EXAMPLE DATA: Assume the drain dimensions are 1 ft x 1 ft square, and flow surrounds drain.

A	B	C	D			E			F			G
Sample Number	Sample Time (min)	Drainage Perimeter (feet)	Distance of Point to Drain (feet)			Time of Travel to Drain (min)			Depth of Water (feet)			Calculated Flow Rate (cfm)
			Pt. A	Pt. B	Pt. C	Pt. A	Pt. B	Pt. C	Pt. A	Pt. B	Pt. C	
1	0	4	3	4	5	0.2	0.3	0.5	0.08	0.08	0.08	4 cfm
2	20	4	3	4	5	0.3	0.4	0.5	0.11	0.12	0.14	5 cfm
3	40	4	3	4	5	0.3	0.4	0.5	0.11	0.12	0.14	5 cfm
4	60	4	3	4	5	0.4	0.5	0.6	0.16	0.17	0.20	6 cfm
5	80	4	3	4	5	0.3	0.4	0.5	0.11	0.12	0.14	5 cfm
6	100	4	3	4	5	0.3	0.4	0.5	0.11	0.12	0.14	5 cfm
7	120	4	3	4	5	0.3	0.4	0.5	0.11	0.12	0.14	5 cfm
8	140	4	3	4	5	0.3	0.4	0.5	0.11	0.12	0.14	5 cfm
9	160	4	3	4	5	0.2	0.3	0.5	0.08	0.08	0.08	4 cfm

Step 3: Place a float at each of the three points and measure the time it takes to reach the drain. Record the times in minutes. See column E.

Step 4: Determine the depth of flow at each place where the float enters the drain from points A, B, and C. Record the depth in feet. See column F.

Step 5: Calculate the flow rate by adding the individual flow rates for points A, B, and C. Record the data in column G.

Formulas:

$$\textit{Velocity } (V) = \frac{\textit{Distance of Point from Drain}}{\textit{Time of Travel}}$$

$$\textit{Area } (A) = \textit{Water Depth} \times \textit{Drainage Perimeter}$$

$$\textit{Flow Rate } (Q) = 1/n \Sigma A_n V_n \textit{ where n equals points A, B, and C}$$

Example: For Sample 1

$$V_A = \frac{3 \textit{ Feet}}{0.2 \textit{ Min}} = 15 \textit{ ft/min}$$

$$A_A = 0.08 \textit{ ft} \times 4 \textit{ ft} = 0.32 \textit{ ft}^2$$

EXHIBIT [illegible] EXAMPLE CALCULATION OF FLOAT METHOD FOR ESTIMATING DRAIN FLOW RATES (Continued)

$$Q_{OPEN} = \tfrac{1}{3}(V_A A_A + V_B A_B + V_C A_C)$$

$$= \tfrac{1}{3}[(15\ ft/min)(0.32\ ft^2) + (13\ ft/min)(0.32\ ft^2) + (10\ ft/min)(0.32\ ft^2)]$$

$$= 4\ cfm$$

the pipe or ditch must be raised above the ground. Also, the flow must be small enough to be captured by a bucket or other suitable container without overflowing. If these conditions are not present, another method must be used. The procedure involves recording the time that each sample is taken, the time it takes for the container to be filled, and the volume of discharge collected. The flow rate is then calculated in gallons per minute (gpm) or in cubic feet per minute (cfm). The basis for the bucket and stopwatch method is the collection of a measured amount of flow over a measured amount of time to determine flow per unit of time (or flow rate) as per the formula below.

$$\textit{Flow Rate Q (gpm)} = \frac{\textit{Volume of Bucket (gal)}}{\textit{Time to Fill (sec)}} \times \frac{60\ sec}{1\ min}$$

Exhibit 3-10 provides an example of estimating flow rates with the bucket and stopwatch method.

<u>Slope and Depth Method</u>

The slope and depth method is also a relatively easy method for estimating flow rates in pipes and ditches. This procedure requires that the slope of the pipe or ditch be known. A survey or engineering design data such as sewer or grading plans may provide the slope or grade of the pipe or ditch. In addition, the flow or effluent to be measured should not fully fill the pipe or ditch from which it is flowing. To measure the depth of the flow at the center of the pipe or ditch at the outfall, the outfall should be accessible. If these conditions are not present, another method should be used. The procedure involves recording the time that each sample is taken and measuring the depth of the flow in the middle of the pipe or ditch. If the flow is coming from a pipe, the inside diameter of the pipe should be recorded. If the effluent is coming from a ditch, the width of the flow in the ditch should be measured. Also, the modified slope of the ditch should be calculated. The flow rate is calculated in cfm using the same formulas for both pipes and ditches. Exhibit 3-11 provides an example of estimating the flow rate with the slope and depth method.

Table [illegible]: EXAMPLE APPLICATION OF BUCKET AND STOPWATCH METHOD FOR ESTIMATING FLOWS

Step 1: When each sample or aliquot is taken, record the data for the time the sample was taken. See column B.

EXAMPLE DATA:

A	B	C	D	E	F
Sample Number	Time (minutes)	Time to Fill Bucket (seconds)	Volume of Bucket (gallons)	Calculated Flow Rate (gpm)	Calculated Flow Rate in (cfm)
1	0	40.0	2.0	3.0	0.4
2	20	26.0	2.0	4.6	0.6
3	40	24.0	2.0	5.0	0.7
4	60	32.0	2.0	3.7	0.5
5	80	45.0	2.0	2.7	0.4
6	.100	31.0	2.0	3.9	0.5
7	120	50.0	2.0	2.4	0.3
8	140	21.0	2.0	5.7	0.8
9	160	28.0	2.0	4.3	0.6
					0.6

Step 2: Put a bucket beneath the flow, while measuring with a stopwatch the time it takes to fill the bucket to a certain level. If the water spills over the sides, the process must be redone. Record the time it took to fill the volume of water. See columns C and D.

Step 3: Calculate the flow rate in gpm and cfm.

Formulas:

$$\textit{Flow Rate, } Q(gpm) = \frac{\text{Volume of bucket (gal)}}{\text{Time to fill (sec)}} \times \frac{60 \text{ sec}}{1 \text{ min}}$$

$$Q(cfm) = Q(gpm) \times 0.1337\ ft^3/gal$$

Example: For Sample 1

$$Q\ (gpm) = \frac{2 \text{ gal}}{40.0 \text{ sec}} \times \frac{60 \text{ sec}}{1 \text{ min}} = 3.0 \text{ gpm}$$

$$Q\ (cfm) = 3.0 \text{ gpm} \times 0.1337\ ft^3/gal = 0.4 \text{ cfm}$$

VOL 12

EXHIBIT [illegible] EXAMPLE CALCULATION OF SLOPE AND DEPTH METHOD FOR ESTIMATING FLOW RATES

Step 1: Obtain the pipe or ditch channel percent slope from engineering data. Determine the inside diameter if the flow is from a pipe.

EXAMPLE DATA: For purposes of this example, a ditch with a 2 percent slope is assumed.

Step 2: When each sample or aliquot is taken, record the data for the time the sample was taken. See column B.

EXAMPLE DATA:

A	B	C	D	E	F	G
Sample Number	Time (minutes)	Depth of Water (in)	Width of Flow (ditch only) (feet)	"M" Modified Slope (ditch only)	Calculated Flow Rate (cfm Pipe only)	Calculated Flow Rate (cfm ditch only)
1	0	3.6	2.2	3.7	-	246.1
2	20	6.0	3.2	3.2	-	713.6
3	40	7.2	4.0	3.3	-	1,237.3
4	60	8.4	4.2	3.0	-	1,532.9
5	80	7.2	4.0	3.3	-	1,237.3
6	100	6.0	3.2	3.2	-	713.6
7	120	6.0	3.0	3.0	-	624.2
8	140	6.0	2.9	2.9	-	581.8
9	160	4.6	2.5	3.3	-	374.1

Step 3: Measure the depth of the water in the center of the pipe or ditch. Record the data in feet. See column C.

Step 4: Measure the width of the flow only if the flow is in a ditch. Record the data in feet. See column D.

Step 5: Calculate the modified side slope only if the flow is in a ditch (leave column E blank if the flow is in a pipe).

Formula:

$$\textit{Modified slope } (M) = \frac{12.0 \text{ in/ft} \times \text{flow width (ft)}}{2.0 \times \text{water depth (in)}}$$

Example: Sample 1:

$$M = \frac{12.0 \text{ in/ft} \times 2.2 \text{ ft}}{2.0 \times 3.6 \text{ in}} = 3.7$$

Step 6: For pipes, calculate the flow rate and record the data in column F.

$$\textit{Flow Rate } (Q) = 0.004 \times (I.D.)^{1.67} \times D \times \sqrt{S}$$

where Q = flow rate in pipe (cfm), I.D. = inside diameter of pipe (in), D = water depth (in), S = pipe slope (%)

Step 7: For ditches or channels, calculate the flow rate in cfm. Record the flow rate in column G.

Formula:

$$\textit{Flow Rate } (Q) = \frac{0.42M \times (M)^{1.67} \times (D)^{2.67} \times \sqrt{S}}{(M^2 + 1)^{0.33}}$$

where Q = flow rate in ditch (cfm), M = modified slope, D = water depth (in), S = ditch slope (%)

Example: For Sample 1:

$$Q_1 = \frac{0.42\,(3.7) \times (3.7)^{1.67} \times (3.6)^{2.67} \times \sqrt{2}}{[(3.7)^2 + 1]^{0.33}}$$

$$Q = 246.1 \text{ cfm}$$

R0037986

Runoff Coefficient Methods

Runoff coefficient methods are the least accurate of all the flow rate estimation methods. These methods should only be used for composite flow-weighted samples if all of the other methods are inappropriate for the site. Although the least accurate, runoff coefficients are the simplest method of estimating runoff rates.

Runoff coefficients represent the fraction of total rainfall that will be transmitted as runoff from the drainage area that flows into the facility outfall. Runoff coefficients consider the ground surface or cover material and determine the amount of storm water flow which may infiltrate or runoff as a discharge. A simple estimate of runoff volume assumes that paved areas and other impervious structures such as roofs have a runoff coefficient of 0.90 (i.e., 90 percent of the rainfall leaves the area as runoff). For unpaved surfaces, a runoff coefficient of 0.50 is normally assumed. A more accurate estimate can be made by using more specific runoff coefficients for different areas of the facility, based on the specific type of ground cover. Commonly used runoff coefficients are listed in Exhibit 3-12.

The average runoff coefficient can be estimated for drainage areas that have both paved and unpaved areas by weighting the coefficients based on their proportion of the total area. An equation for this would be:

$$\textit{Estimated Average Runoff Coef.} = \frac{(\textit{Area A})(\textit{Runoff Coef. A}) + (\textit{Area B})(\textit{Runoff Coef. B})}{\textit{Area A} + \textit{Area B}}$$

The area of the drainage basin can generally be obtained from land surveys conducted at the time of facility purchase or site surveys taken from design documents developed as part of construction planning. If these are not available, the applicant may estimate the drainage areas from a topographic map of the area. The areas used in this calculation should include only those areas drained by the sampled outfall. When determining the basin area that drains through the outfall, some special considerations should be noted: (1) storm water from sources outside an industrial facility's property boundary may contribute to the discharge; and (2) storm water not associated with industrial activity may contribute to the flow volume. Where these conditions occur, the facility should accurately quantify and appropriately address these contributions.

VOL 12

4679

There are two specific methods to estimate flow rate using runoff coefficients. The first method uses depth of flow in a pipe or ditch and an average runoff rate to estimate each of the sample flow rates where the slope/pitch of the pipe or ditch is unknown. Exhibit 3-13 provides an example calculation of estimating flow rates based on depth and runoff coefficients. The second method uses only rainfall accumulation and runoff coefficients to estimate a flow associated with the time the sample was taken. No actual flows or flow depths are measured. Exhibit 3-14 provides an example of estimating the flow rate based on rainfall depth and runoff coefficients.

3.2.3 MEASURING TOTAL FLOW VOLUMES FOR THE SAMPLED RAIN EVENT

Similar to measuring flow rates, flow volumes may be measured using automatic flowmeters or primary/secondary devices as discussed in Section 3.2.1. Measurement of flow volume with these devices provides a reasonably accurate determination of the total flow volume for the entire storm water discharge. In many cases, however, primary or secondary devices have not been installed for storm water flow measurement. Portable flow measurement devices are often expensive. Many of the automatic samplers that are currently on the market can measure flow volumes as well as perform sampling. Where available and when economically feasible, measuring devices should be used to generate data for calculating flow.

3.2.4 ESTIMATING TOTAL FLOW VOLUMES FOR THE SAMPLED RAIN EVENT

Since accurate measurement of total flow volumes is often impracticable due to lack of equipment, total flow volumes are more commonly estimated. The two methods provided in this section require only simple estimated measurements. The first method is based on rainfall depths and runoff coefficients and the second is based on flow rates that can be either measured or estimated.

<u>Runoff Coefficients Methods</u>

Discharge volumes are most easily estimated using the area of the drainage basin contributing to the outfall, the rainfall accumulation, and a runoff coefficient. The total volume of discharge can be estimated using a simple equation that relates the amount of rainfall to the volume of discharge that will leave the site as runoff. The equation is as follows:

VOL 12

4680

[illegible] DEPTH METHOD FOR ESTIMATING FLOW RATES (Continued)

Step 5: Calculate a depth-weight flow factor and record the data in column D.

Formula:

$$\textit{Factor} = \frac{\textit{Measured Water Depth}}{\textit{Sum of all Water Depths}} \times \textit{Number of Flow Measurements}$$

Example: For Sample 1

$$\textit{Factor} = \frac{(1\ ft) \times 9}{11.0} = 0.82$$

Step 6: Calculate the flow rate. Record the data in column E.

Formula:

$$\textit{Flow Rate, } Q\ (cfm) = \textit{Average Runoff Rate} \times \textit{Depth Factor}$$

Example: For Sample 1

$$Q = 47\ cfm \times 0.82 = 39\ cfm$$

$$V_t = R_t \times [(A_{paved} \times C_{runoff}) + (A_{unpaved} \times C_{runoff})]$$

where: V_t = the total runoff volume in cubic feet
R_t = the total rainfall measured in feet
A_{paved} = the area (sq ft) within the drainage basin that is paved or roofed
$A_{unpaved}$ = the area (sq ft) within the drainage basin that is unpaved
C_{runoff} = a specific runoff coefficient (no units) for the drainage area ground cover

Exhibit 3-15 provides an example calculation of total runoff volume from rainfall data.

Discharge Volumes Estimated Based on Measured Flow Rates

Another method of estimating the total volume of a discharge uses a series of measured or estimated flow rates. The total volume of discharge can be estimated by first multiplying each of the flow rates by the time interval in between flow measurements. This time period represents the portion of the total storm duration that can be associated with the flow rate measurement. Adding all such partial volumes results in a total flow volume. A procedure for calculating the total runoff volume from a set of discrete measurements of flow depth and velocity in a ditch during a storm runoff event is presented in Exhibit 3-16.

VOL 12

4682

EXHIBIT [illegible] EXAMPLE CALCULATION OF RUNOFF COEFFICIENT/FLOW DEPTH METHOD FOR ESTIMATING FLOW RATES

Step 1: Estimate the runoff coefficient for the drainage area that contributes flow to the sampled outfall (see Section 3.2.2).

EXAMPLE: Assume the drainage area to the outfall is 3 acres. Two of those acres are paved with a runoff coefficient of .90, and 1 is unpaved with a runoff coefficient of .50. Using the equation for estimated runoff coefficient from the text in Section 2.2.2.2:

$$\textit{Est. Run. Coef.} = \frac{(2\ Ac)\ (0.90) + (1\ Ac)\ (0.50)}{2\ Ac + 1\ Ac} = 0.77$$

The runoff coefficient for the entire drainage area is 0.77.

Step 2: Measure the rainfall depth. Record the total rainfall of the storm or the rainfall that occurred in the first 3 hours (if it lasted more than 3 hours). Also record the duration of the rain event.

EXAMPLE: Assume the rainfall depth to be 1.0 inches in 3 hours.

Step 3: Calculate an average runoff rate.

Formula:

$$\textit{Average Runoff Rate} = \frac{\textit{Drainage Area} \times \textit{Runoff Coef.} \times \textit{Rainfall Depth}}{\textit{Rainfall Duration}}$$

Example:

$$\textit{Average Runoff Rate} = \frac{3\ Ac \times .77 \times 1\ in}{3\ hrs} \times \frac{43{,}560\ ft^2}{Ac} \times \frac{ft}{12\ in} \times \frac{hr}{60\ min} = 47\ cfm$$

When each sample or aliquot is taken, record the data for the time the samples were taken and the depth of the water in the center of the ditch or pipe. Record the data in columns B and C.

EXAMPLE DATA:

A	B	C	D	E
Sample Numbers	Time (minutes)	Channel or Ditch Water Depth (feet)	Calculated Depth-Weighted Flow Factor	Flow Rate (cfm)
1	0	1.0	0.82	39
2	20	1.1	0.90	42
3	40	1.2	0.98	46
4	60	1.25	1.02	48
5	80	1.3	1.06	50
6	100	1.25	1.02	48
7	120	1.2	0.98	46
8	140	1.7	1.39	65
9	160	1.0	0.82	39

Step 4: Sum up all the water depths for each sample taken as indicated above in column C.

Sum = 11.0 feet

EXHIBIT [illegible] EXAMPLE [illegible]ION OF RUNOFF COEFFICIENT [illegible] FLOW RATES

Step 1: Estimate the runoff coefficient for the drainage area that contributes flows to the sampled outfall.

EXAMPLE: See Step 1 in Exhibit 3-14. The site for this example will be similar so a coefficient of .77 will be used for the same 3-acre drainage area.

Step 2: When each sample or aliquot is taken, record the data for the time the sample was taken. Record the data in column B.

EXAMPLE DATA:

A	B	C	D	E	F
Sample Number	Time (minutes)	Total Rainfall Depth (inches)	Time Since Last Sample	Incremental Rainfall (inches) per 20 minutes	Calculated Flow Rate (cfm)
1	0	0.0	0	0.0	–
2	20	0.2	20	0.2	84
3	40	0.3	20	0.1	42
4	60	0.5	20	0.2	84
5	80	0.6	20	0.1	42
6	100	0.8	20	0.2	84
7	120	0.9	20	0.1	42
8	140	1.0	20	0.1	42
9	160	1.1	20	0.1	42

Step 3: Using a rainfall gauge, measure the total rainfall depth (in inches) and record the data in column C.

EXAMPLE: See sample data above.

Step 4: Calculate the incremental time since the last flow measurement and record the data in column D.

EXAMPLE: Samples were taken 20 minutes apart so this increment will be 20 minutes for every sample.

Step 5: Calculate the additional or incremental rainfall that has occurred since the last measurement. Record the data in column E.

Formula:

$$\textit{Incremental Rainfall} = \textit{Total Rainfall Sample 2} - \textit{Total Rainfall Sample 1}$$

Example: For Sample 2

$$\textit{Incremental Rainfall} = .2 - 0 = .2 \textit{ inches}$$

Step 6: Calculate the flow rate. Record the data in column F.

Formula:

$$\textit{Flow Rate (cfm)} = \frac{\textit{(Drainage area)(Runoff coefficient)(Incremental rainfall)}}{\textit{(Incremental time)}}$$

Example:

$$\textit{Flow Rate} = \frac{(3\ Ac)(0.77)(0.2\ in)}{20\ min} \times \frac{(43{,}560\ ft^2)}{Ac} \times \frac{1\ ft}{12\ in} = 84\ cfm$$

[illegible] RAINFALL DATA

Step 1: Determine the area of drainage contributing to the runoff volume at the outfall and convert it to square feet.

Example: Using a land survey, a facility has determined its site encompasses 0.3 acres (13,068 square feet). The entire site is used for industrial activities, and therefore, any storm water discharges from the site will be associated with industrial activity. A berm surrounds the entire site limiting the drainage area to the site itself and preventing any dilution or contamination from other discharges. (Note: To convert acres to square feet, multiply the number of acres by 43,560, which is the conversion factor).

Step 2: Determine the rainfall depth during the event that was sampled to the nearest one-hundredth of an inch and convert it to feet.

Example: From the rain gauge, the rainfall accumulation is measured at 0.6 inches or 0.05 feet (ft). (Note: To convert inches to feet, divide the inches by 12, which is the conversion factor).

Step 3: Determine the runoff coefficients for each area.

Example: The facility has estimated that ⅓ of the site, or 4,356 square feet, is covered by impervious surfaces (i.e., roofs or paved roadways) and ⅔ of the site, or 8,712 square feet, is unpaved.

Step 4: Calculate the volume of flow using the following formula and convert the volume to liters.

Formula: *Total runoff volume in cubic feet (cu ft) = total rainfall (ft) x [facility paved area (sq ft) x 0.90 + facility unpaved area (sq ft) x 0.50]*

Example: *Total runoff volume (cu ft) = 0.05 x [4,356 x 0.90 + 8,712 x 0.50]*

Total runoff volume = 413.8 cu ft or 11,720 liters

(Note: To convert cubic feet to liters, multiply cubic feet by 28.32, which is the conversion factor).

VOL 12

[illegible] FROM FLOW RATE DATA

Step 1: Measure and tabulate flow depths and velocities every 20 minutes (at the same time that the sample is collected) during at least the first 3 hours of the runoff event.

EXAMPLE DATA:

A	B	C	D	E	F
Sample Number	Time (minutes)	Flow Velocity (feet per minute)	Flow Depth (feet)	Width (feet)	Calculated Flow Rate (cfm)
1	0	-	-	-	-
2	20	4	0.2	5	4
3	40	8	0.4	5	16
4	60	12	0.4	5	24
5	80	8	0.4	5	16
6	100	4	0.2	5	4
7	120	8	0.2	5	8
8	140	4	0.2	5	4
9	160	4	0.2	5	4

4685

[illegible] EXAMPLE [illegible] FROM FLOW RATE DATA (Continued)

Step 2: Calculate and tabulate the cross-sectional area of flow for each of the flow depths measured. Calculate the flow rate for each discrete set of measurements.

Formula:

$$\textit{Flow Rate } Q \text{ (cfm)} = \textit{Velocity (ft/min)} \times \textit{Area (sq ft)}$$
$$\textit{Area} = \textit{Depth} \times \textit{Width}$$

Example: For Sample 1

$$\textit{Area} = 0.2 \text{ ft} \times 5 \text{ ft} = 1 \text{ sq ft}$$
$$\textit{Flow Rate} = 4 \text{ ft/min} \times 1 \text{ sq ft} = 4 \text{ cfm}$$

Step 3: Plot the flow rate, Q, versus time. Also, assume that flow drops uniformly from the last calculated flow rate (Q_9) to zero at the time when Q_{10} would have been taken.

Example: The flow rates calculated in Step 3 are plotted against the time between samples.

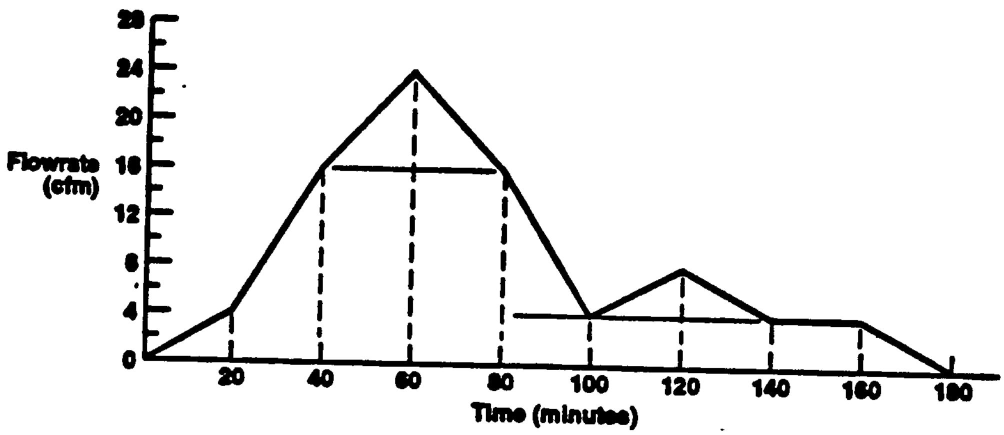
[illegible] EXAMPLE CALCULATION OF [illegible] FROM FLOW RATE DATA (Continued)

Step 4: The total flow volume (V_t) can be calculated by geometrically determining the area under the curve. The summation of the individual volumes per increment of time (V_1 through V_9) is the total flow volume of the event.

Example:



Step 5: Compute the flow volume associated with each observation (V_1, V_2, ..., V_9) by multiplying the measured flow rate by the duration (in this case, 20 minutes). Be sure the units are consistent. For example, if durations are in minutes and flow velocities are in cubic feet per second (cfs), convert the durations to seconds or the velocities to feet per minute.

Example:

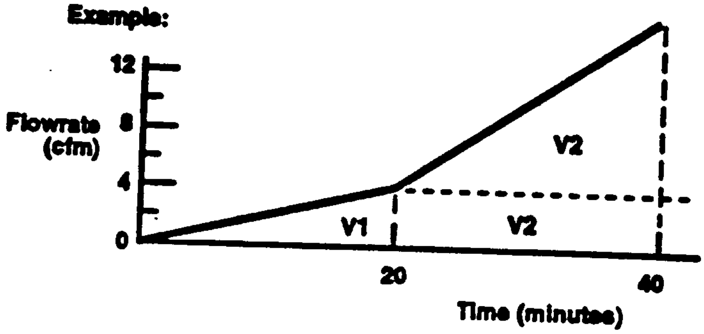


EXHIBIT [illegible] EXAMPLE CALCULATION OF [illegible] FROM FLOW RATE DATA (Continued)

Formula: *Volume (V) = Flow Rate (cfm) x Duration (minutes)*

Example:

$$V_1 = \frac{1}{2}(Q_1 - Q_0)(t_1 - t_0) = \frac{1}{2}(4-0)(20-0) = 40\ ft^3$$

$$V_2 = \frac{1}{2}(Q_2 - Q_1)(t_2 - t_1) + Q_1(t_2 - t_1)$$

$$= \frac{1}{2}(16-4)(40-20) + 4(20)$$

$$= 120 + 80 = 200\ ft^3$$

$V_1 = 40\ ft^3$
$V_2 = 200\ ft^3$
$V_3 = 400\ ft^3$
$V_4 = 400\ ft^3$
$V_5 = 200\ ft^3$
$V_6 = 120\ ft^3$
$V_7 = 120\ ft^3$
$V_8 = 80\ ft^3$
$V_9 = 40\ ft^3$

Step 6: Total the individual volumes calculated in Step 5 to obtain the total runoff volume.
Example:

Total Storm Runoff = 1,600 ft³

VOL 12

3.2.5 REPORTING STORM WATER DISCHARGE FLOW RATES AND VOLUMES

Form 2F requires applicants to provide quantitative data (reported both as concentration and as total mass) based on flow-weighted samples collected during storm events. In addition, applicants are required to provide flow estimates or flow measurements, as well as an estimate of the total volume of the discharge. The method of flow estimation or measurement must be described in the application. Although EPA only requires flow estimates in Form 2F, accurate flow measurement is necessary for collecting representative flow-weighted composite samples and reporting pollutant mass loadings.

3.2.6 MEASURING RAINFALL

Many types of instruments have been developed to measure the amount and intensity of precipitation. All forms of precipitation are measured on the basis of the depth of the water that would accumulate on a level surface if precipitation remained where it fell. There are two types of rain gauges – standard and recording gauges. A standard rain gauge collects the rainfall so that the amount of rain can be easily measured. The standard gauge for the NWS has a collector which is 8 inches in diameter. Rain flows from the collector into a cylindrical measuring tube inside the overflow can. The measuring tube has a cross-sectional area one tenth the size of the collector so that 0.1 inch of rainfall will fill 1 inch of the measuring tube. While this standard gauge is both accurate and easy to use, any open receptacle with vertical sides can be an effective rain gauge. Standard rain gauges are simple and inexpensive; however, with a standard gauge, there is no way to record changes in the intensity of the rainfall without making frequent observations of the gauge during the storm.

4689

The second type of gauge is the recording rain gauge, which provides a permanent record of the amount of rainfall which accumulates over time. Three common types of recording gauges are:

- <u>Tipping Bucket Gauge</u> - Water caught in a collector is funneled into a two-compartment bucket; a known quantity of rain fills one compartment, overbalancing the bucket and emptying it into a reservoir. This moves the second bucket into place beneath the funnel. The tipping of the bucket engages an electric circuit, which records the event.

- <u>Weighing Type Gauge</u> - Water is weighed when it falls into a bucket placed on the platform of a spring or lever balance. The weight of the contents is recorded on a chart, showing the accumulation of precipitation.

- <u>Float Recording Gauge</u> - Water is measured by the rise of a float that is placed in the receiver. These gauges may be self-siphoning, or may need to be emptied periodically by hand.

Recording rain gauges provide a permanent record of rainfall, and they can be used to determine variations in rainfall intensity over time without making frequent observations during the storm. But recording gauges are more complicated mechanically than standard gauges, making them more costly, less durable, and more difficult to operate.

Although all gauges are subject to error, most errors can be minimized. To minimize errors, the gauge should be placed on a level surface that is not windswept and is away from trees or buildings that might interfere with the path of rainfall. When taking measurements, other factors contributing to error should also be considered: mistakes in reading the scale, dents in the collector rim (which changes the receiving area), measuring sticks that may retain some of the water, and water lost to evaporation. In the case of tipping bucket gauges, water may not be collected while the bucket is still tipping. The most common source of inaccuracy is changes in data that are attributable to wind. It is possible to assess wind errors by comparing measurements of gauges that are protected from the wind with those that are not.

3.3 GRAB SAMPLE COLLECTION

Section 3.1.2 discussed both the parameters that must be monitored by grab sample and the conditions under which grab sampling is required. This section explains how to collect grab samples. The entire sample is collected at an uninterrupted interval (i.e., grabbed at one time). A grab sample provides information on the characterization of storm water at a given time and may be collected either manually or automatically as discussed below.

3.3.1 HOW TO MANUALLY COLLECT GRAB SAMPLES

A manual grab is collected by inserting a container under or downcurrent of a discharge with the container opening facing upstream. Generally, simplified equipment and procedures can be used. In most cases, the sample container itself may be used to collect the sample. Less accessible outfalls may require the use of poles and buckets to collect grab samples. To ensure that manual grab samples are representative of the storm water discharged, the procedures set forth in Exhibit 3-17 should be followed.

EXHIBIT [illegible] RECOMMENDED OPERATING PROCEDURES FOR TAKING GRAB SAMPLES

- Label sample containers before sampling event
- Take a cooler with ice to the sampling point
- Take the grab from the horizontal and vertical center of the channel
- Avoid stirring up bottom sediments in the channel
- Hold the container so the opening faces upstream
- Avoid touching the inside of the container to prevent contamination
- Keep the sample free from uncharacteristic floating debris
- Transfer samples into proper containers (e.g., from bucket to sample container), however, fecal coliform, fecal streptococcus, phenols and O&G should remain in original containers
- If taking numerous grabs, keep the samples separate and labelled clearly
- Use safety precautions (see Chapter 6)

Specialized equipment and procedures may be needed, particularly in situations where storm water discharges are inaccessible or where certain parameters are monitored. For example:

- When sampling for O&G and VOCs, equipment that safely and securely houses O&G bottles or VOC vials should be used. This may be necessary because: (1) O&G will adhere to containers and thus should not be transferred from one container to another; and (2) excessive aeration during sampling may result in the partial escape of VOCs.
- Since facilities sometimes use sample bottles that already contain preservatives (as provided by contract laboratories), extreme care should be taken when filling them to avoid spills, splatters, or washout of the preservatives.

All equipment and containers that come into contact with the sample must be clean to avoid contamination. Additionally, sample collection equipment and container materials should be totally unreactive to prevent leaching of pollutants. Cleaning procedures are discussed in detail in Section 3.5.

3.3.2 HOW TO COLLECT GRAB SAMPLES BY AUTOMATIC SAMPLER

Grab samples can also be collected using programmed automatic samplers. Automatic samplers come equipped with computers that can be programmed to collect grab samples. Programming for grabs is specific to the type of automatic sampler. Some samplers are portable and have been developed specifically to sample for storm water discharges. These samplers are frequently attached to a rain gauge and/or a flow sensor. Such samplers can be programmed to initiate sample collection by one or more of the following conditions: (1) depth of flow in a channel; (2) rainfall in inches; (3) flow rate; (4) time; (5) external signal; and (6) combinations of the first three conditions. For example, an automatic sampler could be used to collect a sample at 15-minute intervals after its sensors indicate that rainfall has begun.

When using an automatic sampler, planning is very important. First, all equipment must be properly cleaned, particularly the tubing and the sample containers. There are several different types of tubing available, including rubber and Tygon tubing. Tygon tubing is commonly used since it generally does not leach contaminants. Deionized water should be drawn through the sampler to remove any remaining pollutant residuals prior to taking samples. Tubing should also be replaced periodically to avoid algae or bacterial growth.

Sampling personnel should also use adequate and appropriate containers and ensure they are properly cleaned. Section 3.5 contains information on cleaning procedures which should be followed for all equipment. Additionally, the utilization of blanks (a control used to verify the accuracy of analytical results) is recommended to determine if cross-contamination of sampling equipment has occurred. Samplers should also be programmed, set up, and supplied with a source of power. Properly charged batteries should be readily available for portable samplers in advance of a storm event and, as a backup power supply in case of power failure. Finally, although automatic samplers may be useful in some situations, several parameters are not amenable to collection by automatic sampler. These pollutants include fecal streptococcus, fecal coliforms, oil and grease and VOCs which should be collected manually, not automatically, as discussed in Section 3.1.2.

3.4 FLOW-WEIGHTED COMPOSITE SAMPLE COLLECTION

Composite samples are samples simply comprised of a series of individual sample aliquots that have been combined to reflect average pollutant concentrations of the storm water discharge during the

VOL 12

4692

sampling period. Composite samples can be developed based on time or flow rate. There are four different types of composite samples, as follows:

- Constant Time - Constant Volume - Samples of equal volume are taken at equal increments of time and composited to make an average sample (similar to Exhibit 3-18). This method is not acceptable for samples taken for compliance with the storm water permit application regulations.

- Constant Time - Volume Proportional to Flow Increment - Samples are taken at equal increments of time and are composited proportional to the volume of flow since the last sample was taken (see Exhibit 3-19).

- Constant Time - Volume Proportional to Flow Rate - Samples are taken at equal increments of time and are composited proportional to the flow rate at the time each sample was taken (see Exhibit 3-20).

- Constant Volume - Time Proportional to Flow Volume Increment - Samples of equal volume are taken at equal increments of flow volume and composited (see Exhibit 3-21).

Generally, flow-weighted composite samples must be collected for most parameters. The methods for generating flow-weighted composite samples are discussed in the following sections.

For storm water discharge permit applications, the aliquots for flow-weighted composite samples must be collected during a representative storm for the first 3 hours, or for the duration of the storm event if it is less than 3 hours long. The storm water application regulations allow for flow-weighted composite samples to be collected manually or automatically. For both methods, equal volume aliquots may be collected at the time of sampling and then flow-proportioned and composited in the laboratory, or the aliquot may be collected based on the flow rate at the time of sample collection and composited in the field. When composite samples are collected, the regulations require that each aliquot collection be separated by a minimum of 15 minutes and that a minimum of three sample aliquots be taken within each hour of the discharge. See Exhibit 3-22 for an example of how this requirement may be fulfilled.

The provisions set forth in 40 CFR 122.21(g)(7) for collecting flow-weighted composite samples establish specific requirements for minimum time duration between sample aliquots. Where these conditions cannot be met, the permitting authority may allow alternate protocols with respect to the time duration between sample aliquots (see Chapter 5). However, permission from the permitting

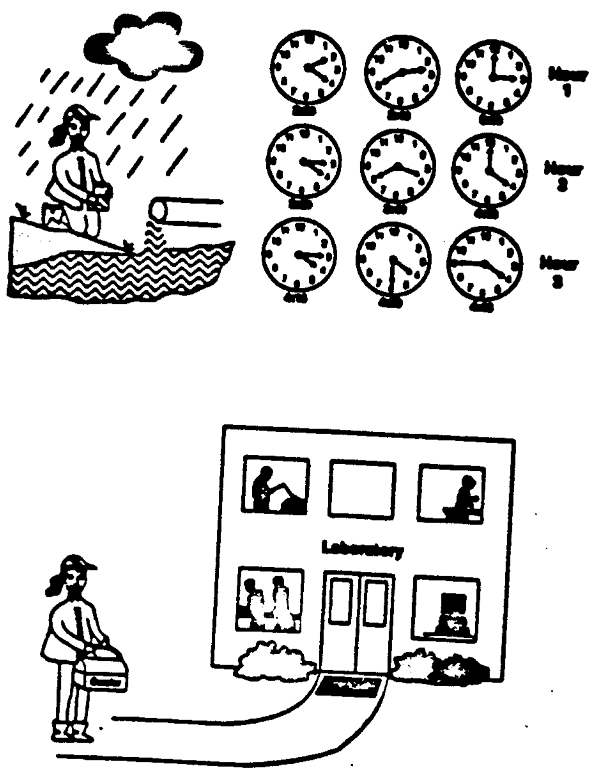
EXHIBIT 3-23 EXAMPLE OF SAMPLING INTERVALS

Suppose that a storm water discharge began at 2:15 p.m. and lasted until 5:15 p.m. on a Friday. The field staff person wants to collect the samples at regular intervals, so s/he plans to collect an aliquot with a volume that is proportional to the flow every 20 minutes. After the third hour of collection, the field staff person must deliver the samples to the laboratory (which is 10 minutes away). The laboratory closes at 5:00 p.m. So, s/he should take the last sample at 4:45 p.m. One way of doing this would be to collect samples (in hour three) at 4:15, 4:30, and 4:45 p.m. This would comply with the three-sample minimum in hour three (4:15-5:15 p.m.) and the required 15-minute minimum interval between collections. It would also allow the field staff person to get the samples to the lab before it closes for the weekend. On the other hand, if s/he missed the sample collection at 4:15 p.m. and instead, collected the sample at 4:20 p.m., then s/he would have to collect the next sample at 4:35 p.m. and the last sample at 4:50 p.m., and the field staff person would not be able to deliver the sample until Monday (by which time the required maximum holding time would be exceeded), and the sampling would need to be repeated.



VOL 12

4696

authority must be obtained before changes are initiated. Considerations applicable to the collection of flow-weighted composites by automatic and manual techniques are discussed in the following sections.

3.4.1 HOW TO MANUALLY COLLECT FLOW-WEIGHTED COMPOSITE SAMPLES

Manually collected, flow-weighted composite samples may be appropriate for a facility that prefers not to invest in automatic equipment. This technique is cost-effective for short-term monitoring programs and for facilities where few outfalls are being sampled. The fundamental requirement for facilities that use these methodologies is that they should have personnel available to perform the sampling when needed. Those facilities where VOCs analysis of storm water discharges are required should manually collect composite samples since these parameters may not be amenable to sampling by automatic samplers. Compositing of VOC samples should be conducted in the laboratory as discussed in Section 3.5.2.

The manual collection of a flow-weighted sample is performed in the same manner as taking manual grab samples (see Section 3.3.1). The only difference is that a series of samples (or aliquots) will be collected. As discussed in the previous section, there are two ways to manually collect and combine the aliquots for a flow-weighted sample:

- Collect sample aliquot volumes based on the flow at the time of sampling which can immediately be combined to make the composite sample in the field (see Exhibit 3-23)
- Collect equal volume sample aliquots at the time of sampling and then flow-proportion and composite the aliquots in the laboratory (see Exhibit 3-24).

When uniform time intervals are used between the collection of the sample aliquots, the volumes of each aliquot used in the composite sample can be determined based on either volumes of flow or the flow rate, as they will result in similar proportions. However, when there are different time intervals between the sample aliquots, the individual sample aliquot volumes should be based on the runoff volume (calculated from the individual flow rates and durations) associated with each sample aliquot.

Generally, 1,000 ml for each aliquot collected should provide enough sample volume, when composited, for pollutant analyses of the required parameters contained in Section VII.A of Form 2F (see Section 3.6). More aliquot volume may be required if sampling is conducted for additional parameters. The laboratory conducting the analyses should always be contacted prior to a sampling event to determine how much sample volume they will require.

[illegible] SAMPLE ALIQUOT [illegible] FIELD

Step 1: Determine the necessary volume for compositing purposes.

Example: To fulfill analyses for all parameters in Section VII.A of Form 2F for which composite samples are required [Biochemical Oxygen Demand (BOD_5), Chemical Oxygen Demand (COD), Total Suspended Solids (TSS), Total Kjeldahl Nitrogen (TKN), nitrate plus nitrite, and phosphorous] a total composite sample volume of 5,000 ml is needed by the contract laboratory.

Step 2: Determine an appropriate interval for collection of samples.

Example: Manually collected flow-weighted composite samples must consist of at least three sample aliquots collected per hour and must be gathered at least 15 minutes apart. For this example, sample aliquots will be collected exactly 20 minutes apart.

Step 3: Estimate or measure the volume of discharge for each sampling event.

Example: A discharge flow volume of 4.8 cubic feet will be used here.

Step 4: Convert the discharge flow volume to liters.

Example: To convert cubic feet to liters, use the conversion factor of 28.32 liters per 1 cubic foot as set forth in the following formula:

$$\textit{Volume (liters)} = \textit{Volume (cubic feet)} \times \frac{28.32\ \textit{liters}}{1\ \textit{cubic foot}}$$

$$\textit{Volume} = 4.8\ \textit{cubic feet} \times \frac{28.32\ \textit{liters}}{1\ \textit{cubic foot}} = 136\ \textit{liters}$$

Step 5: Using Steps 3 and 4, volumes that have been discharged between the collection of each aliquot can be calculated.

(Note that the discharge volumes provided for aliquot numbers 2-9 have already been given for the purposes of this exhibit.)

Example: The procedures set forth in Section 3.2 may be used to calculate discharge volumes. The following table presents aliquot numbers, time of aliquot collection, and discharge volumes.

Aliquot Number	Time of Aliquot Collection	Discharged Volume
1	2:15 p.m.	136 liters
2	2:35 p.m.	200 liters
3	2:55 p.m.	122 liters
4	3:15 p.m.	178 liters
5	3:35 p.m.	156 liters
6	3:55 p.m.	117 liters
7	4:15 p.m.	94 liters
8	4:30 p.m.	21 liters
9	4:45 p.m.	12 liters

VOL 12

4698

EXHIBIT [illegible] EXAMPLE OF HOW TO COLLECT SAMPLE ALIQUOT VOLUMES BASED ON [illegible] PROPORTIONAL COMPOSITE IN THE FIELD (Continued)

Step 6: Determine the appropriate minimum aliquot volume as the basis for collecting other aliquot samples which together will provide adequate volume to fulfill the analytic requirements.
Example: In Step 1, it was determined that at least 5,000 ml of sample were required for flow-weighted composite sample analytical testing. As discussed in Section 3.4.1, basing the sample collection on a minimum aliquot volume of 1,000 ml gathered every interval (i.e., every 15 minutes) should result in adequate sample volume.

Step 7: Calculate the volume of the sample aliquot which must be collected during each aliquot sample period using the following formula:

$$\textit{Aliquot volume (ml)} = \textit{Minimum aliquot volume (ml)} \times \frac{\textit{Aliquot's discharge volume (liters)}}{\textit{Initial discharge volume (liters)}}$$

Step 6 shows that the minimum aliquot volume is 1,000 ml.

$$\textit{Aliquot \#1 volume (ml)} = 1{,}000 \text{ ml} \times \frac{136 \text{ liters}}{136 \text{ liters}} = 1{,}000 \text{ ml}$$

$$\textit{Aliquot \#2 volume (ml)} = 1{,}000 \text{ ml} \times \frac{200 \text{ liters}}{136 \text{ liters}} = 1471 \text{ ml}$$

$$\textit{Aliquot \#3 volume (ml)} = 1{,}000 \text{ ml} \times \frac{122 \text{ liters}}{136 \text{ liters}} = 897 \text{ ml}$$

$$\textit{Aliquot \#4 volume (ml)} = 1{,}000 \text{ ml} \times \frac{178 \text{ liters}}{136 \text{ liters}} = 1{,}309 \text{ ml}$$

$$\textit{Aliquot \#5 volume (ml)} = 1{,}000 \text{ ml} \times \frac{156 \text{ liters}}{136 \text{ liters}} = 1{,}147 \text{ ml}$$

$$\textit{Aliquot \#6 volume (ml)} = 1{,}000 \text{ ml} \times \frac{117 \text{ liters}}{136 \text{ liters}} = 860 \text{ ml}$$

$$\textit{Aliquot \#7 volume (ml)} = 1{,}000 \text{ ml} \times \frac{94 \text{ liters}}{136 \text{ liters}} = 691 \text{ ml}$$

$$\textit{Aliquot \#8 volume (ml)} = 1{,}000 \text{ ml} \times \frac{21 \text{ liters}}{136 \text{ liters}} = 154 \text{ ml}$$

$$\textit{Aliquot \#9 volume (ml)} = 1{,}000 \text{ ml} \times \frac{12 \text{ liters}}{136 \text{ liters}} = 88 \text{ ml}$$

A table of these calculations follows:

Aliquot Number	Discharged Volume	Aliquot Volume
1	136 liters	1,000 ml
2	200 liters	1,471 ml
3	122 liters	897 ml
4	178 liters	1,309 ml
5	156 liters	1,147 ml
6	117 liters	860 ml
7	94 liters	691 ml
8	21 liters	154 ml
9	12 liters	88 ml

In conclusion, a combination of the above sample aliquots result in a composite of 7,617 ml.

VOL 12

4699

R0038008

VOL 12

4700

[illegible] COMPOSITED IN THE LABORATORY

Step 1: Determine the necessary volume for compositing purposes.

Example: To fulfill analyses for all parameters in Section VII.A of Form 2F for which composite samples are required (BOD_5, COD, TSS, TKN, nitrate plus nitrite, and phosphorous) a total composite sample volume of 5,000 ml is needed by the contract laboratory.

Step 2: Determine an appropriate interval for collection of samples.

Example: Manually collected flow-weighted composite samples must consist of at least nine sample aliquots and must be gathered at least 15 minutes apart; only three or four samples per hour may be taken. For convenience, the minimum number of three is chosen. Sample aliquots will be collected every 20 minutes.

Step 3: Determine the aliquot which should be taken during each sampling event.

Example: At least 5,000 ml of sample is required for flow-weighted composite sample analytical testing. As discussed in Section 3.4.1, a minimum aliquot volume of 1,000 ml gathered every interval (i.e., every 15 minutes) should result in adequate sample volume to be used for later flow-weighted compositing.

Step 4: Estimate or measure the volume of discharge for each sampling event while collecting a discrete 1,000-ml aliquot, as discussed in Step 3, for later compositing.

Example: Section 3.2 discusses methods to calculate total discharge volumes. A discharge flow volume of 4.8 cubic feet will be used here.

Step 5: Convert the discharge flow volume to liters.

Example: To convert cubic feet to liters, use the conversion factor of 28.32 liters per 1 cubic foot as set forth in the following formula:

$$Volume\ (liters) = Volume\ (cubic\ feet) \times \frac{28.32\ liters}{1\ cubic\ foot}$$

$$Volume = 4.8\ cubic\ feet \times \frac{28.32\ liters}{1\ cubic\ foot} = 136\ liters$$

EXHIBIT [illegible] EXAMPLE OF HOW TO MANUALLY COLLECT [illegible] SAMPLE ALIQUOTS WHICH [illegible] AND COMPOSITED IN THE LABORATORY (Continued)

Step 6: Using Steps 3 and 4, calculate the volumes that have been discharged between the collection of each aliquot.

Example: The procedures set forth in Section 3.2 may be used to calculate discharge volumes. The following table presents aliquot numbers, time of aliquot collection, and discharge volumes (note that the discharge volumes provided for aliquot numbers 2-9 were chosen for purposes of this exhibit).

Aliquot Number	Time of Aliquot Collection	Discharged Volume
1	2:15 p.m.	136 liters
2	2:35 p.m.	200 liters
3	2:55 p.m.	122 liters
4	3:15 p.m.	178 liters
5	3:35 p.m.	156 liters
6	3:55 p.m.	117 liters
7	4:15 p.m.	94 liters
8	4:30 p.m.	21 liters
9	4:45 p.m.	12 liters

Step 7: Determine the aliquot sample which is associated with the greatest discharge volume.

Example: Aliquot number 2 was taken when the volume was 200 liters. This is the largest discharge volume.

Step 8: Calculate the volume of sample aliquot which must be used subsequent to the sample event to comprise a flow-weighted composite sample. The following formula should be used:

$$\text{Aliquot volume (ml)} = \text{Minimum aliquot volume (ml)} \times \frac{\text{Aliquot's discharge volume (liters)}}{\text{Largest discharge volume (liters)}}$$

Step 3 shows that the minimum aliquot volume is 1,000 ml. Using this value and the data determined as part of Steps 6 and 7, the following can be calculated:

$$\text{Aliquot \#1 volume (ml)} = 1{,}000 \text{ ml} \times \frac{136 \text{ liters}}{200 \text{ liters}} = 680 \text{ ml}$$

$$\text{Aliquot \#2 volume (ml)} = 1{,}000 \text{ ml} \times \frac{200 \text{ liters}}{200 \text{ liters}} = 1{,}000 \text{ ml}$$

$$\text{Aliquot \#3 volume (ml)} = 1{,}000 \text{ ml} \times \frac{122 \text{ liters}}{200 \text{ liters}} = 610 \text{ ml}$$

$$\text{Aliquot \#4 volume (ml)} = 1{,}000 \text{ ml} \times \frac{178 \text{ liters}}{200 \text{ liters}} = 890 \text{ ml}$$

$$\text{Aliquot \#5 volume (ml)} = 1{,}000 \text{ ml} \times \frac{156 \text{ liters}}{200 \text{ liters}} = 780 \text{ ml}$$

$$\text{Aliquot \#6 volume (ml)} = 1{,}000 \text{ ml} \times \frac{117 \text{ liters}}{200 \text{ liters}} = 585 \text{ ml}$$

VOL 12

4701

[illegible] COMPOSITED IN THE LABORATORY (Continued)

Aliquot #7 volume (ml) = 1,000 ml x 94 liters / 200 liters = 470 ml

Aliquot #8 volume (ml) = 1,000 ml x 21 liters / 200 liters = 105 ml

Aliquot #9 volume (ml) = 1,000 ml x 12 liters / 200 liters = 60 ml

A table of these calculations follows

Aliquot Number	Discharged Volume	Aliquot Volume
1	136 liters	680 ml
2	200 liters	1,000 ml
3	122 liters	610 ml
4	178 liters	890 ml
5	156 liters	780 ml
6	117 liters	585 ml
7	94 liters	470 ml
8	21 liters	105 ml
9	12 liters	60 ml

In conclusion, a combination of the above sample aliquots results in a composite sample of 5,100 ml.

Manually collected flow-weighted composite samples can also be prepared by collecting sample aliquots of equal volume where the collection times are related to the volume of discharge which has passed since the last sample aliquot collection. However, this method is subject to fluctuating flow rates and volumes which may dictate that samples be taken prior to the 15-minute interval required by the regulations. In that case, the alternative sampling protocol would have to be approved by the permitting authority.

3.4.2 HOW TO COLLECT FLOW-WEIGHTED COMPOSITE SAMPLES BY AUTOMATIC SAMPLER

The typical automatic sampler collects sample aliquots after a specific interval. These aliquots can be flow-weight composited by the automatic sampler; or by hand in the laboratory. The automatic sampler may be programmed in one of three ways: (1) to collect a sample at equal time intervals and varying aliquot volumes commensurate with the flow (either rate or volume) that has passed; (2) to collect equal volume aliquots at varying time intervals commensurate with the flow volume that has passed; or (3) to collect equal volume aliquots of sample at equal time intervals.

The first two methods automatically composite the sample but require that the sampler be connected to a flow meter such that the sampler determines either the flow rate or the amount of volume that passes. Since these methods automatically composite samples, one main sample container may be used to receive all aliquots. The third method automatically collects the sample aliquots but does not automatically flow-weight composite the sample. As such, discrete sample containers must be used, and manual flow-weighted compositing must be conducted after the aliquots are collected. Exhibits 3-23 and 3-24 in Section 3.4.1 describe the manual compositing procedures that should be followed.

Manufacturers' instructions for the use of an automatic sampler provide the best explanation of programming options and should be consulted for information on programming samplers for storm water collection. Some of the points regarding automatic samplers discussed in Section 3.3.2 should also be considered.

3.5 SAMPLE HANDLING AND PRESERVATION

Samples must be handled and preserved in accordance with 40 CFR Part 136. This section describes acceptable analytical methods, including requirements regarding sample holding times, containers, sizes, and preservation requirements. For each pollutant or parameter that may have to be analyzed, 40 CFR Part 136 includes information on:

- Container types to be used to store the samples after collection
- Procedures to correctly preserve the samples
- The maximum holding time allowed for each parameter.

The following sections present a detailed discussion of preservation techniques and sample handling procedures. Technical Appendix C presents a matrix of required containers, preservation techniques,

VOL 12 4703

and holding times for each parameter. Most laboratories can provide clean sample containers, preservatives, sealing, chain-of-custody forms and can advise further on sample handling and preservation.

3.5.1 DECONTAMINATION OF SAMPLE EQUIPMENT CONTAINERS

Storm water sample containers should be cleaned and prepared for field use according to the procedures set forth in 40 CFR Part 136. A summary of the procedures is presented below for plastic containers, any or all of which may be performed by the laboratory or container distributor:

- Nonphosphate detergent and tap water wash
- Tap water rinse
- 10 percent nitric acid rinse (only if the sample is to be analyzed for metals)
- Distilled/deionized water rinse
- Total air dry.

To clean glass containers, the same steps should be taken; but, after the distilled/deionized water rinse, the containers should be rinsed with solvent if appropriate prior to total air drying. After the decontamination procedures have been accomplished, the sample containers should be capped or sealed with foil, and the sampling device should be protected and kept clean. It is a good idea to label sample containers after cleaning. The laboratory should keep a record of the technician performing the cleaning procedure as well as the date and time. This begins the required chain-of-custody procedure for legal custody (see Section 3.10 for more information). A chain-of-custody record accompanies each sample to track all personnel handling the sample. This record is essential to trace the sample integrity in the event that quality control checks reveal problems. For this reason, as well as to avoid problems if contamination issues arise, it is suggested that the laboratory performing the analysis perform the cleaning.

3.5.2 SAMPLE PRESERVATION AND HOLDING TIMES

Preservation techniques ensure that the sample remains representative of the storm water discharge at the time of collection. Since many pollutants in the samples collected are unstable (at least to some extent), the sample should be analyzed immediately or preserved or fixed to minimize changes between the time of collection and analysis. Because immediate analysis is not always possible, most samples are preserved regardless of the time of analysis.

Problems may be encountered when flow-weighted composite samples are collected. Since sample deterioration can take place during the compositing process, it is necessary to preserve or stabilize the samples during compositing in addition to preserving aggregate samples before shipment to the laboratory. Preservation techniques vary depending on the pollutant parameter to be measured; therefore, familiarity with 40 CFR Part 136 (see Technical Appendix C) is essential to ensure effective preservation. It is important to verify that the preservation techniques for one parameter do not affect the analytical results of another in the same sample. If this is the case, two discrete samples should be collected and preserved accordingly.

Sample preservation techniques consist of refrigeration, pH adjustment, and chemical fixation. pH adjustment is necessary to stabilize the target analyte (e.g., addition of NaOH stabilizes cyanide); acidification of total metal samples ensures that metal salts do not precipitate. Refrigeration is the most widely used technique because it has no detrimental effect on the sample composition (i.e., it does not alter the chemistry of the sample), and it does not interfere with most analytical methods. Refrigeration requires the sample to be quickly chilled to a temperature of 4°C. This technique is used at the beginning of sample collection in the field, and is continued during sample shipment, and while the sample is in the laboratory. Even though samples taken for compositing purposes are taken over time each individual sample must be refrigerated. If taken manually, the samples can be placed in an ice box. If taken by a automatic sampler, the sampler unit should have refrigeration capabilities. The analytical laboratory may provide chemicals necessary for fixation, or may tell sampling personnel where they can be purchased.

In addition to preservation techniques, 40 CFR Part 136 indicates maximum holding times. A detailed list of holding times appears in Technical Appendix C. The holding time is the maximum amount of time that samples may be held before analysis and still be considered valid. Samples exceeding these holding times are considered suspect and sample collection may have to be repeated.

Although Technical Appendix C provides required sample containers, preservation techniques, and holding times, some of the more commonly monitored parameters warrant additional discussion. The following provides a more detailed discussion of considerations pertaining to cyanide, VOCs, organics and pesticides, O&G, pH, total residual chlorine, fecal coliform, fecal streptococcus, and 5-day Biochemical Oxygen Demand (BOD_5).

Cyanide

Cyanide is very reactive and unstable. If the sample cannot be analyzed immediately, it must be preserved by pH adjustment after collection. However, prior to pH adjustment, procedures to eliminate residual chlorine and sulfides must be followed immediately.

Where chlorine has the possibility of being present, the sample should be tested for residual chlorine by using potassium iodide-starch test paper previously moistened with acetate buffer. If the sample contains residual chlorine (a blue color indicates the need for treatment), ascorbic acid must be added 0.6 gram (g) at a time until the tests produce a negative result; then, an additional 0.6 g of ascorbic acid should be added to the sample.

Samples containing sulfides may be removed, in which case the holding time is extended to 14 days. Sulfides must be removed as follows:

- Use lead acetate paper moistened with an acetic acid buffer solution to test for the presence of sulfide. Darkening of the lead acetate paper indicates sulfide is present in the sample.
- Add cadmium nitrate to be added to the sample in a manner similar to the ascorbic acid until the test is negative.
- Filter with a 0.45 micrometer (μm) filter and prefilter combination immediately after.

After chlorine and sulfide residuals have been eliminated, the pH must be adjusted to greater than 12.0 standard units (s.u.) and chilled to 4°C.

VOL 12

4706

VOL 12

If cyanide is suspected to be present, the sampling personnel should bring all materials mentioned above to the sampling location.

VOCs

Sampling for VOCs requires the use of a glass vial. The vial should contain a teflon-coated septum seal. Volatiles will escape from the water to the air if any air is entrapped in the container. Therefore, the sample should be collected so that there are no air bubbles in the container after the screw cap and septum seal are applied. To ensure that air bubbles are not trapped in the vial, the following procedures should be followed:

- Fill the vial until a reverse meniscus forms above the top of the vial
- Screw on the cap (the excess sample will overflow)
- Invert the vial to check for the presence of air bubbles
- If air bubbles are observed, the vial should be opened, emptied, then completely refilled, and the first three actions should be repeated.

4707

VOC samples should not be composited in the field. To composite a sample, the sampling personnel would have to mix it thoroughly. This mixing action would aerate the sample and cause volatiles to be lost. Therefore, VOC samples should be sent to the laboratory where they can be immediately, and carefully, composited and analyzed with minimal volatilization as per method Nos. 502.1, 502.2, 524.1, and 524.2 as described at 40 CFR 141.24(f)(14)(iv) and (v). There are two ways flow-weighted compositing of VOCs can be accomplished—mathematical compositing or procedural compositing as discussed below.

Mathematical Compositing

In this method, the grab samples are analyzed separately. The sampling personnel collect the requisite number of samples and send them to the laboratory. The laboratory performs the individual analyses on each sample. Five ml (or 25 ml if greater sensitivity is required) of each grab sample are placed into the purge vessel of the GC or GC/MS for analysis. Special precautions must be made to maintain zero headspace in the syringe used to transfer the VOC sample into the purge vessel of the GC or GC/MS. These analytical results are mathematically flow-weight composited using the calculation in Exhibit 3-24. The concentrations (C) should be adjusted by using the following formula:

$$\textit{Adjusted Concentration} = \frac{\textit{Individual Aliquot Volume}}{\textit{Total Composite Sample}} \times C$$

Each sample concentration should be adjusted, and all adjusted concentrations added, to obtain the flow-weighted VOC composite using this method.

Procedural Compositing

For the second method, sampling personnel collect the requisite number of samples and provide the laboratory with flow-weighted values for each sample using the calculation in Exhibit 3-24. The laboratory technician then draws the necessary volume from each aliquot into an adequately sized syringe, physically combining the samples to result in a flow-weighted composite sample for VOC analysis. Necessary volumes are drawn into the syringe with a volume control fitting. The samples are thus composited directly in the syringe and then placed in the purge vessel of the GC or GC/MS. The advantage of this procedure is that only one analysis on the GC or GC/MS has to be performed.

Although the applicant is required to report only flow-weighted composite concentrations, the mathematical compositing method may provide more information, as it will indicate the concentrations of each separate grab sample. For example, if the procedural compositing method is employed and one of the samples has a high concentration and the other three have non-detectable concentrations, the result will be an average which does not represent the concentration in any of the separate grab samples. In certain cases it may be important to know the concentration of each grab as well as the composite concentration. The mathematical compositing method would be the most appropriate compositing method in these cases.

Organics and Pesticides

The procedures affecting organics and pesticides [base/neutral/acids and pesticide polychlorinated biphenyls (PCBs)] are less complex than VOC procedures. Glass containers must be used for sample collection purposes, amber glass should be used to eliminate the potential for reactivity caused by light. These samples should be maintained at 4°C during storage and shipment. A preservative in

VOL 12

4708

the form of 0.008 percent sodium thiosulfate ($Na_2S_2O_3$) must be added to organic samples if residual chlorine is present. To determine if chlorine is present, a small color indicator test kit can be used. Eighty ml of $Na_2S_2O_3$ per liter of sample must then be added and mixed well until chlorine tests indicate a negative result as per methods 604 and 625 of 40 CFR Part 136 Appendix A. The pH of pesticide samples must be adjusted to between 5 and 9 s.u.

Oil and Grease

O&G tends to adhere to the surfaces that it contacts. Therefore, it should not be transferred from one container to another; rather, a 1-liter container should be used to take the sample. The container used for O&G must be made of glass. A teflon insert should be included in the glass container's lid. However, if teflon is not available, aluminum foil extending out from under the lid may be used. Samples for O&G must be preserved by adding sulfuric acid (H_2SO_4) or hydrochloric acid (HCl) to a pH of less than 2 s.u. and then stored at 4°C.

Additional Considerations

Some pollutants have specific analysis requirements due to short holding times that the applicant must consider. For example:

- Requirements to analyze immediately (pH, total residual chlorine, temperature, sulfite, and dissolved oxygen)
- Requirements to preserve immediately and analyze within 6 hours (fecal coliform and fecal streptococcus)
- Requirements to analyze within 48 hours (BOD_5).

Because of these requirements, field testing equipment may need to be purchased, borrowed, or rented for those parameters that may require field analysis. If the laboratory is located nearby, analysis in the field may not be required.

Laboratories do not always operate in the evenings or on weekends. As a result, holding times for samples taken in the late afternoon or on a Friday may be exceeded. To prevent this from occurring, close coordination with laboratories is necessary. The latest date and time of delivery should be established to avoid taking samples, only to discover they cannot be accepted by the laboratory and analyzed in accordance with 40 CFR Part 136 requirements.

3.6 SAMPLE VOLUMES

Exhibit 3-25 presents minimal suggested sample volumes for specific parameters. This exhibit should be consulted so that the proper volume is collected for analysis of each pollutant of concern. This exhibit may not include all parameters; if a particular parameter is not listed, refer to 40 CFR Part 136.

3.7 SAMPLE DOCUMENTATION

Information should be submitted to the laboratory with the sample to ensure proper handling by the laboratory. Exhibit 3-26 is an example form which can be used to document the following information.

- Unique Sample or Log Number - All samples should be assigned a unique identification number. If there is a serial number on the transportation case, the sampling personnel should add this number to the field records.
- Date and Time of Sample Collection - Date and time of sample collection (including notation of a.m. or p.m.) must be recorded. In the case of composite samples, the sequence of times and aliquot size should be noted.
- Source of Sample, Including Facility Name and Address - Use the outfall identification number from the site map with a narrative description; a diagram referring to the particular site where the sample was taken should be included.
- Name of Sampling Personnel - The names and initials of the persons taking the sample must be indicated. For a composite sample, the names of the persons installing the sampler and the names of the persons retrieving the sample should be included.
- Sample Type - Each sample should indicate whether it is a grab or composite sample. If the sample is a composite, the volume and frequency of individual aliquots should be noted.
- Preservation Used - Any preservatives (and the amount) added to the sample should be recorded. The method of preservation (e.g., refrigeration at 4°C) should be indicated.
- Analysis Required - All parameters for which the sample must be analyzed at the laboratory should be specified.

3.8 SAMPLE IDENTIFICATION AND LABELING

Prior to collection of the sample, a waterproof, gummed sample identification label or tag should be attached to the sample container. This label should contain relevant information for sample analysis, such as:

- Facility name
- Name of the sample collector
- Sample identification number
- Date and time of sample collection
- Type of analysis required
- Location of sample collection
- Preservatives used
- Type of sample (grab or composite).

Sample lids should be used to protect the sample's integrity from the time it is collected to the time it is opened in the laboratory. The lid should contain the collector's name, the date and time the sample was collected, and a sample identification number. Information on the seal must be identical to the information on the label. In addition, the lid should be taped shut so that the seal must be broken to open the sample container. Caution should be taken to ensure that glue from tape and label tag wires do not contaminate samples, particularly those containing volatile organics and metals. Also, waterproof ink should be used to avoid smearing on the label from melted ice used for cooling.

4715

3.9 SAMPLE PACKAGING AND SHIPPING

If the samples are not hand-delivered to the laboratory or analyzed in an onsite laboratory, they should be placed in a transportation case (e.g., a cooler) along with the chain-of-custody record form, pertinent field records, and analysis request forms, and shipped to the laboratory. Glass bottles should be wrapped in foam rubber, plastic bubble wrap, or other material to prevent breakage during shipment. The wrapping can be secured around the bottle with tape. The container lid should also be sealed with tape. Samples should be placed in ice or a synthetic ice substitute that will maintain the sample temperature at 4°C throughout shipment. Ice should be placed in double-wrapped watertight bags so the water will not leak from the shipping case. Metal or heavy plastic ice chests make good sample transportation cases. Filament tape wrapped around each end of the ice chest ensures that it will not open during transport. Sampling records (preferably laminated or waterproof) can be placed in a waterproof envelope and taped to the inside of the transportation case to avoid getting them wet in case a sample container or an ice bag leaks. Shipping containers should also be sealed to prevent tampering. A copy of all sampling records should be kept onsite in case they are requested by the permitting authority.

Most samples will not require any special transportation precautions except careful packaging to prevent breakage and/or spillage. If the sample is shipped by common carrier or sent through the U.S. mail, it must comply with Department of Transportation Hazardous Materials Regulations (49 CFR Parts 171-177). Air shipment of hazardous materials samples may also be covered by requirements of the International Air Transport Association (IATA). Before shipping a sample, the facility should be aware of, and follow, any special shipping requirements. Special packing and shipping rules apply to substances considered hazardous materials as defined by IATA rules. Storm water samples are not generally considered hazardous materials, but in the event of a spill, leakage, etc., at the collection site hazardous materials may be present in the samples. Be aware, before sampling, of what hazardous materials may be in the discharge drainage area. If the presence of hazardous materials is suspected, do not sample unless properly trained.

3.10 CHAIN-OF-CUSTODY PROCEDURES

Once samples have been obtained and collection procedures are properly documented, a written record of the chain of custody of that sample should be made. This is recommended so the applicant can be confident that the samples have not been tampered with and that the sample once analyzed is representative of the storm water discharge. "Chain-of-custody" refers to the documented account of changes in possession that occur for a particular sample or set of samples. The chain-of-custody record allows an accurate step-by-step recreation of the sampling path, from origin through analysis. Information necessary in chain-of-custody is:

- Name of the persons collecting the sample
- Sample ID numbers

VOL 12

476

- Date and time of sample collection
- Location of sample collection
- Names and signatures of all persons handling the samples in the field and in the laboratory.

To ensure that all necessary information is documented, a chain-of-custody form should be developed. An example of such a form is found in Exhibit 3-27. Chain-of-custody forms should be printed on carbonless, multipart paper so all personnel handling the sample receive a copy. All sample shipments should be accompanied by the chain-of-custody record and a copy of these forms should be retained by the originator. In addition, all receipts associated with the shipment should be retained. Carriers typically will not sign for samples; therefore, seals must be used to verify that tampering has not occurred during shipment.

When transferring possession of samples, the transferee should sign and record the date and time on the chain-of-custody record. In general, custody transfers are made for each sample, although samples may be transferred as a group. Each person who takes custody should fill in the appropriate section of the chain-of-custody record.

4. ANALYTICAL CONSIDERATIONS

All storm water discharges must be sampled and analyzed in accordance with the test procedures provided in 40 CFR Part 136. This section discusses pollutant parameters which must be analyzed by storm water permit applicants. If the applicant wants to use an alternative test method, the facility must apply for approval (by submitting a description of the method to the permitting authority for approval) prior to application submission [see 40 CFR 136.4(d)(3)]. Section 5.4 elaborates on how to obtain approval for an analytical method for a parameter that is not included in 40 CFR Part 136. EPA-approved analytical methods at 40 CFR 136.3, Tables IB and IC are shown in Appendix C of this document.

When choosing the appropriate 40 CFR Part 136 analytical method, the applicant should consider sample interferences and potential field sampling error. Most method detection levels are established under ideal sample conditions (e.g., with little or no sample matrix interferences or sampling error). Thus, for storm water samples, the method chosen should account for sampling error and interferences.

4.1 INDUSTRIAL REQUIREMENTS

Industrial dischargers must provide information on the following parameters, as required in 40 CFR 122.26(c)(1)(I)(E):

4719

- Any pollutant limited in an effluent guideline to which the facility is subject
- Any pollutant listed in the facility's NPDES permit for its process wastewater (if the facility has an existing NPDES permit)
- O&G, pH, BOD_5, COD, TSS, total phosphorus, TKN, and nitrate plus nitrite nitrogen
- Any pollutant known or believed to be present [as required in 40 CFR 122.21(g)(7)]
- Flow measurements or estimates of the flow rate, the total amount of discharge for the storm events sampled, and the method of flow measurement or estimation
- The date and duration (in hours) of the storm events sampled, rainfall measurements or estimates of the storm event (in inches) which generated the sampled runoff, and the time between the storm event sampled and the end of the previous measurable (greater than 0.1 inch rainfall) storm event (in hours).

4.1.1 INDIVIDUAL APPLICANTS

Industrial facilities submitting an individual permit application must provide sampling data in three parts of the Form 2F application form as discussed below. (Form 2F restates requirements listed in 40 CFR 122.21 and 122.26).

Section VII.A Parameters

Section VII.A of Form 2F requires the facility to sample (grab and flow-weighted samples) for O&G, BOD_5, COD, TSS, TKN, nitrate plus nitrite nitrogen, total phosphorus, and pH. These parameters are to be monitored by every facility applying for a storm water discharge permit, regardless of the type of operations that exist at the site. Sampling for additional parameters may be required, depending on the type of facility applying for the permit or the pollutants expected to be present in the discharge. These additional requirements are discussed in detail below.

Section VII.B Parameters

Section VII-B of Form 2F requires the applicant to identify all pollutants that are limited in an effluent guideline to which the facility is subject, as well as other toxic and nonconventional pollutants listed in the facility's NPDES permit for its process wastewater. EPA interprets that for pollutants listed in NPDES process wastewater permits, at a minimum, facilities must sample their storm water discharge for those pollutants specifically limited in their process wastewater permit. States can be more stringent, however, and may interpret this requirement to mean all pollutants listed in the permit. Once these parameters are identified, the applicant will be required to sample for these parameters by both grab and flow-weighted composite samples, except for the specified pollutants which must be grab sampled only. Form 2F requires the applicant to submit maximum values. The average values column is not compulsory, but should be completed if data are available. Applicable effluent guidelines appear in 40 CFR Parts 405-471. A listing of the Subchapter N—Effluent Guidelines and Standards by which the applicant may be regulated appears in Exhibit 4-1. The applicant must refer to the effluent guidelines and standards for the particular industry, and should determine which guidelines apply and which parameters should be listed in Section VII.B of Form 2F.

VOL 12

Section VII.C Parameters

Section VII.C requires the applicant to list, for each outfall, each pollutant described in 40 CFR Part 122, Appendix D, Tables II, III, IV, and V (Tables 2F-2, 2F-3, and 2F-4 of application Form 2F) that it knows, or has reason to believe, may be present in the storm water discharge. These pollutants consist of conventional and nonconventional pollutants, toxic pollutants and total phenol, Gas Chromatography/Mass Spectrometry (GC/MS) fraction volatile compounds, acid compounds, base/neutral compounds, pesticides, and hazardous substances. These tables are also provided on the back of Form 2F. Tables II and III of 40 CFR Part 122 Appendix D have been combined in Table 2F-3 of application Form 2F. Table IV of 40 CFR Part 122 Appendix D is listed as Table 2F-2 of application Form 2F and Table V of 40 CFR Part 122 Appendix D is listed as Table 2F-4 of application Form 2F. There are specific requirements associated with each table. If pollutants in Table IV of 40 CFR Part 122 Appendix D (Table 2F-2 of application Form 2F), are directly or indirectly limited by an effluent guideline limitation, the applicant must analyze for it and report the data. For other pollutants listed in Table IV of 40 CFR Part 122 Appendix D (Table 2F-2 of the application form), the applicant must either report quantitative data, if available, or briefly describe the reasons the pollutant is expected to be in the discharge.

For every pollutant in Tables II and III of 40 CFR Part 122 Appendix D (Table 2F-3 of application Form 2F) expected to be discharged in concentrations of 10 parts per billion (ppb) or greater, the applicant must submit quantitative data. For acrolein, acrylonitrile, 2,4-dinitrophenol, and 2-methyl-4,6-dinitrophenol, the applicant must submit quantitative data if any of these four pollutants is expected to be discharged in concentrations of 100 ppb or greater. For every pollutant expected to be discharged with a concentration less than 10 ppb (or 100 ppb for the four parameters mentioned above), the applicant must either submit quantitative data or briefly explain why the pollutant is expected to be discharged.

For the parameters identified in Table V of 40 CFR Part 122 Appendix D (Table 2F-4 of application Form 2F) that the applicant believes to be present in the discharge, no sampling is required. If previous analyses of these parameters were conducted, the results must be reported. Otherwise, the applicant is required to explain why these pollutants are believed to be present.

4722

VOL 12

Small Business Exemption

Small businesses are exempted from the reporting requirements for the organic toxic pollutants presented in 40 CFR Part 122, Table II of Appendix D. Applicants can claim a small business exemption if:

- The facility is a coal mine and the probable annual production is less than 100,000 tons per year. The applicant may submit past production data or estimate future production data instead of conducting analyses for the organic toxic pollutants listed in Table 2F-3 of application Form 2F.
- The facility is not a coal mine, and the gross total annual sales for the most recent 3 years is, on average, less than $100,000 per year (reflected in second quarter 1980 dollars). The applicant may submit sales data for those years instead of conducting analyses for the organic toxic pollutants listed in Table 2F-3 of application Form 2F.

4723

Section VIII

Section VIII of Form 2F requires the applicant to provide biological toxicity testing data for storm water discharges associated with industrial activity. Applicants are required to perform biological toxicity testing for the storm water application if the facility's NPDES permit for its process wastewater lists biological toxicity (EPA interprets "listed" as limited). For example, if a facility's NPDES process wastewater permit has an acute toxicity limit of a lethal concentration (LC_{50}), equal to 75 percent effluent using ceriodaphnia, then that facility must also test its storm water discharges associated with industrial activity and report the results of the tests in Section VIII of Form 2F.

Until whole effluent toxicity methods are promulgated by EPA in 40 CFR Part 136, toxicity testing should be conducted using the most appropriate methods and species as determined by the permitting authority. In the absence of State acute toxicity testing protocols, EPA recommends using the methods described in Methods for Measuring the Acute Toxicity of Effluents and Receiving Waters to Fresh Water and Marine Organisms. EPA/600/4-90-027 (Rev. September 1991)

4.1.2 GROUP APPLICANTS

Industrial facilities submitting a group application must also provide sampling data (from the sampling subgroup) which is required to be submitted in Sections VII, VIII, and IX along with the certification in Section X of Form 2F. At a minimum, these parameters include O&G, BOD_5, COD, TSS, TKN, nitrate plus nitrite nitrogen, total phosphorous, and pH. Furthermore, all pollutants listed in an effluent guideline or limited in an NPDES permit applicable to the sampling facilities within the group must be sampled, as well as pollutants suspected of being present based on significant materials and industrial activities present onsite.

4.2 MUNICIPAL REQUIREMENTS

For Part 1 of the municipal permit application, municipalities must submit samples from the field screening effort for pH, total chlorine, total copper, phenol, and detergents (or surfactants). A narrative description of the color, odor, turbidity, and presence of oil sheen and surface scum must be included. For Part 2 of the permit application, municipalities must provide quantitative data for the organic pollutants listed in Table II of 40 CFR Part 122 Appendix D, and the pollutants listed in 40 CFR Part 122, Appendix D, Table III, as well as some additional pollutants. These pollutants are listed in Exhibit 4-2.

Furthermore, 40 CFR 122.26(d)(2)(iii)(A)(5) requires that estimates be provided of the annual pollutant load of the cumulative discharges to waters of the U.S. from all identified municipal outfalls, and the event mean concentration of the cumulative discharges to waters of the U.S. from all identified municipal outfalls during storm events for the parameters listed in Exhibit 4-2. Estimates of the parameters must be accompanied by a description of the procedures for estimating constituent loads and concentrations, including any modelling, data analysis, and calculation methods.

4726

5. FLEXIBILITY IN SAMPLING

The requirements for storm water sampling for permit applications offer some flexibility by the permitting authority. The areas of flexibility are discussed below.

5.1 PROTOCOL MODIFICATIONS

The permitting authority may allow sampling protocol modifications for specific requirements on a case-by-case basis. For example, the permitting authority may accept application forms with incomplete sampling data if there was no rainfall at the applicant's facility prior to the submission deadline. However, the permitting authority will require that sampling data be submitted as soon as possible. The reason for not submitting data must be certified by a corporate official (for industrial facilities) or the principal executive officer or ranking official (for municipalities).

Another area where permitting authorities may allow flexibility in storm water sampling is acceptance of quantitative data from a storm event that does not meet the representative rainfall criteria of within 50 percent of the volume and duration for the average storm event for the area. The permitting authority may decide that the discharge data provided is better than no data at all.

In addition, the permitting authority may establish appropriate site-specific sampling procedures or requirements, including sampling locations; the season in which the sampling takes place; the minimum duration between the previous measurable storm event and the storm event sampled; the minimum or maximum level of precipitation required for an appropriate storm event; the form of precipitation sampled (snow melt or rainfall); protocols for collecting samples under 40 CFR Part 136; and additional time for submitting data on a case-by-case basis. The permitting authority should be contacted for preapproval of any necessary protocol modifications. In the case of group applications, EPA Headquarters should be contacted.

5.2 PETITION FOR SUBSTITUTING SUBSTANTIALLY IDENTICAL EFFLUENTS

As described at 40 CFR 122.21(g)(7), when an industrial applicant has two or more outfalls with substantially identical effluents, the permitting authority may allow the applicant to test only one outfall and to report that the quantitative data also apply to the substantially identical outfalls. In the case of group applications, the petition must be submitted to EPA Headquarters.

For facilities seeking to demonstrate that storm water outfalls are substantially identical, a variety of methods can be used as determined by the permitting authority. Three possible petition options are discussed here: (1) submission of a narrative description and a site map; (2) submission of matrices; or (3) submission of model matrices. Detailed guidance on each of the three options for demonstrating substantially identical outfalls is provided below. An owner/operator certification should be submitted with each option. See Section 5.2.3 for an example of this certification.

5.2.1 OPTION ONE: NARRATIVE DESCRIPTION/SITE MAP

Facilities demonstrating that storm water outfalls are substantially identical may submit a narrative description of the facility and a site map to the permitting authority . The narrative portion must include a description of why the outfalls are substantially identical. Petitioners may demonstrate that these outfalls contain storm water discharges associated with:

- Substantially identical industrial activities and processes;
- Substantially identical significant materials that may be exposed to storm water [including, but not limited to, raw materials, fuels, materials such as solvents, detergents, and plastic pellets; finished materials such as metallic products; raw materials used in food processing or production; hazardous substances designated under Section 101(14) of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA); any chemical the facility is required to report pursuant to Section 313 of Title III of the Superfund Amendments and Reauthorization Act (SARA); fertilizers; pesticides; and waste products such as ashes, slag, and sludge that have the potential to be released with storm water discharges as per 40 CFR 122.26(b)(12)];
- Substantially identical storm water management practices (such as retention ponds, enclosed areas, diversion dikes, gutters, and swales) and material management practices (such as protective coverings and secondary containment); and
- Substantially identical flows, as determined by the estimated runoff coefficient and approximate drainage area at each outfall.

The site map should include an indication of the facility's topography; each of the drainage and discharge structures; the drainage area of each storm water outfall; paved areas and buildings within the drainage area for each storm water outfall; all past or present areas used for outdoor storage or disposal of significant materials; identification of the significant materials in each drainage area; and identification of each existing structural control measures used to reduce pollutants in storm water

VOL 12

4728

R0038037

runoff, materials loading and access areas, and areas where pesticides, herbicides, soil conditioners, and fertilizers are applied.

Exhibit 5-1 offers an example of a narrative description/site map petition that sufficiently demonstrates identical outfalls. A demonstration of how to determine runoff coefficient estimates was presented in Section 3.2.2. Exhibit 5-2 presents an example of a site map to be included with the narrative description.

5.2.2 OPTION TWO: USE OF MATRICES TO INDICATE IDENTICAL OUTFALLS

Facilities attempting to demonstrate that storm water outfalls are substantially identical may submit matrices and an owner/operator certification describing specific information associated with each outfall to the permitting authority. Matrix information is required only for those outfalls that the permit applicant is attempting to demonstrate are identical, not for all outfalls. Petitioners must demonstrate, using the matrices, that the outfalls have storm water discharges that meet the criteria listed in Section 5.2.1. Refer to Exhibit 5-3 for examples of matrices that demonstrate substantially identical outfalls and Section 3.2.2 for guidance on determining runoff coefficient estimates.

5.2.3 OPTION THREE: MODEL MATRICES

Facilities attempting to demonstrate that storm water outfalls are substantially identical may submit model matrices and an owner/operator certification to the permitting authority. This option is particularly appropriate for facilities with a large number of storm water outfalls and the potential for numerous groupings of identical outfalls. In addition, this option may be useful in group applications that have a large sampling subgroup.

Model matrices should contain information for <u>one grouping of substantially identical outfalls</u>. For example, if a facility has 150 outfalls and several groupings of identical outfalls, the facility would <u>choose one</u> of the groupings of identical outfalls to provide information in the model matrices. The petitioner must demonstrate, using these matrices, that all outfalls within this grouping have storm water discharges that meet the criteria listed in Section 5.2.1.

The facility should provide an owner certification that all other groupings of outfalls have been examined and certified as substantially identical outfalls according to the criteria established in the

VOL 12

4729

R0038038

EXHIBIT [illegible] PETITION TO SAMPLE SUBSTANTIALLY IDENTICAL OUTFALLS (NARRATIVE DESCRIPTION/SITE MAP)

Examples

I. The Pepper Company of Philadelphia, Pennsylvania, is primarily engaged in manufacturing paperboard, including paperboard coated on the paperboard machine (from wood pulp and other fiber pulp). This establishment is classified under SIC code 2631. Pursuant to the November 16, 1990, NPDES storm water permit application regulations, this facility is considered to be "engaging in industrial activity" for the purposes of storm water permit application requirements in 40 CFR 122.26(b)(14)(i) and (ii).

II. "When an applicant has two or more outfalls with substantially identical effluents, the Director may allow the applicant to test only one outfall and report that the quantitative data also apply to the substantially identical outfalls." [40 CFR 122.21(g)(7)]

In accordance with 40 CFR 122.21(g)(7) of the NPDES regulations, The Pepper Company hereby petitions the State of Pennsylvania (the permitting authority) for approval to sample certain representative storm water outfalls in groupings of storm water outfalls that are substantially identical. The Pepper Company will demonstrate that of the ten (10) outfalls discharging storm water from our paperboard manufacturing plant, there are two pairs of substantially identical outfalls. Outfalls 3 and 4 are substantially identical and should be grouped together. Outfalls 8 and 9 are substantially identical and should be grouped together. Outfalls 1, 2, 5, 6, 7, and 10 have distinct characteristics and, therefore, will not be grouped together with other outfalls for the purposes of storm water discharge sampling.

III. The Pepper Company will demonstrate that the substantially identical outfalls that have been grouped together contain storm water discharges associated with: (1) substantially identical industrial activities and processes that are occurring outdoors; (2) substantially identical significant materials (including raw materials, fuels, finished materials, waste products, and material handling equipment) that may be exposed to storm water; (3) substantially identical material management practices (such as runoff diversions, gutters and swales, protective coverings, and structural enclosures); and (4) substantially identical flows, as determined by the estimated runoff coefficient and approximate drainage area at each outfall.

VOL 12

4730

VOL 12

EXHIBIT ... PETITION TO SAMPLE SUBSTANTIALLY IDENTICAL OUTFALLS (NARRATIVE DESCRIPTION/SITE MAP) (Continued)

1. **Industrial Activities**

A. Description of Industrial Activities at the Pepper Company

The Pepper Company receives wastepaper in bales. This baled wastepaper is sent through a hydropulper and converted to pulp. The fiber material is concentrated, stored, and then drawn through refiners to the paper machines. Wires, plastics, and miscellaneous material are removed during the pulping.

Three systems are used to produce top liner, back paper, and filler. The highest quality fiber is used for the top liner, the medium quality is used for the back paper, and the poorest quality is used for the filler paper. Wireforming or conventional boxboard processes are employed to produce clay-coated boxboard, using a water-based clay-coating material. Additional materials may be used as binders. These are stored indoors and are not exposed to precipitation. Ammonia is used in the clay-coating process. Off-grade fiber and trim material are ground up and returned to the liquid process stream. Slime control agents, consisting of bactericides, are used in association with this process. These agents are organic materials used to prevent souring of mill operations. They are received in drums and stored indoors. Empty drums are returned to the supplier to reuse. In addition, the Pepper Company operates an onsite landfill for the disposal of miscellaneous waste materials removed during pulping and paper cuttings operations.

B. Demonstration of Why Outfalls Are Substantially Identical in Terms of Industrial Activities Conducted Outdoors.

Outfalls 3 and 4

Outfalls 3 and 4 are substantially identical in terms of industrial activities conducted outdoors. Both outfalls contain storm water discharges associated with the outdoor storage of baled wastepaper. The wastepaper, which consists of old corrugated containers, mixed paper, and other types of wastepaper, is received weekly and stored for up to 3 weeks in Storage Areas #1 and #2. These uncovered storage areas are enclosed by chain-link fencing.

Outfalls 8 and 9

Outfalls 8 and 9 drain storm water runoff from areas where all industrial activities occur indoors. The industrial activities occurring under roof cover at these two outfalls include hydropulping, storage of concentrated fiber material, refining, and paperboard production. These industrial processes have no potential for contact with precipitation.

4731

EXHIBIT ... PETITION TO SAMPLE SUBSTANTIALLY IDENTICAL OUTFALLS (NARRATIVE DESCRIPTION/SITE MAP) (Continued)

2. Significant Materials

A. Description of Significant Materials at the Pepper Company

The significant materials listed below are used by the Pepper Company to manufacture paperboard. These materials are stored indoors, unless otherwise indicated.

(i) Raw materials, including baled wastepaper (off-spec damaged paper stock or recycled paper) [wastepaper is stored outdoors at Storage Areas #1 and #2]; clays, ammonias, sizings, and slime control agents (chlorine dioxide); caustic; ammonia, which is stored in two tanks. [See Storage Area #3].

(ii) Waste Materials, including miscellaneous materials removed during pulping and paper cuttings (such as staples, rubber bands, styrofoam, etc.). These waste materials are stored indoors in open dumpsters. However, prior to disposing of the waste in the onsite landfill, these dumpsters are moved outdoors where they are potentially exposed to precipitation for 12 hours or less. [See Storage Area #3].

(iii) Finished Products, including paperboard and molded fiber products. These are always stored indoors.

(iv) Others, including wood pallets (which are used to transport and haul raw materials, waste materials, and finished products) are stored both indoors and outdoors. [See Storage Area #3]. The Pepper Company has an above-ground fuel tank with a pump. [See Storage Area #3].

B. Demonstration of Why Outfalls are Substantially Identical in Terms of Significant Materials that Potentially May be Exposed to Storm Water

Outfalls 3 and 4

Outfalls 3 and 4 are substantially identical in terms of significant materials that may be exposed to storm water. Both outfalls contain storm water discharges associated with the outdoor storage of baled wastepaper. The wastepaper, which consists of old corrugated containers, mixed paper, and other types of wastepaper, is received weekly and stored for up to 3 weeks in Storage Areas #1 and #2. These uncovered storage areas are enclosed by chain-link fencing.

Outfalls 8 and 9

Outfalls 8 and 9 are substantially identical in terms of significant materials. Both outfalls contain storm water runoff from areas that have no significant materials potentially exposed to storm water. All industrial activities occurring in the areas drained by Outfalls 8 and 9 occur completely indoors.

VOL 12

4732

R0038041

EXHIBIT [illegible] PETITION TO SAMPLE SUBSTANTIALLY IDENTICAL OUTFALLS (NARRATIVE DESCRIPTION/SITE MAP) (Continued)

3. Material Management Practices

A. Description of Material Management Practices at the Pepper Company

The Pepper Company uses a wide range of storm water management practices and material management practices to limit the contact of significant materials with precipitation. Non-structural storm water management practices include employee training, spill reporting and clean-up, and spill prevention techniques. Structural storm water management practices include:

(I) Diversion Devices (both above-ground trenches and subterranean drains) are used to divert surface water from entering a potentially contaminated area.

(II) Gutters/Swales (constructed of concrete or grass) channel storm water runoff to drainage systems leading to separate storm sewers.

(iv) Overland Flow (which is the flow of storm water over vegetative areas prior to entrance into a storm water conveyance) allows much of the storm water to infiltrate into the ground. The remainder is naturally filtered prior to reaching the storm water conveyance. This is not considered sheet flow since natural drainage channels may be carved out during a heavy storm event.

B. Demonstration of Why Outfalls Are Substantially Identical in Terms of Storm Water Management Practices Used

Outfalls 3 and 4

Outfalls 3 and 4 are substantially identical in terms of storm water management practices used. Both outfalls contain storm water discharges associated with the outdoor storage of baled wastepaper, located in Storage Areas #1 and #2. Concrete gutters at both sites channel storm water away from the storage areas down to the respective outfalls.

Outfalls 8 and 9

Outfalls 8 and 9 are substantially identical in terms of storm water management practices used. Both outfalls contain storm water runoff from areas that have no significant materials potentially exposed to storm water. All industrial activities occurring in the areas drained by Outfalls 8 and 9 occur completely indoors. Both outfalls receive overland flow storm water. From roof drains, the storm water in both drainage areas is then conveyed over similarly graded vegetative areas prior to entrance into the respective outfalls.

VOL 12

4733

[illegible] SUBSTANTIALLY IDENTICAL [illegible] (NARRATIVE DESCRIPTION/SITE MAP) (Continued)

4. **Flow Characteristics**

   A. **Demonstration of Why Outfalls Are Substantially Identical in Terms of Flow, as Determined by The Estimated Runoff Coefficient and Approximate Drainage Area at Each Outfall**

<u>Outfalls 3 and 4</u>

Outfalls 3 and 4 are substantially identical in terms of flow. Both drainage areas have a 2 to 7 percent grade and contain fine textured soil (greater than 40 percent clay) with a vegetative cover. The estimated runoff coefficient for both outfalls is .2. The approximate drainage area for each outfall is similar. Outfall 3 has an approximate drainage area of 3,500 square feet. Outfall 4 has an approximate drainage area of 2,900 square feet.

<u>Outfalls 8 and 9</u>

Outfalls 8 and 9 are substantially identical in terms of flow. Both drainage areas have a 2 to 7 percent grade and contain fine textured soil (greater than 40 percent clay) with a vegetative cover. The estimated runoff coefficient for both outfalls is .2. The approximate drainage area for each outfall is similar. Outfall 8 has an approximate drainage area of 7,600 square feet. Outfall 9 has an approximate drainage area of 8,700 square feet.

model matrices described in Exhibit 5-3. The owner/operator who signs documents in this section should include the following certification:

> "I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations" [as per 40 CFR 122.22(d)].

5.3 ALTERNATE 40 CFR PART 136 METHOD

As required in 40 CFR 136.4, the applicant must request the approval of an alternate test procedure in writing (in triplicate) prior to testing. The request must be submitted to the Regional Administrator through the Director of the State agency responsible for issuing NPDES permits. The applicant must:

- Provide the name and address of the responsible person or firm making the discharge (if not the applicant), the applicable identification number of the existing or pending permit, the issuing agency, the type of permit for which the alternate test procedure is requested, and the discharge serial number;
- Identify the pollutant or parameter for which approval of an alternate testing procedure is being requested;
- Provide justification for using testing procedures other than those specified in 40 CFR Part 136;
- Provide a detailed description of the proposed alternate test procedure, together with references to published studies of the applicability of the alternate test procedure to the effluents in question;
- Provide comparability data (for applicants applying for nation wide approval of an alternative test procedures).

The permitting authority will notify the applicant within 90 days regarding the approval of the alternate method.

VOL 12

4738

5.4 LACK OF METHOD IN 40 CFR PART 136

If a specific pollutant that must be tested does not have a corresponding analytical method listed in 40 CFR Part 136, the applicant must submit information on an appropriate method to be used. The permitting authority must approve its use prior to collection and analysis of sampling data. The laboratory should be consulted for suggestions and information about analytical methods that can be used. All information justifying the alternative method should be sent to the permitting authority prior to use.

VOL 12

4739

VOL 12

4740

VOL 12

6. HEALTH AND SAFETY

Storm water sampling activities may occur when the sampling environment and/or storm water discharges create hazardous conditions. Hazardous conditions associated with sampling include:

- Hazardous weather conditions (e.g., wind, lightning, flooding, etc.)
- Sampling in confined spaces (e.g., manholes)
- Hazards associated with chemicals
- Biological hazards (e.g., rodents and snakes)
- Physical hazards (e.g., traffic, falling objects, sharp edges, slippery footing, and the potential for lifting injuries from opening or removing access panels and manhole covers, etc.)

It is essential that sampling personnel be aware of these hazards. Sampling personnel should be trained to evaluate potentially hazardous situations and develop ways for handling them. Since sampling hazards can be life threatening, safety must be the highest priority for all personnel. This chapter outlines general health and safety issues and concerns. Additional references discussed below should be consulted for more specific guidance to avoid adverse health and safety situations.

4741

6.1 GENERAL TRAINING REQUIREMENTS

Preparation and training of all sampling personnel should be completed before beginning any sampling task. Extreme care should be taken to allow for safety precautions including proper equipment and appropriate operational techniques, sufficient time to accomplish the task, training on potential hazards, and emergency procedures. EPA's Order 1440.2 sets out the policy, responsibilities, and mandatory requirements for the safety of personnel who are involved in sampling activities. This order, which is found within the EPA NPDES Compliance Monitoring Inspector Training: Sampling manual, provides further guidance to applicants' storm water sampling personnel. Basic emergency precautions include having access to both local emergency phone numbers and communication equipment (i.e., phones or radios), and ensuring that personnel are trained in first aid and carry first aid equipment.

6.2 NECESSARY SAFETY EQUIPMENT

Exhibit 6-1 contains a list of safety equipment that may be appropriate depending on the characteristics of the sampling site.

EXHIBIT 6-1 LIST OF SAFETY EQUIPMENT	
Flashlight	18-inch traffic cones
Meters (for oxygen, explosivity, toxic gases)	Insect/rodent repellant
Ladder	Ventilation equipment
Safety harness	50 feet of 1/2-inch nylon rope
Hard hat	Safety shoes
Safety goggles	Rain wear
Coveralls	Gloves (rubber)
Respirator	First aid kit
Reflective vests	Self-contained breathing apparatus
Source: Adapted from NPDES Compliance Monitoring Inspector Training: Sampling, U.S. EPA, August 1990.	

6.3 HAZARDOUS WEATHER CONDITIONS

Common sense should dictate whether sampling be conducted during adverse weather conditions. No sampling personnel should place themselves in danger during high winds, lightning storms, or flooding conditions which might be unsafe. Under extreme conditions, a less hazardous storm event should be sampled.

6.4 SAMPLING IN CONFINED SPACES

Confined spaces encountered by storm water sampling personnel typically include manholes and deep, unventilated ditches. A confined space is generally defined as a space that is somewhat enclosed with limited access and inadequate ventilation.

The National Institute of Occupational Safety and Health (NIOSH) has developed a manual entitled "Working in Confined Spaces" which should be consulted prior to confined space entry. Also, several States have developed specific procedures which should also be consulted. Unless they have been trained fot confined space entry, sampling personnel should avoid entry under all circumstances.

6.4.1 HAZARDOUS CONDITIONS IN CONFINED SPACES

Confined spaces pose a safety threat to sampling personnel because of low oxygen, explosivity, and toxic gases. When entering a confined space, a qualified person should ensure that the atmosphere is safe by sampling to test for oxygen levels, potential flammable hazards, and toxic materials known or suspected to be present. If atmospheric conditions are detected, the confined space should be ventilated or sampling personnel should use a self-contained air supply and wear a life line. At least one person should remain outside of the confined space in the event that problems arise. If atmospheric testing has not been properly conducted, the confined space should not be entered. Manholes can also pose a threat to safety because of the small confined area, slippery surfaces, sharp objects, unsafe ladders, etc.

6.4.2 SPECIAL TRAINING REQUIREMENTS

Personnel should not enter into a confined space unless trained in confined space entry techniques. Such training covers hazard recognition, the use of respiratory equipment and atmospheric testing devices, use of special equipment and tools, and emergency and rescue procedures. In addition, at least one member of the sampling crew should be certified in basic first aid and Cardiopulmonary Resuscitation (CPR). Sampling personnel should, on an annual basis, practice confined space rescues.

6.4.3 PERMIT SYSTEM

If entry into a confined space is necessary, an entry permit system should be developed which includes a written procedure. This permit should include, at a minimum:

- Description of type of work to be done
- Hazards that may be encountered

VOL 12

4743

R0038052

VOL 12

- Location and description of the confined space
- Information on atmospheric conditions at confined space
- Personnel training and emergency procedures
- Names of sampling personnel.

The manual developed by NIOSH discusses this permit system in more detail. Furthermore, the Occupational Safety and Health Administration (OSHA) proposed a rule on June 5, 1989 (54 FR 24080) that would implement a permit system. The rule is expected to be finalized and published late in 1992.

6.5 CHEMICAL HAZARDS

Sampling personnel can also be at risk of exposure to hazardous chemicals—either chemicals in the actual storm water discharge or the chemicals that have been placed in the sample collection containers for sample preservation. Therefore, direct contact with the preservatives and the storm water (if hazardous chemicals are suspected to be present) should be avoided. Sampling personnel should wear gloves and safety glasses to avoid skin and eye exposure to harmful chemicals. Sampling personnel should be trained to avoid exposure and instructed as to what to do if exposure occurs (e.g., flush the eyes, rinse the skin, ventilate the area, etc.).

4744

6.6 BIOLOGICAL HAZARDS

Storm water sampling personnel may also encounter biological hazards such as rodents, snakes, and insects. The sampling crew should remain alert to these hazards. As mentioned in Section 6.2, necessary sampling equipment, for certain locations, should include insect/rodent repellant and a first aid kit.

6.7 PHYSICAL HAZARDS

The sampling crew should be aware of a number of physical hazards that could cause accidents at the sampling site. These hazards include traffic hazards, sharp edges, falling objects, slippery footing, and lifting injuries from removing manhole covers. Sampling personnel should pay close attention in order to prevent these safety hazards at all times.

If the sample point is in a manhole, a street gutter, or ditch near the street, particular attention must be given to marking off the work area to warn oncoming traffic of the presence of the sampling crew. Traffic cones, warning signs, and barricades should be placed in appropriate places around the sampling point.

Application for Permit to Discharge Storm Water Discharges Associated with Industrial Activity

Paperwork Reduction Act Notice

Public reporting burden for this application is estimated to average 28.6 hours per application, including time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding the burden estimate, any other aspect of this collection of information, or suggestions for improving this form, including suggestions which may increase or reduce this burden to: Chief, Information Policy Branch, PM-223, U.S. Environmental Protection Agency, 401 M St., SW, Washington, DC 20460, or Director, Office of Information and Regulatory Affairs, Office of Management and Budget, Washington, DC 20[illegible]

I. Outfall Location

For each outfall, list the latitude and longitude of its location to the nearest 15 seconds and the name of the receiving water.

A. Outfall Number (list)	B. Latitude			C. Longitude			D. Receiving Water (name)

II. Improvements

A. Are you now required by any Federal, State, or local authority to meet any implementation schedule for the construction, upgrading or operation of wastewater treatment equipment or practices or any other environmental programs which may affect the discharges described in this application? This includes, but is not limited to, permit conditions, administrative or enforcement orders, enforcement compliance schedule letters, stipulations, court orders, and grant or loan conditions.

1. Identification of Conditions, Agreements, Etc.	2. Affected Outfalls		3. Brief Description of Project	4. Final Compliance Date	
	number	source of discharge		a. req.	b. proj.

B. You may attach additional sheets describing any additional water pollution (or other environmental projects which may affect your discharges) you now have under way or which you plan. Indicate whether each program is now under way or planned, and indicate your actual or planned schedules for construction.

III. Site Drainage Map

Attach a site map showing topography (or indicating the outline of drainage areas served by the outfall(s) covered in the application if a topographic map is unavailable) depicting the facility including: each of its intake and discharge structures; the drainage area of each storm water outfall; paved areas and buildings within the drainage area of each storm water outfall, each known past or present areas used for outdoor storage or disposal of significant materials, each existing structural control measure to reduce pollutants in storm water runoff, materials loading and access areas, areas where pesticides, herbicides, soil conditioners and fertilizers are applied; each of its hazardous waste treatment, storage or disposal units (including each area not required to have a RCRA permit which is used for accumulating hazardous waste under 40 CFR 262.34); each well where fluids from the facility are injected underground; springs, and other surface water bodies which receive storm water discharges from the f[illegible]

IV. Narrative Description of Pollutant Sources

A. For each outfall, provide an estimate of the area (include units) of impervious surfaces (including paved areas and building roofs) drained to the outfall, and an estimate of the total surface area drained by the outfall.

Outfall Number	Area of Impervious Surface (provide units)	Total Area Drained (provide units)	Outfall Number	Area of Impervious Surface (provide units)	Total Area Drained (provide units)

B. Provide a narrative description of significant materials that are currently or in the past three years have been treated, stored or disposed in a manner to allow exposure to storm water; method of treatment, storage, or disposal; past and present materials management practices employed to minimize contact by these materials with storm water runoff; materials loading and access areas; and the location, manner, and frequency in which pesticides, herbicides, soil conditioners, and fertilizers are applied.

C. For each outfall, provide the location and a description of existing structural and nonstructural control measures to reduce pollutants in storm water runoff; and a description of the treatment the storm water receives, including the schedule and type of maintenance for control and treatment measures and the ultimate disposal of any solid or fluid wastes other than by discharge.

Outfall Number	Treatment	List Codes from Table 2F-1

V. Nonstormwater Discharges

A. I certify under penalty of law that the outfall(s) covered by this application have been tested or evaluated for the presence of nonstormwater discharges, and that all nonstormwater discharges from these outfall(s) are identified in either an accompanying Form 2C or Form 2E application for the outfall.

Name and Official Title (type or print)	Signature	Date Signed

B. Provide a description of the method used, the date of any testing, and the onsite drainage points that were directly observed during a test.

VI. Significant Leaks or Spills

Provide existing information regarding the history of significant leaks or spills of toxic or hazardous pollutants at the facility in the last three years, including the approximate date and location of the spill or leak, and the type and amount of material released.

EPA ID Number (copy from Item I of Form 1)

VII. Discharge Information

A,B,C, & D: See instructions before proceeding. Complete one set of tables for each outfall. Annotate the outfall number in the space provided. Tables VII-A, VII-B, and VII-C are included on separate sheets numbered VII-1 and VII-2.

E. Potential discharges not covered by analysis - is any toxic pollutant listed in table 2F-2, 2F-3 or 2F-4, a substance or a component of a substance which you currently use or manufacture as an intermediate or final product or byproduct?

☐ Yes (list all such pollutants below) ☐ No (go to Section IX)

VIII. Biological Toxicity Testing Data

Do you have any knowledge or reason to believe that any biological test for acute or chronic toxicity has been made on any of your discharges or on a receiving water in relation to your discharge within the last 3 years?

☐ Yes (list all such pollutants below) ☐ No (go to Section IX)

IX. Contract Analysis Information

Were any of the analyses reported in Item VII performed by a contract laboratory or consulting firm?

☐ Yes (list the name, address, and telephone number of, and pollutants analyzed by, each such laboratory or firm below) ☐ No (go to Section X)

A. Name	B. Address	C. Area Code & Phone No.	D. Pollutants Analyzed

X. Certification

I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

A. Name & Official Title (type or print)	B. Area Code and Phone No.
C. Signature	D. Date Signed

VII. Discharge Information (Continued from page 3 of Form 2F)

Part A - You must provide the results of at least one analysis for every pollutant in this table. Complete one table for each outfall. See instructions for additional details.

Pollutant and CAS Number (if available)	Maximum Values (include units)		Average Values (include units)		Number of Storm Events Sampled	Sources of Pollutants
	Grab Sample Taken During First 30 Minutes	Flow-weighted Composite	Grab Sample Taken During First 30 Minutes	Flow-weighted Composite		
Oil and Grease						
Biological Oxygen Demand (BOD5)						
Chemical Oxygen Demand (COD)						
Total Suspended Solids (TSS)						
Total Kjeldahl Nitrogen						
Nitrate plus Nitrite Nitrogen						
Total Phosphorus						
pH	Minimum	Maximum	Minimum	Maximum		

Part B - List each pollutant that is limited in an effluent guideline which the facility is subject to or any pollutant listed in the facility's NPDES permit for its process wastewater (if the facility is operating under an existing NPDES permit). Complete one table for each outfall. See the instructions for additional details and requirements.

Pollutant and CAS Number (if available)	Maximum Values (include units)		Average Values (include units)		Number of Storm Events Sampled	Sources of Pollutants
	Grab Sample Taken During First 30 Minutes	Flow-weighted Composite	Grab Sample Taken During First 30 Minutes	Flow-weighted Composite

VOL 12

4750

Continued from the Front

Part C - List each pollutant shown in Tables 2F-2, 2F-3, and 2F-4 that you know or have reason to believe is present. See the instructions for additional details and requirements. Complete one table for each outfall.

Pollutant and CAS Number (if available)	Maximum Values (include units)		Average Values (include units)		Number of Storm Events Sampled	Sources of Pollutants
	Grab Sample Taken During First 30 Minutes	Flow-weighted Composite	Grab Sample Taken During First 30 Minutes	Flow-weighted Composite		

Part D - Provide data for the storm event(s) which resulted in the maximum values for the flow weighted composite sample.

1. Date of Storm Event	2. Duration of Storm Event (in minutes)	3. Total rainfall during storm event (in inches)	4. Number of hours between beginning of storm measured and end of previous measurable rain event	5. Maximum flow rate during rain event (gallons/minute or specify units)	6. Total flow from rain event (gallons or specify units)

7. Provide a description of the method of flow measurement or estimate.

EPA Form 3510-2F (Rev. 1-92)

VOL 12

4751

Instructions - Form 2F
Application for Permit to Discharge Storm Water Associated with Industrial Activity

Who Must File Form 2F

Form 2F must be completed by operators of facilities which discharge storm water associated with industrial activity or by operators of storm water discharges that EPA is evaluating for designation as a significant contributor of pollutants to waters of the United States, or as contributing to a violation of a water quality standard.

Operators of discharges which are composed entirely of storm water must complete Form 2F (EPA Form 3510-2F) in conjunction with Form 1 (EPA Form 3510-1).

Operators of discharges of storm water which are combined with process wastewater (process wastewater is water that comes into direct contact with or results from the production or use of any raw material, intermediate product, finished product, byproduct, waste product, or wastewater) must complete and submit Form 2F, Form 1, and Form 2C (EPA Form 3510-2C).

Operators of discharges of storm water which are combined with nonprocess wastewater (nonprocess wastewater includes noncontact cooling water and sanitary wastes which are not regulated by effluent guidelines or a new source performance standard, except discharges by educational, medical, or commercial chemical laboratories) must complete Form 1, Form 2F, and Form 2E (EPA Form 3510-2E).

Operators of new sources or new discharges of storm water associated with industrial activity which will be combined with other nonstormwater new sources or new discharges must submit Form 1, Form 2F, and Form 2D (EPA Form 3510-2D).

Where to File Applications

The application forms should be sent to the EPA Regional Office which covers the State in which the facility is located. Form 2F must be used only when applying for permits in States where the NPDES permits program is administered by EPA. For facilities located in States which are approved to administer the NPDES permits program, the State environmental agency should be contacted for proper permit application forms and instructions.

Information on whether a particular program is administered by EPA or by a State agency can be obtained from your EPA Regional Office. Form 1, Table 1 of the "General Instructions" lists the addresses of EPA Regional Offices and the States within the jurisdiction of each Office.

Completeness

Your application will not be considered complete unless you answer every question on this form and on Form 1. If an item does not apply to you, enter "NA" (for not applicable) to show that you considered the question.

Public Availability of Submitted Information

You may not claim as confidential any information required by this form or Form 1, whether the information is reported on the forms or in an attachment. Section 402(j) of the Clean Water Act requires that all permit applications will be available to the public. This information will be made available to the public upon request.

Any information you submit to EPA which goes beyond that required by this form, Form 1, or Form 2C you may claim as confidential, but claims for information which are effluent data will be denied.

If you do not assert a claim of confidentiality at the time of submitting the information, EPA may make the information public without further notice to you. Claims of confidentiality will be handled in accordance with EPA's business confidentiality regulations at 40 CFR Part 2.

Definitions

All significant terms used in these instructions and in the form are defined in the glossary found in the General Instructions which accompany Form 1.

EPA ID Number

Fill in your EPA Identification Number at the top of each odd-numbered page of Form 2F. You may copy this number directly from item I of Form 1.

VOL 12

4752

VOL 12

Item I

You may use the map you provided for Item XI of Form 1 to determine the latitude and longitude of each of your outfalls and the name of the receiving water.

Item II-A

If you check "yes" to this question, complete all parts of the chart, or attach a copy of any previous submission you have made to EPA containing the same information.

Item II-B

You are not required to submit a description of future pollution control projects if you do not wish to or if none is planned.

Item III

Attach a site map showing topography (or indicating the outline of drainage areas served by the outfall(s) covered in the application if a topographic map is unavailable) depicting the facility including:

each of its drainage and discharge structures;

the drainage area of each storm water outfall;

paved areas and building within the drainage area of each storm water outfall, each known past or present areas used for outdoor storage or disposal of significant materials, each existing structural control measure to reduce pollutants in storm water runoff, materials loading and access areas, areas where pesticides, herbicides, soil conditioners and fertilizers are applied;

each of its hazardous waste treatment, storage or disposal facilities (including each area not required to have a RCRA permit which is used for accumulating hazardous waste for less than 90 days under 40 CFR 262.34);

each well where fluids from the facility are injected underground; and

springs, and other surface water bodies which receive storm water discharges from the facility;

Item IV-A

For each outfall, provide an estimate of the area drained by the outfall which is covered by impervious surfaces. For the purpose of this application, impervious surfaces are surfaces where storm water runs off at rates that are significantly higher than background rates (e.g., predevelopment levels) and include paved areas, building roofs, parking lots, and roadways. Include an estimate of the total area (including all impervious and pervious areas) drained by each outfall. The site map required under item III can be used to estimate the total area drained by each outfall.

Item IV-B

Provide a narrative description of significant materials that are currently or in the past three years have been treated, stored, or disposed in a manner to allow exposure to storm water; method of treatment, storage or disposal of these materials; past and present materials management practices employed, in the last three years, to minimize contact by these materials with storm water runoff; materials loading and access areas; and the location, manner, and frequency in which pesticides, herbicides, soil conditioners, and fertilizers are applied. Significant materials should be identified by chemical name, form (e.g., powder, liquid, etc.), and type of container or treatment unit. Indicate any materials treated, stored, or disposed of together. "Significant materials" includes, but is not limited to: raw materials; fuels; materials such as solvents, detergents, and plastic pellets; finished materials such as metallic products; raw materials used in food processing or production; hazardous substances designated under Section 101(14) of CERCLA; any chemical the facility is required to report pursuant to Section 313 of Title III of SARA; fertilizers; pesticides; and waste products such as ashes, slag and sludge that have the potential to be released with storm water discharges.

Item IV-C

For each outfall, structural controls include structures which enclose material handling or storage areas, covering materials, berms, dikes, or diversion ditches around manufacturing, production, storage or treatment units, retention ponds, etc. Nonstructural controls include practices such as spill prevention plans, employee training, visual inspections, preventive maintenance, and housekeeping measures that are used to prevent or minimize the potential for releases of pollutants.

EPA Form 3510-2F (Rev. 1-92) I - 2

4753

Item V

Provide a certification that all outfalls that should contain storm water discharges associated with industrial activity have been tested or evaluated for the presence of non-storm water discharges which are not covered by an NPDES permit. Tests for such non-storm water discharges may include smoke tests, fluorometric dye tests, analysis of accurate schematics,' as well as other appropriate tests. Part B must include a description of the method used, the date of any testing, and the onsite drainage points that were directly observed during a test. All non-storm water discharges must be identified in a Form 2C or Form 2E which must accompany this application (see beginning of instructions under section titled "Who Must File Form 2F" for a description of when Form 2C and Form 2E must be submitted).

Item VI

Provide a description of existing information regarding the history of significant leaks or spills of toxic or hazardous pollutants at the facility in the last three years.

Item VII-A, B, and C

These items require you to collect and report data on the pollutants discharged for each of your outfalls. Each part of this item addresses a different set of pollutants and must be completed in accordance with the specific instructions for that part. The following general instructions apply to the entire item.

General Instructions

Part A requires you to report at least one analysis for each pollutant listed. Parts B and C require you to report analytical data in two ways. For some pollutants addressed in Parts B and C, if you know or have reason to know that the pollutant is present in your discharge, you may be required to list the pollutant and test (sample and analyze) and report the levels of the pollutants in your discharge. For all other pollutants addressed in Parts B and C, you must list the pollutant if you know or have reason to know that the pollutant is present in the discharge, and either report quantitative data for the pollutant or briefly describe the reasons the pollutant is expected to be discharged. (See specific instructions on the form and below for Parts A through C.) Base your determination that a pollutant is present in or absent from your discharge on your knowledge of your raw materials, material management practices, maintenance chemicals, history of spills and releases, intermediate and final products and byproducts, and any previous analyses known to you of your effluent or similar effluent.

A. **Sampling:** The collection of the samples for the reported analyses should be supervised by a person experienced in performing sampling of industrial wastewater or storm water discharges. You may contact EPA or your State permitting authority for detailed guidance on sampling techniques and for answers to specific questions. Any specific requirements contained in the applicable analytical methods should be followed for sample containers, sample preservation, holding times, the collection of duplicate samples, etc. The time when you sample should be representative, to the extent feasible, of your treatment system operating properly with no system upsets. Samples should be collected from the center of the flow channel, where turbulence is at a maximum, at a site specified in your present permit, or at any site adequate for the collection of a representative sample.

For pH, temperature, cyanide, total phenols, residual chlorine, oil and grease, and fecal coliform, grab samples taken during the first 30 minutes (or as soon thereafter as practicable) of the discharge must be used (you are not required to analyze a flow-weighted composite for these parameters). For all other pollutants both a grab sample collected during the first 30 minutes (or as soon thereafter as practicable) of the discharge and a flow-weighted composite sample must be analyzed. However, a minimum of one grab sample may be taken for effluents from holding ponds or other impoundments with a retention period of greater than 24 hours.

All samples shall be collected from the discharge resulting from a storm event that is greater than 0.1 inches and at least 72 hours from the previously measurable (greater than 0.1 inch rainfall) storm event. Where feasible, the variance in the duration of the event and the total rainfall of the event should not exceed 50 percent from the average or median rainfall event in that area.

A grab sample shall be taken during the first thirty minutes of the discharge (or as soon thereafter as practicable), and a flow-weighted composite shall be taken for the entire event or for the first three hours of the event.

Grab and composite samples are defined as follows:

VOL 12

4754

VOL 12

Grab sample: An individual sample of at least 100 milliliters collected during the first thirty minutes (or as soon thereafter as practicable) of the discharge. This sample is to be analyzed separately from the composite sample.

Flow-Weighted Composite sample: A flow-weighted composite sample may be taken with a continuous sampler that proportions the amount of sample collected with the flow rate or as a combination of a minimum of three sample aliquots taken in each hour of discharge for the entire event or for the first three hours of the event, with each aliquot being at least 100 milliliters and collected with a minimum period of fifteen minutes between aliquot collections. The composite must be flow proportional; either the time interval between each aliquot or the volume of each aliquot must be proportional to either the stream flow at the time of sampling or the total stream flow since the collection of the previous aliquot. Aliquots may be collected manually or automatically. Where GC/MS Volatile Organic Analysis (VOA) is required, aliquots must be combined in the laboratory immediately before analysis. Only one analysis for the composite sample is required.

Data from samples taken in the past may be used, provided that:

All data requirements are met;

Sampling was done no more than three years before submission; and

All data are representative of the present discharge.

Among the factors which would cause the data to be unrepresentative are significant changes in production level, changes in raw materials, processes, or final products, and changes in storm water treatment. When the Agency promulgates new analytical methods in 40 CFR Part 136, EPA will provide information as to when you should use the new methods to generate data on your discharges. Of course, the Director may request additional information, including current quantitative data, if they determine it to be necessary to assess your discharges. The Director may allow or establish appropriate site-specific sampling procedures or requirements, including sampling locations, the season in which the sampling takes place, the minimum duration between the previous measurable storm event and the storm event sampled, the minimum or maximum level of precipitation required for an appropriate storm event, the form of precipitation sampled (snow melt or rainfall), protocols for collecting samples under 40 CFR Part 136, and additional time for submitting data on a case-by-case basis.

B. **Reporting:** All levels must be reported as concentration and mass (note: grab samples are reported in terms of concentration). You may report some or all of the required data by attaching separate sheets of paper instead of filling out pages VII-1 and VII-2 if the separate sheets contain all the required information in a format which is constant with pages VII-1 and VII-2 in spacing and identification of pollutants and columns. Use the following abbreviations in the columns headed "Units."

Concentration		Mass	
ppm	parts per million	lbs	pounds
mg/1	milligrams per liter	ton	tons (English tons)
ppb	parts per billion	mg	milligrams
ug/1	micrograms per liter	g	grams
kg	kilograms	T	tonnes (metric tons)

All reporting of values for metals must be in terms of "total recoverable metal," unless:

(1) An applicable, promulgated effluent limitation or standard specifies the limitation for the metal in dissolved, valent, or total form; or

(2) All approved analytical methods for the metal inherently measure only its dissolved form (e.g., hexavalent chromium); or

(3) The permitting authority has determined that in establishing case-by-case limitations it is necessary to express the limitations on the metal in dissolved, valent, or total form to carry out the provisions of the CWA. If you measure only one grab sample and one flow-weighted composite sample for a given outfall, complete only the "Maximum Values" columns and insert "1" into the "Number of Storm Events Sampled" column. The permitting authority may require you to conduct additional analyses to further characterize your discharges.

4755

EPA Form 3510-2F (Rev. 1-92)

If you measure more than one value for a grab sample or a flow-weighted composite sample for a given outfall and those values are representative of your discharge, you must report them. You must describe your method of testing and data analysis. You also must determine the average of all values within the last year and report the concentration and mass under the "Average Values" columns, and the total number of storm events sampled under the "Number of Storm Events Sampled" columns.

C. Analysis: You must use test methods promulgated in 40 CFR Part 136; however, if none has been promulgated for a particular pollutant, you may use any suitable method for measuring the level of the pollutant in your discharge provided that you submit a description of the method or a reference to a published method. Your description should include the sample holding time, preservation techniques, and the quality control measures which you used. If you have two or more substantially identical outfalls, you may request permission from your permitting authority to sample and analyze only one outfall and submit the results of the analysis for other substantially identical outfalls. If your request is granted by the permitting authority, on a separate sheet attached to the application form, identify which outfall you did test, and describe why the outfalls which you did not test are substantially identical to the outfall which you did test.

Part VII-A

Part VII-A must be completed by all applicants for all outfalls who must complete Form 2F.

Analyze a grab sample collected during the first thirty minutes (or as soon thereafter as practicable) of the discharge and flow-weighted composite samples for all pollutants in this Part, and report the results except use only grab samples for pH and oil and grease. See discussion in General Instructions to Item VII for definitions of grab sample collected during the first thirty minutes of discharge and flow-weighted composite sample. The "Average Values" column is not compulsory but should be filled out if data are available.

Part VII-B

List all pollutants that are limited in an effluent guideline which the facility is subject to (see 40 CFR Subchapter N to determine which pollutants are limited in effluent guidelines) or any pollutant listed in the facility's NPDES permit for its process wastewater (if the facility is operating under an existing NPDES permit). Complete one table for each outfall. See discussion in General Instructions to Item VII for definitions of grab sample collected during the first thirty minutes (or as soon thereafter as practicable) of discharge and flow-weighted composite sample. The "Average Values" column is not compulsory but should be filled out if data are available.

Analyze a grab sample collected during the first thirty minutes of the discharge and flow-weighted composite samples for all pollutants in this Part, and report the results, except as provided in the General Instructions.

Part VII-C

Part VII-C must be completed by all applicants for all outfalls which discharge storm water associated with industrial activity, or that EPA is evaluating for designation as a significant contributor of pollutants to waters of the United States, or as contributing to a violation of a water quality standard. Use both a grab sample and a composite sample for all pollutants you analyze for in this part except use grab samples for residual chlorine and fecal coliform. The "Average Values" column is not compulsory but should be filled out if data are available. Part C requires you to address the pollutants in Table 2F-2, 2F-3, and 2F-4 for each outfall. Pollutants in each of these Tables are addressed differently.

Table 2F-2: For each outfall, list all pollutants in Table 2F-2 that you know or have reason to believe are discharged (except pollutants previously listed in Part VII-B). If a pollutant is limited in an effluent guideline limitation which the facility is subject to, the pollutant must be analyzed and reported in Part VII-B. If a pollutant in Table 2F-2 is indirectly limited by an effluent guideline limitation through an indicator (e.g., use of TSS as an indicator to control the discharge of iron and aluminum), you must analyze for it and report the data in Part VII-B. For other pollutants listed in Table 2F-2 (those not limited directly or indirectly by an effluent limitation guideline), that you know or have reason to believe are discharged, you must either report quantitative data or briefly describe the reasons the pollutant is expected to be discharged.

Table 2F-3: For each outfall, list all pollutants in Table 2F-3 that you know or have reason to believe are discharged. For every pollutant in Table 2F-3 expected to be discharged in concentrations of 10 ppb or greater, you must submit quantitative data. For acrolein, acrylonitrile, 2,4 dinitrophenol, and 2-methyl-4,6 dinitrophenol, you must submit quantitative data if any of these four pollutants is expected to be discharged

VOL 12

4756

R0038065

in concentrations of 100 ppb or greater. For every pollutant expected to be discharged in concentrations less than 10 ppb (or 100 ppb for the four pollutants listed above), then you must either submit quantitative data or briefly describe the reasons the pollutant is expected to be discharged.

Small Business Exemption - If you are a "small business," you are exempt from the reporting requirements for the organic toxic pollutants listed in Table 2F-3. There are two ways in which you can qualify as a "small business". If your facility is a coal mine, and if your probable total annual production is less than 100,000 tons per year, you may submit past production data or estimated future production (such as a schedule of estimated total production under 30 CFR 795.14(c)) instead of conducting analyses for the organic toxic pollutants. If your facility is not a coal mine, and if your gross total annual sales for the most recent three years average less than $100,000 per year (in second quarter 1980 dollars), you may submit sales data for those years instead of conducting analyses for the organic toxic pollutants. The production or sales data must be for the facility which is the source of the discharge. The data should not be limited to production or sales for the process or processes which contribute to the discharge, unless those are the only processes at your facility. For sales data, in situations involving intracorporate transfer of goods and services, the transfer price per unit should approximate market prices for those goods and services as closely as possible. Sales figures for years after 1980 should be indexed to the second quarter of 1980 by using the gross national product price deflator (second quarter of 1980=100). This index is available in National Income and Product Accounts of the United States (Department of Commerce, Bureau of Economic Analysis).

Table 2F-4: For each outfall, list any pollutant in Table 2F-4 that you know or believe to be present in the discharge and explain why you believe it to be present. No analysis is required, but if you have analytical data, you must report them. Note: Under 40 CFR 117.12(a)(2), certain discharges of hazardous substances (listed at 40 CFR 177.21 or 40 CFR 302.4) may be exempted from the requirements of section 311 of CWA, which establishes reporting requirements, civil penalties, and liability for cleanup costs for spills of oil and hazardous substances. A discharge of a particular substance may be exempted if the origin, source, and amount of the discharged substances are identified in the NPDES permit application or in the permit, if the permit contains a requirement for treatment of the discharge, and if the treatment is in place. To apply for an exclusion of the discharge of any hazardous substance from the requirements of section 311, attach additional sheets of paper to your form, setting forth the following information:

1. The substance and the amount of each substance which may be discharged.
2. The origin and source of the discharge of the substance.
3. The treatment which is to be provided for the discharge by:
   a. An onsite treatment system separate from any treatment system treating your normal discharge;
   b. A treatment system designed to treat your normal discharge and which is additionally capable of treating the amount of the substance identified under paragraph 1 above; or
   c. Any combination of the above.

See 40 CFR 117.12(a)(2) and (c), published on August 29, 1979, in 44 FR 50766, or contact your Regional Office (Table 1 on Form 1, Instructions), for further information on exclusions from section 311.

Part VII-D

If sampling is conducted during more than one storm event, you only need to report the information requested in Part VII-D for the storm event(s) which resulted in any maximum pollutant concentration reported in Part VII-A, VII-B, or VII-C.

Provide flow measurements or estimates of the flow rate, and the total amount of discharge for the storm event(s) sampled, the method of flow measurement, or estimation. Provide the data and duration of the storm event(s) sampled, rainfall measurements, or estimates of the storm event which generated the sampled runoff and the duration between the storm event sampled and the end of the previous measurable (greater than 0.1 inch rainfall) storm event.

Part VII-E

List any toxic pollutant listed in Tables 2F-2, 2F-3, or 2F-4 which you currently use or manufacture as an intermediate or final product or byproduct. In addition, if you know or have reason to believe that 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) is discharged or if you use or manufacture 2,4,5-trichlorophenoxy acetic acid (2,4,5,-T); 2-(2,4,5-trichlorophenoxy) propanoic acid (Silvex, 2,4,5,-TP); 2-(2,4,5-trichlorophenoxy) ethyl, 2,2-dichloropropionate (Erbon); O,O-dimethyl O-(2,4,5-trichlorphenyl) phosphorothioate (Ronnel); 2,4,5-trichlorophenol (TCP); or hexachlorophene (HCP); then list TCDD. The Director may waive or modify the requirement if you demonstrate that it would be unduly burdensome to identify each toxic pollutant and the Director has adequate information to issue your permit. You may not claim this information as confidential; however, you do not have to distinguish between use or production of the pollutants or list the amounts.

Item VIII

Self explanatory. The permitting authority may ask you to provide additional details after your application is received.

Item X

The Clean Water Act provides for severe penalties for submitting false information on this application form.

Section 309(c)(4) of the Clean Water Act provides that "Any person who knowingly makes any false material statement, representation, or certification in any application, . . . shall upon conviction, be punished by a fine of not more than $10,000 or by imprisonment for not more than 2 years, or by both. If a conviction of such person is for a violation committed after a first conviction of such person under this paragraph, punishment shall be by a fine of not more than $20,000 per day of violation, or by imprisonment of not more than 4 years, or by both." 40 CFR Part 122.22 requires the certification to be signed as follows:

(A) For a corporation: by a responsible corporate official. For purposes of this section, a responsible corporate official means (i) a president, secretary, treasurer, or vice-president of the corporation in charge of a principal business function, or any other person who performs similar policy- or decision-making functions for the corporation, or (ii) the manager of one or more manufacturing, production, or operating facilities employing more than 250 persons or having gross annual sales or expenditures exceeding $25,000,000 (in second-quarter 1980 dollars), if authority to sign documents has been assigned or delegated to the manager in accordance with corporate procedures.

Note: EPA does not require specific assignments or delegation of authority to responsible corporate officers identified in 122.22(a)(1)(i). The Agency will presume that these responsible corporate officers have the requisite authority to sign permit applications unless the corporation has notified the Director to the contrary. Corporate procedures governing authority to sign permit applications may provide for assignment or delegation to applicable corporate position under 122.22(a)(1)(ii) rather than to specific individuals.

(B) For a partnership or sole proprietorship: by a general partner or the proprietor, respectively; or

(C) For a municipality, State, Federal, or other public agency: by either a principal executive officer or ranking elected official. For purposes of this section, a principal executive officer of a Federal agency includes (i) the chief executive officer of the agency, or (ii) a senior executive officer having responsibility for the overall operations of a principal geographic unit of the agency (e.g., Regional Administrators of EPA).

9 R		(specify)

XI. MAP

Attach to this application a topographic map of the area extending to at least one mile beyond property boundaries. The map must show the outline of the facility, the location of each of its existing and proposed intake and discharge structures, each of its hazardous waste treatment, storage, or disposal facilities, and each well where it injects fluids underground. Include all springs, rivers and other surface water bodies in the map area. See instructions for precise requirements.

XII. NATURE OF BUSINESS (provide a brief description)

XIII. CERTIFICATION (see instructions)

I certify under penalty of law that I have personally examined and am familiar with the information submitted in this application and all attachments and that, based on my inquiry of those persons immediately responsible for obtaining the information contained in the application, I believe that the information is true, accurate and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment.

TCDD (11)	G, Teflon-lined cap	Cool, 4°C 0.008% $Na_2S_2O_3$ (5)	7 days until extraction, 40 days after extraction
Pesticides Tests			
Pesticides (11)	G, Teflon-lined cap	Cool, 4°C pH 5-9 (15)	7 days until extraction, 40 days after extraction
Radiological Tests			
Alpha, beta, and radium	P, G	HNO_3 to pH<2	6 months

40 CFR 136.3 TABLE II NOTES	
(1)	Polyethylene (P) or Glass (G).
(2)	Sample preservation should be performed immediately upon sample collection. For composite chemical samples each aliquot should be preserved at the time of collection. When use of an automated sampler makes it impossible to preserve each aliquot, then chemical samples may be preserved by maintaining at 4°C until compositing and sample splitting is completed.
(3)	When any sample is to be shipped by common carrier or sent through the United States Mails, it must comply with the Department of Transportation Hazardous Materials Regulations (49 CFR Part 172). The person offering such material for transportation is responsible for ensuring such compliance. For the preservation requirements of Table II, the Office of Hazardous Materials, Materials Transportation Bureau, Department of Transportation has determined that the Hazardous Materials Regulations do not apply to the following materials: Hydrochloric acid (HCl) in water solutions at concentrations of 0.04% by weight or less (pH about 1.96 or greater); Nitric acid (HNO_3) in water solutions at concentrations of 0.15% by weight or less (pH about 1.62 or greater); Sulfuric acid (H_2SO_4) in water solutions at concentrations of 0.35% by weight or less (pH about 1.15 or greater); and Sodium hydroxide (NaOH) in water solutions at concentrations of 0.080% by weights or less (pH about 12.30 or less).
(4)	Samples should be analyzed as soon as possible after collection. The times listed are the maximum times that samples may be held before analysis and still be considered valid. Samples may be held for longer periods only if the permittee, or monitoring laboratory, has data on file to show that the specific types of samples under study are stable for the longer time, and has received a variance from the Regional Administrator under § 136.3(e). Some samples may not be stable for the maximum time period given in the table. A permittee, or monitoring laboratory, is obligated to hold the sample for a shorter time if knowledge exists to show that this is necessary to maintain sample stability. See § 136.3(e) for details.
(5)	Should only be used in the presence of residual chlorine.
(6)	Maximum holding time is 24 hours when sulfide is present. Optionally all samples may be tested with lead acetate paper before pH adjustments in order to determine if sulfide is present. If sulfide is present, it can be removed by the addition of cadmium nitrate powder until a negative spot test is obtained. The sample is filtered and then NaOH is added to pH 12.
(7)	Samples should be filtered immediately on-site before adding preservative for dissolved metals.
(8)	Guidance applies to samples to be analyzed by GC, LC, or GC/MS for specific compounds.
(9)	Sample receiving no pH adjustment must be analyzed within seven days of sampling.
(10)	The pH adjustment is not required if acrolein will not be measured. Samples for acrolein receiving no pH adjustment must be analyzed within 3 days of sampling.

VOL 12

4773

VOL 12

40 CFR 136.3 TABLE II NOTES

(11) When the extractable analytes of concern fall within a single chemical category, the specified preservative and maximum holding times should be observed for optimum safeguard of sample integrity. When the analytes of concern fall within two or more chemical categories, the sample may be preserved by cooling to 4°C, reducing residual chlorine with 0.008% sodium thiosulfate, storing in the dark,and adjusting the pH to 6-9; samples preserved in this manner may be held for seven days before extraction and for forty days after extraction. Exceptions to this optional preservation and holding time procedure are noted in footnote 5 (re the requirement for thiosulfate reduction of residual chlorine), and footnotes 12, 13 (re the analysis of benzidine).

(12) If 1,2-diphenylhydrazine is likely to be present, adjust the pH of the sample to 4.0 ± 0.2 to prevent rearrangement to benzidine.

(13) Extracts may be stored up to 7 days before analysis if storage is conducted under an inert (oxidant-free) atmosphere.

(14) For the analysis of diphenylnitrosamine, add 0.008% $Na_2S_2O_3$ and adjust pH to 7-10 with NaOH within 24 hours of sampling.

(15) The pH adjustment may be performed upon receipt at the laboratory and may be omitted if the samples are extracted within 72 hours of collection. For the analysis of aldrin, add 0.008% $Na_2S_2O^3$.

Table IA Notes

[1] The method used must be specified when results are reported.

[2] "Microbiological Methods for Monitoring the Environment, Water and Waste, 1978", EPA-600/8-78-017, U.S. Environmental Protection Agency.

[3] Greeson, P.E., et al. "Methods for Collection and Analysis of Aquatic Biological and Microbiological Samples, "U.S. Geological Survey, Techniques of Water-Resources Investigations, Book 5, Chapter A4, Laboratory Analysis, 1977.

[4] 0.45 μm membrane filter or other pore size certified by the manufacturer to fully retain organisms to be cultivated, and free of extractables which could interfere with their growth and development.

[5] Since the membrane filter technique usually yields low and variable recovery from chlorinated wastewaters, the MPN method will be required to resolve any controversies.

[6] Approved only if dissolution of the KF Streptococcus Agar (Section 5.1, USGS Method B-0055-77) is made in a boiling water bath to avoid scorching of the medium.

VOL 12

TABLE IB—LIST OF APPROVED INORGANIC TEST PROCEDURES—Continued

[1] "Methods for Analysis of Inorganic Substances in Water and Fluvial Sediments," U.S. Department of the Interior, U.S. Geological Survey, Open-File Report 85–495, 1986, unless otherwise stated.

[2] "Official Methods of Analysis of the Association of Official Analytical Chemists," methods manual, 14th ed. (1985).

[3] For the determination of total metals the sample is not filtered before processing. A digestion procedure is required to solubilize suspended material and to destroy possible organic-metal complexes. Two digestion procedures are given in "Methods for Chemical Analysis of Water and Wastes, 1979." One (section 4.1.3), is a vigorous digestion using nitric acid. A less vigorous digestion using nitric and hydrochloric acids (section 4.1.4) is preferred; however, the analyst should be cautioned that this mild digestion may not suffice for all sample types. Particularly, if a colorimetric procedure is to be employed, it is necessary to ensure that all organo-metallic bonds be broken so that the metal is in a reactive state. In those situations, the vigorous digestion is to be preferred making certain that at no time does the sample go to dryness. Samples containing large amounts of organic materials would also benefit by this vigorous digestion. Use of the graphite furnace technique, inductively coupled plasma, as well as determinations for certain elements such as arsenic, the noble metals, mercury, selenium, and titanium require a modified digestion and in all cases the method write-up should be consulted for specific instruction and/or cautions.

NOTE: If the digestion included in one of the other approved references is different than the above, the EPA procedure must be used.

Dissolved metals are defined as those constituents which will pass through a 0.45 micron membrane filter. Following filtration of the sample, the referenced procedure for total metals must be followed. Sample digestion for dissolved metals may be omitted for AA (direct aspiration or graphite furnace) and ICP analyses provided the sample solution to be analyzed meets the following criteria:

a. has a low COD (<20)
b. is visibly transparent with a turbidity measurement of 1 NTU or less,
c. is colorless with no perceptible odor, and
d. is of one liquid phase and free of particulate or suspended matter following acidification.

[4] The full text of Method 200.7, "Inductively Coupled Plasma Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes," is given at Appendix C of this Part 136.

[5] Manual distillation is not required if comparability data on representative effluent samples are on company file to show that this preliminary distillation step is not necessary; however, manual distillation will be required to resolve any controversies.

[6] Ammonia, Automated Electrode Method, Industrial Method Number 379-75 WE, dated February 19, 1976, Technicon AutoAnalyzer II, Technicon Industrial Systems, Tarrytown, NY, 10591.

[7] The approved method is that cited in "Methods for Determination of Inorganic Substances in Water and Fluvial Sediments", USGS TWRI, Book 5, Chapter A1 (19[illegible]).

[9] "Selected Analytical Methods Approved and Cited by the United States Environmental Protection Agency," Supplement to the Fifteenth Edition of *Standard Methods for the Examination of Water and Wastewater* (1981).

[10] The use of normal and differential pulse voltage ramps to increase sensitivity and resolution is acceptable.

[11] Carbonaceous biochemical oxygen demand ($CBOD_5$) must not be confused with the traditional BOD_5 test which measures "total BOD." The addition of the nitrification inhibitor is not a procedural option, but must be included to report the $CBOD_5$ parameter. A discharger whose permit requires reporting the traditional BOD_5 may not use a nitrification inhibitor in the procedure for reporting the results. Only when a discharger's permit specifically states $CBOD_5$ is required, can the permittee report data using the nitrification inhi[illegible].

[24] Nitrogen, Nitrite, Method 8507, Hach Chemical Company, P.O. Box 389, Loveland, CO 80537.

[25] Just prior to distillation, adjust the sulfuric-acid-preserved sample to pH 4 with 1 + 9 NaOH.

[26] The approved method is that cited in *Standard Methods for the Examination of Water and Wastewater*, 14th Edition. The colorimetric reaction is conducted at a pH of 10.0±0.2. The approved methods are given on pp. 576–81 of the 14th Edition: Method 510A for distillation, Method 510B for the manual colorimetric procedure, or Method 510C for the manual spectrophotometric proc[illegible].

[27] R. F. Addison and R. G. Ackman, "Direct Determination of Elemental Phosphorus by Gas-Liquid Chromatography," *Journal of Chromatography*, vol. 47, No. 3, pp. 421–426, 197[illegible].

[28] Approved methods for the analysis of silver in industrial wastewaters at concentrations of 1 mg/L and above are inadequate where silver exists as an inorganic halide. Silver halides such as the bromide and chloride are relatively insoluble in reagents such as nitric acid but are readily soluble in an aqueous buffer of sodium thiosulfate and sodium hydroxide to a pH of 12. Therefore, for levels of silver above 1 mg/L, 20 mL of sample should be diluted to 100 mL by adding 40 mL each of 2 M $Na_2S_2O_3$ and 2M NaOH. Standards should be prepared in the same manner. For levels of silver below 1 mg/L the approved method is satis[illegible].

[29] The approved method is that cited in *Standard Methods for the Examination of Water and Wastewater*, 15th Edition.

[30] The approved method is that cited in *Standard Methods for the Examination of Water and Wastewater*, 13th Edition.

Table IC Notes

[1] All parameters are expressed in micrograms per liter (µg/L).

[2] The full text of Methods 601–613, 624, 625, 1624, and 1625, are given at Appendix A, "Test Procedures for Analysis of Organic Pollutants," of this Part 136. The standardized test procedure to be used to determine the method detection limit (MDL) for these test procedures is given at Appendix B, "Definition and Procedure for the Determination of the Method Detection Limit," of this Part 136.

[3] "Methods for Benzidine: Chlorinated Organic Compounds, Pentachlorophenol and Pesticides in Water and Wastewater," U.S. Environmental Protection Agency, September, 1978.

[4] Method 624 may be extended to screen samples for Acrolein and Acrylonitrile. However, when they are known to be present, the preferred method for these two compounds is Method 603 or Method 1624.

[5] Method 625 may be extended to include benzidine, hexachlorocyclopentadiene, N-nitrosodimethylamine, and N-nitrosodiphenylamine. However, when they are known to be present, Methods 605, 607, and 612, or Method 1625, are preferred methods for these compounds.

[6] 625, Screening only.

[7] "Selected Analytical Methods Approved and Cited by the United States Environmental Protection Agency," Supplement to the Fifteenth Edition of *Standard Methods for the Examination of Water and Wastewater* (1981).

[8] Each analyst must make an initial, one-time, demonstration of their ability to generate acceptable precision and accuracy with Methods 601–613, 624, 625, 1624, and 1625 (See Appendix A of this Part 136) in accordance with procedures each in section 8.2 of each of these Methods. Additionally, each laboratory, on an on-going basis must spike and analyze 10% (5% for Methods 624 and 625 and 100% for methods 1624, and 1625) of all samples to monitor and evaluate laboratory data quality in accordance with sections 8.3 and 8.4 of these Methods. When the recovery of any parameter falls outside the warning limits, the analytical results for that parameter in the unspiked sample are suspect and cannot be reported to demonstrate regulatory compliance.

NOTE: These warning limits are promulgated as an "interim final action with a request for comments."

Table ID Notes

[1] Pesticides are listed in this table by common name for the convenience of the reader. Additional pesticides may be found under Table IC, where entries are listed by chemical name.

[2] The full text of methods 608 and 625 are given at Appendix A, "Test Procedures for Analysis of Organic Pollutants," of this Part 136. The standardized test procedure to be used to determine the method detection limit (MDL) for these test procedures is given at Appendix B, "Definition and Procedure for the Determination of the Method Detection Limit", of this Part 136.

[3] "Methods for Benzidine, Chlorinated Organic Compounds, Pentachlorophenol and Pesticides in Water and Wastewater," U.S. Environmental Protection Agency, September, 1978. This EPA publication includes thin-layer chromatography (TLC) methods.

[4] "Methods for Analysis of Organic Substances in Water," U.S. Geological Survey, Techniques of Water-Resources Investigations, Book 5, Chapter A3 [illegible]

[5] The method may be extended to include α-BHC, δ-BHC, endosulfan I, endosulfan II, and endrin. However, when they are known to exist, Method 608 is the preferred method.

[6] "Selected Analytical Methods Approved and Cited by the United States Environmental Protection Agency," Supplement to the Fifteenth Edition of Standard Methods for the Examination of Water and Wastewater (1981).

[7] Each analyst must make an initial, one-time, demonstration of their ability to generate acceptable precision and accuracy with Methods 608 and 625 (See Appendix A of this Part 136) in accordance with procedures given in section 8.2 of each of these methods. Additionally, each laboratory, on an on-going basis, must spike and analyze 10% of all samples analyzed with Method 608 or 5% of all samples analyzed with Method 625 to monitor and evaluate laboratory data quality in accordance with Sections 8.3 and 8.4 of these methods. When the recovery of any parameter falls outside the warning limits, the analytical results for that parameter in the unspiked sample are suspect and cannot be reported to demonstrate regulatory compliance.

NOTE: These warning limits are promulgated as an "interim final action with a request for comments."

VOL 12

TECHNICAL APPENDIX E

GLOSSARY

4788

GLOSSARY

Aliquot: A discrete sample used for analysis.

Biochemical Oxygen Demand (BOD): The quantity of oxygen consumed during the biochemical oxidation of matter over a specified period of time, usually 5 days (BOD_5).

Chain-of-Custody: Procedures used to minimize the possiblility of tampering with samples.

Chemical Oxygen Demand (COD): Measurement of all the oxidizable matter found in a runoff sample, a portion of which could deplete dissolved oxygen in receiving waters.

Composite Sample: Used to determine "average" loadings or concentrations of pollutants, such samples are collected at regular time intervals, and pooled into one large sample, can be developed on time or flow rate.

Confined Space: Enclosed space that an employee can bodily enter and perform assigned work, that has limited means of exit and entry, that is not designed for continuous employee occupancy, and has one of the following characteristics:

- Contains or has a known potential to contain a hazardous atmosphere
- Contains a material with the potential for engulfment of an entrant
- Has an internal configuration such that an entrant could be trapped or asphyxiated by inwardly converging walls or a floor that slopes downward and tapers to a smaller cross section
- Contains any other recognized serious safety or health hazard.

Conveyance: A channel or passage which conducts or carries water including any pipe, ditch, channel, tunnel, conduit, well, or container.

Detention Ponds: A surface water impoundment constructed to hold and manage storm water runoff.

Discharge: Any addition of any pollutant to waters of the U.S. from any conveyance.

Effluent: Any discharge flowing from a conveyance.

Flumes: A specially shaped open channel flow section providing a change in the channel area and/or slope which results in an increased velocity and change in the level of the liquid flowing through the flume. A flume normally consists of three sections: (1) a converging section; (2) a throat section; and (3) a diverging section. The flow rate through the flume is a function of the liquid level at some point in the flume.

Flow-Weighted Composite Sample: Means a composite sample consisting of a mixture of aliquots collected at a constant time interval, where the volume of each aliquot is proportional to the flow rate of the discharge.

Flow-Proportional Composite Sample: Combines discrete aliquots of a sample collected over time, based on the flow of the wastestream being sampled. There are two methods used to collect this type of sample. One collects a constant sample volume at time intervals which vary based on stream flow. The other collects aliquots at varying volumes based on stream flow, at constant time intervals.

First Flush: Individual sample taken during the first 30 minutes of a storm event. The pollutants in this sample can often be used as a screen for non-storm water discharges since such pollutants are flushed out of the system during the initial portion of the discharge.

Grab Sample: A discrete sample which is taken from a wastestream on a one-time basis with no regard to flow or time; instantaneous sample that is analyzed separately.

Head of Liquid: Depth of flow.

Illicit Discharge: Any discharge to a municipal separate storm sewer that is not composed entirely of storm water except discharges pursuant to an NPDES permit and discharges from fire fighting activities.

Materials Management Practices: Practices used to limit the contact between significant materials and precipitation. These may include structural or nonstructural controls such as dikes, berms, sedimentation ponds, vegetation strips, spill response plans, etc.

Municipal Separate Storm Sewer Systems: A conveyance or system of conveyances including roads with drainage systems, storm drains, gutters, ditches under the jurisdiction of a city, town, borough, county, parish, or other public body.

Outfall: Point source where an effluent is discharged into receiving waters.

Point Source: Any discernible, confined, and discrete conveyance from which pollutants are or may be discharged. This term does not include return flows from irrigated agriculture or agricultural storm water runoff (see 40 CFR 122.3).

Reverse Meniscus: The curved upper surface of a liquid in a container.

Runoff Coefficient: Means the fraction of total rainfall that will appear at the conveyance as runoff.

Significant Materials: Include, but are not limited to, raw materials, fuels, solvents, detergents, metallic products, CERCLA hazardous substances, fertilizers, pesticides, and wastes such as ashes, slag, and sludge that have potential for release with storm water discharges [see 40 CFR 122.26(b)(12)].

Storm Water: Storm water runoff, snow melt runoff, and surface runoff, and drainage.

Storm Water Discharge Associated with Industrial Activity: Discharge from any conveyance which is used for collecting and conveying storm water which is directly related to manufacturing processing or raw materials storage areas at an industrial plant [see 40 CFR 122.26(b)(14)].

Time Composite Sample: Prepared by collecting fixed volume aliquots at specified time intervals and combining into a single sample for analysis.

Turbidity: Describes the capability of light to pass through water.

Weir: A device used to gauge the flow rate of liquid through a channel; is essentially a dam built across an open channel over which the liquid flows, usually through some type of notch.

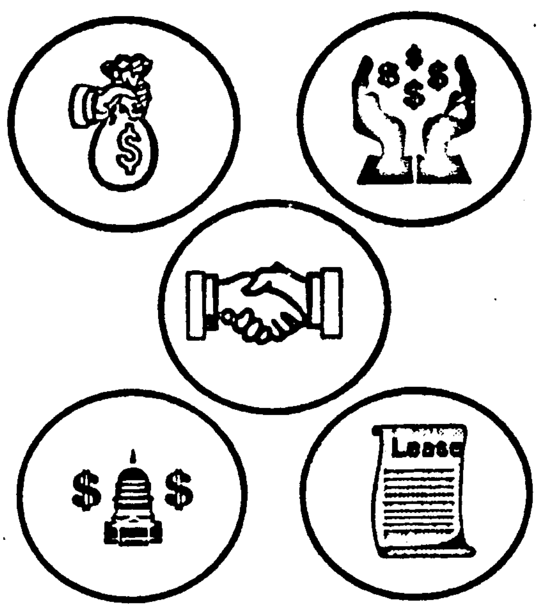
A State and Local Government Guide to Environmental Program Funding Alternatives



VOL 12

4796

Environmental Program Funding Alternatives

Implementation of environmental protection programs at the state and local levels often requires nonfederal government funding. Traditionally, funding for environmental programs has come from general revenue funds. Now that federal, state, and local governments are facing fiscal constraints, alternative sources of funding are becoming important options for implementing nonpoint source pollution controls and other environmental protection measures. Traditional sources of funding, such as taxes and bonds, are being supplemented by innovative funding sources like special license plates and income tax checkoffs.

There are four basic ways to fund public programs and facilities: current revenues (pay as you go), borrowing (bonding), intergovernmental transfers/assistance (fees or taxes collected by one level of government and passed on to another in the form of loans or grants), and public-private partnerships (private sector involvement in historically public sector activities). Since not every financing source or mechanism is appropriate for every state or local program, legal, administrative, and political aspects of financing must be taken into consideration when selecting funding alternatives.

This booklet provides an overview of traditional funding mechanisms and introduces state and local governments to innovative alternatives to traditional funding. The focus is on nonpoint source pollution, but funding sources and mechanisms can be applied to environmental programs in general. A list of contacts and references is included at the back of the booklet to answer questions and provide additional information.

VOL 12

Contents

What Are State Revolving Funds?

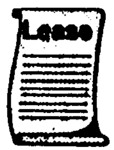
State Revolving Funds (SRFs) provide long-term, low-interest loans to local governments or individuals for capital investments. The repayment of these loans over time allows the fund to revolve its lending ability continuously. In other words, through repayments the number of available loans is increased. Established by the Clean Water Act Amendments of 1987, SRFs are intended to be administered and operated by the states to provide a permanent source of financing for state and local government water quality projects. SRF assistance can be used for the construction of wastewater treatment plants, the implementation of approved state nonpoint source management programs and ground-water protection strategies under section 319 of the

> ***California Uses State Revolving Fund to Control NPS Pollution***
>
> California uses part of its State Revolving Fund (SRF) for nonpoint source pollution control. The fund is administered by the State Water Board. The State Water Board has separated the administration of the fund from the wastewater treatment facilities program and has developed a flexible program that will evaluate and select for funding a wide variety of nonpoint source pollution control projects. Eligible projects include construction of demonstration projects, retention/detention basins, wetlands for stormwater treatment, and a variety of best management practices to reduce or remove nonpoint source pollutants. The nonpoint source program for the SRF also permits the establishment of substate revolving funds that can provide funding to private individuals to finance new onsite septic systems, mound systems, leach fields, etc.

VOL 12

Clean Water Act, and the development and implementation of estuary conservation and management plans under section 320 of the Clean Water Act.

What Are Leases?



A lease is a contract that allows another party to use land or a building for a specified time, usually in return for repayment. Leasing obligations aren't considered debt in most states, and voter approval for financing is not required.

A lease-purchase agreement (municipal lease) grants the party holding the property lease (the lessee) the option of applying lease payments to the purchase of the facility. The lessee is responsible for paying taxes. These agreements can be used to finance the purchase of environmentally sensitive areas, land for wetlands restoration, or other projects.

Georgia Leases Shellfish Beds to Commercial Fishermen

Georgia promotes oyster management through its innovative Shellfish Program. Georgia does not allow open shellfishing. Recreational harvesting by the general public takes place in designated public grounds, and commercial harvesters must obtain a lease for harvesting shellfish from the Georgia Department of Natural Resources, Coastal Resources Division. Leases are awarded on the basis of bids for a specific shellfish harvesting area. The bid is awarded to the most preferable combination of lease payments and the strongest management plan. The shellfish resource management plans are judged on the basis of certain criteria, such as shell deposition methods. Funds gained from the lease program are used to manage the shellfish program.

4-7-99

A sale-lease back arrangement allows the owner of a facility to sell it to another entity and subsequently lease it back from the new owner. Under a tax-exempt lease, for example, Town X sells a sewage treatment plant to Y Corporation in order to finance upgrades and repays Y Corporation's investment with lease payments. These arrangements can provide alternative financing for a facility and may limit a government's liability.

What Are Grants?

Grants are sums of money awarded to state or local governments or nonprofit organizations that do not need to be repaid. Grants are awarded for the purpose of financing a particular activity or facility.

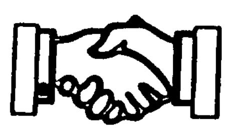
EPA grants provide funding for state and local governments to meet national environmental quality goals. EPA establishes criteria to receive grant funds, which applicants must meet before using the funds for a specific activity or program. Section 319 of the Clean Water Act allocates federal funds to states for implementing approved nonpoint source management programs. Grant money can also be used for post-implementation monitoring and groundwater assessment as part of an approved NPS pollution control program.

Sea Grant Funded through NOAA

The Sea Grant College Chesapeake Bay Studies Program is funded through an environmental research grant financed and administered by NOAA. The program provides a focal point for all of NOAA's Chesapeake Bay efforts. It funds research on fish populations, toxic substance transport, fate and effects, and remote sensing, and it coordinates directly with the state/federal Chesapeake Bay Program on issues related to living resources, habitat restoration, and coastal zone management.

Section 604(b) of the Clean Water Act requires an allotment of funds to provide grants to states to carry out water quality management planning. Section 314 of the Clean Water Act provides funding for project grants to states for assessing the water quality of publicly owned lakes, developing lake restoration and protection plans, implementing the plans to restore and preserve a lake, and performing post-restoration monitoring to determine the longevity and effectiveness of the restoration. Section 106 of the Clean Water Act provides state and interstate agencies and Indian tribes with funding to administer programs for the prevention, reduction, and elimination of water pollution, for example the prevention and abatement of surface water pollution. Other grant programs under the Clean Water Act include section 604(b) (Water Quality Management Planning), section 320 (National Estuary Program), section 104(b)(3) (Water Quality Cooperative Agreements), and section 104(g) (Small Community Outreach). Section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990 (CZARA) requires states to establish Coastal Nonpoint Source Programs, which must be approved by both NOAA and EPA. Approved programs will be implemented through changes to the state nonpoint source management program approved and funded by EPA under section 319 of the Clean Water Act and through changes to the state coastal zone management program approved by NOAA under section 306 of the Coastal Zone Management Act.

What Are Public-Private Partnerships?



Public-private partnerships can be defined as private sector involvement in what historically have been public sector activities. Private sector investment in capital facilities reduces the burden on public budgets. For example, a developer could build a stormwater facility large enough to also treat the runoff from nearby public roads. Partnerships can be used to pay for capital and/or operating costs, when neither the public nor the private entity can afford to fund the project alone. Capital arrangements involve private ownership and operation of a public facility. Private construction and operating costs are often lower than public costs.

> ***Wetlands Mitigation Partnership***
>
> The U.S. Army Corps of Engineers issued a permit to some Florida developers to restore a degraded 345-acre wetland on land owned by the city of Pembroke Pines. These entrepreneurs, who call themselves the Florida Wetlandsbank, sell credits to other developers who have impacted degraded wetlands elsewhere and have gained approval to satisfy the state's wetlands mitigation requirements through offsite mitigation. The Florida Wetlandsbank will transform the land into a public park.

Private sector wastewater treatment programs have been 15 to 20 percent more cost-efficient than public programs (USEPA, *The Clean Air Act of 1990: A Guide to Public Financing Options*). Public-private partnerships often result in higher-quality service and shorter implementation time, according to a 1991 survey of state officials. However, statutory or regulatory changes needed to arrange public-private partnerships may delay implementation of a program. Other issues that may need to be considered include government concern over loss of control in a partnership, political opposition from government workers, and negative public opinion.

What Are Taxes?

A tax is a charge against income, property, or the sale of goods and services. Most jurisdictions do not require that a tax be used for a specific purpose but instead use the funds to provide a variety of public services, such as solid waste management, public safety, education, and environmental programs. However, taxes can be targeted to raise funds for a specific activity.

VOL 12

4BCJ --

Property and sales taxes are charged as a percentage of property value or gross sales and are imposed at the state and local levels. Revenue from a property or sales tax can be used to fund projects. Dare County, North Carolina, for example, has an economy dominated by seasonal tourism. The county uses sales taxes on lodging, meals, and entertainment to obtain funds to finance public facilities that must accommodate the infra-structure needs of sudden, but temporary, population in-creases. Similar local sales taxes could be used by a state or local gov-ernment to fund nonpoint pollution control programs at the local level.

> **Annual NPS Control Tax**
>
> A proposal has been developed to charge Puget Sound, Washington, landowners an annual nonpoint source pollution control tax based on property size and land use. Owners with onsite sewage systems, live-stock, and parcels in areas required to develop comprehensive storm-water management plans would be assessed a surcharge if land uses are not managed to reduce nonpoint source pollution.

Real estate transfer taxes are assessed as a percentage of property values when property is sold. These taxes are imposed on property buyers, sellers, or both. Funds raised by such taxes could be dedicated to help pur-chase environmentally sensitive lands or to support resource conser-vation programs.

Commodity taxes are charged on specific items (commodities) such as gasoline, cigarettes, and hunting or fishing equip-ment. The money raised could be targeted for environmental programs or services. The federal gasoline tax, for example,

> **Tobacco Tax Used to Protect Water Quality**
>
> A tobacco tax helps finance Wash-ington State's water quality protec-tion plan. In 1986, the Washington legislature passed the Centennial Clean Water Act, which established a sales tax on tobacco products. The law dedicates half of the funds raised to the control of wastewater discharged directly into marine wa-ters and the other half to water qual-ity initiatives such as ground water protection.

> **Duck Stamps Used to Propagate Waterfowl**
>
> In 1974, the Maryland General Assembly enacted a bill requiring all who hunt waterfowl in the state to purchase a $1.10 stamp annually that must be signed by the hunter, affixed to his/her statewide license, and carried while hunting. Funds from the sale of the stamps are used for the propagation of waterfowl in the state. The cost of the stamp has since increased to $6.00, generating nearly $400,000 a year. Similar programs can be used to generate funds for a variety of environmental programs such as the purchase of environmentally sensitive habitat.

finances highway improvements. Since 1981, a tax on the diesel fuel consumed by tugboats has helped to finance maintenance of the Nation's system of inland waterways.

Tax surcharges are fees added to established tax rates. They are often used for sudden unforeseen events. A tax surcharge on residential sewer bills, for instance, might be used to finance the replacement of stormwater retention basins destroyed during a hurricane.

Tax incentives and disincentives. A tax system can be set up to encourage or discourage certain behaviors by offering tax reductions or

> **Tax Incentives**
>
> Road capacity can be allocated more efficiently by taxing its users during peak travel times. This tax takes the form of a "congestion toll." It can be used as an incentive to travel before or after rush hour, take the bus, or carpool. The resultant decrease in traffic could reduce capital outlays for highways by making many expansion projects unnecessary. In regions facing severe transportation and air pollution problems, such as southern California, road-use tolls are being implemented. A system of congestion tolls for drivers crossing the San Francisco-Oakland Bay Bridge began in September 1993.
>
> Water can be allocated more efficiently by imposing higher prices during peak hours of use or an increased fee for water use above an allocated amount. This economic incentive fosters conservation.

increases. Incentives often take the form of state tax credits, deductions, or rebates. A tax credit for the use of low-flow plumbing fixtures, for example, can encourage water efficiency. Because of the desire to save money, disincentives often take the form of fees, taxes, or price increases. A tax or fee can discourage the inefficient use of a product because of the increased cost of using more of a product than needed.

Tax differentiation is a tax incentive used to promote the consumption of environmentally safe products. This financing mechanism involves a surcharge added to the cost of a polluting product to encourage the consumer to purchase a cleaner alternative.

A selective sales tax can be levied either as a retail tax or as an inspection fee. Kansas, for example, charges a per-ton fertilizer inspection fee, with proceeds going to support the State Water Plan. A selective sales tax could fund remediation of agricultural nonpoint source pollution or could fund research on farming techniques to reduce environmental impacts. This tax could apply to pesticides, herbicides, automotive lubricants, etc.

Tax increment financing is the dedication of incremental increases in real estate taxes to repay an original investment in improved public facilities, such as stormwater facilities, that resulted in increased real estate values. Tax increment financing is appropriate for areas

Tax Increment Financing Used to Redevelop Depressed Areas

Tax increment financing is appropriate for areas where substantial new development is probable. The City of Orlando, Florida, for example, created a Community Redevelopment Trust in 1982 to establish a fund to redevelop depressed areas of the city. The city created a series of revenue bonds to finance public housing, transportation, and other capital investment. These bonds are not a general obligation of the trust or the City of Orlando; they are secured by an irrevocable lien on the increment in property tax revenues paid into the Trust Fund and interest earned by the Trust Fund.

where substantial new development is anticipated as a result of public investment in roads, sewers, or other infrastructure. A cleaner watershed, for instance, could boost neighboring property values. The tax increment created could be used to support continued environmental protection programs.

What Are Fees?

Fees are charges for services rendered and are one way for governments to recover the costs of providing certain services to the public. Although laws vary widely, many states require that fees be set at rates that cover only the actual costs of the services provided, including administrative services.

Stormwater Utility Fees

There are more than 100 stormwater utilities in the United States. Methods of determining stormwater utility charges vary considerably around the country, depending on local stormwater management goals and conditions. In general, utilities are either publicly owned and operated enterprises or privately owned enterprises whose ability to profit from providing public services is regulated by a public agency. Utility fees provide a more reliable source of funds for local stormwater management than do property taxes.

Plan review fees are assessed by a local government for conducting a review of development plans to ensure that they meet certain requirements. This technical review is used to determine the adequacy of stormwater management facilities or erosion and sediment controls and to ensure proper siting of structures or onsite sewage disposal systems. These fees help cover the cost of conducting plan reviews and inspections.

Stormwater utility fees are imposed on property owners to pay for stormwater management. The charge can be based on the amount of runoff generated from the property, the amount of impervious area (hard surfaces) on the property, or the assessed value of the property.

Impact fees transfer the costs of infrastructure services (roads, sewers, stormwater treatment, etc.) needed for private development directly to developers or property owners. Unlike user fees, which recover costs over the life of a project, impact fees are usually collected in one lump sum at the beginning of a project. These fees are particularly attractive to local governments because they relieve up-front financing pressures on local budgets. In California, for example, several wastewater treatment plants have been financed with fees paid by developers based on the projects' anticipated treatment requirements. Impact fees can be used to fund the installation and maintenance of stormwater management facilities on newly developed sites.

> ***Impact Fees for New Development***
>
> Carroll County, Maryland, charges an impact fee on new land development. The amount of the fee depends on the type of development (i.e., a single-family home, commercial development, etc.). These fees fund a variety of programs ranging from water supply protection to elementary school education.

Inspection fees are charged to cover the costs of making sure that development plans are properly implemented. These fees may defray the program costs of erosion and sediment control, septic system siting and installation inspections, and stormwater treatment facility operation and maintenance.

> ***Homeowners Pay Inspection and Operation and Maintenance Fees***
>
> Otter Tail County, Minnesota, has developed an onsite utility to protect its lakes from contamination due to onsite sewage disposal system failures. All onsite system owners pay a basic fee for inspections and administration costs and have the option to pay an additional amount for additional services. Operation and maintenance costs are financed by fees paid by homeowners.

User fees are the most common way to recover the costs of providing a service. These fees can be tied directly to the use of a resource or facility (sports fishing and hunting license fees, park entrance fees, etc.). User fees are particularly useful at the local level where user groups are easily identified.

Product charges, similar to commodity taxes, are fees that can be added to the price of products that could potentially cause degradation of water quality, such as nonreturnable containers, batteries, lubricating oil, fertilizers, and pesticides. These revenues can be earmarked for environmental programs.

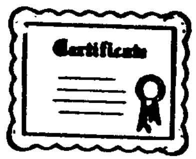
Capacity credits are a form of financing in which private interests (usually developers) purchase future capacity in a public facility such as a stormwater treatment facility. Applicants are guaranteed future access to the excess capacity of that particular facility. Where project construction hinges on adequate funding, capacity credits can contribute to project completion.

Effluent discharge fees are levied on an industrial facility by a government authority, based on the volume of pollutants discharged into water. Under an effluent discharge fee system, a discharger is required to pay a certain amount for every unit of pollution discharged into surface water. The system can be based on water quality objectives, the costs for financing a pollution abatement scheme, or effluent standards. The system has several advantages: it allows firms to reduce pollution at lower costs than those incurred under a

> ***Effluent Discharge Fees for Industrial and Municipal Sources***
>
> Wisconsin has established an unusually comprehensive fee system for its water program to recover total direct and indirect program costs. The state issues general permits and levies permit fees for discharges based on volume and type of pollutant. Such pollutants are associated with various industrial sources or users, such as concrete products operations; sand, gravel, or crushed stone operations; swimming pools; petroleum storage terminals; water treatment plants; and dredging projects involving uncontaminated sediments. This effluent discharge fee program generated more than $7 million in 1993.

command-and-control approach; it provides incentives to firms to invest in pollution control technology; and it can generate revenue that can be used to fund activities that promote environmental quality. The disadvantages of the charge system are the complex planning, analysis, monitoring, enforcement, litigation, and interjurisdictional negotiation required by local authorities. In addition, assigning monetary values to pollution damage may be difficult.

What Are Bonds?



Bonds are a mechanism to borrow capital for a project and distribute the burden of repayment over the life span of the project among those who benefit from it. Just as individuals borrow to finance their homes through bank-issued mortgages, governments borrow funds from investors by issuing debt in the form of bonds. Bonds usually finance capital facilities, such as erosion control structures and stormwater treatment facilities. Typically, bonds are used only to finance projects that have both known and proven life expectancies.

$75 Million Bond Passed to Protect Environmentally Sensitive Lands

Broward County, Florida, residents voted to pass a $75 million bond to purchase environmentally sensitive lands. The money has been used to purchase more than 560 acres of wetlands, pristine uplands, endangered species habitat, and lands necessary for maintaining the integrity of the Everglades ecosystem. Initial site maintenance (exotic plant removal, fencing, etc.) will be paid for with bond money. Long-term maintenance will be funded as part of the county parks department's operating budget.

Short-term bonds are usually payable within 1 year. Establishing short-term debt provides interim funding of projects waiting to receive long-term financing. There are two categories of short-term bonds: notes and

tax-exempt commercial paper. Notes are loans issued in anticipation of grants, bonds, or taxes. Tax-exempt commercial paper is a form of unsecured debt backed by a letter or line of credit.

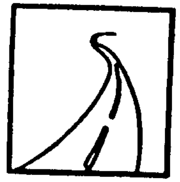
Long-term bonds traditionally match the term of financing with the life expectancy of the project. A stormwater treatment facility, for example, might be expected to perform adequately for 30 years; therefore, the community could issue bonds that have a term of up to 30 years. There are two categories of long-term bonds. Term bonds are loans for which the entire loan amount and interest are payable on the final maturity date. Serial bonds are similar to traditional home mortgages: the principal and interest are repaid in periodic installments over the life of the bond. Long-term bonds can be issued as general obligation bonds or as revenue bonds, as described below.

General obligation bonds are long-term municipal bonds that are backed by the full faith and credit of the state or local government. This means that the state or local government pledges to use all of its taxing and other revenue-raising powers to repay bond holders. Both state and local governments have used general obligation bonds to finance capital projects related to environmental programs, including purchases of environmentally sensitive lands.

Revenue bonds are long-term municipal bonds guaranteed solely by the dedication of project income or system funds (e.g., user fees from the infrastructure where capital costs are covered by the bond) rather than by a general tax. Both state and local governments have used revenue bonds to provide start-up capital for stormwater utilities and to finance environmental projects, including the renovation of wastewater treatment plants.

Bond banks, of which there are at least 11 across the country, are financial institutions created primarily to provide smaller communities access to the national bond market to finance infrastructure projects. Typically, a bond bank either sells bonds in the bond market and uses the proceeds to purchase bonds from local communities or buys bonds directly from local communities and pools several small issues into one large bond issue to be sold in the bond market. Small communities could take advantage of bond banks to finance environmental infrastructure projects.

Look to the Future... Pollutant Trading



Point and nonpoint source pollutant trading involves financing reductions in nonpoint source pollution in lieu of undertaking more expensive point source pollution reduction efforts. A trading program is intended to produce cost savings to point source dischargers while improving water quality. Implementing a trading program requires a waterbody identifiable as a watershed or segment, as well as a measurable combination of point sources and controllable nonpoint sources. There must be significant load reductions for which the cost per pound reduced for nonpoint source controls is lower than the cost for upgrading point source controls. Lastly, point source dischargers must face requirements to either upgrade facility treatment capabilities or trade for nonpoint source reductions in order to meet water quality goals.

Such a program allows the private sector to allocate its resources to reduce pollutants in the most cost-effective manner, and it encourages the development of a watershed-wide or basin-wide approach to water quality protection. Such a program also entails cooperation between agencies, however, and requires a

Pollutant Trading for Nutrients

In a North Carolina watershed, the Tar-Pamlico Basin Association (a coalition of point source dischargers) and state and regional environmental groups have proposed a two-phased nutrient management strategy that incorporates point and nonpoint source pollutant trading. The plan requires association members to finance nonpoint source reduction activities in the basin if their nutrient discharges exceed a base allowance.

system to arrive at trading ratios between point and nonpoint source controls.

Be Creative!

The State of Maryland has been imaginative in its acquisition of funding to restore the Chesapeake Bay. The Chesapeake Bay Trust was created in 1985 to bring the financial support of the business community and private donors together with the many community groups and educators that need financial assistance for their Bay projects. Maryland's programs exemplify successful implementation of innovative funding alternatives.

State lotteries are becoming a potential source of revenue for environmental programs. For

License Plates to Save the Bay

The State of Maryland has implemented a license plate program to fund its Chesapeake Bay Trust. More than 400,000 "Treasure the Chesapeake" license plates have been sold, raising more than $4 million. In the Baltimore area, automobile dealers offered Bay license plates at no cost to their new car and truck customers by paying the $10 fee in June and July 1992, raising $20,000 for the Trust.

Tax Checkoff to Fund Restoration and Conservation Programs

Maryland's tax checkoff for the Chesapeake Bay and Endangered Species Fund is included on the standard tax form. Taxpayers can contribute a portion of their taxes to the fund, which yielded a record $1.1 million in 1992. Divided equally between the Chesapeake Bay Trust and the Department of Natural Resources' Endangered Species Fund, the checkoff funds a variety of Bay restoration and conservation programs.

VOL 12

4865

Lottery Revenues

Kansas uses a portion of its lottery receipts to help finance its water resource management programs, including wetland protection activities. Kansas created the State Water Plan Fund in 1989, for which half of the revenues are derived from the state general fund and state lottery funds. The other half are derived from a system of fees on municipal water use, industrial water use, stockwater use, pesticides, fertilizers, and pollution fines and penalties. In Minnesota, voters approved state constitutional amendments establishing the Environmental and Natural Resources Trust Fund and a state lottery to finance the fund.

example, Kansas and Minnesota use lottery receipts to help finance natural resource management programs.

Comparing Your Options

Several funding alternatives may be available for a particular project. For example, the following four funding strategies to control solid waste could easily be adapted to fund nonpoint source programs: property taxes, tax incentives/disincentives, user fees, or tax surcharges. Funding for regional stormwater management facilities or a shoreline erosion control project could be obtained in similar ways.

Capital and operating costs and cost-effectiveness must be carefully analyzed before choosing a funding alternative. Legal, administrative, and political aspects and impacts of each alternative need to be considered. One must consider the legal workability and political attractiveness of a financing mechanism; the effort needed for implementation, including start-up costs and costs for ongoing collection and management of funds; the fairness of distribution of the funding burden among individuals; and the public's willingness to pay or to make a particular sector pay.

Four Funding Strategies to Control Solid Waste

Tax Incentive/Disincentive

Estherville, Iowa, uses the pay-by-the-bag approach to trash collection. This system gives households an incentive to recycle, compost, and change their buying habits to reduce the volume of waste they generate.

Property Tax

Fairfax City, Virginia, uses property taxes to finance trash collection. Residents are charged a flat annual amount that is not related to the volume or type of trash they discard.

User Fee

Hollywood, Florida, charges residents a standard monthly "fee" for solid waste management services. This establishes a direct link between those who use the services and those who pay for them.

Tax Surcharge

Oregon funds solid waste management through proceeds from the Bottle Bill, a law that requires consumers to pay a deposit on each container purchased. The deposit is refunded when the container is returned for recycling.

Additional Information on Selected Reference Materials

USEPA. 1992. *Alternative Financing Mechanisms for Environmental Programs*. Final draft. Office of Administration and Resources Management.

This report provides information to resolve two types of funding shortfalls: state capacity (program personnel) and capital infrastructure needs. This comprehensive encyclopedia of alternative financing mechanisms can be used as an information resource for states and local governments. It is intended to provide information about principal features of alternative financing mechanisms, their relative advantages and disadvantages (with particular attention given to administrative considerations), and some of the key questions and issues associated with their use.

For more information contact: U.S. EPA, Office of Administration and Resources Management, Office of the Comptroller, Resource Management Division (3304), 401 M Street, SW, Washington, DC 20460, (202) 260-1020.

U.S. EPA's Environmental Financing Information Network (EFIN)

EPA's Office of Water has opened the Environmental Financing Information Network (EFIN) to disseminate financial information to public entities. This electronic bulletin board system provides information on financing alternatives for state and local environmental programs and projects. You can use EFIN to ask your own questions about environmental financing approaches, publications, and activities. Answers will be provided by EPA staff and a wide audience of local government users.

For more information contact: U.S. EPA, EFIN Center, Environmental Finance Program, Resource Management Division (3304), 401 M Street, SW, Washington, DC 20460, (202) 260-0710.

Document Distribution Centers

There are five national sources for the distribution of EPA publications:

EPA's Public Information Center (PIC)
Phone: (202) 260-7751 Fax: (202) 260-6257
The PIC provides the main contact between the public and EPA with a visitor's center featuring environmental videos, photographic displays, and databases.

Center for Environmental Research Information (CERI)
Phone: (513) 569-7562 Fax: (202) 260-6257
CERI is the focal point for the exchange of scientific and technical environmental information produced by EPA. It supports the activities of the Office of Research and Development, its laboratories, and associated programs nationwide.

National Center for Environmental Publications and Information (NCEPI)
Phone: (513) 891-6561 Fax: (513) 569-6685
The central dissemination point for EPA is NCEPI, which has 4,200 current titles and more than 9 million copies of publications and multimedia products. NCEPI has an electronic ordering and inventory system available on EPA's mainframe for EPA staff. The system links EPA regions, program offices, and field offices.

National Technical Information Service (NTIS), U.S. Department of Commerce
Phone: (703) 487-4650 Fax: (703) 321-8547

U.S. Government Printing Office (GPO)

FOREWORD

This document contains proposed guidance specifying management measures for sources of nonpoint pollution in coastal waters. Nonpoint pollution is the pollution of our Nation's waters by runoff from the land surface. In the Coastal Zone Act Reauthorization Amendments of 1990, Congress recognized that nonpoint pollution is a key factor in the continuing degradation of many coastal waters, and established a new program to address this pollution.

The new program established by Congress recognizes that the solution to nonpoint pollution lies in State and local action. It calls for the development and implementation of State coastal nonpoint pollution programs. These State programs are to be developed in conformity with technical guidance developed by EPA on the best, economically achievable measures available to protect coastal waters from nonpoint pollution. This document proposes that "management measures guidance."

The proposed management measures guidance addresses five source categories of nonpoint pollution: agriculture, silviculture, urban, marinas, and hydromodification. A suite of management measures is provided for each source category. The number and type of systems identified per source category are based upon the range and diversity of substantively different subcategories, activities, and pollutants. In addition, the guidance contains a chapter that provides information on other tools available to address many source categories of nonpoint pollution; these include vegetated filter strips, forested buffer strips, and wetlands. EPA regards this proposed guidance as a significant beginning to a year-long process of refinement, ending with publication of the final guidance in May 1992. We welcome public comments, information and data relevant to this continuing effort.

EPA will also soon be publishing, jointly with the National Oceanic and Atmospheric Administration, proposed guidance for the approval of State programs that implement management measures. That guidance will explain more fully how the management measures guidance proposed today would be implemented in State programs. EPA encourages reviewers of this document to review and comment upon that forthcoming guidance as well.

Robert H. Wayland, III, Director,
Office of Wetlands, Oceans, and Watersheds

CHAPTER 1

INTRODUCTION

I. BACKGROUND

This proposed guidance on management measures is required under section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990. It provides guidance to States and Territories on the types of management measures that should be included in State and Territorial coastal nonpoint pollution control programs. This Chapter explains in detail the statutory requirements, the approach used to develop management measures, and the process for developing final management measures guidance, and discusses issues related to State program development and approval. While the program development and approval issues discussed in this Chapter provide a framework for understanding the management measures guidance, the issues will be more fully developed in draft program guidance scheduled to be published for public comment in July 1991.

A. Nonpoint Source Pollution

1. What Is Nonpoint Source Pollution?

Nonpoint source pollution is the pollution of our nation's waters from diffuse sources. It is caused by rainfall or snowmelt moving over and through the ground and carrying natural and manmade pollutants into lakes, rivers, streams, wetlands, estuaries, other coastal waters, and ground water. (As discussed below, some diffuse sources are regulated under the NPDES program as point source discharges.)

A more detailed discussion of the range of nonpoint sources and their effects on water quality and riparian habitats is provided in subsequent chapters of this guidance.

2. National Efforts to Control Nonpoint Pollution

a. Nonpoint source program

During the first fifteen years of the national program to abate and control water pollution, EPA and the States have focused most of their water pollution control activities upon traditional "point sources", such as discharges through pipes from sewage treatment plants and industrial facilities. These point sources have been regulated by EPA and the States through the National Pollutant Discharge Elimination System (NPDES) permit program established by Section 402 of the Clean Water Act. Discharges of dredged and fill materials into wetlands have also been regulated by the U.S. Army Corps of Engineers and EPA under Section 404 of the Clean Water Act.

As a result of the above activities, the Nation has greatly reduced pollutant loads from point source discharges and has made considerable progress in restoring and maintaining water quality.

VOL 12

4832

However, the gains in controlling point sources have not solved all of the nation's water quality problems. Recent studies and surveys by EPA and by State water quality agencies indicate that the majority of the remaining water quality impairments in our nation's rivers, streams, lakes, estuaries, coastal waters, and wetlands result from nonpoint source pollution and other nontraditional sources, such as urban stormwater discharges and combined sewer overflows.

In 1987, given the progress achieved in controlling point sources, coupled with the growing national awareness of the increasingly dominant influence of nonpoint source pollution on water quality, Congress amended the Clean Water Act to focus greater national efforts on nonpoint sources.

In the Water Quality Act of 1987, Congress amended Section 101, "Declaration of Goals and Policy", to add the following fundamental principle:

> It is the national policy that programs for the control of nonpoint sources of pollution be developed and implemented in an expeditious manner so as to enable the goals of this Act to be met through the control of both point and nonpoint sources of pollution.

More importantly, Congress enacted Section 319 of the Clean Water Act, which established a national program to control nonpoint sources of water pollution. Under Section 319, States address nonpoint pollution by assessing nonpoint source pollution problems and causes within the State; adopting management programs to control the nonpoint source pollution; and implementing the management programs. Section 319 provides for the issuance by EPA of grants to States to assist them in implementing those management programs or portions of management programs that have been approved by EPA.

b. National estuary program

EPA also administers the National Estuary Program under Section 320 of the Clean Water Act. This program focuses upon point and nonpoint pollution in geographically targeted, high-priority estuarine waters. In this program, EPA assists State, regional and local governments to develop comprehensive conservation and management plans that recommend priority corrective actions to restore estuarine water quality, fish populations, and other designated uses of the waters.

c. Pesticides program

Another program administered by EPA that controls some forms of nonpoint pollution is the pesticides program under the Federal Insecticide, Fungicide, and Rodenticide Act. Among other things, this program authorizes EPA to control pesticides that may threaten ground and surface water. This approach entails determining the pesticide's potential for leaching into ground and surface waters; if there is such potential, determining whether national-label restrictions will adequately address leaching concerns; if not, determining whether additional training required by restricted use classification for the pesticide will provide adequate protection; and if not, determining whether providing States with the opportunity to develop State Management Plans for the chemical will effectively address the contamination risk. In the event EPA cannot determine that State plans would sufficiently reduce the risks to human health and the environment (i.e., an unreasonable risk remains), then EPA would resort to national cancellation.

EPA's approach to State management is described in a proposed Pesticides and Ground-Water Strategy currently undergoing review by the Office of Management and Budget. The strategy describes the policies and regulatory approaches that the Agency will use to protect the Nation's ground-water resources from risks of contamination by pesticides. Linkage to and integration with other evolving EPA/State programs is critical in order to avoid duplication of effort while promoting related activities.

B. Coastal Zone Management

The Coastal Zone Management Act of 1972 established a program for States and Territories to voluntarily develop comprehensive programs to protect and manage coastal resources (including the Great Lakes). In order to receive federal approval and implementation funding, States and Territories had to demonstrate that they had programs, including enforceable policies, that were sufficiently comprehensive and specific to regulate land uses, water uses, and coastal development; and to resolve conflicts among competing uses. In addition, they had to have the authorities to implement the enforceable policies.

There are 29 federally approved State and Territorial programs. Despite institutional differences, each program must protect and manage important coastal resources, including: wetlands, estuaries, beaches, dunes, barrier islands, coral reefs, and fish and wildlife and their habitats. Resource management and protection is accomplished in a number of ways through State laws, regulations, permits, and local plans and zoning ordinances.

While water quality protection is integral to the management of many of these coastal resources, it was not specifically cited as a purpose or policy of the original statute. The Coastal Zone Act Reauthorization Amendments of 1990 described below specifically charged State coastal programs, as well as State nonpoint source programs, with addressing nonpoint source pollution affecting coastal water quality.

C. Coastal Zone Act Reauthorization Amendments of 1990

1. Background and Purpose of the Amendments

On November 5, 1990, Congress enacted the Coastal Zone Act Reauthorization Amendments of 1990. These Amendments were intended to address several concerns, a major one of which is the impact of nonpoint source pollution on coastal waters. In Section 6202(a) of the Amendments, Congress made a set of findings; the following findings are pertinent here:

"1. Our oceans, coastal waters, and estuaries constitute a unique resource. The condition of the water quality in and around the coastal area is significantly declining. Growing human pressures on the coastal ecosystem will continue to degrade this resource until adequate actions and policies are implemented.

"2. Almost one-half of our total population now lives in coastal areas. By 2010, the coastal population will have grown from 80,000,000 in 1960 to 127,000,000 people, an increase of approximately 60 percent, and population density in coastal counties will be among the highest in the Nation.

"3. Marine resources contribute to the Nation's economic stability. Commercial and recreational fishery activities support an industry with an estimated value of $12,000,000,000 a year.

"4. Wetlands play a vital role in sustaining the coastal economy and environment. Wetlands support and nourish fishery and marine resources. They also protect the Nation's shores from storm and wave damage. Coastal wetlands contribute an estimated $5,000,000,000 to the production of fish and shellfish in the United States coastal waters. Yet, 50 percent of the Nation's coastal wetlands have been destroyed, and more are likely to decline in the near future.

"5. Nonpoint source pollution is increasingly recognized as a significant factor in coastal water degradation. In urban areas, storm water and combined sewer overflow are linked to major coastal problems, and in rural areas, runoff from agricultural activities may add to coastal pollution.

"6. Coastal planning and development control measures are essential to protect coastal water quality, which is subject to continued ongoing stresses. Currently, not enough is being done to manage and protect coastal resources.

. . . .

"8. There is a clear link between coastal water quality and land use activities along the shore. State management programs under the Coastal Zone Management Act of 1972 (16 U.S.C. 1451 et seq.) are among the best tools for protecting coastal resources and must play a larger role, particularly in improving coastal zone water quality. . . ."

Based upon these findings, Congress declared that:

"It is the purpose of Congress in this subtitle [the Coastal Zone Act Reauthorization Amendments of 1990] to enhance the effectiveness of the Coastal Zone Management Act of 1972 by increasing our understanding of the coastal environment and expanding the ability of State coastal zone management programs to address coastal environmental problems." (Section 6202(b))

VOL 12

2. State Coastal Nonpoint Pollution Control Programs

To address more specifically the impacts of nonpoint source pollution on coastal water quality, Congress enacted Section 6217, "Protecting Coastal Waters". This section provides that each State with an approved coastal zone management program must develop and submit to EPA and NOAA for approval a Coastal Nonpoint Pollution Control Program. The purpose of the program "shall be to develop and implement management measures for nonpoint source pollution to restore and protect coastal waters, working in close conjunction with other State and local authorities."

Coastal nonpoint pollution control programs are not intended to supplant existing coastal zone management programs and nonpoint source management programs. Rather, they are to serve as an update and expansion of existing nonpoint source management programs and are to be coordinated closely with the existing coastal zone management programs. The legislative history indicates that the central purpose of section 6217 is to strengthen the links between Federal and State coastal zone management and water quality programs and to enhance State and local efforts to manage land use activities which degrade coastal waters and coastal habitats. The legislative history further indicates that State coastal zone and water quality agencies are to have co-equal roles, analogous to the sharing of responsibility between NOAA and EPA at the Federal level.

Section 6217(b) states that each State program must "provide for the implementation, at a minimum, of management measures in conformity with the guidance published under subsection (g) to protect coastal waters generally," and also to:

(1) Identify land uses which, individually or cumulatively, may cause or contribute significantly to a degradation of (a) coastal waters where there is a failure to attain or maintain applicable water quality standards or protect designated uses, or (b) coastal waters that are threatened by reasonably foreseeable increases in pollution loadings from new or expanding sources;

(2) Identify critical coastal areas adjacent to coastal waters identified under the preceding paragraph;

(3) Implement additional management measures applicable to land uses and areas identified under paragraphs (1) and (2) above that are necessary to achieve and maintain applicable water quality standards and protect designated uses;

(4) Provide technical assistance to local governments and the public to implement management measures;

(5) Provide opportunities for public participation in all aspects of the program;

4836

(6) Establish mechanisms to improve coordination among State and local agencies and officials responsible for land use programs and permitting, water quality permitting and enforcement, habitat protection, and public health and safety; and

(7) Propose to modify State coastal zone boundaries as necessary to implement NOAA recommendations under Section 6217(e), which are based on findings that inland boundaries must be modified to more effectively manage land and water uses to protect coastal waters.

EPA is required to publish proposed management measures guidance under section 6217(g) by May 1991 and final guidance by May 1992. Within 30 months of EPA's publication of final guidance, States must develop and obtain EPA and NOAA approval of their coastal nonpoint pollution control programs. Failure to submit an approvable program (i.e., one that meets the requirements of section 6217(b)) results in a reduction of Federal grant dollars under the nonpoint source and coastal zone management programs. The reductions begin in Fiscal Year 1996 as a 10% cut, increasing to 15% in FY 1997, 20% in FY 1998, and 30% in FY 1999 and thereafter.

3. Management Measures Guidance

Section 6217(g) of the Coastal Zone Act Reauthorization Amendments of 1990 requires EPA to publish (and periodically revise thereafter), in consultation with NOAA, the Fish and Wildlife Service, and other Federal agencies, "guidance for specifying management measures for sources of nonpoint pollution in coastal waters." "Management measures" are defined in section 6217(g)(5) as:

> economically achievable measures for the control of the addition of pollutants from existing and new categories and classes of nonpoint sources of pollution, which reflect the greatest degree of pollutant reduction achievable through the application of the best available nonpoint pollution control practices, technologies, processes, siting criteria, operating methods, or other alternatives.

The management measures guidance is to include at a minimum six elements set forth in section 6217(g)(2):

"(A) a description of a range of methods, measures, or practices, including structural and nonstructural controls and operation and maintenance procedures, that constitute each measure;

"(B) a description of the categories and subcategories of activities and locations for which each measure may be suitable;

"(C) an identification of the individual pollutants or categories or classes of pollutants that may be controlled by the measures and the water quality effects of the measures;

VOL 12

4837

R0038145

"(D) quantitative estimates of the pollution reduction effects and costs of the measures;

"(E) a description of the factors which should be taken into account in adapting the measures to specific sites or locations; and

"(F) any necessary monitoring techniques to accompany the measures to assess over time the success of the measures in reducing pollution loads and improving water quality."

State coastal nonpoint pollution control programs must implement management measures that are in conformity with this management measures guidance.

The legislative history (Floor statement of Rep. Gerry Studds, House Sponsor of Section 6217, as part of debate on Omnibus Reconciliation Bill, October 26, 1990) confirms that, as indicated by the statutory language, the "management measures" approach is technology-based rather than water-quality based. That is, the management measures, in a manner analogous to the technology-based requirements previously established for point sources, are to be based upon technical and economic achievability, rather than on establishing cause and effect linkages between particular land use activities and particular water quality problems. Congress' rationale is that, with few exceptions, neither States nor EPA have the money or the time to create the complex monitoring programs that would be required to document a causal link between specific land use activities and specific water quality problems. Under the approach adopted by Congress, States will be able to concentrate their resources on developing and implementing measures that experts agree will reduce pollution significantly.

The legislative history indicates that the range of management measures anticipated by Congress is broad and may include, among other measures, use of buffer strips, setbacks, techniques for identifying and protecting critical coastal areas and habitats, soil erosion and sedimentation controls, and siting and design criteria for water-related uses such as marinas. However, Congress has cautioned that the management measures should not unduly intrude upon the more intimate land use authorities properly exercised at the local level.

The legislative history also indicates that the management measures guidance, while patterned to a degree after the point source effluent guidelines technology-based approach (see 40 CFR Parts 400-471 for examples of this approach), is not expected to have the same level of specificity as effluent guidelines. Congress has recognized that the effectiveness of a particular management measure at a particular site is subject to a variety of factors too complex to address in a single set of simple, mechanical prescriptions developed at the federal level. Thus, the legislative history indicates that EPA's guidance should offer State officials a number of options and permit them considerable flexibility in selecting management measures that are appropriate for their State.

An additional major distinction drawn in the legislative history between effluent guidelines for point sources and management measures guidance is that the management measures will not be directly or automatically applied to categories of nonpoint sources as a matter of Federal law.

VOL 12 4838

Instead, the measures must be established under State law, or under local authorities as described through the State coastal nonpoint pollution control program. The State program must provide for the implementation of management measures in conformity with the management measures guidance. Under section 306(d)(16) of the CZMA, coastal zone programs must provide for enforceable policies and mechanisms to implement the applicable requirements of the State coastal nonpoint pollution control program, including management measures.

II. DEVELOPMENT OF PROPOSED MANAGEMENT MEASURES GUIDANCE

A. Schedule and Process Used to Develop Proposed Guidance

1. Schedule

Congress established a six-month deadline (May 5, 1991) for publication of this proposed guidance, and an eighteen-month deadline (May 5, 1992) for publication of the final guidance.

Given the extremely tight statutory deadline for publishing proposed guidance, EPA has worked to make this proposed guidance as broad and comprehensive as possible. To assist the public in commenting on the proposal, we have included below a discussion of our plans for completing the guidance by May 1992. While significant revisions are likely over the course of the next twelve months, we hope that this proposed guidance clearly outlines EPA's direction and technical approach being considered for the final guidance, thereby providing for fair opportunity for review and comment by interested persons, organizations, and agencies.

2. Work Groups

To meet the tight statutory deadline and draw upon existing sources of technical nonpoint source expertise, EPA chose a work group approach to develop the guidance. Since the guidance is to address all significant categories of nonpoint sources that impact or could impact coastal waters (see Background), EPA drew upon expertise covering the very wide range of subject areas addressed in this guidance.

Because nonpoint experts tend to specialize in particular source categories, EPA decided to form work groups on a category basis. Thus, in consultation with NOAA, the U.S. Fish and Wildlife Service, and other Federal and State agencies, EPA established five work groups to develop this proposed guidance:

(1) Urban, Construction, Highways, Airports/Bridges, and Septic Systems
(2) Agriculture
(3) Forestry
(4) Marinas and Recreational Boating
(5) Hydromodification, Dams and Levees, Shoreline Erosion, and Wetlands

VOL 12

4839

A list of the members in each of these Federal-State workgroups is provided in Appendix A of this guidance.

3. Meetings

EPA focused its initial efforts on briefing various governmental and other groups on the scope of the new coastal legislation; obtaining a broad range of input on potential approaches to developing the management measures guidance; scoping out options for writing management measures; and inviting participation by various interested EPA and NOAA offices and other Federal and State agencies in the work groups.

Some of the groups that EPA met with to discuss potential approaches to implementing the new legislation include the Association of State and Interstate Water Pollution Control Administrators (ASIWPCA), the Coastal States Organization (CSO), several Federal agencies, and the Natural Resources Defense Council.

On January 16, 1991, EPA held the first work group meeting, attended by over 30 Federal and State agency staff with expertise in coastal nonpoint pollution issues. That meeting resulted in commitments for assistance and, in some cases, substantial participation in the effort, especially by USDA and NOAA. Each workgroup has held at least one meeting since February, 1991, with the agriculture work group meeting three times and the urban group holding a two-day meeting. Other groups have utilized teleconferencing for additional communication. Both Federal and State work group members have participated in drafting and reviewing this proposed guidance.

B. Scope and Contents of This Proposed Guidance

1. Categories of Nonpoint Sources Addressed

Many categories and subcategories of nonpoint sources could affect coastal waters and thus could potentially be addressed in this management measures guidance. Including all such sources in this proposed guidance would require more time than the tight statutory deadline allows. For this reason, Congressman Studds stated in his floor statement, "The Conferees expect that EPA, in developing its guidance, will concentrate on the large nonpoint sources that are widely recognized as major contributors of water pollution."

This proposed guidance thus focuses on five major categories of nonpoint sources that impair or threaten coastal waters nationally: (1) agricultural runoff; (2) urban runoff (including developing and developed areas); (3) silvicultural (forestry) runoff; (4) marinas and recreational boating; and (5) hydromodification, dams and levees, and shoreline erosion. EPA has also included management measures for wetlands, riparian areas, and filter strips that apply generally to various categories of sources of nonpoint pollution. Some categories that have not been addressed but may be responsible for nonpoint source pollution in some coastal waters include oil and gas operations; mining activities; land disposal of wastes; and in-place contamination

VOL 12

4840

(sediments). EPA intends to investigate these activities' impacts on coastal waters as time and resources allow. We welcome comments from the public on these and other categories that might appropriately be addressed in the management measures guidance.

2. Overlaps Between Nonpoint Sources and Point Sources

Historically, there have always been overlaps and ambiguity between programs designed to control nonpoint sources and point sources. The primary overlap occurs between the stormwater permit program (under section 402(p) of the Clean Water Act) and traditional urban runoff programs. Often, runoff may originate as a nonpoint source but ultimately be channelized and become a point source. A further complication arises because the Clean Water Act currently requires a permit for some municipal stormwater sources while postponing regulatory coverage of other (generally smaller) municipalities' storm water.

A second overlap occurs in connection with confined animal feeding operations. Concentrated animal feeding operations that meet particular size or other criteria are defined and regulated as point sources under the section 402 permit program. Other confined animal feeding operations are not currently regulated as point sources. Other overlaps may occur with respect to aspects of mining operations, oil and gas extraction, land disposal, and other activities.

EPA intends that the coastal nonpoint pollution control programs to be developed by the States apply only to sources that are not currently required to apply for and receive an NPDES permit, and that the management measures similarly apply only to sources that are not required to apply for and receive an NPDES permit. In this proposed guidance, EPA has attempted to avoid addressing activities that are clearly regulated point source discharges. However, for pollution sources for which there may be overlap or ambiguity, EPA has chosen to err on the side of inclusiveness in this proposed guidance and to include management measures to address those sources.

For example, the management measures guidance for marinas does not address pollution from vessels, including marine sanitation devices, which are regulated as point sources under sections 312 and 402 of the Clean Water Act. Nor does it address construction sites exceeding five acres in size, which are regulated under section 402 of the Act. On the other hand, the guidance does include urban runoff management measures. These will apply only to stormwater discharges that are not required to apply for and receive stormwater permits; however, they include some of the same measures that may be addressed in such stormwater permits. Readers should also note that a stormwater discharge that is currently exempt from permit requirements may be required to obtain a permit under section 402(p)(2)(E) of the Clean Water Act if EPA or a State determines that it contributes to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States. Additional stormwater discharges may also be regulated as point sources under section 402(p)(6).

EPA will continue to evaluate overlapping areas and welcomes comment on our proposed attempts to deal with these areas.

3. Contents of This Proposed Guidance

This proposed guidance includes, for the five source categories addressed to date, the following:

(1) A specification of management measures;

(2) A description of the categories and subcategories of activities and locations for which each measure may be suitable;

(3) An identification of the individual pollutants or categories or classes of pollutants that may be controlled by the measures;

(4) A description of the water quality effects of the measures;

(5) Information regarding pollution reductions achievable with the management measures;

(6) Information on costs of the measures; and

(7) A description of some factors which should be taken into account in adapting the measures to specific sites or locations.

Due to the extremely tight time constraints imposed by the statute, EPA could not include detailed information on all of the items identified above, most notably pollutant reduction effectiveness and cost data. EPA will endeavor over the next year to obtain additional information for inclusion in the final guidance.

C. Development of Final Guidance: Request for Comments

Much needs to be accomplished between now and May 1992. EPA intends to examine and evaluate various data sources, including those listed in references listed at the end of many of the chapters of this document. In addition, EPA has existing, yet incomplete, data bases regarding the effectiveness of agricultural and urban management practices, and we will use this information to the extent possible. These data bases include information regarding the study conditions, practices applied, and pollutant reductions achieved. Other literature will be accessed through existing libraries of nonpoint source publications, including information maintained by Universities, other agencies, and State government. EPA will rely primarily on those articles published in the peer-reviewed technical literature, but will use other reliable sources as necessary.

EPA solicits comments on the proposed guidance, including additional information and supporting data on the measures specified in this guidance as well as additional management measures that may be as effective in controlling nonpoint source pollution. In particular, EPA requests the following:

(1) Information on the activities and locations for which each measure may be suitable and on factors which should be taken into account in adapting the measures to specific sites or locations.

(2) Information on the pollutants that may or may not be controlled by the measure.

(3) Data regarding the pollutant reduction effectiveness of the measures.

(4) Data regarding the costs of each measure.

EPA also welcomes comments on the general approach used in the proposed guidance, including the level of detail used to describe management measures.

Comments on this guidance should be mailed, within 120 days of publication of the Federal Register notice announcing the availability of this proposed guidance, to Steven Dressing, Assessment and Watershed Protection Division (WH-553), Office of Water, U.S. Environmental Protection Agency, 401 M Street, S.W., Washington, DC 20460.

The review comments received as a result of public notice will be assessed and summarized. EPA will draw upon the information provided through public review and comment, the technical materials referenced throughout this proposed guidance, and other expertise as available to make final determinations as to the scope and content of the guidance.

III. TECHNICAL APPROACH TAKEN IN DEVELOPING THIS GUIDANCE

A. The Nonpoint Source Pollution Process

Nonpoint source pollutants are transported to surface water by a variety of means, including runoff and ground-water infiltration. Ground water and surface water are both considered part of the same hydrologic cycle when designing management measures. Ground-water contributions of pollutant loadings to surface waters in coastal areas are often very significant. The transport of nonpoint source pollutants to coastal waters through ground-water discharge is governed by physical and chemical properties of the water, pollutant, soil, and aquifer. Appendix B of the proposed guidance contains a discussion of the effects of various nonpoint source management practices on ground water.

1. Source Control

Source control is the first opportunity in any nonpoint source control effort. Source control methods very for different types of nonpoint source problems. Examples of source control include:

(1) Reducing or eliminating the introduction of pollutants to a land area. Examples include reduced nutrient and pesticide application.

(2) Preventing non-introduced pollutants from leaving the site during land-disturbing activities. Examples include conservation tillage; planning forest road construction to minimize erosion; siting marinas adjacent to deep waters to eliminate or minimize the need for dredging; and managing grazing to protect against overgrazing and the resulting increased soil erosion.

(3) Preventing interaction between precipitation and introduced pollutants. Examples include installing gutters and diversions to keep clean rainfall away from barnyards; diverting rainfall runoff from areas of land disturbance at construction sites; and timing chemical applications or logging activities based upon weather forecasts or seasonal weather patterns.

(4) Protecting riparian habitat and other sensitive areas. Examples include protection and preservation of riparian zones, shorelines, wetlands, and highly erosive slopes.

(5) Protecting natural hydrology. Examples include the maintenance of pervious surfaces in developing areas (conditioned based upon ground-water considerations); riparian zone protection; and water management.

2. <u>Delivery Reduction</u>

Pollution prevention often involves delivery reduction (intercepting pollutants prior to delivery to the receiving water) in addition to appropriate source control measures. Management measures include delivery reduction practices to achieve the greatest degree of pollutant reduction economically achievable, as required by the statute.

Delivery reduction practices intercept pollutants leaving the source by capturing the runoff or infiltrate, followed either by treating and releasing the effluent or by permanently keeping the effluent from reaching a surface or ground water resource.

By their nature, delivery reduction practices often bring with them side effects that must be accounted for. For example, management practices that intercept pollutants leaving the source may reduce runoff, but also increase infiltration to ground water. For example, infiltration basins trap runoff and allow for its percolation. These devices, although highly successful at controlling suspended solids, may not, because of their infiltration properties, be suitable for use in areas with high ground-water tables and nitrate or pesticide residue problems.

The performance of delivery reduction practices is to a large extent dependent on suitable designs, operational conditions, and proper maintenance. For example, filter strips may be effective for controlling particulate and soluble pollutants where sedimentation is not excessive,

VOL 12 4844

but may be overwhelmed by high sediment input. In many cases, filter strips are used as pretreatment or supplemental treatment for other practices within a management system.

These examples illustrate that the combination of source control and delivery reduction practices, and the application of those practices as components of management measures, are dependent upon site-specific conditions. Technical factors that may affect the suitability of management measures include, but are not limited to, land use, climate, size of drainage area, soil permeability, slopes, depth to water table, space requirements, the type and condition of the water resource to be protected, depth to bedrock, and the pollutants to be addressed. In the proposed management measure guidance below, some of these factors are discussed as they affect the suitability of particular measures. EPA expects to expand this aspect of management measures in the final guidance.

B. Management Measures as Systems

Technical experts who design and implement effective nonpoint source control measures do so from a management systems approach as opposed to an approach that focuses on individual practices. That is, the pollutant control achievable from any given management system is viewed as the sum of the parts, taking into account the range of effectiveness associated with each single practice, the costs of each practice, and the resulting overall cost and effectiveness. Some individual practices may not be very effective alone, but, in combination with others, may provide a key function in highly effective systems. This is analogous to the use of treatment "trains," or series of treatment steps, in most point source wastewater treatment systems.

Therefore, this guidance adopts the approach of specifying management measures (defined by 's the "best available...") as systems of management practices. This is primarily reflected in two ways: (1) the management measures are usually presented as systems, and (2) for those sources that generate pollutants from a number of somewhat discrete activities or unit areas the guidance includes management measures for each activity or area.

For example, the agriculture category includes separate management measures for sediment control on agricultural land; nutrient management; pesticide management; irrigation management; and livestock management. Taken together, however, these measures constitute comprehensive management measures that can address a wide range of farm operations, several of which are frequently found on the same farm.

C. Distinction Between Management "Measures" and "Practices"

Readers should note that the statute provides that State programs need to be "in conformity" only with "management measures", not with "management practices". The "management measures" contained in this guidance are the heart of the guidance. The "practices" listed in the guidance are provided strictly for informational purposes; they are designed to provide ideas on effective tools to achieve the management measures. However, the selection of these or other practices is within the discretion of the State and managers of the sources of nonpoint pollution, provided that the selected set of practices achieves the management measure.

Since nonpoint source pollutants have a limited number of pathways by which they reach water resources, the practices that constitute management measures for the various source categories may be similar in several cases. For example, filter strips of one sort or another are used to address a variety of sources, including agricultural, forestry, and urban sources. At the same time, the filter strip design specifications, operation and maintenance, and pollutant reductions for each of these sources and specific activities within these source categories may vary considerably, however. In this proposed guidance, filter strips are addressed in the final chapter as a multi-source management measure. Similarly, the water-quality benefits of protecting and restoring coastal wetlands apply across many categories of nonpoint sources and are thus addressed in the final chapter. EPA may identify other management measures in the final guidance that can be applied to more than one source category.

D. Management Measures: Adaptation to Local Conditions

It is generally not possible to prescribe a highly specific management measure that will be uniformly applicable nationally or regionally. For example, when designing erosion and sediment control systems on agricultural lands, one considers soil types, cropping patterns, precipitation patterns, slopes, depth to water table, and other factors to determine the proper system for each parcel of land. Similarly, in determining management measures for developing urban areas, a local community might consider transportation system needs, land use, soils, slopes, precipitation patterns, permeability, rate of growth, and other factors. The multitude of combinations of site-specific factors that arise across the nation, within States, and even within watersheds, makes it impractical to develop a list of specific management measures that is most effective to control all of the existing and potential nonpoint source problems affecting our coastal waters.

Rather than developing an exhaustive list of specific management measures (each of which is a system of practices) tailored to all scenarios (an impossible task), or even a defined subset of possible scenarios, EPA proposes to specify management measures in a manner that can be applied on a broader scale to categories of nonpoint sources. By identifying measures that reflect best achievable pollutant reductions, yet allowing for approaches that achieve equivalent or better pollutant control, EPA's proposal enables adaptation to site-specific conditions. This adaptation would occur through flexible application of management measures contained in State coastal nonpoint pollution control programs approved by NOAA and EPA.

This proposed guidance provides a suite of management measures for each source category. The number and type of systems identified per source category are based upon the range and diversity of substantively different subcategories, activities, and pollutants.

EPA used a consistent approach to determine the number and type of management measure systems needed under each category. We first determined the range of subcategories and activities that fall under each source, and how they related to each other. We then identified the types of nonpoint source pollution and impacts that could be caused by each subcategory and activity, as well as by combinations of subcategories and activities. This step is key to preventing pollution at the source. Management measures were then identified based upon several factors, including the types of pollutants, pollutant fate and transport, and land management patterns and opportunities.

Pollution prevention was always considered as the first component of management measures. Pollutant delivery reduction measures were typically added only after it was determined that additional control was necessary to reach the greatest degree of pollutant reduction economically achievable.

For each management measure, a list of management practices that can be used in designing an equivalent or better system is provided. The list of practices reflects the best available set of practices, or components of best available systems, but is not all-inclusive of those practices that could be used to develop systems that are equivalent to or better than specified management measures.

The pollutant reductions that can be achieved using the specified management measures are also described in this guidance, quantitatively wherever possible. These reductions serve as the benchmarks for equivalent or better management measures. Pollutant reductions achievable with the management practices listed are also given to the extent data are available.

The proposed guidance also describes factors that need to be taken into account in adapting the systems to specific sites or locations. These factors are illustrative of conditions that may lead to (1) selection of equivalent or better management measures for any given application, (2) special design considerations, or (3) special operation and maintenance considerations. As for other aspects of the proposed guidance, EPA intends to expand this information in the final guidance.

E. Pollution Reduction Estimates

Estimates of pollution reduction are provided for the management measures and a subset of the management practices contained in this proposed guidance. All estimates provided are based upon data available to EPA, but EPA has to date performed little or no analysis of these data due to the tight statutory deadline for proposal. Therefore, the estimates provided should be considered only indicative of the types of estimates that will be given in the final guidance, but should not be considered best estimates at this time.

EPA expects during the coming year to assemble and analyze additional pollutant reduction data on the effectiveness of various practices and measures; improve its understanding of the site-specific variability of pollutant reduction estimates by identifying factors that appear to cause differences in reductions; and characterize reduction results more rigorously. EPA will also examine the specific practices to determine if differences in design or application affected the study results. For example, pipe outlet terraces may have a very different impact upon ground water than terraces with no pipe outlets. Further, pipe outlet terraces on soils underlain by carbonate rock may have very different effects than terraces underlain by noncarbonate rocks.

In many cases, EPA was unable to obtain or analyze data that would enable EPA to estimate pollutant reduction effects of proposed management measures. EPA intends to do considerable work in the coming year to develop such quantitative information and welcomes commenters' ideas and data in this regard.

F. Costs, Economic Achievability, and Net Economic Benefits of Proposed Management Measures

A limited amount of cost information is provided in various chapters of this proposed guidance. The cost data, like the pollutant reduction effects estimates provide a preliminary indication of the type and range of estimates likely to appear in the final guidance, but should not be considered final or best estimates at this time. EPA has also prepared a preliminary scoping analysis of the net economic benefits of management measures for coastal waters.

Congress defined "management measures" to mean "economically achievable measures ... which reflect the greatest degree of pollutant reduction achievable through the application of the best available nonpoint pollution control practices, technologies, processes, siting criteria, operating methods, or other alternatives. Thus the management measures must be "economically achievable".

Congress has not defined the term "economically achievable"; nor has it explained the term in legislative history. However, as noted previously, the legislative history indicates that the management measures approach of Section 6217 is "patterned" after the "best available technology economically achievable" (BAT) approach used in the Clean Water Act for point sources. Thus, the meaning of "economically achievable" would seem to be its historical interpretation in the point source program.

It is unclear that "economically achievable" would be interpreted precisely the same way for nonpoint source management measures guidance as it has been for point source BAT regulations. Indeed, there are important distinctions between the "management measures" guidance and BAT regulations that clearly limit the extent to which economic achievability can be assessed and factored into a general analysis of proposed guidance. These distinctions relate to the more extensive flexibility inherent in implementing nonpoint source management measures.

The ability of a particular management measure to deal with nonpoint source pollution from a particular site is subject to a variety of factors (e.g., geography, geology, soils, hydrology, and production methods) too complex to address in a single set of simple, mechanical prescriptions developed at the federal level. Thus, Congress indicated the need to provide in the management measures guidance considerable flexibility for local selection of management measures. Furthermore, unlike BAT regulations, the management measures guidance is not directly applicable to nonpoint sources, but, rather, will be directly implemented only through state programs developed in conformity with the guidance. These considerations make it very difficult to predict the costs and economic impacts of management measures that will ultimately be developed, applied, and implemented on a localized basis.

Many of the proposed management measures are generally regarded as low-cost, yet highly effective. Examples include agricultural measures such as sediment control and nutrient management. Others are more expensive, yet are widely practiced (e.g., animal waste controls and construction of vegetative filter strips). Further, it should be noted that significant cost-share assistance is available to farmers from a variety of federal and state programs to assist in the implementation of the agricultural management measures.

The exceptionally tight six-month statutory deadline, coupled with the analytical limitations outlined above, have precluded a formal economic analysis. To assist readers in evaluating the effect of this guidance, EPA has prepared a preliminary net benefits analysis of nonpoint source management measures for coastal waters. This preliminary analysis indicates that implementation of nonpoint pollution management measures in coastal areas may yield significant net economic benefits. EPA solicits comments on this preliminary benefits analysis.

Commenters are also invited to identify particular management measures that they believe are or are not economically achievable; provide information or analyses to support their comments; and suggest alternative analytical methodologies that they believe would be useful in determining economic achievability. Commenters are also invited to suggest methods for analyzing economic achievability in a manner that overcomes the analytical limitations outlined above and that could be performed rapidly, consistent with the May 1992 deadline for publication of final management measures guidance.

IV. ISSUES TO BE ADDRESSED IN PROGRAM GUIDANCE

A complete understanding of the proposed management measures depends on a consideration of how they will be implemented in State programs. As described in "Background", each State Coastal Nonpoint Pollution Control Program (CNPCP) must "provide for the implementation, at a minimum, of management measures in conformity with the guidance published under subsection (g) to protect coastal waters generally,...." States will implement the CNPCP through amendments to their existing State nonpoint source program under section 319 of the Clean Water Act (as amended in 1987) and their Coastal Zone Management Program.

EPA and NOAA plan to publish draft state program development and approval guidance in August 1991. This guidance will address the key issues of how the management measures are to be implemented in State programs, as well as other program requirements. States and other interested parties will be given the opportunity to review and comment on the guidance at that time. The agencies expect to publish final state program guidance in May 1992.

We recognize that many reviewers of the proposed management measures guidance will wish to understand how these measures will apply programmatically as they evaluate and comment upon the measures. Therefore, to assist readers to consider the proposed measures in the broader implementation context, pending publication of the proposed state program guidance, we identify below some of the key management measures implementation issues that EPA and NOAA expect to address in the proposed program guidance, along with an indication of the range of options being considered.

A. State Conformity with Management Measures Guidance

Section 6217 assigns to the States the responsibility for developing and implementing management measures "in conformity" with the subsection (g) guidance. The interpretation of this requirement is key in that it will prescribe the degree of discretion that States will have in developing alternative management measures and targeting specific sources and areas. NOAA and EPA are currently developing programmatic guidance which will explain how the Agencies will make decisions with respect to whether State programs are "in conformity with" the guidance.

Some options currently under consideration are:

(1) States could be required to implement the specified management measures for all sources that contribute nonpoint source pollution to coastal waters.

(2) States could be required to implement either the specified management measures or tailored management measures that are equivalent in performance to the specified management measures for all sources that contribute nonpoint source pollution to coastal waters.

(3) States could be required to identify significant sources of nonpoint pollution and implement the specified management measures, or equivalent State management measures, as necessary to protect and restore coastal water quality.

(4) States could be required to develop performance requirements to determine where to implement the specified management measures, or equivalent State management measures, to guarantee protection of coastal waters, on a case-by-case basis.

B. Applicability of Management Measures to Individual Sources

A major issue in the implementation of management measures is whether the management measures should be required by State programs for all sources or only for a subset of sources or geographic areas that are determined to be significant sources of nonpoint source pollution. The most stringent approach would require that every land owner or manager should implement a minimum set of management measures to prevent nonpoint source pollution, without first

VOL 12 4850

estimating the extent of a coastal water quality problem or threat and the land's relationship to the problem or threat. This approach would parallel the highly effective point source program, in which uniform BAT controls applicable to all sources in a particular category has led to relatively rapid progress in the treatment of point source discharges. The approach also establishes equal requirements for all competing producers.

A potential pitfall of this approach is that costs and pollutant reduction effects cannot readily be taken into account by States in developing management measures appropriate to individual sources or classes of activities. By requiring minimum measures of all land owners or managers, the agencies may thus impose unnecessary costs and requirements upon those that do not contribute to nonpoint source problems or the threat of such. Furthermore, a broadly uniform approach may divert implementing agencies' efforts from focussing on the primary problems that contribute most significantly to coastal water quality problems.

Between the two extreme options (applying management measures to all sources, and applying management measures only to sources demonstrated to have particular well-defined impacts on coastal waters) lie certain intermediate options. For example:

(1) A tiered approach could set different levels of minimum control based upon the extent and type of the problem, and the likelihood that any given land area or class of sources might contribute to the problem. (Readers should note that section 6217(b)(3) already provides for additional management measures to address critical coastal areas and land uses. See the next section below.)

(2) A targeted approach that identifies certain areas or classes of sources for treatment, while leaving others untreated, presents a similar way to achieve effective control at lower cost within each tier.

(3) A tiering or targeting approach could use tiering or targeting not to distinguish among different sources' control requirements, but rather to prioritize and schedule State implementation activities.

C. Land Uses and Critical Coastal Areas

Section 6217(b) requires that states identify land uses which, individually or cumulatively, may cause or contribute significantly to a degradation of (a) coastal waters where there is a failure to attain or maintain applicable water quality standards or protect designated uses, or (b) coastal waters that are threatened by reasonably foreseeable increases in pollution loadings from new or expanding sources. The section also requires states to identify critical coastal areas adjacent to the coastal waters identified above. Finally, the section requires that the state coastal nonpoint pollution control program provide for implementation of additional management measures that are necessary to achieve and maintain applicable water quality standards.

Unlike the management measures specified in this guidance, the implementation of these additional measures is tied directly to water quality standards and designated uses of coastal waters. EPA and NOAA will work with the states to determine the scope and application of these additional management measures and their relationship to the measures developed in accordance with section 6217(g).

D. Conclusion

EPA reminds readers that the above issues, together with other implementation issues, will be addressed in forthcoming State program approval guidance, scheduled for publication in draft form in August 1991. The brief discussion above has been intended to assist the public in understanding related implementation issues as they review and comment upon the proposed management measures guidance. However, we request that commenters on this proposed management measures guidance focus their comments upon the technical soundness of the proposed management measures and reserve implementation-related considerations until the forthcoming State program approval guidance is published for public comment.

V. REQUEST FOR INFORMATION AND COMMENTS

EPA is soliciting comments on the proposed guidance on management measures to control coastal nonpoint pollution. We are seeking additional information and supporting data on the measures specified in this guidance and on additional measures that may be as effective or more effective in controlling nonpoint source pollution. The following information is sought by EPA in preparing the final guidance:

(1) Information on the activities and locations for which each measure may be suitable and information on factors which should be taken into account in adapting the measures to specific sites or locations;

(2) Information on the pollutants that may or may not be controlled by the measures;

(3) Data regarding the pollution reduction effects of the measures;

(4) Data regarding the costs of each measure; and

(5) Appropriate monitoring techniques for each resource.

EPA also welcomes comments on the general approach used in the proposed guidance, including the level of detail used to describe management measures. As mentioned above, EPA requests that commenters focus their comments upon the technical soundness of the proposed management measures guidance and reserve implementation-related considerations until the forthcoming state program approval guidance is published for public comment.

CHAPTER 2

AGRICULTURAL MANAGEMENT MEASURES

I. INTRODUCTION

This chapter specifies management measures for agricultural sources of nonpoint pollution. Agriculture is the nation's largest contributor of nonpoint source pollution. In coastal waters, its effect varies regionally. In some coastal waters, agriculture has been identified as the single largest contributor of sediment, nutrients, and other pollutants of concern. For example, agricultural runoff has been identified as the leading source of pollution in the Chesapeake Bay and in other estuaries. Thus, applying management measures to control agricultural nonpoint pollution is an essential component of a State program to protect coastal waters from nonpoint pollution.

II. POLLUTANTS THAT CAUSE AGRICULTURAL NONPOINT SOURCE POLLUTION*

The primary agricultural nonpoint source pollutants are nutrients, sediment, animal wastes, salts, and pesticides. These pollutants' effects on water quality are discussed below.

A. Nutrients

Nitrogen and phosphorus are the two major nutrients from agricultural land that degrade water quality. All plants, whether land based, aerial, or aquatic, require nutrients for growth. In an aquatic environment, nutrient availability usually limits plant growth. Nitrogen and phosphorus generally are present at background or natural levels below 0.3 and 0.05 mg/l, respectively. When these nutrients are introduced into a stream, lake, or estuary at higher rates, aquatic plant productivity may increase dramatically. This process, referred to as cultural eutrophication, may adversely affect the suitability of the water for other uses.

Increased aquatic plant productivity results in additional organic material being added to the system that eventually dies and decays. The decaying organic matter produces unpleasant odors and depletes the oxygen supply required by aquatic organisms. Excess plant growth also may interfere with recreational activities such as swimming and boating. Depleted oxygen levels,

---

especially in colder bottom waters where dead organic matter tends to accumulate, will reduce the quality of fish habitat and encourage the propagation of fish which are adapted to less oxygen or to warmer surface waters. Highly enriched waters will stimulate algae production, with consequent increased turbidity and color. Algae growth is also believed to be harmful to coral reefs (e.g., Florida coast). Furthermore, the increased turbidity results in less sunlight penetration and availability to submerged aquatic vegetation (SAV). Since SAV provides habitat for small or juvenile fish, the loss of SAV has severe consequences for the food chain. Chesapeake Bay is an example where nutrients are believed to have contributed to SAV loss.

B. <u>Nitrogen</u>

All forms of transported nitrogen are potential contributors to eutrophication in lakes, estuaries, and some coastal waters. In general, though not all cases, nitrogen availability is the limiting factor for plant growth in marine ecosystems. Thus, the addition of nitrogen can have a significant affect on the natural functioning of marine ecosystems.

In addition to eutrophication, excessive nitrogen causes other water quality problems. Dissolved ammonia at concentrations above 0.2 mg/l may be toxic to fish, especially trout. Nitrates in drinking water are potentially dangerous, especially to newborn infants. Nitrate is converted to nitrite in the digestive tract, which reduces the oxygen-carrying capacity of the blood (methemoglobinemia), resulting in brain damage or even death. The U.S. Environmental Protection Agency has set a limit of 10 mg/l nitrate-nitrogen in water used for human consumption (Robillard, et al., 1981).

Nitrogen is naturally present in soils but must be added to increase crop production. Nitrogen is added to the soil primarily by applying commercial fertilizers and manure, but also by growing legumes (biological nitrogen fixation) and incorporating crop residues. Not all nitrogen that is present in or on the soil is available for plant use at any one time. Organic nitrogen normally constitutes the majority of the soil nitrogen. It is slowly converted (2 to 3 percent per year) to the more readily plant available inorganic ammonium or nitrate.

The chemical form of nitrogen affects its impact on water quality. The most biologically important inorganic forms of nitrogen are ammonium (NH_4+), nitrate (NO_3-), and nitrite (NO_2). Organic nitrogen occurs as particulate matter, in living organisms, and as detritus. It occurs in dissolved form in compounds such as amino acid, amines, purines, urea, etc.

Nitrate-nitrogen is highly mobile and can move readily below the crop root zone, especially in sandy soils. It can also be transported with surface runoff, but not generally in large quantities. Ammonium on the other hand, becomes adsorbed by the soil and is lost primarily with eroding sediment. Even if nitrogen is not in a readily available form as it leaves the field, it can convert to an available form later.

C. Phosphorus

The phosphorus content in most soils is low, between 0.01 and 0.2 percent by weight. Most of this is unavailable for plant uptake. Manure and fertilizers are used to increase the level of available phosphorus in the soil to promote plant growth. If runoff and erosion occur, some of the applied phosphorus can reach nearby bodies of water. High-intensity storms increase the loss of particulate inorganic phosphorus from croplands because this form of phosphorus is associated with eroding sediments.

Phosphorus can be found in the soil in dissolved, colloidal, or particulate forms. Dissolved inorganic phosphorus (orthophosphate phosphorus) is probably the only form directly available to algae. Algae consume dissolved inorganic phosphorus and convert it to the organic form. Phosphorous is rarely found in concentrations high enough to be toxic to higher organisms.

Phosphorus unavailable in the soil system may erode with soil particles and later be released when the bottom sediment of a stream becomes anaerobic, creating water quality problems. While phosphorus typically plays the controlling role in freshwater systems, in some estuarine systems, both nitrogen and phosphorus can limit plant growth. Thus, the addition of phosphorus as a nonpoint source pollutant can have an adverse effect in both freshwater and estuarine systems.

D. Sediment

Sediment is the result of erosion. It is the solid material, both mineral and organic, that is in suspension, is being transported, or has been moved from its site or origin by air, water, gravity, or ice. The types of erosion associated with agriculture that produce sediment are: (1) sheet and rill erosion and (2) gully erosion. Sediments from different sources vary in the kinds and amounts of pollutants that are adsorbed to the particles. For example, sheet and rill erosion mainly move soil particles from the surface or plow layer of the soil. Eroded soil is either redeposited on the same field or transported from the field in runoff.

Sediment which originates from surface soil will have a higher pollution potential than that from subsurface soils. The topsoil of a field is usually richer in nutrients and other chemicals because of past fertilizer and pesticide applications, as well as nutrient cycling and biological activity. Topsoil is also more likely to have a greater percentage of organic matter. Sediment from gullies and streambanks usually carries less adsorbed pollutants than sediment from surface soils.

Sediment from cropland usually contains a higher percentage of finer and less dense particles than the soil from which it originates. Large particles are more readily detached from the soil surface because they are less cohesive. They will also settle out of suspension more quickly because of their size. Organic matter is not easily detached because of its cohesive properties, but once detached it is easily transported because of its low density. Clay particles and organic residues will remain suspended for longer periods and at slower flow velocities. This selective erosion process can increase overall pollutant delivery, because small particles have a much

VOL 12

4859

greater adsorption capacity per mass than larger particles. As a result, eroding sediments generally contain higher concentrations of phosphorus, nitrogen, and pesticides than the original soil.

Sediment affects the use of water in many ways. Suspended solids reduce the amount of sunlight available to aquatic plants, cover fish spawning areas and food supplies, smother coral reefs, and clog the filtering capacity of filter feeders and the gills of fish. This reduces fish, shellfish, coral and plant populations, and decreases the overall productivity of lakes, streams, estuaries, and coastal waters. Turbidity interferes with feeding habits of fish. Recreation is limited because of the decreased fish population and the water's unappealing, turbid appearance. Turbid water reduces visibility, thus it is less safe for swimming.

Chemicals such as some pesticides, phosphorus, and ammonium are transported with sediment in an adsorbed state. Changes in the aquatic environment, such as a lower concentration in the overlying waters or the development of anaerobic conditions in the bottom sediments, can cause these chemicals to be released from the sediment. Adsorbed phosphorus transported by the sediment may not be immediately available for aquatic plant growth but does serve as a long-term contributor to eutrophication.

E. Animal Wastes

Animal wastes (manure) includes the fecal and urinary wastes of livestock and poultry, process water (such as from a milking parlor), and the feed, bedding, litter, and soil with which they become intermixed. Animal wastes can contribute nutrients, organic materials, and pathogens to receiving waters.

Manure will be more easily removed in runoff when applied to the soil surface than when incorporated in the soil. Spreading manure on frozen ground or snow can result in high concentrations of nutrients being transported from the field during rainfall or snowmelt. The problems associated with nitrogen and phosphorus, as discussed in the section **Nutrients**, also apply to animal wastes. If sufficient manure is applied to meet the nitrogen needs of a crop, phosphorus will generally be in excess. The soil generally has the capacity to adsorb any phosphorus leached from manure applied on land. However, as previously mentioned, nitrates are easily leached through soil into ground water or to return flows, and phosphorus can be transported by eroded soil.

The demand for oxygen exerted by carbonaceous materials (individually or in combination with nitrogen) can deplete dissolved oxygen supplies in water, resulting in anoxic or anaerobic conditions. When the decomposition process causes water to become anaerobic, methane, amines, and sulfide are produced. The water acquires an unpleasant odor, taste, and appearance and becomes unfit for drinking, and for fishing and other recreational purposes.

Animal diseases can be transmitted to humans through contact with animal feces. Runoff from fields receiving manure will contain extremely high numbers of bacteria if the manure has not been incorporated or the bacteria have not been subject to stress. Pathogen contamination from animal waste has been responsible for shellfish contamination in some coastal waters. However, bacteria levels in receiving waters may be attributed in some cases to either agricultural runoff or septic systems, and determination of actual sources is difficult.

Conditions which cause a rapid dieoff of bacteria are low soil moisture, low pH, high temperatures, and direct solar radiation. Manure storage generally promotes dieoff, although pathogens can remain dormant at certain temperatures. Composting the wastes is quite effective in decreasing the number of pathogens.

F. Salts

Salts are a product of the natural weathering process of soil and geologic material. They are present in varying degrees in all soils and in freshwater, coastal/estuarine waters, and ground waters.

In soils that have poor subsurface drainage, high salt concentrations are created within the root zone where most water extraction occurs. The accumulation of soluble and exchangeable sodium leads to soil dispersion, structure breakdown, decreased infiltration, and possible toxicity; thus, salts often become a serious problem on irrigated land, both for continued agricultural production and for water quality considerations. High salt concentrations in streams can harm freshwater aquatic plants just as excess soil salinity damages agricultural crops. While salts are generally a more significant pollutant for freshwater ecosystems than for saline ecosystems, they may also adversely affect anadromous fish, which while living in coastal and estuarine waters most of their lives, depend on freshwater systems near the coast for crucial portions of their life cycle.

The movement and deposition of salts depend on the amount and distribution of rainfall and irrigation, the soil and underlying strata, evapotranspiration rates, and other environmental factors. In humid areas, dissolved mineral salts have been naturally leached from the soil and substrata by rainfall. In arid and semiarid regions, salts have not been removed by natural leaching and are concentrated in the soil. Soluble salts in saline and sodic soils consist of calcium, magnesium, sodium, potassium, carbonate, bicarbonate, sulfate, and chloride ions. They are fairly easily leached from the soil. Sparingly soluble gypsum and lime also occur. The amounts present range from traces to more than 50 percent of the soil mass. The total dissolved solids of ions in ground water and streams include the soluble ions mentioned above. Irrigation water, whether from ground water or surface water sources, has a natural base load of dissolved mineral salts. As the water is consumed by plants or lost to the atmosphere by evaporation, the salts remain and become concentrated in the soil. This is referred to as the "concentrating effect."

The total salt load carried by irrigation return flow is the sum of the original salt in the applied water resulting from the concentrating effect plus salt pick-up. Irrigation return flows provide the means for conveying the salts to the receiving streams or ground-water reservoirs. If the

VOL 12 4861

amount of salt in the return flow is low in comparison to the total stream flow, water quality may not be degraded to the extent that use is impaired. However, if the process of water diversion for irrigation and the return of saline drainage water is repeated many times along a stream or river, water quality will be progressively degraded for downstream irrigation use as well as for other uses.

G. Pesticides

Pesticides--insecticides, herbicides, fungicides, miticides, nematicides, etc.--are used extensively in agriculture to control plant pests and enhance production. However, despite the documented benefits, these chemicals may, in some instances, endanger surface and ground water and ultimately human health.

Pesticides may harm the environment by eliminating or reducing populations of desirable organisms, including endangered species. Some types of pesticides or their metabolites are resistant to degradation. These pesticides or their degradation products may persist and accumulate in the aquatic ecosystems. The entire food chain, including man, can be affected. Sublethal effect include the behavioral and structural changes of an organism that jeopardize its survival. For example, certain pesticides have been found to inhibit bone development in young fish or affect reproduction by inducing abortion.

Herbicides in the aquatic environment can destroy the food source for higher organisms, which may then starve. Also, decaying plant matter causes a reduction in dissolved oxygen.

Sometimes a pesticide is not toxic by itself, but is lethal in the presence of other pesticides. This is referred to as a synergistic effect and may be difficult to predict or evaluate. Bioconcentration is a phenomenon that occurs if an organism ingests more a pesticide than it excretes. During its lifetime, the organism will accumulate a higher concentration of that pesticide than is present in the surrounding environment. When the organism is eaten by another animal higher in the food chain, the pesticide will then be passed to that animal and up the food chain.

The amount of field-applied pesticide that leaves a field in the runoff and enters a stream primarily depends on:

(1) The intensity and duration of rainfall; and

(2) The length of time between pesticide application and rainfall occurrence.

Pesticide losses are largest when rainfall is intense and occurs shortly after pesticide application, a condition for which water runoff and erosion losses are also greatest.

The rate of pesticide movement through the soil profile to ground water is inversely proportional to the pesticide "adsorption partition coefficient" or K (defined as a measure of the sorption phenomenon, whereby a pesticide is divided between the soil and water phase). The larger the

K the slower the movement and the greater the quantity of water required to leach the pesticide to a given depth. In general, it appears that only pesticides with K values less than 0.5 ml/g, water solubilities greater than 100 mg/l, and/or long half-lives pose a serious threat to deep ground-water resources.

Pesticides can be transported to receiving waters either in dissolved form or attached to sediment. Dissolved pesticides may be leached to ground-water supplies. Pesticides have varying characteristics as to degradation and the percent to which they will attach to sediment.

III. REQUEST FOR COMMENTS

In Chapter 1 of this guidance (Introduction), EPA has generally requested submission of comments, information and data on relevant management practices, their effectiveness, and their costs. We also request specific comment on the following aspects of the agricultural management measures:

Erosion and Sediment Control. In Section IV.A below, EPA sets forth the management measure for Erosion and Sediment Control. This measure consists in major part of reducing erosion as close to zero as possible, but no greater than the lesser of (1) T, or (2) the erosion produced after application of conservation tillage. T is the soil loss tolerance of the Universal Soil Loss Equation, used by soil conservationists to estimate the maximum rate of annual soil erosion that will permit crop productivity to be sustained economically and indefinitely. There are five classes of T factors ranging from 1 ton per acre per year for shallow or otherwise fragile soils to 5 tons per acre per year for deep soils that are least sensitive to damage by erosion.

T does not address the acceptability of a particular rate of erosion from a water quality perspective, nor does it necessarily reflect the reduced rate of erosion that can be accomplished through application of the best available control measures that are economically achievable. For example, Wisconsin is currently using a T-1 standard (which allows one less ton per acre of soil loss than a T standard allows) in its water quality program to address agricultural erosion. It may be that T-1 more accurately reflects the best available measures for erosion control.

EPA has attempted in this proposed guidance to partially compensate for the shortcomings of T as a management measure to protect water quality by specifying conservation tillage as an alternative management measure where it yields less erosion. However, this measure too may not reflect the best available measure that is economically achievable. Indeed, given the low net costs associated with conservation tillage in many contexts, it may be that additional management measures that would provide substantial incremental pollutant reduction benefits that reduce the delivery of pollutants (e.g., contour farming and/or vegetated filter strips) would be achievable.

EPA requests comment on the above issues and on options available to address them.

VOL 12 4863

Nutrient and Pesticide Management. Two of the agricultural management measures, nutrient and pest management, do not actually specify the measures to be taken "on the ground", but rather define broad goals ("eliminate excess nutrient use"; "eliminate application of excess pesticides") and then describe a process of evaluating certain relevant considerations.

EPA requests comment on whether the nutrient and pesticide management measures are sufficiently specific to assure that compliance with them would achieve the desired water quality objectives. If not, what additional specific practices could be added that are generally achievable and add significant pollutant reduction effectiveness?

IV. SOURCES OF AGRICULTURAL NONPOINT POLLUTION

EPA has identified six major categories of sources of agricultural nonpoint pollution that affect coastal waters. These are: erosion from cropland; confined animal facilities; the application of nutrients to cropland; the application of pesticides to cropland; land used for grazing; and irrigation of cropland.

Each of these source categories are addressed separately in the following section of this chapter. For each source the following items are identified: the pollutants that result from these sources; the management measures representing the best available systems of practices economically achievable to reduce off-site delivery of these pollutants; a performance expectation for the management measures; and some preliminary information on the pollutant reduction effectiveness and cost of the measures and, in some cases, the particular practices that comprise the measure.

V. MANAGEMENT MEASURES

In this section, the management measures that represent systems of practices which reflect the best available, economically achievable, nonpoint pollution control practices, technologies, processes, siting criteria, operating methods, or other alternatives are specified for each of the major sources of agricultural nonpoint source pollution. Major sources of agricultural nonpoint source pollution include:

(1) Agricultural land needing treatment for erosion control;

(2) Concentrated animal production facilities;

(3) Land receiving nutrients from sources such as commercial fertilizers, animal wastes, and sludge;

(4) Land receiving pesticide applications;

(5) Land used for grazing; and

(6) Irrigated lands.

Each of these sources is addressed separately in the following section and the following items are discussed for each of the sources:

(1) Where the management measures should be utilized or where they are applicable (for example, the erosion and sediment control management measures are utilized on all agricultural lands and the pesticide management measures are utilized on all agricultural lands that have pesticides applied to them);

(2) Pollutants associated with each source such as nutrients, sediment, salts, etc.;

(3) The management measures which represent the best available systems of practices economically achievable to reduce off-site delivery of the pollutants resulting from each source (in some cases a performance expectation is specified and variety of practices may be used to achieve the performance expectation; in other cases, particular practices are specified);

(4) Information on management practices that are available as tools to achieve the management measures.

(5) Preliminary information on the pollutant reduction effectiveness of the management measures;

(6) Preliminary information on the cost of the management measures; and

(7) Operation and maintenance information.

Several agricultural sources may need to be addressed on a given piece of agricultural land in the coastal zone to protect water quality. For example, in some cases, erosion and sediment control measures, nutrient management measures as well as pesticide management measures will be needed i.e., systems of management measures. In other areas, depending on site-specific conditions, only one source may need to be addressed.

A. Erosion and Sediment Control

1. Management Measure Applicability

This management measure is to be utilized on all agricultural lands, including all land that is converted from other land uses to agricultural land. Agricultural lands include, but are not limited to:

- Cropland, dryland;
- Cropland, irrigated;
- Range and pastureland;
- Orchards;
- Specialty crop production; and
- Nursery crop production.

Those agricultural lands that also meet the applicability definitions of the concentrated animal facility management measure; nutrient management measure; pesticide management measures; grazing management measure; irrigation water management measure; or other management measures are also subject to those management measures.

2. Pollutants Produced by Soil Erosion and Transported by Runoff and Sediment

Runoff water from agricultural land may transport the following types of pollutants:

- Sediment and particulate organic solids;

- Particulate bound nutrients, chemicals and metals, such as phosphorus, organic nitrogen, a portion of applied pesticides, and a portion of the metals applied with some organic wastes and found naturally within the soil;

- Soluble nutrients, such as nitrogen, a portion of the phosphorus, a portion of the applied pesticides, a portion of the soluble metals and many other major and minor nutrients;

- Salts; and

- Bacteria, viruses and other microorganisms.

3. Management Measure for Erosion and Sediment Control

The management measure for erosion and sediment control on agricultural lands is a combination of practices that (1) control gully erosion, (2) protect wetlands and riparian zones, and (3) minimize the detachment and transport of soil by water, wind, ice, or gravity such that the average annual erosion rate (expressed as tons per acre per year, or T/Ac/Yr) is as close to zero as feasible (taking cost into account), but is in no case greater than the lesser of (a) "T" (the soil loss tolerance value* for the soil series in the field) or the average annual erosion rate achieved with conservation tillage.

EPA recognizes that USDA is changing from the Universal Soil Loss Equation to the USDA-Water Erosion Prediction Project (WEPP) model (Laflen et. al., 1991) now scheduled for FY 92. The WEPP system will not only estimate the erosion to a tolerable rate for productivity maintenance, but will estimate on-site deposition to prevent excessive adverse effects from deposition, sediment yield from fields to allowable rates that prevent excessive off-site sedimentation, and sediment yield from fields to prevent excessive degradation of off-site water quality. It will also estimate sediment characteristics needed to develop erosion control plans for improvements in downstream water quality. EPA will track developments regarding WEPP, particularly as they apply to this management measure.

4. Erosion and Sediment Control Management Practices

Following is a list of management practices for agricultural erosion and sediment control that are available as tools to achieve the erosion and sediment control management measure. Under each management practice, the U.S. Soil Conservation Service (SCS) practice number and a definition are provided. The list of practices included in this section is not exhaustive and does not preclude States or local agencies from developing special management measures in cooperation with the appropriate technical agency within the State for unique conditions and problems that may be encountered in particular areas, provided that the management measures (the system of individual practices adopted) achieve a level of performance that is as effective as that provided by the management measure specified in this guidance. There may also be State or local standards that would require additional practices.

Conservation cover (327)
Establishing and maintaining perennial vegetative cover to protect soil and water resources on land retired form agricultural production.

The purpose is to reduce soil erosion and sedimentation, improve water quality, and create or enhance wildlife habitat.

Conservation cropping sequence (328)
An adapted sequence of crops designed to provide adequate organic residue for maintenance or improvement of soil tilth.

---

*The "T" factor is the soil loss tolerance of the Universal Soil Loss Equation. It is defined as the maximum rate of annual soil erosion that will permit crop productivity to be sustained economically and indefinitely. There are five classes of T factors ranging from 1 ton per acre per year for shallow or otherwise fragile soils to 5 tons per acre per year for deep soils that are least sensitive to damage by erosion.

The purpose of this practice is to improve or maintain good physical, chemical, and biological conditions of the soil; help reduce erosion; improve water use efficiency and water quality; improve wildlife habitat; or break reproduction cycles of plant pests.

<u>Conservation tillage (329)</u>
Any tillage or planting system that maintains at least 30 percent of the soil surface covered by residue after planting to reduce soil erosion by water; or where soil erosion by wind is the primary concern, maintains at least 1,000 pounds of flat, small grain residue equivalent on the surface during the critical erosion period.

The purpose is to reduce soil erosion; help maintain or develop good soil tilth, efficient moisture use, and cover for wildlife.

<u>Contour systems</u>

<u>Contour farming (330)</u>
Farming sloping land in such a way that preparing land, planting, and cultivating are done on the contour. This includes following established grades of terraces or diversions.

The purpose is to reduce erosion and control water.

<u>Contour orchard and other fruit area (331)</u>
Planting orchards, vineyards, or small fruits so that all cultural operations are done on the contour.

The purpose is to reduce soil and water loss, to better control and use water, and to operate farm equipment more easily.

<u>Cover and green manure crop (340)</u>
A crop of close-growing grasses, legumes or small grain grown primarily for seasonal protection and soil improvement. It usually is grown for 1 year or less, except where there is permanent cover as in orchards.

The purpose is to control erosion during periods when the major crops do not furnish adequate cover; add organic material to the soil; and improve infiltration, aeration, and tilth.

<u>Critical area planting (342)</u>
Planting vegetation, such as trees, shrubs, vines, grasses, or legumes, on highly erodible or critically eroding areas (does not include tree planting mainly for wood products).

The purpose is to stabilize the soil, reduce damage from sediment and runoff to downstream areas, and improve wildlife habitat and visual resources.

Crop residue use (344)
Using plant residues to protect cultivated fields during critical erosion periods.

The purpose is to conserve soil moisture, increase soil infiltration, reduce soil loss, and improve soil tilth.

Delayed seed bed preparation (354)
Any cropping system in which all of the crop residue and volunteer vegetation are maintained on the soil surface until approximately 3 weeks before the succeeding crop is planted, thus shortening the bare seedbed period on fields during critical erosion periods.

The purpose is to reduce soil erosion by maintaining soil cover as long as practical to minimize raindrop splash and runoff during the spring erosion period. Other purposes include moisture conservation, improved water quality, increased soil infiltration, improved soil tilth, and food and cover for wildlife.

Diversion (362)
A channel constructed across the slope with a supporting ridge on the lower side.

The purpose is to divert excess water from one area for use or safe disposal in other areas.

Field border (386)
A strip of perennial vegetation established at the edge of a field by planting or by converting it from trees to herbaceous vegetation or shrubs.

The purpose is to control erosion, protect edges of fields that are used as "turnrows" or travel lanes for farm machinery, reduce competition from adjacent woodland, provide wildlife food and cover, or improve the landscape.

Filter strip (393)
A strip or area of vegetation for removing sediment, organic matter, and other pollutants from runoff and wastewater.

The purpose is to remove sediment and other pollutants from runoff or wastewater by filtration, deposition, infiltration, absorption, decomposition, and volatilization, thereby reducing pollution and protecting the environment.

Grade stabilization structure (410)
A structure used to control the grade and head cutting in natural or artificial channels.

The purpose is to stabilize the grade and control erosion in natural or artificial channels, to prevent the formation or advance of gullies, and to enhance environmental quality and reduce pollution hazards.

Grassed waterway (412)
A natural or constructed channel that is shaped or graded to required dimensions and established in suitable vegetation for the stable conveyance of runoff.

The purpose is to convey runoff from terraces, diversions, or other water concentrations without causing erosion or flooding, and to improve water quality.

Grasses and legumes in rotation (411)
Establishing grasses and legumes or a mixture of them and maintaining the stand for a definite number of years as part of a conservation cropping system.

The purpose is to produce forage for hay, silage, seed, or grazing; reduce soil and water loss; maintain a favorable level of organic matter; and improve soil productivity.

Sediment basins (350)
A basin constructed to collect and store debris or sediment.

The purpose is to preserve the capacity of reservoirs, ditches, canals, diversions, waterways, and streams; to prevent undesirable deposition on bottom lands and developed areas; to trap sediment originating from construction sites; and to reduce or abate pollution by providing basins for deposition and storage of silt, sand, gravel, stone, agricultural wastes, and other detritus material.

Stripcropping systems

Contour stripcropping (585)
Growing crops in a systematic arrangement of strips or bands on the contour to reduce water erosion. The crops are arranged so that a strip of grass or close-growing crop is alternated with a strip of clean-tilled crop or fallow or a strip of grass is alternated with a close-growing crop.

The purpose is to reduce erosion and control water.

Field stripcropping (586)
Growing crops in a systematic arrangement of strips or bands across the general slope (not on the contour) to reduce water erosion. The crops are arranged so that a strip of grass or a close-growing crop is alternated with a clean-tilled crop or fallow.

The purpose is to help control erosion and runoff on sloping cropland where contour stripcropping is not practiced.

Terraces (600)
An earthen embankment, a channel, or combination ridge and channel constructed across the slope.

The purpose is to: (1) reduce slope length, (2) reduce erosion, (3) reduce sediment content in the runoff water, (4) improve water quality, (5) intercept and conduct surface runoff at a nonerosive velocity to a stable outlet, (6) retain runoff for moisture conservation, (7) prevent gully development, (8) re-form the land surface, (9) improve farmability, or (10) reduce flooding.

Water and sediment control basin (638)
An earthen embankment or a combination ridge and channel generally constructed across the slope and minor watercourses to form a sediment trap and water detention basin.

The purpose is to: improve farmability of sloping land; reduce watercourse and gully erosion; trap sediment; reduce and manage onsite and downstream runoff; and improve downstream water quality.

Wetland and Riparian Zone Protection
Wetlands and riparian zone protection practices are described in Chapter 7.

5. Effectiveness Information

Following is information to illustrate the pollution reductions that can be achieved from installation of some of the management practices that may be used to implement this management measure. Two tables (Tables 2-1 and 2-2) are presented to show the variability in effectiveness information as reported by different sources. Also, general, qualitative information of the effectiveness of selected management practices is included in Table 2-3.

The information contained herein is primarily practice-oriented, yet EPA seeks data regarding the overall effectiveness of management measures, or systems of practices. To this end, EPA is continuing to collect and analyze more information regarding pollutant reductions, and solicits comments regarding information sources to utilize.

USDA estimates that the level of erosion control provided for by the specified management measure ("T") will result in an average annual savings of 9 Tons/Ac/Yr in the 28 coastal States. This will be achieved by bringing average erosion rate down from 11.4 Tons/Ac/Yr to an of 4.5 Tons/Ac/Yr ("T" values).

6. Cost Information

Cost estimates for control of erosion and sediment transport from agricultural lands are provided in Tables 2-4, 2-5, and 2-6. The costs in Table 2-4 are based upon experiences in the Chesapeake Bay Program, but are illustrative of the costs that could be incurred in coastal areas across the Nation. The costs in Table 2-5 are based on modeling runs for Indiana. The costs in Table 2-6 are national summaries provided by the USDA, and represent costs on a much broader scale. Only the costs in Table 2-5 represent net costs to the landowner or operator. It

Table 2-3. Water Quality Statement for Selected Management Practices

Practice	Water Quality Statement
Conservation cover (327)	Agricultural chemicals are usually not applied to this cover in large quantities and surface and ground water quality may improve where these material are not used. Ground cover and crop residue will be increased with this practice. Erosion and yields of sediment and sediment related stream pollutants should decrease. Temperatures of the soil surface runoff and receiving water may be reduced. Effects will vary during the establishment period and include increases in runoff, erosion and sediment yield. Due to the reduction of deep percolation, the leaching of soluble material will be reduced, as will be the potential for causing saline seeps. Long-term effects of the practice would reduce agricultural nonpoint sources pollution to all water resources.
Conservation croppping sequence (328)	This practice reduces erosion by increasing organic matter, resulting in a reduction of sediment and associated pollutants to surface waters. Crop rotations that improve soil tilth may also disrupt disease, insect and weed reproduction cycles, reducing the need for pesticides. This removes or reduces the availability of some pollutants in the watershed. Deep percolation may carry soluble nutrients and pesticides to the ground water. Underlying soil layers, rock and unconsolidated parent material may block, delay, or enhance the delivery of these pollutants to ground water. The fate of these pollutants will be site specific, depending on the crop management, the soil and geologic conditions.
Conservation tillage (329)	This practice reduces soil erosion, detachment and sediment transport by providing soil cover during critical times in the cropping cycle. Surface residues reduce soil compaction from raindrops, preventing soil sealing and increasing infiltration. This action may increase the leaching of agricultural chemical into the ground water.

VOL 12

4874

Table 2-3. (Continued)

Practice	Water Quality Statement
	In order to maintain the crop residue on the surface it is difficult to incorporate fertilizers and pesticides. This may increase the amount of these chemicals in the runoff and cause more surface water pollution. The additional organic material on the surface may increase the bacterial action on and near the soil surface. This may tie-up and then breakdown many pesticides which are surface applied, resulting in less pesticide leaving the field. This practice is more effective in humid regions. With a no-till operation the only soil disturbance is the planter shoe and the compaction form the wheels. The surface applied fertilizers and chemicals are not incorporated and often are not in direct contact with the soil surface. This condition may result in a high surface runoff of pollutants (nutrient and pesticides). Macropores develop under a no-till system. They permit deep percolation and the transmittal of pollutants, both soluble and insoluble to be carried into the deeper soil horizons and into the ground water. Reduced tillage systems disrupt or bread down the macropores, incidentally incorporate some of the materials applied to the soil surface, and reduce the effects of wheeltrack compaction. The results are less runoff and less pollutants in the runoff.
Contour farming (330)	This practice reduces erosion and sediment production. Less sediment and related pollutants may be transported to the receiving waters. Increased infiltration may increase the transportation potential for soluble substances to the ground water.

Table 2-3. (Continued)

Practice	Water Quality Statement
Contour orchard and other fruit area (331)	Contour orchards and fruit areas may reduce erosion, sediment yield, and pesticide concentration in the water lost. Where inward sloping benches are used, the sediment and chemicals will be trapped against the slope. With annual events, the bench may provide 100 percent trap efficiency. Outward sloping benches may allow greater sediment and chemical loss. The amount of retention depends on the lope of the bench and the amount of cover. In addition, outward sloping benches are subject to erosion form runoff from benched immediately above them. Contouring allows better access to rills, permitting maintenance that reduces additional erosion. Immediately after establishment, contour orchards may be subject to erosion and sedimentation in excess of the now contoured orchard. Contour orchards require more fertilization and pesticide application than did the native grasses that frequently covered the slopes before orchards were started. Sediment leaving the site may carry more adsorbed nutrients and pesticides than did the sediment before the benches were established from uncultivated slopes. If contoured orchards replace other crop or intensive land use, the increase or decrease in chemical transport from the site may be determined by examining the types and amounts of chemical used on the prior land use as compared to the contour orchard condition. Soluble pesticides and nutrients may be delivered to and possibly through the root zone in an amount proportional to the amount of soluble pesticides applied, the increase in infiltration, the chemistry of the pesticides, organic and clay content of the soil, and amounts of surface residues. Percolating water below the root zone may carry excess solutes or may dissolve potential pollutants as they move. In either case, these solutes could reach groundwater supplies and/or surface downslope from the contour orchard area. The amount depends on soil type, surface water quality, and the availability of soluble material (natural or applied).

Table 2-3. (Continued)

Practice	Water Quality Statement
Cover and green manure crop (340)	Erosion, sediment and adsorbed chemical yields green manure could be decreased in conventional tillage systems crop because of the increased period of vegetal cover. Plants will take up available nitrogen and prevent its undesired movement. Organic nutrients may be added to the nutrient budget reducing the need to supply more soluble forms. Overall volume of chemical application may decrease because the vegetation will supply nutrients and there may be allelopathic effects of some of the types of cover vegetation on weeds. Temperatures of ground and surface waters could slightly decrease.
Critical area planting (324)	This practice may reduce soil erosion and sediment delivery to surface waters. Plants may take up more of the nutrients in the soil, reducing the amount that can be washed into surface waters or leached into ground water. During grading, seedbed preparation, seeding, and mulching, large quantities of sediment and associated chemicals may be washed into surface waters prior to plant establishment.
Crop residue use (344)	When this practice is employed, raindrops are intercepted by the residue reducing detachment,use oil dispersion, and soil compaction. Erosion may be reduced and the delivery of sediment and associated pollutants to surface water may be reduced. Reduced soil sealing, crusting and compaction allows more water to infiltrate, resulting in an increased potential for leaching of dissolved pollutants into the ground water.

Table 2-3. (Continued)

Practice	Water Quality Statement
	Crop residues on the surface increases the microbial and bacterial action on or near the surface. Nitrates and surface-applied pesticides may be tied-up and less available to be delivered to surface and ground water. Residues trap sediment and reduce the amount carried to surface water. Crop residues promote soil aggregation and improve soil tilth.
Diversion (362)	This practice will assist in the stabilization of a watershed, resulting in the reduction of sheet and rill erosion by reducing the length of slope. Sediment may be reduced by the elimination of ephemeral and large gullies. This may reduce the amount of sediment and related pollutants delivered to the surface waters.
Field border (386)	This practice reduces erosion by having perennial vegetation on an area of the field. Field borders serve as "anchoring points" for contour rows, terraces, diversions, and contour strip cropping. By elimination of the practice of tilling and planting the ends up and down slopes, erosion from concentrated flow in furrows and long rows may be reduced. This use may reduce the quantity of sediment and related pollutants transported to the surface waters. When the field borders are located such that runoff flows across them in sheet flow, they may cause the deposition of sediment and prevent it from entering the surface water. Where these practice are between cropland and a stream or water body, the practice may reduce the amount of pesticide application drift from entering the surface water.
Filter strip (393)	Filter strips for sediment and related pollutants meeting minimum requirements may trap the coarser grained sediment. They may not filter out soluble or suspended fine-grained materials. When a storm caused runoff in excess of the design runoff, the filter may be flooded and

VOL 12

4878

Table 2-3. (Continued)

Practice	Water Quality Statement
	may cause large loads of pollutants to be released to the surface water. This type of filter requires high maintenance and has a relative short service life and is effective only as long as the flow through the filter is shallow sheet flow. Filter strip for runoff form concentrated livestock areas may trap organic material, solids, materials which become adsorbed to the vegetation or the soil within the filter. Often they will not filter out soluble materials. This type of filter is often wet and is difficult to maintain. Filter strips for controlled overland flow treatment of liquid wastes may effectively filter out pollutants. The filter must be properly managed and maintained, including the proper resting time. Filter strips on forest land may trap coarse sediment, timbering debris, and other deleterious material being transported by runoff. This may improve the quality of surface water and has little effect on soluble material in runoff or on the quality of ground water. All types of filters may reduce erosion on the area on which they are constructed. Filter strips trap solids from the runoff flowing in sheet flow through the filter. Coarse-grained and fibrous materials are filtered more efficiently than fine-grained and soluble substances. Filter strips work for design conditions, but when flooded or overloaded they may release a slug load of pollutants into the surface water.

VOL 12

4879

Table 2-3. (Continued)

Practice	Water Quality Statement
Grade stabilization structure (410)	Where reduced stream velocities occur upstream and downstream from the structure, streambank and streambed erosion will be reduce. This will decrease the yield of sediment and sediment-attached substances. Structures that trap sediment will improve downstream water quality. The sediment yield change will be a function of the sediment yield to the structure, reservoir trap efficiency and of velocities of released water. Ground water recharge may affect aquifer quality depending on the quality of the recharging water. If the stored water contains only sediment and chemical with low water solubility, the ground water quality should not be affected.
Grassed waterway (412)	This practice may reduce the erosion in a concentrated flow area, such as in a gully or in ephemeral gullies. This may result in the reduction of sediment and substances delivered to receiving waters. Vegetation may act as a filter in removing some of the sediment delivered to the waterway, although this is not the primary function of a grassed waterway. Any chemicals applied to the waterway in the course of treatment of the adjacent cropland may wash directly into the surface waters in the case where there is a runoff event shortly after spraying. When used as a stable outlet for another practice, waterways may increase the likelihood of dissolved and suspended pollutants being transported to surface waters when these pollutants are delivered to the waterway.

VOL 12

4880

Table 2-3. (Continued)

Practice	Water Quality Statement
Grasses and legumes in rotation (411)	Reduced runoff and increased vegetation may lower erosion rates and subsequent yields of sediment and sediment-attached substances. Less applied nitrogen may be required to grow crops because grasses and legumes will supply organic nitrogen. During the period of the rotation when the grasses and legumes are growing, they will take up more phosphorus. Less pesticides may similarly be required with this practice. Downstream water temperatures may be lower depending on the season when this practice is applied. There will be a greater opportunity for animal waste management on grasslands because manures and other wastes may be applied for a longer part of the crop year.
Sediment basin (350)	Sediment basins will remove sediment, sediment- associated materials and other debris from the water which is passed on downstream. Due to the detention of the runoff in the basin, there is an increased opportunity for soluble materials to be leached toward the ground water.
Contour stripcropping (585)	This practice may reduce erosion and the amount of sediment and related substances delivered to the surface waters. The practice may increase the amount of water which infiltrates into the root zone, and, at the time there is an overabundance of soil water, this water may percolate and leach soluble substances into the ground water.
Field stripcropping (586)	This practice may reduce erosion and the delivery of sediment and related substances to the surface waters. The practice may increase infiltration

Table 2-3. (Continued)

Practice	Water Quality Statement
	and, when there is sufficient water available, may increase the amount of leachable pollutants moved toward the ground water. Since this practice is not on the contour there will be areas of concentrated flow, from which detached sediment, adsorbed chemicals and dissolved substances will be delivered more rapidly to the receiving waters. The sod strips will not be efficient filter areas in these areas of concentrated flow.
Terraces (600)	This practice reduces the slope length and the amount of surface runoff which passes over the area downslope from an individual terrace. This may reduce the erosion rate and production of sediment within the terrace interval. Terraces trap sediment and reduce the sediment and associated pollutant content in the runoff water which enhance surface water quality.Terraces may intercept and conduct surface runoff at a nonerosive velocity to stable outlets, thus, reducing the occurrence of ephemeral and classic gullies and the resulting sediment. Increases in infiltration can cause a greater amount of soluble nutrients and pesticides to be leached into the soil. Underground outlets may collect highly soluble nutrient and pesticide leachates and convey runoff and conveying it directly to an outlet, terraces may increase the delivery of pollutants to surface waters. Terraces increase the opportunity to leach salts below the root zone in the soil. Terraces may have a detrimental effect on water quality if they concentrate and accelerate delivery of dissolved or suspended nutrient, salt, and pesticide pollutants to surface or ground waters.
Water and sediment control basin (638)	The practice traps and removes sediment and sediment-- attached substances from runoff. Trap control efficiencies for sediment and total phosphorus, that are transported by runoff, may exceed 90 percent in silt loam soils. Dissolved substance, such as nitrates, may be removed

Table 2-3. (Continued)

Practice	Water Quality Statement
	from discharge to downstream areas because of the increased infiltration. Where geologic condition permit, the practice will lead to increased loadings of dissolved substances toward ground water. Water temperatures of surface runoff, released through underground outlets, may increase slightly because of longer exposure to warming during its impoundment.

[1] Total acres treated is the actual area upon which the practice is applied. Some practices, such as filter strips and diversions, actually serve or benefit several times more acreage than is treated, so cost per acre served or benefitted can be substantially lower, and cost per ton of sediment "saved" can also be much lower.

[2] Annual cost is calculated as total amortized cost (10%) over life span of practice, divided by (acres treated x life span).

[3] Net costs are often much lower than this, frequently being negative.

VOL 12

4886

is important to note that for some practices such as conservation tillage the net costs often approach zero and in some cases can be negative due to the savings in labor and energy.

For example, modeling has been used to demonstrate that in Minnesota (Conservation Tillage Information Center, 1986) the return over total cost (i.e., total profit) increases for corn after beans when changing from moldboard plow ($8.52/Ac) to chisel till ($18.09/Ac), ridge till ($28.71), or no-till ($27.80). Similarly, modeling has shown that the relative cost (1982 dollars) for no-till versus conventional tillage in Indiana can vary from losses of $27.87/Ac to savings of $18.13/Ac (Griffith, 1983).

The net cost of conservation tillage depends upon several factors, including crops, soils, and climate. For example, a modeling study for a 750-acre cash grain operation in central Indiana (Griffith et al., 1986) compared projected returns for moldboard plowing, ridge tillage, and no-till planting for poorly drained soils (Group I), somewhat poorly drained soils (Group II), and well-drained soils (Group III). The results are given in Table 2-5 Either no-till or ridge till provides greater returns than moldboard in all nine scenarios, while moldboard provides a greater return than either no-till or ridge till in only three of nine scenarios.

Cost estimates for practices to control erosion and sediment on agricultural lands are also taken from the U.S. Department of Agriculture (USDA, Agricultural Stabilization and Conservation Service, 1991). Cost estimates reported by USDA are given by primary purpose, type of agreement (long term agreement or regular Agricultural Conservation Program (ACP)), and as overall estimates. The costs reported in Table 2-6 are for the primary purpose of erosion control, and long-term agreements and regular ACP agreements are lumped. The components of each practice are given in Appendix 2-A.

The cost to install stripcropping systems (practice SL3) for the primary purpose of erosion control was about $300 per acre treated in 1990. This cost is not amortized. Practice SL3 decreased the average annual erosion rate from 11 to 4.2 T/Ac/Yr, a reduction of 62 percent.

The cost to install permanent vegetative cover on critical areas (practice SL11) for the primary purpose of erosion control was about $152.00 per acre served in 1990. This cost is not amortized. Practice SL11 decreased the average annual erosion rate from 31 to 2.1 T/Ac/Yr, a reduction of 93 percent.

The cost to install contour farming (practice SL13) for the primary purpose of erosion control was about $200 per acre treated in 1990. This cost is not amortized. Practice SL13 decreased the average annual erosion rate from 18 to 6 T/Ac/Yr, a reduction of 67 percent.

The cost to install reduced tillage systems (practice SL14) for the primary purpose of erosion control was about $100 per acre treated in 1990. This cost is not amortized. Practice SL14 decreased the average annual erosion rate from 12 to 3.7 T/Ac/Yr, a reduction of 69 percent.

The cost to install no-till systems (practice SL15) for the primary purpose of erosion control was about $25.00 per acre treated in 1990. This cost is not amortized. Practice SL15 decreased the average annual erosion rate from 12 to 3.7 T/Ac/Yr, a reduction of 69 percent.

7. Operation and Maintenance

Operation:

Most structural practices for erosion and sediment control are designed to operate without human intervention. Water table control structures for example, would require some "operation" to change the water level in the system. Management practices such as conservation tillage, on the other hand, do require "operation" each time they are used. They must be factored into each field operation that takes place to produce the crop, in order to ensure that they are not destroyed. Extreme care must be used to ensure that herbicides are not applied to any practice that uses a permanent vegetative cover, such as waterways and filter strips.

Maintenance:

Structural practices such as diversions, grassed waterways and other practices that require grading and shaping may need to be repaired to maintain the original design; they may also need reseeding to maintain the vegetative cover. Trees and brush should not be allowed to grow on berms, dams or other structural embankments. Sediment retention basins will need to be cleaned to maintain the design volume and efficiency.

Filter strips and field borders need to be maintained to prevent channelization of flow and the resulting short-circuiting of filtering mechanisms. Reseeding of filter strips may be required on a frequent basis.

Cost: The annual cost of operation and maintenance is estimated to range from zero to ten percent of the investment cost (U.S. Department of Agriculture, Soil Conservation Service-Michigan, 1988).

8. Planning Considerations

Site specific resource information should be obtained from the SCS Field Office Technical Guide. Before deciding on the management practices for building a management measure system, there are several planning issues that should be considered. System adaptation to the site conditions, acceptability of the practice(s) in the system to the land user, and the reduction in erosion that will be realized by installation of the practices are key aspects that must be considered.

Local or state laws and regulations may dictate a specific level of erosion reduction or specific conservation practices that must be included. Practices that are chosen for the management measure must also meet objectives of the land user.

There are many conservation practices that can be used in developing a management measure. Standards for these practices can be found in the local Soil Conservation Service Field Office Technical Guide. Other site specific resource information necessary for good system planning can be found in these SCS guides.

Generally, more than one conservation practice will be needed to meet the sediment delivery required of the management measure. Several combinations of practices are likely to exist for meeting the established sediment delivery rate.
Management measure system options should be prepared based on water quality objectives and the land users' objectives. Each alternative should contain erosion and sediment reduction evaluations. The land user can then choose the system that best addresses personal objectives while also meeting the erosion and sediment control guidelines as well as water quality goals.

Other conservation practices, such as wildlife upland habitat management, tree planting, farmstead and feedlot windbreak, pastureland and hayland planting, or other land use conversion practices should be considered when developing a management measure. Adding one or more of these practices may provide additional erosion and sediment control, improve the environment, and add aesthetic values previously not realized.

VOL 12

B. Confined Animal Facility Management

1. Management Measure Applicability

Confined animal facilities are: areas used to grow or house the animals; equipment and supplies for production, processing and storage of product; the land near the buildings that the animals have access to that does not support vegetative cover; manure and runoff storage areas; and silage storage areas. These areas are subject to runoff control. The land upon which the manure, runoff and other wastes are utilized is considered agricultural crop, hay and pasture land and also subject to management measures for: erosion and sediment control, pesticides, nutrients irrigation water and grazing, where applicable.

This management measure is to be applied to all existing confined animal facilities, except those facilities that are required to apply for and receive discharge permits under 40 CFR, Section 122.23 ("Concentrated Animal Feeding Operations"). All new facilities are expected to be built and operated in accordance with this measure.

2. Pollutants Produced by Confined Animal Facilities

The following pollutants may be contained in manure and associated bedding materials and may be transported by runoff water from confined animal facilities and process wastewater:

- Nitrogen, phosphorus and many other major and minor nutrients or other deleterious materials;
- Salts;
- Bacteria, virus and other microorganisms;
- Organic solids;
- Oxygen demanding substances; and
- Sediments.

3. Management Measure to Control Confined Animal Facilities

The management measure for confined animal facilities control is a combination of practices that reduce discharge of pollutants from a confined animal facility by storing the runoff from storms up to and including a 24 hour, 25 year frequency storm and preventing pollutant movement to ground water. Manure and runoff water that is utilized on agricultural land will be applied in accordance with the nutrient management measure. Disposal of dead animals will be accomplished in a manner that will prevent any pollution to surface and ground waters. The management measure for confined animal facilities consists of:

4890

(1) Storing the runoff from an confined animal facility from storms up to and including of 24 hour, 25 year frequency storm, and preventing contamination of ground water.This will require diversion of clean water around the facility and from roofs; control of runoff from lot surfaces and from storage areas for runoff and manure; and control of process wastewater.

(2) Utilizing manure and runoff water on agricultural lands in accordance with the nutrient management measure; utilizing manure for bedding; or processing of manure for commercial marketing.

(3) Disposing of dead animals from the facility by composting, incineration, utilization of an approved burial site or, removal via commercial service.

4. Confined Animal Facilities Management Practices

Following is a list of management practices for confined animal facilities that are available as tools to achieve the management measure as set forth in section B.3. Under each management practice, the U.S. Soil Conservation Service (SCS) practice number and a definition are provided. The list of practices included in this section is not exhaustive and does not preclude States or local agencies from developing special management practices in cooperation with the appropriate technical agency within the State for unique conditions and problems that may be encountered in particular areas, provided that the management measures (the system of individual practices adopted) achieve a level of performance that is as effective as that provided by the management measure specified in this guidance. There may also be State or local standards that would require additional practices.

a. For runoff control at the production facility

Dikes (356)
An embankment constructed of earth or other suitable materials to protect land against overflow or to regulate water.

The purpose is to permit improvement of agricultural land by preventing overflow and better use of drainage facilities, to prevent damage to land and property, and to facilitate water storage and control in connection with wildlife and other developments. Dikes can also be used to protect natural areas, scenic features, and archeological sites from damage.

Diversions (362)
A channel constructed across the slope with a supporting ridge on the lower side.

The purpose is to divert excess water from one area for use or safe disposal in other areas.

VOL 12 4891

Grassed waterway (412)
A natural or constructed channel that is shaped or graded to required dimensions and established in suitable vegetation for the stable conveyance of runoff.

The purpose is to convey runoff from terraces, diversions, or other water concentrations without causing erosion or flooding and to improve water quality.

Heavy use area protection (561)
Protecting heavily used areas by establishing vegetative cover, by surfacing with suitable materials, or by installing needed structures.

The purpose is to stabilize urban, recreation, or facility areas frequently and intensely used by people, animals, or vehicles.

Lined waterway or outlet (468)
A waterway or outlet having an erosion-resistant lining of concrete, stone, or other permanent material. The lined section extends up the side slopes to a designed depth. The earth above the permanent lining may be vegetated or otherwise protected.

The purpose is to provide for safe disposal of runoff from other conservation structures or from natural concentrations of flow, without damage by erosion or flooding, where unlined or grassed waterways would be inadequate. Properly designed linings may also control seepage, piping, and sloughing or slides.

Roof runoff management (558)
A facility for controlling, and disposing of runoff water from roofs.

The purpose is to prevent roof runoff water from flowing across concentrated waste areas, barnyards, roads and alleys, and to reduce pollution and erosion, improve water quality, prevent flooding, improve drainage, and protect the environment.

Terrace (600)
An earthen embankment, a channel, or combination ridge and channel constructed across the slope.

The purpose is to: (1) reduce slope length, (2) reduce erosion, (3) reduce sediment content in the runoff water, (4) improve water quality, (5) intercept and conduct surface runoff at a non-erosive velocity to a stable outlet, (6) retain runoff for moisture
conservation, (7) prevent gully development, (8) re-form the land surface, (9) improve farmability, or reduce flooding.

VOL 12

4892

b. Manure and runoff storage

Waste storage pond (425)
An impoundment made by excavation or earthfill for temporary storage of animal or other agricultural wastes.

The purpose is to store liquid and solid wastes, waste water, and polluted runoff to reduce pollution and to protect the environment.

Waste storage structure (313)
A fabricated structure for temporary storage of animal wastes or other organic agricultural wastes.

The purpose is to temporarily store liquid or solid wastes as part of a pollution-control or energy-utilization system to conserve nutrients and energy and to protect the environment.

Waste treatment lagoon (359)
An impoundment made by excavation or earthfill for biological treatment of animal or other agricultural wastes.

The purpose is to biologically treat organic wastes, reduce pollution, and protect the environment.

c. Utilization of manure and runoff water

1. Application of manure and/or runoff water to agricultural land
Manure and/or runoff water will be applied to agricultural lands and incorporated into the soil in accordance with the management measures for nutrients.

Waste Utilization (633)
Using agricultural wastes or other wastes on land in an environmentally acceptable manner while maintaining or improving soil and plant resources.

The purpose is to safely use wastes to provide fertility for crop, forage, or fiber production; to improve or maintain soil structure; to prevent erosion; and to safeguard water resources.

2. Commercial marketing of manure

Composting facility (317)
A facility for the biological stabilization of waste organic material.

The purpose is to treat waste organic material biologically by producing a humus-like material that can be recycled as a soil amendment and fertilizer substitute or otherwise utilized in compliance with all laws, rules, and regulations.

d. Disposal of dead animals

"Dead Bird" composting

Composting facility (317)
A facility for the biological stabilization of waste organic material.

The purpose is to treat waste organic material biologically by producing a humus-like material that can be recycled as a soil amendment and fertilizer substitute or otherwise utilized in compliance with all laws, rules, and regulations.

Commercial Disposal Services

Incineration

Approved Burial Sites

5. Effectiveness Information

Pollution reductions that can be expected from installation of the management practices outlined above are as follows:

When runoff from storms up to and including the 24 hour, 25 year storm is stored, there will be no release of pollutants from a confined animal facility via the surface runoff route. Rare storms of a greater magnitude may produce runoff, but the "first flush" from them would be contained by the 24 hour, 25 year storage volume. Table 2-7 reflects the occurrence of such storms by indicating less than 100 percent control for runoff control systems.

Table 2-7. Runoff Control Efficiency

Management Practice	Removal efficiency Solids	Removal efficiency Phosphorus
Runoff Control System	80 to 90	70 to 95

SOURCE: Development Planning and Research Associates, Inc., 1986.

The information contained herein is primarily practice-oriented, yet EPA seeks data regarding the overall effectiveness of management measures, or systems of practices. To this end, EPA is continuing to collect and analyze more information regarding pollutant reductions, and solicits comments regarding information sources to utilize.

6. Cost Information

Cost factors for control of runoff and manure from confined animal facilities.

Table 2-8. Estimated Cost for Runoff Control Systems, by Size Range
Runoff Control Systems Only

Feedlot Capacity (head)	Investment	Cost Ranges Annual Dollars	Annualized
100	5000-12000	300-600	770-1730
500	9000-16000	400-800	1250-2310
1000	11000-20000	500-1000	1540-2900

SOURCE: Development Planning and Research Associates, Inc., 1986.

7. Operation and Maintenance of this Measure

a. Runoff control system

Operation: The holding ponds or lagoons should be drawn down to design storm capacity within 14 days of a runoff event. Solids should be removed from the solids separation system after a runoff event to ensure that solids will not enter the runoff holding facility.

VOL 12

4895

Maintenance: Diversions will need to be reshaped periodically and should be free of trees and brush growth. Gutters and downspouts should be inspected annually and repaired when needed. Established grades for lot surfaces and conveyance channels must be maintained at all times.

Channels must be free of trees and brush growth. Debris basins, holding ponds and lagoons will need to be cleaned to assure that design volumes are maintained. Irrigation equipment, if used to apply runoff water, should be flushed with fresh water after use. This is usually done twice per year. In warm climates this may be done four times per year, while in other colder climates, only once per year. Clean water should be excluded from the storage structure unless it is needed for further dilution in a liquid system.

Table 2-9. Estimated Cost Implications for Selected Management Practices

Practice	Unit	Capital (approximate)	Operating and Maintenance (Approximate)
Terrace systems	$14-39 per ha	$120-330 per ha	est. 5% of capital annually
Sod waterways	$7/ha drained	$100/ha drained	$500/ha/yr
Diversions	$90/ha	$600/ha	est. 5% of capital annually
Manure storage and use of nutrients	$10-20 per ha	$250-500 per ha	pumping, spreading of manure
Feedlot runoff control	$4/ha	$50/ha	5% of capital annually
Exclusion or limited access to water courses	$12/ha	$100/ha	5% of capital annually

SOURCE: Non-Point Source Task Force, International Joint Commission, 1983.
NOTE: All costs are 1982 dollars and amortized at a zero discount rate.

b. Manure storage system

Operation: The storage structure should be emptied when manure can be applied to cropland.Maintenance: Storage structures should be inspected for cracks and leaks after each use cycle. Manure transfer equipment must be inspected and repaired after each use cycle.

c. Cost

The annual cost of maintenance is estimated to be five percent of the investment cost.

C. Nutrient Management Measure

The basic concept of nutrient management is pollution prevention, by using only the nutrients necessary to produce a crop. This measure may result in some reduction in the amount of nutrients being applied to the land, thereby reducing the cost of production as well as protecting water quality.

1. Management Measure Applicability

This management measure is to be utilized on all agricultural lands that have nutrients applied to them. When the source of the nutrients is other than commercial fertilizer, the material must be tested to determine the nutrient value and the rate of availability of the nutrients. Also, for municipal and/or industrial treatment plant sludge and effluent, the concentration of metals and organic toxics must be known before these wastes are considered for application to agricultural lands as nutrient sources.

Those agricultural lands that also meet the applicability definitions of the pesticide management measure, erosion and sediment control management measure, grazing management measure, irrigation water management, or other management measures, are also subject to those management measures.

2. Pollutants Produced by Application of Nutrients Sources

Surface water runoff from agricultural lands that have had nutrients applied to them, may transport the following pollutants:

- Particulate bound nutrients, chemicals and metals, such as phosphorus, organic nitrogen, metals applied with some organic wastes and found naturally within the soil;
- Soluble nutrients and chemicals, such as nitrogen, phosphorus, metals and many other major and minor nutrients;
- Sediment, particulate organic solids, oxygen demanding material;

- Salts; and
- Bacteria, viruses and other microorganisms.

Ground-water infiltration from agricultural lands that have had nutrients applied to them, may transport the following pollutants:

- Soluble nutrients and chemicals, such as nitrogen, phosphorus, metals and many other major and minor nutrients, and salts.

3. <u>Sources of Nutrients That Are Applied to Agricultural Lands</u>

Nutrients are applied to agricultural land in several different forms and come from various sources, including;

- Commercial fertilizer in a dry or fluid form, containing N,P,K, secondary nutrients and micro-nutrients;
- Manure from animal production facilities including bedding and other wastes added to the manure, containing N,P,K, secondary nutrients, micro-nutrients, salts, some metals and organics;
- Municipal and/or industrial treatment plant sludge, containing N,P,K, secondary nutrients, micro-nutrients, salts, metals and organic solids;
- Municipal and/or industrial treatment plant effluent, containing N,P,K, secondary nutrients, micro-nutrients, salts, metals and organics;
- Irrigation water; and
- Atmospheric deposition of nutrients such as nitrogen and sulphur.

4. <u>Management Measure to Control Nutrients</u>

Following are the management measures for controlling excess nutrient use in agriculture. To eliminate application of excess nutrients, to improve timing of application, and to increase the use efficiency of nutrients, a nutrient management plan should be developed and implemented:

(1) Prepare a farm and field map containing soils information, a history of previous crops and current crop rotation.

(2) Assess soil productivity by field to determine expected yields for the target crop.

(3) Calculate the nutrient resources available to the producer for the target crop.

(4) Utilizing the limiting nutrient/element concept, establish nutrient/element requirement for the soil or the target crop and the nutrient sources available.

(5) Identify timing and application methods for nutrients that maximize plant utilization of nutrients and minimize the loss to the environment.

(6) Evaluate using cover crops to scavenge nutrients that might remain in the soil after harvest and water level control to keep nitrogen laden water within the root zone for plant use and to promote denitrification in drainage system.

(7) Evaluate field limitations based on environmental hazards or concerns.

(8) Control phosphorus loss from a field by controlling sediment loss. The primary management measure for control of phosphorus will be the erosion and sediment management measure, Section A., which is hereby included within the measure.

5. Nutrient Management Practices

Following is a list of management practices for nutrient management that are available as tools to achieve the management measure as set forth in section C.4. This list of practices is not exhaustive and does not preclude States and local agencies from developing special management practices, in cooperation with appropriate technical agencies for unique conditions and problems that may be encountered in particular areas, provided that the management measures (the system of individual practices adopted) achieve a level of performance that is as effective as that provided by the management measures specified in the guidance. There may also be State and local standards that would require additional nutrient management practices.

Following are the necessary components of a nutrient management plan:

(1) Soils information, a history of previous crops and current crop rotation for each field.

(2) An assessment by field to determine expected yields for the target crop. The expected yield is determined by using the following:

- University fertility recommendations (based on soil series where available),
- SCS Soils 5 information for the soil series, and
- Average yield history for the field.

(3) A summary of the nutrient resources available to the producer for the target crop. This would include the following steps:

VOL 12

4899

R0038207

- Testing of the soil in the field for phosphorus, potassium and nitrates;*

- Plant tissue testing for nutrient needs during the growing season (where tissue tests are calibrated with crop nutrient needs);

- Estimate of the nitrogen contribution form soil organic matter mineralization, where important;

- Nutrient analysis of manure and sludge; and

- Calculation of the nitrogen contribution to the soil from legumes grown in rotation.

(4) Use of proper timing and application methods for nutrients that maximize plant utilization of nutrients and minimize the loss to the environment, including split application and banding of the nutrients and incorporation of fertilizers, manures and other organic sources.

(5) Use of cover crops (see practice 340 below) to scavenger nutrients and water level control to keep nitrogen-laden water within the root zone for plant use and to promote denitrification in drainage system.

Cover and Green Manure Crop (340))
A crop of close-growing grasses, legumes or small grain grown primarily for seasonal protection and soil improvement. It usually is grown for 1 year or less, except where there is permanent cover as in orchards.

The purpose is to control erosion during periods when the major corps do not furnish adequate cover; add organic material to the soil and improve infiltration, aeration and tilth.

(6) Evaluate field limitations based on environmental hazards or concerns such as:

- Sinkholes, wells and other routes of direct access to ground water such as karst topography;
- Proximity to surface water;
- Highly erodible soils;
- Highly permeable soils; and
- Shallow aquifers.

* Soil testing for nitrates in humid regions has produced inconsistent results and should be used with caution. Consideration should be given to the alternative approach of plant tissue testing early in the growing season to determine the nitrogen needs of the crop.

(7) Provide a narrative explaining the plan and its use.

Nutrient Management (590)
Manage the amount, form, placement, and timing of applications of plant nutrients.

The purpose is to supply plant nutrients for optimum forage and crop yields, minimize entry of nutrients to surface and ground water, and to maintain or improve chemical and biological condition of the soil.

6. Effectiveness Information

Following is a summary of some of the available information regarding pollution reductions that can be expected from installation of nutrient management practices.

The State of Maryland estimates that average reductions of 34 pounds of nitrogen and 41 pounds of phosphorus per acre can be achieved through the implementation of nutrient management plans (Maryland Department of Agriculture, 1990). These average reductions may be high because they are mostly for farms that utilize animal wastes, average reductions for farms that only use commercial fertilizer may be much lower. However, they do represents a significant amount of nutrients that will not be applied to the fields and will not be available for transport from the field in surface water or for movement into the ground-water system. The actual percent reduction in the amount of these nutrients reaching coastal waters is difficult to measure or predict at this time. However, field scale and watershed models can be use to predict the reduction in nutrients moving to the edge of the field and to the ground water.

As of July 1990, the Chesapeake Bay drainage basin States of Pennsylvania, Maryland, and Virginia reported that approximately 114,300 acres (1.4 percent of eligible cropland in the basin) had nutrient management plans for in place (USEPA, Chesapeake Bay Program, 1991). The average nutrient reduction of total nitrogen and total phosphorus was 31.5 and 37.5 pounds per acre, respectively. The States initially prioritized nutrient management efforts toward animal waste utilization. Because initial planning was focused on animal wastes (which have a relatively high total nitrogen and phosphorus loading factor), estimates of nutrient reduction (see Table 2-10) attributed to nutrient management may decrease as more cropland using only commercial fertilizer is enrolled in the program.

Table 2-10. Estimated Nutrient Reductions for Selected Management Practices

Management Practice	Total P Load Reduction (%) (approximate)
Proper Rate of Fertilizer Application	3
Optimum Timing of Fertilization	20
Optimum Method of Fertilization	up to 90

SOURCE: Non-Point Source Task Force, International Joint Commission, 1983.

7. Cost Information

Following is available information on the costs of implementing nutrient management practices.

In general, most of the costs are associated with providing additional technical assistance to landowners to develop nutrient management plans. In many instances landowners can actually save money by implementing nutrient management plans. For example, Maryland estimates from the over 750 nutrient management plans that were completed prior to September 30, 1990, that if plan recommendations are followed, the landowners will save an average of $23 per acre per year (Maryland Department of Agriculture, 1990). The average saving may be high because most plans were for farm utilizing animal waste, future saving may be reduced as more farms using commercial fertilizer are included in the program.

VOL 12

4902

Table 2-11. Estimated Cost Implications for Selected Management Practices

Practice	Unit	Capital (approximate)	Operating and Maintenance (approximate)
Proper Rate of Fertilizer Application	0	0	0
Optimum Timing of Fertilization	minimal	0	minimal
Optimum Method of Fertilization	minimal	NA	minimal

SOURCE: Non-Point Source Task Force, International Joint Commission, 1983.

8. Planning Considerations for a Nutrient Management Measure

When developing a nutrient management plan the following items should be given careful consideration.

- A farm and field map

  The land that will be included in the nutrient plans should be located on a map of the farm and detailed on field maps showing the location of crop to be grown. A soils map for each field should be included in this initial information package. The map should be accompanied by the exact acres within the field, a five year average of crop yield for the field and an indication of the soil productivity of the field.

- Nutrient requirements of the target crop

  The most critical element of the plan is the yield goal established for the crop. This is to be based on the yield history and productivity of the soil in the field. The goal must be realistic for the soil, the growing season rainfall and management ability of the producer. Once the yield goal for a target crop is established, the nutrient requirements for the target crop can be calculated.

- Nutrient sources available by field and rotation system used for the field

  A list of all sources of nutrients must be developed for each field. This would include results from soil testing, analysis of animal wastes that will be applied to

VOL 12

4903

the field, analysis of any other organic wastes that will be applied to the field, credit for crop residues from previous crops, credit for cover crop if grown prior to the target crop, credit for nitrogen in irrigation water and atmospheric deposition on nitrogen on the field during the growing season.

- Indication of any environmental hazards or concerns

  A list of environmental hazards for each field should be developed at this time. The list should indicate areas of excessive leaching within the field, depth to ground water, distance to surface water, location of sink holes, indication of karst subsurface formations, location of water supply wells and areas of the field that are included in a wellhead protection zone.

- The narrative explaining the plan and its use

  The plan will specify the nutrients needed to reach the yield goal and the sources of these nutrients. It will recommend times of application for the sources and the methods of application. This may include split applications of commercial fertilizer, incorporation of manure and the use of slow release nutrient sources. The plan may require either soil testing or tissue testing after the crop reaches a specified stage as a guide for the application of additional nutrients to complete the requirements for the yield goal. Winter cover crops may also be specified to hold nutrients during this time period.

9. <u>Operation and Maintenance for Nutrient Management</u>

<u>Operation</u>:

The utilization of a nutrient management plan requires periodic soil testing for each field, soil and/or tissue testing during the early growth stages of the crop and testing of manure, sludge and irrigation water if they are used. The plan may call for multiple applications of nutrients requiring more that one field operation to apply the total nutrients required for the crop.

<u>Maintenance:</u>

A nutrient management plan should be updated whenever the crop rotation is changed or the nutrient source is changed. Application equipment must be calibrated and inspected for wear and damage periodically and repaired when necessary. Records of nutrient use and source should be maintained along with other production records for each field. These will be used to update or modify the management plan when necessary. The management plan should be reviewed at least every three years.

D. Pesticide Management

The basic concept of pesticide management is pollution prevention. The most effective approach to reducing pesticide pollution of waters is, first, to release fewer pesticides into the environment and, second, to use practices which minimize the movement of pesticides to surface and ground water. In addition, pesticides should only be applied when an economic benefit to the grower will be achieved. Such an approach emphasizes using pesticides only when, and to the extent, necessary to control the target pest. This usually results in some reduction in the amount of pesticides being applied to the land, thereby enhancing the protection of water quality as well as reducing the cost of production.

1. Management Measure Applicability

The management measures set forth in this section are to be utilized on all agricultural lands that have or are intended to have pesticides applied to them.

Those agricultural lands that also meet the applicability definitions of the erosion and sediment management measure, nutrient management measure, grazing management measure, or other management measures are also subject to those management measures.

2. Pollutants Associated with Agricultural Pesticide Use

Pesticides include any substance or mixture of substances intended for preventing, destroying, repelling, or mitigating any pest or intended use as a plant regulator, defoliant, or desiccant. The principal pesticidal pollutants that may be detected in surface water and in ground water are the active and inert ingredients and any persistent degradation products. Pesticides may enter ground and surface water in dissolved form or bound to eroded soil particles.

3. Sources of Pesticides

A major source of contamination from pesticide use is the result of application of pesticides. Other sources of pesticide contamination are atmospheric deposition, spray drift during the application process, misuse, and spills, leaks, and discharges that may be associated with pesticide storage, handling and waste disposal.

4. Management Measures to Manage Pesticide Use

Following are the management measures for managing agricultural pesticide use. They will reduce surface and ground-water contamination, eliminate application of excess pesticides, improve timing and efficiency of application, increase the use efficiency of pesticides, and reduce the generation of pesticide wastes. Specific pesticide management measures are as follows:

(1) Evaluate the pest problems, previous pest control measures, and cropping history.

(2) Evaluate the physical characteristics of the site for the leaching of soluble pesticides or runoff of soluble or soil-borne pesticides.

(3) Utilize integrated pest management (IPM) systems to reduce the amount of pesticides applied to the maximum extent that is technically and economically achievable. IPM is defined as a pest control strategy based on the determination of an economic threshold that indicates when a pest population is approaching the level at which control measures are necessary to prevent a decline in net returns. In principle, IPM is an ecologically based strategy that relies on natural mortality factors, such as natural enemies, weather, and crop management, and seeks control tactics that disrupt these factors as little as possible (National Research Council, 1989).

(5) If pesticide applications are necessary and a choice of materials exists, consider the persistence and leachability of products along with other factors in making a selection. Users must apply pesticides in accordance with the instructions on the label of each pesticide product, and when required, be trained and certified in the proper use of the pesticide.

(6) Ensure that pesticides are handled safely, and stored and disposed of properly.

5. <u>Pesticide Management Practices</u>

Following is a list of management practices for pesticide management that are available as tools to achieve the management measure as set forth in section D.4. This list of practices is not exhaustive and does not preclude States and local agencies from developing special management practices, in cooperation with the appropriate technical agency within the State for unique conditions and problems that may be encountered in particular areas, provided that the management measures (the system of individual practices adopted) achieve a level of performance that is as effective as the provided by the management measures specified in the guidance. There may also be State and local standards that would require additional pesticide management practices:

(1) Inventory of current and historical pest problems, cropping patterns and use of pesticides for the field.

(2) Consider soil and physical characteristics of the site, including the potential for the leaching or runoff of pesticides. In situations where the potential for loss is high, emphasis should be given to practices and/or management measures that will minimize these potential losses. The physical characteristics to be considered should include limitations based on environmental hazards or concerns such as:

- Sinkholes, wells and other areas of direct access to ground water such as karst topography;

- Proximity to surface water;
- Highly erodible soils;
- Soils with poor adsorptive capacity;
- Highly permeable soils; and
- Shallow aquifers;

(3) Following is a list of the primary practices available to implement IPM systems:

- More efficient application methods e.g. spot spraying;
- Pesticide application based on economic thresholds;
- Use of resistant crop strains;
- Use less environmentally persistent pesticides;
- Use pesticides with reduced mobility in water;
- Use timing of field operations (planning, cultivating, and harvesting) to minimize application of pesticides;
- Conduct scouting (use periodic scouting to determine when pest problems reach the economic threshold on the farm);
- Use of biological controls:
  - (a) introduction and fostering of natural enemies;
  - (b) preservation of predator habitats; and
  - (c) release of sterilized male insects;
- Use of pheromones:
  - (a) for monitoring populations;
  - (b) for mass trapping;
  - (c) for disrupting mating or other behaviors of pests; and
  - (d) to attract predators/parasites;
- Crop rotations
- Use cover crops in the system, as needed, to promote water use and reduce deep percolation of water that contributes to leaching of pesticides into ground water;
- Destruction of pest breeding, refuge and overwintering sites;
- Use of "trap" crops;
- Habitat diversification; and
- Use of botanicals.

(4) Maintain a history of pesticide use for each field. This could include the types of pesticides used, amount, and the method of application.

(5) A strong State role and linkage with other evolving ground and surface water protection programs is critical to protect water resources from contamination from pesticide chemicals. Therefore, States should integrate this aspect of their Coastal program with State and Federal strategies designed to reduce ground and surface water contamination associated with pesticide use. Particular attention should be paid to practices which provide flexibility for decisions to be made on a geographic basis--taking into account use, value and vulnerability of ground-water resources.

6. Implementation of Management Measure

The management measures specified in section D.4 identify the changes in behavior and thought processes that are needed to manage pesticides to reduce excess pesticide use. FIFRA can be used to enforce requirements to follow pesticide label instructions and for applicator training and certification, when necessary. States are using a variety of approaches to encourage change in behavior and thought processes regarding pesticide use, such as State wide and regional strategies and farm-specific plans. EPA believes that farm-specific pesticide management plans may be necessary to document the changes in behavior and the thought processes necessary to implement the management measure.

EPA solicits comment on whether the pesticide management measure should include development of a pesticide management plan so that the behavior and thought process associated with the management measures is documented.

7. Effectiveness Information

Following is a summary of available information regarding pollution reductions that can be expected from using pesticide management practices.

Table 2-12 summarizes estimates of potential pesticide loss reductions from various management practices and systems of practices at a field level as compared with a hypothetical field utilizing cropping practices which were typical until the late 1970's. The uncertainty of the estimates is a function of the rapid transitions in production methods coupled with the variance among regions and seasons. Traditional sediment and erosion control practices are not as effective on cotton as with corn and soybeans because much cotton is grown on relatively flat land with little or no water erosion problem (Heimlich and Bills, 1984).

Table 2-13 summarizes the estimates of pesticide loss reductions from various management practices and combinations of practices for corn (North Carolina State University, 1984). These estimates are made at the field level as compared with a hypothetical field utilizing conventional, traditional or typical cropping practices realizing that these practices may vary considerably between geographic regions.

The Non-Point Source Task Force of the International Joint Commission (1983) for the Great Lakes Basin also estimated pesticide reductions associated with selected management practices and the data are summarized in Table 2-14. The Task Force found that the most effective, although not necessarily the most acceptable method of pesticide Great Lakes loading control, is regulation of the use of volatile and persistent pesticides (see practice no. 2 below). They noted that this has been effective in the Great Lakes Basin.

The Great Lakes Pollution from Land Use Activities Reference Group (PLUARG) agricultural watershed studies found that 66 percent of simazine loadings and 22 percent of atrazine loadings were due to spills in 1976-77 (Frank et al., 1978). Thus, safe handling, storage and disposal practices (see practice no.6 below) alone, can significantly reduce pesticide losses.

Pest Resistant Varieties	All Routes	0-60 A 0-30 B
Alternative Pesticides	All Routes	60-95 A 0-20 B

SOURCE: North Carolina State University, 1984.

* Refers to estimated increases in movement through soil profile.
\# SR = Surface Runoff
SL = Soil Leaching
$ Particularly drift and volatilization

[1]The hypothetical traditionally cropped comparison field utilizes the following management system:
a) conventional tillage without other SWCPs,
b) aerial application of all pesticides with timing based only on field operation convenience,
c) ten insecticide treatments annually with a total application of 12 kg/ha based on a prescribed schedule,
d) cotton grown in 3 out of 4 years,
e) long season cotton varieties.

[2]Assumes field loss reductions are proportional to application rate reductions.
A = insecticide (toxaphene, methylparathion, synthetic pyrethroids).
B = herbicides (trifluralin, fluometron).
Ranges allow for variation in production region, climate, slope and soils.
[3]Defined for cotton as ground application using optimal droplet or granular size ranges with spraying restricted to calm periods in late afternoon or at night when precipitation is not imminent.

Table 2-13. Estimates of Potential Reductions in Field Losses of Pesticides for Corn Compared to a Conventionally and/or Traditionally Cropped Field[1]

Management Practice	Transport Route(s) Affected	Range of Pesticide Loss Reduction (Percent)[2]
SWCPs	SR and/or SL(#)	
Terracing	SR and/or SL	40-75AB (25*)
Contouring	SR and/or SL	15-55AB (20*)

Table 2-14. Estimated Pesticide Reductions for Selected Management Practices

Management Practice	Percent Reduction (Approximate)
1. Proper rate of pesticide application	50 - 75% (in conjunction with No. 3)
2. Use of pesticides with minimum persistence and volatility	100%
3. Optimum method of pesticide application	50 - 75% (in conjunction with No. 1)
4. Optimum timing of pesticide application	50% (if application prior to spring runoff can be avoided)
5. Integrated pest management	Undocumented (but up to 100% is possible)
6. Safe handling, storage and disposal of pesticides	up to 50%

SOURCE: Non-Point Source Task Force, International Joint Commission, 1983.

8. Cost Information

In general, most of the costs of implementing a pesticide management plan are program costs associated with providing additional technical assistance to landowners to develop pesticide management plans and for field scouting during the growing season. Producers can actually save money by implementing pesticide management plans.

The Non-Point Source Task Force of the International Joint Commission for the Great Lakes Basin (1983) estimated the cost implications for selected pesticide management practices and the data are summarized in Table 2-15.

Costs for erosion and sediment control and for irrigation management are in Sections A and F, respectively.

VOL 12

Table 2-15. Estimated Cost Implications for Selected Pesticide Management Practices

Management Practice	Unit	Capital Approximate	Operating
1. Proper rate of pesticide application	minimal	0	minimal
2. Use of pesticides with minimum persistence and volatility	0	0	
3. Optimum method of pesticide application	minimal	minimal	0
4. Optimum timing of pesticide application	minimal	0	minimal
5. Integrated pest management	minimal	0	major inconvenience

9. <u>Planning Considerations for Implementing Pesticide Management</u>

Following is a more detailed discussion regarding effective pesticide management:

- A farm and field map.

  The land where pesticides will be used should be located on a map of the farm. In addition, the following information should be compiled for each field:

  - Crops to be grown and a history of crop production;
  - Information on soils types;
  - The exact acres within each field; and
  - Record on past pesticide use on each field.

- Pesticide requirements for the target pest(s).

  The most critical element is establishment of the economic yield reductions thresholds for each crop. The reduction thresholds must be <u>realistic</u> for the producer.

4912

- Pesticide sources available by field and rotation system used for the field.
- Indication of any environmental hazards or concerns.

  A list of environmental hazards for each field should be developed at this time. The list should indicate
  areas of excessive leaching within the field, depth to ground water, distance to surface water, location of sink holes, indication of karst subsurface formations, location of water supply wells and areas of the field that are included in a wellhead protection zone.

10. <u>Operation and Maintenance for Pesticide Management</u>

<u>Operation</u>:

Effective pesticide management may require periodic scouting of each field for pests. Also, multiple applications of pesticides may require more that one field operation to apply the pesticides required for the crop.

<u>Maintenance</u>:

Pesticide management measures should be updated whenever the crop rotation is changed or the pesticide source is changed. Application equipment must be calibrated and inspected for wear and damage periodically and repaired when necessary. Records of pesticide application should be maintained along with other production records for each field. These will be used to update or modify the management measure when necessary. The management measure for each field should be reviewed every year.

VOL 12

E. Grazing Management

This management measure is designed to improve water quality from, and protect riparian zones within, range or pasture land. The key elements are grazing management for the proper utilization of the forage component of the vegetation, controlling access to or excluding livestock from sensitive areas such as streambanks and riparian zones, and improving of vegetative cover to reduce erosion.

1. Management Measure Applicability

The management measure is to be utilized on all irrigated and non-irrigated agricultural pasture lands and range lands.

Those range and pasture lands that also meet the applicability definitions of the erosion and sediment control management measure, pesticide management measure, nutrient management measure, irrigation water management, or other management measures are also subject to those management measures.

2. Pollutants Produced by Utilization of Agricultural Range and Pasture Lands

Runoff water from agricultural pasture lands and range lands may transport the following types of pollutants:

- Sediment and particulate organic solids;
- Particulate bound nutrients, chemicals and metals, such as phosphorus, organic nitrogen, a portion of applied pesticides, and a portion of the metals applied with some organic wastes and found naturally within the soil;
- Soluble nutrients, such as nitrogen, a portion of the phosphorus, a portion of the applied pesticides, a portion of the soluble metals and many other major and minor nutrients;
- Salts; and
- Bacteria, viruses and other microorganisms.

4914

3. Management Measure to Control Range and Pasture Land Grazing

The range and pasture land grazing control management measure is a combination of practices to reduce the discharge of sediment, nutrients and chemicals from agricultural pasture land and range lands to receiving waters; to prevent streambank erosion caused by livestock; and to enhance or maintain riparian zones at the good to excellent conditional status. At a minimum, for range land this measure will maintain the range condition at the good condition status* or above; for pasture this measure will maintain a vegetation cover that will reduce erosion to, or maintain soil stability within, the soil loss tolerance value or below. For both range and pastures, areas will be provided for livestock watering, salting and shade that are located away from streambanks and riparian zones. This will be accomplished by managing livestock grazing and providing facilities for water, salt and shade, as needed.

4. **Range and Pasture Land Management Practices**

Following is a list of management practices for range and pasture grazing control that are available as tools to achieve the range and pasture land management measure as set forth in Section E.3. Under each management practice the U.S. Soil Conservation (SCS) practice number and a definition is provided. The list of practices included in this section is by no means exclusive and does not preclude States or local agencies from developing special management practices in cooperation with the appropriate technical agency within the State for unique conditions and problems that may be encountered in particular areas, provided that the management measures (the system of individual practices adopted) achieve a level of performance that is as effective as that provided by the management measure specified in this guidance. There may also be state or local standards that would require additional practices.

(1) Implementation of a grazing management scheme that assures proper grazing use by grazing at an intensity that balances the number of livestock with the available forage and feed and describes the animal movement through the operating unit of range or pasture lands. Proper grazing use will maintain enough live vegetation and litter cover to protect the soil from erosion, and will maintain or improve the quality and quantity of desirable vegetation. Practices that accomplish this are:

<u>Deferred Grazing (352)</u>
Postponing grazing or resting grazing land for prescribed period.

The purpose is to: (1) promote natural re-vegetation by increasing the vigor of the forage stand and permitting desirable plants to produce seed, (2) provide a feed reserve for fall and winter grazing or emergency use, (3) improve the appearance of range having inadequate cover, and (4) reduce soil loss and improve water quality.

<u>Planned Grazing System (556)</u>
A practice in which two or more grazing units are alternately rested and grazed in a planned sequence for a period of years, and rest periods may be throughout the year or during the growing season of key plants.

---

* Range land condition rating (percent climax vegetation): Excellent = 76-100%, Good = 51-75%, Fair = 26-50%, and Poor = 0-25%.

VOL 12

4915

The purpose is to: (1) maintain existing plant cover or hasten its improvement while properly using the forage of all grazing units, (2) reduce erosion and improve water quality, (3) increase efficiency of grazing by uniformly using all parts of each grazing unit, (4) insure a supply of forage throughout the grazing season, (5) increase production and improve quality of forage, (6) enhance wildlife habitat, (7) promote flexibility in the grazing program and buffer the adverse effects of drought, and (8) promote energy conservation through reduced use of fossil fuel.

Proper Grazing Use (528)
Grazing at an intensity that will maintain enough cover to protect the soil and maintain or improve the quantity and quality of desirable vegetation.

The purpose is to: (1) increase the vigor and reproduction of key plants; (2) accumulate litter and mulch necessary to reduce erosion and sedimentation and improve water quality; (3) improve or maintain the condition of the vegetation; (4) increase forage production; (5) maintain natural beauty; and (6) reduce the hazard of wildfire.

(2) Providing water and salt supplement facilities away from streams will help keep livestock away from streambanks and riparian zones. The establishment of alternate water supplies for livestock is an essential component of this measure when distribution problems of livestock occurs in a grazing unit. In some locations, artificial shade may be constructed to encourage use of upland sites for shading and loafing. This will be accomplished through the following:

Pipeline (516)
Pipeline installed for conveying water for livestock or for recreation.

The purpose is to convey water from a source of supply to a point of use.

Pond (378)
A water impoundment made by constructing a dam or an embankment or by excavation a pit or dugout.

The purpose is to provide water for livestock, fish and wildlife, recreation, fire control, and other related uses, and to maintain or improve water quality.

Trough or Tank (614)
A trough or tank, with needed devices for water control and waste water disposal, installed to provide drinking water for livestock.

The purpose is to provide watering facilities for livestock at selected locations that will protect vegetative cover through proper distribution of grazing or through better grassland management for erosion control. Another purpose on some sites

VOL 12

4916

is to reduce or eliminate the need for livestock to be in streams, which reduces livestock waste there.

Well (642)
A well constructed or improved to provide water for irrigation, livestock, wildlife, or recreation.

The purpose is to facilitate proper use of vegetation on rangeland, pastures, and wildlife areas; and to supply the water requirements of livestock and wildlife.

(3) Minimizing access to or excluding livestock from streambanks and riparian zones is essential to the implementation of this management measure. This could be accomplished by fencing of areas where animals tend to congregate, including stream corridors and riparian zones.

Fencing (516)
Enclosing or dividing an area of land with a suitable permanent structure that acts as a barrier to livestock, big game, or people (does not include temporary fences).

The purpose is to: (1) exclude livestock or big game from areas that should be protected from grazing, (2) confine livestock or big game on an area, (3) control domestic livestock while permitting wildlife movement, (4) subdivide grazing land to permit use of grazing systems, (5) protect new seedings and plantings from grazing, and (6) regulate access to areas by people or prevent trespassing.

Livestock exclusion (472)
Excluding livestock from an area not intended for grazing.
The purpose is to protect, maintain, or improve the quantity and quality of the plant and animal resources; to maintain enough cover to protect the soil; to maintain moisture resources; and to increase natural beauty.

(4) Where existing conditions result in excessive erosion, it will be necessary to improve or re-establish the vegetative cover on range and pasture lands. When re-establishment of vegetation is required, it may be accomplished using the following practices:

Pasture and Hayland Planting (512)
Establishing and reestablishing long-term stands of adapted species of perennial, biannual, or reseeding forage plants. (Includes pasture and hayland renovation. Does not include grassed waterways or outlets or cropland.)

The purpose is to reduce erosion,or maintain soil stability and to produce high quality forage.

VOL 12

4917

VOL 12

Range Seeding (550)
Establishing adapted plants by seeding on native grazing land (does not include pasture and hayland planting).

The purpose is to: (1) prevent excessive soil and water loss and improve water quality; (2) produce more forage for grazing of browsing animals on rangeland or land converted to range from other uses; and (3) improve the visual quality of grazing land.

Critical area planting (342)
Planting vegetation, such as trees,shrubs, vines grasses, or legumes, on highly erodible or critically eroding areas (does not include tree planting mainly for wood products).

The purpose is to stabilize the soil, reduce damage from sediment and runoff to downstream areas, and improve wildlife habitat and visual resources.

5. **Effectiveness Information**

Table 2-16 presents information on pollution reductions that can be expected from installation of the management practices outlined within this management measure.

Table 2-16. Estimated Pollutant Reductions for Selected Management Practices

Practice	Sediment Load Reduction	Total P Load Reduction
Permanent Veg. Cover	less than 1 T/Ac/Yr delivered	very high
Reforestation of Erodible Crop and Pastureland	less then 1 T/Ac/Yr delivered	very high

SOURCE: Non-Point Source Task Force, International Joint Commission, 1983.
NOTE: All reductions are relative to conventional (moldboard plow) tillage.

The information contained herein is primarily practice-oriented, yet EPA seeks data regarding the overall effectiveness of management measures, or systems of practices. To this end, EPA is continuing to collect and analyze more information regarding pollutant reductions, and solicits comments regarding information sources to utilize.

4918

The Soil Conservation Service has developed a set of water quality statements for each practice that provide some insight into the use of the practice for water quality improvement. They also include warnings of negative water quality impacts that might occur by using the practice. Water quality statements for the practices listed in this management measure are contained in Table 2-17.

6. Cost Information

Cost factors for control of erosion and sediment transport from agricultural lands.

The cost to install the Grazing Land Protection system (SL6) for the 42 states which used the practice, was $5.68 per acre in 1990 (USDA, ASCS, 1991).

The system reduced erosion by an average of 2.2 tons per acre at an amortized cost of $0.50 per ton (USDA, ASCS, 1991).

The SL6 Grazing Land Protection contain many of the practices recommended in this management measure (see Appendix 2-A).

7. Planning Considerations

The selection of management practices for this measure will be based on an evaluation of current conditions, problems identified, quality criteria, and management goals.

Successful resource management on range and pasture land is the correct application of a combination of practices that will meet the needs of the range and pasture land ecosystem - the soil, water, air, plant and animal resources and the objectives of the land user.

For a sound grazing land management system to function properly and to provide for a sustained level of productivity, the following should be considered.

(1) Know the key management plant species and their response to different seasons and degrees of use by various kinds and classes of livestock.

(2) Know the demand for, and seasons of use, of forage and browse by wildlife species.

Table 2-17. Water Quality Statement for Selected Management Practices

Practice	Water Quality Statement
Deferred Grazing (352)	In areas with bare ground or low percent ground cover, deferred grazing will reduce sediment yield because of increased ground cover, less ground surface disturbance, improved soil bulk density characteristics, and greater infiltration rates. Areas mechanically treated will have less sediment yield when deferred to encourage re-vegetation. Animal waste would not be available to the area during the time of deferred grazing and there would be less opportunity for adverse runoff effects on surface or aquifer water quality. As vegetative cover increases, the filtering processes are enhanced, thus trapping more silt and nutrients as well as snow if climatic conditions for snow exist. Increased plant cover results in a greater uptake and utilization of plant nutrients.
Fencing (382)	Fencing is a practice that can be on the contour or up and down slope. Often a fence line has grass and some shrubs in it. When a fence is built across the slope it will slow down runoff, and cause deposition of coarser grained materials reducing the amount of sediment delivered downslope. Fencing may protect riparian areas which act as sediment traps and filters along water channels and impoundments. Livestock have a tendency to walk along fences. The paths become bare channels which concentrate and accelerate runoff causing a greater amount of erosion within the path and where the path/channel outlets into another channel. This can deliver more sediment and associated pollutants to surface waters. Fencing can have the effect of concentrating livestock in small areas, causing a concentration of manure which may wash off into the stream, thus causing surface water pollution.

VOL 12

4920

Table 2-17. (Continued)

Practice	Water Quality Statement
Pasture and Hayland Planting (556)	The long-term effect will be an increase in the quality of the surface water due to reduced erosion and sediment delivery. Increased infiltration and subsequent percolation may cause more soluble substances to be carried to ground water.
Planned grazing system (556)	Planned grazing systems normally reduce the system time livestock spend in each pasture. This increases quality and quantity of vegetation. As vegetation quality increases, fiber content in manure decreases which speeds manure decomposition and reduces pollution potential. Compacted layers of the soil tend to diminish because of the opportunity for freeze-thaw, shrink-swell, and other natural soil mechanisms to occur that reduce compacted layers during the absence of the grazing animals. This increases infiltration, increases vegetative growth, slows runoff, and improves the nutrient and moisture filtering and trapping ability of the area. Decreased runoff will reduce the rate of erosion and movement of sediment and dissolved and sediment-attached substances to downstream water courses. No increase in ground water pollution hazard would be anticipated from the use of this practice.
Range seeding (550)	Increased erosion and sediment yield may occur during the establishment of this practice. This is a temporary situation and sediment yields decrease when reseeded area becomes established. If chemicals are used in reestablishment process, chances of chemical runoff into downstream water courses are reduced if application is applied according to label instructions. After establishment of the grass cover, grass sod slows runoff, acts as a filter to trap sediment, sediment attached substances,

Table 2-17. (Continued)

Practice	Water Quality Statement
	increase infiltration, and decreases sediment yields.
Pipeline (516)	Pipelines may decrease sediment, nutrient, organic, and bacteria pollution from livestock. Pipelines may afford the opportunity for alternative water sources other than streams and lakes, possibly keeping the animals away from the stream or impoundment. This will prevent bank destruction with resulting sedimentation, and will reduce animal waste deposition directly in the water. The reduction of concentrated livestock areas will reduce manure solids, nutrients, and bacteria that accompany surface runoff.
Trough or tank (614)	By the installation of a trough or tank, livestock may be better distributed over the pasture, grazing can be better controlled, and surface runoff reduced, thus reducing erosion. By itself this practice will have only a minor effect on water quality; however when coupled with other conservation practices, the beneficial effects of the combined practices may be large. Each site and application should be evaluated on their own merits.
Pond (378)	Ponds may trap nutrients and sediment which wash into the basin. This removes these substances from downstream. Chemical concentrations in the pond may be higher during the summer months. By reducing the amount of water that flows in the channel downstream, the frequency of flushing of the stream is reduced and there is a temporary collection of substances held temporarily within the channel. A pond may cause more leachable substance to be carried into the ground water.

VOL 12

4922

Table 2-17. (Continued)

Well (642)	When water is obtained it has poor quality because of dissolved substances, its use in the surface environment or its discharge to downstream water courses the surface water will be degraded. The location of the well must consider the natural water quality and the hazards of its use in the potential contamination of the environment. Hazard exists during well development and its operation and maintenance to prevent aquifer quality damage from the pollutants through the well itself by back flushing, or accident, or flow down the annual spacing between the well casing and the bore hole.

SOURCE: USDA, Soil Conservation Service, 1988.

(3) Know the amount of plant residue or grazing height that should be left to protect grazing land soils from wind and water erosion and to provide for plant regrowth.

(4) Know the range site production capabilities and the pasture land suitability group capabilities so an initial stocking rate can be established.

(5) Know how to use livestock as a tool in the management of the range ecosystems and pasture lands to insure the health and vigor of the plants, soil tilth, proper nutrient cycling, erosion control, and riparian area management, while at the same time meeting livestock nutritional requirements.

(6) Establish grazing unit sizes, watering, shade and salt locations, etc. to secure optimum livestock distribution and utilization.

(7) Provide for livestock herding, as needed, to protect sensitive areas from excessive use at critical times.

(8) Encourage proper wildlife harvesting to ensure proper population densities and forage balances.

(9) Know the livestock diet requirements in terms of quantity and quality to ensure that there are enough grazing units to provide adequate livestock nutrition for the season, kind and classes of animals on the farm/ranch.

(10) Maintain a flexible grazing system to adjust for unexpected environmentally and economically generated problems.

F. Irrigation Water Management

1. Management Measure Applicability

This management measure is to be utilized on all irrigated agricultural lands, including but not limited to the following: cropland, pastureland, orchards, specialty crop production, and nursery crop production.

Those irrigated agricultural lands that also meet the applicability definitions of the erosion and sediment management measure, nutrient management measure, pesticide management measure, grazing management measure, or other management measures are also subject to those management measures.

2. Pollutants Produced by Irrigation

Runoff water and leachate from irrigated land may transport the following types of pollutants:

- Sediment and particulate organic solids;
- Particulate bound nutrients, chemicals and metals, such as phosphorus, organic nitrogen, a portion of applied pesticides, and a portion of the metals applied with some organic wastes and also found naturally within the soil;
- Soluble nutrients, such as nitrogen, soluble phosphorus, a portion of the applied pesticides, soluble metals, salts and many other major and minor nutrients; and
- Bacteria, viruses and other microorganisms.

3. Management Measure to Control Irrigation Water

The management measure for irrigation water on agricultural lands is a combination of practices that maximizes the water use efficiency of the irrigation system, minimizes the amount of water that is wasted or discharged from the system, and improves the water quality of both surface and subsurface return flows from the system by: (1) scheduling and managing the application of irrigation water; (2) minimizing to the extent possible irrigation water runoff from all irrigation systems except for surface irrigation, which will be recovered and reused with a tailwater recovery system*; and (3) eliminating unnecessary deep percolation, thereby reducing the amount of pollutants entering nearby surface waters and groundwater. When chemigation is used, the management measure includes backflow preventers.

---

* In some locations, tailwater or runoff of applied irrigation water are subject to other water rights or are required to be released to maintain stream flow. In these special cases, reuse on-site may not be allowed and would not be considered part of the management measure for such locations.

(1) Proper irrigation scheduling is a key element in irrigation water management. Irrigation scheduling should be based on knowing the daily water use of the crop, the water holding capacity of the soil, the lower limit of soil moisture for each crop and soil and measuring the amount of water applied to the field. Also natural precipitation should be considered and proper adjustment made in the scheduled irrigations.

(2) Irrigation water should be applied properly in a manner that assures efficient use and uniform distribution of irrigation water and minimizes runoff or deep percolation.

(3) Irrigation water transportation systems that move water from the source of supply to the irrigation system should be designed and managed in a manner that minimizes evaporation, seepage flow-through water losses from canals and ditches.

(4) The utilization of runoff water for additional irrigation or to reduce the amount of water diverted increases the efficiency of use of irrigation water. For surface irrigation systems that require runoff or tailwater as part of the design and operation, a tailwater management practice be installed and used.

(5) Drainage water from an irrigation system should be managed to reduce deep percolation, move tailwater to the reuse system, reduce erosion at the end of the irrigated field and help control adverse impacts on surface and ground water. A total drainage system should be an integral part of the planning and design of an efficient irrigation system.

4. Irrigation Water Management Practices

Following is a list of management practices for irrigation water management that are available as tools to achieve the irrigation water management measure as set forth in Section F.3. Under each management practice the U.S. Soil Conservation Service (SCS) practice number and a definition are provided. The list of practices included in this section is not exhaustive and does not preclude States or local agencies from developing special management practices in cooperation with the appropriate technical agency within the State for unique conditions and problems that may be encountered in particular areas, provided that the management measures (the system of individual practices adopted) achieve a level of performance that is as effective as that provided by the management measures specified in this guidance. There may also be state or local standards that would require additional practices.

(1) Proper irrigation scheduling

Practices that may be used to accomplish proper irrigation scheduling are:

Irrigation water management (449)
Determining and controlling the rate, amount, and timing of irrigation water in a planned and efficient manner.

The purpose is to effectively use available irrigation water supply in managing and controlling the moisture environment of crops to promote the desired crop response, to minimize soil erosion and loss of plant nutrients, to control undesirable water loss, and to protect water quality.

To achieve this purpose the irrigator must have knowledge of: (1) how to determine when irrigation water should be applied, based on the rate of water used by crops and on the stages of plant growth, (2) how to measure or estimate the amount of water required for each irrigation, including the leaching needs, (3) the normal time needed for the soil to absorb the required amount of water and how to detect changes in intake rate, (4) how to adjust water stream size, application rate, or irrigation time to compensate for changes in such factors as intake rate or the amount of irrigation runoff from an area, (5) how to recognize erosion caused by irrigation, (6) how to estimate the amount of irrigation runoff from an area, and (7) how to evaluate the uniformity of water application.

Water measuring device
An irrigation water meter, flume or other water measuring device installed in a pipeline or ditch. The measuring device must be installed between the point of diversion and water distribution system used on the field. The device should be a recording meter that will indicate both the rate of flow and the total water used.

The purpose is to provide the irrigator the rate of flow and/or application of water, and the total amount of water applied to the field with each irrigation.

Soil and crop water use data
From soils information the water holding capacity of the soil can be determined along with the amount of water that the plant can extract from the soil before additional irrigation is needed. Water use information for various crops can be obtained from various USDA publications.

The purpose is to allow the irrigator to estimate the amount of available water remaining in the root zone at any time, thereby indicating when the next irrigation should be scheduled and the amount of water needed. There are methods to measure the soil moisture and these should be employed for high value crops or where the water holding capacity of the soil is very low.

(2) Proper application of irrigation water

The type of irrigation system employed will vary with the type of crop grown, the topography, and soils. There are several systems that, when properly designed and operated, can be used as follows:

Irrigation system, drip or trickle (441)
A planned irrigation system in which all necessary facilities are installed for efficiently applying water directly to the root zone of plants by means of applicators (orifices, emitters, porous tubing, or perforated pipe) operated under low pressure. The applicators can be placed on or below the surface of the ground.

The purpose is to efficiently apply irrigation water directly to the plant root zone to minimize water loss, erosion, impacts to water quality, and salt accumulation while maintaining soil moisture within the range for good plant growth.

Irrigation system, sprinkler (442)
A planned irrigation system in which all necessary facilities are installed for efficiently applying water by means of perforated pipes or nozzles operated under pressure.

The purpose is to efficiently and uniformly apply irrigation water to minimize water loss, erosion, and impacts to water quality while maintaining soil moisture for optimum plant growth.

Irrigation system, surface and subsurface (443)
A planned irrigation system in which all necessary water control structures have been installed for efficient distribution of irrigation water by surface means, such as furrows, borders, contour levees, or contour ditches, or by subsurface means.

The purpose is to efficiently convey and distribute irrigation water to the point of application to minimize water loss, erosion, and impacts to water quality while maintaining soil moisture for optimum plant growth.

Irrigation field ditch (388)
A permanent irrigation ditch constructed to convey water from the source of supply to a field or fields in a farm distribution system.

The standard for this practice applies to open channels and elevated ditches of 25 ft^3/second or less capacity formed in and with earth materials.

The purpose is to prevent erosion or loss of water quality or damage to the land, to make possible proper irrigation water use, and to efficiently convey water to minimize conveyance losses.

VOL 12

4927

Irrigation land leveling (464)
Reshaping the surface of land to be irrigated to planned grades.

The purpose is to permit uniform and efficient application of irrigation water without causing erosion, loss of water quality, or damage to land by waterlogging and at the same time to provide for adequate surface drainage.

(3) Irrigation water transportation systems

Transporting irrigation water from the source of supply to the irrigation system can be a significant source of water loss and cause of degradation of both surface water and ground water. Losses during transmission include seepage from canals and ditches, evaporation from canals and ditches, and flow-through water (water that is never applied to the land but is needed to maintain hydraulic head in the ditch). The primary water quality concern is the development of saline seeps below the canals and ditches and the discharge of saline waters. Another water quality concern is the potential for erosion caused by the discharge of flow-through water. Practices that are used to assure proper transportation of irrigation water from the source of supply to the irrigation system are:

Irrigation water conveyance, ditch and canal lining (428)
A fixed lining of impervious material installed in an existing or newly constructed irrigation field ditch or irrigation canal or lateral.

The purpose is to prevent waterlogging of land, to maintain water quality, to prevent erosion, and to reduce water loss.

Irrigation water conveyance, pipeline (430)

A pipeline and appurtenances installed in an irrigation system.

The purpose is to prevent erosion or loss of water quality and damage to land, to make possible proper water use, and to reduce water conveyance losses.

Structure for water control (587)
A structure in an irrigation, drainage, or other water management systems that conveys water, controls the direction or rate of flow, or maintains a desired water surface elevation.

The purpose is to control the stage, discharge, distribution, delivery, or direction of flow of water in open channels or water use areas. Also used for water quality control, such as sediment reduction or temperature regulation. These structures are also used to protect fish and wildlife and other natural resources.

(4) Utilization of runoff water for additional irrigation or to reduce the amount of water diverted. The practice is described as follows:

<u>Irrigation system, tailwater recovery (447)</u>
A facility to collect, store, and transport irrigation tailwater for reuse in the farm irrigation distribution system.

The purpose is to conserve farm irrigation water supplies and water quality by collecting the water that runs off the field surface for reuse on the farm.

(5) Management of drainage water

There are several practices to accomplish this:

<u>Filter strip (393)</u>
A strip or area of vegetation for removing sediment, organic matter, and other pollutants from runoff and waste water.

The primary purpose is to remove sediment and other pollutants from runoff or waste water by filtration, deposition, infiltration, absorption, decomposition, and volatilization, thereby reducing pollution and protecting the environment. An additional purpose is to prevent erosion at the upland edge of fields by dissipating the energy of irrigation water applied as concentrated flow.

<u>Surface drainage field ditch (607)</u>
A graded ditch for collecting excess water in a field.

The purpose is to drain surface depressions for recovery and reuse of excess water or for the controlled delivery of excess water to a filter strip for treatment; collect or intercept excess surface water, such as sheet flow, from natural and graded land surfaces or channel flow from furrows and carry it to an outlet for recovery and reuse or for the controlled delivery of excess water to a filter strip for treatment; and collect or intercept excess subsurface water and carry it to an outlet for recovery and reuse or for the controlled delivery of excess water to a filter strip for treatment.

5. <u>Effectiveness Information</u>

Following is information on pollution reductions that can be expected from installation of the management practices outlined within this management measure.

The Rock Creek Rural Clean Water Program (RCWP) project in Idaho is the source of much information regarding the benefits of irrigation water management (Idaho Department of Health and Welfare, 1990). All crops in the Rock Creek watershed are irrigated with water diverted from the Snake River and delivered through a network of canals and laterals. The combined implementation of irrigation management practices, sediment control practices, and conservation tillage has resulted in high reductions (from 61 percent to 95 percent reduction for all six stations) in suspended sediment loadings in Rock Creek from 1981 to 1988. Similarly, eight of ten sub-basins showed reductions in suspended sediment loadings over the same time period.

The Soil Conservation Service has developed a set of water quality statements for each practice that provide some insight into the use of particular irrigation water management practices for water quality improvement (USDA, SCS, 1988). They also include warnings of negative water quality impacts that might occur by using the practices. Water quality statements for the practices listed in this management measure are contained in Table 2-18.

6. Cost Information

Cost estimates for practices to control irrigation water on agricultural lands are taken from the U.S. Department of Agriculture (USDA ASCS, 1991). Cost estimates reported in this document are given by primary purpose, type of agreement (long-term agreement or regular ACP), and as overall estimates. The costs reported here lump long term agreements and regular ACP agreements. The components of each practice are given in Appendix 2-A.

The cost to install the irrigation water conservation system (practice WC4) for the primary purpose of water conservation in the 28 states which used the practice, was about $77.00 per acre served in 1990. Practice WC4 increased the average irrigation system efficiency from 47 percent to 63 percent at an amortized cost of $9.74 per acre foot of water conserved.

The cost to install water management systems for pollution control (practice SP35) with the primary purpose being water quality was about $103 per acre served. Overall, the cost of practice SP35 was about $50 per acre served.

Table 2-19 shows the cost (per ton of soil saved) of implementing practices WC4 and SP35 for the primary purpose of erosion control.

Table 2-18. Water Quality Statement for Selected Management Practices

Practice	Water Quality Statement
Irrigation water management (449)	Management of the irrigation system should management provide the control needed to minimize losses of water, and yields of sediment and sediment attached and dissolved substances, such as plant nutrients and herbicides, from the system. Poor management may allow the loss of dissolved substances from the irrigation system to surface or ground water. Good management may reduce saline percolation from geologic origins. Returns to the surface water system would increase downstream water temperature.
Irrigation system, drip or trickle (441)	Surface water quality may not be significantly affected by transported substances because runoff is largely controlled by the practice. Chemical applications may be applied through the system. Reduction of runoff will result in less sediment and chemical losses from the field during irrigation. If excessive, local, deep percolation should occur, a chemical hazard may exist to shallow ground water or to areas where geologic materials provide easy access to the aquifer.
Irrigation system, sprinkler (442)	Proper irrigation management controls runoff and prevents downstream surface water deterioration from sediment and sediment attached substances. Over irrigation through poor management can produce impaired water quality in runoff as well as ground water through increased percolation. Chemigation with this system allows the operator the opportunity to mange nutrients, waste water and pesticides. For example, nutrients applied in several incremental applications based on the plant needs may reduce ground water

VOL 12

4931

Table 2-18 (Continued)

Practice	Water Quality Statement
	contamination considerably, compared to one application during planting. Poor management may cause pollution of surface and ground water. Pesticide drift from chemigation may also be hazardous to vegetation, animals, and surface water resources. Appropriate safety equipment, operation and maintenance of the system is needed with chemigation to prevent accidental environmental pollution or backflows to water sources.
Irrigation system, surface and subsurface (443)	Operation and management of the irrigation system in a manner which allows little or no runoff may allow small yields of sediment or sediment-attached substances to downstream waters. Pollutants may increase if irrigation water management is not adequate. Ground water quality from mobil dissolved chemicals may also be a hazard if irrigation water management does not prevent deep percolation. Subsurface irrigation that requires the drainage and removal of excess water from the field may discharge increased amounts of dissolved substances such as nutrients or other salts to surface water. Temperatures of downstream water courses that receive runoff waters may be increased. Temperatures of downstream waters might be decreased with subsurface systems when excess water is being pumped from the field to lower the water table. Downstream temperatures should not be affected by subsurface irrigation during summer months if lowering the water table is not required. Improved aquatic habitat may occur if runoff or seepage occurs from surface systems of from pumping to lower the water table in subsurface systems.

VOL 12

4932

Table 2-18 (Continued)

Practice	Water Quality Statement
Irrigation field ditch (388)	Salinity changes may occur in the soil and water. This will depend on the irrigation water quality, the level of water management, and the geologic materials of the area. The quality of ground and surface water may be altered depending on environmental conditions. Water lost from the irrigation system to downstream runoff may contain dissolved substances, sediment, and sediment-attached substances that may degrade water quality and increase water temperature. This practice may make water available for wildlife, but may not significantly increase habitat.
Irrigation land leveling (464)	The effects of this practice depend on the level of irrigation water management. If root zone water is properly managed, then quality decreases of surface and ground water may be avoided. Under poor management, ground and surface water quality may deteriorate. Deep percolation and recharge with poor quality water may lower aquifer quality. Land leveling may minimize erosion and when runoff occurs concurrent sediment yield reduction. Poor management may cause an increase in salinity of soil, ground and surface waters.
Irrigation water conveyance, ditch and canal lining (428)	Potentials for ground water effects from infiltration of poor quality water with and canal lining dissolved substances would be reduced. Potential for ground water effects from infiltration of high quality water would be reduced. Increased stability of the conveyance will also reduce bank or bed erosion which would provide sediment yield reduction within the system and to downstream waters.

Table 2-18 (Continued)

Practice	Water Quality Statement
Irrigation water conveyance, pipeline (430)	Potentials for ground water effects from infiltration of poor quality water would be eliminated by this practice. No streambank or bed erosion would occur which may provide sediment or sediment attached substances to downstream water courses. Deep percolation of saline water may be avoided. Temperature increases that occur from flow in an open conveyance may be eliminated by the pipeline. Wildlife or aquatic habitat that had depended on seepage from the irrigation water conveyance will be decreased.
Structure for water control (587)	Use of the practice to conduct water one elevation to a lower elevation within, to or from a ditch, channel, or canal may not have any effect on the quality of surface or ground water. Use of the practice to control the elevation of water in drainage or irrigation ditches may reduce bank erosion and scouring in the channel; this results in the reduction of sediment and related pollutants delivered to the surface water. When used to control, the division or measurement of irrigation water may have an insignificant effect on the quality of surface and ground water. Use of the practice to keep trash, debris, or weed seeds from entering pipelines has little effect on the quality of surface and ground water. Use of the practice to control the direction of channel flow resulting from tides and high water or backflow from flooding has little effect on the quality of surface and ground water.

Table 2-18 (Continued)

Practice	Water Quality Statement
	Use of the practice to control the level of water table or to remove surface subsurface water from adjoining land, to flood land for frost protection, or to manage water levels for wildlife or recreation may increase infiltration and percolation of water by supplying a surplus of water to the surface when used for flooding. This will enable soluble pollutants to be carried into the ground water. When used to remove drainage water from the surface or subsurface, substances may be "straight-lined" into the surface waters. When the function is to impound water, the pH of the surface water may be lowered with a consecutive increase in tannic acid and iron content. Water temperature may be increased in the summer months. Use of the practice to convey water over, under, or along a ditch, canal, road, railroad, or other barriers will have little effect on the quality of surface or ground water. Use of the practice to modify water flow to provide habitat for fish, wildlife, and other aquatic animals may increase the dissolved oxygen content of the stream, and may lower the water temperature.
Irrigation system, trailwater recovery (447)	The reservoir will trap sediment and sediment attached substances from runoff waters. Sediment and chemical will accumulate in the collection facility entrapping would decrease downstream yields of these substances. Salts, soluble nutrients, and soluble pesticides will be collected with the runoff and will not be released to surface waters. Recovered irrigation water with high salt and/or metal content will ultimately

VOL 12

4935

Table 2-18 (Continued)

Practice	Water Quality Statement
	have to be disposed in an environmentally safe manner and location. Disposal of these waters should be part of the overall management plan. Although some ground water recharge may occur, little if any pollution hazard is expected.
Filter strip (393)	Filter strips for sediment and related pollutants meeting minimum requirements may trap the coarser grained sediment. They may not filter out soluble or suspended fine-grained materials. When a storm caused runoff in excess of the design runoff, the filter may be flooded and may cause large loads of pollutants to be released to the surface water. This type of filter requires high maintenance and has a relative short service life and is effective only as long as the flow through the filter is shallow sheet flow. Filter strip for runoff form concentrated livestock areas may trap organic material, solids, materials which become adsorbed to the vegetation or the soil within the filter. Often they will not filter out soluble materials. This type of filter is often wet and is difficult to maintain. Filter strips for controlled overland flow treatment of liquid wastes may effectively filter out pollutants. The filter must be properly managed and maintained, including the proper resting time. Filter strips on forest land may trap coarse sediment, timbering debris, and other deleterious material being transported by runoff. This may improve the quality of surface water and has little effect on soluble material in runoff or on the quality of ground water. All types of filters may reduce erosion on the area on which they are constructed.

Table 2-18 (Continued)

Practice	Water Quality Statement
	Filter strips trap solids from the runoff flowing in sheet flow through the filter. Coarse-grained and fibrous materials are filtered more efficiently than fine-grained and soluble substances. Filter strips work for design conditions, but when flooded or overloaded they may release a slug load of pollutants into the surface water.
Well (642)	When water is obtained it has poor quality because of dissolved substances, its use in the surface environment or its discharge to downstream water courses the surface water will be degraded. The location of the well must consider the natural water quality and the hazards of its use in the potential contamination of the environment. Hazard exists during well development and its operation and maintenance to prevent aquifer quality damage from the pollutants through the well itself by back flushing, or accident, or flow down the annual spacing between the well casing and the bore hole.

7. **Planning Considerations for Irrigation Water Management**

During the development and implementation of this management measure for irrigation, the following water quality effects and impacts should be considered.

(1) Effects on erosion and the movement of sediment and soluble and sediment-attached substances carried by runoff.

(2) Effects on the movement of dissolved substances below the root zone or to ground water.

(3) Short-term and construction related effects on the quality of downstream water courses.

(4) Potential of uncovering or redistributing toxic materials such as saline soil.

(5) Effects of water management on the salinity of soils, soil water, or aquifers.

(6) Potential for development of saline seeps or other salinity problems resulting from increased infiltration near restrictive layers.

(7) Effects of soil water levels on such nutrient processes as nitrification and denitrification.

(8) Effects on the temperatures of downstream waters that could prevent undesirable effects on aquatic and wildlife communities.

(9) Effects of installing the lining on the erosion of the earth conveyance and the movement of sediment and soluble and sediment-attached substances carried by water.

(10) Effects of installing the pipeline (replacing other types of conveyances) on channel erosion or the movement of sediment and soluble and sediment-attached substances carried by water.

(11) Effects on the nutrient budget within the filter strip as related to removal, residence, or accumulation of nutrients. Nutrient budgets should account for effects of growing and decaying vegetation.

(12) Filtering effects of vegetation on movement of sediment, pathogens, organic loads, and dissolved and sediment-attached substances.

(13) Effects of the filter strip vegetation's uptake of nutrients on surface and ground water.

(14) Effects of the timing of the vegetation's management, including clipping, harvesting, removal and re-establishment on the nutrient balance within the filter strip.

(15) Effects on the visual quality of on-site and downstream water resources.

(16) Effects on wetlands or water-related wildlife habitats.

VI. MANAGEMENT PRACTICE TRACKING

Tracking of the installation of agricultural management measures and systems of management measures is critical to knowing how well a program is working. It is also important to know where and by whom a management measure is installed, when it was certified, and how long it should stay in place. This will allow program managers to go back to a farm or field and re-certify that the management measure or practice is still there and operating according to design.

Such tracking systems may be used and/or developed to track initial installation of management measures and to provide a system to check on them at specific time intervals in the future. The funding agency for a particular management practice should know when and where a management measure or practice is installed and should certify it for payment, as appropriate. This should be the first check needed. For later re-certification, field evaluations will be needed to re-certify a practice. The funding agency may decide that it is most practical for county conservation districts to fulfill the role of checking and re-certifying management measures and practices.

VII. SOURCES OF ASSISTANCE TO IMPLEMENT MANAGEMENT MEASURES

This section is to be developed in a later draft. Following is a preliminary draft outline for this section:

A. Federal

1. USDA

- SCS, ES, ASCS, etc.
- Agricultural Conservation Program
- Hydrologic Unit Projects
- Demonstration Projects
- PL 566 Projects
- Conservation Reserve Program
- New Farm Bill programs (Water Quality Incentive Program, etc.)

VOL 12

4939

2. **EPA**

- Section 319, Nonpoint Source Program
- Section 320, National Estuary Program
  Section 117, Chesapeake Bay Program
- Section 314, Clean Lakes Program
- Wellhead Protection Program
- Nitrogen Action Plan

B. **State/Local**

- State/Local NPS Programs
- State Revolving Funds
- State/Local Land Use Control Programs
- Conservation Districts

CHAPTER 3

FORESTRY MANAGEMENT MEASURES

I. TYPES OF NPS PROBLEMS FROM FORESTRY ACTIVITIES

The potential for forestry related activities to cause water pollution has long been recognized. Water quality concerns for forestry were addressed in the 1972 Clean Water Act and later more comprehensively under Sections 208 and 319 as nonpoint sources. The types of problems related to Forestry activities include generation of sediment from roads and landslides, loss of shade from stream canopy removal, woody debris jams from poorly managed logging slash, increased channel erosion and increased stream bedload sediments. In some areas this has resulted in:

- Suspended and bedload sediments
- Turbidity
- Woody material accumulations on bottoms
- Temperature increases, including potential temperature induced effects to the development of salmonid smolts and changes in aquatic communities
- Loss of important stream structural habitat provided by large woody debris from fallen trees, especially conifers. In smaller streams these obstructions perform many important functions including: pool formation, cover, habitat complexity, nutrient and energy retention, stream bank and bed stability, and bed sediment storage.
- Concentration and channelization of flows entering wetlands from road drainage systems and drainage of wetlands due to mechanical site preparation.
- Loss of chum, humpback, pink, chinook, atlantic, and coho salmon, steelhead and sea-run cutthroat trout (salmonids), smelt, and other anadromous fish species.
- Nutrient accumulations from forest fertilizer mis-applications or spills.
- Toxic pollutant accumulations from mis-applications of pesticides or spills.

II. APPROACHES TO THE USE OF MANAGEMENT MEASURES

If management measures are needed to prevent or correct the problems listed, then they should be comprehensively designed to prevent or address the causes of the problems. Often this means a site specific design to best achieve effectiveness. In some cases it may mean a prohibition of

4953

activity in certain especially sensitive areas to ensure prevention of impairment. For example, some harvesting practices may need to be avoided on steep slopes or the amounts of pesticide or herbicide applied may be reduced in order to prevent pollution. It should focus on the pathways and causes of the NPS pollution to be an effective control.

There may be a number of Management Measures approaches to a certain problem. States should remain flexible to work with operators and other agencies to find feasible solutions to water quality and habitat problems which achieve equivalent NPS control levels specified in this guidance.

III. PRESENT STATE FORESTRY NPS PROGRAMS

All states with important forestry activities have identified Best Management Practices (BMP's) to control silviculturally (forestry activities) related nonpoint source (NPS) water quality problems. Often the water quality problems which are presently occurring are not due to the ineffectiveness of the practices themselves, but of the failure to implement them appropriately.

There are two basic types of state forestry NPS programs. One is a voluntary program relying upon a set of Best Management Practices as guidelines to operators. Sometimes BMP's can be applied in the normal course of forest harvest operations with few significant added costs. Operator education and technology transfer is a primary activity of the state departments of forestry. Workshops, brochures, field tours are continually held to educate and demonstrate to operators the latest water quality management techniques. Landowners hiring operators are often encouraged to require operators who have attended state sponsored workshops or to stipulate in contracts that the state forestry BMP's must be applied.

The other type of state forestry program is a set of Forest Practice Rules and Regulations based on a State Forest Practices Act or local government regulations. These Rules and Regulations may closely resemble the sets of BMP guidelines described previously, but have requirements which are enforceable. Often streams are classified based upon importance for municipal water supply or propagation of aquatic life as the most sensitive designated use. Protective requirements of various kinds for shade, large woody debris recruitment, bank stability, and others are often stipulated for streamside zones, riparian areas, filter, or buffer strips. Harvest plans of operations or applications to perform a timber harvest are frequently required for review by the State Department of Forestry and other state agencies.

Present state Coastal Zone Management (CZM) programs may already include specific regulations or BMP guidelines for forestry activities. In some states, CZM programs have adopted by reference, or as part of a networked program, the state forestry regulations or BMPs.

IV. FEDERAL LAND MANAGEMENT AGENCIES

Federal land management agencies engaged in forestry activities such as the USDA Forest Service and the USDI Bureau of Land Management are to meet all federal, state, interstate, and local requirements to the same extent as any nongovernmental entity. Similarly, the revised CZMA Act requires federal agencies to comply with state Coastal Zone NPS Management Plans to protect coastal water quality and habitat.

The USFS and BLM in nearly all of the states where agency lands are situated have developed Memoranda of Understanding (MOU) with the water quality agencies to develop and use BMP's which meet or exceed the state BMP'S and Forest Practice Rules. Many of these MOU's have been recently updated to become a part of states' 319 NPS Management Programs. In most cases these agencies have become a Designated Management Agency (DMA) under authority in Section 208 of the Clean Water Act. The DMA authority requires the agency to develop its own Water Quality Program which must be approved by the State. The agency then is delegated responsibility to manage the waters under its jurisdictions according to state law meeting water quality standards and other state requirements. Often there is an action plan required by the state, and agency progress is evaluated on an annual basis. State enforcement of the MOU and DMA programs varies among states. A few states require the agencies to provide annual monitoring reports and annual monitoring plans.

V. LOCAL GOVERNMENTS

Counties, municipalities, and local soil and water conservation management districts may also impose additional requirements on landowners and operators conducting forestry activities. In urban settings this often relates to the conversion of forested lands to urban uses, primarily for residential and business developments. Developers are not always familiar with forestry activity BMP'S or state forest practice rules and regulations. In some cases, the potential for speculative investing leads to major land development which may overwhelm a small government agencies ability to monitor and manage these types of forestry activities.

In rural areas additional requirements for forestry activities may be made by soil and water conservation districts. These requirements primarily apply to small non-industrial forest owners who manage small woodlots. Collectively, non-industrial forest owners control a majority of the productive timber lands in the eastern U.S. and sizeable acreages in some western states. The major industrial privately owned timber lands are located in the Southeast and Northwest parts of the U.S.

VI. MANAGEMENT MEASURES

A. MM No. 1 Identification and Designation of Streamside Special Management Areas

1. Components and Specifications

The objective of this MM is to protect water quality and aquatic habitat and prevent the occurrence of adverse impacts from logging, roadbuilding, and other land disturbing management activities. Streamside Special Management Areas are the areas immediately neighboring streams or waterbodies, which greatly influence water quality and aquatic habitats. These areas function in the following ways:

(1) Filters sediments from waters flowing across the surface toward waterbodies,

(2) Provides a renewable source of large woody debris for cover for fishes and other aquatic organisms, hydraulic control features to dissipate flow energy and develop pools, and bed and bank structure to improve stream channel stability. This large woody debris also provides hydraulic control features to dissipate flow energy and develop pools, and bed and bank structure to improve stream channel stability,

(3) Provide important water surface shading to moderate stream temperature during extreme weather conditions in the summer and winter,

(4) Provide hydraulic roughness on banks and within stream channels to attenuate flood flows, thereby reducing the extreme nature of high flow events

(5) Provide a source of energy and nutrients (litter and leaves) for small tributary streams supporting efficiently functioning aquatic communities.

The identification and designation of streamside areas is needed to determine the extent and distribution of highly valued and sensitive riparian resources. The boundaries of these areas are determined by the minimum distance needed to provide protection to the water quality and habitat functions. Distances needed may vary depending on soil type, slope and riparian cover. Some States and forest management agencies and companies have set minimum distances to protect water quality and ecosystem function. Additional distance is required if there is reasonable risk of pollution or loss of the functions described above.

Use of existing resource inventories, water quality data, stream classifications, state water quality designations, topographic maps, aerial photos, and best professional judgment of the harvest sale planner and resource specialists are needed to define the boundaries of the streamside special management area. Any activities planned within the area must not degrade water quality or habitat value. Most states have identified streamside management zone widths in BMP guidelines or State regulations.

Boundaries of this area must be clearly identified to avoid any misunderstanding by the forestry operator. This will prevent the inadvertent continuation of forestry activities which are occurring outside of the streamside special management area which would impair the water quality and habitat values if conducted in the SSMA. The designation of this area must accomplish the following:

(1) Reduce delivery of forestry activity created sediments from upland or adjacent areas to the waterbody being protected except during storm events with

recurrence intervals greater than 10 years estimated using standard procedures and appropriate storm durations for the local climatic conditions.

(2) Provide a source of large woody debris within the Streamside Special Management Area to the stream at a rate that is equivalent to natural rates of supply over a time period that is the average lifespan of the tree species in the stand.

(3) Provides shading to the stream water surface which is equivalent to natural levels for the potential natural vegetation present. If the existing shading condition prior to activity is less than the natural levels for the potential natural vegetation present, then there should be no reductions of shading caused by proposed activities.

(4) Provide sufficient width to withstand wind damage or blowdown.

2. <u>Effectiveness</u>

The effectiveness of SSMA identification to prevent impacts to streamside areas is 75-85%. This rate of effectiveness is limited by runoff from roads which drains directly to the stream network. Errors in marking and identification of the appropriate boundary occur. Temporary boundary markers occasionally are removed or become lost permitting accidental incursions into the special management with higher disturbance levels. In the west landslides may deliver large quantities of sediments from upslope roads or harvest units across the SSMA.

3. <u>Costs</u>

The net cost for the establishment of streamside management zones may include the costs of layout and marking of the zone. It may also include any additional costs from special harvesting techniques which are used to extract merchantable timber from the streamside management zone. However, these extra harvesting costs are generally offset by the value of the harvested stumpage. It is possible that merchantable timber which is not harvested from the streamside zone due to percent removal restrictions or other management considerations, may be considered an indirect cost of the SMZ. If there is existing vegetation on the site direct cost of implementing this management measure will be limited.

For situations where existing vegetation is not present, cost estimates for control of erosion and sediment transport from forestry activities in streamside areas have been summarized by the USDA Agricultural Stabilization and Conservation Service (ASCS). For streamside management zones the ASCS Stream Protection Practice (WP2) the average cost to install was about $130.00 per mile.

In the State of Virginia Best Management Practices Handbook for forestry, forest filter strips were estimated to have no direct costs if preserving existing vegetation. If the management

VOL 12

4957

measure requires the planting of a filter strip on a disturbed area the costs estimated to be the same as for revegetation.

The following example costs for activities related to the establishment of streamside special management zones are USDA Forest Service estimates from the Pacific Northwest:

Activities	Costs
Streamside prescription	$250/mile
Boundary marking	$200/mile
Indirect or Foregone Opportunity Cost of Merchantable stumpage not harvested	

10 MBF/ac @ $100/MBF = $1000/acre
20 MBF/ac @ $150/MBF = $3000/acre
50 MBF/ac @ $200/MBF = $10000/acre

B. MM No. 2 Identification and Designation of Wetland Special Management Areas

1. Components and Specifications

The objective in designating boundaries for Wetland Special Management Areas (WSMA) is to maintain wetland functions and values and to prevent adverse impacts to water quality and habitat in wetland areas from logging.

Wetlands are important in providing moderating influences for water quality and habitats in coastal areas. Wetland ecosystems are commonly key components to a healthy coastal environment. The CWA protects the chemical, physical and biological integrity of wetlands as waters of the United States. Management activities in these areas must not degrade or adversely affect the functions and values of these ecosystems. Effects to the hydrologic conditions in wetlands are commonly the most permanently destructive to the ecosystems. Vegetation communities may also be adversely affected by the introduction of exotic plants or selective removal of key component species.

The boundaries of these WSMAs are determined by the minimum distance needed to provide protection to the water quality and habitat. Additional distance is required if there is reasonable risk of impairment or loss of the functions described above.

Information from resource inventories, topographic maps, aerial photos, and soil surveys and the Federal Manual for Identifying and Delineating Jurisdictional Wetlands will be useful to identify areas needing protection as WSMAs. Planning must identify the areas where operation of heavy equipment may not be appropriate. Flowing wetlands connected to riverine systems should be distinguished from isolated wetlands, because these ecosystems function differently.

VOL 12

4958

Forestry access must be designed to avoid wetland areas and minimize road construction across wetlands. Where roads must be constructed across wetlands flow passages should be planned to prevent disturbances and hydrologic differences between the two sides of the road. Driest seasons should be used to access and harvest these areas.

Boundaries of Wetland Special Management Areas must be clearly identified to prevent misunderstanding by the forestry operator about the location and extent of the WSMA. In many cases this will require on site boundary marking with flagging, paint, or signs where the WSMA adjoins an area with planned forestry activities. The designation and planning of activities in the WSMA'S must provide a level of protection that:

(1) Prevents ground disturbing activities which would cause wetland areas to drain during wet periods or clearly cause a disruption of the hydrologic conditions of the wetland.

(2) Prevents delivery of human activity created sediments from the areas outside of the area to the wetland being protected except during storm events with recurrence intervals estimated using standard procedures to be greater than 10 years.

(3) Prevents loss of sensitive aquatic habitat conditions which otherwise would occur without the designation of the Wetland Special Management Area.

2. <u>Effectiveness</u>

The effectiveness of wetland boundary identification to prevent impacts to wetlands is 75-85%. This rate of effectiveness is limited by runoff from roads which drains directly to wetlands or to the stream network upstream. Errors in marking and identification of the appropriate boundary occur. Boundary markers occasionally are removed or become lost permitting accidental incursions into the special management area with higher disturbance levels.

3. <u>Costs</u>

The net cost for the establishment of wetland special management zones may include the costs of layout and marking of the zone. The following example costs for activities related to the establishment of streamside special management zones are USDA Forest Service estimates from the Pacific Northwest:

Activities	Costs
Wetland prescription	$250/mile
Boundary marking	$200/mile

VOL 12

C. MM No. 3 Transportation System Planning and Design

1. Components and Specifications

The objective of this MM is to locate and design roads with minimal sediment delivery potential to streams and coastal areas. Roads have been shown consistently to be the largest cause of sedimentation resulting from forestry activities. Good location and design of roads can greatly reduce sources and transport of sediment materials.

Important sediment sources are associated with stream crossings, fills on slopes greater than 60 percent, poorly designed road drainage structures, and road locations close to streams. In the west the largest sources of sediment are often associated with landslides. Certain rock types and geomorphic conditions are conducive to the risk of landslides. Such areas can be identified and avoided. In other areas inadequate cross drainage and poor location are the greatest sources of sediment to waterbodies.

a. Location

Location of roads on ridges versus natural drainages is an important way to distance, and thereby prevent, the effects of surface erosion of road surfaces, cut, and fills from streams. Roads must not be located along stream channels where the road fill extends within 25 horizontal feet of the average annual high water level, except for crossings. Existing roads in poor locations must be relocated when the road is to be reconstructed. Roads on gentle slopes drain more freely than roads on flat areas. Roads on steep terrain should avoid use of switchbacks through more favorable locations. "Stacking" of roads above one another should be avoided by the use of longer span cable harvest techniques.

b. Drainage crossings

Sizing of bridges and large culverts for major drainage crossings must be designed based upon reliably tested regionalized methods for permanent well trafficked roads. Appropriate equipment and materials must be planned for installation of the drainage crossing structures. Crossings should be designed to cross drainages at 90° to the flow to minimize effects to the channel and flow capacity through the structure. Designs must provide suitable measures to facilitate fish passage when fish-bearing streams are crossed. This is especially important in the west for streams with anadromous fish.

Structures for permanent road crossings should be adequately designed to avoid failure as follows:

(1) Small culverts should be designed to pass the 25 year recurrence interval discharge without entrance head above the top of the structure

4960

(2) Major culverts and small bridges should pass the 50 year recurrence interval discharge without head above the top of the structure and

(3) Major bridges should pass the 100 year recurrence interval discharge without head above the structure.

(4) Additional capacity must be provided when debris loading above the structure would potentially become lodged in the structure opening and reduce its capacity.

Use of fords should be limited to extreme situations where use of bridges and culverts is not feasible. Fords should be located where streambeds are stable having bedrock or a concrete apron carefully installed. Springs flowing continuously for more than 1 month must have drainage structures, rather than allowing use of road ditches to carry the flow to a drainage culvert.

c. Road prism

Design of the road prism must be appropriate to the terrain where the road is located. Alignments that roll with the terrain cause less slope disturbance than strongly controlled sections with sustained grades and alignments. Balanced construction of the road cross-section must be limited to reasonable sideslopes. Sideslopes greater than 60 percent requires full-bench construction and removal of the excavated road cut material to a suitable disposal area. Surface design as crowned, insloped, or outsloped must be consistent with the road drainage structures.

d. Road drainage

Careful design of the surface drainage to match natural sideslope drainage swales and appropriate spacings must occur. Inlet and outlet structures for culverts must be planned to avoid sedimentation where erosion of ditches and fills occurs. Road dips must be designed to drain freely without eroding the road surface. Roads in flat areas should have elevated roadbeds to avoid development of mudholes (this practice may not be appropriate in flat areas with periodic surface flows.

e. Surfacing

Roads planned for all-weather use must be surfaced with suitable materials unless native surfaces support truck traffic without becoming rutted or eroding. Planning for rock quarry locations must include a quarry development and rehabilitation plan.

f. Landslides

Use of available geologic information, soil maps, topographic maps, aerial photos, local experience, and technical consultation with a geologist, a geotechnical engineer or a qualified specialist must be made when landslide prone areas are known to exist in the planned area to be accessed. Landslide prone areas should be avoided even if alternative routes are longer or more costly to construct. If there are no alternative routes and landslide prone areas must be crossed, specialized construction techniques will be planned to prevent landsliding. Sufficient testing of the bearing materials, piezometric surface of shallow groundwater during storm events, and other site specific investigative techniques must be used to appropriately design slope drains, locations of bin walls, use of geotextile materials, riprap, and other specialized techniques to prevent landslides.

g. Water sources

Locations of water sources used to wet and compact road beds and surfacing must be preplanned. The water source development and water tank-truck access must be planned to minimize sedimentation and protect the natural water source. Road fills at drainage crossings must not be used as water impoundments unless they have been suitably designed as an earthfill dam. Such earthfill embankments must have outlet controls to allow draining prior to runoff periods.

h. Muskegs

Roads crossing muskegs (high water table areas in northern climates typified by humus and acid waters) must use overlay construction techniques with suitable non-hazardous materials. Cross drains must be provided to allow free drainage especially in sloping areas.

The following are specifications for this MM:

(1) Location: The locations of new roads must not encroach on streams, fills must not be located within 25 horizontal feet of the annual high water level. Construction of new switchback roads must not occur near streams. There must not be planned construction of a streamside road when there is an existing road on the opposite side of the drainage, unless the existing road is being replaced and will be obliterated.

(2) Drainage crossings: Must meet the design levels described above. Must be designed to allow fish passage in fish-bearing streams. Fish passage specifications should be designed for the fish species present.

(3) Road prism: Sideslopes greater than 60 percent for new construction require full bench construction and removal of fill material to a suitable location. Planning of the road surface prism must match the road surface drainage system.

(4) Road drainage: Spacing of drainage structures must match terrain and be appropriate to endure the 25 year precipitation recurrence interval for a storm duration appropriate to the area without rilling, gullying or loss of drainage structures.

(5) Surfacing: Appropriate sized aggregate, percent fines, and suitable particle hardness must protect the surface from rutting and eroding under heavy truck traffic during wet periods of operation. Ditch runoff should not be visibly turbid during these conditions. Aggregate must not contain high sulfide ores that would produce acid drainage or be contaminated with hazardous materials.

(6) Landslides: Designs must prevent the occurrence of landslides for storms with a precipitation recurrence interval of 100 years or less for an appropriate design storm duration typically causing flooding in the area being considered.

(7) Water sources: Planned water source developments to be used to wet and compact roadbeds and surfaces should not impact channel banks and streambeds of the watercourses being used for this purpose. Access roads to water sources should not provide sediment to the water source.

(8) Muskeg roads: Roads must not pond water on the upslope side of the road. Overlay materials cannot include hazardous materials.

2. Effectiveness

The effectiveness of this MM to prevent sedimentation is 85-90 percent. Careful planning is the most effective aspect of road management. The variation in effectiveness is due to the differing complexity of terrain. Landslide prone areas present a difficult challenge for road planners. Vertical relief, slope steepness are other factors influencing design effectiveness. Available funding to allow certain expensive structural designs may be lacking. Design tools and techniques are continually improving. Models for predicting unstable slope conditions are presently available, if data can be collected.

3. Costs

Activities	Costs
Planning	Add 25%

D. MM No. 4 Transportation System Construction/Re-construction

1. Components and Specifications

The objective of this MM is to minimize erosion and sedimentation during road construction/reconstruction projects. The disturbance of soil and rock during road construction/reconstruction creates a significant potential for erosion and sedimentation of nearby streams and coastal waters. Road construction includes: (1) the clearing phase to remove trees and woody vegetation from the road right-of-way, (2) the pioneering phase, where the slope is excavated and filled to establish the road centerline and approximate grade, (3) the construction

VOL 12 4953

phase, where final grade and road prism design specifications are made, bridges, culverts and road drainage structures are installed, and (4) the surfacing phase when the road bed is placed, compacted; road fills are compacted, and the lifts of gravel surfacing and pavement (if planned) is placed and compacted.

Slash materials from right-of-way clearing should not be left in streams. This material is often useful if placed as windrows along the base of the fill slope. This operation is efficiently handled by an excavator or "big hoe". This same piece of equipment is often used in the pioneering and road construction phases. Right of way material that is merchantable is often utilized by the operator.

Pioneering earthwork activities should not be allowed to proceed more than .5 miles from the finished road surface. During rainy seasons this distance should be reduced due to the necessity for shutdown if wet conditions develop. Crossing of flowing streams during the pioneering operation should be minimized. Operation within streams during seasons when spawning and where salmonid eggs are incubating must not occur. Careful planning of equipment operation is necessary to minimize the movement of excavated material downslope as unintentional sidecast. Disposal sites identified in the planning phase must be used.

Construction of bridges and culverts must be conducted carefully. The construction should occur during low flow conditions. Equipment operation within the streambed must be minimized. Construction of piers, footing, abutments, wingwalls, and other structures within the normally wetted portion of the stream will require measures to redirect flows within the channel area and contain turbid waters in settling basins. Care must be taken to minimize sedimentation.

Construction of cuts, fills, and the roadway must be done according to planning and design specifications. Care must be used to contain materials and minimize loss of excavated material downslope. Culverts and ditches must be properly bedded, and placed according to appropriate procedures. Inlet and outlet structures must be installed properly.

Compaction of the road base at the proper moisture content, surfacing, and grading is accomplished to give the designed rcad surface drainage shaping. Surface drainage waterbars, open-top culverts, or slit-troughs are installed to prevent rilling and intercept rut drainage which may develop.

Use of straw bales, straw mulch, grass-seeding, hydromulch, and other erosion control and re-vegetation techniques complete the construction project. Freshly disturbed soils will need protection until vegetation is established. Construction and Reconstruction activities must be managed to minimize impacts to streams and coastal areas as follows:

(1) Slash material must not be left in watercourses. It must be removed before the appropriate equipment to retrieve it leaves the area.

VOL 12

4964

(2) Excess fill material must be carefully managed and not permitted to slough downslope beyond reach of construction equipment.

(3) Bridges, culverts, and other stream crossing structure installations must be conducted to minimize production of sediment. Turbid waters must be contained and diverted to settling basins or flat areas before discharge to the stream. Equipment should not operate within the streambed, but should be limited to making the minimum number of crossings for access to the site.

(4) Installation of road drainage culverts and structures must be made according to planned and designed specifications. Road surfacing and shaping must follow designs.

(5) Mulching and revegetation must be done as quickly as possible to protect disturbed soils from excessive erosion such as rilling and gullying.

2. Effectiveness

This MM has an effectiveness range of 65-80 percent to prevent entry of sediment into area waterbodies. The reason that complete prevention of sedimentation does not occur is the fine particles that are eroded from freshly exposed soils. Studies show that 80 percent of erosion on studied roads occurred during the first 3 years following construction. A certain amount of fillslope material sloughs downslope and finally, the road drainage systems acts as a new stream network on the landscape which must establish an equilibrium with its bed. The variation in effectiveness is due to slope steepness, rock type and soils, climate, landslide sensitivity, runoff events during the first 3-year period, execution error, and unanticipated springs, supplying additional runoff and erosion.

3. Costs

The cost of implementing erosion control practices for forest land management access roads has been estimated to be $11.00 per mile based on national summaries provided by the USDA Agricultural Stabilization and Conservation Service (ASCS). In the State of Virginia Best Management Practices Handbook for forestry, the following costs were estimated[1] for the construction of woodland access roads and skid trails:

Activities	Costs
Construction of Access Roads:	$160.00/100 feet
Land clearing and earthwork	
Culverts	
Bridges	
Drainage Dips	
Water Bars	$4.75 each

VOL 12

4965

Surface Materials	
Seed	$4.75/100 feet
Mulching	$160.00/acre
Construction of Skid Trails (Water Bars) (Drainage Dips)	$40.00/100 feet

The following example percentages for activities related to the construction of forest roads are based on USDA Forest Service estimates from the Pacific Northwest:

Activities	Costs
Clearing phase	Add 5%
Pioneering phase	Add 30%
Construction phase	Add 30%
Surfacing phase	Add 50%

E. MM No. 5 Road Management

1. Components and Specifications

Landowners with roads must manage those roads to prevent sedimentation and pollution from transported materials. Roads that are actively eroding and providing sediment to waterbodies, whether in use or not, must be treated to prevent erosion. Major sources such as landslides must be prevented by maintenance or removal of drainage crossings such as bridges, culverts, and fords as well as road surface drainage structures such as ditches, culverts, dips, waterbars, etc. Large deposits of sediment due to sloughing or road related landsliding must be stabilized to the greatest degree practicable to reduce sedimentation.

If roads are no longer needed, an effective treatment is to remove drainage crossings and culverts if there is a risk of plugging or failure from lack of maintenance. In other cases it is economically more viable to periodically maintain the crossing and drainage structures. Roads subject to rutting must either be maintained to properly drain without excess sediment or be blocked from traffic. While road maintenance is an expensive proposition, it is far cheaper than repair after failure or decades of fish population losses. For some unstable sections, the only effective treatment is excavation and haul of the road section or expensive geotechnical solutions such as groundwater drainage, grouting, or support by pilings.

2. Effectiveness

The effectiveness of this MM is 75-90% due to the periodic nature of road maintenance activities, especially for older roads not in use. The effectiveness varies with the landslide sensitivity, slope steepness, rock type and soils, runoff events, and overall condition of the road system.

3. Costs

In the State of Virginia Best Management Practices Handbook for forestry, the following costs were estimated[1] for the management and maintenance of forest roads and skid trails:

Activities	Costs
Road Maintenance	
Cleaning Culverts	$3.25/100 feet
Filling Ruts and Grading	$3.25/100 feet
Retirement of Roads	$8.00/100 feet
Filling Ruts and Grading	$3.25/100 feet
Bedding with Brush	$2.00/100 feet
Water Bars	$4.75/each
Seeding	$4.75/100 feet
Retirement of Skid Trails	$ .80/100 feet
Bedding with Brush	$2.00/100 feet
Water Bars	$4.75/each
Seeding	$4.75/100 feet
Mulching	$160.00/acre

The following example costs for activities related to the construction of forest roads are based on USDA Forest Service estimates from the Pacific Northwest:

Activities	Costs
Routine maintenance of drainage	$200-600/mile structures
Routine maintenance of the road surface	
native surface	$200-$1200/mile
gravel	$200-$600/mile
Road barriers	$300-5,000 each
Replacement of drainage culverts	$30-50,000/mile
Replacement of drainage crossings	
culverts	$5-500,000 each
bridges	$.1-5.0 million
Excavation of unstable road section	$.1-1.0 million
Underground drainage, piles	$.2-1.0 million

F. MM No. 6 Timber Harvest Planning

1. Components and Specifications

Timber harvest is usually selected for areas with merchantible stands of timber that economically are viable. Selection of stands for harvest also is made based on silvicultural considerations for the regeneration or future condition of the stand. Such planning must also include provisions to identify unsuitable areas which may have merchantible trees, but pose risks for landslides. These concerns are greatest for steeply sloping areas in areas of high rainfall or snowpack in sensitive rock types. Decomposed granite, highly weathered sedimentary, fault zones in metamorphic rocks are potential rock-types of concern. Deep soils derived from these rocks, colluvial hollows, and fine textured clay soils often referred to as "blue goo" are soil conditions causing potential problems. Such areas usually have a history of landslides either naturally or related to earlier land disturbing activities. When risks of landslides are present, a technical specialist such as a geologist, soil scientist, hydrologist or geotechnical engineer should be consulted.

Studies have identified cumulative sedimentation effects from the incremental additions of small sediment volumes added together within a drainage basin. In some climatic zones often related to elevation and orientation to the prevailing winds, streamflow peaks may be increased from timber harvest at certain points in the drainage network. These peaks may cause adjustments in channel beds and banks with net sediment increases. In areas where the cumulative effects of timber harvest activities are affecting water quality and habitats, adjustments in planned harvest are necessary. This includes selection of harvest units with low risks of sedimentation, such as flat ridges or broad valleys, postponement of harvesting until erosion sources are stablilized, and selection of limited areas of harvest using existing roads.

Planning of the silvicultural system of harvest as even-aged (eg. clearcut, seedtree, shelterwood,) or un-evenaged (eg. group selection, or individual tree selection) and the type of yarding system must consider potential water quality and habitat impacts. At first, it may appear more beneficial to water quality to use un-even aged silvicultural stand management, because less ground disturbance and loss of canopy cover occurs. This may be misleading, because more acres must be treated to yield equivalent timber volumes which require more miles of road construction and/or re-construction. Roads have been shown repeatedly to produce the greatest volumes of sediment in forestry activities.

Additionally for moderately sloping areas, yarding of uneven-aged silvicultural systems is most often accomplished by ground-skidding equipment which disturbs soils several times more in total area than cable yarding systems. Cable yarding systems may be used in sloping areas for even-aged silvicultural systems. Whichever silvicultural system is selected will require planning to minimize erosion and sediment delivery to waterbodies. Harvested areas should be immediately replanted or regenerated to prevent further erosion and potential impact to waterbodies. The following are specifications for this MM:

(1) Planned harvest units will not add to problems of cumulative sedimentation effects.

(2) Selection of the silvicultural system will include consideration of potential water quality impacts from needed roads and skidding operations.

(3) Areas with identified risks of landslides by a qualified specialist, eg. geologist, soil scientist, geotechnical engineer, or hydrologist will not be harvested.

2. Effectiveness

This MM will provide a 85-100% effectiveness in preventing the entry of sediments into waterbodies. This variation is due to uncertainties in identifying landslide prone areas, the slope steepness, the uncertainty of assessing cumulative effects, and the runoff events.

3. Costs

Provide an additional 15 percent of planning time for water quality considerations in timber harvest planning.

G. MM No. 7 Landings and Groundskidding of Logs

1. Components and Specifications

Landings and skidtrails will be pre-planned to control erosion and delivery of sediments to watercourses. Locations are primarily determined in the field based upon the distribution of timber volumes designated for harvest. Generally, this pre-planning will take place when the harvesting unit is layed out as described in MM No. 6. The most economically efficient locations for landings and skidtrails will be adjusted to protect waterbodies from the delivery of sediments. Landings must be located outside of the Streamside or Wetland Special Management Areas.

Landings will be no larger than necessary to safely and efficiently store and load trucks. Drainage structures such as waterbars, culverts, and ditches will be constructed. Slope of the landing surface should be less than 5 percent and will be shaped to promote efficient drainage of runoff. Landing fills must not exceed 40 percent slope and must not have incorporated woody or organic materials. If landings are to be used during wet periods a suitable depth of gravel surfacing will be necessary to prevent rutting.

Groundskidding of logs will be limited to slopes less than 40 percent. For sensitive soils further limitation of activities on slopes is needed. During wet periods, groundskidding should be stopped when rutting and churning of the soil begins and when runoff from skidtrails is turbid and no longer infiltrates within a short distance from the skidtrail. Groundskidding on frozen soils or frozen snowpack should be conducted as a method to avoid disturbance of sensitive soils during winter logging. Winter logging may still lead to sedimentation if provisions for drainage during the spring thaw or break up are not made.

Skidtrails should also be pre-planned (again, this should be done prior to harvest - MM No. 6) to minimize disturbance and compaction of soils. In SSMAs felling of trees should be carried out with the large ends toward the skidtrails (felling to the lead) to minimize disturbance and yarding costs. Skidtrails will not be located within Streamside or Wetland Special Management Areas. Yarding of trees within these areas must be accomplished by endlining, use of winch and cable to each log turn. Unimproved skidtrails should not be located across flowing drainages. Improved crossings may be constructed as long as earth material does not enter waters and woody materials are removed immediately following skidding operations in the area. Skidtrails must not exceed 1200 feet in length. The pattern of skidtrails will disperse rather than concentrate runoff. Drainage waterbars will be constructed with appropriate spacing and locations to prevent rilling and gullying of the skidtrail and for areas receiving the drainage.

2. Effectiveness

Depending upon the sensitivity of the area considering factors such as percent slope, amount of area in skidtrails, volume of timber yarded, soils, climate, runoff events, proximity to streams, proper location and pre-planning of landings and skidtrails should provide 85-100 percent effectiveness in preventing sediment entry to watercourses immediately after harvest.

3. Costs

	Cost
Landings	
Pre-planning and drainage design	$80-100/landing
Construction drainage structures	$30-50/landing
Skidtrails	
Pre-planning	$20/mile
Construction, drainage structures	$40/mile

H. MM No. 8 Landings and Cable Yarding

1. Components and Specifications

Landings for cable yarding equipment will be carefully located and designed. Locations with risk of landslides identified by a qualified specialist (geologist, geotechnical engineer, soil scientist, or hydrologist) will not be used. Landings will not be located within Streamside or Wetland Special Management Areas or located over drainages.

VOL 12 4970

Landings will be no larger than necessary to operate yarding and loading equipment safely and efficiently. Drainage structures such as waterbars, culverts, and ditches will be constructed to efficiently control runoff. Slope of the landing surface will be less than 5 percent and will be carefully shaped for efficient drainage. Landing fills must not exceed 40 percent slope and must not incorporate woody and organic materials. Landing fills will not slough or fail into watercourses. If landings are to be used during wet periods, a suitable depth of gravel surfacing will be necessary to prevent rutting.

Landings will be located where slope profile data indicate favorable deflection conditions for the yarding equipment planned for use. Profiles must allow only minimal area of yarding corridor gouge or soil plowing. Such disturbed areas will be hand water-barred and covered with straw mulch if the continuous disturbance area is greater than 450 square feet.

High lead cable systems should be used on an average profile slope of less than 15 percent to avoid soil disturbance from side wash. Skyline cable systems are suitable for average profile slopes greater than 15 percent. Yarding corridors for Special Streamside Management Areas will meet Components and Specifications for these areas. Yarded logs will not make surface contact within the major channel banks of the watercourse of the SSMA. Yarding generated slash materials will be removed from watercourses by the end of the workday.

2. Effectiveness

Preplanning of landings and yarding corridors for cable yarding should provide a range of effectiveness of 70-100 percent effectiveness depending upon the sensitivity of the site to landsliding, based on such factors as percent slope, proximity to streams, rock type, soils, climate, runoff events, and the volume of timber harvested.

3. Costs

Landings	Cost
Pre-planning and drainage design	$80-100/landing
Construction drainage structures	$30-50/landing
Cable Corridors	
Pre-planning	0
Hand water-barring	$5-30/corridor
Straw mulching	$30-50/corridor

VOL 12

4971

VOL 12

I. MM No. 9 Mechanical Site Preparation

1. Components and Specifications

Mechanical site preparation will not be applied to slopes greater than 30 percent. On sloping terrain greater than 10 percent, ground disturbing activities will be conducted on the contour leaving slash windrows also on the contour. The objective is to provide a seedbed or remove competing vegetation species from seedlings while minimizing the potential for erosion. Mechanical site preparation will not be conducted within Streamside Special Management Areas. Filter strips of suitable width will protect all drainages to prevent sedimentation by the 10 year precipitation event for storms of common duration for the climate of the area. All slash material must be removed from drainages by the end of the workday. Operation is prohibited during wet periods when equipment begins to cause rutting or churning of the soil. Windrows will be located a safe distance from drainages to prevent movement of the material during high runoff conditions. Breaks in the windrows will occur at regular intervals to equalize water levels on both sides of the windrow.

Bedding operations in high water table areas will be conducted during dry periods of the year. Bedding areas will be located on the contour or at right angles to the direction of flow when flooded. Openings in the beds will occur at sufficient intervals to avoid ponding and allow water levels to equalize on both sides of the bed. Disturbed soil area between beds will be minimized. Special care will be used to prevent changes in the natural hydrologic conditions of these forested wetlands.

2. Effectiveness

The use of this MM should provide 80-100% effectiveness in preventing sedimentation to streams and in protecting the hydrologic conditions in wetlands.

3. Costs

The cost to conduct erosion control practices during site preparation for forest regeneration averaged about $62.00 per acre treated in 1990 based on national summaries provided by the ASCS. In the State of Virginia Best Management Practices Handbook for forestry, the following costs were estimated[1] for the site preparation:

Activities	Costs
Prescribed Burning	$16.00/acre
Bulldozing or Shear Blading	$105.00/acre
Chemical	
Ground	$41.00/acre
Aerial	$38.00/acre
Chopping	$70.00/acre

4972

Discing	$40.00/acre
Bedding	$24.00/acre

The following example costs for activities related to site preparation are USDA Forest Service estimates from the Pacific Northwest:

Add 5 percent to the cost of mechanical site preparation for achieving these MM's.

J. MM No. 10 Prescribed Fire

1. Components and Specifications

No prescribed fire for site preparation or forestry slash removal purposes will be conducted in SSMAs. Prescribed fire in wetland areas should be carefully designed to protect wetland values and prevent erosion. Intense prescibed fire will not occur in streamside vegetation for small drainages where there is risk of sedimentation due to the loss of canopy and the soil binding ability of vegetation roots. Firelines will be constructed outside of the streamside zones protected from prescribed fire. Intense prescribed fire on steeply sloping areas must not increase the risk of sedimentation to nearby drainages. Prescriptions for prescribed fire will avoid conditions requiring extensive blading of fire lines by heavy equipment. Where possible, prescriptions should rely on hand lines, firebreaks, and hose lays to minimize soil disturbance, especially on sloping areas where firelines must be parallel to the slope. All firelines must be water-barred at appropriate intervals to prevent rills and gullies on the fireline and in the area receiving the runoff. Waterbars should be constructed to drain runoff outside of the burned area.

2. Effectiveness

Use of this MM to reduce erosion related to prescribed fire should provide 90-100% effectiveness in preventing sedimentation to waterbodies in the area. Variation in effectiveness is due to slope, soils, intensity of the burn, runoff events, and climate.

3. Cost

In the State of Virginia Best Management Practices Handbook for forestry, the following costs were estimated[1] for the use of prescribed fire for site preparation:

Activities	Costs
Prescribed Burning	$16.00/acre

The following example cost percentages for prescribed fire are USDA Forest Service estimates from the Pacific Northwest:

VOL 12

4973

Firelines	Cost
Additional to protect drainages, fall	Add 30-50%
Reductions due to wetter conditions	Minus 30-50%

K. MM No. 11 Mechanical Tree Planting

1. Components and Specifications

Equipment will be operated on the contour to prevent erosion. Mechanical planting will not be conducted within Streamside Special Management Areas. When crossing small ephemeral drainages (drainages which only flow during storms or snowmelt), the plow will be raised until the equipment passes well beyond the zone of flow. Slits should be turned upslope before crossing the drainage to prevent entry of slit runoff.

2. Costs

The cost to install forest tree plantations for the primary purpose of erosion control was about $137.00 per acre in 1990 based on national summaries provided by the ASCS. In the State of Virginia Best Management Practices Handbook for forestry, the following costs were estimated[1] for tree planting:

Activities	Costs
Tree Planting	
Hand	
Loblolly Pine	$47.00/acre
White Pine	$70.00/acre
Hardwoods	$141.00/acre
Machine	
Loblolly Pine	$50.00/acre
White Pine	$71.00/acre

The following are example cost percentage for mechanical tree planting based on USDA Forest Service contracts from the Pacific Northwest:

Add 5 percent to the cost of mechanical site preparation for achieving these MM's.

L. MM No. 12 Revegetation of Disturbed Areas

1. Components and Specifications

The objective of this MM is to reduce erosion by the fastest revegetation possible. Revegetation efforts will be conducted in the most efficient and effective manner economically feasible appropriate to the area. In humid areas during the growing season, grass and legume seeding will be done immediately following the completion of the earth disturbing activity, preferably within days after the activity has ended. Use of straw as mulch, hydromulch, lime and fertilizer, wetting agents, jute netting, woven fabrics, etc. will depend on the most successful mixes of species and treatments for the area.

In dry areas during the growing season, it is most often successful to postpone seeding and related treatments to just prior to the normal beginning of the wet period, often fall and spring. Seeding done earlier would commonly fail due to the lack of sufficient moisture. Late fall or winter seeding often fails due to cold soil temperatures inhibiting germination, and being conducive to seed-killing mold and fungi.

Revegetation efforts should be concentrated on the largest areas of disturbance near waterbodies. On steep slopes use of native woody plants planted in rows, cordones, or wattles may be more effective than grass in becoming established and binding the soil with roots. Seed mixtures will contain plants with soil binding properties. Cattle grazing must be prevented on newly re-established vegetation plantings. Seed selection should include natives where possible, and should consist primarily of annuals to allow natural revegetation of native understory plants in time. Exotic species which may spread to other areas must not be used.

2. Effectiveness

The effectiveness of revegetation to prevent sedimentation of area waterbodies varies from 40% to 60% This variation and limited effectiveness is due to the period of time that soils are exposed to rain and snowmelt before vegetation is established. The period of exposure is strongly related to the weather, climate, antecedant soil moisture, soils, slope steepness, runoff events, and grazing by animals.

3. Costs

The cost to establish permanent vegetative cover on critical areas for the primary purpose of erosion control was about $140.00 per acre in 1990 based on national summaries provided by the ASCS. In the State of Virginia Best Management Practices Handbook for forestry, the following costs were estimated[1] for the use of prescribed fire for site preparation:

Activities	Costs
Seedbed Preparation	
Lime	$19.00/ton
Fertilizer	Variable- depending on sowing rate
Seed	$4.75/100 feet
Mulching	$158.00/acre

The following example costs for revegetation methods are based on USDA Forest Service contracts from the Pacific Northwest:

Method	Cost
Grass-seeding (hand)	$50/acre
Grass-seeding (helicopter)	$100/acre
Hydromulching seed and fertilizer	$150/acre
Straw mulch	$500/acre
Jute netting	$1,000/acre
Woven fabric	$5,000/acre
Woody plant rows, cordon, wattles	$1/foot

M. MM No. 13 Stream Protection for Pesticide and Fertilizer Projects

1. Components and Specifications

Pesticides: Pesticides are used for many different purposes. Since they are toxic materials, they must be mixed, transported, loaded, applied, and their containers disposed of with great care. Their use must be prescribed for the appropriate pest after consideration of integrated pest management (IPM) approaches. Application must be conducted according to label instructions for the certified use. Applicators must be licensed by the appropriate state agency.

Spray programs must meet state requirements. For aerial applications this commonly involves inspection of the mixing and loading process, nozzle calibration, and approval of appropriate weather conditions, and spray area and buffer area monitoring. Buffer areas for identifiable flowing waters must be established and made identifiable for applicators. Accidental spills of toxic materials into waterbodies must be immediately reported to the state water quality agency. Spill contingency plans must be in place and include effective means to control spills to the maximum extent practicable.

Streams must be sampled adjacent to or below application areas at time intervals to measure the expected peak concentration based upon time of application, travel time, and nature of the material. Sampling results must be reported to the state water quality agency and licensing agency.

Fertilizers: Fertilizers may also be toxic materials depending upon the concentration. Similar planning, care in use, sampling, and reporting are necessary. Serious consideration of the costs and benefits of fertilizer use in forest applications will be made. Spill contingencies apply as well. Appropriate buffers for flowing waters and aerial weather conditions will be properly managed to prevent the entry of fertilizers into waterbodies.

2. Effectiveness

This MM varies between 95-100% effective in preventing entry of pesticides and fertilizers in waterbodies. While the consequences of entry of pesticides and fertilizers is high, the risk of entry is low when this MM is applied.

3. Costs

In the State of Virginia Best Management Practices Handbook for forestry, the following costs were estimated[1] for control of the use of pesticides to protect water quality:

Activities	Costs
Chemical application for Pine Release	
Ground	$32.00/acre
Aerial	$32.00/acre

The following cost estimate is based on USDA Forest Service information from the Pacific Northwest:

Activities	Costs
Planning and coordination	Equal to Application Costs

N. MM No. 14 Petroleum Products Pollution Prevention

1. Components and Specifications

Planning to designate appropriate areas for petroleum storage, procedures and equipment for dispensing, and procedures for spill containment and contingencies will be done. Sites for storage and transfer must meet state and federal regulations. Spills of fuels must be contained and treated. Fuel trucks and pickup mounted fuel tanks must not have leaks. Fuel storage and transfer sites must be located sufficiently distant from waterbodies to prevent entry of petroleum products should the storage tank lose its entire capacity of storage.

VOL 12 4977

A specified area must be designated for draining lubicants from equipment during routine maintenance. The area should allow all waste lubricants to be collected and stored until transported off-site for recycling, re-use, or disposal at an approved site. Waste oil, filters, grease cartridges, and other petroleum contaminated materials will not be left as refuse in the forest, but must be transported to an approved disposal site.

2. Effectiveness

This MM is 95% effective in preventing the entry of petroleum products into streams. The small percentage of failure occurs as fuel spills from leaking tanks or traffic accidents. Leaking of petroleum from moving vehicles cannot be completely eliminated nor can traffic accidents.

3. Costs

Activities	Costs
Preventive measures	$0 These measures are already required by state and federal rules and regulations

NOTE: Comments are solicited on all aspects of this section, and particularly on the amount and the level of detail in this discussion. In addition, comments on the cost and effectiveness information which is provided or additional information which may be available elsewhere are requested. Additional or alternative management measures required to address a given practice or pollutant source, or which are more applicable to a specific region of the United States, are also requested. EPA will be collecting additional information on management measures, and their costs and effectiveness, during the revision of this draft guidance. The contributions and suggestions of commenters on these subjects will be welcome.

CHAPTER 4

MANAGEMENT MEASURES FOR URBAN SOURCES OF NONPOINT POLLUTION

I. INTRODUCTION

This chapter specifies management measures to abate and control water quality problems in coastal areas resulting from urban runoff. Urbanizing and urbanized areas, construction, onsite sewage disposal systems (septic systems), highways, and bridges will be covered under this heading.

It has been well documented that urban sources of pollution contribute significantly to the degradation of coastal and estuarine water resources. The National Urban Runoff Program (NURP), State 305(b) reports, and the Section 319 Assessment reports all indicate that urban loadings of sediments, nutrients and toxic substances to surface waters are significant and may cause impairment or denial of beneficial uses.

Curtailment of recreational and commercial uses of coastal waters due to contamination from urban runoff has been well publicized. Land conversion associated with the urbanization of undeveloped lands has resulted in the loss of vegetation and sensitive wetlands, alteration of natural drainage patterns and the creation of expanded areas of imperviousness. This loss of infiltrative capacity has been correlated with increases in the velocity, volume and frequency of stormwater runoff. Mitigation and prevention of this process is inherently difficult in that sources are diverse, changes in water quality may be gradual and cumulative, existing institutional frameworks often fail to address NPS pollution in a comprehensive manner, and political constraints tend to limit the number of viable options for meaningful change.

Management measures appropriate to control urban runoff must address an array of pollutants. As urbanization occurs, strategies must comprehensively address pollutants generated during all phases of this process. Management practices or systems need to be developed for urban sources of NPS which anticipate and adjust to these ongoing changes. In such an environment, a phased approach is often necessary to prevent and control each type of pollutant generated. Planning and site design can be effective means to prevent and control nonpoint source pollution. Both watershed and site planning can be used to (1) locate development away from sensitive land forms which may be highly erodible or serve as natural filters for stormwater runoff and (2) design developments to allow more effective or efficient control of nonpoint source runoff. This subject will be addressed in more detail within the body of this section. To further illustrate this point, where development or construction are planned, site suitability evaluations are appropriate prior to the planning and design phase. As planning and design occur, best management strategies should assess the environmental effects of the project and identify practices or controls needed to prevent or mitigate runoff during and after construction. During construction, management practices should schedule activities to minimize site disturbance and include the use of sediment control measures and practices. Finally, post construction measures should ensure that proper operation and maintenance of control devices such as buffer strips and detention basins occur on a long term basis.

The management measures presented in the following sections represent the EPA's preliminary effort to specify the best practices or management systems to control urban sources of nonpoint pollution. Where possible, data on effectiveness, cost of implementation and operation and maintenance has been provided. In the absence of readily available data, the guidance contains examples or cites existing State practices which are under consideration as best management practices. The Agency is soliciting information both on additional management measures that apply to urban problems and any cost or effectiveness data which is applicable to these or previously identified measures. The Agency will consider these and additional information regarding costs and pollution reduction effects prior to publishing the final guidance.

Listed below are some of the major sources of urban nonpoint pollution:

(1) Construction on sites less than five acres in size
(2) Onsite Sewage Disposal Systems - septic tanks
(3) Households
(4) Roads, Highways and Bridges
(5) Golf Courses/Parks
(6) Service stations

As pointed out in the introduction, some of these activities may be required to apply for and receive point source permits. In such cases, they are not subject to this guidance. (See the National Pollutant Discharge Elimination System Permit Application Regulations for Storm Water Discharges published in 55 Fed. Reg. 47990 (November 16, 1990) for more information concerning point source discharges.)

A. Urban Nonpoint Pollutants and Water Quality Effects

Most pollutants enter coastal waters either as soluble forms or bound to sediments. Additional pollutants result from atmospheric deposition. Data from both the National Urban Runoff Program (NURP) and the §319 Report documents that sediments, nutrients and pathogens are the most likely pollutants to impair water quality and designated uses. Heavy metals, oils and grease, toxic organic chemicals and oxygen-demanding materials may also contribute to water quality problems.

Volume and pollutant concentration in urban runoff affect the extent receiving coastal waters are impaired. Daniel (1978) found high concentrations of pollutants are generally associated with the following conditions: (1) densely populated and/or industrial areas; (2) intensive storms; (3) beginning stages of storms; (4) prolonged dry periods prior to a runoff event; and (5) drainage areas with significant construction activity.

VOL 12

4984

Some generic water quality impacts associated with urban runoff include: (1) rapid short-term changes in water quality during and shortly after storm events which result from the discharge of pollutants at relatively high concentrations; (2) longer-term water quality impacts on biological communities and health associated with the discharge of toxic pollutants at lower concentrations; (3) long-term effects associated with the discharge of nutrients and other pollutants into estuaries and wetlands; (4) physical changes related to the erosion of stream banks and/or the creation of sediment deposits in near coastal areas; and (5) water quality changes associated with the scouring and resuspension of in place pollutants.

B. Urban Nonpoint Source Pollutants

Listed below are the principal types of NPS pollutants found in urban runoff with brief descriptions of their potential to adversely affect surface and coastal waters (Schueler, 1987). Table 4-1 further illustrates types and sources of hazardous urban pollutants (EPA, Urban Targeting and BMP Selection, 1990)

Sediment: Suspended sediments comprise the bulk of urban nonpoint source pollutants. Sediment has both short and long term impacts on receiving waters. Some immediate detrimental impacts of high sediment loadings include: increased turbidity, impaired respiration of fish and aquatic invertebrates, reduced fecundity and impairment of commercial and recreational fishing. High sediment concentrations may also cause long term effects. Heavy sediment deposition in low velocity receiving waters may result in smothered benthic communities, increased sedimentation of watercourses, changes in bottom substrate composition and alteration of the water's aesthetic value. Additional chronic effects may occur where sediments rich in organic matter or clay are present. Such sediments tend to bind and transport nutrients, toxic substances and trace metals. These enriched depositional sediments may present a continued risk to aquatic and benthic life especially where the sediments are disturbed and resuspended.

Oxygen Demanding Substances: Dissolved oxygen levels are critical to healthy waters. Decomposition of organic matter by microorganisms depletes dissolved oxygen (DO) levels in receiving waters, especially estuaries. Data has shown that urban runoff with high concentrations of decaying organic matter can severely depress DO levels after storms (EPA, 1983). The NURP study found that oxygen demanding substances are present in urban runoff at concentrations approximately equal to those in secondary treatment discharges. The Chesapeake Bay Office is currently recommending that DO levels not fall below specified thresholds for selected habitats (see Table 4-2: Note, however, that Table 4-2 only applies to the Chesapeake Bay and should not be applied elsewhere without adjustment).

Nutrients: The problems created by excess phosphorus and nitrogen loading to water bodies are well known and discussed in detail in Chapter 2 (agriculture). Accelerated eutrophication, decreases of submerged aquatic vegetation (SAV) and toxicity to humans or wildlife may occur when the concentration of certain forms of nutrients exceed a critical level. Surface algal scum,

Table 4-2. Recommended DO Habitat Requirements

Category	DO Value (mg/L)	Specific Requirements
Spawning Reaches: Instantaneous DO	5.0	DO should not fall below 5.0 mg/L at any time within anadromous fish spawning reaches and nursery areas during late winter through late spring (February 1 - June 15).
All Tidal Waters of the Chesapeake Bay for All Seasons Except the Spawning Areas and Times Defined Above:		
Category I - Instantaneous DO	0.5	DO should not be below 0.5 mg/L at any location, at any season, or for any duration.
Category II - One-hour DO	1.0	DO should not fall below 1.0 mg/L for more than one hour at any location or at any time. Excursions below 1.0 mg/L should not occur more frequently than every 12 hours.
Category III - Twelve-hour DO	3.0	DO should not fall below 3.0 mg/L for more than 12 hours at any location or time. Twelve-hour excursions below 3.0 mg/L should not occur more frequently than every 48 hours.
Category IV - Monthly Average DO	5.0	Monthly mean DO should not be below 5.0 mg/L at any location or season.

VOL 12

4987

water discoloration, strong odors, depressed oxygen levels, and release of toxins are also common problems.

Heavy Metals: Heavy levels of copper, lead and zinc are the most prevalent priority pollutant constituents found in urban runoff. The presence and concentrations of these metal is in some cases high enough to impact beneficial uses and cause detrimental effects to aquatic life. Groundwater sources of drinking water supplies may also be degraded or endangered by the presence of heavy metals and nitrates.

Oil and Grease: Oil and grease contain a wide variety of hydrocarbon compounds. Some polynuclear aromatic hydrocarbons (PAH's) are known to be toxic to aquatic life at low concentrations. The precise impacts of hydrocarbons on the aquatic environment are not well understood.

Pathogens: The presence of pathogens in surface water may cause public health standards for water contact to be exceeded and restrict shell fish harvesting. Although high fecal coliform counts have documented in urban runoff, the health implications are unclear where contamination is not from improper sanitary connections or septic systems.

Other Pollutants: Other toxic chemicals are rarely found in urban runoff from residential and commercial land use areas in concentrations that exceed current water quality criteria. Pesticide concentrations in urban runoff generally are near detection limits. PAHs commonly detected organic compounds found in urban runoff have not been correlated with known problems. There is currently a lack of data on industrial runoff to draw conclusions about the fate and effects of related pollutants.

VOL 12

4989

II. CONSTRUCTION MANAGEMENT MEASURE

A. Management Measure Applicability

This management measure is applicable to all construction activities which result in land development or disturbance and are not subject to a requirement to apply for and receive an NPDES permit [Note: All construction activities, including clearing, grading and excavation which result in the disturbance of areas greater or equal to 5 acres or are part of a larger development plan are covered by the NPDES regulations]. Activities subject to this management measure include, but are not limited to, commercial or residential development, road, highway, airport and bridge construction, landscaping and installation of underground storage tanks or sewer/stormwater conveyances.

B. Pollutants Generated by Construction Activities

Construction related pollutants transported in urban runoff, listed in decreasing order of importance include:

- Sediment and particulate organic solids;
- Toxic metals and hydrocarbons (deposited from onsite equipment);
- Nutrients (applied to promote revegetation and site stabilization).

The major pollutant generated from construction activities is sediment. Sediment loadings from construction sites may be as much as 100 times greater per acre than those from agricultural lands and perhaps 2,000 times per acre greater than from undisturbed forestland (IEN p. 64, Bergquist, 1986). Exposed, disturbed and stockpiled soils are extremely susceptible to erosion and transport off site. In general, downstream suspended sediment levels are greatest during the advanced stages of construction when sediment delivery conditions are optimal (Schueler, 1990).

C. Construction Management Measures

Management measures for construction consist of the following sets of measures.

(1) Reduce site disturbance and the detachment and transport of soil on construction sites by disturbing the smallest area for activities, stabilizing disturbed areas within a reasonable time, reducing runoff velocities, and protecting disturbed areas from stormwater runoff.

(2) Control eroded sediment on site such that off-site sediment and particulate organic solids delivery is reduced to or below the lower of either pre-development sediment loadings (to the extent practicable) or the acceptable soil loss tolerance for agricultural lands.

(3) Reduce toxic and nutrient loadings to pre-development levels (to the extent practicable) by reducing the generation and migration of toxic substances and avoiding excess applications of nutrients.

D. Available Management Practices to Achieve Management Measures

Listed below is a selection of state-of-the-art erosion and sediment control practices ideal for coastal regions. These practices are available as tools to achieve the construction management measure specified in section II.C.

1. Practices Available to Achieve Management Measures 1 and 2

Practices for general use:

- Plan development to fit the topography, soils, drainage patterns and natural vegetation of the site.
- Avoid mass clearing and grading of the entire site (e.g., use phased construction sequencing to limit the amount of disturbed area at any given time).
- Establish vegetative cover on all disturbed sites where construction activity has been interrupted for an unreasonable time.
- Configure site plans to retain the maximum area of open vegetated space.
- Divert and convey off-site runoff around disturbed soils and steep slopes to stable areas in order to retain sediment onsite and prevent transport of pollutants offsite.
- Utilize grading methods which impede vertical runoff and provide maximum runoff infiltration capacity.
- Implement a maintenance and follow-up program for control practices including post storm event inspections of all control practices.
- Restrict the clearing and grading of all areas that will later function as post development buffer zones.
- Locate large graded areas on the most level portion of the site and avoid the development of steep vegetated slopes.
- Reestablish vegetative areas that have been filled or damaged by construction equipment or activities.
- Conduct temporary construction and fill activities outside of floodplains.

VOL 12

4990

- Prepare an erosion and sediment control plan which specifies location, installation, and maintenance of practices to prevent and control erosion and sediment loss at the site. The efficacy of this practice can be further enhanced by communicating the provisions of the control plan to all employees associated with the project and by designating responsibility for implemention of the plan to an individual certified in erosion and sediment control practices by the local authority.

- Use surface roughening (horizontal depressions) to control erosion and aid the establishment of vegetative cover.

- Avoid the placement of entrances on steep grades or curves.

- Protect inlets to storm sewers by suitable filtering devices during construction.

- Construct access roads with grades less than 10%.

- Stockpile topsoil and reapply it to revegetate the site.

- Use practices such as benching, terracing, or diversional structures where development occurs on steep vegetated slopes.

- Physically mark off limits of land disturbance on the site with tape, signs or barriers to ensure preservation of offsite areas.

- Evaluate the need for extraordinary controls and, if necessary, implement such controls.

Vegetative Stabilization Practices - Rapid establishment of a grass or mulch cover on a cleared or graded area at construction sites is the single most important factor in reducing downstream sediment and can reduce suspended sediment levels to receiving waters by up to six fold (Schueler, 1990).

- Temporary seeding - Temporary seeding may be the single most important factor in reducing construction related erosion ("New York Guidelines for Urban Erosion and Sediment Control:, USDA - Soil Conservation Service, March 1988). Temporary seeding practices have been found to be up to 95% effective in reducing erosion ("Guides for Erosion and Sediment Control in California"- Soil Conservation Service, Davis, CA, Revised 1985). For critical areas, vegetation should cover 90% of each square yard of disturbed area to adequately stabilize soils. Moderately sloped areas with fertile soils require at least 75% of each square yard of exposed area to be vegetated. (Pennsylvania Soil and Erosion Control Manual, 1983)

- Permanent Seeding
- Mulching - wood Fiber hydroseeder slurries are well suited to establish vegetation on steep slopes, in critical areas, and areas with severe climates
- Sod stabilization - good sod cover may be up to 98% effective in controlling erosion (PA S & E,1983)
- Vegetative buffer strips
- Tree and shrub protection: fencing, tree armoring, retaining walls or tree wells

(See Chapter 7 for additional data on vegetative stabilization/filtration practices.)

Perimeter Control practices - Perimeter controls are devices placed at the edge or boundary of construction site disturbance to: (1) prevent sediments from washing off site and; (2) direct surface runoff into a sediment trap or basin.

- Temporary and permanent diversions - "among the most effective and least costly practices for controlling erosion and sediment" (North Carolina Erosion and Sediment Control Planning and Design Manual, 1988).
- Grass covered earthen berms
- Silt fences or curtains
- Infiltration trenches
- Straw bales - When installed properly straw bales can remove up to 67% of the sediment provided rotten or broken bales are replaced (VA Erosion and Sediment Control Handbook, 1980).

Trap & Basin Practices - Sediment traps and basins are used at construction sites to capture surface runoff of sediment during storm events. The sediment-laden water is retained for a period or time to allow sediment particulates to settle to the bottom of the trap. Current designs of sediment traps and basins have been found to be only moderately effective. Sattherwaithe, found that for 2/3 of storms in the Northeast, sediment controls were less than 50% effective. In Maryland, current recommendations have been proposed to require traps and basins with 1800 cubic feet/acre of permanent pool and 1800 cf/acre of "dry de-watering storage". This design with a total volume of 3600 cf/acre will effectively treat 90% of the storms each year assuming (1) a runoff coefficient of .5 during the most active stage of construction and (2) 90% of annual runoff results from storms of 1.5 inches or less (Performance of Current Sediment Control Measures at Maryland Construction Sites, Schueler and Lugbill, 1990).

Super Basin Practices - Super basins have wet and dry storage equivalent to one-inch of sediment per acre of upland watershed area. Properly designed and maintained super basins can provide reliable high rates of sediment removal for most annual storm events.

Extraordinary and Redundant Control Practices - Extraordinary controls apply to both stormwater management and sediment and erosion control.

- Oversized devices such as sediment basins or traps
- Immediate stabilization of disturbed areas
- Inspections of erosion and sediment control practices following every storm event

(Note: For additional extraordinary practices, refer to section E.)

2. Additional Practices Available to Achieve Management Measures 1 and 2

Listed below are other practices which have varying degrees of effectiveness and can be utilized in combination with the preceding practices to achieve the level of reduction specified in management measures 1 and 2. This list is not all inclusive.

- Riprap - use on or for:
  - Steep cut and fill slopes subject to severe weathering or seepage;
  - Channel liners;
  - Inlet and outlet protection at culverts;
  - Streambank protection;
  - Shorelines subject to wave action.
- Temporary construction entrance/exit - gravel buffer to collect mud and sediment and prevent tracking of soils offsite
- Vehicle washing in area with drainage and sediment trap
- Dune stabilization - vegetative planting
- Diversion dikes (Perimeter protection) - require immediate vegetation after construction and stabilization of the channelized area according to flow conditions
- Grass-lined channels
- Riprap lined and paved channels
- Temporary slope drains
- Level spreaders
- Temporary stream crossings (fords, culverts, bridges)
- Streambank stabilization practices - vegetative and structural including gabions, deflectors, log cribbing, reinforced concrete and grid pavers. (Stream channel velocities for 10 year storm must be less than 6 ft/sec for vegetative stabilization to be effective)
- Subsurface drains
- Check dams
- Paved flumes
- Nets and mats
- Dust control measures - vegetative, sprinkling, wind barriers

VOL 12

4993

3. Practices Available as Tools to Achieve Management Measure 3

Toxic substances and nutrients tend to bind to fines. In most cases where proper erosion and sediment controls have been utilized, heavy metals, hydrocarbons and nutrients will be immobilized. There is, however, an additional set of practices which can be utilized to reduce the volume and concentration of floatable and soluble pollutants such as oil and grease and nitrates.

- Provide sanitary facilities for construction workers.
- Maintain highway equipment and machinery only in confined areas specifically designed to control runoff (BMP Handbook, VA State Water Control Board Planning Bulletin 321, 1979).
- Use absorbent materials such as hay bales, cat litter and absorbent pads to collect and prevent migration of pollutants.
- Store, cover and isolate construction materials, including topsoil and chemicals to prevent runoff of pollutants and contamination of groundwater.
- Spill Prevention and Control Plan - Spill prevention and control is an important element of a runoff control strategy. Agencies, contractors and other commercial entities that store, handle, or transport fuel, oil or hazardous materials should develop a spill response counter measures plan.
- Maintain and wash highway equipment and machinery in confined areas specifically designed to control runoff (BMP Handbook, VA State Water Control Board Planning Bulletin 321, 1979).

E. Erosion and Sediment Practices for Particularly Sensitive Watersheds

Sensitive watersheds may need additional protection above the level required for most construction activities. Consistent with other measures in this guidance, the watershed affected and the type of resources needing protection will dictate the combination of practices which are necessary. Comments are solicited on the following set of practices and their suitability for inclusion in the final guidance as a management measure for particularly sensitive watersheds. (Note: The Maryland Chesapeake Bay Critical Area Program regulations define sensitive areas as having the following features: hydric soils or soils with hydric properties, highly erodible soils with high K values, steep slopes greater than 15%)

(1) 72-hour stabilization requirement;
(2) Installation of double rows of silt fencing;
(3) Oversizing of sediment traps and basins;

(4) Immediate installation of infiltration practices with provisions to maintain these devices until vegetation is established;
(5) Innovative scheduling for paving vs. vegetative stabilization and implementation of infiltration practices to reduce thermal impacts;
(6) Minimization of cleared forest lands;
(7) Establishment or protection of forested buffers along streams;
(8) Phased clearing operations;
(9) Installation of traps and basins prior to grading;
(10) Installation of turbidity curtains;
(11) Maintenance of controls following every storm-event; and
(12) Increased inspection intervals (once a week minimum; the 1983 Maryland Standards and Specifications for Erosion and Sediment Control suggest daily inspections).

(Maryland State Highway Administration Chesapeake Bay Initiatives Action Plan, August 15, 1990)

F. Effectiveness and Cost

Table 4-3 provides information on effectiveness, cost and applicability of some of the erosion and sediment control practices discussed above.

III. URBAN STORMWATER RUNOFF MANAGEMENT

A. Applicability of This Management Measure

This management measure applies to all urban areas other than those which are required to apply for and receive NPDES stormwater permits.

B. Problem Description

Urbanized areas, or those in which development has altered the natural infiltration characteristics of the land, experience increased surface runoff. Land development alters the natural balance between stormwater runoff and natural absorption areas by replacing them with greater amounts of impervious surface. This results in increased surface runoff at greater velocity.

As a result of increased quantity and velocity of runoff, greater amounts of pollutants are carried in the increased runoff flow, streambanks are eroded, greater amounts of pollutants are carried in the increased runoff flow, and the likelihood of flooding, erosion and water quality degradation increases. Moreover, streambank erosion results in degraded aquatic habitat.

Urbanized areas experience pollutant runoff loadings many times that of land in its pre-development state. The principal pollutants found in urban runoff include sediment, oxygen-demanding substances, nutrients, heavy metals, bacteria & pathogens, oil & grease, and toxics & pesticides.

C. Management Measures for Urban Stormwater Management

(1) Limit the creation of impervious surface and retain the appropriate amount of pervious surface in order to achieve optimal infiltration of runoff into soil. Protect natural vegetation and drainageways.

(2) Limit disturbance of areas such as steep slopes and unstable areas.

(3) Control the first flush of runoff to reduce loadings of sediment and toxic pollutants, taking into account cost and pollutant reduction effects.

(4) Protect against streambank erosion by reducing post-development stormwater runoff peak flows.

(5) Implement source controls where appropriate to reduce the availability of pollutants to be entrained in stormwater runoff.

(6) Control the application of nutrients and pesticides to golf courses and parks.

D. Principal Management Practices

Following is a list of management practices for urban stormwater runoff management that are available as tools to achieve the urban stormwater runoff management measure:

(1) Pond Systems (Detention/Retention)

(a) Detention devices: Runoff is temporarily stored, then subsequently discharged to a surface water. Pollution abatement results from the settling of pollutants during the detention period.

(b) Retention devices: Runoff is permanently captured so that it is never discharged directly to surface waters. Wetlands may often be constructed in such devices to promote nutrient uptake.

(2) Biofiltration

These methods accomplish pollutant removal by filtration, biological uptake, or trapping sediment. These controls comprise an infiltration system which not only allows pollutant removal but also recharges the groundwater through infiltration. These methods may also be incorporated as components of pond systems. (See Chapter 7 for further discussion of biofiltration)

(3) Infiltration Devices

Infiltration devices utilize various methods for removing the soluble and fine particulate pollutants found in stormwater runoff.

The devices or practices described above are the primary means by which to control the bulk of pollutants in urban stormwater runoff after they leave the site.

E. Effectiveness of Stormwater Runoff Controls

The best available procedures for urban stormwater management include both structural and non-structural components and involve a combination of detention, infiltration and filtering devices. Treatment systems, rather than individual practices, will tend to achieve the greatest pollutant reduction goal. Systems should include source control, stormwater management and riparian protection to achieve the highest level of effectiveness.

Stormwater treatment systems are site-specific; their effectiveness is highly variable and dependent on many factors, including the following: contributing drainage area; the infiltration characteristics of soils on site; site topography; and available space for a treatment structure on site.

In addition, practices or combinations of practices which are considered to be "best available" in some or in many situations, may nevertheless not be the most effective or economically achieveable for a particular site, and may even be entirely ineffective for the site. A system of practices should be tailored to a particular site to avoid selection of unsuitable practices, maintenance problems, or failure to achieved desired pollutant reduction.

Table 4-4 provides a matrix that shows the relative suitability, effectiveness, and costs of a variety of stormwater runoff treatment or control practices. A brief discussion of these practices follows immediately below.

1. Pond Systems (Detention/Retention)

The ponds described below (and referred to in D(1) above) range from completely dry structures to permanently wet structures with various combinations included. In addition, wetland components are discussed for their ability to enhance pollutant removal, create habitat diversity, and provide visual interest.

Wet Extended Detention Pond - A permanent pool system containing a forebay near the inlet to trap sediments and a deeper pool near the riser. This pond system provides an optimal combination of downstream channel protection and urban pollutant removal. Extended detention wet ponds are generally the most cost effective urban/coastal practices available for pollutant removal and stormwater control.

Wet Pond - A pond system with all of its storage utilized as a permanent pool. This system provides high levels of urban pollutant removal through biological uptake from aquatic wetland plant species. In addition, a wet pond can be an attractive community feature.

ED Micro-Pool - A dry ED system containing one or two small permanent pools for pollutant removal. One micro-pool located near the riser protects the ED pipe from clogging. A second micro-pool located near the inlet acts as a sediment forebay. The micro-pool system has a much lower maintenance burden than conventional dry ED pond systems and is a particularly useful design for fingerprinting a pond into a sensitive woodland or wetland area.

ED Shallow Marsh - A system utilizing emergent aquatic wetland plant species as its principal pollutant removal mechanism. The ED shallow marsh typically consists of a 0-3 foot deep irregularly shaped permanent pool, creating diverse wetland habitats in a relatively small space, while providing moderate levels of soluble pollutant removal.

Shallow Marsh - A system with much of its storage devoted to a shallow marsh, this pond design can consume a great deal of land area. However with proper grading, design and propagation techniques, this system can result in the creation of extensive, high quality emergent wetland habitat. The shallow marsh can achieve high removal rates of soluble and particulate pollutants through the biological uptake mechanism of emergent aquatic plants.

5000

In-Filter Dry Pond - An innovative dry pond system for sites having permeable soils that promote infiltration. Design includes stormwater detention, pretreatment via plunge pools and grassed swales, and a series of infiltration trenches and basins.

Dry ED Pond - A pond system typically comprised of two stages: The upper stage is graded to remain dry except for infrequent storms; whereas the lower stage is designed for regular inundation. Runoff pretreatment is difficult to achieve with this pond system, and it is equally difficult to prevent clogging of the ED control device.

Evaluation

Wet Ponds and Wet Extended Detention Ponds are extremely effective water quality practices. When properly sized and maintained, Wet Ponds and Wet Extended Detention Ponds can achieve a high removal rate for sediment, BOD, nutrients, and trace metals. Biological processes within the pond also remove the soluble nutrients (nitrate and ortho-phosphorous) that contribute to nutrient enrichment (eutrophication). Soluble nutrient removal is achieved through a process known as biological uptake where aquatic plants convert the soluble nutrients into biomass which then settles into pond sediments and is later consumed by bacteria and thus removed from the pond system.

Wet Extended Detention Ponds are most cost effective in larger, more intensely developed sites. Pond practices normally require a significant contributing watershed area (greater than 10 acres) to ensure proper operation. Positive impacts associated with wet pond systems can include: creation of local wild life habitat, increased property values, recreation, and landscape amenities.

Extended Detention Ponds are effective in controlling post-development peak stormwater discharge rates to a desired pre-development level for the design storm(s) specified. If stormwater is detained for 24 hours or more, as much as 90% removal of particulate-form or suspended solid pollutants is possible.

However, it should be noted that extended detention ponds have the disadvantage of elevating water temperatures. Thus their use may be inappropriate in some locations, such as trout habitat. In addition, care should be taken not to reduce base flows below levels necessary to sustain the aquatic habitat.

2. Infiltration Systems

The infiltration systems described below (and described in D(3) above) range in design from stone-filled trenches and basins to permeable asphalt pavement. All utilize differing methods for removing soluble and fine particulate pollutants found in stormwater runoff. To prevent infiltration systems from becoming clogged with fine sediment, it is essential to pretreat the incoming runoff. Methods of pretreatment range from filter cloth to vegetated filter strips. With pretreatment, infiltration systems can be an effective component of an urban water quality practices.

It is important to recognize that infiltration systems create a risk of transferring pollutants from surface water to ground water. Therefore, infiltration systems should not be used near wells or in wellhead protection areas or in settings in which drinking water supplies may become contaminated.

Infiltration Trench - An Infiltration Trench works by diverting stormwater runoff into a shallow (3 - 8 feet) excavated trench which has been back-filled with stone to form an underground reservoir. Runoff is then either exfiltrated into the sub-soil or collected in under-drain pipes and conveyed to an outflow facility. Infiltration Trenches are an adaptable practice that adequately remove both soluble and particulate pollutants. Infiltration Trenches are primarily an on-site control and are seldom practical or economical for drainage areas larger than 5 to 10 acres. Infiltration Trenches are one of the few practices that adequately provide pollutant removal on small sites or infill development. Infiltration Trenches preserve the natural groundwater recharge capabilities of a site and can often fit into margins, perimeters, and other unutilized areas of the site. A disadvantage is that Infiltration Trenches require careful construction, pretreatment, and regular maintenance to prevent premature clogging.

Infiltration Trench #2 - Similar to the trench system described above, this design accepts sheet flow from the lower end of a parking lot or paved surface. Runoff is diverted off the paved parking lot through slotted curbs. The slotted curbs function as a level spreader for stormwater. A grass filter strip separates the trench from the paved surface for capture of sediments. This trench includes a perforated PVC-type pipe for passage of large design storm events. At the end of the trench is a grassed berms to ensure that runoff does not escape.

Infiltration Basin - Infiltration Basins are an effective means for removal of soluble and fine particulate pollutants. Unlike other infiltration systems, basins are easily adaptable to provide full control for peak storm events. Basins can also serve large drainage areas (up to 50 acres). Basins are a feasible option where soils are permeable. Basins are advantageous in that they can preserve the natural water table of a site, serve larger developments, can be used as a construction sediment basin, and are reasonable cost effective in comparison to other practices. One disadvantage is the need for frequent maintenance. In addition, infiltration basins have sometimes failed because they were installed in unsuitable locations or soils.

Dry Well - A small infiltration system designed to accept stormwater from a roof-drain down-spout. Rather than dispersing its stormwater across a paved surface or grassed area, the down spout pipe connects directly into the dry well which filters roof top runoff into soils.

Porous Pavement - Porous Pavement is a permeable pavement having the capability to remove both soluble and fine particulate pollutants in urban runoff and provide groundwater recharge. Use is restricted to low traffic volume parking areas. Porous Pavement systems can receive runoff from adjacent roof tops. This reasonably cost-effective practice is only feasible on sites with gentle slopes, permeable soils, deep water tables and bedrock levels. Requires careful design, installation, and maintenance. Although Porous Pavement has the high capability to

VOL 12

5002

remove both soluble and fine particulate pollutants from urban runoff, it can become easily clogged and is difficult and costly to rehabilitate.

Evaluation

From a pollutant removal standpoint, Infiltration Trenches, Basins, and Porous Pavement have a moderate to high removal capability for both particulate and soluble urban pollutants, depending upon how much of the annual runoff volume is effectively exfiltrated through the soil layer. It should be noted that infiltration practices should not be entirely relied upon to achieve high levels of particulate pollutant removal (particularly sediments), since these particles can rapidly clog the device. For these systems to be effective, particulate pollutants must be removed before they enter the structure by means of a filter strip, sediment trap or other pre-treatment devices, and these devices must be regularly maintained.

In summary, infiltration systems can adequately remove soluble urban pollutants on smaller sites (10 acres or less). As a practice for controlling coastal non-point source pollution, infiltration systems should only be considered as part of an integrated system of management measures.

3. Filter Systems

The filter systems described below (and described in D(2) above) rely on various forms of erosion resistant vegetation to amplify particulate pollutant removal, improve terrestrial habitat, and enhance the appearance of a development site. In addition, filter systems can improve both the performance and amenity value of pond and infiltration practices via stormwater pretreatment, and can be used in such areas as golf courses and parks to intercept runoff and prevent its entry into surface waters and coastal shorelines.

Grass Filter Strip - Similar to a grassed swale, but can only accept overland sheet flow. Filter strips are effective when used to protect surface infiltration trenches from clogging by sediment. Effective in removal of sediment, organic material, and trace metals. Should be used as a component in an integrated stormwater management system. Filter strips are inexpensive to establish and cost almost nothing if preserved prior to site development. As with all filter systems, long-term maintenance (mowing, inspection for short circuiting, etc.), should be included in overall costs. Grass filter strips are discussed in detail in chapter 7 of this guidance.

Riparian Buffer Strip - Riparian buffer strips improve water quality by removing nutrients, sediment and suspended solids, and pesticides and other toxics from surface runoff, as well as subsurface and groundwater flows. The pollutant removal mechanism associated with riparian vegetation combines the physical process of filtering and the biological processes of nutrient uptake and denitrification. Riparian buffer strips are discussed in detail in chapter 7 of this guidance.

Grassed Swale - A grassed, low gradient conveyance channel that provides some water quality improvements for stormwater via natural filtration, settling, and nutrient uptake of the grass cover. Often used as an alternative to curb and gutter drainage conveyance. Grassed swales affect peak discharges by lengthening time of concentration. Can be fitted with low check dams to increase removal efficiency via temporary ponding.

Sand Filters - A water quality control filtration system used to remove large particulates from runoff and protect filter media from excessive sediment loading at stormwater quality control basins. Sand filters can be used independently or with a dry pond/basin element.

Peat/Sand Filters - A man-made soil filter system utilizing the natural absorptive features of peat. The system features a grass cover crop and alternating sub-layers of peat, sand, and a perforated pipe underdrain system. Systems are presently used for municipal waste effluent treatment and are being adapted for use in stormwater management.

Evaluation

Filter strips have a low to moderate capability of removing pollutants in urban runoff, and exhibit higher removal rates for particulate rather than soluble pollutants. Pollutant removal techniques include filtering through vegetation and/or soil, settling/deposition, and uptake by vegetation. Riparian buffer strips appear to have a higher pollutant removal capability than grass filter strips. However, length, slope, and soil permeability are critical factors which influence the effectiveness of any strip. Another practical design problem is prevention of stormwater from concentrating and thereby "short-circuiting" the strip.

Filter Systems are an essential component of a comprehensive nonpoint source control strategy, but should generally be used in conjunction with infiltration systems and/or pond systems, as a pre-treatment for runoff.

4. Source Control Systems

Source control systems reduce the availability of pollutants that can become entrained in stormwater runoff.

Street Maintenance - Implementation of street-cleaning programs, scheduled on a regular basis, can be effective at removing pollutants attached to fine sediment. Street-cleaning should occur on a more frequent basis during periods of more frequent storm events. Street maintenance can be effective in reducing the total amount of pollutant load which is carried off-site by runoff. Implementation of catch-basin maintenance and cleaning programs to remove sediment and debris from storm drains is an additional practice.

Leaf & Lawn Vegetation Collection - Implementation of leaf and lawn vegetation collection programs to reduce the amount of nutrient load in stormwater runoff can be an effective, yet

VOL 12

5004

inexpensive management practice. Collection frequency should be increased during autumn and spring periods of increased leaf fall.

Toxic and Hazardous Pollutants Recycling - Sources of toxic and hazardous pollutants can be identified and programs to educate and inform citizens about how to control and recycle them can be implemented. Used motor oil recycling programs are one example of this management practice.

REQUEST FOR COMMENTS

In Chapter 1 of this guidance (Introduction), EPA has generally requested submission of comments, information and data on relevant management practices, their effectiveness, and their costs. We also request specific comment on the following aspects of the urban stormwater management measures:

1. One of the stormwater management measures for control of the first flush of runoff, does not specify the amount of runoff to be treated or the length of time it should be treated. EPA requests comment and information on the costs and pollution reduction effects of specifying the treatment of the first flush of stormwater runoff by detaining at least 1/2 inch of runoff from the drainage area for 12-48 hours, depending on particle size and settling velocity. If this is not feasible or appropriate, what management measure should be established for controlling the first flush of urban stormwater runoff?

2. Another of the stormwater management measures calls for implementing source controls to reduce the availability of pollutants to be entrained in stormwater runoff, but does not specify source controls for runoff from service stations. Other, specific controls are listed in the section on recommended practices. EPA requests comment on the costs and pollutant reduction effects of specifying, in the management measure, service station runoff controls and collection systems, including the control of oil and grease through appropriate disposal methods utilized off-site.

IV. ROADS AND HIGHWAYS

A. Management Measure Applicability

This management measure applies to new and existing roads and highways located in coastal areas.

B. Pollutants of Concern

The primary pollutants associated with roads and highways are:

- Deicing chemicals
- Vehicular deposits
- Erosion and sediment
- Herbicides
- Dust, dirt, and debris

In areas where deicing agents are used, deicing chemicals and abrasives are the largest source of pollutants during winter months. The major source of pollutants are from vehicular deposits and runoff. (FHWA, US DOT, Technical Summary, Sources and Migration of Highway Runoff Pollutants, Reports No. FHWA/RD-84/057-060-XX, June 1987.)

Table 4-5 lists the pollutants found in stormwater runoff from roads and highways and their sources. The disposition and subsequent magnitude of pollutants found in highway runoff are site-specific and affected by traffic volume, highway design, surrounding land use, climate, and accidental spills. The major impacts of these pollutants can cause impairment to coastal area surface and ground waters.

C. Management Measures

The management measures for roads and highways are devised to (1) prevent direct discharge of stormwater runoff from impervious road surfaces into coastal receiving waters, and (2) to minimize the flow of runoff to coastal waters.

1. Location and Design

Locate roads and highways away from wetlands, critical habitat areas, and drainage channels in the coastal zone, and to minimize cut and fill. Design drainage systems to avoid direct discharge into surface waters. Additional management measures set forth in Section VIII of this chapter should be used where applicable.

5006

Table 4-5. Highway Runoff Constituents and Their Primary Sources

Constituents	Primary Sources
Particulates	Pavement wear, vehicles, atmosphere, maintenance
Nitrogen, Phosphorus	Atmosphere, roadside fertilizer application
Lead	Leaded gasoline (auto exhaust), tire wear (lead oxide filler material, lubricating oil and grease, bearing wear)
Zinc	Tire wear (filler material), motor oil (stabilizing additive), grease
Iron	Auto body rust, steel highway structures (guard rails, etc.), moving engine parts
Copper	Metal plating, bearing and bushing wear, moving engine parts, brake lining wear, fungicides and insecticides
Cadmium	Tire wear (filler material), insecticide application
Chromium	Metal plating, moving engine parts, break lining wear
Nickel	Diesel fuel and gasoline (exhaust), lubricating oil, metal plating, bushing wear, brake lining wear, asphalt paving
Manganese	Moving engine parts
Cyanide	Anticake compound (ferric ferrocyanide, sodium ferrocyanide, yellow prussiate of soda) used to keep deicing salt granular
Sodium, Calcium, Chloride	Deicing salts
Sulphate	Roadway beds, fuel, deicing salts
Petroleum	Spills, leaks or blow-by of motor lubricants, antifreeze and hydraulic fluids, asphalt surface leachate
PCB	Spraying of highway rights-of-way, background atmospheric deposition, PCB catalyst in synthetic tires

Source: U.S. DOT, FHWA, Report No. FHWA/RD-84/057-060, June 1987.

VOL 12

5007

2. Construction

Minimize construction debris and deposits. Cut and fill areas are to be stabilized to prevent sink holes and erosion. Additional management measures set forth in Section II of this Chapter should be used where applicable.

3. Operation and Maintenance

Establish inspection and compliance programs. Stabilize slopes in accordance with Section II. Prevent herbicides from entering drainage systems. Maximize overland flow for runoff containing deicing salts and abrasives to prevent direct discharge to surface and coastal waters. Additional management measures for erosion and sediment control in Section III of this chapter also apply.

D. Management Practices

Following is a list of management practices for roads and highways that are available as tools to achieve the management measures specified above. These practices can be used separately or as combined systems and are applicable for new roads and highways, and are also suitable for retrofitting to existing roads and highways. See Sections II, III, and VIII for detailed information on extended detention ponds, wet ponds, infiltration practices, filter strips, and grassed swales.

In addition, the following practices can be effective:

(1) Washing and Cleaning- Wash construction vehicles to remove mud and other deposits prior to leaving the construction site. Construction vehicles entering or leaving the site with debris or other loose material should be covered with protective tarps. Construction materials and stockpiles on-site should be covered to prevent transport of dust, dirt, and debris. Install and maintain mud and silt traps.

Sweeping and vacuuming road surfaces is a practical means of removing accumulated dust, dirt, and debris. Road cleaning programs need to be effective at removing pollutants attached to fine sediment. Cleaning should occur on a scheduled basis with more frequent cleaning during periods of frequent storm events. This reduces the total amount of pollutant load which is carried away by runoff.

(2) Restabilize Slopes - Eroded slopes and washed-out areas should be stabilized with newly applied vegetative cover, rocks or gabions. Vegetative cover is preferred to reduce runoff and to filter/absorb pollutants. Vegetative materials that require minimal maintenance should be used.

(3) Herbicide Controls - Ensure proper handling, application, and disposal of herbicides used to control weeds and other unwanted vegetative material.

(4) Education Programs - Encourage public participation through programs such as " Adopt A Highway" to alert action to remove animal debris and wastes, and call attention to abuses affecting the disposal of toxic wastes such as waste crankcase oil into drainage systems.

(5) Water Quality Inlets - Current designs of water quality inlets appear to have low to moderate removal rates for particulate pollutants, and low to zero rates for soluble pollutants. Water quality inlets rely primarily on settling for removal, and given their small storage capacity and brief residence times, it is likely that only coarse grit, sand, and some silts will be trapped. Inlets do show some promise in removing hydrocarbons, such as oil, gas and grease, from runoff. Due to resuspension problems, however, pollutant removal can only be attained in water quality inlets if they are cleaned regularly.

E. Effectiveness and Cost

Effectiveness of each of the management practices identified, with approximate costs where available, are discussed in the appropriate sections referenced above. EPA intends to collect additional information on effectiveness and costs of these and the additional practices identified.

V. BRIDGES

A. Applicability

This management measure is applicable to new and existing bridges with solid roadways that cross coastal waters or their tributaries.

This management measure does not apply to U.S. Coast Guard-approved bridges that are covered by Nationwide Permit No. 15 issued by the U.S. Army Corps of Engineers under Section 404 of the Clean Water Act.

B. Problem Description

Bridge construction in coastal areas may cause significant erosion and sedimentation resulting in the loss of wetlands and riparian vegetation. Runoff from bridges may deliver considerable loadings of heavy metals, hydrocarbons and toxic substances from cars and de-icing of roads as a result of direct delivery through scupper drains into coastal waters with no overland buffering or treatment. Maintenance of structures can result in runoff and direct discharge of lead, rust, paint, particulates, solvents, and cleaners.

C. Management Measures for Bridges

The management measures for bridges are devised to control direct delivery of pollutants to coastal waters and reduce the pollutants which reach coastal waters in stormwater runoff.

(1) Site new bridges so that significant adverse impacts to wetlands and riparian vegetation are minimized.

Implement applicable measures identified in Development Section VIII.

(2) Design new bridges to reduce the amount of pollutants transported to surface water, where appropriate.

Route runoff to land for treatment in accordance with management measures for stormwater runoff identified in Section III.

(3) Control sedimentation activities during bridge construction (especially on steep slopes at crossing).

Implement applicable measures identified in Construction Section II.

(4) Control sediment from dredging.

(5) Reduce the delivery of any pollutants used or generated during maintenance

operations (paint, rust and paint removal agents) to coastal waters by capturing, containing storing and properly disposing of work or waste materials. (COMAR)

D. **Management Practices**

(1) Site bridges as far as possible from wetlands, sensitive areas such as shellfish beds, and critical habitat areas.

(2) Limit the use of scupper drains (which drain runoff directly into coastal waters) on bridges. Scupper drains allow runoff in the bridge gutters to drain directly into coastal waters (South Carolina Coastal Council Policy).

(3) Capture, contain and collect scrapings, paint, and sand blast material that could fall into coastal waters using suspended tarps, vacuums, or booms in water.

(4) Require proper disposal of wastes; prohibit the disposal of any waste material into coastal waters.

VOL 12

5011

VOL 12

VI. HOUSEHOLD MANAGEMENT MEASURES

A. Applicability

The following management measures apply to households and workplaces.

B. Pollutants Generated

Pollutants generated from households include:

(1) Household toxics - used oil, paint, solvents and pesticides
(2) Nutrients - nitrogen and phosphorus
(3) Pathogens - bacteria, fecal coliform and other pathogens

Municipal housekeeping and homeowner participation have been shown to have an effect on water quality especially in areas of high population density (The Jones Falls Watershed Urban Stormwater Runoff Project, 1986). Public education and outreach are crucial to the effectiveness of these measures.

The main sources of household pollution are:

- Landscaping activities - erosion (see construction section)
- Lawn/garden care - over-fertilization, unnecessary herbicide or pesticide use, improper leaf management
- Household toxics - improper disposal of oil/grease, antifreeze, paint, household cleaners and solvents
- Pets - improper disposal of fecal matter
- Car/boat care - poor maintenance, washing

C. Management Measure

Communities should establish and implement programs to educate, assist, and where appropriate, require households and workplaces to minimize the introduction of pollutants and pollutant sources into surface water or terrestrial areas in a manner that may result in runoff to surface or ground waters.

D. Management Practices Available as Tools to Achieve the Management Measure

The management practices listed below are principles and tools that local communities may use to build household management programs to achieve the management measure in section VI.C. These practices are arranged by source and implementable on an individual basis. These practices, based on the principle of source reduction, are self-implementing, reduce use of materials and in general lower operating and maintenance costs to existing pollution reduction systems:

5012

(1) Lawn Management and Landscaping

- Reduce herbicide application and watering by mulching to retain moisture and inhibit weeds
- Do not apply pesticides or fertilizers before rainstorms or pesticides on windy days; reduce chemical lawn additives to bare minimum or use organic methods; test soils for nitrogen and phosphorous content before fertilizing; leave grass clippings on lawn to provide nutrients; compost leaf matter and other yard waste; avoid late spring fertilization; use manual or mechanical weed control methods where possible
- Prevent soil erosion - do not mow within 5 feet of water body; plant ground cover in bare areas; reduce disturbed areas as much as possible
- contour lawns to avoid erosion, impede runoff and facilitate infiltration
- limit amount of water applied to lawns and gardens; water only when necessary preferably in the morning

(2) Household Toxics

- Dispose of used paints, pesticides, toxic household cleaners and solvents at hazardous waste collection centers
- Recycle used oil at designated service stations or collection centers
- Soak up oil spills and other automobile fluid leaks with absorbent materials; place used material in municipal trash
- Minimize use of toxic cleaners, encourage use of biodegradable cleaners.

(3) General

- Refrain from placing materials down the storm drains; keep drains clear of foreign matter
- Retain as much permeable area as possible; consider alternatives to concrete such as permeable pavement or flagstones
- Use phosphate free detergents

(4) Pet Wastes

- Manage pet waste to minimize runoff into surface waters

(5) Car/boat Care

- Dispose of antifreeze down household drain while running tap water (this practice is not applicable for septic systems)
- Minimize use of antifouling paint; dispose paint and paint scrapings at hazardous waste collection center
- Use biodegradable cleaners

VOL 12

5013

- Use absorbent materials (e.g., cat litter) to soak up household chemical spills or engine leaks

E. **Effectiveness**

Pet waste control has been shown to remove greater than 50% of nutrients and pathogens (Maryland Regional Planning Council, 1986). The Agencies solicit information on cost and effectiveness of the above practices.

VOL 12

5014

VII. ONSITE SEWAGE DISPOSAL SYSTEMS

A. Applicability

This management measure applies to any residential sewage that is not treated or planned for treatment in a centralized public sewer system. Onsite sewage disposal systems (OSDS) include conventional septic systems, large scale conventional systems, alternative and innovative designs, and private sewage treatment facilities.

B. Coastal Water Pollution Caused by Onsite Sewage Disposal Systems

Proper treatment of wastewater effluent with onsite disposal systems is an essential component of coastal water quality protection. When properly sited, designed, installed, and maintained, individual sewage disposal systems can be used to treat most pollutants found in household waste simply and effectively. Treated wastewater usually reaches coastal waters by groundwater recharge or by groundwater/surface water interfaces.

1. Nutrients Cause Eutrophication

Nitrogen is generally not removed by conventional onsite systems, and can therefore cause eutrophication in coastal areas. For example, Nixon (1982) found OSDS effluent to contribute an estimated 12 to 44 percent of the annual nitrogen load to eight south shore coastal lagoons in Rhode Island.

Under most conditions, phosphorus tends to be attenuated quickly and effectively by soil processes. Except in sensitive waterbodies (including fresh waters and some fresher inshore sectors of estuaries), phosphorus presents less hazard as a transportable nutrient than does nitrogen. In sensitive phosphorus limited waterbodies, however, extremely low phosphorus concentrations can induce eutrophication, and concern is warranted. For example, Sikora and Corey concluded that phosphorus contamination of groundwater could be anticipated primarily in sandy soils with low organic matter content, soil having high water table, and shallow soils over creviced bedrock. Systems in sandy soil near surface water bodies, therefore, are most likely to contribute phosphorus loading to receiving waters.

2. Nitrogen/Pathogens Cause Drinking, Swimming, and Shellfish Contamination

Many coastal areas depend on groundwater sources for water supplies, and are vulnerable to loss of supplies to OSDS-related contamination. EPA has established a drinking water standard of 10 mg/L nitrate nitrogen to reduce the risk of infant cyanosis or methemoglobinemia caused by elevated nitrate levels in drinking water. Improperly treated OSDS effluent can also create significant health hazards if pathogens (bacteria & viruses), which may be present in effluent, contaminate groundwaters, saturated surface soils, or coastal waters. Research indicates that bacteria and viruses are capable of traveling considerable distances, and that transport may be particularly rapid in highly permeable soils. Heufelder (1988) prepared an extensive review of many pertinent issues relating to entrainment of nonpoint source pathogens in groundwater, transport of groundwater entrained organisms in estuarine areas, and survival of viruses in marine systems. In many coastal states, closure of shellfish areas and swimming areas, and restriction of other beneficial uses, have been attributed to pollutant concentrations traceable to improperly functioning septic systems within the contributing watershed or recharge area.

3. Poorly Operating Systems Worsen Problems

The degree of the problems can increase significantly in poorly operating systems. In overt system failure, soils can no longer accept effluent and sewage may break out onto the ground surface where it is transported by drainage systems or overland runoff to surface runoff. Overland pipes and subsurface drainage pipes, designed to prevent system flooding, may intercept contaminated groundwater and discharge contaminants directly to surface waters. Hydraulic overloading(too much wastewater for the system to handle) can cause bacteria, viruses, and nutrients to enter coastal waters via groundwater. Often, both groundwater and surface waters are vulnerable to contamination, due to coastal areas' susceptibility to flooding and sea level rise, high water tables, and groundwater recharge of coastal embayments.

C. Management Measures

Five management measures apply to OSDS in coastal areas. The goals of the management measures are to: (1) minimize pollutants discharges to OSDS; (2) minimize the flow of water to OSDS through conservation, thereby prolonging OSDS life and improving operation, and (3) minimize or eliminate the discharge of nutrients, pathogens (viruses & bacteria), and other pollutants from the OSDS into ground and surface waters.

1. Phosphate Limits in Detergents

a. Management measure

Detergents should contain low amounts of phosphates. Phosphate restrictions are already in place in many coastal States, including the District of Columbia, Indiana, Maryland, Michigan, Minnesota, New York, Virginia, Wisconsin (see Table 4-6).

This measure is especially protective of systems located near where groundwater discharges to the surface or that are failing/overloaded, enabling phosphorus to reach sensitive, phosphorus limited embayments.

b. Effectiveness/Costs

The use of these detergents in place of high phosphate detergents is expected to reduce the loadings of phosphates to OSDS by 50 percent (EPA, 1980). Cost should be negligible.

Table 4-6. Phosphate Limits in Detergents

State	Phosphorus (P) Laundry Detergents	Phosphorus (P) Dishwashing Detergents	Phosphorus (P) Levels Industry
District of Columbia	≤ 0.5% by weight as elemental P		
Indiana [1,2]	≤ 0.5% by weight as elemental P		1mg/L total P effluent conc. at discharges ≥ 3,785m³/d (1MGD) within Great Lake Basin
Maryland	≤ 0.5% by weight as elemental P	≤ 8.7% by weight as elemental P	
Michigan[1]	≤ 0.5% by weight as elemental P	≤ 8.7% by weight as elemental P	1mg/L total P effluent conc. at discharges ≥ 3,785m³/d (1MGD) within Great Lake Basin
Minnesota[1]	≤ 0.5% by weight as elemental P		1 mg/L total P effluent conc. at discharges ≥ 3,785m³/d (1MGD) within Great Lake Basin
New York[1]	≤ 0.5% by weight as elemental P		1mg/L total P effluent conc. at discharges ≥ 3,785m³/d (1MGD) within Great Lake Basin
Wisconsin[1]	≤ 0.5% by weight as elemental P		1mg/L total P effluent conc. at discharges ≥ 3,785m³/d (1MGD) within Great Lake Basin

VOL 12

5017

2. **High Efficiency Plumbing Fixtures**

a. **Management measure**

New or replacement plumbing fixtures should be high-efficiency. Plumbing fixtures in failing systems should be replaced as soon as possible.

b. **Effectiveness/Costs**

Water conservation will help solve hydraulic overloading problems and reduce the cost of retrofit management measures for system improvement and nitrogen removal. Modern, high efficiency fixtures include: 1.5 gallon or less per flush toilets, 2.0 gallon per minute (gpm) or less shower heads, faucets of 1.5 gpm or less, and front loading washing machines of up to 27 gallons per 10 to 12 pound load. These can result in a 30 to 70 percent reduction of total in-house water use (Consumer Reports July 1990 and Feb. 1991 and Krause, et al, 1990). When used in connection with management practices for new and replacement construction, the reduced flows save costs by reducing the size of new and retrofit treatment facilities, extending the life of OSDSs, increasing performance of existing facilities, and lowering costs of operation for holding tanks. Cost savings have also been documented due to reduced demands for potable water (Logsdon, 1987). The cost is minimal, especially for replacement when a fixture breaks.

3. **Garbage Disposals**

a. **Management measure**

Garbage disposal use should not be allowed when an on-site system is failing. Garbage disposals should generally be avoided to: (1) reduce loadings of nitrogen to OSDS, and (2) reduce solids/BOD and decrease pumping frequency for septic/holding tanks.

b. **Effectiveness/Costs**

The use of a garbage disposal contributes substantial quantities of biochemical oxygen demand (BOD), suspended solids, and nutrients to the wastewater load (Table 4-7). As a result, it has been shown that the use of a garbage disposal may increase sludge and scum, and also produce a higher failure rate for conventional OSDS under otherwise comparable situations (EPA, 1980). Also, most waste handled by a garbage disposal could be handled as solid wastes, either for compost piles or trash pick up to public landfills. The cost is minimal as other disposal options are available, such as home composting and solid waste removal to municipal disposal sites. The effectiveness would be to remove from the total household loadings to the OSDS about 28 percent of the BOD, 37 percent of suspended solids, 5 percent of total nitrogen, and 2 percent of total phosphorus from entry into OSDS's (Table 4-7).

Table 4-7. Pollutant Contributions of Major Residential Wastewater Fractions (gm/cap/day)

Parameter	Garbage Disposal	Toilet	Basins, Sinks, Appliances	Approximate Total
BOD_5	18.0 (10.9 - 30.9)	16.7 (6.9 - 23.6)	28.5 (24.5 - 38.8)	63.2
Suspended Solids	26.5 (15.8 - 43.6)	27.0 (12.5 - 36.5)	17.2 (10.8 - 22.6)	70.7
Nitrogen	0.6 (0.2 - 0.9)	8.7 (4.1 - 16.8)	1.9 (1.1 - 2.0)	11.2
Phosphorus	0.1	1.2 (0.6 - 1.6)	2.8 (2.2 - 3.4)	4.0

Means and ranges of results reported by EPA, 1980.

VOL 12

4. Onsite Sewage Disposal Systems for Removal of Pathogens, Phosphorus, BOD

a. Management measure

A properly designed and maintained septic system, with appropriate set-backs from coastlines based on soil types, should be used to achieve almost complete removal of pathogens, phosphorus, and BOD within the property line of an individual residence.

b. Effectiveness/Costs

Modern conventionally designed septic systems are composed of a building sewer, a septic tank, a distribution box, and a drainfield or leachfield. Most solids entering the septic tank settle to the bottom and are partially decomposed by anaerobic bacteria. Some treatment of the wastewater occurs in the septic tank, which is primarily designed to remove 30-40% of the biochemical oxygen demand (BOD) and most solids to prevent their entering the drainfield. Periodic septic tank pumping is essential to preserve the capacity of the tank and prevent clogging of the drainfield and premature system failure. Periodic inspections should be required. The liquid effluent from the tank is discharged to a distribution box, which separates effluent flow into approximately equal flow, for discharge to a drainfield perforated pipe network, usually crushed stone surrounded by native soil. Once in the drainfield, effluent leaving the perforated pipe network percolates through the crushed stone and moves downward into the underlying soil material where treatment takes place. Nutrients and pathogens may be mechanically filtered out, microbially decomposed, or chemically attached to soil particles. The rate and efficiency of this treatment depends upon the characteristics of the soil, depth to water table, and the nature of the wastestream.

There are a number of alternative designs which apply to areas of high water tables, sandy soils, and other site specific factors. Some of these are discussed below and in the EPA Onsite Wastewater Treatment and Disposal Systems Design Manual, 1980 - which is being updated. Costs of a Septic System usually range from $4,000 to $10,000.

5020

5. Onsite Sewage Disposal Systems for the Removal of Nitrogen

a. Management measure for OSDS in existing development

Install Denitrifying Treatment Systems where appropriate to reduce nitrogen from existing onsite sewage disposal systems.

b. Practices available to achieve this management measure

A number of treatment systems, two of which are identified below, are known to remove nitrogen using denitrification, which is carried out under anoxic conditions by microorganisms which convert nitrate to nitrogen gasses. Most are in early stages of development and require nitrification of septic tank effluents as an intitial part of the treatment process, because between

65%-75% of the total nitrogen in septic tank effluents is in ammonia form. Operation and maintenance of denitrification systems are complex. EPA solicits cost and effectiveness information on these and other systems to remove nitrogen onsite from sewage.

(1) Intermittent Sand Filters - The intermittent sand filter consists of a pretreatment unit such as a septic tank, a dosing unit, and a sand filter with underdrains. A sand filter is an open bed of 2 to 3 feet of sand underlain by graded gravel with collector drains. Dose recycling between sand filter and septic tank can reportedly remove 50 to 70 percent of the total nitrogen. These systems can also treat BOD and suspended solids to less than 10 mg/l and pathogens to 100 to 900 colonies/100 ml. To meet the management measure for BOD, suspended solids, and pathogens a leaching field, either existing or new, must be included. Costs from $5,000 - $10,000.

(2) Upflow Anaerobic Filter (UAF) and Sand Filter - The UAF and sand filter are an emerging technology which could provide nitrogen removal from existing onsite disposal systems. The UAF is a tank resembling a septic tank filled with 3/8 inch gravel with a deep inlet tee and a shallow outlet tee. Dosed recycling between the sand filter and UAF has been shown in research to result in 60-75 percent overall nitrogen removal. This technology would have to be used between existing septic tanks and leaching fields to provide equivalent removal of other pollutants. Costs from $3,000 - $8,000.

c. Management measures for OSDS in new development

Use either a wastewater separation or siting approach to minimize nitrogen discharges from OSDS in areas of new development.

d. Practices available to implement this management measure

(1) Wastewater Separation with Holding Tank (Blackwater) and Conventional System (Greywater) - Wastewater separation consists of separating toilet wastes (blackwater) from other residential wastes (greywater) using watertight holding tanks, hauling the blackwater offsite, and treating of greywater in a conventional septic tank and absorption field.

Coupled with elimination of garbage disposals, the waste separation with holding tanks for blackwater and conventional treatment for greywater is expected to result in a reduction of 55 percent of the BOD, 75 percent of the suspended solids, 83 percent of the nitrogen, and 32 percent of phosphorus. The remaining pollutant loadings in greywater, except for nitrogen, will be removed by conventional treatment. The effectiveness of this measure is dependent on periodic inspections of the holding tank, routine pumping and hauling, and effective treatment of the hauled waste. The incremental cost increase in new construction will be for the

VOL 12

5021

additional plumbing, for which EPA, soliciting cost information, and a water-tight holding tank, which should cost about $1,000. The costs to haul and treat the blackwater will be about $200/yr to haul it a reasonable distance plus treatment costs.

(2) Site Density Controls to Limit Loadings of Nitrogen to Coastal Waters - The total loadings of nitrogen from combined OSDS can be controlled to the equivalent treatment level of the nitrogen management measures using low density zoning or other site restrictions to limit the number of sources in a discrete area under the control of one or more jurisdictions.

D. Other Practices That May Be Used as Tools to Achieve OSDS Management Measures

Many practices are available or being developed which could treat pollutants from OSDS to levels equivalent to those obtained using the Management Measures above. These include:

(1) Wastewater Separation and Hauling for Existing Systems - Low volume toilets would result in pumping/hauling costs of 200 dollars per year (at $50 every 3 months), but the high cost and inconvenience for replumbing residences to separate sewer lines is expected to make this option less preferable than some practices discussed above. Estimated removals due to separation and hauling of blackwater (including elimination of garbage disposals) will be the same as in 5.d.i. above. Existing conventional treatment for greywater would likely remove pathogens and the remaining BOD and suspended solids unless the system is failing.

(2) Wastewater Separation and RUCK Systems - This system may be used in lieu of hauling separated wastes. A RUCK system is designed to nitrify blackwater in a buried sand filter and then mix the nitrified blackwater with greywater in an anaerobic tank. The greywater provides the carbon source for denitrification within the anaerobic tank. Final disposal of the effluent is in a conventional soil absorption system. The RUCK system requires blackwater/greywater separation, tanks and a buried sand filter. Supposedly, effectively treats BOD, suspended solids, and as much as 50 percent of the nitrogen. The Agency is soliciting for actual application and cost-effectiveness data.

(3) Holding Tanks for All Wastewater from Existing Systems - Holding tanks are most effective as controls for all pollutants but are usually too costly an option for existing housing due to the high cost of pumping and hauling. A watertight holding tank of a 1000 gallon capacity would have to be pumped out every 5-10 days at 50 gallons/capita/day and a family of four, even with flow reduction from high efficiency fixtures. At 50 dollars per load the operating cost is 150-300 dollars per month.

VOL 12

5022

(4) Elevated Sand Mounds - A mound system is a pressure dosed, absorption system that is elevated above the natural soil surface in a sand fill. The general design configuration overcomes certain site restrictions such as slowly permeable soils, shallow permeable soils over porous bedrock, and permeable soils with water tables somewhat higher than otherwise allowable by local codes. This system consists of a septic tank, dosing chamber, and the elevated mound, and can treat septic tank waste effluent to approach Primary Drinking Water Standards for BOD, suspended solids, and pathogens. Nitrogen is not usually removed. Costs are $7,000 with a septic tank.

(5) Evapotranspiration Systems - Evapotranspiration (ET) Systems combine the process of evapotranspiration from the surface of a bed and transpiration (water used by plants) to dispose of wastewater. Wastewater is given pretreatment by some mechanism, such as a septic tank or aerobic unit. It then flows into the ET system for final treatment and disposal. An ET bed usually consists of a liner, drainfield tile, and gravel and sand layers. ET systems can be a viable means of on-site disposal where evapotranspiration rates consistently exceed rainfall. A majority of the systems in use in the United States are combinations of evapotranspiration and soil absorption systems. Properly designed, sited, and maintained, this system should provide no discharge of wastewater. Construction costs are expected to be high. Careful inspection of the linerbed and periodic checks of the ground water are required to insure integrity of the liner.

(6) Wetlands and Greenhouses - These are new, innovative approaches which are climate specific, delicate, and expensive to operate and maintain. The Agency solicits data on design, effectiveness and cost.

E. Implementation

Effective implementation of the OSDS measure generally depends on formation of specific wastewater management entities. With adjoining communities, local governments should consider adoption of joint wastewater management districts to complement inter-local facilities planning and community education for sewage and septage disposal. Public education and outreach can effectively address the ineffectiveness and dangers associated with use of septic tank cleaners/additives, and disposal of paint/thinners in OSDSs. Density zoning and similar practices also become valid alternatives to these management measures when developed jointly by districts that represent large coastal areas.

VIII. URBAN RUNOFF IN DEVELOPING AREAS

A. Applicability

This management measure is applicable to areas which currently contain significant undeveloped areas which are or will be experiencing development. This measure is in addition to other applicable management measures contained in this chapter that may apply to such areas.

B. Urban Runoff Problems in Developing Areas

The problems caused by urban runoff in developing areas are the same as those discussed generally for urban runoff elsewhere in this chapter.

C. Management Measures for Urban Runoff in Developing Areas

Undeveloped areas provide the opportunity for local communities to implement solutions that are either unavailable or costly to implement in areas that are already heavily developed. These opportunities include the ability to apply siting criteria and processes, as specified in section 6217(g)(5), to encourage development to take place in a manner that is compatible with maintaining water quality. This section contains management measures that focus on those opportunities:

(1) Maintain natural hydrology at both the watershed and site levels. In practice, this often is achieved by: 1) minimizing impervious surface area 2) protecting natural vegetation and 3) retaining natural drainageways to the maximum extent possible;

(2) Minimize disturbance of unstable areas: locate development on the most suitable areas within the watershed and within individual sites; direct development away from critical areas within the watershed such as steep slopes and highly erodible soils;

(3) Protect natural forms which contribute to beneficial water quality impacts within the watershed, i.e., wetlands, forest areas and riparian areas; where possible, contiguous buffer areas within the watershed should be retained.

D. Practices Available as Tools to Implement the Management Measures

This section discusses practices that available as tools to achieve the management measures set forth in section VIII.C. The key opportunity to protect water from urban nonpoint pollution occurs prior to development. Local communities and state and regional agencies have found that pre-development protection can best be provided through the adoption of environmentally-based decisions to govern the development process. The greatest level of coastal protection is afforded where a single development ordinance is adopted by a community, and administered by a single

5025

authority within that community. Practices available to the regional and local authorities include:

1. District Classification System

District classification systems can be used to direct heavy development away from sensitive areas and assure any development in sensitive areas is limited in a manner that protects and sustains water quality. The use of districting controls allows local authorities to address preservation of critical areas necessary for coastal water quality protection and retain flexibility in planning development.

2. Environmental Reserves

Environmental reserves include, but are not limited to, establishing a comprehensive buffer system for protection of environmentally sensitive coastal areas. The preservation of these areas can greatly reduce the detrimental impacts commonly associated with coastal NPS pollution. The following buffers and development restrictions are useful tools to help coastal communities maintain the integrity of coastal environmental resources.

(1) Stream Buffers - A stream buffer is a variable width strip of vegetated land for protection of water quality, aquatic and terrestrial habitats. Development should not be allowed within a variable width buffer strip on each side of an ephemeral and perennial stream channel. Minimum widths for buffer strips of 50 feet for low-order headwater streams and 200 feet or more for larger streams, are recommended. Stream buffers should be expanded to include floodplains, wetlands, steep slope areas, and open space to form a contiguous system.

(2) Wetland Buffers - No habitat disturbing activities should occur within tidal or non-tidal wetlands and a perimeter buffer area (a 25 - 50 foot buffer is recommended).

(3) Coastal Buffers - A coastal buffer is a variable width strip of vegetated land preserved from development activity to protect water quality, aquatic and terrestrial habitats. A 100 foot minimum buffer of natural vegetation landward from the mean high tide line is recommended to remove or reduce sediment, nutrients, and toxic substances from entering coastal waters.

(4) Expanded Buffers - Buffers should be expanded to include contiguous sensitive coastal areas which, if developed or disturbed, may impact streams, wetlands, or other aquatic environments. Expansion of buffers is a good practice whenever new land development or other disruptive activities occur.

3. Site Design

Site design can be used to identify the best site-specific practices to minimize site imperviousness, attenuate runoff from development and also improve the effectiveness of the conveyance and treatment components of a runoff control system. Two highly effective tools are clustering and fingerprinting.

(1) Cluster - Clustering concentrates development and construction activity to a limited portion of the site while leaving the remaining portion undisturbed. Concentrating developed areas allows stormwater to be more effectively treated by a system of runoff management practices.

(2) Site Fingerprinting - The total amount of disturbed area within a site can be minimized by fingerprinting development. Fingerprinting can reduce impacts to surface waters by locating development outside of environmentally sensitive areas which buffer runoff or which may be more prone to erosion (steep slopes). Further erosion and sediment control is achieved by disturbing areas only where structures, roads, and rights of way will exist after construction is complete.

E. Additional Practices Available as Tools to Control Urban Runoff

(1) Floodplain Limits - Limiting development to areas outside of the boundaries of the recommended post development 100 year floodplain will preserve streamside buffers necessary for biofiltration and generally eliminate any needed future flood protection.

(2) Steep Soils Limits - Slope restrictions help reduce erosion and sediment loading. Clearing or grading should generally not occur on slopes in excess of 25%.

(3) Watershed plans - Watershed plans identify existing or potential water quality problems within the watershed, define goals to address water quality problems, and specify measures or practices to prevent or mitigate degradation of water quality.

(4) Environmental Impact Statements (EIS) - An EIS identifies significant environmental impacts from potential development, including water quality impacts, and provides alternatives to minimize short and long term impacts of the proposed development.

(5) Offsets - Structures or actions that compensate for undesirable impacts. Offsets can be a tool to help communities minimize the construction of impervious surfaces and provide other forms of water quality protection. Methods used to meet this goal include reduced side walk widths, the use of porous or gritted pavement and the design of narrow-width roadways in low density residential development.

(6) Capital Improvement Plans (CIP) - Localities may use the development of capital facilities, roads, and sewage lines and POTWs, to guide development in coastal areas away from sensitive areas which protect coastal water quality. Localities can adopt CIPs which describe the location and timing for capital improvements, etc. By establishing development schedules, the locality finalizes those improvements it will implement within a given period (usually 5 years). This type of development may provide incentives to developers to cluster around these improvements and reduce development of critical areas.

(7) Wetland Protection - Tidal and Non-tidal wetlands are vital to the maintenance of water quality in addition to providing flood control benefits. In many cases, the establishment of a stream or coastal buffer will have already protected these important areas. (See the Biofiltration section of this guidance.)

(8) Forest Protection - Forests filter runoff and are a protective land use which provides significant water quality and wildlife habitat benefits. Where possible, tree-save areas should be large blocks and linked to the buffer system rather than small isolated stands. Studies have indicated that linked areas provide more effective sediment filtration and erosion control. (See Chapter 7 of this guidance.)

CHAPTER 5. MANAGEMENT MEASURES FOR MARINAS AND RECREATIONAL BOATING

CHAPTER 5. MANAGEMENT MEASURES FOR MARINAS AND RECREATIONAL BOATING

VOL 12

50032

CHAPTER 5

MANAGEMENT MEASURES FOR MARINAS AND RECREATIONAL BOATING

I. INTRODUCTION

Properly designed and operated marinas can reduce impacts to the marine environment, as well as benefit the boating public. Many NPS impacts of boats can more easily be prevented and contained at the centralized site a marina provides, than at individual docks and moorings. Denying opportunities for marina development does not necessarily prevent NPS impacts. Ensuring the best possible siting for marinas, as well as best available design and construction practices and ensuring appropriate marina and boating operations and maintenance procedures can greatly reduce NPS pollution from marinas.

The management measures or systems of best management practices described in this chapter are designed to reduce NPS pollution from marinas and recreational boating. Effective implementation will:

- Prevent the introduction of nonpoint source pollutants (or impacts) at the source and/or,

- Reduce the delivery of pollutants from the source to water resources.

This chapter specifies the management measures (in Sections III.B., IV.B., and V.B.) that represent the best systems of practices available to prevent NPS pollution from marinas and recreational boating or reduce NPS pollutant delivery from these sources to coastal waters. The management measures are grouped in three categories: siting (III.B.), design (IV.B.), and operation and maintenance (V.B.). For each of these three categories, following the management measures, the guidance provides information on a variety of practices that may be used as tools to accomplish the management measures. An attempt is also made to identify effectiveness of these measures, or performance goals that can be achieved by these measures. Comments are welcome on the composition, effectiveness and cost of these management measures.

It is expected that each coastal State's decision on implementation of these management measures will be based on the management strategy developed as part of its vision for the future. Pollution prevention should be at the fore of any such strategy. Hence, while flexibility is a keystone we expect that all States will need a process for State or local-level review/ management of environmental impacts from marinas and recreational boating.

A site selection process based upon a clear understanding of potential water quality impacts is the most important factor for avoidance of NPS pollution from marina development and operation. Determination of potential water quality impacts as part of the marina siting process can avoid NPS pollution impacts and degradation of the water body, also protecting designated uses.

A. Nonpoint Source Pollution Impacts from Marinas and Associated Boating Activities

Nonpoint pollution from marinas and recreational boating activities may result in detectable adverse environmental effects to nearby water column and benthic resources. These impacts can be caused by physical and chemical disturbances. A few important examples of these impacts include:

- Toxicity in the water column, both lethal and sublethal, related to decreased levels of dissolved oxygen and elevated levels of metals and petroleum hydrocarbons,
- Increased levels of metals and organic chemicals in the tissues of organisms such as algae, oysters, mussels or other filter feeders,
- Increased levels of pollutants in sediments resulting in toxicity or avoidance of the area by benthic organisms,
- Levels of pathogen indicators that result in shellfish bed or swimming area closure,
- Disruption of the bottom during dredging and positioning of pilings may destroy habitat, resuspend bottom sediment (resulting in the re-introduction of toxic substances into the water column), and increase turbidity which affects the photosynthetic activity of algae and estuarine vegetation, and
- Shoaling, and shoreline and shallow area erosion due to bulkheading, motorboat wake, or changes in circulation.

Degradation of the nearby biological community and sediment should also be considered during the process of assessing NPS pollution impacts from marina development and operation. (EPA is developing methods for assessing risks associated with toxic substances in sediments and standardized bioassays to assess chronic effects and bioaccumulation resulting from sediment contamination. Guidance for the development of biological and wildlife criteria are also being developed by EPA.) Following is a list of specific pollutants and measures of pollution, as well as affected communities that should be considered in siting a marina:

(1) Chemical
- (a) dissolved oxygen (DO)
- (b) nutrients (nitrogen and phosphorus)
- (c) pathogens (coliform as indicator)
- (d) metals (copper, lead, tin)
- (e) petroleum hydrocarbons
- (f) total suspended solids

VOL 12

5034

(g) biochemical oxygen demand (BOD)

(2) Biological
  (a) endangered species
  (b) bird rookeries
  (c) benthos
  (d) fish, shellfish and corals
  (e) submerged aquatic vegetation
  (f) wetlands

(3) Sediments
  (a) contaminated sediments (criteria under development)
  (b) turbidity

B. Sources of NPS Impacts

Some sources at marinas are point sources. These include sewage discharges, both from marinas and from boats, and stormwater discharges. In addition, an entire marina may be potentially be required to apply for and receive permits under the NPDES stormwater permit program. to the extent they are required to do so, they are not covered by the coastal nonpoint source pollution control program. However, many marinas are not currently required to apply for and receive NPDES permits. The nonpoint source pollution control program and these management measures guidelines are applicable to these marinas. Similarly, some aspects of marina dredging may be subject to the section 404 permits for the discharge of dredge and fill material. This guidance is not applicable to dredging subject to section 404 permit requirements. There are essentially three source categories of marina and boating operations that may cause nonpoint pollution:

(1) Marina Construction

(2) Marina and boat operation, repair, and maintenance

(3) Dredging and dredge disposal

The most important step in controlling the impacts of these source categories is appropriate marina siting. Marinas should be sited adjacent to deep waters, in locations where flushing is adequate to avoid shoaling and contamination problems, and where effects on important habitat are minimized.

Runoff from marina construction activities is similar to that of any type of urban development. (See discussion under appropriate chapter for management measures.) Installment of pilings can cause considerable turbidity (as well as possible contaminant resuspension), impairing

VOL 12

5035

photosynthesis and harming benthos. Dredging during construction has essentially the same effects as dredging for maintenance, as discussed below.

Day-to-day marina operation can be a source of stormwater runoff from impervious surfaces, including car parking lots and buildings and sanitary and greywater disposal on land (e.g., poorly functioning or overloaded septic systems in sandy coastal soils). Contaminants from land-side boat maintenance projects, including hull scraping, sanding, welding, painting and varnishing can be carried in stormwater runoff or by air.

Boat maintenance that occurs in the water will be a direct source of contaminants (as described above). Chemicals, such as chromated copper arsenic-, copper- and tributyltin-based antifouling paints used to protect boats and wooden docks from destruction and fouling, may leach heavy metals directly into surrounding waters. Debris lost or thrown overboard is another problem area.

Concerns related to boat operation include fueling operations, bilge water discharge, accidental fuel or oil spills, propwash within channels (causing turbidity and resuspension of possible contaminated sediments) and shoreline erosion due to motorboat wake. Disposal of sanitary wastes, both legal and illegal (both from boats fitted with marine sanitation devices (MSDs) and those without), and discharge of greywater are other sources.

Another category of NPS pollution from marinas is dredging. For the purposes of this chapter, only the dredging within the marina itself and dredging to ensure access from the marina to the channel is discussed.

Dredging disturbs bottom habitat communities temporarily, increases turbidity (possibly disrupting photosynthetic activity), and may resuspend contaminated sediments. Disposal of dredged material in shallow water or in wetlands may smother habitat, contaminate sites and increase turbidity.

Some of the most visible controversy associated with recreational boating deals with the disposal of sanitary wastes. As a source of fresh pathogen pollution, untreated sewage discharges from boats have a greater potential for the presence and survival of disease-causing organisms than do discharges from treated municipal sewage sources. However, boats are considered point sources under the CWA, and sewage discharges from boats are regulated under section 312 of the CWA.

C. Federal Programs that Apply to Marinas and Recreational Boating

The siting and permitting process which marinas are subject to varies from State to State. State and Federal agencies both play a role in this process. Boats are not required to be equipped with a MSD. However, if a boat does have a MSD, the MSD has to meet certain standards. Section 312 of the CWA required EPA to develop standards for MSD discharges to prevent the discharge of untreated or inadequately treated sewage into or upon the navigable waters of the

U.S. from new and existing vessels. To meet those standards, the CWA required the Coast Guard to promulgate regulations governing design, construction, installation, and use of MSDs. Management measures to address regulated MSDs will not be a part of this chapter, since they are already regulated under the CWA. However, sanitary wastes will be included in regard to siting and design of marinas. In addition to EPA standards for MSDs, EPA may allow a State to prohibit all discharges (treated or untreated) from marine toilets, thus declaring the area a "No Discharge Zone." Any State may petition the EPA Administrator for a "No Discharge Zone" to be designated in some or all of the waters of the state. However, EPA must ensure these waters meet certain tests before considering granting the petition.

Under Section 10 of the Rivers and Harbors Act of 1899, the Army Corps of Engineers (COE) regulates all work and structures in navigable waters of the United States. Under Section 404 of the CWA, COE permits are issued or denied to regulate discharges of dredged or fill materials in navigable waters of the United States including wetlands. Guidelines which the COE applies in evaluating disposal sites for dredged or fill material are developed by EPA. The expressed goal of the 404 program is to protect water quality, aquatic resources and wetlands.

The Food and Drug Administration has established fecal coliform standards for certified shellfish growing waters. Shellfish cannot be harvested in waters with fecal coliform counts of 14/100 ml or higher. Each coastal State regulates its own shellfish sanitation program under the voluntary National Shellfish Sanitation Program. States must participate if they wish to export shellfish across State lines. Various approaches are used to comply.

D. State Programs

Some States issue separate dredge and fill, marshlands or wetlands permits for marina developments, while other States review Federal permit applications and do not issue State permits. All States with Federally approved coastal programs have the authority to object to Section 10/Section 404 permits if the proposed action is inconsistent with the State's Coastal Zone Management Program. Some States require permits for the use of State water bottomlands. All States have authority under the Clean Water Act to issue Section 401 water quality certifications for Federally permitted actions as part of their water quality standards program.

Some States also have a State coastal zone management permit providing them authority over development activities in areas located within their defined coastal zone. Alternatively, or in addition to this permitting authority, some States have regulatory planning authority in given areas of the coast, allowing them to affect the siting of marinas, if not their actual design and construction.

E. Management Measures

Control of NPS pollution from marinas and recreational boating requires the combination and coordination of many management measures: siting and design considerations, implementation

VOL 12

5037

of operation and maintenance plans, and public education. Management measures for marinas and recreational boating are organized under the following activities:

- Siting,
- Design, and
- Operation and maintenance.

As with all other management measures in this guidance, there may be more than one way to achieve the same or better pollutant reduction than achieved with the specified management measure. Approaches that equal or exceed the performance of the specified management measures, without resulting in harmful side effects, are for purposes of this guidance considered as alternative management measures.

F. Applicability of Management Measures

These management measures are applicable to:

- Any commercial facility which contains five or more slips, or any facility where a boat for hire is docked, or a boat maintenance/repair yard that is on or adjacent to the water.
- Any residential or planned community marina with ten or more slips.
- Public or commercial boat ramps.
- Any mooring field where 10 or more boats are anchored on a regular basis.
- Any Federal, State, or local facility that involves docking of five or more boats or involves boat maintenance/repair that is on or adjacent to the water.

States may wish to apply these measures to other situations as well.

II. MANAGEMENT MEASURES FOR MARINA SITING

A. Environmental Concerns

The marina siting Management Measures, listed in Section B below, are designed to address the following water quality concerns.

Maintaining water quality within a marina basin depends primarily on how readily the marina renews its waters, a process aptly known as "flushing." If a marina is not properly flushed, pollutants will concentrate to unacceptable levels resulting in impacts to biological resources.

VOL 12

5038

Methods approved for analyzing the flushing potential of a marina are discussed under the Water Quality Assessment section of this chapter.

As discussed in more detail in another chapter of this guidance, wetlands perform many vital functions, such as serving as highly productive nursery areas for aquatic and terrestrial organisms, providing nutrients, reducing flood damages, and maintaining water quality by trapping sediment and filtering pollutants. There is a significant possibility that NPS pollution from marinas could result in loss of are values.

Marinas are commonly located in biologically productive areas that are sensitive to disturbances. The popularity of shellfish make them significant commercial and recreational resources. Submerged aquatic vegetation (SAV) are important because of the shelter which they provide to aquatic organisms, the food source which they provide to waterfowl, and their natural filtering capability to remove suspended solids and disperse wave energy. Benthic resources should be protected because they are important in the food chain, they are also valuable as commercial and recreational food sources. Critical habitats are areas which are essential for maintaining wildlife, particularly for winter survival and breeding, and as nesting areas for migrating species. Highly productive primary nursery areas for aquatic organisms (e.g., fish or crustaceans) should also be considered critical habitats. Marina-related dredging may impact shellfish beds, SAVs, or other benthic resources and habitats directly through construction activities or indirectly through increased turbidity and sediment deposition. Resuspension of sediments by boats also may affect biological resources adversely.

B. Management Measures

This section contains the management measures to be applied in the siting of marinas:

(1) Site marinas such that tides and currents are adequate to flush the site, or renew its water regularly. Marina construction should only be allowed in areas where a water quality assessment reveals that standards will not be violated and biological resources dependent upon clean water will not be degraded.

(2) Site marinas adjacent to deep water to avoid or minimize dredging needed. The area to be dredged should be the minimum needed for the marina itself, including the docking areas, fairways, and channels, and for other maneuvering areas that are needed. In no case should the bottom of the marina be deeper than the adjacent open water. During dredging operations, turbidity should be minimized through the proper placement of silt screens or turbidity curtains.

(3) Site marinas near currently permitted public areas for disposal of dredged materials.

(4) Site marinas away from wetlands, shellfish resources, submerged aquatic vegetation, and critical habitat areas.

VOL 12

5039

(5) Locate piers such that shading of submerged aquatic vegetation is minimized.

(6) Site marinas such that they have easy access to roads, utilities, public sewers (where available), and water lines, to avoid NPS impacts associated with developing these services.

(7) Site marinas away from surface or ground water that is used for water supply.

C. Marina Siting Practices

This section provides technical guidance on practices that may be used as tools to assist in the implementation of the management measures set forth in Section III.B. above.

1. Water Quality

To aid in the determination as to whether a site is appropriate for marina construction, a water quality assessment of the proposed project is recommended. Also, the cumulative impacts of proposed new and existing development projects should be considered. For instance, if a group of small marinas were proposed in one area, whether by design or by chance, the impact of the marinas taken together should be examined. Therefore, even if any one of the projects would cause negligible impacts on water quality, one or more projects may be precluded based on the cumulative impacts. Alternately, each marina developer may be required to modify their project so that the cumulative impacts of all the projects can be made acceptable. In any event, based on the ecological sensitivity of the proposed site, a water quality monitoring plan may be required for the periods of time prior to, during, and after construction.

A water quality assessment should include appropriate modeling, monitoring, and data analysis to determine the proposed marina's impact on:

(1) Fecal coliform concentrations (to indicate potential impacts due to microbial pathogens),

(2) Dissolved oxygen concentrations, and

(3) Other parameters, if there is a concern that the water quality standards for those parameters may be violated.

Examples of other types of parameters which could be of concern include:

- Various polycyclic aromatic hydrocarbons (derived from petroleum products) - Other toxic organics (i.e. PCB's, benzene, various solvents, etc.)

- Heavy metals such as chromium, copper, cadmium, mercury, lead, nickel, and zinc, and

- Nutrients (i.e. nitrogen and phosphorus).

The discussion below provides guidance in assuring adequate flushing, compliance with water quality standards, and protection of shellfish harvest areas. The water quality assessment may be divided into a two tiers, as follows:

Tier 1 - If screening methods are determined to be appropriate for the system being investigated, the initial screening methods described in this guidance can be used. Screening methods are acceptable provided that they are appropriate for the system and they do not predict water quality problems.

Tier 2 - If screening-level analysis predicts water quality problems, then additional, more detailed, investigations of water quality impacts should be performed.

A valid water quality assessment should include, at a minimum, appropriate modeling, monitoring, and data analysis to determine:

- The flushing characteristics of the proposed marina.
- The spatial extent of the shellfish harvest closure zone resulting from presumed or actual pathogen contamination.
- If the 24-hour average dissolved oxygen concentration and the one-hour (or instantaneous) minimum dissolved oxygen concentration both inside the marina and in adjacent ambient waters would violate state water quality standards. (The national recommended water quality criteria are dependent upon water temperature.)

For each of the items described above, the analyses should be conducted based on the following conditions:

(1) Average ambient water temperature and salinity for the critical season of marina operation. The critical season is defined as the season which has the highest potential for adverse water quality impacts.

(2) For tidally influenced sites, the average tidal conditions (high and low tide elevations, tide range, and current velocities) for the critical season of marina operation.

(3) Sediment Oxygen Demand (SOD) rates of at least 2.0 gm/sq m/d at 20 degrees C. SOD varies from area to area. The default value should be used unless it can be demonstrated that another value is more appropriate. This base rate should be adjusted to the temperature of the analysis based on the following formula:

$$SOD_T = SOD_{20}\,(1.065)^{(T-20)}$$

Where,

SOD_{20} = SOD at 20° Celsius
SOD_T = SOD at temperature of analysis
T = Temperature in degrees Celsius

(4) Seasonal average background BOD_5 and BOD_{20} concentrations of the adjacent ambient waters.

(5) Seasonal 24-hour average background dissolved oxygen concentrations of the adjacent ambient water.

(6) A typical instantaneous minimum and maximum dissolved oxygen concentration determined by continuous dissolved oxygen, temperature, and possibly salinity monitoring of the adjacent waters at the site. The monitoring should be conducted during the season of interest. Temperatures should approximate the average critical season temperature identified in 1) above.

(7) Additional or alternative conditions may be required or approved if there is documented evidence that the additions or alternatives are appropriate.

a. <u>Flushing of marina sites</u>

The method chosen to estimate expected flushing from a marina site depends upon the hydrographic characteristics of the location. Marinas anticipated to be located within a confined area with one or two relatively narrow openings would have flushing characteristics considerably different from marinas located directly on larger bays or estuaries or along river shorelines. Two openings may improve flushing in semi-enclosed marina basins.

Flushing time within a semi-enclosed area can be estimated using simplified dilution calculations. The parameters required for the estimation are:

- Average marina depth at low and high tide following completion of dredging, based upon the representative tidal range of the area,
- Volume of non-tidal freshwater inflow into the marina,
- Surface area of the marina, and
- The percentage of discharged water returning to the basin on the following tidal cycle.

The flushing time of a semi-enclosed marina can be approximated by the following equation:

$$T_f = \frac{T_c \mathrm{Log} D}{\mathrm{Log} \dfrac{AL + BAR - IT_c}{AH}}$$

where:

T_f = Time of flushing (hours)
T_c = Tidal cycle, high tide to high tide (hours)
A = Surface area of marina (m^2)
D = Desired dilution factor
R = Range of tide (m)
b = Return flow factor (dimensionless)
I = Non-tidal freshwater inflow (m^3/hour)
L = Average depth at low tide (m)
H = Average depth at high tide (m)

The parameter "b" represents the percentage of the tidal prism ("AR" in Equation 1) that was previously flushed from the marina on the outgoing tide; has returned on the subsequent incoming tide; and is expressed as a decimal fraction. For example, if a river had a relatively low flow rate, water discharged from a marina at the completion of one tidal cycle may still exist in proximity to the marina inlet and portions may flow back into the marina on the incoming tide. This water mass portion would not be considered as aiding flushing for water quality considerations.

Non-tidal freshwater inflow from runoff or stream discharge into the marina basin can be estimated using hydrologic techniques. If "IT_c" is much less than "AL + BAR," this component of the equation can be ignored. Estimating the flushing time of a marina may be dependent upon several factors. Additional information on estimating flushing time can be found in the Coastal Marinas Assessment Handbook (EPA, 1985) or Draft Final Report on Marina Water Quality Models (Morton, M. and Moustafa, Z., 1991). Many characteristics of the marina site, including location relative to other water bodies, ambient water quality, biological activity, total volume and expected marina activity, and type and volume of discharge, would all affect flushing time. For most cases a two to four day flushing time is satisfactory while longer flushing times could result in unacceptable buildup of toxic pollutants or decrease in dissolved oxygen.

b. Shellfish harvest closure zones

Federal regulations administered by the Food and Drug Administration require that States establish closure zones around marinas to protect the food supply from contaminated shellfish. Good water quality is an absolute necessity in order to provide this protection. This is because shellfish are filter feeding organisms and are therefore able to concentrate pollutants. Even if overlying waters contain low levels of pollutants, shellfish can assimilate and magnify both biological and chemical contaminants.

Construction of a marina or docking facility may result in short term localized water quality problems due to alteration of existing upland vegetation and changes in the area's watershed. However, the long term effects of marina maintenance and operations cause the greatest concern. Marina operation may contribute pathogenic organisms as well as petroleum hydrocarbons and heavy metals. The concentration of human activity in the area of a marina also poses a particular water quality concern because of the potential problem of sewage disposal.

Fecal coliform bacteria are used as an indicator of the pathogenic organisms (viruses, bacteria, and parasites) that may be present in sewage. Therefore, all water quality assessments for water-based marina designs should identify and document potential fecal coliform loadings and the shellfish closure zones that would result from those estimated loadings (see Figure 5-1).

The shellfish harvest closure zone for the proposed project should be determined based upon a water quality standard for fecal coliform of 14 organisms MPN (most probable number) per 100 milliliters of water. Once the closure zone has been determined, it should be determined if the shellfish closure zone would result in any impact to existing shellfish harvest areas. If the closure zone intersects productive shellfish areas that are approved for shellfish harvesting, development of the marina should not be allowed as planned.

c. Dissolved oxygen concentrations

All water quality assessments should address the potential for violations of water quality standards for dissolved oxygen concentrations. In most States' waters, a standard exists for the 24-hour average concentration and an instantaneous minimum concentration. The assessment must present reasonable estimates of these concentrations for the planned marina and adjacent waters. The estimates should be based on monitoring or modeling, depending on the nature of the marina.

The water quality assessment should be based on marina location and configuration. The first and most basic distinction made is that of open versus semi-enclosed marinas (marinas located within an embayment which effectively partitions the marina from the open ambient waters). Within the semi-enclosed marina category, further distinctions are made for existing versus proposed embayments, and whether the waters at the site are completely mixed or vertically stratified due to temperature and salinity gradients.

i. Tier 1 assessments: open marinas

Marinas are considered to be open if they are located along an existing shoreline and have no man-made or natural barriers which tend to restrict the exchange of water between ambient water and water within the marina area. These marinas generally consist of a number of piers or docks which extend from the shoreline (Figure 5-2). The water quality assessment for dissolved

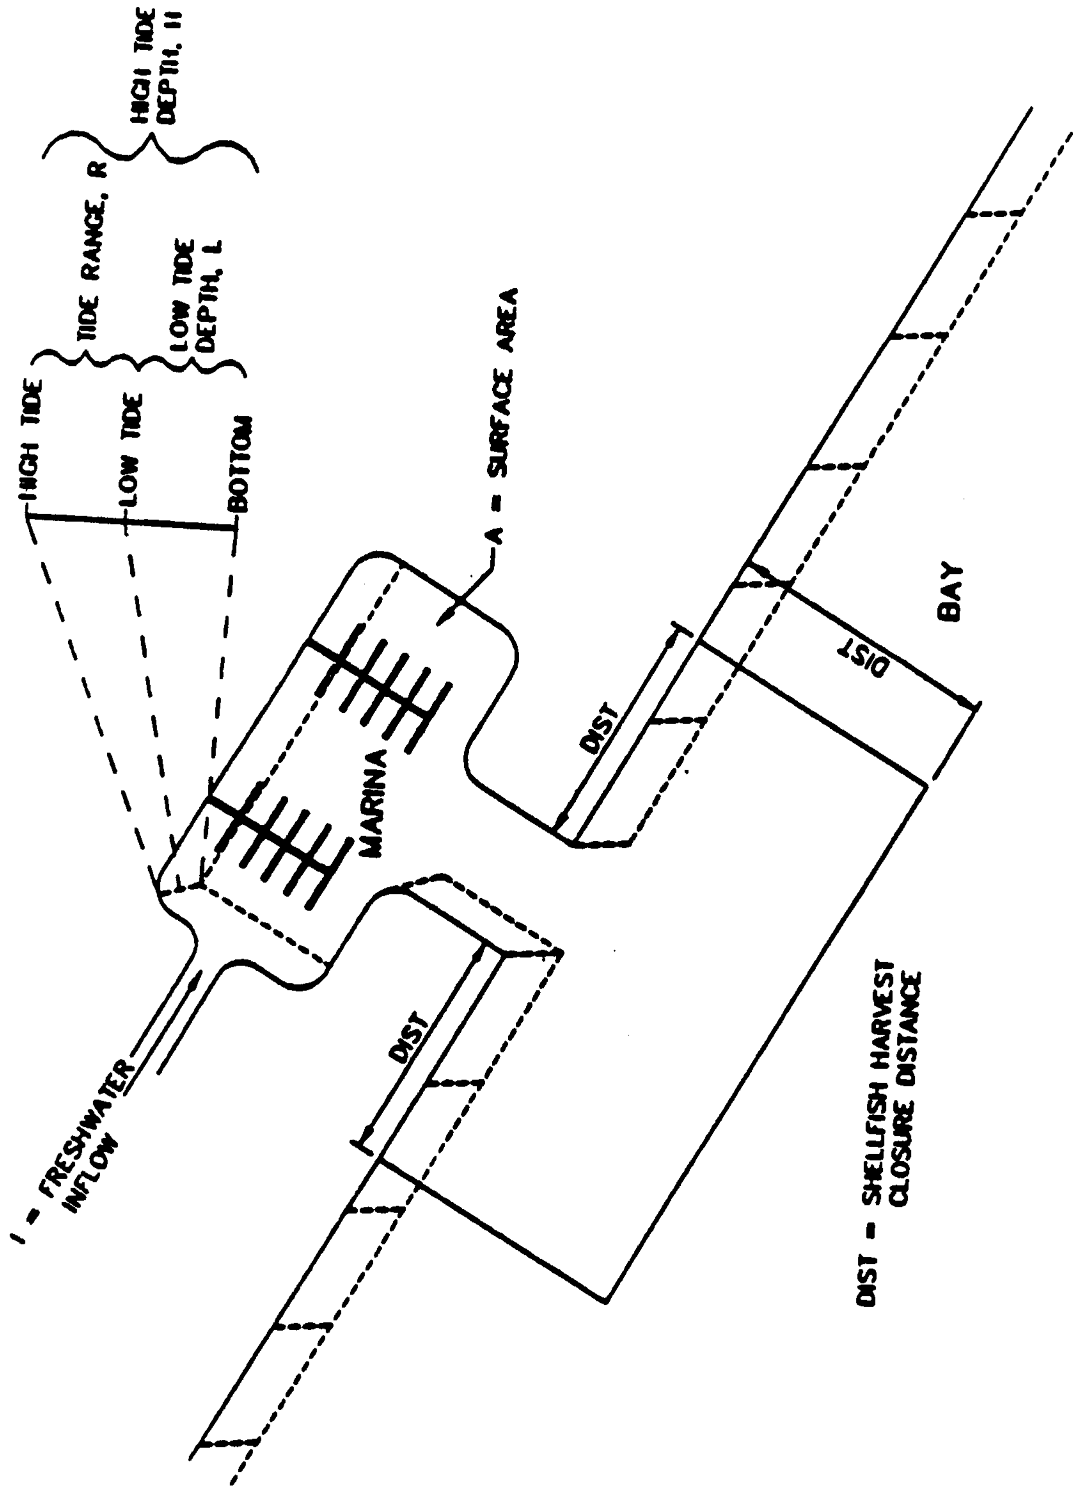

FIGURE 5-1 – REPRESENTATIVE UPLAND BASIN MARINA WITH ASSOCIATED SHELLFISH HARVEST CLOSURE ZONE

VOL 12

5045

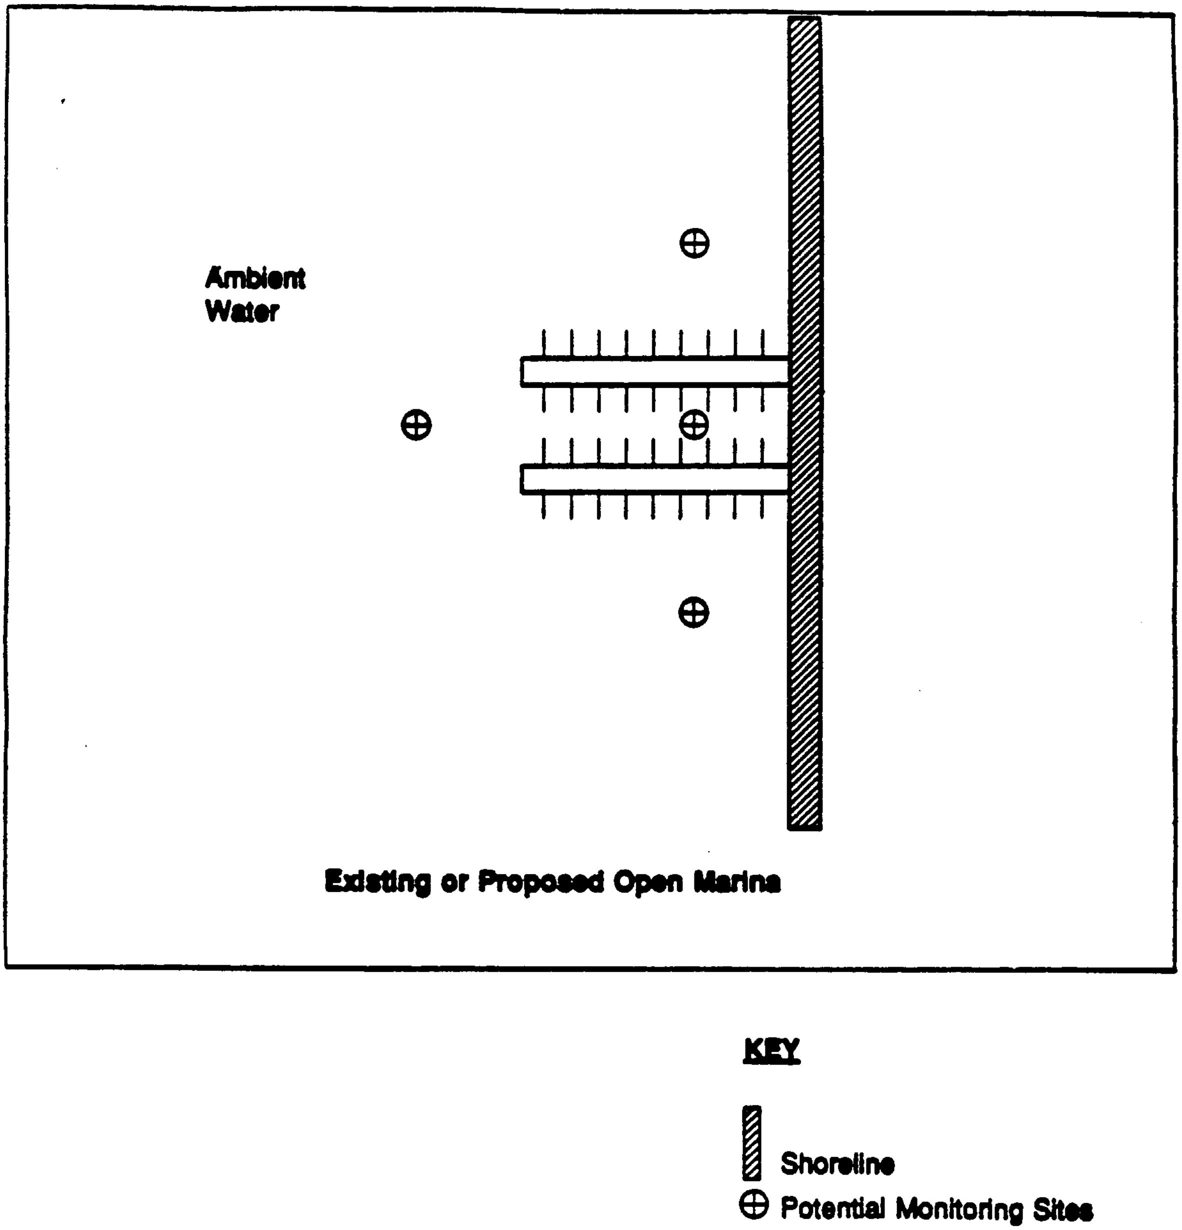

Figure 5-2. Illustration of Open Marinas and Potential Monitoring Sites

oxygen should rely on actual monitoring of dissolved oxygen concentrations within the proposed marina area. The monitoring should be representative of conditions which will be most critical in terms of meeting dissolved oxygen standards. These conditions generally occur during periods of high water temperature and low freshwater flow. In tidal areas, the monitoring should occur during average or neap tide conditions since mixing will be restricted during these periods. Occurrences of algal blooms or other conditions may influence when the critical condition occurs for a particular site.

A minimum of two days of dissolved oxygen monitoring should be collected. The monitoring should be conducted at no less than two-hour intervals and should include dissolved oxygen concentration, temperature, and salinity (if in estuarine or marine waters). The site or sites selected should be representative of the range of conditions found within the marina area. If the water column is stratified at the site, samples should be collected near the bottom, middle and surface of the water column. From the data collected, the twenty-four hour average, maximum, and minimum dissolved oxygen concentrations should be reported and compared to water quality standards to assess the potential for violations.

ii. Tier 1 assessments: **semi-enclosed marinas**

Marinas are considered to be semi-enclosed if they are located in a natural or man-made embayment which limits the mixing of waters in the marina area with ambient waters (Figure 5-3). The water quality within the embayments may differ significantly from the water quality of adjacent ambient waters. In cases like these, a combination of monitoring and modeling may be needed to estimate dissolved oxygen concentrations. If the embayment for the marina exists, the analysis may rely primarily on monitoring similar to that discussed for open marinas. If the embayment does not exist, a combination of monitoring and modeling may be necessary.

iii. Tier 1 assessments: existing embayments

For semi-enclosed marinas in which the embayment currently exists and no changes are proposed that would change the hydrodynamics of the embayment, the analysis may be limited to diel monitoring of dissolved oxygen concentrations during the critical period. The monitoring guidance provided for the open marinas applies. Modeling may be required if additional loadings of oxygen demanding substances are likely to be introduced during the operation or construction of the marina. The models discussed below in the Proposed Embayments section would be applicable.

iv. Tier 1 assessments: proposed embayments

For semi-enclosed marinas which have not yet been excavated, or for which changes have been proposed that would affect the hydrodynamics of the embayment, the water quality assessment should rely on monitoring and the application of appropriate models to predict dissolved oxygen concentrations. The dissolved oxygen screening procedures will serve as an initial assessment to determine if dissolved oxygen water quality standards are likely to be violated. If problems

VOL 12

5047

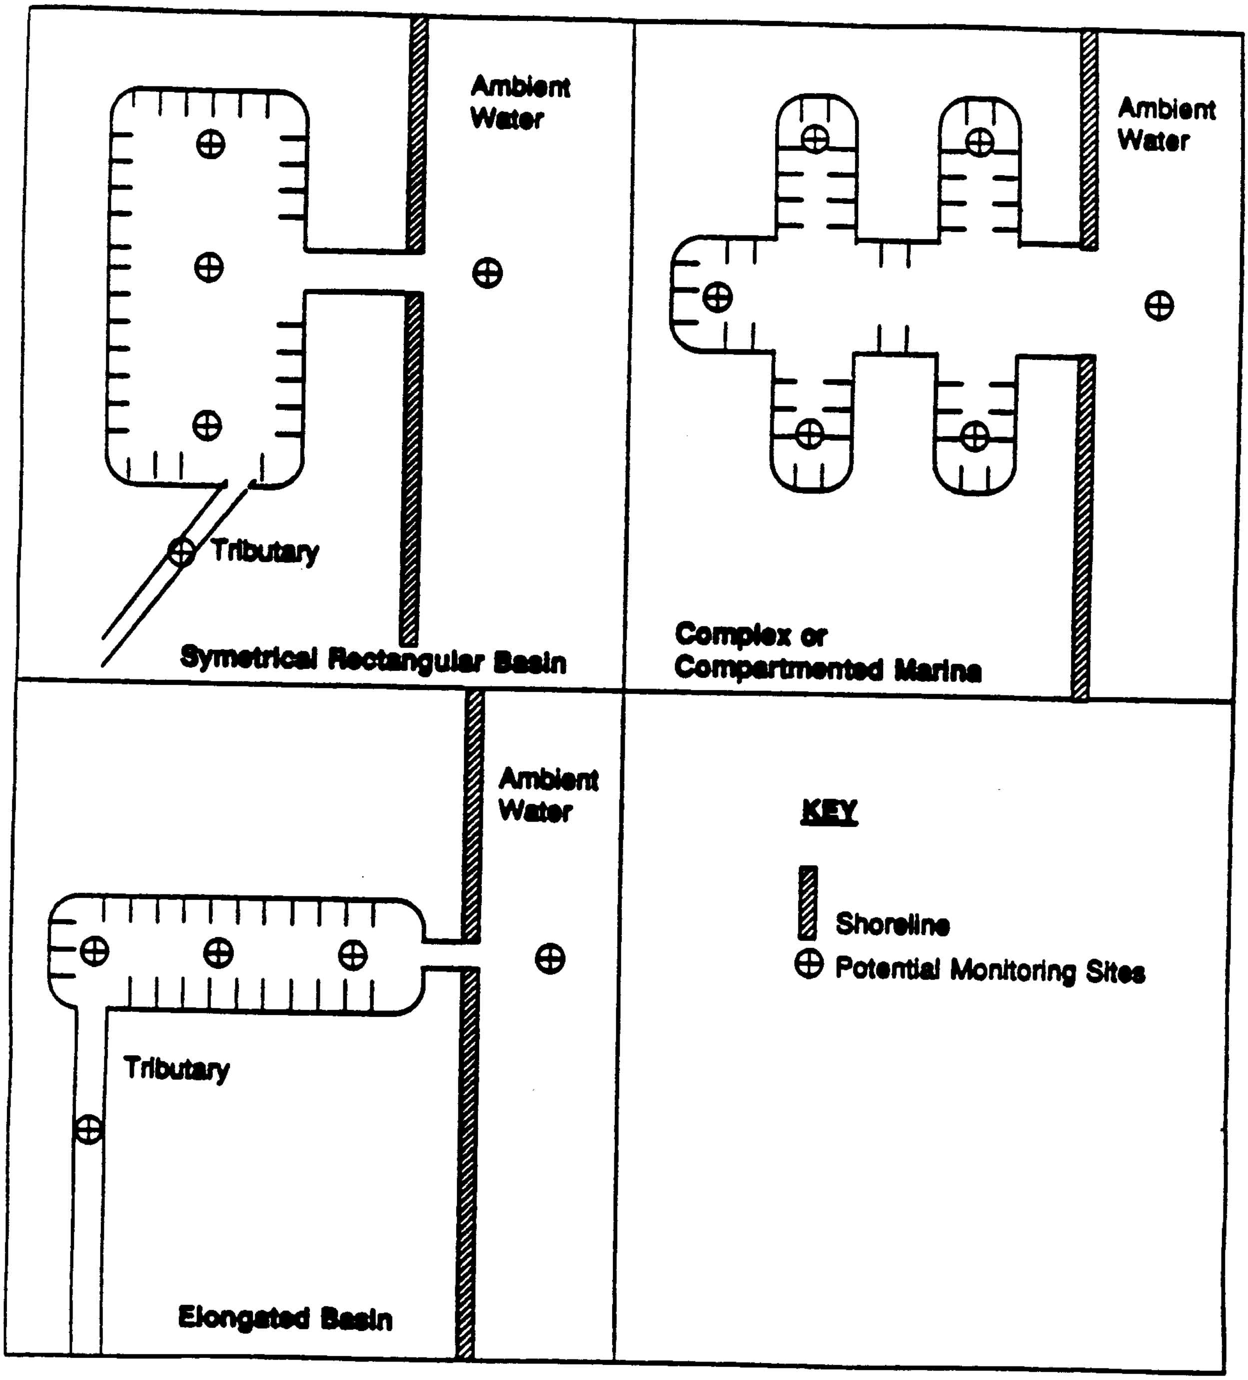

Figure 5-3 -Illustration of Enclosed Marinas and Potential Monitoring Sites

VOL 12

5048

are indicated at the screening level, more detailed procedures may be applied to examine dissolved oxygen concentrations (see Figure 5-4).

The presence of salinity, dissolved oxygen or temperature gradients that result in stratification (as discussed in the open marina monitoring section) will require detailed procedures. The screening procedures for dissolved oxygen concentrations for proposed marinas located in semi-enclosed embayments should be based on a combination of dissolved oxygen monitoring coupled with the application of a steady state, tidally averaged water quality model and a flushing model. The monitoring guidance provided in the Open Marina section, above, should serve as the basis for the screening procedure. In addition, the average tide range and high and low water depths of the adjacent ambient waters, as well as the proposed marina, should be required to implement the screening models. Flow rates (seven day, ten year low), BOD, and dissolved oxygen concentrations of tributaries that will enter the proposed basin should also be provided or monitored. Additional monitoring may be necessary in areas where there is significant algal productivity, or in cases where detailed models are applied. Typical sampling sites for enclosed marinas are illustrated in Figure 5-3.

The screening level assessment of the minimum dissolved oxygen concentration should be based on the average dissolved oxygen concentration for the proposed basin as calculated above, and on the deviation between the average and minimum dissolved oxygen concentration measured in the ambient waters.

v. Tier 2 assessments: detailed procedures

Detailed procedures for dissolved oxygen analyses are recommended for proposed marinas that are not expected to be completely mixed due to stratification within the water column or due to the configuration of the marina basin. For example, proposed marina basins that are significantly elongated or segmented will prevent thorough mixing and will require detailed modeling. Detailed procedures may also be necessary to evaluate potential problems indicated by the screening level analysis. The detailed procedures used will be dependent on the specific site and model being considered.

As with the screening-level analysis, the detailed analysis should include a combination of monitoring and modeling. The model selected for the detailed analysis should have demonstrated applications in predicting average and minimum dissolved oxygen concentrations for systems that are similar to the marina basin configuration being proposed. The most available and accepted model with these abilities is the WASP model, which was developed and is supported by EPA. In most situations it will be the model of choice. The monitoring required to support a detailed model will vary with the model and the specific site. Sufficient data should be collected to calibrate the hydrodynamic and water quality components of each model for the specific site.

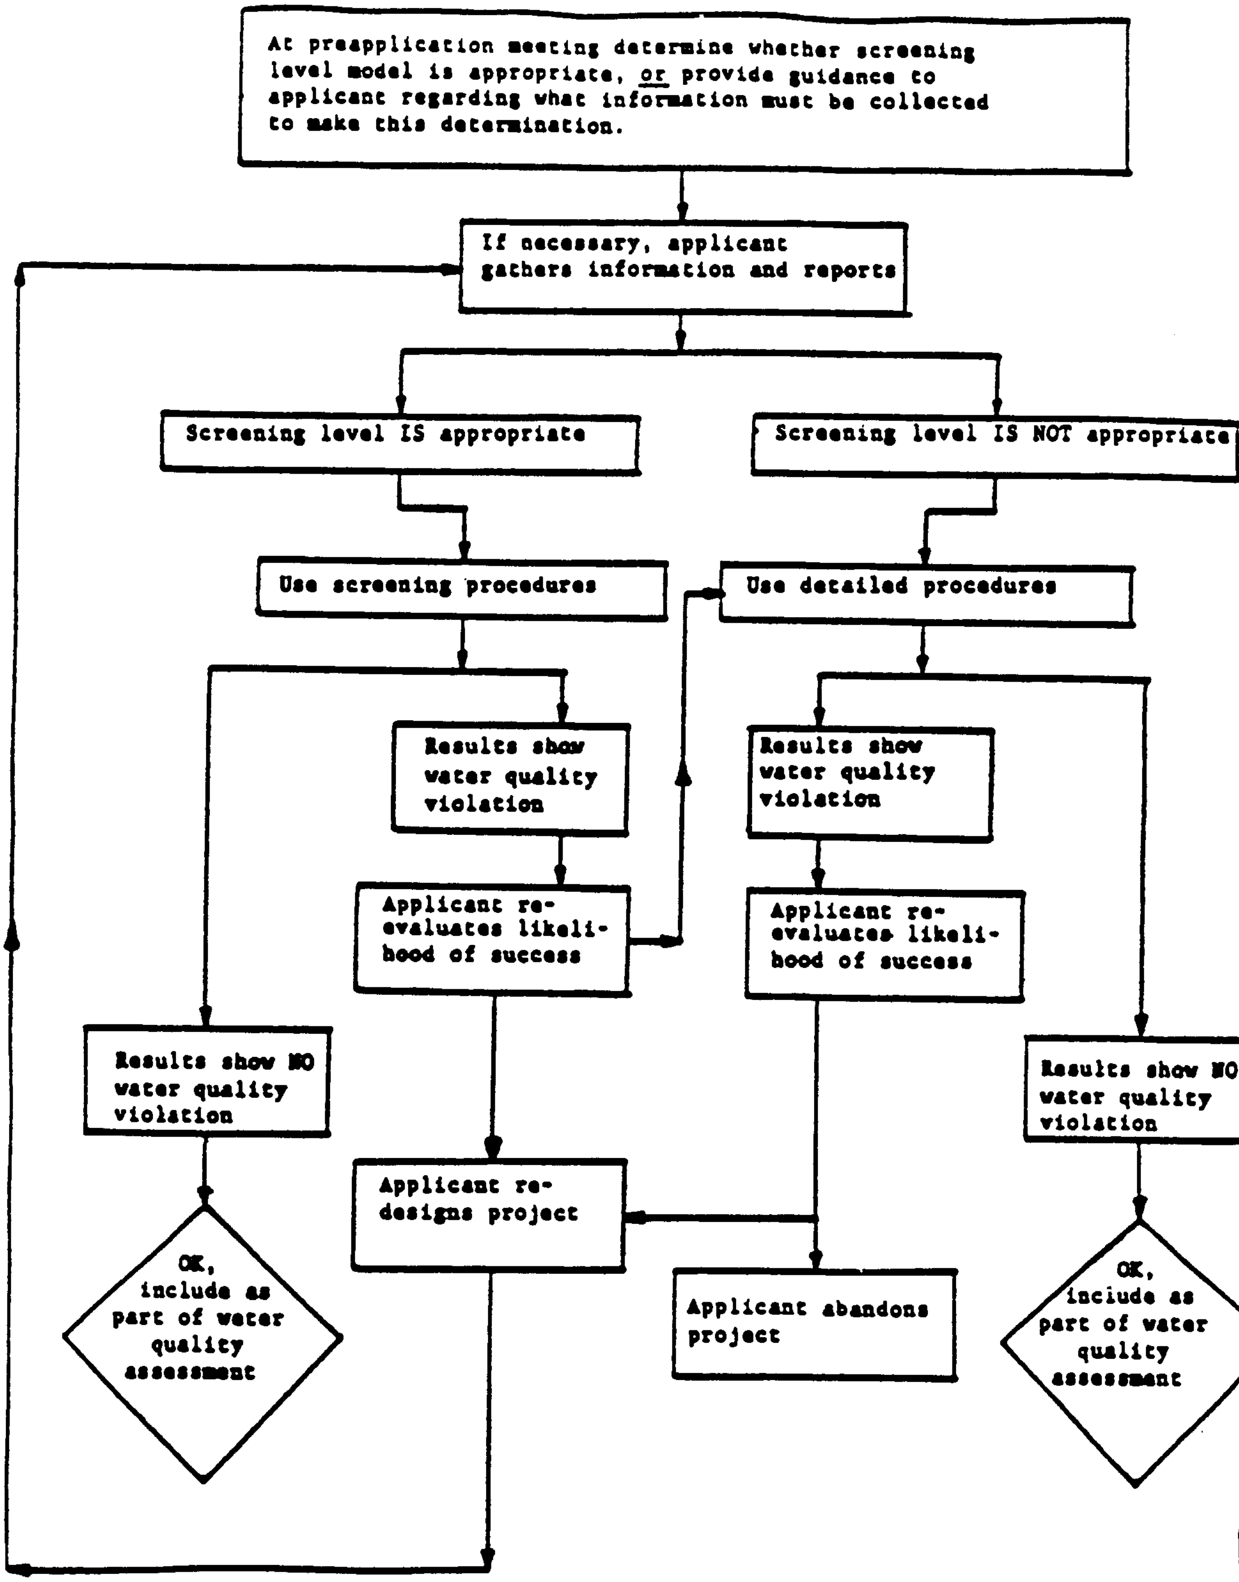

Figure 5-4. Flow Chart for Water Quality Assessments Requiring Modeling Analysis

d. Other parameters

Other parameters need only be investigated if there is a concern about the potential for violation of water quality standards.

2. Wetlands

The despoliation and destruction of public and private wetlands during marina construction and operation should be avoided. Further discussion on wetlands can be found in another chapter of this guidance.

3. Submerged Aquatic Vegetation

The net loss of submerged aquatic vegetation (SAV) should not be allowed. In no case should highly productive SAV be adversely impacted. If a marina is sited in the proximity of SAV, any related disturbance of these SAV areas should require compensation measures. Before such measures are approved it should be determined that substantial, prudent, and reasonable measures have been taken to avoid the impacts. Since this kind of vegetation cannot survive when heavily shaded, shading of SAV by piers crossing over them should be avoided.

4. Benthic Resources

The benthic community at the marina site should be evaluated using rapid bioassessment techniques (EPA, 1989; Luckenbach, Diaz and Schaffner, 1989). Benthic areas that are found to have degraded benthic communities should be considered for marina siting over those areas that are found to be healthy and productive. It is recommended that each state should develop rapid bioassessment techniques and criteria appropriate to their bioregions.

5. Critical Habitats

Marinas should not be sited in proximity to such areas if the project would adversely affect natural populations. A buffer zone should be established around critical habitats located near the project. The size of this zone should be decided on a case-and species-basis. No general or specific guidance regarding the extent of these buffer zones can be given because of the wide variation in requirements between species.

6. Dredging and Dredged Material Disposal

Ideally, marinas should be located where dredging will not be necessary to allow safe navigation. In many locations, unfortunately, this is not possible. Therefore, marinas should be sited at locations that require the least amount of dredging for the draft of the boats that will use that marina. In some cases, the draft may have to be limited to avoid or to minimize the amount of dredging. The area to be dredged should be the minimum needed for the marina itself, including the docking areas, fairways, and canals, and for other maneuvering areas that are needed. In

VOL 12

5051

no case should the bottom of the marina be deeper than the adjacent open water. Marinas should not be built in sites that will require maintenance dredging more frequently than once every four years.

Previous sections of this guidebook have described natural resources which may be impacted by the construction and operation of a marina. Dredging to construct or maintain a marina can result in losses of these resources and/or adverse impacts to nearby resources because of the turbidity associated with dredging. In addition, because certain times of the year are more critical than others due to migration, spawning and early development of important species, dredging should not occur at all at such times.

During dredging operations, any project-related turbidity should be contained, thus minimizing adverse impacts to the surrounding habitat and avoiding possible violations of water quality standards. Proper placement of silt screens or turbidity curtains is a common and relatively effective method of containment. Marinas should not be built in sites that will require maintenance dredging more frequently than once every four years.

Whenever dredged material may be contaminated, disposal in an upland diked containment area is the preferred disposal method. Wherever feasible, applicants should use existing diked disposal areas. Diked disposal areas must be sized and designed to prevent resuspension or erosion of the dredged material and subsequent transport back into adjacent waters. They must also be sited to avoid ground water contamination.

Another disposal option, available only for clean, uncontaminated fill, is placement on or near shore, where it is desirable to enhance beach profiles, stabilize shorelines, and/or build or enhance wetlands.

Dredging in waters of the United States is regulated by the Army Corp of Engineers, as discussed earlier in the introduction. This guidance on dredging and dredge disposal is provided so that prospective marina owners have an indication as to what they may expect from efforts to site a marina.

7. Water Supply

Marinas should be sited and designed to preclude any contamination of surface water or groundwater that is used for water supply. Runoff from potential areas of contamination, such as maintenance areas should be treated, as described under the Stormwater Management Section of this section.

Upland basins should not be excavated in areas upgradient or within 1000 feet of public or private well fields, nor should excavation occur within water supply protection areas, or where an increased threat of saline water encroachment is likely. A danger exists that dredging may improve the hydrologic "connection" between brackish water and the fresh water aquifer, which, when coupled with a head loss from pumpage within the aquifer, may result in contamination of the aquifer. A buffer of less than 1000 feet may be used if it can be demonstrated that a lesser distance will result in no adverse impact on groundwater.

It should be demonstrated that there is an adequate water supply to serve all of their project needs. As a rule of thumb, 30 gallons/slip/day will be needed during peak usage periods.

D. Pollutant Reductions and Costs

Proper siting of marinas can completely avoid some of the NPS pollution impacts associated this type of development. Direct impacts to shellfish areas, wetlands, SAVs, and other benthic resources and habitats can be averted. Water quality problems can be greatly reduced or eliminated entirely through proper siting. The costs of identifying a good site for a marina and preparing a water quality assessment will be dependent upon regional and local conditions. Past efforts have varied from $2,000 to $16,000.

III. MANAGEMENT MEASURES FOR THE DESIGN OF MARINAS

A. Environmental Concerns

The management measures, listed in Section B below, are designed to address the following water quality concerns.

Design considerations for the minimization of NPS pollution associated with marinas should include: shoreline stabilization, location of navigation channels, stormwater, dryboat storage, boat maintenance areas, fueling areas, and control of spills. Improper shoreline design can result in erosion or degradation of habitat. Placement and design of navigation channels is a major factor in flushing and resulting water quality. Boat maintenance activities that can result in NPS pollution include:

- Painting and paint removal,
- Welding, brazing, soldering, and metal cutting,
- Woodworking,
- Engine repair and service,
- Servicing LPG and CNG systems, and
- Boat washing and hull cleaning.

Rainfall runoff from areas where these activities occur becomes polluted with oils, greases, organic and inorganic wastes, and other potentially harmful substances. Introduction of these substances into adjacent waters can have significant adverse water quality impacts.

VOL 12

5053

Marina fueling systems typically consist of storage tanks (usually underground) and pumps on shore, with fuel meters and dispensers mounted on a fuel pier or dock. Areas where boats are fueled are subject to contamination from petroleum hydrocarbons from leaks and spills.

B. Management Measures

This section contains the management measures to be applied in the design of marinas:

(1) Use natural vegetation to stabilize shorelines wherever possible.

(2) Navigation and access channels should be located in areas with safe and convenient access to waters of navigable depth, based on the kind of vessel expected to use the marina, but in no case exceeding the depth of adjoining channels and waters.

(3) The first one-half inch of runoff from the entire marina property for a 10-year 24-hour storm should be detained and released over a 24-hour period.

(4) All stormwater management systems should be provided with a bypass or overflow system so that the peak discharge from a 10-year 24-hour storm will be safely conveyed to an erosion and scour-protected storm water outfall.

(5) Dry boat storage should be utilized over wet slips wherever feasible.

(6) Boat maintenance areas should be designed so that all maintenance activities that are significant potential sources of pollution can be accomplished over dry land and under roofs (where practical), allowing for proper control of by-products, debris, residues, solvents, spills, and stormwater runoff. All drains from maintenance areas should lead to a sump, holding tank, or pumpout facility from which the wastes can later be extracted for treatment and/or disposal. Drainage of maintenance areas directly into surface or ground water or wetlands should not be allowed.

(7) Fueling stations generally should be located such that they are accessible by boat without entering or passing through the main berthing areas in order to avoid collisions.

(8) Marina operators should have a spill contingency plan and the proper equipment and training to implement the plan.

C. Marina Design Practices

This section provides technical guidance on practices that may be used as tools to assist in the implementation of the management measures set forth in Section IV.B. above.

VOL 12

5054

1. <u>Shoreline Protection and Basin Design</u>

Natural vegetation should be used wherever feasible to stabilize shorelines. However, when additional stabilization becomes necessary, sloping riprap revetments are preferred over vertical bulkheads, since they generally provide greater habitat and reduce wave reflections. Shoreline intertidal areas should be preserved to the greatest extent possible.

In instances where bulkheads are to be installed, they should be constructed in such a manner that they are effective against erosion and provide adequate bank stabilization. The potential for erosion and scour at the mudline should be evaluated. Bulkheads should be constructed to prevent losses of fine material through joints or cracks from the land side to the water side, which could ultimately lead to failure of the wall. Bulkheads should be stabilized by providing adequate anchorage (such as batter piles or tie backs) or adequate embedment, depending on the type of bulkhead. Where public walkways, steps, or ramps run adjacent to bulkheads, handrails or other safety provisions should be provided along the top of the wall where the vertical drop to the current mean low water line or mud line exceeds three feet, unless local or State building codes stipulate otherwise. Any interference with public access should be avoided.

Basins that are constructed with square corners or other stagnant water areas will tend to trap sediment and debris. If this debris is allowed to collect and settle to the bottom, an oxygen demand will be imposed on the water and water quality will suffer. Therefore, square corners should be avoided in critical down-wind or similar areas where this is most likely to be a problem. If square corners are unavoidable because of other considerations, then points of access should be provided in those corners to allow for easy clean out of accumulated debris.

Riprap revetments are considered to be flexible since they can accommodate minor consolidation and settlement of their foundations. Still, adequate provisions should be made to prevent migration and loss of fine materials through the riprap, such as placement of a filter fabric beneath the armor layer. The slope of the revetment should be sufficiently flat to maintain stability, but in no case should the slope be steeper than one vertical to 1.5 horizontal. In addition, adequate toe protection should be provided to compensate for known or anticipated scour.

Considerations for new construction are addressed in the urban section of this document. Control measures such as turbidity curtains, vegetative barriers, etc. should be used to contain erosion.

2. <u>Navigation and Access Channels</u>

Channels should be located in areas with safe and convenient access to waters of navigable depth, based on the kind of vessels expected to use the marina, but in no case exceeding the depths of adjoining channels and waters. "Safe and convenient" access should be determined on a case-by-case basis, taking into account such factors as existing water depths, distance to existing canals and their depths, and tidal and wave actions. Before considering dredging,

VOL 12

5055

should attempt to gain access to deeper water by extending docks and piers farther from shore. The maximum extent to which a pier should extend into the waterway should be determined by each state and applied in a consistent manner (10% of the width of the channel has been set in some cases). In some cases, rather than dredging (and possibly having to develop a compensation plan), it may make more sense to simply limit the maximum boat drafts in the marina or utilize dingy access to moorings. Where channels are narrow, dry stacking of boats should be considered.

Where dredging is unavoidable, natural or existing channels should be used to minimize the amount of dredging. Also, naturally existing channels are less likely than surrounding shallow areas to contain shellfish beds, submerged aquatic vegetation, or other resources which may complicate permitting and require mitigation or compensation measures.

3. Wastewater Facilities

Three types of onshore collection systems are available: marina-wide systems, portable/mobile systems, and dedicated slipside systems. Marina-wide collection systems include one or more centrally located sewage pumpout stations. These stations are generally located at the end of a pier, often on a fueling pier so that fueling and pumpout operations can be combined. Boats requiring pumpout services dock at the pump-out station, a flexible hose is connected to the wastewater fitting in the full of the boat, and pumps or a vacuum system move the wastewater to an on-shore holding tank, a public sewer system, a private treatment facility, or other approved disposal facility. In cases where the boats in the marina use only small portable (removable) toilets, a satisfactory disposal facility could be a toilet into which the portable (removable) toilets can be dumped. Portable/mobile systems are similar to marina-wide systems except that the pumpout stations are mobile. The mobile unit includes a pump and a small storage tank. The unit is connected to the deck fitting on the vessel, and wastewater is pumped from the vessel's holding tank to the pumping unit's storage tank. When the storage tank is full, its contents are discharged into one of the previously listed approved disposal facilities. Dedicated slipside systems provide continuous wastewater collection at a slip. Slipside pumpout should be provided to live-aboard vessels. The remainder of the marina can still be served by either marina-wide or mobile pumpout systems.

Note that chemicals from holding tanks may retard the normal functioning of septic systems. Neither the chemicals nor the concentration of wastes has proven to be a significant problem for properly operating public treatment plants provided there is adequate dilution between the marina and the treatment plant. In some cases, the effluent from the marina may have to be diluted before introducing it to the sewer system.

Shoreside restroom facilities for the use of marina patrons should be required at all marinas. Adequate restroom facilities for any given marina are dependent upon the nature (recreational or public, or residential or planned community) and size of the marina and its ancillary features. Restroom facilities should be conveniently located and well-maintained to encourage their use by boaters at the marina. At residential or planned community marinas public restrooms may not be required unless there are non-residents who routinely use the marina who do not have access to a private bathroom, or unless the convenient travel time from the slips to the residences is longer than five minutes.

Marina operators should post ample signs prohibiting the discharge of sanitary wastewater, dishwater, or greywater from boats into the waters of the State, including the marina basin, and also explaining the availability of pumpout services and public restroom facilities. Signs should also fully explain the procedures and rules governing the use of the pumpout facilities.

4. Stormwater Management

All stormwater management systems should be provided with a bypass or overflow system so that the peak discharge from a 10-year 24-hour storm will be safely conveyed to an erosion and scour-protected storm water outfall. All discharges shall be calculated using methods developed by the U.S. Soil Conservation Service and described in either their Technical Release 20 or 55.

For new construction:

(1) The first one-half inch of runoff from the entire marina property for a 10-year 24-hour storm should be detained and released over a 24-hour period. Runoff to should be controlled with a weir that will direct the first one-half inch of runoff to the are and bypass the rest to the receiving water body. This is known as control of the first flush and is important because this first one-half inch of runoff has high concentrations of pollutants compared with the bulk of the remaining runoff.

(2) Use of infiltration practices may also be an acceptable alternative. Paving materials which allow for increased infiltration include permeable asphalt paving, paving blocks, and, in lighter use areas, coquina, gravel, oyster shells, or similar surfaces. Such infiltration practices are acceptable only in areas with appropriate soils, slopes, and depths to ground water. A strict maintenance schedule should be prepared and adhered to by the marinas operator. Porous asphalt should be used only as a last resort and only after a regular vacuuming schedule has been approved. This is needed because porous pavements can quickly become impermeable when clogged with small quantities of fines. Once they have become impermeable, their storm runoff benefits are nullified.

(3) Other treatment practices for storm runoff may be considered on a case-by- case basis if they can achieve an equivalent removal efficiency of 80% of suspended solids in addition to removal of other pollutants as needed.

VOL 12

5058

5. Dry Boat Storage

Dry boat storage is the storage of boats on dry land (inside or outside) when they are not in use, often in multi-level vertical racks using a forklift truck or crane system. Dry storage of boats drastically reduces the in-water requirements for structures, typically requiring only a few wet staging slips for short term berthing of vessels after being taken from storage for subsequent boarding, and then upon their return before being placed back into storage. Dry storage should be utilized over wet slips wherever feasible due to the reduced potential for adverse environmental impacts from NPS pollution.

Construction of dry storage buildings must conform to all applicable requirements of municipal, county, or State housing, electrical, plumbing, fire protection, and building codes. In the absence of any such fire protection codes, fire protection procedures for dry storage areas are covered in the National Fire Protection Association (NFPA) 303, Fire Protection Standard for Marinas and Boatyards.

6. Boat Maintenance Areas

Boat scraping, sanding, washing, etc. should only be done in areas designed to handle runoff in a manner that prevents it from reaching adjacent waters and wetlands (see sections on stormwater and operations and maintenance).

7. Fuel Storage and Delivery Facilities

In the event of a spill of fuel, oil, or other toxic or hazardous substance, it is the responsibility of the marina operator to properly contain and clean up the spill in a timely and diligent manner. This is true even if the spill has been caused by some negligent or inadvertent action of a patron of the marina. Coast Guard regulations require that all spills that cause a visible sheen on the water must be reported. All spills should also be reported immediately to the proper state authority. A spill contingency plan should be posted and include:

(1) Posting of notification procedures in the event of a spill.

(2) Immediate on-site availability (less than 1/4 hour) of containment equipment such as booms, absorbent materials, or skimmers. This equipment should be conveniently stored on site. Responsible marina personnel should be trained in the proper use of this equipment. Marina personnel should be required to participate in annual drills to demonstrate their readiness in the event of a spill and to assure that containment equipment is in working order.

(3) Disposal of the collected fuel or other material contaminated by the pollutant in accordance with applicable State and Federal regulations.

8. Piers and Dock Systems

All timber used for construction above the water line should be pressure treated with a preservative such as chromated copper arsenate (CCA) or creosote to avoid damage by wood borers. Underwater, or periodically submerged portions of timber structures should not be constructed with CCA or creosote-treated timber. Treated piles that project above deck level should be protected with battens or some protective sheathing.

The use of concrete pilings should be seriously considered both in planned marinas and those undergoing expansion or repair/replacement of piers. Use of concrete pilings eliminates leaching of preservatives and decreases pier maintenance costs.

D. Pollutant Reductions and Costs

Actual numbers on pollutant reductions and costs are not currently available. The following discussion is on the relative pollution reduction of the management measures.

The proper design of marina channels and basins will result in avoidance of impacts to important habitat and protection of water quality. Properly flushed channels and basins will prevent build-up of natural and man induced substances that degrade the environment. Pollutant reductions and cost for the control of stormwater are discussed in the chapter of this guidance on urban management measures.

With dryboat storage, dredging is minimized since there is no large basin, only a small staging area. This will minimize water quality and flushing concerns, as well as flow disruptions caused by structures built to protect boats from wind and wave action. Large amounts of treated timber for docks and bulkheads are not needed, thus minimizing the leaching of wood preservatives into the water and the shading effects of docks, piers, pilings, and boats. The amount of contact time between pesticide-containing bottom paints and the water is minimized, perhaps even eliminating the need for the use of bottom paints. The use of construction material that does not contain CAA or creosote may not add to initial construction costs (unless concrete is used), but may add maintenance costs due to upkeep (unless concrete is used).

Proper design of fueling facilities and prepositioning of spill containment and cleanup equipment (100 feet of boom and absorbent material) will add approximately \$2000 to \$10,000 in cost to a marina project. Pollutant reduction is difficult to quantify because of the episodic nature of fuel spillage.

IV. MANAGEMENT MEASURES FOR OPERATIONS AND MAINTENANCE OF MARINAS AND BOATS

A. Environmental Concerns

The Management Measures, listed in Section B below, are designed to address the following water quality concerns.

The operation and maintenance of a marina and associated boating produces the same concerns as those addressed in the design of marinas as well as day-to-day activities such as disposal of fish wastes and the repair, maintenance, and operation of boats.

During the summer months, dissolved oxygen depressions, odor complaints and aesthetic problems may result from disposal of fish wastes into the water in concentrations that overload the natural ecosystem.

Small boat yards and marinas are confronted with handling a significant number of hazardous waste sources due to the variety of maintenance and repair operations that result from boat operations. Owners of marinas have a responsibility to see that no hazardous materials enter the body of water on which they are located.

Many of the wastes generated by boat yards and marinas must not be discharged into either sanitary sewers, storms or deck drains. Although there are some exceptions, most inside drains go to sanitary sewers and most outside drains go to natural waters. Wastes improperly, disposed down drains may cause water pollution, damage or impair sewage treatment plants and can be harmful to workers. Contaminants of concern include, antifreeze, oils, detergents, wash water from cleaning floors and decks and paint dust.

B. Management Measures

This section contains the management measures to be applied in the operation and maintenance of marinas and boats:

(1) Encourage the recycling of fish wastes back into the natural ecosystem in a manner that will not degrade water quality or cause other adverse environmental impacts.

(2) Tarps and vacuums should be used to collect solid wastes produced by cleaning and repair of boats. Such wastes should be prevented from entering adjacent water.

(3) Vacuum or sweep up and catch debris, sandings, and trash from boat maintenance areas on a regular basis so that runoff will not carry it into the water.

(4) An oil water separator should be used on outside drains and maintained to ensure performance.

(5) Curbs, berms or other barriers should be built or placed around areas used for the storage of liquid hazardous materials to contain spills.

(6) Tarps should be used to catch spills of paints, solvents, or other liquid materials used in the repair or maintenance of boats.

(7) Used antifreeze should be stored in a barrel labeled "Waste Antifreeze Only" and should be recycled.

(8) Valves should be used on the air vents of fuel tanks that prevent fuel from overflowing and spilling.

(9) All boats with inboard engines should have oil absorption pads in bilge areas and they be changed when they are no longer useful or at least once a year.

(10) Only phosphate-free and biodegradable detergents should be used for boat washing.

C. Marina Operation and Maintenance Practices

This section provides technical guidance on practices that may be used as tools to assist in the implementation of the Management Measures set forth in Section V.B. above.

1. Fish Wastes

A fish waste policy may need to be developed. In order to implement the policy in a consistent manner, guidelines could be established that meet the following requirements:

(1) Fish wastes should not be discharged into surface waters in any dead end lagoons, other poorly flushed locations, or other areas where such discharge could result in a water quality or public nuisance problem.

(2) Where fish waste disposal will not result in water quality or public nuisance problems, fish wastes could be recycled back into the ecosystem from which the organisms were originally harvested.

(3) Fish waste recycling within marina basins should only be allowed if in accordance with approved Operations and Maintenance Plans. Marinas should not provide fish cleaning stations unless the activity has been included in the Operations and Maintenance Plans. Marinas which are not approved for fish waste recycling

VOL 12

5061

should post signs warning fishermen that fish wastes should not be disposed of in the water at that location.

(4) Fish wastes should not be recycled into surface waters in such a way that they will wash up onto any shoreline, or cause odors or other nuisances.

2. Boat Maintenance Areas

Small boat yards and marinas are confronted with handling a significant number of hazardous waste sources due to the variety of maintenance and repair operations that result from boat operations.

a. Hydroblast containment

This practice entails the containment of hydroblast (pressure washing) wastewater to prevent paint chips and oil from being discharged into natural waters and storm drains. In most states, permission must be obtained to discharge these wastes to the local sanitary sewer. The local utilities should be consulted for pretreatment possibilities. Cleaning processes that use chemical additives such as solvents or degreasers must be done in a self-contained system that prevents discharge to storm drains or sanitary sewer. Wastewater without such additives should be directed into wetpond detention basins as described in another section of this guidance. Where feasible, wastewater from this operation can be collected and reused.

b. Abrasive blasting containment

Grit from abrasive blasting contains paint chips and other materials should be prevented from entering natural waters or storms. 'Dockside' blasting, outside a drydock or containment area should not be done. Workshops and yards must be kept clean of debris and grit from sand blasting operations so that runoff and wind will not carry any waste into the water. During blasting operations, outdoor areas should be enclosed in plastic tarps and no blasting should be done on windy days. The bottom edge of tarpaulins and plastic sheeting must be weighted so that it will remain in place during light breezes. A spray booth should be used whenever possible to capture the blast grit and should be used if sand is being used.

c. Spray booths

Spray Booths concentrate paints and as such represent a hazard to both employees and the environment. Booths must meet local building and fire code requirements and must ensure adequate ventilation for people working in them. Paint guns used in spray booths should be either High Velocity Low Pressure (HVLP) or High Efficiency Low Pressure (HELP) which are rated at 65% efficient paint transfer, or electrostatic paint spraying methods. In replacing existing spray guns, convert to HVLP or HELP types. Cleaning paint guns can also be hazardous since spent solvent must be treated as a hazardous waste and not discharged directly into drains. Cleaning should be done in an enclosed gun cleaner/recycler machine.

VOL 12

5062

d. <u>Waste storage</u>

Waste oil, fuels stored above ground and hazardous material must be protected by a berm (a built-in curb or barrier) in an area that is sufficiently large to contain a spill. Its purpose is to catch anything that spills or leaks, in case a container is tipped, overfilled or ruptured. No drains should be inside the secondary containment. If for some reason there is a drain, it should lead to a blind sump. Secondary containment should have a concrete floor and, if outdoors, be roofed. Other measures that count as secondary containment that may be used instead are;

(1) A sump, with no drain, near the tank to catch an accidental spill,

(2) Build a 2 to 4 inch sill across the doorway, high enough to contain a spill yet low enough to allow machinery to access the building,

(3) Buy or build double-containment tanks, and

(4) Or build high drip pans installed under existing tanks.

Outdoor storage of hazardous materials (drums, smaller container, batteries) must be covered and have secondary containment. Containers of hazardous materials should be placed under cover and on impervious pads (concrete is not impervious unless the surface is properly coated). Secondary containment may be a berm or a pallet with a tray. All drums must be labelled with the date, the words "Hazardous Waste", the associated hazards (ie, flammable) and the contents of the container.

e. <u>Waste oil storage</u>

Waste oil should not be contaminated with any other hazardous substances and if it does become contaminated, it should be labelled as a hazardous waste which entails expensive disposal procedures. Drums should be labelled "Waste Oil Only" to prevent mixing in other wastes, especially solvents. The labelling also aids fire fighters who, in case of fire, must treat an unlabeled drum as the worst case. Waste oil should be disposed of according to appropriate statutes and regulations. Recycling is strongly encouraged.

f. <u>Drainage systems</u>

Most local sewer utilities, via pretreatment ordinances and discharge permits, restrict what can be poured into inside drains since some contaminants are not removed by the treatment process. Drains connected to sanitary sewers may need sand traps and oil water separators. Lack of an oil-water separator for steam cleaning and pressure washing of engines and other oily parts may result in a violation of discharge limits. However, an oil-water separator is designed for the specific purpose of removing oil from water and will not remove all hazardous waste. Oil-water separators should be regularly maintained and cleaned whenever three inches of oil has accumulated. Local sewer utilities should be contacted for help in determining the best way to

VOL 12

5063

dispose of liquid wastes since discharge limits vary. Great care must be taken not to allow any contaminants to enter outside drains since most drain directly in streams or rivers without any type of treatment. Oil water separators should be installed on outdoor drains in areas where engine maintenance occurs.

g. Liquid waste management

Paints and solvents must be prevented from entering waterways by the use of drip pans, drop cloths or tarpaulins. Whenever possible, paints and solvents should be mixed in bermed areas away from storm drains, surface waters, shorelines and piers. Only one gallon (or less) of paint and solvent should be opened at a time when working on floats and should be contained within drip pans or tarpaulins. Paint and solvent spills should be prevented from reaching storm or deck drains, cleaned up and disposed of appropriately. Cleanup materials soaked with solvent must be handled as hazardous waste.

h. Solid waste management

Cleaning must be done in such a way that no debris falls into the water and is done to prevent the accumulation of waste material that may get blown onto surface waters. Cleaning with a vacuum is the preferred method for collecting sandings and trash. Sandblasting debris should be collected and stored with the spent grit and removed frequently. Hosing of decks and docks should not be done when it might cause debris to be washed into the drains. After the contents of a drum or a container is used they should be flattened and made unusable. If possible, reuse or recycle empty drums rather than dispose as solid waste.

Marina operators are responsible for the contents of their dumpsters and hazardous waste should never be placed in them. Dumpsters should be locked within an enclosure to prevent "midnight dumping". Liquid wastes should not be placed in dumpsters but disposed of properly by other methods. Recycling of non-hazardous solid waste such as scrap metal, aluminum, glass wood pallets, papers and cardboard is recommended wherever feasible. Dumpsters, that store items such as used oil filters should, while awaiting transfer to a landfill, be covered to prevent rain from leaching material from the dumpster onto the ground.

i. Antifreeze

Antifreeze from boat engines may be recycled if it is not mixed with other wastes. Some facilities elect to purchase on-site recycling equipment. However, filters from the recycling units must be handled as hazardous waste and may not be disposed of in solid waste. Runoff that contains antifreeze should be prevented from entering storm drains or natural waters.

j. Boating

Discharges from boats are subject to regulation under the Clean Water Act. However, many activities associated with the use of boats result in impact to coastal waters. Activities that may mitigate some of the impacts associated with boating include:

(1) Prohibitions on the use of environmentally damaging materials and encouragement of environmentally sensitive substitutes,

(2) Speed zones where erosion or other detrimental results could occur,

(3) No boating and/or anchorage zones where sensitive or critical habitats could be damaged by "prop-wash",

(4) No discharge zones where water quality standards could be violated by such a discharge,

(5) Limitations on in-the-water boat hull cleaning if it can be demonstrated that this is a significant local problem,

(6) If in-the-water boat hull cleaning can be an acceptable practice if it is done with a soft cloth (instead of scraping) several times a year, and

(7) Prohibitions of disposal of wastes from boats into State waters.

D. Pollutant Reduction and Costs

Pollutant reduction and costs have not been determined for the Management Measures related to the operation and maintenance of marinas and boats. NPS pollution resulting from some of the activities identified above can be eliminated entirely and others can be greatly reduced through implementation of the prescribed Management Measures.

V. RECOMMENDATIONS FOR STATE PROGRAMS TO IMPLEMENT MANAGEMENT MEASURES FOR MARINAS AND RECREATIONAL BOATING

The information in the remainder of this chapter does not represent management measures but are recommendations for States to consider in their overall approach to marina and recreational boating NPS pollution management. The draft program guidance to be published by EPA and NOAA in the summer of 1991 will contain information on State Coastal Nonpoint Pollution Control Program development and approval.

A. Management Process

It is recommended that a process be developed by every State to permit and regulate recreational boating and marina development and operation. This process should be the foundation on which the actual management measures identified in the rest of this chapter can be designated and implemented. Most States already have programs designed to accomplish many of the actions suggested in this guidance and States are not encouraged or discouraged from reorganizing their programs as described in this chapter. However, it is recommended that States review and, if needed, revise their programs to meet the performance goals identified. Marina and boating programs should consist of the following:

(1) Marina regulations,

(2) Marina development application form,

(3) Technical guidance for locating, planning, design and construction of marinas,

(4) Boating regulations,

(5) Chemical bans/controls of certain boat washing or stripping chemicals,

(6) Enforcement/ monitoring plans, and

(7) Public education.

Marina regulations should deal with potential pollution sources that may originate due to the physical presence or operation of marinas. The intent of the regulations should be three-fold. First, to apply strict environmental controls over the siting, design, construction, and operation of new marinas. The controls should be most comprehensive for new marinas because new construction offers the greatest opportunity for proper environmental planning and management. Second, to allow upgrading of existing facilities in ways which can benefit the environment by imposing reasonable restrictions which would effectively discourage or prevent environmentally detrimental impacts. In this case, it is recognized that physical constraints at existing sites may present insurmountable limitations over the scope of feasible improvements that can occur. Third, to provide for safe and environmentally sound operation of existing and future marinas through prevention of pollution by good housekeeping procedures.

B. Public Education

To improve success in reducing NPS pollution from marinas and recreational boating, a public education program is vital. The public should be educated about causes of NPS pollution and practices that will reduce NPS pollution. Specific areas in which boaters should be educated include:

(1) The types and sources of NPS pollution impacts associated with marinas and boats,

(2) Locations and types of sensitive coastal resources and wildlife habitat areas in local waters, and methods of minimizing boater impacts,

(3) New environmental protection initiatives and new operational measures implemented to respond to these initiatives,

(4) Marina operation and maintenance plans,

(5) Encourage limited use of detergents or use of detergents with 0.5% phosphates by weight,

(6) Proper collection and disposal of hazardous material (bottom paint scrapings and sanding dust, fiberglass resins, epoxy, MSD pumpout waste, dump station wastes, acid-type cleaners, wood bleaches, varnishes, etc.),

(7) Environmentally sensitive boat maintenance and upkeep procedures,

(8) Inform the public as to EPA and Coast Guard regulations prohibiting the discharge or oil or oily waste that causes a visible film or sheen,

(9) Proper use of sewage pumpout facilities, and

(10) Other boating regulations.

CHAPTER 6

HYDROMODIFICATION, DAMS AND LEVEES, AND SHORELINE EROSION MANAGEMENT MEASURES

This chapter addresses nonpoint pollution caused by hydromodification and shoreline erosion. Hydromodification covers a wide range of different activities, each presenting varying degrees of a range of nonpoint source (NPS) problems. Identified below are a range of hydraulic activities that may cause NPS pollution. A subset of these activities is addressed through the management measures identified in the section. EPA is seeking suggestions on which activities to focus on most extensively over the next year as it develops the final guidance. Hydraulic modifications vary significantly depending on the geographic region of the country. Therefore, we are also soliciting suggestions on geographic-specific activities and accompanying management measures.

In addition, this chapter addresses shoreline erosion which, unlike the previous chapters, is a symptom or result of other activities, rather than an independent activity that causes a problem. Nonetheless, it is a source of nonpoint pollution that significantly affects many coastal waters.

I. HYDROMODIFICATION

A. Overview of Sources

The following is a list of major activities that can cause alterations of the hydrologic characteristics of coastal and non-coastal waters which, in turn, could cause degradation of water resources.

(1) Dredging (e.g., marina basin, channels, borrow pits, underwater mining activities) - These activities alter the depth, width, and/or location of waterways or embayments and potentially reduce flushing characteristics. The reductions in flushing may reduce dissolved oxygen and change bottom sediments. Specifically, there is a tendency for finer textured sediments to accumulate in these areas impacting the benthic biota. Such areas may attract organic material and concentrate pollutants. In addition, dredging for channelization may increase salt water intrusion from the ocean during low river flow periods but decrease salinities during high flow periods by hastening passage of flood flows.

(2) Dams and Impoundments - Dams and impoundments may alter the distribution 'of sediments in the estuary and may cause migration of the turbidity maximum zone (i.e., the zone of greatest sediment concentration) thereby increasing sedimentation rates in some areas and decreasing them in others. Also, by reducing the discharge volumes, downstream current velocities and total flows may be reduced which in turn may promote the accumulation of fine textured sediments with high organic matter content and the reduction of aquatic habitat

5071

dependent upon higher flows. Aquatic habitat may also be lost through inundation. These issues are addressed more extensively in the dams and impoundments section (section II below).

(3) Tidal Flow Restrictors (undersized culverts, transportation embankments, undersized bridges, tide gates, sluice gates, weirs) - These structures may reduce tidal flushing and decrease exchange volumes thereby creating or exacerbating water quality problems. Tidal flow restrictors also cause ponding and may cause a loss of vegetation. There may also be a concurrent change in the sediment quality. Such changes may also restrict movement and migration of fish and crustaceans and affect shellfish populations.

(4) Flow Regime Alterations (e.g. diversions, withdrawals, fixing banklines to accelerate flows or to prevent migration of waterway) - Removing freshwater that otherwise enters the estuary or increasing freshwater flows into an estuary can alter hydraulic characteristics and water chemistry, thus impacting shellfish, fisheries, and habitat. Changes to the distribution, amount, or timing of flows affects living resources. Hardening banks along waterways eliminates habitat, decreases organic matter entering aquatic system, and may improve the efficiency of NPS pollutant movement from upper reaches of watershed into coastal waters.

(5) Breakwaters and Wave Barriers - These activities may, through the dissipation of wave energy, cause sediment quality to degrade especially if accumulated sediment contain contaminants and organic material. These devices may also reduce the flushing characteristics of coastal and inland waters and may cause or exacerbate existing water quality problems.

(6) Excavation of Uplands to Increase Water Area (e.g., excavation of marinas from upland; artificial lagoonal systems) - This activity frequently results in poorly flushed areas. Depending upon the location along a tidal waterbody, there may be a reduction in the height of tides downstream. Such changes may create or exacerbate water and sediment quality.

B. Nonpoint Source Problems Caused by Hydromodification

Nonpoint source constituents/parameters of interest that may be influenced by hydromodification include: sediment, turbidity, salinity, temperature, nutrients, dissolved oxygen and oxygen demand, and contaminants. Hydraulic modifications alter the physical environment which may have either harmful or beneficial nonpoint source effects. The nonpoint source parameters can cause problems if they occur outside of normal or desired ranges. For example, salinity fluctuations within range of about 5 to 20 parts per thousand are needed for optimal production of oysters. Periods of lower salinity within this range enable the oysters to thrive and periods of higher salinity are needed to reduce population of predators that destroy oysters. However, extremes of either prolonged low salinity or prolonged high salinity can reduce oyster populations.

The significance of hydromodification lies not only in how such modifications alter the physical environment but, perhaps more importantly, how they ultimately affect freshwater and marine biota and habitat. In many cases, aquatic life is impacted due to disruption of flow, circulation patterns, and other changes in the characteristics of the waters on which these organisms depend. Hydromodifications have deprived wetlands and estuarine shorelines of enriching sediments, prevented natural systems from absorbing energy and filtering pollutants from other sources, and impacted fish and shellfish landings. Nonpoint source problems associated with hydromodification are characterized in this chapter into the following six areas:

(1) Changes in sediment supply. Erosion of bed sediments may increase turbidity, release nutrients, expose contaminants, or expose organic materials that increased oxygen demand. New or eroded sediments may deposit elsewhere, covering benthic communities, or altering habitat. Insufficient sediment supply may not keep up with subsidence and sea level rise, leading to marsh subsidence and loss, as in Louisiana. Erosion or deposition may lead to loss of habitat, migration pathways, or conditions unsuitable for reproduction and growth of biota.

(2) Loss of water contact with wetlands and non-wetland overbank areas during floods or other high water events. The loss of contact may result in reduced filtering of nonpoint source materials by vegetation and soils. (See Wetlands and Riparian Areas chapter.)

(3) Loss of ecosystem benefits such as habitat, pathways for migration, and conditions suitable for reproduction and growth. For example, in California, flow modifications have resulted in reversal of river/stream flow regimes resulting in disorientation of anadromous fish that rely on flow to direct them downstream to spawn.

(4) Reduced freshwater availability for municipal, industrial, or agricultural purposes. Salinity above threshold levels constitutes pollution of freshwater supplies or alteration of salinity regime such that vegetation die-off occurs. (Some cooling and process water uses are unaffected by salinity.)

(5) Increased delivery or rate of delivery of pollutants from upstream.

(6) Secondary effects such as movement of the estuarine turbidity maximum (zone of higher sediment concentrations caused by salinity and tide-induced circulation) with salinity changes, eutrophication caused by inadequate flushing, and trapping large quantities of sediments.

C. Management Measures

Nonstructural measures are one category of management measures that can be used to prevent or minimize water pollution due to hydrologic modifications. While consideration should be given to both nonstructural and structural measures during the early planning stages, nonstructural measures should be given preference in the planning stage given their potential to protect or restore habitat. Certain environmental conditions such as might exist in wetlands or other sensitive aquatic sites, for example, may rule out structural considerations. A nonstructural program will be easiest to implement if it can be developed and adopted for areas not yet experiencing rapid, urban, commercial or industrial expansion. Where circumstances and costs rule against a complete nonstructural program, an appropriate use of both structural and nonstructural modifications may be satisfactory.

Management Measures for the NPS problems listed above are given below.

1. Management Measures for Changed Sediment Supply

(1) Proper project design. Sediment erosion from (and deposition to) the bed of a coastal waterway can be managed by proper project design. Proper design is site and flow condition specific and cannot be generalized, but appropriate models should be used to design waterway modifications. The best available technology includes 2-dimensional numerical and hybrid (numerical plus physical) models. (McAnally, 1986, "Modeling Estuarine Sedimentation Processes," Proceedings, Symposium to Reduce Maintenance Dredging in Estuaries, National Academy of Sciences, Washington, DC.)

(2) Vegetative cover. Sediment erosion from overbank areas that flood during high water events can best be controlled by vegetative cover.

(a) In salt and brackish water areas, the best available technique is planting marsh grasses suitable to the salinity level. Grasses anchor the soil with roots and detritus and reduce flow stresses on the bed by sheltering it. (Allen, H. H., Webb, J. W. & Shirley, S.O., 1983, Proceedings, 3rd Symposium on Coastal Ocean Management, American Society of Civil Engineers, pp 735-748; Fredette, et al., 1985, "Seagrass Transplanting, 10 Years of CE Research, Wetlands Research Conference.)

(b) In fresh water areas, the best technique is planting of tree breaks, which function much as grasses do plus diminish downstream water flow energy. Tree breaks diminish the flow capacity of the overbank area, so evaluation of the tradeoff between upstream flood control and overbank erosion must be made. (Lower Mississippi Valley Division, U.S. Army Corps of Engineers).

(3) Using noneroding roadways. Noneroding roadways, such as board roads, should be used to access sites within and near wetlands.

(4) Effectiveness. Benefits of these measures consist of significant reduction (but not elimination) of sediment bed erosion during high flow events. Use of models to design projects can result in diminished amounts of sediment deposition away from the modification site.

2. Management Measures for Loss of Water Contact with Overbank Areas During Flood Events

(1) Setback levees and compound-channel designs. Contact between flood waters and overbank soil and vegetation can best be increased by a combination of setback levees (see section on Levees, Dams, and Impoundments) and use of compound-channel designs. Compound-channel designs consist of an incised, narrow channel to carry water during low (base) flow periods, a staged overbank area for the flow to expand into during design flow events, and an extended overbank area, sometimes with meanders for high flow events. Planting of the extended overbank as described above completes the design. (W.M. Linder. 1976. "Designing for Sediment Transport", Water Spectrum. Spring-Summer).

(2) Effectiveness. Benefits of this design practice include (a) improved conveyance with less sediment deposition during low and moderate flows, (b) improved habitat, (c) open migration pathways for fish, and (d) improved filtering with minimal erosion during high flow events.

(3) "Wing wall" impoundment for overbank flow in frequent storm events. Construct a notched impoundment within the stream channel immediately upstream of small stream culvert crossings. Designed to back up flows during frequent storm events and expand flow over streambanks into vegetated floodplain. Flow from larger storm events (typically two-year or greater) will overtop the wall and continue through stream culvert.

(4) Effectiveness. Benefits are directly associated with reduction of sediment loadings. Reduction of nitrogen and phosphorous estimated at 5-15%. Restores or maintains habitat of overbank areas and provides a pathway for fish migration.

3. Management Measures for Loss of Ecosystem Benefits

(1) Site specific design. Preserving ecosystem benefits is best achieved by site specific design to obtain pre-defined optimum/existing ranges of physical environmental conditions. The use of models is one way to achieve this. The process consists of these steps:

VOL 12

5075

(a) Define which ecosystem benefits may be placed at a risk by a project.

(b) Define the range of acceptable values for the system-significant parameters listed in part 1 and the range of flow and net transport values that will maximize/maintain ecosystem benefits. Note that specifying zero change in the parameters may not optimize ecosystem benefits.

(c) Use appropriate models to evaluate system behavior under project alternative plans and appropriate conditions of flow and climate. Verify that the models are capable of reproducing significant processes in the area of interest, then use the sequence of modeling hydrodynamic response, transports, and then water quality.

(d) Refine the project design so as to obtain an acceptable range of significant parameters.

Appropriate models may be 1-dimensional, 2-dimensional, or 3-dimensional, depending on system behavior and economics, and may be physical, numerical or hybrid models, depending on system characteristics and parameters/processes of interest. (Hudson, et al., Coastal Hydraulic Models, SR-5, Sept. 1979. U.S.A.E. Coastal Engineering Research Center, Vicksburg, MS).

4. <u>Management Measures for Reduced Freshwater Availability</u>

(1) For most cases, reduction in freshwater availability is best managed by the same techniques described in item 3 above. In this case, the salinity threshold levels should be selected using defensible criteria, not arbitrary specifications of "zero change" or "zero salinity," neither of which occur in nature.

(2) Salinity increases in fresh or brackish marshes that are caused by canal construction are best managed by the same techniques described in item 3 above.

(3) Artificial nourishment. Salinity increases caused by land subsidence, which lowers marsh levels faster than reduced sediment supply can maintain them are best managed by artificial nourishment with diverted sediment.

5. <u>Management Measures for Increased or Accelerated Delivery of Pollutants</u>

Increased or accelerated delivery of pollutants from upstream are best managed by the techniques described in item 3 above. (For example, the Chesapeake Bay Program's numerical modeling effort provides effective consideration of pollutant delivery. However, it may not adequately consider effects on habitat.)

6. Management Measures for Secondary Effects

(see problem description p. 6-3)

Secondary effects are best managed by techniques described in Section I.C.3 above.

D. Costs of Management Measures

Appropriate model studies described in the preceding best management practices have highly variable costs, but common cost ranges are:

(1) 1-dimensional hydrodynamics and water quality - $5,000 - $50,000.

(2) 2-dimensional hydrodynamics and water quality
  (a) Creeks, small river sections - $10,000 - $100,000
  (b) Sections of rivers to large estuaries - $25,000 - $500,000

(3) 3-dimensional hydrodynamics and water quality
  $100,000 - $5,000,000

Planting overbank and marsh grasses cost between $2,000 and $9,000 per hectare.

Planting overbank tree strips costs between $10,000 and $25,000 per acre.

Channel design and construction to incorporate compound channel design may increase initial and maintenance costs.

Costs of construction of concrete, notched wing wall are in the $10,000-$15,000 range.

E. Overview of Federal, State, and Local Programs and Processes

1. Existing Regulations

a. Administration and background for nonpoint sources

(1) Clean Water Act (Section 404)--permit program for the discharge of dredged and fill material

(2) National Environmental Policy Act--sets the policy requiring all Federal agencies to write an Environmental Impact Statement (EIS) for any major Federal action "significantly" affecting the environment. An EIS must include consideration of environmental factors which tend to help minimize nonpoint source pollution when it has been found abandonment of the proposed action is impractical.

VOL 12

5077

(3) US Army Corps of Engineers permit process for dredging and filling.

(4) Section 73 of Public Law 93-251 on nonstructural flood damage reduction measures.

b. Examples of present State guidelines

(1) Best Management Practices Guidelines for Virginia
(2) Better Quality Management Plan for the State of Louisiana
(3) Puget Sound Water Quality Management Plan, 1989
(4) San Francisco Bay Conservation and Development Commission (BCDC) policies on fill in tidal areas.

II. DAMS AND LEVEES

A. Coastal Problems Caused by Dams and Levees

1. Overview

Dams and levees can adversely impact coastal and near coastal water quality, as well as the hydrologic regime of stream systems. Direct impacts associated with the siting, construction, and operation of dams and levees are due primarily to the disturbance of soil and ground cover, changes in stream hydraulics, and modification of existing ecosystems (i.e., loss or reduction of ecosystem filtering and uptake functions).

There are two large classes of impoundments (Virginia Department of Conservation and Recreation, 1979). First, there is the run-of-the-river impoundment, which is an impoundment that usually has a small hydraulic head (low dam), limited storage area (thus, a short detention time), and no positive control over lake storage. The amount of water released from this class of impoundments is dependent upon the amount of water entering the impoundment form upstream sources.

The second class is the storage impoundment, in which there is a large hydraulic head (high dam), large storage capacity (long detention time), and a positive control on the amount of water released from the dam. Flood control dams and hydro-power dams are usually of the storage class. Run-of-the-river impoundments generally have a much less pronounced overall effect on water quality than do storage impoundments.

There are several possible intended uses for impoundments:

(1) Flood control
(2) Power generation
(3) Navigation
(4) Water supply - domestic, industrial, irrigation
(5) Other - recreation, fish and wildlife propagation, low flow augmentation, etc.

These various uses often require differing design and management practices and, in cases of multiple-use objectives, present conflicting operational requirements. For example, flood control impoundments have large storage capacities to contain flood waters. As the wet or rainy season approaches, water is released to insure that adequate storage capacity is available for the periods of high flow. The dam is operated to trap excess flow during the wet season, and to later release this flow during periods of low stream flow.

In contrast, the operation of dams for power generation has traditionally been focused on meeting peak electricity demands. The dams, therefore, usually must impound and store large quantities of water, providing control over downstream releases to meet peak needs.

As a further contrast, dams for navigation purposes must be operated to maintain a minimum depth in the impoundment. These dams usually have locks to facilitate the movement of commercial traffic, and control over downstream releases. Water supply dams impound large quantities of water to meet user needs.

Multi-purpose impoundments can have conflicting operational requirements that must be balanced in order to meet all specified uses. For example, the Shasta Dam in northern California (U.S. Fish and Wildlife Service, 1976) is operated for flood control, irrigation, navigation, fish and wildlife conservation, hydroelectric power, recreation, and salinity control in the Sacramento-San Joaquin River Delta.

2. Siting and Construction

The siting of dams and diversions can result in the inundation of wetlands and special aquatic and terrestrial sites above the structures, and the drainage of aquatic and wetland habitats downstream. They can also impede or block migration routes of important sport and commercial fishes. For example, 95 percent of the historic spawning habitat for salmon and steelhead trout in California has been either destroyed or made unavailable by dams.

Construction activities can cause increased sedimentation of coastal and near-coastal waters due to vegetation removal, soil disturbance, and soil rutting. Fuel and chemical spills, and the cleaning of equipment (e.g., concrete washout) are also potential nonpoint source problems associated with construction. The proximity of most dams and levees to streambeds and floodplains heightens the need for on-site pollutant prevention.

Dam construction can have other effects on the local hydraulics (Virginia Department of Conservation and Recreation, 1979). In order to guard against dam failure, the flow of water under and around the sides of the dam site must be impeded. This is done by embedding an impervious core into the ground to prevent the flow of groundwater under or around the dam (piping). While this construction technique is necessary to ensure the safety of the dam, it can impede the flow of groundwater in the vicinity of the dam. This interference might not become apparent until the dam is fully constructed and the impoundment filled. These effects on the groundwater flow can cause drops in the water table below the dam site, and increases upstream. A rise in the water table can lead to the formation of marshes in areas that had been dry. Other effects include the possible accumulation of pollutants in the groundwater because the flow of the groundwater is disrupted.

3. Operation

The operation of dams and levees can also cause a variety of nonpoint source pollution impacts to coastal and near-coastal waters. For example, dams can severely reduce downstream movement of sediment, causing a change in stream hydraulics. This change in stream hydraulics can cause increased downstream scouring and streambank erosion, resulting in increased sediment and nutrient delivery to coastal waters. As another example, lower instream flows and flattening of peak flows associated with controlled releases from dams can result in aggradation of near-coastal stream beds and estuaries, degrading valuable spawning and rearing habitats. Dams can also limit recruitment of favorably sized substrate needed by aquatic fauna, and lower nutrient inflows to estuaries and near-coastal waters. In addition, dams can cause elevated downstream water temperatures and lower downstream dissolved oxygen levels.

Levees can cause increased transport of suspended sediments to coastal and near-coastal waters during high-flow events. Levees can also prevent the lateral movement of sediment-laden waters into adjacent wetland and riparian areas which would otherwise serve as depositories for sediments, nutrients, and other pollutants. This has been a big factor, for example, in the rapid loss of coastal wetlands in Louisiana. Levees also interrupt natural drainage from upland slopes and can cause concentrated, erosive flow of surface water.

B. Management Measures for Dams and Levees

Management Measure Applicability:

These management measures are to be utilized on all dams, and the erosion and sediment control for construction, erosion and sedimentation control for operation, habitat protection, and chemical and other pollutant control for construction apply to all levees.

These management measures do not apply to the extent that their implementation under State law is precluded under California v. Federal Energy Regulatory Commission, 110 S.Ct. 2024 (1990) (addressing the supercedence of State in-stream flow requirements by Federal flow requirements set forth in FERC licenses for hydroelectic power plants under the Federal Power Act).

1. Erosion and Sedimentation Control for Construction

a. Problems to be addressed

Erosion and sedimentation control techniques can be used to address the erosion problems resulting from dam or levee construction.

b. Erosion and sedimentation management measure for construction

The management measure for control of erosion and sedimentation during the construction of dams and levees is a combination of practices that minimizes the detachment and transport of soil by human-induced disturbance, water, wind, ice, or gravity such that the delivery of sediment caused by the construction activities, either directly or indirectly, to natural waterways is not significantly greater than the delivery of sediment from the construction area prior to construction activities.

c. Management practices

Following is a list of management practices for erosion and sedimentation control that are available as tools to achieve the erosion and sedimentation management measure for construction of dams and levees.

Soil Bioengineering - These techniques can be used to address the resulting erosion from dam and levee construction. Grading or terracing a problem streambank or eroding area and using interwoven vegetation mats installed alone or in combination with structural measures will facilitate infiltration stability.

Environmental Design of Waterways (ENDOW) - This problem-solving computer program is a practice that consolidates information on environmental features and facilitates their selection for use in the planning and design of streambank protection and flood control projects (Shields and Schaefer, 1990). The type of project, dominant mechanisms(s) of erosion, and environmental goals are entered into the ENDOW program. The program then lists and determines the relative feasibility of the environmental goals and features (e.g., pool/riffle complexes, preservation and creation of wetlands, low flow channels) within the program.

Other applicable practices are listed in the "Construction Management Measure" section of the urban chapter in this guidance.

2. Erosion and Sedimentation Control for Operation

a. Problems to be addressed

Erosion and sedimentation control techniques can be used to address the erosion problems resulting from dam or levee operation.

b. Erosion and sedimentation management measure for operation

The management measure for control of erosion and sedimentation during the operation of dams and levees is a combination of practices that minimizes the detachment and transport of soil by human-induced disturbance, water, wind, ice, or gravity such that the delivery of sediment caused by dam or levee operation, either directly or indirectly, to natural waterways is not significantly greater than the delivery of sediment from the area influenced by the dam or levee prior to establishment of the dam or levee.

c. Management practices

Following is a list of management practices for erosion and sedimentation control that are available as tools to achieve the erosion and sedimentation management measure for operation of dams and levees.

Downstream Erosion Controls - The release waters from an impoundment can cause problems downstream by eroding the stream channels and by scouring the stream bed (Virginia Department of Conservation and Recreation, 1979). The amount of erosion potential is determined by the erodibility of the stream channel and banks, and by the amount of "excess" energy the water possesses.

The usual method of controlling erosion is to place energy dissipators downstream of the water release to consume the excess energy, lowering the erosion potential. Energy dissipators can take many forms, including:

Riprap or quarried stone can be used to line the streambed, and is resistant to dislodgment because of its jagged shape. Riprap "liner" will not fail due to settling and shifting.

River Rock is frequently used to line the streambed and channels because it is usually available at the site. Advantage is that the rock "liner" is flexible and can withstand settling and shifting without failure. Problem is that river rocks are generally rounded, and, therefore, dislodged easily by flows.

Gabions are wire mesh baskets filled with rock, and can be placed in the stream to form a "liner." Gabions can be anchored into the stream banks or streambed for stability. Gabions are flexible and seldom fail because of settling or shifting. However, gabions require periodic maintenance to insure that none of the wire is broken or corroded.

Concrete Blocks and Liners can usually be made on-site since dam construction typically requires some concrete. Because concrete is less dense than either river rock or riprap, it is necessary to make concrete blocks larger to provide the same resistance to dislodgment. Concrete structures are inflexible, and therefore more likely to fail due to settling and shifting.

Soil Bioengineering techniques can be used to address the resulting erosion from dam and levee operation. Grading or terracing a problem streambank or eroding area and using interwoven vegetation mats installed alone or in combination with structural measures will facilitate infiltration stability.

Environmental Design of Waterways (ENDOW). This practice is described under the management practice for erosion and sediment control for construction.

d. Cost information

River rock is obtained at essentially no cost because it is obtained on site in most cases (Virginia Department of Conservation and Recreation, 1979).

Riprap is more expensive than river rock because of quarrying and transportation costs. In Tennessee, riprap is estimated to cost $2,000 per 100 feet, assuming 1 cubic yard of riprap per linear foot (Tennessee Department of Health and Environment, ca. 1990).

VOL 12

5084

Gabions are usually filled with rock found at the site; however, they require additional hand labor to place the rock and ensure that the containers are not damaged.

3. Habitat Protection

a. Problems to be addressed

The loss of aquatic and terrestrial habitat or habitat function associated with the construction or operation of dams and levees is addressed by this management measure. This includes the preservation and protection of wetlands, riparian zones, and adjacent terrestrial habitat.

The control of natural fluctuations in stream flow can cause an increase in the occurrence of rooted aquatic vegetation and an increase in the deposition of fine particles (U.S. Fish and Wildlife Service, 1976). Fine particles can compact spawning gravels, thus affecting spawning success.

b. Management measure

The management measure for habitat protection is a combination of practices that minimizes the loss of aquatic and terrestrial habitat and habitat function such that habitat function in the area affected by the dam or levee is not significantly degraded. Habitat function includes both the range of environmental benefits provided by habitat (e.g., spawning, food supply, protection), as well as the capacity to support the numbers and diversity of species dependent upon the habitat.

c. Management practices

Following is a list of management practices for habitat protection that are available as tools to achieve the habitat protection management measure.

Setback Levees - Setback levees avoid habitats which serve flood control functions and act as filters for sediment and other pollutants. They allow a given level of high flow to maintain existing floodplain habitats. They also allow the transport of lesser amounts of pollutants than rapid transmission structural systems, lowering the delivery of pollutants to coastal waters.

Low flow gates, channels, and weirs - Allow flow maintenance of fishery and other habitats with the same resultant benefits as cited for setback levees.

Flushing and Scouring Flows for Habitat Maintenance - This practice is intended to maintain habitats and substrates by periodically flushing away sandbars and excessive deposits of fine particles and rooted vegetation in areas downstream from the structure. It is essential to establish an actual ecological need for a flushing or scouring flow before proceeding to predict or prescribe the requirements (U.S. EPA, 1988). Predictive and evaluative methods should be selected which are compatible with site-specific conditions, such as the watershed characteristics, instream flow regime, bed material composition, and channel morphology. It is wise to compare results of several methodologies, which could vary by one or even two orders of magnitude, when predicting flushing or scouring flow requirements, and, if possible, provide field verification. An awareness of the assumptions and limitations inherent in any predictive methodology is important because sediment transport mechanics and channel maintenance theory are still in an early stage of development.

Environmental Design of Waterways (ENDOW) - This practice is described under the management practice for erosion and sediment control for construction.

4. Fisheries Protection for Dams

a. Problems to be addressed

This management measure addresses impacts to fisheries caused by the amount and scheduling of flow releases, downstream sedimentation of spawning areas, changes to water temperature, and fish passage. The generation of power at hydroelectric dams results from the movement of reservoir water through penstocks and turbines to downstream areas. Migrating young fish may suffer significant losses when passing through the turbines unless these facilities have been designed for fish passage.

b. Management measure

The management measure for fisheries protection is a combination of practices that minimizes the loss of desirable fish species by: (1) maintaining minimum instream flows for the protection of desirable aquatic species, (2) controlling flow fluctuations within seasonal bounds to protect against damage to aquatic life, (3) providing for flushing or scouring flows as needed for aquatic habitat maintenance, and (4) providing for adequate fish passage for spawning and migratory (both upstream and downstream) purposes.

c. Management practices

Following is a list of management practices for fisheries protection that are available as tools to achieve the fisheries protection management measure.

Maintaining Minimum Flows - In the design, construction, and operation of structures, the minimum flow requirements to support aquatic and other water-dependent wildlife in downstream areas are addressed. Instream flows are usually maintained to protect or enhance one or a few harvestable species of fish (U.S. Fish and Wildlife Service, 1976). Other fish, aquatic organisms, and riparian wildlife are assumed to also be adequately protected by these flows.

Reduction of Flow Fluctuations - Seasonal discharge limits are established to prevent excessive, damaging rates of flow release. Limits are also placed on the rate of change of flow and river

VOL 12

5086

stage (as measured at a point downstream of the release) to further protect against damage to aquatic communities (U.S. Fish and Wildlife Service, 1976).

Fish Ladders - Fish ladders or similar types of structures should be provided to enable upstream and downstream passage of mature fish. Safe downstream passage of mature fish and fry should also be provided (see screens and barriers to intakes). Some fish, such as steelhead and cutthroat trout, migrate to the ocean more than one time during a lifetime, making necessary the provision for safe downstream passage of mature fish.

Screens and Barriers to Intakes - Fish can be prevented from moving into intakes for water pumps and turbines through the use of various types of screens or barriers (U.S. EPA, 1979). The survival chances of the downstream migrating fish can be increased by providing facilities that bypass them into a gatewall before they enter the turbines and direct them into a channel where they can move safely downstream. Fish can be diverted into holding tanks, collected, and transported away from the area of influence of the pumps, and then released back into the water.

Created Spawning Beds - When the effects of a dam on the habitat of anadromous fish are severe, constructed spawning beds may be designed into the project (Virginia Department of Conservation and Recreation, 1979). Additional facilities are then required to channel the fish to these spawning beds. These can include electric barriers, fish ladders, and bypass channels.

Fish Hatcheries - Only use in existing dams where adequate fish passage not possible or as compensation for loss of fish passage (e.g., fish population supplementation). Native stocks should be used wherever practicable.

When reservoirs flood spawning beds for anadromous fish, hatcheries are established to collect, kill, and obtain the roe from migrating fish (U.S. EPA, 1979). The roe is fertilized and then placed in the hatchery under controlled conditions until the fish are hatched. After having reached an appropriate stage in their development, the fish are released into the river downstream (or above dam to enhance reproduction in the upper watershed) of the dam to migrate back to the ocean.

Transference of Anadromous Fish Runs - This practice involves the inducement of anadromous fish to utilize different spawning grounds in the vicinity of the impounded waters. The extent of the spawning grounds to be lost by blockage of the river is assessed, and the feasibility of transferring existing anadromous fish runs affected by the structure to alternative tributaries is determined.

Environmental Design of Waterways (ENDOW) - This practice is described under the management practice for erosion and sediment control for construction.

5. Temperature Control and Aeration of Reservoir Releases and Tailwaters

a. Problems to be addressed

This management measure is intended to increase dissolved oxygen levels from reservoir releases and tailwaters such that aquatic communities are maintained at levels of abundance, diversity, and function that existed prior to the construction of the dam. Changes in temperature are also addressed to prevent damage to fisheries.

One drawback associated with aeration of release water is the increased possibility of nitrogen supersaturation (Virginia Department of Conservation and Recreation, 1979). Water that discharges over the spillway of a dam and plunges into the spillway basin or plunge pool immediately downstream can become saturated with nitrogen, oxygen, and other gases. As the water plunges rapidly to depths, hydrostatic pressures increase. Entrained air is forced into solution by the pressure before it can rise to the surface and escape. Since air is approximately 80 percent nitrogen, the water becomes supersaturated with nitrogen. Nitrogen levels of 115 percent saturation have been documented to cause mortalities in fish.

b. Temperature and aeration management measure

The management measure for temperature control and aeration of reservoir releases and tailwaters is a combination of practices that restores dissolved oxygen levels to the levels existing prior to the construction of the dam, and maintains temperatures within ranges appropriate for desirable fishes.

c. Temperature control and aeration practices

Following is a list of management practices for temperature control and aeration of reservoir releases and tailwaters that are available as tools to achieve the temperature and aeration management measure.

The following information is taken from Tennessee's Section 319 (Clean Water Act) nonpoint source management program (Tennessee Department of Health and Environment, ca. 1990) unless otherwise noted.

Turbine Venting - Includes Hub baffle, draft tube wall baffle, compressed air through hub or wall. Modify air supply system to increase airflow.

Surface Water Pumps - Pumps surface water with higher dissolved oxygen downward to mix with deeper water as the two strata are entering the turbine.

High Purity Oxygen Injection - Used in combination with turbine venting or surface water pumps to add more oxygen.

Diffused Aeration or Oxygenation of the Reservoir - Used to lower concentrations of dissolved iron, manganese, and hydrogen sulfide.

Surface Water Intake - It may be feasible when constructing a new dam to provide upper elevation outlets to withdraw oxygenated surface water.

Multi-Level Discharge Systems - Multi-level discharge systems have been used successfully to mix waters from all levels of an impoundment to provide some control over the temperature and dissolved oxygen concentrations of the release waters (Virginia Department of Conservation and Recreation, 1979). This consists of providing a release structure with several intake structures at various depths, thus allowing controlled withdrawals from the different levels in the lake. Although this is normally provided during construction, such a structure can be added to an established impoundment. The use of such a system must be carefully considered and designed before implementation because multi-level discharge systems change the thermal structure of the impoundment as a function of withdrawal patterns.

Watershed Management - Control of all point and nonpoint sources of pollutants to achieve improved reservoir inflow quality.

Reregulation Weir - Used to capture hydropower release a short distance downstream and regulate flows to the desired level in reach below the weir.

Small Turbine - Provides continuous generation of power using small flow as opposed to peaking with large turbine units and high flow.

Pulsing - Provides pulse flow on a frequent basis to minimize draining or drying out of tailwater area. This technique requires off-peak operation and decreases the ability to produce peaking power where pulses are needed on a daily basis during certain parts of the year.

Sluice - Modification is made to existing sluice outlet to maintain continuous minimum flow.

Spillway Modification to Prevent Supersaturation of Gases - Spillways are designed or modified to cause the flows to be flipped as they are discharged. Upturned deflectors, cantilevered extension, "flip buckets," or "flip lips" can be designed for spillway terminal structures to deflect the water in a downstream direction and prevent the discharge from plunging straight down. Flows can even be caused to fan out into a thin sheet through the use of a flaring device.

Alternative measures to prevent nitrogen and other gases from reaching supersaturation levels include (1) decreasing spillway flows by providing additional reservoir storage, and (2) decreasing spillway flows by passing water through any available outlet conduit where turbulence will not entrain air.

d. Effectiveness information

The following information is taken from Tennessee's Section 319 (Clean Water Act) nonpoint source management program (Tennessee Department of Health and Environment, ca. 1990) unless otherwise noted.

Turbine Venting - Expect a 2 mg/L to 4 mg/L increase in dissolved oxygen. This is a proven method, but there is a question regarding cavitation resulting from venting.

While the actual design of the turbines is dependent upon many factors, the use of wedge-shaped deflector plates in the draft tubes, slightly below the turbine wheel will create a negative pressure in the flow and thus induce aeration (Virginia Department of Conservation and Recreation, 1979). Howell-Burger valves produce a spray discharge or release that reportedly (TVA) had reaeration efficiencies of 80 percent when the exit velocities exceeded nine meters per second.

Surface Water Pumps - Expect a 2 mg/L to 4 mg/L increase in dissolved oxygen.

High Purity Oxygen Injection - Used in combination with turbine venting or surface water pumps, dissolved oxygen levels can be increased beyond a 2 mg/L to 4 mg/L increase.

Watershed Management - Not expected to correct all dissolved oxygen depletion problems, but is used in combination with other techniques to provide better overall dissolved oxygen levels.

e. Cost information

The cost information provided in Table 6-1 is based upon data provided by the Tennessee Valley Authority (Tennessee Department of Health and Environment, ca. 1990).

6. Chemical and Other Pollutant Control for Construction

a. Problems to be addressed

This management measure addresses fuel and chemical spills associated with dam and levee construction, as well as concrete washout and related construction activities.

b. Management measure

The management measure for control of chemicals and other pollutants during the construction of dams and levees is a combination of practices that minimizes the risk of delivery to natural waterways of chemicals and other pollutants associated with the construction activities.

Table 6-1. Approximate Costs for Reservoir Release and Tailwater Practices (ca. 1990 dollars)

Practice	Cost Description
Turbine Venting	Capital cost can range from $15,000 to $1,000,000 per turbine unit. Annual operation and maintenance cost can range from $50,000 to $100,000 at a project like Norris Dam, and $10,000 to $20,000 at a project like Tims Ford Dam.
Surface Water Pumps	Capital costs about $200,000 per turbine unit. Annual operating cost about $25,000/unit. Operating cost consists primarily of power costs to run the pumps.
High Purity Oxygen Injection	Cost for an experimental system on one turbine unit is as much as $300,000, with an annual operating cost of about $50,000/unit.
Diffused Aeration the Reareation	Capital cost for a small non-power lake is $50,000 to $100,000 with an annual cost of $5,000 to $10,000.
Reregulation Weir	Capital cost of $500,000 to $750,000.
Small Turbine	Capital cost of $500,000 to $750,000, with operating costs at about the break-even point.
Pulsing	Annual cost can be as low as $5,000 to $10,000 where few pulses are needed. This technique requires off-peak operation, and may be subject to additional demand charge because it decreases ability to produce peaking power. Additional charge could range from $100,000 to $700,000 where pulses are needed on a daily basis during part of the year.
Sluice	Capital cost of $150,000, with annual operating cost of about $200,000 to $300,000.

Tennessee Valley Authority water use cost is based on the assumption of lost power-generating potential.

VOL 12

c. Management practices

Following is a list of management practices for chemical and other pollutant control that are available as tools to achieve the management measure for chemical and other pollutant control for construction.

Nutrient Management - The nutrient management measure for agriculture should be applied for all use of nutrients associated with construction (e.g., revegetation).

Pest Management - The pest management measure for agriculture should be applied for all use of pesticides associated with construction.

Spills - Spill containment and cleanup procedures should be in place to address fuels and chemical spills.

Equipment Washout - Treatment or detention of concrete washout and related washout should be provided such that direct entry of washout contaminants to surface waters is prevented.

III. SHORELINE EROSION

A. Introduction

This section addresses NPS problems related to shoreline erosion in bays, estuaries, tidal streams, and watersheds within the coastal zone. It does not address open coastal shorelines as erosion into open ocean is not likely to cause NPS problems.

Numerous factors affect the processes along the shore zone (see section D on planning and design considerations). Eroding shorelines and streambanks contribute NPS sediment loads and nutrients to the neighboring waterway. The sediment may have beneficial or harmful impacts. Beneficial impacts include beach nourishment, sandbar creation or nourishment of wetlands that combat erosion. Adverse water quality impacts (turbidity, BOD, sediment), burial of shellfish beds, smothering of submerged aquatic vegetation (SAV), impacts to spawning areas and property loss are several detrimental impacts of erosion. Eroding shorelines also contribute nitrogen, phosphorus and other pollutants to the waterbody.

[EPA requests additional information addressing more arid areas and shoreline measures further upstream in coastal watersheds.]

B. Specific NPS Problems

This section focuses on controls for erosion caused or exacerbated by human land use or water activities. Erosion rates ranging from 1 to 20 feet per year are typical in many coastal areas where the fastland along the shore is itself composed of older deposits of interbedded sand, silt, and clay. This type of eroded shoreline sediment may often contain adsorbed nutrients. It has been demonstrated that nutrient loadings from eroded shoreline sediments are significant. High nitrogen concentrations have been found in upper bank sediments, especially on eroding farm fields. For 14 sites in the Virginia portion of the Chesapeake Bay, for example, average loading rates were 0.51 lbs/ton for nitrogen and 0.35 lbs/ton for phosphorous of eroded sediments from the estuarine shorelines. Shoreline erosion can also adversely affect living bay resources by increasing sedimentation rates and turbidity.

C. Management Measures

To address the NPS problems identified in Section B above, shoreline management measures in the coastal bay/estuarine system should incorporate the upland, shore zone and nearshore regimes in order to accomplish the following objectives:

(1) Avoid the generation of NPS pollution from shoreline erosion during a "25-year" event. For fluvial environments (upstream), this event is the "25-year" flood. For estuaries or coastal bays, this event includes tidal storm surge and wind induced wave action.

(2) Achieve no significant sedimentation from the shoreline source and minimal visible loss of shoreline.

(3) Do not transfer erosion energy to or negatively impact other shoreline areas due to management actions. Minimize impacts of controllable erosion potential (form wave energy and overland storm runoff) such as boat wakes or channelized runoff.

(4) Protect natural shoreline vegetation and aquatic habitats such as wetlands, submerged aquatic beds, riffle pool complexes, and riparian habitat. Restore damaged habitat as a shoreline stabilization practice when conditions allow.

Nonstructural management practices are preferred. Structural shoreline erosion practices should be used only in areas where nonstructural practices are ineffective (i.e., areas with high wave energy). Satisfaction of all of the measures for any reach may be difficult. For example, management practices that are effective for certain water quality objectives may be ineffective or even counter productive in achieving other water quality objectives. For instance, even though bulkheads effectively reduce sediment input, they provide little benefit for restoration of habitat, and in some cases, they have caused other NPS problems due to leaching of chemical wood preservatives from the structure.

D. Planning and Design Considerations to Select Management Practices

The following process outlines an approach for selecting the appropriate management practices to achieve the management measures described in Section C above.

(1) Identify extent of erosion problem. The rates of shoreline erosion can be estimated by comparing present and historic shoreline locations through use of maps, photographs, or pre-existing surveys. Additional site-specific information on the bank height of the fastland can be considered with the historic recession rate, to identify areas contributing the greatest volumes of sediment and related pollutants (i.e., agricultural lands).

(2) Evaluate the effects of the adjacent land use. It is important to consider both the adjacent land use activities and water use activities (such as boat wake) that may cause or exacerbate shoreline erosion problems. Therefore, the shoreline management practice should be implemented in conjunction with the management measures prescribed in the earlier chapters of this guidance. (See Chapters on Agriculture, Forestry, Urban, and Marinas.)

(3) Evaluate the natural causes of shoreline erosion. Shorelines along rivers, bays, and estuaries may degrade gradually due to the daily action of tides, waves, and currents. Alternatively, only the most severe storm conditions may cause loss of fastland or wetlands along the shore. Shoreline erosion in coastal areas is

strongly related to an area's wave climate. A relatively simple measure of potential wave climate is the measure of fetch (the distance over open water that winds can generate waves). In coastal bays and estuaries, the fetch is limited to the distance to the opposite shore. For instance, a low energy shore may have a short fetch across a creek but a very long fetch toward the northeast (i.e., storm exposure). Further upstream, the driving factor may be overland runoff and velocities generated by storm events. The Great Lakes shorelines, on the other hand, may have an almost unlimited fetch due to their great widths and deep water. Selection of the appropriate erosion control measure should be directly related to the extent of the problem and an understanding of the underlying causes.

(4) Determine limits of the reach. A reach is a segment of shoreline wherein the erosion processes and responses are mutually interactive. For example, appreciable littoral sand supply would not pass the boundaries of the reach. A reach may also be defined as a shoreline segment wherein manipulation of the shoreline within that segment would not directly influence adjacent segments. That is, measures implemented on an individual property should minimize impacts to neighboring properties in the reach.

(5) Identify wetlands, riparian, submerged aquatic beds, and other nearshore habitats in the shoreline area of concern. Allow adequate flow and circulation to protect the functional value of adjacent wetlands or other aquatic habitat. If wave climate and other erosive conditions allow, consider nonstructural measures such as restoring pre-existing habitat or using a combination of low profile structures with re-establishing aquatic habitats.

E. Management Practices

This section discusses management practices that are available as tools to achieve the shoreline erosion management measures. There are various practices available to achieve the management measures. These practices range from biological and physical engineering processes to zoning/restrictions. The planning process described above is essential in selecting the appropriate management practice. Eroding areas may be influenced by wind-driven wave action, tidal fluxes, storm discharges from land, operation of water craft, or various land use activities. Selection of the appropriate management practice depends upon a comprehensive understanding of the driving forces behind shoreline erosion. The three basic categories of shoreline erosion control measures are:

(1) Nonstructural: includes bank grading and beach nourishment. Also include restoration and re-vegetation of wetlands (emergent marsh, shrub-scrub, or forested) and other vegetation re-establishment (see chapter on wetlands/riparian restoration for additional information).

(2) Combinations and Bioengineering: includes mixed use of structural and nonstructural approaches such as biological engineering practices, including live staking, live fascine, brushlayer, branchpacking, brushmatresses; also headland breakwaters and beach nourishment with vegetation re-establishment, bank grading and beach fill, groins with vegetation re-establishment.

(3) Structural: includes bulkheads, stone revetments, seawalls, groins and breakwaters.

There are various methods and combinations of methods available from which to choose once a decision has been made to stabilize a shoreline. The method or methods selected must be compatible with other methods (if combinations are selected) and with the objectives of the management strategy. Some methods, with price estimations, are as follows:

1. <u>Nonstructural</u>

a. <u>Bank grading</u>

Bank grading is basically the reshaping of the upper shoreface of a sediment bank to enhance upland vegetative growth. This method is typically used in combination with other methods described below. The cost for bank grading ranges from $2.50 to $5.00 per cubic yard of material moved.

b. <u>Marsh vegetation</u>

The use of marsh vegetation to abate shoreline erosion can be attractive in terms of cost. The initial cost of creating a substantial marsh grass fringe ranges from $30.00 to $60.00 per linear foot, depending on the desired width. Yearly maintenance of a marsh fringe generally involves fertilization and debris removal as well as additional planting. Not all estuarine shorelines are suitable for treatment with marsh grass plantings. Shorelines exposed to high energy categories would be excluded from the vegetative alternative due to more frequent damaging wave action (Knutson, 1977). However, it may be possible to establish a marsh fringe under these conditions in conjunction with some type of offshore breakwaters or other wave damping device.

c. <u>Other re-vegetation</u>

(See Wetlands and Riparian area chapter on restoration for additional information beyond emergent marshes like restoring vegetation in areas further upstream such as bottomland forest or scrub-shrub.)

d. Beach nourishment

There are a variety of techniques available to artificially re-nourish beach systems, however the source, quality, and grain size of material used for re-nourishment needs to be economically evaluated in order to determine its suitability for placement. Truck hauling, cutterhead pipeline dredging, hopper dredging, and combinations of these techniques can be used to effectively re-nourish a beach. In evaluating the quantity of material needed to construct the required beach width, the volume of the material needed to fill the offshore zone where the profile is not in dynamic equilibrium must be considered. If this subaqueous portion of the shore is not filled, the erosion rate of the new material might accelerate until the profile adjusts to the dynamic equilibrium condition. In this case the visible portion of the beach may be displaced offshore with little chance of returning.

The location of the optimum placement of material is another important aspect of beach re-nourishment. This location is mostly dependent on the physical characteristics of the shoreline and the desired result of the project. Placement on the visible portion of the beach can occur in the form of a dune and/or berm construction. The benefits of this type of erosion control measure are readily observed due to the increased beach width for recreation and as a storm protection method. However the berm life might be of short duration due to the previously mentioned processes. Other placement options exist in the foreshore zone and in an offshore zone in the form of a bar.

The cost for beach nourishment varies widely based on the distance to the sand source, the type of equipment used, and the method of placement.

2. Combinations and Bioengineering

Soil bioengineering provides an array of practices that are effective for both prevention or mitigation of NPS problems. This applied technology combines mechanical, biological and ecological principles to construct protective systems that prevent slope failure and erosion. Adapted types of woody vegetation (shrubs and trees) are initially installed as key structural components, in specified configurations, to offer immediate soil protection and reinforcement. Soil bioengineering systems normally utilize cut, unrooted plant parts in the form of branches or rooted plants. As the systems establish themselves and develop roots (fibrous inclusions), they provide an additional resistance to sliding or shear displacement in streambanks or upland slopes.

Specific soil bioengineering practices contributing to these systems include live staking, live fascine, brushlayer, branchpacking, brushmatresses, joint planting, live cribwall and live gully repair. Environmental benefits include diverse and productive riparian habitats, shade and organic additions to streams or small water bodies, cover for fish, aesthetic values and water quality.

Soil bioengineering systems contribute to the following partial list of desired effects:

- Protection of soil surface against wind, rain and frost erosion
- Improved water quality through higher interception of rainfall, and stabilization of soil against erosion.
- Increased shade and reduced temperatures in soil, water, and air layers near ground surface.
- Improved soil permeability.
- Improved riparian and aquatic habitat.
- Improved soil enrichment (decaying organics and symbiosis) and improved water retentive capacity of soil.
- Improved subsurface drainage.
- Reduced wave action.
- Stabilization of slopes prone to shallow failure.
- Control of rills and gullies.
- Filtration of runoff sediment.
- Restoration of aesthetically degraded areas of protection of existing aesthetic attributes.
- Minimum disturbance of existing desired site conditions.
- Reduced operation and maintenance costs.

3. Structural

a. Revetments

The primary purpose of a revetment is to protect the land and upland areas behind the structure from erosion by waves and currents. The stability of a revetment depends on the underlying soil conditions and should therefore be constructed on a stabilized slope. Erosion may continue or accelerate on an adjacent shore if it was formerly supplied with material eroded from the now protected area. The three basic components of a revetment are the armor layer which absorbs the wave energy, the underlying filter layer supporting the armor layer, and the toe protection to prevent displacement of the armor units.

Revetments are commonly constructed of graded quarrystone, precast interlocking blocks, gabions, stacked bags, or special mats. The size and quantity of the construction material and therefore the price of a structure varies with the energy category of the shoreline. Important design considerations include use and overall shape of the structure, location with respect to the existing shoreline, structure length and height, soil stability, normal and storm surge water elevations, availability of construction materials, economics, environmental concerns, institutional constraints, and aesthetics. Average costs for revetments constructed from Class II riprap range from $175 to $225 per linear foot.

b. Seawalls and bulkheads

A seawall is a structure that is built to protect the landward side of the wall from damaging tidal elevations and wave attack. Seawalls may be constructed with concrete, steel sheet piles or wood. Bulkheads have two functions. The first is to retain or prevent sliding of material seaward, and the second, to protect the upland against damage from wave action. Seawalls or bulkheads may be used in all three energy categories; however, the effects of these types of structures on the entire reach of shoreline must be evaluated. The costs of bulkheads varies with the energy category and the locality of the project. Typical costs (for timber bulkheads) are $200.00 to $275.00 per linear foot. These costs may vary $25% to 40% depending on the location of the project.

c. Groins

A groin is a shore protection device, usually oriented perpendicular to the shore, that may consist of one or more structures. The purpose of these structures is to trap littoral drift, thus creating a beach on the updrift side of the groin. Careful planning and design of a single groin or groin field is necessary to avoid adverse erosional effects on the downdrift side of a project. Groin fields usually require maintenance in the form of beach nourishment if the volume of longshore drift is insufficient to bypass around the groin tip. The cost per linear foot varies from $35 to $180 depending on the wave energy category and the locality of the project.

d. Breakwaters

The functions of breakwaters is to intercept incoming waves, dissipate their energy, and thus form a low-energy shadow zone on the landward side. This reduction in wave energy reduces the ability of sediment transport. Sand moving along the shore is therefore trapped behind the structures and accumulated. Breakwaters are often placed as segmented structures that allow for the protection of longer reaches of shoreline for less cost.

The headland control concept is to take advantage of the shoreline's natural movement toward equilibrium. Less resistant shorelines between stable headlands continue to erode until the equilibrium point is reached. As the shoreline reaches a stable configuration, a shallow embayment is formed between the headlands. This equilibrium state will depend on the wave climate and the sediment transport mechanisms acting on the shoreline. By maintaining natural headlands as focal points for stabilization or by inducing artificial ones, the shoreline should stabilize between these headlands. An extensive eroding shoreline reach may be controlled by structurally protecting only about 30 percent of the total reach. Breakwaters and headland breakwaters average $90.00 to $350.00 per linear foot.

CHAPTER 7. MANAGEMENT MEASURE FOR WETLANDS PROTECTION AND BIOFILTRATION

CHAPTER 7

MANAGEMENT MEASURE FOR WETLANDS PROTECTION AND BIOFILTRATION

CHAPTER 7

MANAGEMENT MEASURE FOR WETLANDS PROTECTION AND BIOFILTRATION

I. INTRODUCTION

A. Overview

The preceding five chapters of this guidance have specified management measures that represent the most effective systems of practices to prevent or reduce coastal nonpoint pollution from five specific categories of sources. Below, we specify a management measure that, in contrast, applies to a broad variety of sources. This measure addresses wetlands protection, riparian zone protection, and vegetative filter strips.

The loss of wetland and riparian areas as buffers between uplands and the parent waterbody allows for more direct contribution of NPS pollutants to the aquatic ecosystem. Often, loss of these systems is concomitant with other alteration of land features which increase drainage efficiency. As a result, excessive fresh water, nutrients, sediments, pesticides, oils, greases, and heavy metals from nearby land use activities may be discharged through storm events and seepage to the water column and downstream to the coastal waters without the benefits of filtration and attenuation that would normally occur in the wetland (riparian area), if present.

A study performed in the southeastern United States Coastal Plain illustrates, dramatically, the prevention role that wetlands and riparian areas play. The study examined the water quality role played by mixed hardwood forests along stream channels adjacent to agricultural lands. Based on the input/output budgets, these streamside forests were shown to be effective in retaining N, P, Ca, and Mg. It was projected that total conversion of the riparian forest to a mix of crops typically grown on uplands would result in a twenty-fold increase in NO_3-N loadings. (Lowrance, et al 1983).

Land use activities that alter the structure or hydrologic regime of wetlands and riparian areas may contribute significantly to NPS problems. When riparian vegetation is removed or degraded, the banks of streams, bays, or estuaries are destabilized and become more vulnerable to erosion from storm events, wave action, or concentrated runoff. Floodplain wetlands are very efficient in retaining sediments when the wetlands come in contact with flood waters. However, when the hydrology of these same wetlands is modified, such as by channelization, they may become exporters of sediments instead. Tidal wetlands perform many water purification functions. However, when they are severely degraded such as when drained by tide gates, they have been shown to be a source of nonpoint pollution. When such tidal wetlands underlain by a layer of organic peats are drained, the rapidly decomposing soils may release sulfuric acid that may significantly reduce pH in surrounding waters.

VOL 12

5/03

Wetlands and riparian zones also offer important advantages in habitat protection. Protection and protective use of wetlands and riparian zones should allow for both nonpoint source control and other corollary benefits of these natural aquatic systems. Land managers should, therefore, utilize proper management techniques to protect and restore the multiple benefits of these systems. For these reasons, EPA recommends that land managers should factor both protection and restoration of wetlands and riparian areas into their NPS and coastal management programs.

Vegetative filter strips can also provide important benefits in protecting coastal waters from nonpoint source pollution. As discussed below, properly designed and maintained vegetative filter strips can substantially reduce the delivery of sediment and some nutrients to coastal waters from nonpoint sources.

B. Definitions

EPA provides definitions for wetlands, riparian areas, and vegetative filter strips below. These definitions are provided for clarification purposes only. Identifying the exact boundaries of wetland or riparian areas is less critical than identifying ecological systems of concern. In fact, in many cases, the area of concern may include an upland buffer adjacent to sensitive wetland areas to protect them from excessive nonpoint source impacts.

1. Wetlands Definition

Below is the regulatory definition used by EPA and the U.S. Army Corps of Engineers.

> "Those areas that are inundated or saturated by surface or groundwater at a frequency and duration to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally includes swamps, marshes, bogs, and similar areas."

Wetlands are generally waters of U.S. and as such afforded protection under the Clean Water Act. Although we are focusing on the function of wetlands in reducing nonpoint source pollutants, it is important to keep in mind that they are ecological systems that perform a range of hydrologic and habitat functions as well as transforming or trapping pollutants.

2. Riparian Area Definition

Simply stated, a "riparian area" is the vegetated area along a waterbody. There is no one well-established definition; however, these areas are typically part of a "riparian system", a complex assemblage of organisms and their environment existing adjacent to and near waterbodies. Riparian areas are zones that are strongly influenced by an adjacent aquatic environment, have linear characteristics, and experience hydrological fluxes at least once within the growing season. These areas are associated with bays, estuaries, rivers, lakes, reservoirs, springs, seeps, and ephemeral, intermittent, or perennial streams. They occur as complete ecosystems or as an ecotone between aquatic and terrestrial ecosystems, but have distinct vegetation and soil characteristics because of high soil moisture. Topographic relief and presence of depositional soils most strongly influence the extent of water regimes and associated riparian zones. Riparian ecosystems may be classified as uplands, wetlands, or some mixture of the two. Generally, riparian wetland soils are high in clay content, organic matter, water-holding capacity, and natural fertility. The term "riparian ecosystem" does not convey definitive boundaries.

Riparian zones differ functionally from vegetative filter strips in that riparian zones have the ability to filter subsurface as well as surface flows, while filter strips are primarily involved in the filtration of surface flows.

3. Vegetative Filter Strips Definition

Vegetative filter (or buffer) strips (VFS) are permanent, maintained strips of planted or indigenous vegetation located between nonpoint sources of pollution and receiving water bodies for the purpose of removing or mitigating the effects of nonpoint source pollutants such as nutrients, pesticides, sediment and suspended solids. VFS employ strips of perennial grasses, legumes, and/or hay crops to act as a filter to remove sediment and suspended solids, to reduce runoff velocity, and to facilitate rain absorption into the soil.

The pollutant-removal mechanism of the filter strip results from a combination of functions, including a change in flow hydraulics and the process of neutralizing or assimilating pollutants. The physical process of removing pollutants involves filtering particulates and sediment through vegetation, its settling and deposition, and, in some cases, uptake by vegetation.

[EPA REQUESTS COMMENT: Should this chapter also address other aquatic resources that are important to maintaining water quality? A proposal to include two other categories of aquatic resources follows:

> Intertidal Flats: trap sediments and reduce the amount of suspended sediments in adjacent coastal waters; flats also influence the chemistry of adjacent coastal waters.
>
> Submerged Aquatic Vegetation: tend to dampen wave energy thereby promoting sedimentation. This in turn reduces amount of suspended sediments in the water.]

II. MANAGEMENT MEASURE FOR WETLANDS, RIPARIAN AREAS, AND VEGETATIVE FILTER STRIPS

Wetlands, riparian areas, and vegetative filter strips are important components of systems to control nonpoint sources of pollution. A principle of protection involves minimizing impacts to wetlands and riparian areas serving to control nonpoint source pollution, by maintaining existing functions of the wetlands and riparian areas, including: vegetative composition and cover; flow characteristics of surface and ground water; hydrology and geochemical characteristics of substrate; and species composition. In addition, vegetated filter strips have wide applicability and should be broadly employed to protect coastal waters from sediments and nutrients.

III. MANAGEMENT PRACTICES FOR WETLANDS

A. Benefits of Wetlands in NPS Control

Wetlands provide many beneficial uses including habitat, flood attenuation, water quality improvement, shoreline stabilization, and groundwater recharge and discharge. Wetlands can play a critical role in reducing nonpoint source pollution problems in open bodies of water by trapping and/or transforming pollutants before releasing them to adjacent waters. Their role in water quality includes processing, removing, transforming and storage of such pollutants as sediment, nitrogen, phosphorus, pesticides, and certain heavy metals in exchanges with adjacent waters or with waters that pass through the wetland. Wetlands are also major exporters of carbon and nutrients.

A wetland's position in the landscape, both in relation to the pollutant source and the wetland's position in the watershed, affects its water quality functions. Wetlands in the upper reaches of the watershed are believed to have the greatest overall impact on water quality because a larger percentage of water in the river has contact with adjacent wetland environments. It has been estimated that the first 20 meters of a wetland (both riparian and salt marshes) immediately below the source of nonpoint source pollution may be the most effective filter.

In its June 18, 1990, "National Guidance: Wetlands and Nonpoint Source Control Programs", EPA formally recognized and advised EPA Regional and State program managers of the importance of linking NPS and wetland program activities to enhance the effectiveness of both. That linkage can be extended to include the State coastal zone programs to address the new NPS requirements in the Coastal Nonpoint Pollution Control Program. This linkage between wetlands and nonpoint source programs is particularly appropriate given the special emphasis placed on wetlands within the enhancement grants provisions of the CZMA.

B. Management Practices to Protect and Restore Wetlands

There are two overall management practices for wetlands: 1) Establish a preference for protection of existing wetland systems adjacent to parent waterbodies (impact avoidance), 2) Identify wetland areas in a watershed to target for restoration for their NPS reduction and other benefits.

1. Management Practice - Protection

Establish a preference in NPS programs for protecting wetlands (impact avoidance). Avoiding impact to wetlands is fundamental to pollution prevention. A principle emphasizing protection advocates avoiding impact to wetland areas when practicable to maintain existing beneficial uses (functions) and to meet existing water quality standards.

(1) **Consider wetlands and riparian areas on a watershed or landscape scale so that they form a continuum of filters before waters enter an estuary.** This practice includes basin wetlands, riparian buffers and wetlands adjacent to streams and rivers that together serve important NPS functions to buffer the estuary from the sources of NPS pollution.

(2) **Identify wetlands with significant nonpoint source control potential within coastal watersheds.**

(3) **Existing wetlands should not be altered to maximize their water quality function at the expense of their other functions as waters of the U.S.** For example, the following practices should be avoided: location of stormwater ponds or sediment retention basins within a wetland; or extensive dredging and plant material harvest as part of nutrient or metals management in natural wetlands.

(4) **Conduct permitting, licensing, certification, and nonregulatory NPS activities in a manner that protects existing beneficial uses (functions) and meets applicable water quality standards for wetlands.** Because almost all wetlands are "waters of the U.S." they are provided the same protection under water quality standards as other waters. EPA has issued guidance for States to develop or improve standards for their wetlands no later than 1993 (U.S. EPA. 1990). These standards include not only chemical numeric criteria, but biological and physical narrative or numeric criteria designed to protect the designated uses (functions) of the wetland.

(5) **Use upland buffers around existing wetlands when necessary to prevent NPS impairment to wetlands.** For example, if sediment runoff is a problem in an area, consider the assimilative capacity of a wetland area to determine what other measures such as upland buffers are needed to handle the volume of sediment.

a. Effectiveness of protection practices

Inorganic solids (sediments) - The role of wetlands in trapping suspended sediments is well documented. Due to their relatively low slope, wetlands positioned between sediment sources and open bodies of water, such as a bottomland hardwood forested wetland, can remove moderate amounts of sediment from turbid runoff without ecological damage to the wetland. In addition, vegetated wetlands along streams or rivers stabilize soils and help to minimize sediments transported downstream to the estuary. Sediment removal rates of 80 to 90% are common in floodplain wetland and riparian areas.

Fecal coliform - Bacteria are generally associated with particulates in the water column. When sediments settle out in wetland areas, a long retention time of the particulates promotes die off of the bacteria.

VOL 12

5/07

Nutrients - The vegetation in a wetland is important both for uptake of nutrients and as a carbon and litter source for the soil. The carbon, in turn, fuels the immobilization of phosphorus and nitrogen by microorganisms in the soil and the transformation of nitrogen into a gaseous form through denitrification. The layer of litter along the riparian area surface also serves to trap sediments which in turn also captures the particulate phosphorus.

Nitrogen - The effectiveness of wetlands in removing and transforming nitrates varies with retention time of the water in the wetland and the wetland type. Nitrogen is removed primarily from ground water flowing near the surface and is transformed and released as a gas. The net effect of wetlands is to reduce nitrate concentrations. However, nitrate may be flushed from wetlands during periods of high flow (Brown, 1985) (Johnston, Detenbeck, Niemi, 1990).

Riparian vegetation that borders first order streams appears to most efficiently remove nitrate due to contact of a large percentage of the water with the wetland or riparian area. In higher order streams, the primary contact with wetlands occurs during flooding periods (e.g., palustrine wetlands) or when water is impounded (Whigham and Chitterling, 1988). Some examples of effectiveness of nitrogen removal are (Whigham and Chitterling, 1988; Johnston, 1990):

Vegetation Type	Removal
Cypress swamp in Louisiana:	49%
Riparian zone in Piedmont of Georgia:	68%
Cypress dome in Florida:	74%
Riparian forest of North Carolina coastal plain:	86%
Riparian forest of Maryland inner coastal plain	89%

Phosphorus - The role of wetlands in retaining phosphorus has shown mixed results, depending on the wetlands location. Because total phosphorus is sorbed to fine silts and clays, the sediment retention functions of wetlands tend to trap phosphorus as well. In contrast, studies have shown that phosphorus is not efficiently trapped in upland riparian areas because the fine sediments with attached phosphorus either move through the riparian zone, or particulate phosphorus is trapped and released as dissolved phosphorus (Cooper, 1986; Whigham and Chitterling, 1988).

The most important wetlands for phosphorus removal appear to be palustrine wetlands further down the watershed from first order streams. In addition, phosphorus removal appears to be greatest where the surface water comes in contact with the wetland vegetation and litter zone.

Riverine wetlands have also been shown to reduce both nitrogen and phosphorus, but it depends on contact time with the wetland usually associated with flooding events. For example, one study shows a 10-17 percent retention of phosphorus when 50% of the wetland is inundated, and a 46-69 percent retention when more than 50% is inundated. When surface flow is diffuse rather than channelized, fine silts and clays along with attached phosphorus are deposited in wetlands along rivers.

b. Programs to protect wetlands

In highly developed urban areas, the riparian area may virtually be destroyed by construction, filling in wetlands, channelization or other significant alteration. In agricultural areas, the wetland and riparian systems may either involve no management, use of the area for grazing, or removal of native vegetation and replacement by annual crops or perennial cover. Significant hydrologic alterations may have occurred to expedite drainage of farmland. Agricultural impacts to riparian systems may involve clear cutting, filling for stream crossings, and other activities that may significantly affect hydrology and sediment deposition in the riparian zone and the neighboring stream, lake, or estuary. Similar destruction or significant impact may occur as a result of various other activities such as highway construction, silviculture, surface mining, deposition of dredged material, and excavation of ports and marinas. All of these activities have the potential to degrade or destroy the water quality functions of wetlands and riparian areas and may generate additional nonpoint source problems as well.

General approaches - There are many programs, both regulatory and nonregulatory, to protect wetland functions. The list includes elements such as:

Acquisition - Obtain easements or full acquisition rights for wetland and riparian areas along impaired streams, bays, and estuaries. There are numerous federal programs such as Soil Conservation Service Wetlands Reserve and Fish and Wildlife Service National Waterfowl Management Plan funding that can provide assistance for acquiring easements or full purchase.

Zoning - Control activities negatively impacting these targeted areas through special area zoning and transferable development rights.

Water Quality Standards - Put water quality standards in place for wetlands. Factor natural water quality functions into designated uses for wetlands, and include biological and hydrologic criteria to protect the full range of wetland functions.

Regulation and Enforcement - Establish, maintain, strengthen regulatory and enforcement programs. Include nonpoint source conditions in permits and licenses under CWA §401 and §404, state regulations, etc.

Restoration - Maximize opportunities to set aside and restore wetland and riparian areas using USDA's Conservation Reserve and Wetlands Reserve Programs and other federal assistance.

Education and Training - Educate farmers and urban dwellers and other agencies on the role of wetland and riparian areas in protecting water quality and BMP's for restoring stream edges. Teach courses in simple restoration techniques for landowners.

Comprehensive watershed planning - Establishes a framework for multi-agency program linkage and presents opportunities to link implementation efforts aimed at protection or restoration of wetlands or riparian areas. A number of State and Federal agencies carry out programs with compatible mechanisms and objectives to NPS implementation goals in the coastal zone. For example, the Corps of Engineers administers the CWA Section 404 program; USDA implements Swampbuster, Conservation Reserve and Wetlands Reserve Programs; EPA, the COE and States work together to perform Advance Identification of wetlands for special consideration (Section 404); and States administer the CZM program which provides opportunity for consistency determinations and the CWA 401 certification program which allows for consideration of wetland protection and water quality objectives.

As an example of a linkage to protect nonpoint source and other benefits of wetlands, a State could determine under CWA Section 401 or a State regulatory program that a proposed activity in wetlands is inconsistent with State water quality standards or the objectives of the established watershed strategy. Or, if a proposed permit is allowed contingent upon mitigation by creation of wetlands, such mitigation might be targeted in areas defined in the watershed assessment as needing restoration. Watershed or site specific permit conditions may be appropriate (i.e., specific buffer widths/structure based on adjacent land use activities). Similarly, USDA's Conservation or Wetlands Reserve Programs could provide landowner assistance in areas identified by the NPS program as needing particular protection or riparian zone re-establishment.

c. Examples from State and local programs

Baltimore County, Maryland, adopted a bill to protect the water quality of streams, wetlands, and floodplains that requires forest buffers for any activity that is causing or contributing to pollution including: nonpoint pollution of the waters of the State in that county; erosion and sedimentation of stream channels; or degradation of aquatic and riparian habitat.

The county has management requirements for the forest buffers including wetlands and floodplains tha specify limitations on alteration of the natural conditions of these resources. The provisions also call for public and private improvements to the forest buffer to abate and correct water pollution, erosion and sedimentation of stream channels, and degradation of aquatic and riparian habitat.

Washington has developed draft wetland water quality standards to protect wetlands that include enforceable provisions to address stormwater and nonpoint discharges into wetlands. The primary means for requiring compliance with standards will be through waste discharge permits, rules, orders, and directives issued by the Department of Ecology. In cases where BMPs are not being implemented, the Department may pursue voluntary corrective action, orders, directives, permits, or civil or criminal sanctions to gain compliance with standards.

2. Management Practice - Restoration

When conditions are appropriate, restoration of wetlands and riparian areas should be preferred over structural management measures to gain NPS and additional benefits for waters of the U.S. Restoration of wetlands refers to re-establishing a wetland and its range of functions where one existed previously by re-establishing the hydrology, vegetation, and other habitat characteristics.

Restoration of wetlands and riparian areas in the watershed have been shown to result in NPS benefits.

A restoration management practice should be used in conjunction with other measures addressing the adjacent land use activities and in some cases water activities as well.

A preference should be established for restoring multiple ecological functions of waters of the U.S. When conditions are appropriate, restoration of the aquatic ecosystem is a wholistic approach to water quality that addresses NPS problems while meeting the goals of the Clean Water Act to protect and restore the chemical, physical, and biological integrity of the nation's waters. Full restoration of complex wetland and riparian functions may be difficult or expensive, based on site conditions, complexity of system to be restored, availability of native plants, etc. The following are general approaches to factor into wetland and riparian restoration projects for NPS benefits. Specific practices under these approaches must be tailored to specific ecosystem type and site conditions. The preceding chapter's section on shoreline erosion also discusses restoration in the context of mitigating shoreline erosion in wetland or riparian areas.

(1) **Restoration of hydrology is a critical factor to gain NPS benefits and increase probability of successful restoration.**

(2) **Restore native plant species when possible either allowing natural succession or through selected planting.** When consistent with pre-existing wetland type, plant a diversity of plant types, or manage natural succession of diverse plant types rather than planting monocultures. Deep rooted plants may work better than grasses for transforming nitrogen because they reach the water moving under the surface. For forested systems, a simple approach to successional restoration would be to plant one native tree species, one shrub species, and one ground cover species and allow natural succession to add diversity of native species over time.

(3) **When possible plan restoration as part of naturally occurring aquatic ecosystems. Factor in ecological principles when selecting sites and designing restoration such as:** seek high habitat diversity and high productivity in the river/wetland systems; look for opportunities to maximize habitat connectedness (between different habitat types); and restore to provide refuge or migration corridors along rivers between larger patches of upland habitat -- animals are most likely to colonize new areas if they can move upstream and downstream under cover.

(4) **Seek a range of pre-existing functions:** Maximize the wetland functions restored to replicate pre-existing functions. In addition to pollutant transformation, functions to restore may include flood control, food chain support, and habitat. Additional measures (such as adjacent land use BMPs) and

monitoring should be used to ensure that there are no detrimental impacts to wildlife if loadings include pollutants toxic to wildlife. See chapters on Agriculture, Silviculture, and Urban Activities for specifications of applicable management measures.

a. Effectiveness of restoration practices

The ultimate goal of wetland and riparian restoration is to restore ecosystems as opposed to buffer strips, but this may evolve over time through managed succession.

- An ecosystem should be self-sustaining, whereas buffer strips are generally not.
- Restore targeted water quality functions.
- Restore a range of wetland or riparian functions that used to exist at that site.
- Do not degrade value of surrounding natural habitats through uncontrolled expansion of exotic species.

See section II.B.1.b. for typical removal effectiveness of NPS pollutants by these systems.

b. Planning and siting considerations

A relatively high degree of success has been achieved with revegetation of coastal, estuarine, and freshwater marshes because hydrology is relatively easy to restore, native seed stocks are often present, and natural revegetation often occurs. Marsh vegetation also quickly reaches maturity in comparison with shrub or forest vegetation. Success rates for marshes seem to be correlated to proper elevation. Spartina patens has been difficult to restore due to sensitivity to elevation requirements. Spartina alterniflora restoration has succeeded where the elevation and soils are within a given range (depending on the site) and the wave conditions are not extreme (Walker, 1988). Since many of the factors vary with site conditions and wetland type, a careful review of existing literature and case-studies (both successful and unsuccessful) is needed.

Planning:

- Identify sources of NPS problems. Consider the role of restoring sites within a broader landscape context.

- Set goals for the restoration project based on location and type of NPS problem; when practical, replicate multiple functions while still gaining NPS benefits.

- Locate historic accounts (i.e., maps, descriptions, photographs) to identify sites that were previously wetland or riparian. These sites are likely more suitable for restoration if the original hydrology has not been permanently altered.

VOL 12

5/1/2

Site considerations:

It is difficult to establish any single methodology for identifying potential restoration sites on a national scale. Project goals, NPS problems, and site specific parameters all must be considered in restoration design. The following list identifies some important information or considerations for siting a restoration project. This should not be regarded as the final word on considerations, but should be adapted as appropriate for a given project or proposal.

- Site history. Past uses of site including past functioning as wetland.
- Topography. Surface topography including elevations of levees, drainage channels, ponds, islands.
- Slope and tidal range.
- Existing water control structures. Location of culverts tide gates, pumps, and outlets.
- Hydrology. Hydrologic conditions affecting the site. Wave climate, currents, overland flows and flood events.
- Sediment budgets. Sediment inflow, outflow, and retention.
- Soil. Description of existing soils with analysis of suitability for supporting wetland plants.
- Existing (or native) vegetation.
- Salinity.
- Timing of restoration project.
- Potential impact to site from adjacent human activities.

c. Cost considerations for restoration

The cost of wetland and riparian restoration projects will vary significantly depending on the degree of grading, hydrologic changes required, the availability and cost of native vegetation, and whether any physical structures are needed to help ensure success.

An example of restoration costs for an east coast coastal marsh includes the following:

- If substrate is already sufficient and minimal site preparation is required, costs average less than $30.00 per linear foot to plant a single marsh species (Spartina).
- If more extensive bank grading, preparation, or fill is required, the same marsh restoration costs may range from $60.00 to $100.00 per linear foot.
- If a protective structure, typically a low-crested sill, is necessary to reduce erosional forces, the costs can range from $120.00 to 150.00 per linear foot.

EPA requests additional cost data for other wetland and riparian types such as mangrove swamp, scrub-shrub swamp, forested wetland or riparian zone, or grassland riparian zone.

IV. MANAGEMENT PRACTICES FOR RIPARIAN AREAS

A. Benefits of Riparian Areas in NPS Control

Riparian areas are able to intercept surface runoff, wastewater, subsurface flow, and certain groundwater flows from sources upland of the area, removing or buffering the receiving water body from the effects of the pollutants, or preventing the entry of pollutants into the receiving water body. A riparian buffer strip should be used to protect a stream from land use activities adjacent to the stream, and normally consists of grasses, shrubs and trees in the streambank area (New York DEC, 1986). Riparian buffers perform much like wetlands by filtering, storing and even transforming nonpoint source pollutants (Stuart and Greis, 1991).

Like planted vegetation in riparian zones, naturally-occurring vegetation has been shown to be effective in removing sediment, nutrients, pesticides and other nonpoint source contaminants from upland runoff as well as in the abatement of streambank erosion (U.S. EPA, 1988). The pollutant removal mechanisms associated with riparian vegetation combines the physical process of filtering (much like the vegetative filter strip), and the biological processes of nutrient uptake and denitrification (Peterjohn and Correll, 1984). In addition to these two functions, the preservation of vegetation along the streambank shades the stream and helps to maintain lower water temperatures, which preserves fish habitat. The presence of riparian vegetation also helps to prevent streambank erosion.

B. Management Practices to Protect Riparian Areas

1. Management Practice - Protection

As for wetlands, the best way to ensure riparian areas provide NPS benefits in the watershed is to establish a preference for protection of existing riparian areas adjacent to parent waterbodies (impact avoidance). The nonpoint source goal in protecting riparian areas is to improve water quality (1) by removing nutrients, sediment and suspended solids, and pesticides and other toxics from surface runoff, wastewater, subsurface and groundwater flows from sources upland of the riparian area, and (2) by buffering the effects of upland nonpoint source pollution before its entry into waters of the riparian zone.

(1) **Consider wetlands and riparian areas on a watershed or landscape scale so that they form a continuum of filters before waters enter an estuary.** This practice includes basin wetlands, riparian buffers and wetlands adjacent to streams and rivers that together serve important NPS functions to buffer the estuary from the sources of NPS pollution.

(2) **Identify riparian areas with significant nonpoint source control potential within coastal watersheds.**

VOL 12

5/14

The identification and designation of streamside areas is needed to determine the extent and distribution of highly valued and sensitive riparian resources. The boundaries of these areas are determined by the minimum distance needed to provide protection to the water quality and habitat functions. Distances needed may vary depending on soil type, slope, and riparian cover. Some States and forest management agencies have set minimum distances to protect water quality and ecosystem function. Additional distance is required if there is reasonable risk of pollution or loss of riparian functions.

This practice applies to the following water bodies where they are located downslope of croplands, pastures, etc.:

(1) Adjacent to streams (streambanks)

(2) Around lakes or ponds

(3) Adjacent to wetlands

(4) Near groundwater recharge areas

(5) In areas where soil erosion and sediment deposition is a significant problem

2. <u>Effectiveness of Protection Practices</u>

One study suggests that good water quality for streams and water bodies in agricultural watersheds is directly related to nutrient removal and uptake in the riparian ecosystem. It concludes that the absence of riparian vegetation will result in higher nutrient loadings and stresses that maintenance of the riparian ecosystem is vital to the preservation of high water quality (Peterjohn and Correll, 1984).

Research indicates that nonpoint source pollutant mitigation can also be achieved through the process of denitrification in the riparian zone. Bacterial denitrification in anaerobic sites has been shown to remove large quantities of nitrates from riparian zone groundwater (Schipper, et al., 1989).

A riparian buffer is most effective as a component of an integrated land management system which combines nutrient, sediment and soil erosion control management. The riparian ecosystem consists of a complex organization of biotic and abiotic elements. Like planted vegetative filter strips or grassed swales, riparian buffer strips have been shown to be effective in removing sediment, suspended solids, nutrients, pesticides and other contaminants from upland runoff. In addition, some studies suggest that riparian vegetation acts as a nutrient sink, taking up and storing nutrients, and that this function may be related to age (Lowrance, et al.).

It is clear that the long-term maintenance of natural riparian vegetation zones in areas subject to inputs from upland areas can be an effective management practice for reducing certain types

VOL 12

5/1/5

of nonpoint source pollution and that efforts to improve watershed water quality should emphasize maintenance of riparian vegetation (Fail, et al.). Other studies confirm the important role of riparian ecosystems as nutrient sinks and buffers against runoff from surrounding lands.

Studies done in agricultural watersheds suggest that good water quality is directly related to nutrient removal and nutrient uptake in the riparian ecosystem (Lowrance, et al.). While some data supports the hypothesis that bottomland riparian ecosystems act as short- and long-term nutrient filters and sinks through vegetative uptake of upland-applied nutrients, these studies are not conclusive (Fail, et al.).

While the exact nature of the process by which pollutant reduction is achieved may be open to debate, numerous research studies have documented the effectiveness riparian buffer areas in removing nutrient loadings from runoff from upland agricultural areas. Three major studies from Maryland, North Carolina, and Georgia are summarized below Stuart and Greis, 1991):

Study	Total P	Total N
Peterjohn/Correll (MD)	76%	88%
Jacobs/Gilliam (NC)	50%	93%
Lowrance (GA)	50%	83%

Additional data regarding the effectiveness of riparian areas can be found under section II.B.1.b.

3. Cost Considerations

The following costs are provided to give some indication of the cost of restoring riparian zones.

$100/acre (conifer seedling)
$200/acre (deciduous seedling)
$1000-5000/acre (nursery stock)

There is no direct cost involved in preserving existing vegetation in the riparian zone.

C. Maintenance

The maintenance of riparian buffer areas is especially important in preventing sediment from entering streams where its effect on fish and spawning can be a serious problem.

V. MANAGEMENT PRACTICES FOR VEGETATIVE FILTER STRIPS

A. General Role

Runoff water quality management methods generically referred to as biofiltration methods have been shown to provide significant reductions in pollutant delivery. These include vegetative filter strips, grassed swales or vegetated channels, and created wetlands. These methods have been applied in a wide range of settings, including cropland, pastureland, forests, and developed as well as developing urban areas, where biofiltration methods can perform a complementary function in terms of sediment control and stormwater management. When properly installed and maintained, biofiltration methods have been shown to effectively prevent the entry of sediment and sediment-bound pollutants, nutrients, and oxygen-consuming substances into water bodies.

Vegetative filter strips are discussed and described in particular source category-specific chapters of this guidance, but it is clear that they should be considered to have wide-ranging applicability to various nonpoint source categories. Vegetative filter strips SHOULD be widely adopted as components of management systems to address nonpoint source pollutants in runoff from a wide variety of sources.

B. Management Practices for Vegetative Filter Strips

The purpose of vegetative filter strips is to remove sediment and other pollutants from runoff and wastewater by filtration, deposition, infiltration, absorption, adsorption, decomposition and volatilization and thereby reduce the amount of pollution entering adjacent water bodies (U.S.D.A., 1988). Vegetative filter strips are used in areas adjacent to water bodies which may be subject to sediment, suspended solid, and/or nutrient runoff. They improve water quality by removing nutrients, sediment, suspended solids, pesticides, etc., from surface runoff and waste water.

1. Effectiveness

A substantial body of research suggests that vegetative filter strips improve water quality and are an effective management practice for the control of silvicultural, urban, construction and agricultural nonpoint sources of sediment, phosphorus, bacteria, and some pesticides. There are also studies which suggest that the results are inconclusive and variable. However, the following are sources for which filter strips may provide some removal capability (Lanier, 1990):

(1) Forestry - Forest filter strips are used to prevent entry of sediment into riparian water bodies.

(2) Cropland - The primary function of grass filter strips is to filter sediment from soil erosion and sediment-borne nutrients. However, filter strips should not be relied upon as the sole or primary means of preventing nutrient movement from cropland.

VOL 12 5/17

(3) Urban - Filtering and removal of sediment, organic material and trace metals. According to the Washington Council of Governments, filter strips have a low to moderate capability of removing pollutants in urban runoff, and have higher removal rates for particulate than for soluble pollutants (Schueler, 1987).

Filter strips are designed to be used under conditions in which runoff passes over the vegetation in a uniform sheet flow. The distribution of runoff across the filter in such a manner is critical to the success of the filter strip. If runoff is allowed to concentrate or channelize, the filter strip is easily inundated and its purpose defeated.

Filter strips need the following elements to work properly: 1.) a device such as a level spreader which ensures that runoff reaches the filter strip as a sheet flow (berms can be used for this purpose if they are placed at a perpendicular angle to the filter strip area to prevent concentrated flows); 2.) a dense vegetative cover of erosion-resistant plant species; 3.) a gentle slope of no more than 5%; 4.) length at least as long as the adjacent contributing area (Schueler, 1987). If these requirements are met, the VFS has been shown to remove a high degree of particulate pollutants. Its effectiveness at removing soluble pollutants, however, is not well-documented (Schueler, 1987).

The effectiveness of vegetative filter strips varies with topography, vegetative cover, implementation and use with other management practices, as well as the following key variables:

(1) Slope - Filter strips function optimally at slopes of less than 5%; slopes greater than 15% render them ineffective because surface runoff flow will not be sheet-like and uniform. Their effectiveness is strongly site-dependent, i.e., VFS have been demonstrated to be ineffective on hilly plots or in terrain which allows concentrated flows.

(2) Site Considerations - Filter strips are most effectively employed at sites which generate suspended solids, sediment and sediment-bound pollutants. As sediment increases in the filter, effectiveness decreases; if the filter strip becomes inundated, it becomes ineffective. Without maintenance, the effectiveness of filter strips will decline over time, as more runoff events occur (Magette, et al., 1989).

(3) Pollutant Type - Sediment and sediment-bound nitrates, phosphorus, and toxics are efficiently removed by filter strips. However, removal rates are much lower for soluble nutrients and toxics. Soluble nutrients are more effectively removed by riparian vegetation.

(4) Vegetated Area - Criteria for choosing the best vegetation type include dense growths of grasses and legumes which are resistant to overland flow. Effectiveness increases as the ratio of vegetated filter area to unvegetated area increases. A filter strip should be at least as long as the runoff-contributing area. "Contact time" between runoff and the vegetation is a critical variable.

Different filter strip characteristics such as size and type of vegetation can result in different pollutant loading characteristics as well as loading reductions. Following are some reduction rates based on strip size and vegetation:

Study/Source	Size	Vegetation	Reduction[1]
Barker/Young	21x91m	Fescue/rye	89.9% TSS 97.3% TN 98.4% TP
Dillaha et al	6x5m	Orchard grass	95% TSS 77% TN 80% TP
Overman/Schanze	5 ha	Bermuda grass	81.3% TSS 67.2% TN 38.8% TP

Dillaha, et al., (1988) found vegetative filter strips to be very effective at removing sediment and sediment-bound pollutants from feedlot runoff, but much less effective at removing pathogens, fine sediment and soluble nutrients such as nitrate (NO_3) and orthophosphorus (PO_4).

Filter width	Percent reduction/Pollutant
9.1 m	95% TSS 69% NH_4 4% NO_3 30% PO_4 80% P_t
4.6 m	87% TSS 34% NH_4 -36% NO_3 -20% PO_4 63% P_t

As the data above shows, the study found that the filter strips were not very effective at removing nitrate (NO_3) and orthophosphate (PO_4). Effluent nitrate loadings exceeded influent loadings, indicating that the filter strips not only did not trap nitrate, but through mineralization actually released previously trapped nitrogen as nitrate. Although sediment-bound phosphorus

[1]Reductions in concentration.

VOL 12

5/19

was fairly effectively removed, soluble phosphorus (PO_4) also produced greater effluent loadings than influent ones (Dillaha, et al., 1988).

The universality of these results should not be assumed. The same researcher determined that VFS were frequently ineffective for water quality improvement because of the difficulty in assuring sheet flow of runoff. This study found that filter strips are most appropriate in small fields where runoff cannot concentrate before reaching the strip (Dillaha, et al., 1989).

Furthermore, the long-term effectiveness of vegetative filter strips is unclear. In addition, trials conducted under controlled experimemtal conditions may differ from on-site effectiveness in "real world" conditions.

2. Design Criteria

Whereas a grassed swale or waterway is used to control or reduce the pollutant load from concentrated stormwater runoff, **preventing concentrated flows** is the key element of filter strip design. Filter strips are designed to accept overland sheet flow of runoff only.

The primary factors in determining filter strip effectiveness are filter length; uniformity of runoff flow through the filter, field slope, type and density of vegetation, and sediment size. The following critical factors should be observed:

(1) The contour of the filter strip should be identical (in terms of elevation) to the adjacent area.

(2) A device, such as a berm placed at a perpendicular angle to the filter strip area, should be used to distribute runoff over the filter strip in an even manner.

(3) The filter strip should be directly adjacent to the impervious area to avoid runoff bypassing or short-circuiting the device.

(4) Minimum filter strip width for flat terrain should be 20 feet if a grass or turf strip. Studies suggest that a minimum 50-75 feet width is preferable, while others suggest attempting to achieve a one-to-one vegetated to unvegetated area ratio.

(5) Generally speaking, increasing slope steepness requires increased filter strip width to maintain effectiveness. Grass filter strips function best on slopes of 5% or less. They will not function effectively on slopes greater than 15%.

(6) Grasses with a high runoff retardance value, such as Bahia and Bermuda grass, are recommended for use in the filter strip.

(7) Contact time between runoff and the filter strip should be maximized to permit infiltration and sedimentation to occur.

VOL 12

5/20

C. Cost

Vegetative filter strips can be an inexpensive component of an overall pollutant reduction system. If they are preserved before development occurs, they are virtually free (Schueler, 1987). There is, however, an opportunity cost for leaving land undeveloped.

Establishment of filter strips of grass, trees, or permanent wildlife plantings on cropland adjoining a stream, creek, river or other water body may be eligible for enrollment in the Conservation Reserve Program of the U.S. Department of Agriculture.

The following table briefly describes representative costs for establishing filter strip vegetation (Schueler, 1987):

Comparative Costs for Establishing Vegetative Control Practices

Method	Avg. Cost per Acre
Conventional Seeding	$1633
Hydroseeding	$1725
Sodding	$10,900
Riparian buffer	$100 (conifer seedling) $200 (deciduous seedling) $1000-5000 (nursery stock)

D. Maintenance

The design, placement and maintenance of filter strips are all very critical to their effectiveness and serious attention should be directed to prevent concentrated flows from occurring. Although intentional planting and naturalization of the vegetation will enhance the effectiveness of the larger filter strip, it should be inspected periodically to determine if concentrated flows are bypassing or overwhelming the device, particularly at the perimeter.

For shorter filter strips, where natural vegetative succession is not intended, the vegetation should be managed like a lawn. It should be mowed 2-3 times a year, fertilized, and weeded in an attempt to achieve dense, hearty vegetation. The goal is to increase vegetation density for maximum filtration.

VOL 12

5/21

Accumulated sediment and particulate matter in the filter strip should be removed at regular intervals to prevent inundation of the device. Frequency of this type of service will depend on the frequency and volume of runoff flows.

Development of channels and erosion rills within the filter strip area must be avoided. To ensure effectiveness, sheet flow must be maintained at all times.

VI. MONITORING CONSIDERATIONS

The effectiveness of practices to protect and restore wetland and riparian systems as management measures should be monitored. Establish specific objectives and milestones to aid in assessing effectiveness. Following are examples of ways to monitor results. Additional monitoring tools which are more appropriate for specific projects and conditions may be needed. Establish a feedback mechanism to provide opportunity for management considerations during the implementation and maintenance period.

Assess effectiveness of protection/restoration through some or all of the following:

- Assess maintenance/restoration of beneficial uses
- Conduct baseline mapping (quantification and spatial distribution)
- Monitor water quality changes
- Track restoration and losses (acreage and type)
- Track structural changes (i.e., forest removal, restoration of pasture/cropland to wetland/forest)
- Monitor institutional progress in avoidance/protection such as: (1) State or local tax incentives (2) multi-agency participation in protection/restoration efforts, (3) watershed initiatives, (4) acreage protected through long-term protection/restoration through acquisition or easements, (6) number of zoning restrictions, local adoption of restriction ordinances, (7) citizen participation, (8) emphasis on wetlands/riparian protection/restoration across NPS activity areas (not limited to agriculture, but also urban, construction, silviculture, etc.), (9) number of Wetlands Reserve or Conservation Reserve sign-ups.

Success often depends upon the long-term ability to manage, protect, and manipulate wetlands and adjacent buffer areas. Restored wetland and riparian systems often require "mid-course corrections" and management over time. Careful monitoring of systems after their original establishment and, in some cases, active management of the systems, are often critical to long term success. To increase chances of success, restored wetlands should be designed as self sustaining or self managing systems. This is more likely if the project is re-establishing a wetland area where one existed previously.

APPENDIX B. EFFECT OF COASTAL ZONE MANAGEMENT BMPS ON NONPOINT SOURCE CONTAMINANT LOADING IN GROUND WATER

Effect of Coastal Zone Management BMPs on Nonpoint Source Contaminant Loading in Ground Water

VOL 12

5140

INTRODUCTION

Coastal Zone Management (CZM) best management practices (BMPs) are designed to reduce or eliminate the degradation of coastal waters by controlling contaminant migration from agricultural, forest, and urban lands. In doing so, these BMPs can alter the quality and quantity of water discharging into coastal waters that either runs off the land surface or percolates through the soil. For example, BMPs that are designed to reduce surface water discharge of stormwater may substantially increase infiltration into ground water (Mannering et al., 1987; Baker, 1987). In addition, selection of BMPs should be coordinated with State ground-water protection priorities based on ground-water use value and vulnerability. Otherwise, certain BMPs that increase infiltration of water could contribute to contamination of private and public drinking water wells. As a result, BMPs should be assessed in terms of their impact on both surface-water and ground-water resources.

The transport of contaminants in subsurface waters is governed by the physical and chemical principles associated with soil-water flow and contaminant transport. An understanding of these principles will facilitate assessments of the potential effects that BMPs may have on contaminant loading in ground water and the subsequent pollution of coastal waters. Section I will discuss basic principles of contaminant transport associated with the flow of water through soil and aquifers. Section II will compare the effects of general BMP types on the quantity and quality of water movement to ground and surface waters.

I. PRINCIPLES OF CONTAMINANT LOADING IN GROUND WATER

Transport of nonpoint source pollutants to coastal waters through ground-water discharge is governed by physical and chemical properties of the water, pollutant, soil, and aquifer (Cheng and Koskinen, 1986). This section will discuss general influences of soil water flux, contaminant properties, soil properties and aquifer properties on the migration of contaminants through soil and ground waters.

A. Water Flux

Water is the transport mechanism most responsible for pollutant movement in the subsurface environment (Nielsen et al., 1989). Saturated and unsaturated water flow through the soil provide mass and diffuse transport of soluble pollutant constituents, as well as displacement of non-soluble constituents. This discussion influencing water flux through the soil addresses the following factors:

- infiltration;
- infiltration from impoundments; and
- water balance.

i. Infiltration

Transport of pollutants to ground water is a function of the amount of water that enters the soil (infiltration) over a specified area. Infiltration can be characterized by the following equation (Hanks and Ashcroft, 1980):

$$\text{Infiltration} = \text{Precipitation} + \text{Irrigation} - \text{Run-off} \qquad (1)$$

Precipitation and irrigation (influx) intensities and duration that exceed the water intake ability of the soil surface will result in run-off. Soils may accept brief periods of high intensity influx or prolonged periods of low intensity influx before run-off occurs (Taylor and Ashcroft, 1972). This is because infiltration is driven by soil hydraulic conductivity and hydraulic gradients that change rapidly during an infiltration event (Kirkham and Powers, 1972). These hydraulic properties are governed by soil physical properties. Infiltration rates will also generally decrease after tillage, in relation to run-off, with progressive infiltration events due to changing soil physical properties (Baker and Laflen, 1983; Onstad and Voorhees, 1987). Soil physical properties related to water intake ability are the soil texture, antecedent (previous) soil water content, and soil structure (compaction or bulk density). In general, coarser soil textures (larger soil particle size), lower antecedent water contents, and better soil structure (lower bulk densities) will provide increased infiltration. Time-related factors such as antecedent soil moisture contents, soil compaction, and the occurrence of frozen soil conditions significantly affect infiltration rates (Schepers, 1987).

VOL 12

5141

The presence of vegetation and organic matter on the soil surface also may substantially increase the water intake ability of the soil (Baker and Laflen, 1983). Vegetation will provide interception and limited storage of stormwater by the plant canopy (Banerjee, 1973). Interception of rainfall by vegetation will also reduce displacement of soil particles and degradation of surface soil structure due to direct impact of raindrops (Onstad and Voorhees, 1987; Brady, 1974). The presence of vegetation also has the effect of increasing soil moisture holding capacities, increasing surface storage of water, and slowing the rate of run-off (Baker et. at., 1987). These plant-related properties will change with season and site activities due to decomposition of organic matter and the seasonal nature of plant growth.

ii. Induced Infiltration from Impoundments

Rainfall in excess of soil infiltration capabilities can be collected in impoundments designed to control run-off (as cited in Nightingale et. al., 1985). This provides increased localized opportunity for water to infiltrate and carry pollutants through the soil by extending infiltration times over a limited area (Hannam and Leece, 1986). Infiltration amounts and rates will depend on the design and construction of the impoundment and the properties of the underlying soil. Impoundments built over soils with low hydraulic conductivities, lined with clay or other artificial liners, or that experienced substantial compaction of the soil during construction will reduce infiltration rates and prolong surface storage of the run-off.

Such prolonged surface storage in impoundments may reduce the total amount of stormwater infiltrating and discharging into surface streams by increasing the amount of run-off water evaporated into the atmosphere. This may be due to direct evaporation from the impoundment or from subsequent use of the stored water such as for irrigation or artificial wetlands (Edwards et al., 1985).

iii. Water Balance

The amount of pollutant that migrates to ground water is dependent upon the site-specific water balance. Drainage is calculated from the water balance as the amount of water entering the soil minus the amount of water leaving the soil surface. This is dependent upon site-specific rainfall, irrigation, vegetation, soil properties, and climatic energy. This relationship is characterized by the soil water balance equation (Hanks and Ashcroft, 1980):

$$Dr = Inf + Ds\,(\theta_{v,sat} - \theta_{v,fc}) - Es - Tp \qquad (2)$$

where:

- Dr = drainage in equivalent depth
- Inf = infiltration in equivalent depth
- Ds = maximum depth of soil subject to Es or Tp
- $\theta_{v,sat}$ = volumetric water content of the soil
- $\theta_{v,fc}$ = volumetric water content of the soil at field capacity
- Es = soil evaporation in equivalent depth
- Tp = plant transpiration in equivalent depth

Gravitational force will remove water from soils as drainage when their water contents are above a soil moisture level commonly referred to as field capacity (soil water holding capacity). This term is associated with a condition of equilibrium between gravitational forces and the attractive forces exerted on water by the soil particles (Brady, 1974).

Soil water can also be removed from the soil at soil water contents below field capacity by soil evaporation and plant transpiration. Soil evaporation and plant transpiration are inter-dependent and are often considered collectively as evapotranspiration (Hanks and Ashcroft, 1980). For areas where plants are not present or not actively transpiring, it may be inappropriate to include the plant transpiration or evapotranspiration component. Similarly, when plants completely cover the ground surface, the soil evaporation component may also be negligible (Kidman, 1990). Soil water loss due to evaporation is limited to a relatively shallow surface layer of the soil (Hanks, 1985). Transpiration, however, may remove soil water from depths corresponding to the depth of root penetration. Once water has infiltrated below the surface layer of bare soils, or below the root zone of vegetated soils, a discharge of water into the ground water (drainage) will be induced.

As infiltration induces drainage when soil moisture content in the root zone and/or surface soil layer exceeds field capacity, drainage can be minimized by reducing the soil water content. This can be accomplished on irrigated land by regulating irrigation amount and timing to maintain soil water contents at or below field capacity. This rigorous control of irrigation water may necessitate improved irrigation and water delivery systems. Drainage in non-irrigated areas can also be minimized through the establishment of appropriate plant species that will enhance extraction of soil water and provide increased capacity in the soil to store infiltrating stormwater.

B. Contaminant Migration

The amount of pollutant reaching coastal waters will depend on the physical and chemical properties of the pollutant. These properties will define, in conjunction with soil and water properties, the persistence, mobility, and migration pathway of the pollutant (Cheng and Koskinen, 1986). This discussion on contaminant migration through the soil includes an examination of the following factors:

- persistence; and
- mobility.

i. Persistence

Pollutant persistence is the relative measurement of the portion remaining after a period of time. The two major processes affecting persistence are, in general, volatilization and degradation (Helling, 1987). Volatilization is a potentially major movement pathway for contaminants with high vapor pressures, especially when exposed to the atmosphere at or near the soil surface (Glotfelty, 1987). Degradation of organic pollutants in the soil to non-toxic end products is the result of chemical reactions and soil microbial activities (Cheng and Koskinen, 1986). The rate at which this degradation proceeds is related to the concentration of the pollutant. Organic chemical degradation rates are commonly assumed to be described by the exponential decay function (Strenge and Peterson, 1989):

$$C(t) = C_o \cdot 0.5^{\left(\frac{t}{T_h}\right)} \qquad (3)$$

where:

C(t) = amount of pollutant present at time t

VOL 12

5144

C_o = amount of pollutant initially present
t = time in days from initial time
T_o = time in days for ½ the initial pollutant concentration to degrade

ii. Mobility

The rate of pollutant migration through the unsaturated zone, relative to soil water velocity, is dependent upon complex geochemical interactions such as precipitation/dissolution and adsorption/desorption (Strenge and Peterson, 1989). Pollutant properties affecting these interactions include water solubility, viscosity, density, volatility, and adsorptivity (Camp Dresser and McKee, 1986). Mobility of the contaminant is strongly related to its degree of water solubility (Wagenet, 1987).

For insoluble contaminants, viscosity and density determine its mobility through the soil and aquifer. Insoluble contaminants with a solution density greater than water tend to sink to the bottom of an aquifer and move slowly in relation to ground-water flow. In contrast, contaminants with a solution density less than water tend to remain at the top or float to the top as they move through an aquifer and upon discharge into coastal surface waters (Camp Dresser and McKee, 1986). The rate of migration for liquid contaminants that do not mix with water will depend, in large measure, on the viscosity of the contaminant. The physical and chemical nature of the soil provides charged surface area that can attract and immobilize contaminants in soil water (Jurinak, 1988). The adsorptivity of a pollutant is its relative attraction to these charged soil surfaces (Strenge and Peterson, 1989).

The complex physical and chemical interactions that dictate the mobility of the contaminant are not completely understood. However, their effects on contaminant mobility can be simplified by the use of distribution coefficients. This is a "bulk" chemical parameter that estimates the relative amount of the contaminant immobilized in the soil (Strenge and Peterson, 1989):

$$\text{Distribution Coefficient } (K_d) = \frac{\text{Concentration of Contaminant Immobilized}}{\text{Concentration of Contaminant in Solution}} \quad (4)$$

VOL 12

5/45

For example, nitrate has a K_d of zero which means that its movement is not retarded in the soil and will move as fast as the soil water (Bouwer, 1989). Other contaminants, with higher retardation factors, such as chlorinated aromatics move as much as 40 times slower than the water (Bouwer, 1987). These less mobile chemicals will pose less immediate risk to ground water contamination but may concentrate at the soil surface and have a higher risk to surface water contamination due to migration with sediments in run-off (Baker and Laflen, 1983; Dick and Daniel, 1987).

These characterizations of contaminant degradation rate and mobility are generalizations based largely on laboratory studies and their application to field conditions should be viewed with some skepticism (Jury et. al., 1983). Application of these relationships should be limited to surface soils where organic carbon contents and microbial activities are high (Bouwer, 1987) as they may be of little value in predicting transport of pesticides in the ground water.

C. Soil Properties

The soil provides resistance to the movement of the pollutant by limiting the flow of water and providing surface area for adsorption of the pollutant. The amount of this resistance will vary with different soil materials, configurations of different soil materials, and the thickness of the unsaturated portion of the soil. Layering of differing soil materials or densities will affect the rate and direction of water flow (Taylor and Ashcroft, 1972). Palmer (1986) indicates that unsaturated flow might travel laterally as much as several kilometers before reaching the water table. This discussion on soil properties includes examination of factors governing:

- preferential soil water flow; and
- soil chemical properties.

i. Preferential Soil Water Flow

Preferential soil water flow is the principal factor responsible for underestimation of chemical movement in the soil by chemical transport models (Jury et. al., 1983). The amount of soil disturbance and the occurrence and frequency of preferential flow paths may differ significantly among forest, agricultural, and urban soils. Forest soils, and other undisturbed soils, have a

VOL 12

5146

higher potential for preferential water flow due to increased occurrence of animal burrows, root and worm holes, and cracks. Van Wesenbeeck and Kachanoski (1991) indicate that tillage of agricultural soils reduces bypass or channel flow by reducing the lateral variability of soil properties. Certain configurations of soil material, such as karst formations may also induce preferential soil water flow allowing very minimal resistance to percolating water (Palmer, 1986). Preferential flow conditions (enhanced contaminant migration rates) occur in relatively uniform soils and will be intensified by intermittent applications of non-uniform irrigation (Bouwer, 1987; Bouwer, 1989).

ii. Soil Chemical Properties

Chemical properties of the soil such as cation exchange capacity, pH, and organic matter content will affect the capacity of the soil to store and immobilize the pollutant. Cation exchange capacity (CEC) is a measure of the soil adsorption capacity for positively charged solutes (Brady, 1974). This capacity is related to the amount of surface area which is a function of the size of soil particles and the type of minerals within the soil. Representative surface areas of soils and clay minerals (Jurinak, 1988) include the following:

	Surface Area (m^2/g)
Montmorillonite	600-800
Illite	70-120
Kaolinite	10-20
Clay soil	150-200
Loam soil	50-100
Sandy soil	10-40
Humus	600-850

Effective CEC will generally decrease with lower pH levels, as hydrogen ions will dominate the exchange complex, and increase with higher organic matter contents (Wagenet, 1987; Tisdale et. al., 1985), largely due to increased surface area as shown above.

The pH of the soil solution will also have important effects on pollutant degradation and solubility (mobility) due to hydrolysis (Dick and Daniel, 1987; Glotfelty, 1987). For inorganic contaminants, hydrolysis determines metal species that exist in solution. For organic contaminants, the effects of hydrolysis

VOL 12 5147

are indirectly addressed through consideration of degradation rates or rate constants (Strenge and Peterson, 1989).

Cation exchange does not explain the retention by soils of heavy metals and organic anions. This retention is often determined by the formation of complexes between the pollutant and the organic matter or soil surface (EPA, 1983). Organic matter complexes within the soil are complicated and not well understood but do significantly contribute to the retardation or immobilization of pollutants.

D. Aquifer Properties

The release of contaminants into coastal waters from an aquifer is dependent on the discharge rate of ground water and the movement of contaminants in the aquifer. This discussion on aquifer properties includes examination of factors governing:

- ground water flow and
- contaminant movement in aquifers.

i. Ground Water Flow

The discharge of ground water is controlled by the permeability (hydraulic conductivity) of the aquifer, the distribution of hydraulic potential over the aquifer, and the cross sectional area of an aquifer perpendicular to the ground-water flow (Todd, 1960).

Gravitation is the primary force driving water flow in the unsaturated zone causing water flow, in the absence of interfering layers, tends to be mainly vertical. In the saturated zone, however, water flow will be in response to water pressure gradients along the flow path of the aquifer.

The rate of aquifer flow in response to pressure gradients will be determined by the permeability of the material comprising the aquifer. Permeability is a function of the interconnected pore space within the material. For consolidated material (rock formations), permeability will depend on the presence and extent of fractures, joints, or the inherent permeability of the material itself. Configurations of subsurface materials

VOL 12

5148

of differing permeabilities will determine the rate and pathway for water flow within the aquifer.

ii. Contaminant Movement in Aquifers

Transport of contaminants in an aquifer is controlled by the processes of advection and dispersion. Advection is the transport of a contaminant at an average ground-water velocity which is dependent on the hydraulic conductivity, hydraulic gradient, and effective porosity of the aquifer (Freeze and Cherry, 1979). Dispersion, on the other hand, refers to the spreading of a contaminant as it flows through the aquifer. Because dispersion causes the mixing of contaminated ground water with uncontaminated ground water, it is a mechanism for dilution. Both advection and dispersion are controlled by the physical properties of the aquifer, the distribution of hydraulic potentials within the aquifer, and chemical processes within the aquifer.

The advection of contaminants in an aquifer is directly associated with the flow of ground water. In aquifers of high hydraulic conductivity (i.e., permeable), rapid movement of contaminants is facilitated by rapid movement of ground water. The movements of ground water and contaminants are also dependent on the steepness of the hydraulic gradient in the direction of ground-water flow. Finally, in aquifer with high porosity (e.g., fine grain material), the movement of ground water is generally slow and the transport of contaminants is dominated by dispersion.

The dispersion of contaminants in an aquifer is controlled by mechanical dispersion and molecular diffusion. Mechanical dispersion is directly related to velocity of ground-water flow, and molecular diffusion can be determined by the contaminant diffusion coefficient and the particle size of the aquifer media. In aquifers with low hydraulic conductivity and small particle size, diffusive transport of contaminants is large when compared to advective transport. In this case, dispersion can cause contaminants to arrive at a discharge point (e.g., coastal water) prior to the arrival time derived from the average ground-water velocity.

The movement of contaminants in an aquifer is also controlled by properties of the contaminants. The properties affecting contaminant persistence and mobility, as previously discussed, generally apply to contaminants in the aquifer with the exception of chemical and microbial degradation processes. Degradation within the aquifer

VOL 12

5149

environment may be severely restricted due to limited amounts of oxygen and organic material.

II. ASSESSMENT OF BMPS

The preceding Section I, presented an overview of the factors influencing water and contaminant movement through the soil. The following section addresses the impacts that specific types of BMPs may have on surface water and ground-water supplies. The following describes the general types of agricultural, forestry, and urban BMPs and the rational for these impacts which are summarized in Exhibit 1.

A. Sedimentation Controls

Reduction of run-off velocity: BMPs which provide obstructions to surface water flow. These may include techniques that use soil surface alteration (pitting, primary tillage), slope modification (leveling, terracing), residue management (conservation tillage), and contour agricultural practices to slow run-off velocities. These BMPs affect ground and surface waters through:

- decreased transport of sediments and contaminants adsorbed on sediments to surface waters;
- increased infiltration and evaporation thus decreasing run-off; and
- increased ground water transport of soluble contaminants and/or decreased concentration of contaminants in the ground water.

Surface stabilization: BMPs which physically reduce or prevent displacement of soil particles. These may include techniques such as surfacing of rural and forest roads, use of surface mulches, and establishment of permanent vegetative cover on disturbed roadsides and fields. These BMPs affect ground and surface waters through:

- decreased transport of sediments and contaminants adsorbed on sediments to surface waters.

The effect on run-off, infiltration, and ground water contamination will depend on the permeability of the material used to stabilize the surface.

VOL 12

5150

Filtration of sediments: BMPs which remove sediments from run-off waters by passing run-off water through vegetated areas. These may include techniques such as strip farming, buffer zones around surface waters, and artificial wetlands. These BMPs affect ground and surface waters through:

- decreased transport of sediments and contaminants adsorbed on sediments to surface waters;
- increased infiltration and evaporation thus decreasing run-off; and
- increased ground water transport of soluble contaminants and/or decreased concentration of contaminants in the ground water.

Settling impoundments: BMPs which include diversion of run-off into impermeable surface impoundments thus reducing turbulence and allowing sediments to settle. These BMPs affect ground and surface waters through:

- decreased transport of sediments and contaminants adsorbed on sediments to surface waters and
- increased evaporation.

The effect on run-off, infiltration, and ground water contamination will depend on the use of the stored water and collected sediments.

Infiltration impoundments: BMPs which collect run-off water in permeable surface impoundments such that collected water will recharge ground water or evaporate. These BMPs affect ground and surface waters through:

- decreased transport of sediments and contaminants adsorbed on sediments to surface waters;
- increased infiltration and evaporation thus decreasing run-off;
- increased evaporation; and
- increased ground water transport of soluble contaminants and/or decreased concentration of contaminants in the ground water.

Watercourse stabilization: BMPs which physically reduce or prevent the displacement of soil particles lining watercourses. These may include techniques such as establishment of permanent streambank vegetation or the lining of streambanks with geotextiles, rocks, or concrete. These BMPs affect ground and surface waters through:

- decreased transport of sediments and contaminants adsorbed on sediments to surface waters.

The effect on run-off, infiltration, evaporation, and ground water contamination will depend on the permeability of the materials used to stabilize the watercourse.

Timing of activities: BMPs which reduce the disturbance of soils during periods when the potential for displacement of soil particles is high. These may include management practices that restrict site activities when the soil is excessively wet, dry, devoid of cover, or frozen and during periods when high winds or precipitation occurs or is expected to occur. These BMPs affect ground and surface waters through:

- decreased transport of sediments and contaminants adsorbed on sediments to surface waters; and
- increased capacity for soil to retard migration of adsorbed contaminants to ground water.

Localized use restriction: BMPs which restrict site activity on areas of high sediment producing potential. These may include techniques such as restricting livestock access to susceptible streambanks, restricting cultivation of areas with excessive slope, and restricting timber operations on sensitive watersheds. These BMPs affect ground and surface waters through:

- decreased transport of sediments and contaminants adsorbed on sediments to surface waters;
- decreased run-off;
- increased evaporation; and
- decreased contamination of surface and ground waters due to elimination of activity-related contamination.

The effect on infiltration will depend on the water use of the vegetation at the site.

B. Nutrient Controls

Reducing excess in soil: BMPs which include careful nutrient management techniques to meet but not substantially exceed the nutrient requirements of the managed vegetation (i.e., crops, pasture, turf, or timber). This also includes BMPs which maximize production (therefore

VOL 12

5152

nutrient uptake) through cultural management and control of pests and diseases. These BMPs affect ground and surface waters through:

- decreased contamination of surface and ground waters by reducing the quantity of contaminant in the soil.

Application timing: BMPs which alter timing of nutrient applications based on climatic conditions which affect the transport and fate of nutrients. These may include techniques such as multiple fertilizer applications, fertigation, and the avoidance of applications during the fall, early spring or at other times when precipitation is in excess of evapotranspiration. These BMPs affect ground and surface waters through:

- decreased contamination of surface and ground waters by reducing the quantity of contaminant in the soil.

Surface application of nutrients: BMPs which minimize soil disturbances, such as conservation tillage, may impose restrictions on the incorporation of soil-applied nutrients. Surface application of nutrients affect ground and surface waters through:

- increased surface water contamination due to concentration of nutrients at or near the soil surface and
- decreased ground water contamination due to a reduction in contaminant quantity through surface run-off, volatilization, or photodegradation.

The effect on ground water contamination may change if nutrient applications are increased to compensate for these losses.

Shelter of manure sources: BMPs which reduce or exclude precipitation from manure source and storage areas. These BMPs affect ground and surface waters through:

- decreased contamination of surface and ground waters by reducing the quantity of contaminant in run-off water;
- increased run-off; and
- decreased infiltration.

Containment of manure sources: BMPs which prevent surface and subsurface migration of manure at manure source or storage sites. This includes BMPs which specify the use of cement floors or other restrictive liner materials in commercial animal and poultry producing operations. These BMPs affect ground and surface waters through:

- decreased contamination of surface and ground waters by eliminating run-off and infiltration.

This effect may be dependent upon the final use of the manure and effluent.

C. Pesticide Controls

Biological pest control: BMPs which utilize biological competition and predators to control pests and reduce pesticide usage. These include techniques which introduce or enhance biological controls as well as those which minimize the disturbance to natural biological controls. These BMPs affect ground and surface waters through:

- decreased contamination of surface and ground waters by reducing the usage of pesticides.

Mechanical pest control: BMPs which physically limit, remove, or destroy the pest without the use of pesticides. These include techniques such as cultivation, insect traps, timing of operations to afford maximum resistance or competition to managed vegetation from pests, and avoidance of diseased vectors such as the presence of certain plant residues. These BMPs affect ground and surface waters through:

- decreased contamination of surface and ground waters by reducing the usage of pesticides; and
- increased infiltration and decreased run-off due to increased tillage.

Crop selection/rotation: BMPs which prevent buildup of pest populations due to a monoculture environment or the use of a crop or variety which has increased pest resistance. These include techniques such as crop rotation, use of varieties with increased resistance, or the use of a different crop type to facilitate pest control. These BMPs affect ground and surface waters through:

VOL 12

5154

- decreased contamination of surface and ground waters by reducing the usage of pesticides.

On demand pesticide use: BMPs which minimize pesticide usage through correlation of the amount and type of pesticide to actual pest conditions. These include techniques which monitor the presence and population of pests as a basis for pesticide usage instead of predetermined application schedules. These BMPs affect ground and surface waters through:

- decreased contamination of surface and ground waters by reducing the usage of pesticides.

Pesticide application timing: BMPs which minimize pesticide usage through adventitious timing of pesticide applications. These include techniques that correlate applications to the most vulnerable periods of pest life cycles, those that prevent major infestations through monitoring of pest populations, and those that correlate applications with climatic conditions. These BMPs affect ground and surface waters through:

- decreased contamination of surface and ground waters by reducing the amount of pesticide used through control of pest populations and
- decreased contamination of surface and ground waters by restricting pesticide usage when storms are likely to occur.

D. Water Controls

Irrigation scheduling: BMPs which include continual evaluation of soil moisture conditions to determine the optimal irrigation timing and amounts to minimize ground-water recharge. These include techniques which combine soil moisture measurements with computer programs that forecast water demands of the crop so that irrigation applications do not produce excess ground-water recharge. These BMPs affect ground and surface waters through:

- decreased contamination of surface water by increasing infiltration and reducing run-off; and
- decreased contamination of ground water by reducing drainage.

Selective irrigation: BMPs which minimize irrigation quantities by limiting the area irrigated to the root zone of the crop. These include irrigation application techniques that utilize localized

VOL 12

5155

point- and line-source drip and seepage irrigation systems. These BMPs affect ground and surface waters through:

- decreased contamination of surface water by reducing run-off; and
- decreased drainage from the root zone.

Selective irrigation may tend to concentrate contaminants at specific locations within the soil. Therefore the effect of this practice on ground-water contamination may depend on site specific conditions.

Irrigation uniformity: BMPs which reduce the amount of ground-water recharge due to irrigation by increasing the ability to uniformly place irrigation water within the root zone. These include the use of higher technology irrigation systems such as center pivot, fixed line, and lateral move sprinklers. These BMPs affect ground and surface waters through:

- decreased contamination of ground water by reducing the amount of drainage from the root zone.

Soil moisture control: BMPs which manipulate soil moisture in non-irrigated areas. These include techniques which establish vegetation or crops for the purpose of extracting water from the soil to limit water table recharge. These BMPs affect ground and surface waters through:

- decreased contamination of surface water by increasing infiltration and reducing run-off; and
- decreased contamination of ground water by reducing drainage.

CHAPTER 1

CHAPTER 1
INTRODUCTION

INTRODUCTION

Urbanization and industrial activities around the country have significantly altered the natural landscape of our Nation's watersheds. This, in turn, has adversely affected both the quantity and the quality of storm water runoff and has contributed to the chemical, physical, and biological impairment of receiving waters. Studies, such as the Nationwide Urban Runoff Program (NURP) study (EPA, 1983), have shown that storm water from urban and industrial areas is commonly contaminated by heavy metals, synthetic organics, pesticides, fuels, waste oils, and pathogens.

Congress, recognizing the importance of controlling these discharges, passed amendments to the Clean Water Act (CWA) in 1987 requiring that the U.S. Environmental Protection Agency (EPA) issue regulations addressing storm water discharges under the National Pollutant Discharge Elimination System (NPDES) program. Promulgated on November 16, 1990, the NPDES regulations establish permit application requirements for operators of certain municipal separate storm sewer systems (MS4), as well as of storm water discharges "associated with industrial activity." Regulated municipalities include those cities and counties operating medium and large MS4s (serving a population of 100,000 or greater) and other MS4s specifically designated by the permitting authority.

According to CWA mandate, municipalities regulated under the NPDES program must, at a minimum, achieve technology-based requirements (i.e., must reduce pollutant loadings in MS4s to the "maximum extent practicable" [MEP] and must effectively prohibit non-storm water discharges through their MS4s) as a first step toward achieving loading reductions consistent with applicable water quality standards. While MEP was not explicitly defined by Congress, EPA interpreted it to mean that municipalities will develop and implement comprehensive storm water management programs. These programs, proposed by the regulated municipalities under Part 2 of the permit application, are required to address a number of storm water control measures, including methods to detect and remove illicit discharges entering municipal storm sewer systems, as well as appropriate best management practices (BMPs) to address discharges from industrial, commercial, and development activities.

At this time, all regulated Phase I[1] municipalities should have submitted both Parts 1 and 2 of the municipal storm water permit application and will soon begin implementing the storm water management programs they have proposed.

PURPOSE OF THIS MANUAL

The purpose of this manual is to provide hands-on guidance for municipalities on how to best implement their storm water management programs. As mentioned above, most municipalities have already proposed these programs under Part 2 of the application. Upon approval by the permitting authority, these programs will then be incorporated into the municipality's permit and will serve as the blueprint for the municipality's storm water management activities. Permit requirements, however, cannot specify all the procedures necessary to put storm water management programs into effect. Municipalities will need to take steps to ensure that storm water management programs are implemented in a practical, cost-effective manner. As noted throughout this manual, the storm water program is a watershed protection program. Storm water sources include a host of source categories, many of them associated with residential, commercial, and industrial land uses. Thus, a host of controls is available for this diverse set of sources. An effective Storm Water Management Plan (SWMP) program will consider all sources and make decisions on establishing control priorities on an holistic, watershed basis.

This manual is intended to help municipalities through this implementation process. A basic seven-step planning process described in this chapter provides a framework for effective decision-making and long-term planning. Municipalities are encouraged to revisit decisions made during Parts 1 and 2 of the permit application process to reassess their overall planning strategies, selected controls, policies, and programmatic measures. In addition, this manual is intended to help municipalities transform their storm water management program elements from words into action. For example, many municipalities pledged to develop "public outreach programs" to promote awareness about the effects of storm water runoff. But how should such programs be structured? What are the most cost-effective methods for educating

[1]Pursuant to Section 402(p)(2) of the Clean Water Act, Phase I of the storm water program covers the following: A) a discharge with respect to which a permit has been issued under Section 402 before February 4, 1987, B) a discharge associated with industrial activity, C) a discharge from a municipal separate storm sewer system serving a population of 100,000 or more, and D) a storm water discharge that the administrator or State determines may be contributing to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States. Phase II of the storm water program potentially could cover any sources not covered under Phase I. A request for public comment on Phase II targeting and control options appeared in the *Federal Register* on September 9, 1992.

VOL 12

5/7/4

VOL 12

5/7/5

community members? What are the advantages of pursuing a public outreach program versus a public participation event? This manual will help municipalities answer such questions and provide guidance on implementing storm water management program activities into the future.

Finally, this manual emphasizes a watershed protection approach, an integrated, holistic strategy for more effectively restoring and protecting aquatic ecosystems and protecting human health. This approach represents a renewed effort by EPA to focus on hydrologically defined drainage basins—watersheds—rather than on areas defined solely by political boundaries. For a given watershed, regulated municipalities are encouraged to consider not only the water resource (e.g., stream, lake, estuary, or aquifer) but all the land from which water drains to that resource. As water drains off the land, it carries with it the effects of human activities throughout the watershed. Consequently, to protect water resources, it is important to address the condition of land areas within the watershed. By concentrating on natural resources and systems, it is possible to detect and take remedial action for such problems as declines in living resources and habitat loss, as well as to identify the more commonly recognized problems associated with elevated pollutant concentrations. This manual provides guidance for municipalities to implement their storm water management programs within a watershed protection framework.

INTENDED AUDIENCE

This manual is intended to provide guidance for regulated municipalities as they begin implementing their storm water management programs. Regulated municipalities include cities and counties operating municipal separate storm sewer systems that serve populations of 100,000 or more, as well as certain municipalities specifically designated by the permitting authority. Individuals from a variety of different municipal departments could potentially be involved with program development and implementation and will benefit from reading this manual. Table 1-1 identifies the municipal agencies and personnel who may be involved in implementing the storm water management program. This manual is also intended for use by State and Federal employees administering the NPDES storm water program.

ORGANIZATION OF THIS MANUAL

This manual provides specific guidance on how to implement particular aspects of the storm water management program. The manual does not track all requirements of the two-part permit application;

TABLE 1-1. AGENCIES AND PERSONNEL INVOLVED IN STORM WATER MANAGEMENT PROGRAM DEVELOPMENT/IMPLEMENTATION

Municipal Agencies	City/County Personnel	Other Members of Community
Building Department	Council members or other elected officials	Community representatives
City/County Attorney's Office	Emergency response teams	Educators
Department of Environmental Management	Engineers and environmental planners	Environmental advocates
Engineering Department	Financial officers	
Fire Department	Inspectors	
Health Department	Public health officers	
Planning Department	Public outreach personnel	
Police Department	Public works directors	
Public Works Department	Site/building inspectors	
Site Plan Review Department	Site plan reviewers	
Water and Sewer Department	Treatment works operators	
Zoning Department	Zoning board members	

rather, it addresses certain elements of the storm water management program (developed under Part 2 of the application) that could be problematic for municipalities to implement, such as illicit detection and removal procedures, public education efforts, and ongoing monitoring programs. Case studies from municipalities around the country have been provided at the end of each chapter. Wherever possible, worksheets, pictures, maps, and charts have been included to help illustrate a particular process. Chapters are organized as follows:

- **Chapter 1:** Provides an overview of the NPDES storm water program, reviews the topics addressed by the manual, outlines the storm water management program planning process, and examines the relationship between the NPDES program and other urban runoff management programs.
- **Chapter 2:** Helps municipalities establish priorities for storm water management activities to ensure the greatest return on their investment. The chapter also provides methods for ranking problems (i.e., pollutant sources and receiving waters) and appropriate controls.
- **Chapter 3:** Offers hands-on guidance for fulfilling certain administrative requirements, including procedures for developing effective public outreach/public participation programs, financing the storm water management program, and completing required annual reports.
- **Chapter 4:** Provides specific guidance on how municipalities may develop effective programs to detect and remove illicit discharges and illegal dumping into their MS4s.

- **Chapter 5:** Provides matrices of source control and structural BMPs indicating applicability, effectiveness, advantages, and disadvantages of particular controls.
- **Chapter 6:** Provides guidance on operation and maintenance required for structural BMPs and residuals management practices.
- **Chapter 7:** Offers detailed guidance on developing in-stream MS4 water quality monitoring programs.
- **Chapter 8:** Presents appendices, including (A) BMP Fact Sheets, (B) Fact Sheets on Other Federal Regulations Affecting Storm Water Management, (C) Case Studies, (D) Storm Water Contacts Lists, (E) References, (F) Glossary, (G) List of Hazardous Substances and Reportable Quantities, (H) List of Emergency Planning and Community Right-to-know Act (EPCRA) Title III Section 313 Water Priority Chemicals.

DIFFERENCE BETWEEN THIS MANUAL AND OTHER PUBLICATIONS

A number of guidance materials address municipal storm water permit application requirements and urban runoff management (see Chapter 1 References), including the following EPA publications:

- *Guidance Manual for the Preparation of Part 1 of the NPDES Permit Application for Discharges From Municipal Separate Storm Sewer Systems* (April 1991). EPA-505/8-91-002.
- *Guidance Manual for the Preparation of Part 2 of the NPDES Permit Application for Discharges From Municipal Separate Storm Sewer Systems* (November 1992). EPA-833-B-92-002.

This manual differs from most of the other publications because rather than focusing on completing municipal permit application requirements, it provides guidance on how to plan and implement a long-term, cost-effective storm water management program. Specifically, the manual will help municipalities set priorities for successful program implementation. While the manual concentrates on NPDES requirements, it also encourages municipalities to consider a broad range of related storm water/watershed management programs (e.g., nonpoint source programs or coastal zone pollution control programs). This holistic approach to storm water management provides a framework that allows a municipality to integrate its storm water program effectively with other watershed protection efforts at the local, State, and Federal levels. This manual is part of a family of literature available from EPA and other sources. Where information is already provided in other publications, the manual will direct the reader to those documents.

VOL 12

5/7/7

OVERVIEW OF PART 1 AND PART 2 PERMIT APPLICATION REQUIREMENTS

Before outlining the seven-step planning process of storm water management program development, it is important to review briefly the municipal permit application requirements at 40 CFR Part 122.26(d). The regulations established a two-part application requirement for municipalities operating large or medium MS4s.

Part 1 of the application required municipalities to gather information about existing watershed conditions and storm water management activities. In addition, they were to examine existing legal authorities to enforce their storm water management programs. Part 1 also required that field screening of major outfalls be conducted to characterize storm water discharges and detect illicit connections in the storm sewer system.

Part 2 of the application required municipalities to elaborate on information provided in Part 1. Applicants were to establish adequate legal authority, provide additional information on pollutant sources, collect quantitative data from selected sampling points, and analyze fiscal needs versus available resources. Once existing conditions had been assessed and monitoring data collected, municipalities were required to propose a comprehensive storm water management program.

Deadlines for submitting Parts 1 and 2 of the permit applications were as follows:

- Large Municipal Systems with a Population of 250,000 or More: Part 1 - November 18, 1991; Part 2 - November 16, 1992
- Medium Municipal Systems with a Population of 100,000 To 250,000; Part 1 - May 18, 1992; Part 2 - May 17, 1993.

Figure 1-1 briefly summarizes the application requirements for Part 1 and Part 2.

DEVELOPING A WATER MANAGEMENT PROGRAM: THE PLANNING PROCESS

As noted above, this manual delineates a basic seven-step planning process that will help municipalities design cost-effective and sensible storm water management programs. For municipalities that have already completed Parts 1 and 2 of the NPDES municipal permit application, this planning process may suggest ways to improve or enhance the proposed storm water management program. The flow chart

VOL 12

5/7/8

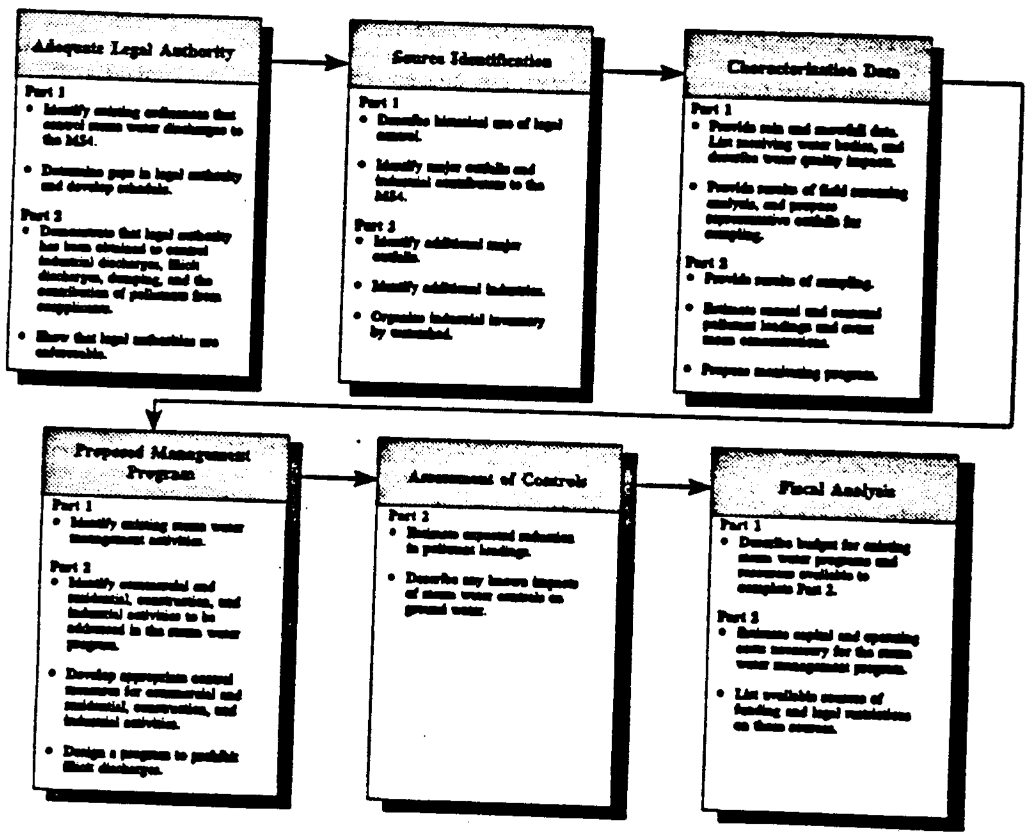

FIGURE 1-1. PART 1 AND PART 2 STORM WATER APPLICATION REQUIREMENTS

appearing in Figure 1-2 has been developed to give municipalities a sense of how each step in the planning process logically leads to the next and ultimately of how the process feeds back into itself, thereby forming a cycle.

After the flow chart, a brief description of each planning step is provided. Other useful guidance materials are listed under the Reference section at the end of this chapter.

- For detailed guidance on Steps 1 and 2 (setting goals and assessing existing conditions), refer to *Guidance Manual for the Preparation of Part 1 of the NPDES Permit Application for Storm Water Discharges From Municipal Separate Storm Sewer Systems* (April 1991) and *Guidance Manual for the Preparation of Part 2 of the NPDES Permit Application for Storm Water Discharges From Municipal Separate Storm Sewer Systems* (November 1992).
- Steps 3 and 4, which describe methods for ranking pollutants sources and impaired watersheds and for ranking control measures, are addressed in Chapter 2.
- Step 5, which identifies storm water management program administrative requirements, is further discussed in Chapter 3 (guidance for developing public outreach/public participation programs) and Chapter 4 (guidance for developing an illicit detection/removal program).
- Step 6, which addresses data collection programs, is further discussed in Chapter 7.
- Step 7, which addresses evaluating the effectiveness of the program, is elaborated upon at the end of Chapter 3. Other useful guidance materials are listed under the Reference section at the end of this chapter.

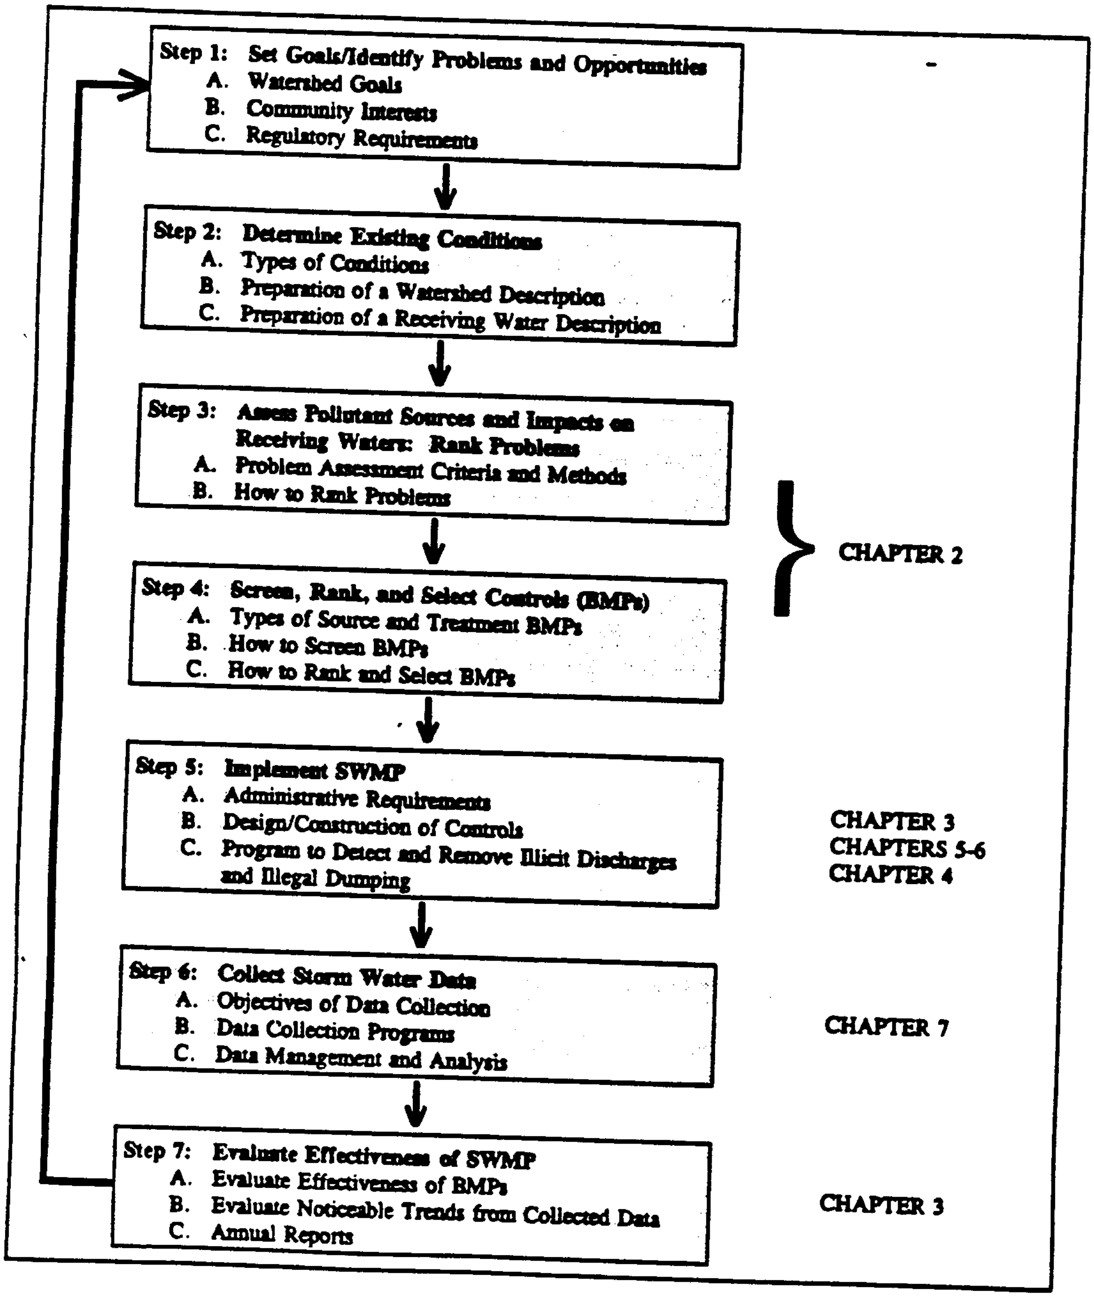

FIGURE 1-2. THE SEVEN-STEP STORM WATER MANAGEMENT PROGRAM PLANNING PROCESS

THE SEVEN-STEP STORM WATER MANAGEMENT PROGRAM PLANNING PROCESS

Step 1: Set Goals/Identify Problems and Opportunities

The primary goal of the Clean Water Act and the NPDES permitting program is to protect the physical, chemical, and biological integrity of our Nation's waters. Toward this end, municipalities are required to develop storm water management programs that will control discharges through their storm sewer systems to the "maximum extent practicable" and to prohibit non-storm water discharges through their MS4s. Within this statutory and regulatory framework, regulated municipalities will define their own set of goals that address all aspects of water quality, including chemical water quality (e.g., toxics and conventional pollutants), physical water quality (e.g., temperature, flow, and circulation), habitat quality (e.g., channel morphology, composition, and biotic communities), and biodiversity (e.g, species number and range). Table 1-2 identifies sample goals for a municipal storm water management program.

Step 2: Define Existing Conditions

Types of Conditions

Once initial program goals have been articulated, the municipality must assess existing water resource conditions. Much of this information was collected during Parts 1 and 2 of the municipal permit application. Guidance on how to begin to assess existing conditions may be found in the *Guidance Manual for the Preparation of Part 2 of the NPDES Permit Applications for Discharges from Municipal Separate Storm Sewer System*. Existing conditions that should be assessed for the SWMP include those identified below..

Pollutant Sources

Municipalities must identify areas or sources known or suspected to contain significant concentrations of pollutants, including industrial sites (those required to obtain permits under the NPDES program), commercial areas, residential areas, and construction activities. In some cases, these areas of concern may be defined on a categorical basis (e.g., all service stations), while in other cases, the area of concern may be more site-specific (e.g., a particular service station). A significant nonpollutant source of concern is excessively high flow, which results in bank erosion, channel scouring, and sediment deposition.

Receiving Waters

Understanding the characteristics of receiving waters is essential for storm water management program development. Municipalities should evaluate available data on the physical, chemical, and biological conditions of receiving waters—and examine existing uses versus designated uses for particular resources—to determine which waterbodies and which specific areas demand highest priority. A wide range of information should be available from State and Federal agencies and local universities. Similarly, the planning and public works department should have relevant information on receiving waters in its possession.

TABLE 1-2. EXAMPLES OF SPECIFIC WATER QUALITY, ECOLOGICAL, AND RESOURCE MANAGEMENT GOALS

Parameter	Goal	Reference
Examples of Water Quality Goals		
Dissolved Oxygen	At least 1 mg/l at all times throughout the Chesapeake Bay Dissolved oxygen monthly means concentrations of at least 5 mg/l at all times throughout the Chesapeake Bay, with the exception of subpycnocline waters	Part of quantitative criteria established for dissolved oxygen by the Chesapeake Bay Program
Dissolved Oxygen	3.0 mg/l minimum (for other than early life stages) 4.0 mg/l weekly average minimum 5.0 mg/l minimum for early life stages 4.0 mg/l minimum 5.0 mg/l daily average minimum 5.0 mg/l minimum	EPA water quality criteria Virginia standard Pennsylvania criterion District of Columbia standard Maryland standard
Nutrients	Low enough to prevent nuisance growth of algae, weeds, and slimes	Specific objective under the Great Lakes Water Agreement
Solids (settleable and suspended) and Turbidity	Settleable and suspended solids should not reduce the depth of the compensation point for photosynthetic activity by more than 10 percent from the seasonally established norm for aquatic life	EPA Water Quality Criteria
Mercury	Less than 2.1 ppb/0.025 ppb	Quantitative water quality acute criteria/chronic criteria for priority metal (EPA criteria under development)
Polynuclear Aromatic Hydrocarbons (PAH)	Less than 300 ppb/ND	Preliminary marine water quality criteria under development by EPA
Examples of Living Resource Goals		
Wetlands	No overall net loss	Federal Policy
Wetlands	"...diking, filling, or dredging in existing estuaries and wetlands shall maintain or enhance the functional capacity of the wetland or estuary. Any alteration of coastal wetlands...shall be limited to very incidental public facilities, restorative measures, nature study, commercial fishing facilities in Bodega Bay, and development in already developed parts of south San Diego Bay..."	Specific objectives set forth in the California Coastal Act
Waterfowl Habitat	Regional land acquisition targets set to meet goals of the Migrating Bird Conservation Act	U.S. Fish and Wildlife Service priority list for land acquisition
Examples of Quality of Life Goals		
Shoreline Access	Substantially expand recreational beach access	South Carolina's State Comprehensive Outdoor Recreation Plan
Park and Recreation Area	Increase urban wildlife programs and public use of opportunities, particularly watchable wildlife programs	U.S. Fish and Wildlife Service "Vision for the Future"

VOL 12

5183

R0038491

Watershed Characteristics

In addition to identifying pollutants sources and their impacts on receiving waters, municipalities should assess other aspects of the watershed, such as land use and development patterns (e.g., general plan, zoning, subdivision requirements), physical characteristics (e.g., soils, slope, subsurface conditions, climate), and characteristics of the drainage system (e.g., physical storm drain characteristics, base flow characteristics, and water quality objectives). Again, such information should be available from existing sources, including local, State, and Federal agencies.

Institutional Considerations

Municipalities must assess their institutional capabilities for developing and implementing a storm water management program. The items to consider are existing funding mechanisms, available staffing, legal authority to carry out stormwater management program activities, and the institutional interest in marshalling joint efforts for storm water management among different municipal agencies. Municipalities should consider existing municipal programs that either affect storm water quality (e.g., road maintenance) or that may be expanded to address storm water concerns (e.g., pretreatment, fire inspections).

Community Character

To ensure the political and financial support of SWMP activities, municipalities must work in conjunction with community members to determine what issues are important to them and which programs they would be likely to support. The factors to consider include municipal demographics; types of community organizations; environmental, land use, and aesthetic issues; and the local business climate.

Existing Programs and Controls

Many cities and counties already have programs that, to one degree or another, address storm water management. The SWMP will be more cost-effective if municipalities can incorporate these existing programmatic measures or controls into those now envisioned for an expanded comprehensive SWMP. The existing programs to consider include those that currently manage pollutant sources and those that currently manage other activities of parties responsible for pollutant sources. Examples of such programs may be found on page 1-16.

Preparation of a Watershed Description

Once municipalities have gathered together available data about sources of pollution and the status of receiving waters, these data need to be organized to facilitate decisionmaking for storm water management activities. As discussed in EPA's Part 2 guidance manual, municipalities are required to prepare a map-based watershed description to obtain a visual sense of the topography in their city, drainage areas, locations of industries, and existing control measures and to pinpoint major sources of pollution. Much of the data listed in Table 1-3, which municipalities are required to collect under Parts 1 and 2 of the permit application, can be plotted on a base map to form a watershed description.

TABLE 1-3. TYPES OF DATA TYPICALLY INCLUDED IN A WATERSHED PROFILE

Environmental	Potential Sources/Existing Structural Controls
• Topography • Land use • Recreational areas (beaches, boating areas) • Designated water uses • Soils and surface/bedrock geology • Vegetation • Natural resources • Temperature • Precipitation • Hydrology	• Landfills • Illicit connections • Waste handling areas • Salt storage facilities • Underground tanks • NPDES industrial activities • Pollution control facilities • Retention/detention ponds • Flood control structures
Infrastructure	**Municipal**
• Roads and highways • Storm drainage systems • Sanitary sewer systems • Treatment facilities • Other utilities (water, electric, gas)	• Population density and projected growth • Zoning • Land ownership • Regulations • Ordinances • Municipal source controls (e.g., street sweeping, catch basin cleaning)

For more information about the sources of watershed mapping and data, as well as methods for analyzing watershed data, refer to *Urban Runoff Pollution Prevention and Control Planning*, EPA CERI, 1993.

Preparation of a Receiving Water Description

In addition to preparing a watershed description, municipalities are encouraged to assess receiving water conditions. Effective identification and use of existing water resources data will reduce the schedule program and cost, in some cases by reducing the need for additional sampling and analysis. Municipalities should work closely with States and Regional EPA offices to obtain available data on receiving waters in various States. States must collect receiving water data as required by CWA sections 304(1), 305(b), and 319 reports. Data should be available from various local departments (e.g., planning, public works, parks and recreation) as well as State and Federal departments (U.S. EPA, United States Geological Survey [USGS], Fish and Wildlife Service, U.S. Department of Agriculture). In some cases, State and Federal agencies may have conducted intensive surveys of a particular watershed or sub-watershed. Municipalities should contact these agencies prior to initiating any data collection efforts on their own. Table 1-4 identifies the data that should be collected to prepare a receiving water description.

Step 3: Assess Pollutant Sources and Their Impacts on Receiving Waters; Rank Problems

Once municipalities have gathered data to determine existing conditions within their jurisdictions, they must determine the most critical problems. During this step, municipalities should consider the following issues: (1) the types of storm water runoff pollution (and their sources) in the watershed, (2) the extent to which these pollution sources affect the receiving water resources, (3) institutional needs and constraints in solving problems, and (4) the degree to which program goals

TABLE 1-4. TYPES OF DATA TYPICALLY INCLUDED IN A RECEIVING WATER PROFILE

Source Input	Chemical
• CSO data • Storm water data • Other NPS data	• Water quality data • Sediment data • Bioconcentration
Physical/Hydrologic	**Biological**

are being met. Finally, municipalities should take steps to rank their problems using the decisionmaking and analysis methods presented in Chapter 2, which provides additional information on this step.

Step 4: Screen, Rank, and Select Controls (BMPs)

After municipalities have ranked and targeted storm water runoff problems (i.e., particular areas, sources, and waterbodies of concern), efforts can then be focused on solving those problems in a cost-effective manner. First, the municipality should compile readily available lists of pollution prevention and treatment practices to assess their relative effectiveness. In most cases, more than one set of BMPs will be identified as feasible to address a particular problem. From the list of feasible alternatives, the municipality will then rank and select its final list of BMPs. Chapter 2 discusses this process of screening, ranking, and finally selecting appropriate BMPs.

Step 5: Implement SWMP

Once priorities have been articulated and a list of BMPs drawn up, the program team is responsible for moving from planning to implementation. During this step, near- and long-term program responsibilities must be clearly delineated. All involved persons must be familiar with, and accept their role in, implementing and enforcing the plan. Some of the most important aspects of implementing a storm water management program include completing administrative requirements (discussed in Chapter 3), developing a program to detect and remove illicit discharges (discussed in Chapter 4), and knowing exactly when certain BMPs would be effective/appropriate (discussed in Chapter 5).

VOL 12

5/86

Step 6: Collect Storm Water Quality Data

Although the municipality may already have existing data, additional data will need to be gathered as part of the NPDES permit application process and throughout the life of the SWMP. When proposing their monitoring programs under the SWMP, municipalities will have to make important decisions about when, where, and how often to monitor their storm water. Ultimately, the permit writer will establish monitoring conditions for each municipality's permit. Chapter 7 presents detailed guidance for developing municipal in-stream water quality monitoring programs.

Step 7: Evaluate Effectiveness of SWMP

The final step, evaluating the effectiveness of the storm water management program, encourages municipalities to reassess decisions previously made and, if necessary, to make alterations in the program plan. As part of this process, the NPDES regulations require that municipalities complete an annual report outlining the effectiveness of their programs on an yearly basis (discussed in Chapter 3).

DISCUSSION OF RELATED REGULATIONS/STATUTES AND PROGRAMS THAT ADDRESS MUNICIPAL STORM WATER RUNOFF

While this manual focuses on providing guidance for NPDES storm water program implementation, municipalities should carefully consider other related watershed protection programs. By integrating these programs into the storm water programs, municipalities will enhance the overall effectiveness of the SWMP. A knowledge of such programs can save startup costs (e.g., by minimizing the need to collect data that may have previously been collected for other purposes) and long-term costs (e.g., by piggybacking BMP planning and implementation activities with other watershed protection efforts). Furthermore, by working in conjunction with other runoff management programs, municipalities can more efficiently address a broad range of watersheds problems concurrently. Listed below (Table 1-5) and identified in the following paragraphs are related Federal statutes, regulations, and programs that address municipal storm water runoff, pollution prevention, and control.

Combined Sewer Overflow Policy

Combined sewer systems are designed to carry both storm water and sanitary sewage. When wet weather flows exceed the carrying capacity of the system, these combined systems discharge the excess flow through designated overflow points. This event is known as a combined sewer overflow (CSO). Such combined sewer discharges, if not treated before overflowing into receiving waters, can cause significant water resource effects and threaten human health. NPDES permits for CSOs include prohibition of CSOs

- Safe Drinking Water Act
- Clean Lakes Program (CWA 314)
- 404 Regulations/Wetlands Program
- National Estuary Program
- Federal Emergency Management Agency Regulations
- Pollution Prevention Act of 1990

Chapter 8, Appendix B, presents a summary fact sheet for each of these statutes, regulations, and programs, along with a list of contact telephone numbers. Given below are brief descriptions of programs that have components related to the NPDES municipal storm water program.

during dry-weather flow conditions, compliance of all wet-weather CSOs with the technology-based requirements of the CWA and applicable State water quality standards, and minimization of water quality impacts from wet-weather generated overflows.

Relationship to SWMP Implementation

Municipalities that own/operate both storm sewer systems and combined sanitary/storm sewer systems are required to comply with many of the same NPDES permit program requirements, including the following:

- Receiving water quality assessment
- Monitoring
- Public education programs
- Enforcement.

SOURCE: *Combined Sewer Overflow Control Policy*, 4/19/94

Nonpoint Source (NPS) Program (CWA §319)

This program requires States to perform nonpoint source assessments of navigable waters of the United States. They must identify impaired and threatened waters, the activities causing impairment, and controls and programs necessary to address impairments. In addition, States must develop Nonpoint Source Assessment Reports and Nonpoint Source Management Plans that include an inventory of BMPs, a schedule containing annual milestones for program implementation, certification of adequate legal authority, and available Federal and State funding sources to be used. Under this program, many States

R0038496

VOL 12

5/88

have also developed State Priority Ranking Systems and undertaken monitoring programs to track progress.

Relationship to SWMP Implementation

Program information may be used by municipalities completing their storm water management programs for the following purposes:

- Assessing wetland boundaries
- Assessing the water quality of receiving waters
- Identifying major sources of impairment of receiving waters
- Identifying and implementing effective controls
- Prioritizing implementation of SWMP components
- Identify Total Maximum Daily Loads (TMDLs).

SOURCE: *Selecting Priority Nonpoint Source Projects*, EPA 506/2-89/003, pp. vi, 1, and *NATIONAL GUIDANCE, Wetlands and Nonpoint Source Control Programs*, U.S. EPA Office of Water Regulations and Standards, Office of Wetlands Protection, June 1990.

Coastal Zone Nonpoint Source Pollution Control (CZARA §6217)

The Coastal Zone Act Reauthorization Amendments of 1990 require States with existing coastal zone management programs to establish coastal NPS programs that must be approved by the National Oceanic and Atmospheric Administration (NOAA) and U.S. EPA. This program is limited to NPS pollution control in coastal areas and the contribution of inland sources of pollution to degraded coastal water quality. To secure an approved coastal nonpoint program, States are required to do the following:

- Coordinate with existing State programs, including State and local water quality plans and programs under sections 208, 303, 319, and 320 of the CWA
- Submit State coastal zone boundaries and section 6217 management areas to NOAA for review and modification, if necessary
- Implement management measures in conformity with section 621 7(g) of the guidance (referenced below) and additional measures where coastal water quality remains impaired.
- Provide technical and other assistance to local governments and the public for implementing additional management measures

VOL 12
5/89

R0038497

- Provide opportunities for public participation in all aspects of the programs and ensure that there will be administrative coordination among various State, regional, and local agencies
- Develop enforceable policies and mechanisms to implement the Coastal Nonpoint Pollution Control Program.

Relationship to SWMP Implementation

There are many similarities between nonpoint source program goals (under 319 and CZARA 6217) and NPDES program goals. Both programs address storm water runoff from areas of industrial activity, as well as new development, pollution prevention, and watershed management. However, these programs target different classes of discharges. For example, municipalities subject to NPDES permit application requirements are not subject to requirements under nonpoint source control programs, including CZARA §6217; small municipalities (under population 100,000) are currently covered under CZARA §6217. However, pursuant to §122.26(b)(4)(iii), the permitting authority is authorized to require an NPDES permit for any city under 100,000 that may currently be covered by CZARA §6217.

The distinction between point and nonpoint source programs becomes more problematic in relationship to industrial activities. While certain industrial activities are covered under the NPDES program (40 CFR 122.26(b)(14), many other activities fall under the purview of CZARA §6217. For example, construction activity that disturbs five or more acres or that is part of a larger common plan of development or sale is covered under the NPDES program, whereas construction disturbing fewer than five acres is covered under CZARA.

SOURCE: *Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters*, U.S. EPA, January 1993.

__Safe Drinking Water Act__

The Surface Water Treatment Rule (SWTR) of the Safe Drinking Water Act (SDWA) outlines requirements for watershed protection of surface drinking water supplies from urban runoff and nonpoint source pollutants. Municipalities using surface waters for drinking water supplies are required by U.S. EPA or the approved State agency to develop a watershed protection plan for such surface waters that includes the following: a watershed description, identification of physical watershed characteristics and

VOL 12

5/90

a description of activities potentially affecting water quality, a program to control pollutant sources (including implementation of appropriate BMPs), and an ongoing program to conduct monitoring.

Relationship to SWMP Implementation

The NPDES storm water management program and the Safe Drinking Water Act have many overlapping requirements, and municipalities are urged to share information between these two programs. Activities common to both include:

- Identifying critical areas and watersheds
- Determining watershed characteristics
- Identifying activities detrimental to surface water quality
- Implementation of control practices to address pollution sources.

SOURCE: *Surface Water Treatment Rule*, EPA 570/9-91-300, June 1991, and *Safe Drinking Water Act 1986 Amendments*, EPA 570/9-86-002.

Clean Lakes Program

The Clean Lakes Program sets goals for defining the cause and extent of pollution problems in the lakes of each State. Emphasis is placed on developing watershed assessments and effective technology that considers all point and nonpoint sources that affect lake quality.

Relationship to SWMP Implementation

Information developed under this program that may be useful to municipalities implementing SWMPs include:

- Identification of environmental conditions
- Description of the lake's sources of pollution and abatement actions to reduce the pollution caused by these sources

VOL 12

5/9/

- Monitoring data on receiving waters
- Alternative BMPs for pollution control.

SOURCE: *A Commitment to Watershed Protection, A Review of the Clean Lakes Program*, EPA 841-R-93-001.

404 Regulations/Wetlands Program

The Army Corps of Engineers and EPA jointly implement section 404 of the Clean Water Act, which regulates the discharge of dredged and fill material into waters of the United States, including most wetlands, and establishes a permit program to ensure that such discharges comply with environmental requirements.

Relationship to SWMP Implementation

Information available through this regulation may assist the municipality by helping to:

- Identify wetlands and delineate boundaries *(Corps of Engineers Wetland Delineation Manual*, 1987)
- Enforce SWMP restrictions on discharging fill materials
- Develop water quality standards specifically for wetlands.

SOURCE: *EPA WETLANDS FACT SHEETS #7, #9, #13, and #24* and *HIGHLIGHTS OF SECTION 404, FEDERAL REGULATORY PROGRAM TO PROTECT WATERS OF THE UNITED STATES*, EPA Office of Wetland Protection, October 1989, and *THE SECTION 404 PROGRAM*, EPA Office of Wetland Protection, 6-9/89.

National Estuary Program (NEP)

The National Estuary Program (NEP) focuses on point and nonpoint pollution in geographically targeted, high-priority, estuarine watersheds. Under this program, EPA assists State, regional, and local governments in developing estuary-specific comprehensive conservation and management plans that recommend corrective actions to restore and maintain estuarine water quality and to protect fish populations and other designated uses of these targeted waters.

Relationship to SWMP Implementation

Information obtained under the NEP may be helpful to the municipalities in their efforts to:

- Assess pollutant sources/loadings in particular watersheds
- Monitor trends in receiving water quality
- Implement public outreach elements of the program.

SOURCE: *The National Estuary Program After Four Years, A Report to Congress*, pp. 2-4, EPA 502/9-92/007, April 1992.

Federal Emergency Management Agency Regulations (FEMA)

FEMA works closely with local communities to identify flood hazard areas and flooding risks. Flood plain maps are also available through the agency.

Relationship to SWMP Implementation

Municipalities developing storm water management programs may use this information to:

- Effectively place structural controls
- Determine floodplains boundaries.

SOURCE: *Disaster Assistance Programs - A Guide to Federal Aid in Disasters*, Federal Emergency Management Agency, DAP 19/July March 1993, and *Answers to Questions About The National Flood Insurance Program*, Federal Emergency Management Agency, FIA-2/March 1992.

Pollution Prevention Act of 1990

The Pollution Prevention Act of 1990 established a national policy specifying that pollution prevention should be emphasized over pollution control or treatment. With this policy, Congress defined a pollution prevention hierarchy to be followed by all pollution reduction programs:

- Prevent or reduce at the source whenever feasible

- Where prevention is unfeasible, recycle in an environmentally safe manner

VOL 12

5/93

- Where prevention or recycling is not feasible, treat in an environmentally safe manner
- As a last resort, dispose of (or otherwise release to the environment) materials in an environmentally safe manner.

Relationship to SWMP Implementation

Management practices set forth in EPA's pollution prevention policy include public education, household hazardous waste collection, location and elimination of illicit connections to separate storm systems, reduction of roadway sanding and salting, and reduction of pesticide, herbicide, and fertilizer use. Many of these measures are required or suggested elements of the storm water management program and can, therefore, be implemented in conjunction with one another.

VOL 12

5/94

SUMMARY

Chapter 1 provided an overview of the NPDES storm water program and briefly summarized the remaining chapters. In particular, this chapter introduced the storm water management program planning, a seven-step process that involves establishing goals, collecting data, establishing priorities, and implementing the program. This planning process incorporates the requirements of Parts 1 and 2 of the NPDES municipal storm water permit application. Finally, this chapter examined the relationship between the NPDES program and programs addressing urban runoff management.

Chapter 2 will provide guidance for municipalities as they attempt to establish priorities for storm water management activities. The chapter will describe methods for ranking "problems" (i.e., pollutant sources and receiving waters) and ranking appropriate controls.

5/99

INTRODUCTION

The NPDES regulations require that municipalities develop storm water management programs to control storm sewer system discharges to the maximum extent practicable. But how do municipalities know what their biggest storm water runoff problems are? How do they know which solutions are most cost effective?

This chapter[1] is designed to help municipalities answer these questions by identifying sources of information to recognize the existing conditions of a watershed, suggesting ways to identify and prioritize sources of water quality problems, and evaluating the effectiveness of potential control measures. Municipalities have already complied some of this information as part of the application requirements. However, other watershed information was not included in the applications and will involve additional data collection activities. Using information available on watershed conditions will enable municipalities to set priorities for conducting storm water management activities. As information is gathered and analyzed, a municipality may find it will need to modify SWMP planning and implementation activities. This chapter also emphasizes the use of water quality models to determine this information. However, there are non-computer based methods for determining the benefits and impacts of different pollution prevention alternatives.

[1]Chapter 2 has been adapted in part from U.S. EPA, Office of Research and Development. *Urban Runoff Pollution Prevention and Control Planning*. September 1993.

ORGANIZATION OF THE CHAPTER

This chapter consists of 3 primary sections. The first section addresses methods for assessing problems and ranking them in order of importance. The second section of the chapter offers methods for evaluating and selecting controls to solve these problems. The criteria used to assess problems (e.g., consideration of public opinion, costs, goals) will often be similar, if not identical, to those used for selecting control measures. The third section includes case studies of municipalities assessing storm water runoff problems and evaluating/selecting appropriate BMPs.

As mentioned in Chapter 1, Steps 1 and 2 (setting goals and assessing existing conditions) are not extensively discussed in this manual because they were covered in the application guidance manuals; *Guidance Manual for the Preparation of Part 1 of the NPDES Permit Application for Discharges From Municipal Separate Storm Sewer Systems* (April 1991) and *Guidance Manual for the Preparation of Part 2 of the NPDES Permit Applications for Discharges From Municipal Separate Storm Sewer Systems* (November 1992). Readers should refer to these manuals for detail on Steps 1 and 2. This chapter addresses Steps 3 and 4. Step 3, assessing receiving waters and sources of any impaired conditions, is described below. Step 4 is discussed later in this chapter. Step 6, which addresses data collection programs, is discussed in Chapter 7.

STEP 3: ASSESS POLLUTANT SOURCES AND IMPACTS ON RECEIVING WATERS: RANK PROBLEMS

To determine the need for, and appropriate level of, pollution prevention and control measures under their SWMPs, municipalities need to assess and rank existing watershed conditions. To assess watershed conditions, a municipality must gather information concerning the physical, chemical, and biological integrity of the water bodies in its jurisdiction. This type of information can be accessed through numerous sources, including Federal, State, and local sources. Some of these sources are a biennial report (known as the 305(b) report) on water quality conditions; the State's listing of impaired water bodies (known as 304(l) listings) prepared by the State for submittal to EPA; State Nonpoint Source Assessments; Fish and Wildlife Service biological surveys; United States Geological Survey (USGS) sources, including maps, water quality and quantity data, and aerial photographs; water quality data compiled by State environmental agencies; Geographic Information System (GIS) data compiled by State or Federal agencies (e.g., EPA, Department of Agriculture, and Department of the Interior); as well as

VOL 12

information available by local park departments, health departments, public works departments, and local universities.

Information concerning watershed conditions that may have been collected as part of the application requirements includes the following:

Part 1

- Major outfalls and industrial contributions to the MS4
- Topographic map
- Rain and snowfall data
- List of receiving water bodies, with a description of water quality impacts
- Results of field screening analysis
- Existing storm water management activities.

Part 2

- Runoff sampling results
- Estimate of annual and seasonal pollutant loadings and event mean concentrations
- Estimate of expected reduction in pollutant loadings.

5201

Using the information collected from the sources listed above, a municipality must identify the watershed conditions in its jurisdiction. When identifying the problems, a municipality must consider the chemical, physical, and biological conditions of a water body and determine the degree to which flow volumes and/or associated pollutants led to impaired conditions. For example, when eutrophication occurs in a lake, excess nutrients are of concern. The municipality, in turn, needs to assess the problem, which in this case may be too much fertilizer reaching the water body through runoff. Another example may involve storm water flow resulting in bank erosion and/or changing the strata of the streambed. In large part, the traditional water quality program has focused on chemical impairments. However, in developing a storm water program, municipalities will also need to consider physical impairments.

Once the problems have been identified, they need to be assessed. While many different types of problem assessments may be conducted as part of the storm water management program, to simplify the process this chapter focuses on four major types:

R0038509

- Resource Assessments: Evaluating the extent to which these pollution sources adversely affect water resources
- Pollutant Source Assessments: Assessing the sources of urban runoff pollution in the watershed
- Institutional Assessments: Assessing existing BMPs, costs, public opinion, and technical feasibility
- Goals and Objectives Assessments: Evaluating whether program goals and objectives are being met.

Municipalities may establish criteria (such as those presented in Table 2-1) for assessing problems. Methods for assessing the problems can also be explored. A discussion of the most commonly used methods of problem assessment is presented under each of the four headings. Finally, methods for ranking problems using both quantitative and qualitative measures are explained.

Once storm water runoff problems have been fully assessed and ordered, municipalities will begin to screen and select BMPs (discussed in the second section of this chapter).

Resource Assessments

The critical element for ranking storm water runoff problems is assessing storm water effects on receiving water physical, chemical, and biological integrity and determining locations where preventive and corrective measures are needed.

Criteria To Consider

In assessing receiving waters, municipalities need consider the importance or value of a resource (with respect to such issues as aquatic habitat, recreational use, and public water supplies), the current and desired uses of a resource, and the degree to which a resource is impaired. Water resource values are reflected in a State's water quality standards. Municipalities should consider the following when evaluating which receiving waters need to be addressed by storm water control activities:

- Extent to which the waterbody is meeting its designated use
- Level of waterbody impairment due to pollution (chemical integrity), loss of aquatic habitat, or riparian or terrestrial area modification (physical integrity)

VOL 12

5202

TABLE 2-1. CRITERIA FOR ASSESSING POLLUTION PROBLEMS

<u>Resource</u>
- Existing use of the affected resource (type, status, and level of use)
- Designated use of receiving water
- Type and severity of impairment
- Relative value of resource affected

<u>Pollutant Source</u>
- Type of pollutant
- Pollutants typically associated with the source
- Source magnitude/pollutant loading
- Transport mechanisms to water resource (direct pipe, overland flow, or ground water)

<u>Institutional</u>
- Available resources and technologies
- Problems and opportunities
- Potential for solving identified problems
- Implementability of controls
- Applicable regulations
- Multi-agency responsibilities
- Costs of controls
- Funding sources and limitations
- Public perception

<u>Goals and Objectives</u>
- Water resource goals (water use objectives)
- Technology-based goals
- Land use objectives

Adapted in part from U.S. EPA, 1987.

- Relative value of resource from functional perspective, for instance, for aquatic habitat (biological integrity), recreation, and water supply

- Threat of waterbody impairment, habitat destruction, or terrestrial area destruction if no action is taken (i.e., new impairments are anticipated)

- Feasibility of implementing corrective or protective (e.g., pollution preventative) measures and achieving demonstrable results in the watershed

- Availability of information necessary to target waterbodies and watersheds and to develop and implement effective management strategies.

R0038511

Methods for Assessing Water Resources and Receiving Waters

Water resource assessments address the effect of storm water flow and associated pollutants on the water bodies of interest. Water resource assessments frequently involve taking the results of the pollutant source assessments described in the following part of this chapter and determining the effect of these pollutant sources on water resources. Water resource assessments may include chemical water quality assessments, as well as aquatic life assessments, sediment quality evaluations, and assessments of any other relevant conditions, such as streambed strata. The methods to perform water quality assessments can range from simple evaluations, involving the comparison of measured concentrations to water quality standards, to detection modeling, to more complex, mathematically based computer models. It is more than likely that sufficient State and local data exist to assess the chemical quality of the waters. It is less likely that State and Federal agencies have data on the physical and biological integrity of the water body of concern. Nonetheless, the municipality should work with the permit writer to access any available information. If necessary, municipal staff, perhaps with the assistance of local universities, can conduct biological assessments. EPA has issued a valuable guide to biological assessments entitled, *Rapid Bioassessment Protocols for Use in Streams and Rivers* (EPA/444/4-89-001) 1989.

Some municipalities may choose to use receiving water models to assess existing water quality conditions and to simulate future conditions of the water resource under various pollution prevention and control scenarios. These models can also be used to differentiate the impacts of sources from one another, thereby enabling the decisionmaker to make informal decisions concerning control options. Receiving water models can also be used to assess the impacts of alternative BMPs. These models receive input from runoff model results, field-measured parameters, and the values of parameters found in the literature. The level of complexity of the receiving water model chosen should parallel that of the model used to assess urban runoff flows and loads. Some commonly used receiving water models include the following:

- The Enhanced Stream Water Quality Model (QUAL2E)
- The Water Quality Analysis Simulation Program (WASP4)
- The Exposure Analysis Modeling System II (EXAMSII).

VOL 12

5204

These models are available from U.S. EPA's Center for Exposure Assessment Modeling, Environmental Research Laboratory, in Athens, Georgia. For further information, refer to *Urban Runoff Pollution Prevention and Control Planning*, EPA, 1993.

<u>Pollutant Source Assessments</u>

Using the Federal, Regional, State, or local sources discussed above, it can be determined which physical and chemical conditions are threatening the water bodies and/or their designated uses. Previous studies on water quality have indicated that certain pollutants are associated with a discrete number of sources. Some of these sources are more easily controlled at a local level than others. For example, controlling runoff from gas stations can be more practically controlled at the local level than can atmospheric deposition.

This section presupposes that municipalities are already aware, or can gain ready access to, information identifying the pollutants of concern. In still other cases, municipalities may be able to anticipate pollutants that may be of concern in the years ahead based on, for example, a knowledge of growth patterns. The purpose of this section is to help municipalities determine which sources they want to control based on impacts to water bodies. In heavily industrialized watersheds, for example, municipalities may want to control industrial sources by using detention ponds to filter runoff. In residential areas, municipalities may want to focus on non-structural measures, such as public education campaigns encouraging used oil recycling. In choosing a source to focus on, municipalities need to consider pollutant loading estimates for storm water runoff and to calculate such estimates on a sub-watershed basis.

Criteria To Consider

To evaluate which sources should be addressed first, municipalities will want to consider the range of pollutant characteristics and sources, the size of each source, the distance between the source and the receiving water, and the mode of pollutant transport. In keeping with the watershed approach, impacts should not be confined to exceedances of chemical criteria. Rather, flow impacts on the physical regime and biological community structure need also be considered. "High-tech" tools useful in evaluating criteria for assessing pollutant sources include geographic information systems (GIS) and urban runoff models. However, high-tech technologies are not essential to step 3. Hand-drawn maps and desk top calculators can be just as effective in problem assessment and solution identification. The criteria a municipality would consider when determining which sources to address include an estimate of pollutant loadings from the source and an estimated impact of that source on water quality conditions. Sources can be identified in an incremental fashion by targeting areas of the watershed first, then by further focusing on individual sources or source categories (e.g., large parking lots, service stations) within the sub-watershed. Other important criteria to consider include the use of environmental indicators. The discussion below relates the goals of storm water management programs to the use of environmental indicators to meet the goals.

Environmental Goals and Indicators for Storm Water Management Programs

The "seven-step" planning process for storm water management programs must identify both the overall and project-specific environmental goals for the program. Overall environmental goals include those identified in local watershed strategies, basin-wide plans, local ordinances, community local master plans, and State water quality standards, especially the narrative statements. Project-specific goals include specific actions that will be taken to ensure that the environmental goals will be met. Such specific actions can involve pollutant loadings reductions, bank stabilization, elimination of hydraulic disturbances, increasing the effectiveness of buffers, and other common activities. Environmental indicators are used to measure the progress in meeting the overall environmental goals. Tracking of the completion of the project-specific goals must also be done.

EPA has identified four overall environmental goals and specific objectives for the nation's surface and ground waters (Table 2-2). The two ultimate overall environmental goals are to (1) Protect and Enhance Human Health, and (2) Conserve and Enhance Ecosystems. These goals will be achieved by Improving Ambient Conditions and Reducing Pollutant Loadings (Table 2-2). There are a variety of types of indicators to consider which apply to all water management programs, including storm water, traditional point sources, CSOs, and nonpoint sources. A source to assist municipalities in targeting the use of indicators for specific management actions is the *Guidance for Specifying Management Measures for Sources of Non Point Pollution in Coastal Waters* (EPA 1993). Despite its title, this document broadly addresses specific actions for all types of storm water management in freshwater.

The following discussion provides a summary of the types of indicators available to meet the overall environmental goals and the specific objectives. We are not suggesting that all of these indicators must

TABLE 2-2. EPA's ENVIRONMENTAL GOALS, OBJECTIVES, AND INDICATORS

Environmental Goal	Objective	Indicator Type
Protect and Enhance Public Health	Safe Drinking Water	Meet Public Water Supply Designated Use
	Safe Aquatic Recreation	•Beach Closures

be measured. Indicators should be selected based upon the overall and specific goals of the project. For example, if contaminated sediments is not suspected to be a problem, then there is no need to routinely sample for sediment toxicity or chemistry. However, sediment toxicity and chemistry may need to be sampled in the future to help diagnose a problem. The Intergovernmental Task Force for Monitoring Water Quality is recommending a core set of parameters be measured in all water management programs followed by more detailed parameters to meet specific needs. Among those core parameters include basic water chemistry and physical measurements (temperature, pH, nutrients, solids), biological community measurements (benthic macroinvertebrates, fish, and/or algae), and physical habitat.

Human Health Indicators

Indicators for human health protection are fairly straightforward. These would include the measures used by the State to determine whether the designated use for public water supplies are met, as well as the designated uses for swimming and secondary contact use. These would typically include beach closures, if applicable.

Ecosystem Health Indicators

Determining the biological health, or integrity, of the communities inhabiting the surface waters requires more than just chemical and physical sampling. Even toxicological measures usually only account for a portion of the community effects due to other potential impacts such as habitat degradation, cumulative and synergistic effects of toxicants, and the conventional and other non-toxic pollutants. Two categories of indicators should be examined to measure progress towards meeting this goal: biological diversity and biological criteria or condition. Biological diversity measures usually are limited to determining the presence of threatened/endangered or rare species that may appear on State or Federal lists. Consultation with the State regulatory and natural resource agencies, The Nature Conservancy, and the National Biological Survey should reveal whether any "special status" species have been encountered in the area. Correction of storm water impacts could bridge important gaps in the natural range of special status species and reintroduce them into the management area.

Biological criteria, or condition, is monitored and assessed by most State regulatory, or natural resource, agencies. This process requires the collection of at least two assemblages, such as fish and benthic macroinvertebrates (and/or algae) and the results are compared with reference conditions developed by sampling least-impacted conditions within specific ecoregions, or by other means available to State biologists. States are working towards adoption of numeric biological criteria into their State water quality standard similar to that done by the State of Ohio, so measurements of the biological health of the waters should be a standard part of the program.

Ambient Condition Indicators

Improvement of ambient conditions can be measured in a number of ways. Table 2-2 shows the types of pollutants that could be monitored associated with various types of storm water management activities. This table summarizes the information in EPA's coastal zone guidance (EPA 1993), but for more detailed information not in this text, we encourage you to refer to the original document. The traditional approach for determining the improvement in ambient conditions is to compare the receiving water chemistry with State water quality standards or national criteria. However, this does not provide much information for determining the reduction in the extent of contaminated sediments. Conducting sediment toxicity testing is an effective screening tool for determining whether additional sampling and measurement of sediment chemistry is needed.

Pollutant Loading Indicators

This chapter addresses methods for assessing pollutant sources. It is important to document the reductions in pollutant loadings due to management activities to be sure that these activities resulted in measurable progress towards meeting the ultimate environmental goals. The success or failure of these activities can help us learn more about the effectiveness of best management practices.

Methods for Assessing Pollutant Sources

Once criteria have been developed to evaluate pollutant sources—including consideration of the type, magnitude, and transport mode of the pollutants (existing or potential)—the municipality can assess these sources. Pollutant assessments are frequently aimed at quantifying the source flows and pollutant loads under various conditions. Many municipalities may have already completed this step under their municipal permit application. Described below is one widely used assessment method for pollutants source.

Source Determination and Data Evaluation

Urban runoff pollution sources can be defined by completing a comprehensive watershed description that includes the following: the type(s) of pollution affecting a water resource, the pollutant transport mechanisms, the characteristics of drainage patterns and drainage structures, and the land uses in the program area. (Refer to Chapter 1 and the EPA Part 2 NPDES Guidance Manual.)

Those activities or land uses within a watershed that are, or potentially could be, causing pollution problems need to be identified. Both point source and nonpoint source discharges should be considered. Pollutant types found in the watershed can provide some clues regarding the source(s) of the problems. To isolate sources of pollution, it is helpful to divide the watershed into smaller areas so that individual pollution sources can be identified. Depending on the size of the watershed, a drainage basin can first

VOL 12

5209

be divided into subbasins. If necessary, subbasins can then be divided into individual tributaries, pipe systems, or drainage channels. Table 2-3 lists pollutant types typically associated with certain activities or land uses. This information can be used to identify potential sources. Problem sources can also be identified according to water resource conditions, such as eutrophication of a water body resulting from excessive nutrients, or closures of shellfish beds because of high concentrations of bacteria. In addition, sediments from aquatic systems and storm sewers can provide useful information for tracing and identifying potential sources (Livingston, 1991).

Computer modeling is valuable in quantifying the flows and loads of pollutant sources needed for pollution source assessments. Available models range from simple screening tools to numerical models with varying levels of complexity based on the number of processes incorporated and the level of detail provided. The level of application of a given model may also vary depending on the objectives of the analysis and available resources. Municipalities must keep in mind that modeling can be quite expensive and should only be used when the potential benefits justify their use.

In addition to the magnitude of a pollutant load and the location of a pollution source with respect to its receiving waters, the mode of transport to the receiving water and the degradation of the pollutant should also be considered. Sources with a clear path to a waterway, such as pipes, ditches, and gullies, often cause more adverse effects in a receiving water than similar sources that must travel through natural filters, such as forested or grassy areas, before entering a surface water body. Changes in loads, from the initial source discharge to the point where they affect the receptor, occur because of such factors as travel time, dilution, and decay. The fate and transport of pollutants can be modeled using hydrologic and pollutant buildup-washoff models that account for these factors. The more simple modeling methods (i.e., unit load or statistical) can only empirically estimate these factors, and, thus, the level of uncertainty and error is likely to be higher.

Models available for urban runoff assessments vary widely in their levels of complexity, ranging from simple estimation techniques to sophisticated and expensive computer models. Simple methods are compilations of expert judgement and empirical relationships between physiological characteristics of the watershed and pollutant export that can be solved by a spreadsheet program or hand-held calculator. These methods are often used when data limitations, budget, and time constraints preclude the use of more detailed models. Simple models frequently include information on land use, percent impervious factors, runoff coefficients, size of the drainage area, pollutant loading values, and rainfall data. The

Source: Morehouse, 1988.

Federal Highway Administration (FHWA) has made great strides in researching pollutant loadings from highway storm water discharges. FHWA has a number of models and statistical methods that municipalities may find useful in determining the benefits and impacts of various pollution prevention alternatives.

Mid-range models, on the other hand, attempt to compromise between the empiricism of the simpler methods and the complexity of detailed models. Detailed models use storm event or continuous simulation to develop historic time series of stormwater runoff and pollutant loadings and concentrations. These models often consider, among other factors, soil type and percent imperviousness factors. To select the model that will best achieve the project objectives, analysts need to consider the available required input data, watershed pollutant characteristics, and time and resources available (*Compendium of Watershed-Scale Models for TMDL Development*, June 1992).

Several models are available from EPA's Center for Exposure Assessment Modeling in Athens, GA. For more detailed information on urban and nonurban models, refer to the following publications:

- U.S. EPA, Office of Water. *Compendium of Watershed-Scale Models for TMDL Development*. EPA841-R-92-002. June 1992.
- U.S. EPA, Office of Research and Development. *Urban Runoff Pollution Prevention Planning and Development*. EPA/625/R-93/004. March 1993.
- U.S. EPA. *Guide to Nonpoint Source Pollution Control*. 1987b.

Example Models

The following discussion highlights a number of commonly used methods and focuses on models used to predict pollution characteristics in an urban environment. The methods include constant concentration or unit load estimates, preliminary screening procedure, statistical method, rating curve or regression approaches, and hydrologic and pollutant buildup-washoff models.

VOL 12

5213

Constant Event Mean Concentration or Unit Load Estimates

Constant event mean concentrations or unit pollutant loads can be used to estimate pollutant source loads. They can be obtained from available data or estimated according to the types and sizes of land uses in the watershed. Constant event mean concentrations can be coupled with runoff volume estimates to calculate runoff loads or can be used in hydrologic models to calculate time variable flows and loads. The constant event mean concentration or unit load method is easy to use and can be helpful in identifying which areas within a watershed contribute the largest pollutant loads. Constant event mean concentrations or unit loads can also be estimated using a spreadsheet. Where local resources allow, these calculations can be facilitated using a GIS to keep track of such information as pollutant concentrations from different sources, land use or source boundaries, and quantities of flow produced in individual areas. However, a GIS system is not necessary to prepare load estimates, and municipalities without access to such systems should use other methods.

Where actual measurements are not available, input data can be taken from the literature. For example, the U.S. EPA's Nationwide Urban Runoff Program provides a comprehensive study of storm water runoff from residential, commercial, and light industrial areas throughout the United States and contains a large data base of pollutant concentrations and loads measured during various storm events from 1978 through 1983 (U.S. EPA, *Results of the Nationwide Urban Runoff Program*, 1983). The Metropolitan Washington Council of Governments has published a manual entitled *Controlling Urban Runoff: A Practical Manual for Planning and Designing Urban BMPs* (1987). It recommends a simple method for calculating pollutant export from urban development sites. Included in this manual are recommended concentration values for phosphorus, nitrogen, COD, BOD_5, lead, zinc, and copper from new suburban sites, older urban areas, and a central business district.

Other data bases of storm water pollutant concentrations and loads include Driver and Tasker (1990), Tasker and Driver (1988). These data can be used as inputs to source load estimation techniques, such as the constant concentration or unit load method.

Preliminary Screening Procedure

Simple equations can be used to estimate annual average loading contributions of urban runoff for BOD, suspended solids, volatile solids, total phosphate phosphorus, and total nitrogen. Pollutant loadings can be estimated based on the relative contribution of pollutants from each land use; however, the equations are not location-specific and are only useful for screening purposes.

Statistical Method

The statistical method of modeling urban runoff assumes that event mean concentrations (EMC) are distributed log-normally and characterizes EMCs by their median values and their coefficients of variation. The U.S. EPA's statistical method (Driscoll et al., 1989) includes statistical properties of rainfall, area, runoff coefficients, median EMCs, and coefficients of variation of EMCs of various pollutants. The FHWA has implemented U.S. EPA's statistical method for various locations in the United States (Driscoll, 1989, and Woodward-Clyde Consultants, 1990).

Regression-Rating Curve Approaches

Rating curve or regression models, such as the 31 storm-runoff-load models developed by the USGS for metropolitan areas throughout the United States (Driver and Tasker, 1990, and Tasker and Driver, 1988), use site-specific rainfall, runoff, and water quality data, such as the data collected for U.S. EPA's Nationwide Urban Runoff Program and similar studies, to relate concentrations and loads of pollutants to flow rates and volumes (see Driver and Tasker, 1990).

Hydrologic and Pollutant Buildup-Washoff Models

Hydrologic and pollutant buildup-washoff models address the accumulation of pollutants during dry-weather periods and runoff of these pollutants during rainfall events. Of the many models available, some of the more widely used models that use a buildup-washoff mechanism include:

- Hydrological Simulation Program-Fortran (HSPF) (U.S. EPA, 1981); also described in (U.S. EPA 1991)
- Storm Water Management Model (SWMM) (U.S. EPA, 1988); also described in (U.S. EPA 1991)
- Source Loading and Management Model (SLAMM) (Pitt, 1989).

Institutional Assessments

In ranking urban runoff related problems, it is also essential to assess institutional constraints/capabilities for the regulators, owners, and the public.

Criteria To Consider

To assess institutional constraints/capabilities, municipalities may want to consider the following: applicable regulations, preferences of the local authorities and regulatory agencies, funding sources and limitations, multi-agency responsibilities and overlaps, and public acceptance of the program. The criteria a municipality would consider when considering which sources to target or which receiving waters to address include:

- Potential for solving the identified problem
- Degree to which existing resources, technology, or (municipal, State, Federal) programs could be used
- Potential for adverse effects due to a particular action
- Willingness of municipal agencies to take steps (use their tools and resources) to help address this problem
- Potential for combined action (involving government agencies, citizens, interest groups, or nongovernmental organizations) in conducting storm water management activities
- Extent to which there are existing programs/activities to support measures required under the SWMP
- Implementability of controls in a particular area
- Level of public support for a) protecting a given resource, b) developing a particular program measure, or c) funding recommended controls
- Availability of funds to undertake a particular project
- Extent to which regulatory/permit requirements are satisfied.

Methods for Assessing Institutional Constraints/Capabilities

The institutional issues of a program are assessed by evaluating the program's potential and limitations and by reviewing the requirements of involved agencies and the public. One major institutional issue that must be addressed by an urban runoff program is determining the responsibilities of each involved party. This is especially true for programs involving multiple agencies. Interviews and meetings with all interested parties can be conducted to help develop institutional criteria. Questionnaires can be prepared and distributed to help identify concerns. Complaints, either filed with local authorities or available through public interaction programs, can help develop urban runoff pollution prevention and control programs to be implemented later.

Issues related to the control of the program, such as enforcement, maintenance, permitting, and funding, can affect the program's emphasis and the selection of its corrective measures. Another institutional issue involves the limitations of available technology. Implementability of controls may also be considered, particularly in areas involving limited access to private properties. In addition, the potential for eliminating or reducing an urban runoff problem or improving affected water resources can be considered. Public questions and concerns can be influential during the decision-making processes. Applicable regulations and permit conditions may force the sequencing of corrective measures so that those addressing compliance with the regulations or permit conditions are implemented first.

<u>Goals and Objectives Assessments</u>

Finally, municipalities should evaluate storm water runoff problems with respect to current and future goals.

Criteria To Consider

Municipalities will generally want to focus on those problems where preventive or corrective measures would provide the greatest benefit. One goal, for example, might be to increase the use of public beaches by decreasing bacteria counts and aesthetic nuisances associated with storm water events. Application of goals and objectives criteria could identify where corrective measures would provide the greatest benefit, perhaps at beaches only slightly degraded and needing only minimal cleanup before they are restored, or at beaches in heavily populated areas where many people could benefit from restoration of the water body. Criteria a municipality may consider when considering which sources to target or which receiving waters to address include:

VOL 12

5217

- Potential for achieving water resource goals as described in the water quality standard
- Potential for realizing short-term benefits, thereby building good will and commitment to long-term objectives
- Consistency with other land use objectives
- Consistency with programmatic goals of SWMP
- Opportunity to maximize efforts by coordinating activities with other agencies.

Methods for Assessing Attainment of Goals and Objectives

The relative importance of an urban runoff problem may be assessed by comparing that problem to the program's water resource and technology-based goals and objectives. By considering pollution problems in connection with the program's goals and objectives, the program team can identify and focus on the urban runoff problems most important in attaining the overall aims of the program. The assessments conducted on pollutant sources, water resources, and institutional aspects provide input to these determinations.

How to Rank Storm Water Runoff Problems

Municipal storm water pollution problems can be numerous, and funding to correct these problems is usually limited. It is desirable, therefore, that a priority list of sources or impacts be developed to allow for targeting of limited resources. Ranking is a subjective process that requires the judgement of decision-makers. A ranking methodology can range from simple, descriptive methods (qualitative) to numerically complex (quantitative) methods, depending on the requirements of the urban runoff program objectives and the constraints of program funding. Ranking methods can be applied to a variety of geographic areas, ranging from counties or communities with multiple watersheds or individual water bodies or pollution sources.

A ranking methodology is developed for a specific study area to encourage a phased approach and to ensure the optimal allocation of available resources. Several methodologies can be used to rank pollution problems for control, depending on the complexity of the watershed, water resources, and their problems.

Criteria such as those presented in Table 2-1 can be used in problem ranking. Ranking should be conducted following consultation with involved parties, including local, State, and Federal agencies, local environmental groups, and concerned citizens.

VOL 12

Qualitative Rankings

The simplest approach is to use qualitative rankings, such as high, moderate, or low, to prioritize pollution problems. Table 2-4 provides an example of such a ranking system. The assigned ratings must then be interpreted to determine which areas should receive the highest priority as appropriate controls are developed. The use of rating points or categories can allow all the criteria to be evaluated on an equivalent basis. For each problem, the ranking criteria can be assigned relative ratings of 1 to 10, with a higher rating indicating a higher priority. In Table 2-4, the criteria used to gauge which area should receive highest priority for storm water management include imperviousness of the site, land use, runoff coefficient, annual runoff volume.

Quantitative Rankings

To perform numerical ranking, a rating is assigned to each ranking criterion for each problem. The assigned ranking for a criterion can then be multiplied by its relative weight for each pollution problem. All of the products (Criterion Ranking × Relative Weight) should be summed for a given problem. This procedure is then repeated for all problems being evaluated. The sums thus assigned should be compared, and the problems with the highest sums should receive the highest priority during implementation of urban runoff controls. An example of numerical ranking is given on page 2-23.

5219

An important point for municipalities to consider when using the rankings is that the ultimate goal is to address their specific water quality problems. For example, in a given municipality, stream scouring may be a bigger problem than eutrophication. In this case, the municipality would weigh runoff volume heavier than nutrients in runoff.

STEP 4: SCREEN, RANK, AND SELECT CONTROLS

Once particular waterbodies and sources have been targeted for action (based on the criteria discussed in Step 3), the municipality's task is to determine the most cost-effective solutions to solve the identified problems. This section discusses the tools needed to prioritize and rank solutions or control measures in relationship to program goals.

VOL 12

EXAMPLE: NUMERICAL RANKING SYSTEM

The following is an example of a numerical ranking system for prioritizing pollution sources. A hypothetical application of this weighted ranking methodology uses the following criteria: water body importance (as reflected by stream or lake size), type of use (ranging from urban drainage to recreational contact), status of use (impaired versus denied), level of use (low, moderate, or high), pollutant loads (not actual loads but estimates for comparative purposes), and implementability of controls (based on institutional factors, existing ordinances, or technical considerations). The criteria used for this example are similar to those identified in Table 2-1. Other criteria may be just as valid. The relative importance of the ranking criteria is designated by assigning each criterion a weight appropriate for the site-specific conditions of the watershed under consideration. The sum of all weights used to rank the problems equal 100. Next, for each problem, the criteria are ranked using a suggested range of 1 to 9, with a higher numerical ranking indicating a higher need for corrective action. This listing allows relative comparisons to be made among problems with respect to a single criterion.

This numerical ranking method for prioritizing pollution problems is illustrated in the hypothetical urban watershed (below) which consists of three streams and several types of land use (Figure 2-1). Information describing the system is presented in Tables 2-5 and 2-6. Typical sources for these data include site-specific pollutant loading data, model results, and literature values from such projects as the NURP study. For this example, the three "use" criteria are clustered together as subcriteria of a "beneficial use" criterion. There are, thus, four prioritization criteria of equal weight: stream size, beneficial use, pollutant load, and ability to implement (Table 2-7).

Ranking for "stream size" is determined according to the total drainage area of each of the three streams. Consistent with the goals for the hypothetical watershed, Stream C is ranked highest with respect to "type of use" because of its recreational uses in the city park, Stream B receives the lowest ranking because it is used mainly as an urban drain, and Stream A is ranked between the other two streams because it is used to support aquatic life. With respect to "status of use," Stream A ranks highest because although somewhat impaired, it has the potential to be improved by control of pollution sources. Stream B receives a low ranking for use status because its water quality is poor and its function as part of an urban drainage system has long been accepted. Stream C also receives a low ranking for use status since the water is of high quality. Rankings for "level of use" reflect the number of people using or affected by each stream.

Mass pollutant loadings are calculated based on runoff coefficients (functions of the amount of impervious area), runoff concentrations of pollutants, and the amount of land use type in each stream's drainage area. Each stream is ranked based on the proportion of pollutant load from its watershed (in this example, total suspended solids is used). The watershed of Stream B is judged to be easiest to implement controls because it is predominantly industrial. Based on the method presented in this example, the watershed of Stream C should receive priority during implementation of controls, followed by the watershed of Stream A and then that of Stream B.

Selecting BMPs for preventing and controlling storm water runoff pollution is a two-step process. First, a comprehensive list of BMPs should be compiled and screened to eliminate those that are inappropriate for the program. The appropriate BMPs are then assessed to select those that will ultimately be implemented in the SWMP.

The construction of facilities to collect and treat urban runoff may be prohibitively expensive. Therefore, the emphasis of storm water pollution control should be on developing a cost-effective approach that includes nonstructural controls and low-cost structural controls. Nonstructural controls include both regulatory controls (e.g., pollution prevention measures and land use controls) and source controls (e.g., controls that reduce pollutant buildup or lessen its availability for wash-off during rainfall). Low-cost structural controls include the use of facilities that reduce pollutant loads through infiltration or biological degradation. Given below is a list of the types of controls and BMPs available to municipalities for managing their storm water runoff (discussed in detail in Chapter 5).

EXAMPLES OF SOURCE CONTROL AND TREATMENT BMPs
Regulatory Controls • Land use regulations • Comprehensive runoff control regulations • Land acquisition
Source Controls • New development controls • Illicit discharge controls • Illegal dumping controls • Materials management controls (fertilizers, chemical storage and use) • Street/storm sewer maintenance controls • Spill prevention and cleanup • Public education/pollution prevention
Treatment Controls • Detention facilities • Infiltration practices • Vegetative practices • Filtration practices • Water quality inlets • Retrofitting existing flood control facilities

How to Screen BMPs

The goal of the BMP screening process is to reduce the list of BMPs to a more manageable number to be considered for implementation. Because this is an initial step, the methods used are generally qualitative and require that good engineering judgement be exercised.

For the purposes of screening, BMPs are divided into two general categories: structural and nonstructural. Structural BMPs, such as detention ponds and infiltration practices, are designed to address specific pollutants from known sources. In contrast, nonstructural BMPs, which include regulatory practices (such as those that limit impervious areas or protect natural resources) and source controls (such as street sweeping or solid waste management) are typically implemented throughout an entire community, watershed, or special area to be protected. Municipal storm water management programs will, in most cases, rely on a combination of both structural and nonstructural practices. Methods for screening these

VOL 12

5225

two types of BMPs are outlined below. Chapters 5 and 6 present detailed guidance on implementing structural and nonstructural BMPs.

Nonstructural Practices

Nonstructural BMPs are a good solution when limited funds are available. In addition, these BMPs can perform an auxiliary role to a structural BMP. Many low-cost techniques can lead to significant improvements in water quality. Urban storm water management programs typically include a number of nonstructural BMPs. For example, an urban runoff management plan for the Santa Clara Valley identified more than 100 separate potential nonstructural BMPs used throughout the county (Woodward-Clyde, 1989). To reduce the large number of available BMPs, municipalities must screen these regulatory and source control BMPs for their appropriateness to the watershed. The case study at the end of Chapter 2 discusses the Santa Clara Valley program and the BMP screening and selection method.

One screening method involves applying screening criteria to each nonstructural practice to determine its applicability to the conditions in the watershed. The screening criteria will be specific to the watershed and will depend on the goals of the program. Typical criteria include:

- Pollutant Removal: Different regulations and source control practices are designed to address different pollutants and, therefore, the program team should ensure that the screened list of controls includes those practices designed to address the pollutants of primary concern. Certain source control measures (e.g., development of a public information program) may not be measured in terms of reduction in pollutants loads. Therefore, municipalities may want to use alternate measures, such as the level of public participation in recycling programs or the number of community outreach activities completed.

- Existing Government Structure: Some practices implemented throughout the country require a specific government structure. For example, a strong county government may be important for implementing a specific regulatory control. However, the role of county governments can vary from one section of the country to another. Practices requiring specific government structures that do not exist in the area of concern could, therefore, be eliminated from the list.

- Legal Authority: For regulatory controls to be effective, municipalities must have the legal authority to implement and enforce regulations. Municipal boards and officials may lack this authority and may be required to obtain it through local action.

- Public or Municipal Acceptance: It may be difficult to implement some practices because of resistance from the public or an involved municipal agency. An improved communications strategy or other appropriate measures may improve the perception of these practices.

- Technical Feasibility: Some of the municipal BMPs described may require large expenditures, extensive efforts, and long-term operation and maintenance costs. Therefore, they may not be suitable for implementation in small municipalities that lack the required resources.

Additional screening criteria may also be used, as shown in the Santa Clara Valley case study at the end of Chapter 2.

Another method of screening involves the use of a comparative summary matrix, an example of which is presented in Figure 2-2. This matrix was developed for screening nonstructural control practices in coastal areas; however, it is at least in part applicable to inland areas as well. In this matrix, various regulatory and source control practices are listed and compared for their ability to meet various criteria. The criteria listed generally include ability to remove specific pollutants, such as nutrients and sediments, maintenance requirement, longevity, community acceptance, secondary environmental impacts, costs, and site requirements. Other criteria are also listed, and some of these are only applicable in coastal areas. For each practice and criterion, an assessment of effectiveness is indicated, with the solid circle indicating high effectiveness and the open circles indicating low effectiveness. This type of matrix may provide a basis for making an initial assessment of practices and their applicability to the program.

Structural Practices

Because structural practices generally are more site-specific and have more restrictions on their use than nonstructural practices, the initial screening step for these practices can be more precise than the initial screening step for nonstructural practices. Table 2-8 outlines some of the more important criteria for screening structural BMPs, including their pollutant removal efficiencies, land requirements, the drainage area that each BMP can effectively treat, the desired soil conditions (e.g., soils favorable for infiltration), ground water elevation, and costs. By using these criteria and the information obtained in the data collection and analysis and problem identification and ranking steps, the program team can narrow the choice of BMPs to a list that can be further assessed in the BMP selection step.

The initial screening criteria for structural practices include the following:

- Pollutant Removal: It is important for the municipality to ensure that the BMPs selected address the primary pollutants of concern to the level of removal desired.

VOL 12

- Land Requirements: Large land requirements for some of the above-ground structural BMPs can often restrict their use in highly developed urban areas.

- Drainage Area: The structural BMPs listed in Table 2-8 are used primarily to treat runoff from watersheds extending to 50 or 60 acres. Drainage areas above this size might have to be treated by locating BMPs in sub-watersheds.

- Soil Characteristics: Structural BMPs have differing requirements for soil conditions. Infiltration facilities generally require permeable soils, while detention BMPs generally require impermeable soils. The municipality must become familiar with soil conditions in the watershed.

- Ground Water Elevation: The ground water elevation in the watershed can be a limiting factor in siting and implementing structural BMPs. Generally, high ground water elevation can restrict the use of infiltration facilities.

- Public Acceptance: It may be difficult for a municipality to implement a structural BMP that meets with general public approval. Public acceptance of the BMP is an important consideration in the screening step.

- Technical Feasibility: Some of the municipal BMPs described may require large expenditures, extensive efforts, and long-term operation and maintenance costs. Therefore, they may not be suitable for implementation in small municipalities that lack the required resources.

Of the screening criteria listed, the pollutant removal, land requirements, and drainage area served are usually absolute restrictions. Soil condition and ground water elevation, on the other hand, impose restrictions that can potentially be overcome by importing needed soil or constructing facilities with clay liners to restrict ground water inflow. These modifications, however, can add significantly to BMP costs.

5231

BMP Selection Process

Having screened the initial list of BMPs, municipalities can now rank and select a final set of BMPs using the decision-making process (Figure 2-3) described below. This process evaluates the relative merits of each BMP or group of BMPs. Because of the complexity of urban runoff control problems, a number of factors must be taken into account in assessing alternative plans. These are presented in Figure 2-3 as inputs to the decision process and include analysis tools and decision factors. The analysis tools are those used to assess and rank the existing pollution problems (see beginning of Chapter 2). The decision factors are the criteria used to compare the alternatives. All of these inputs are then used to evaluate the alternatives using one or more decision analysis methods. The following discussion discusses each input

R0038539

to the decision analysis, then describes the various decision analysis methodologies that may be used to select BMPs for ultimate inclusion in the SWMP.

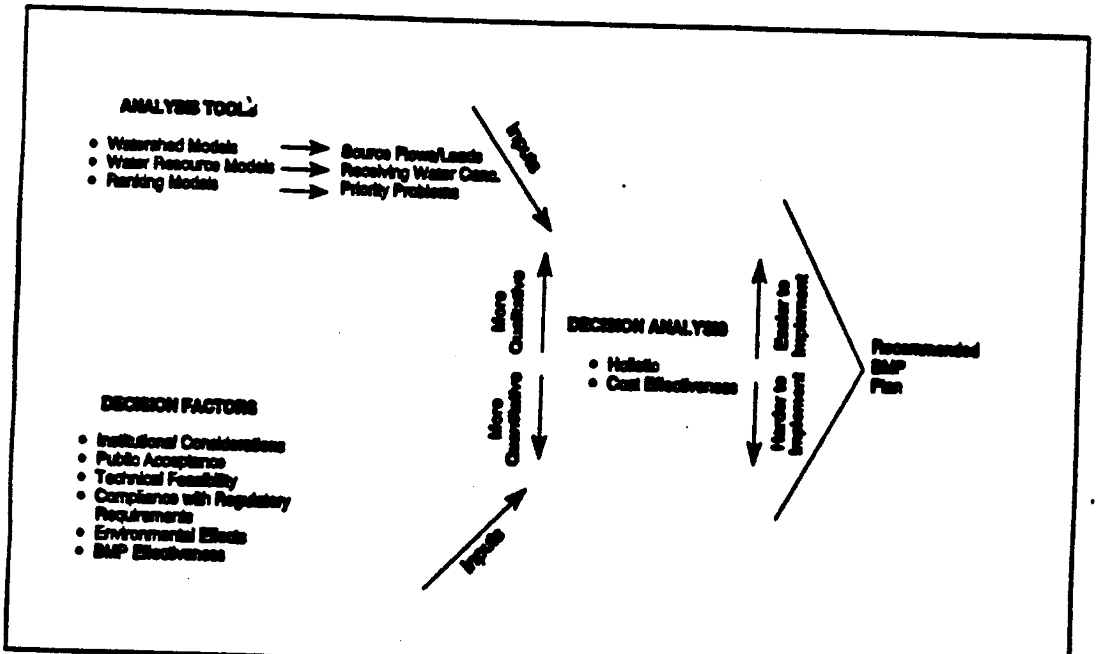

FIGURE 2-3. CONCEPTUAL DIAGRAM OF BMP SELECTION METHOD

Analysis Tools

These tools were described in detail during the discussion of Step 3. They can consist of watershed models, receiving water models, and ranking models. The analysis tools are used to project future conditions, given the alternatives being investigated. For example, the total pollutant loads for each alternative may be calculated (whether using a unit load method or complex models, such as SWMM). This will serve as one item of input information as the alternatives are being compared. Similarly, the impacts to receiving waters may be assessed using these tools, so that the impacts can be compared when making a decision.

Criteria for Decisionmaking

An important step in BMP plan selection is to determine the decision factors of importance. The selection of these criteria is site-specific and needs to be determined by the program team based on the characteristics of the watershed and the financial and personnel resources available. Typical decisionmaking criteria are discussed below. Note that they are similar to the problem assessment criteria use in Step 3.

Institutional Considerations

To evaluate and select appropriate BMPs, municipalities may want to consider a number of institutional factors, including existing governmental structures, legal authority, and implementation responsibilities. If the proper legal authority does not exist, an analysis for attaining this authority must be undertaken (as required under Part 2 of the application). In addition to these considerations, the team should investigate existing urban runoff programs in the community, region, or State. Often, cost savings are realized and total program efforts reduced by taking advantage of material and data compiled from existing programs. It should be noted that these decision factors are similar to the assessment criteria used to rank pollution problems. Factors to consider when ranking BMPs are:

- Degree to which existing technologies or programs (municipal, State, Federal) could be used
- Availability of tools (technical methods and measures) to address adverse side effects of a particular action
- Extent to which legal authority exists to implement the BMP.

Public Acceptance

In many instances, the public will be responsible for at least a portion of the funding required to implement the recommended plan. Public reaction to aspects of the storm water management program should, therefore, be assessed through the use of public meetings. Measuring public acceptance can be difficult, but is often important to the overall success of a program. The main factors to consider are:

- Level of public support to address problems
- Level of public support for implementing a particular BMP
- Public perception of the value of the resource.

VOL 12

5233

Technical Feasibility

Cost is one of the most important factors to consider when selecting BMPs. Municipalities should consider the costs associated with both the development and implementation of nonstructural BMPs and the construction and operation of structural BMPs. Total costs should be reflected in addition to capital and operation and maintenance costs for each alternative. The benefits associated with the implementation of a control plan are usually more difficult to determine. For example, if an urban runoff control plan is designed to reduce the discharge of fecal coliform to a closed shellfish area, there will be monetary benefits when these beds are reopened. These benefits are difficult to quantify but should not be neglected when selecting BMPs. The factors to consider are:

- Relative costs for a particular BMP
- Availability of funds (capital) to initiate the project
- Availability of funds to operate and maintain BMPs over time.

Construction Issues

In evaluating and selecting BMPs (particularly structural BMPs), municipalities should consider various aspects of construction, including site requirements, the extent of disruption, and the degree of construction difficulty. When relying on complex structural controls, there are difficulties inherent in construction and future maintenance that need to be overcome. Construction issues are not as important when assessing source control and regulatory control practices. However, for structural controls, they can often be very important. The factors to consider include:

- Land requirements
- Soil requirements
- Ground water elevation.

Compliance With Regulatory Requirements of the SWMP

BMPs should also be assessed on their capacity to meet the regulatory requirements of the SWMP. For example, as part of the SWMP, municipalities must prevent illicit discharges from entering the storm sewer system. In addition, they must control discharges into their storm sewer systems from industries. BMPs that work toward achieving these programmatic requirements would be assigned higher priority

VOL 12

5234

than those that do not. Priority considerations and pollution sources should be the focus of the selected alternative. The factors to consider are:

- Extent to which regulatory requirements are satisfied
- Extent to which specific programmatic measures of the SWMP are satisfied.

Environmental Effects

The implementation of pollution control measures for storm water runoff can affect the environment in a number of ways. When evaluating various BMPs, municipalities should consider the potential effects—both positive and negative—that may result from their implementation. The many resources that can be positively affected include water resources, aquatic animal and plant life, wildlife, and wetlands. The negative environmental effects, which can include aesthetic problems, cross-media contamination, the loss of useable land, and wetlands impacts, may also be considered.

The importance of considering BMP side effects is becoming more widely recognized. Indeed, there is a shift away from viewing BMPs simply in terms of their pollution control ability. Incorporating structures into new developments or retrofitting them in existing areas can gain wider acceptance if aesthetic qualities are considered. For example, unvegetated above-ground infiltration basins or extended detention basins are generally not attractive elements of the environment and may serve as insect breeding grounds. However, natural-looking wet ponds or vegetated wetlands can be incorporated into the environment and even improve aesthetics. These are issues that can greatly affect public acceptance. The main factors to consider are:

- Potential for positive effects of BMP on the community (e.g., property value, aesthetics), water resources, aquatic animal and plant life, wildlife, or wetlands
- Potential for negative effects due to BMP, such as aesthetic problems, cross-media contamination, the loss of useable land, wetlands impacts, operation and maintenance costs to the community (taxes).

Secondary environmental impacts from municipal BMPs most often affect wetlands because of the role they play in storm water management. Wetlands are used in the treatment of urban storm water discharges within a storm water management program. The impacts of urban storm water discharges on

VOL 12

5235

wetlands include degradation of wetland hydrology, wetland water quality, wetland soils, and wetland plants and animals. As a result of urbanization, wetland hydrology is affected by the increased quantity and poor quality of the storm water discharges. The impacts to wetland hydrology include lower wetland response time, change in water levels in the wetland, and a change in the wetland's detention time. The changes in wetland water quality that result from urban storm water runoff are physical and chemical. The physical changes occur in temperature, conductivity, and the level of suspended solids. The chemical changes result from the increased levels of toxics, metals, and nutrients contained in the storm water runoff. Impacts to wetland soils include changes in the pH and redox potential. The combined results of the above impacts negatively affect plants and animals in the wetland. The increased levels of storm water runoff can flood plants and the feeding and breeding grounds of many animals. Also, the toxicity levels in storm water runoff may kill plants and other food for animals within the wetland habitat.

BMP Effectiveness

Estimating the effectiveness of a BMP is one of the most important factors a municipality will consider as part of the BMP selection process. In most cases, determining BMP effectiveness for structural controls is easier than for nonstructural controls. Structural controls (e.g., detention facilities and infiltration basins) may be assessed in terms of their demonstrated capacities to remove pollutants (see Chapter 5), whereas nonstructural controls (e.g., street sweeping, land use regulations, and solid waste management) may be evaluated according to indirect measures, such as the degree to which public awareness is heightened or the number of community outreach programs that are implemented.

Some municipalities may choose quantitative, decision analysis techniques to assess BMPs, whereas others may prefer to use more basic qualitative assessments backed by basic statistics, such as cost-effective data. While qualitative factors may be subjective by their very nature, the need for more quantitative, decision analysis models may be unnecessary during the early steps of BMP selection.

One type of qualitative analysis involves a holistic approach, which relies on the use of certain basic facts, intuition, and professional judgment. One key deciding factor (cost, for example) can guide the process. Given the inherent complexity of assessing alternative urban runoff control plans and the large number of available inputs to the decision, this approach is usually over-simplified. The selection of an appropriate plan from the developed alternatives will generally require an assessment of multiple factors and should be done in as quantitative a manner as is reasonably possible.

VOL 12

5236

Quantitative approaches include such measures as cost-effectiveness analyses. A cost-effectiveness analysis helps the municipality attain a predetermined goal with the least expensive method possible.

SUMMARY

The process of targeting storm water runoff problems and selecting BMPs to control those problems is difficult and can best be performed by undertaking a systematic assessment process. Because of the qualitative nature of some inputs to these assessments and decisions, subjective comparisons among the alternative plans will likely be necessary. Where cost-benefit issues need to be addressed, or where technically complex cases are encountered, more quantitatively based, analytical tools may be necessary. The process outlined in this chapter acts as a guide for decision making and cannot account for all of the circumstances that might be encountered. Professional judgment and care is needed at each step along the way. Once these choices have been made and BMPs have been selected, the storm water management program is ready to be implemented.

WORKSHEETS

The next two pages contain worksheets developed for the *State of California Storm Water Best Management Practice Handbook (Municipal)*. These worksheets may be useful in setting priorities for selecting municipal source and treatment controls.

WORKSHEET 1
SOURCE CONTROL BMP

PROGRAM ACTIVITIES:

PROGRAM ELEMENTS:

BMPs	Meets Regulatory Requirements (1 - 5)	Effectivenes s of Pollutant Removal (1 - 5)	Public Acceptance (1 - 5)	Implementable (1 - 5)	Institutional Constraints (1 - 5)	Costs (1 - 5)	Total (30 MAX)

WORKSHEET 2
TREATMENT CONTROL BMP

Pollutants of Concern	BMPs	Area of Application (Ac)	Annual Pollutants Removed (Lb/Yr)	Annual Capital Costs[1] ($/Yr)	Annual O&M Cost[2] ($/Yr)	Annual Admin. Costs ($/Yr)	Total Annual Costs ($/Yr)	Removal Cost[3] ($/Lb)

[1] Annual capital costs based on a 20-year design period.
[2] Annual administration costs are best determined by a given community once a city-wide program is established.
[3] Removal costs are in units ($/Yr)/(Lb/Yr) = $/Lb.

CASE STUDIES

The following case studies provide examples of methods for both assessing storm water runoff problems and evaluating/selecting appropriate BMPs to address those problems.

This section summarizes the Virginia Beach, Virginia, Part 2 Storm Water permit application. The example illustrates the overall program priorities considered by Virginia Beach for the initial implementation of its storm water management program.

Program priorities were developed based on a qualitative approach rather than a rigorous quantitative approach using specific evaluation criteria that are assigned values and weights. Priorities, however, were considered by evaluating each activity listed in Table 2-9 using the following guidelines:

- Level of pollution load reduction (if high, then higher priority)
- Cost (if low, then higher priority)
- Public acceptance (if high, then higher priority)
- Type of program (if ongoing program, then higher priority than enhanced ongoing program; if new program, then lower priority than existing program; if program designed to meet a minimum requirement not presently undertaken by city, then a higher priority)
- Type of development (if program for new development, then higher priority than for program for existing development).

Using these guidelines, the first priority programs and the second priority programs were selected and are presented in Table 2-9 under the heading Priorities with either a "1st" priority or a "2nd" priority indication.

<u>Schedule</u>

Figure 2-4 shows an overall schedule for the program activities listed in Table 2-9. Many of the ongoing programs (e.g., BMP Reinspection Program) and some of the new programs (e.g., implementation and enforcement of new storm sewer system ordinance) will be fully implemented during each year of the term of the permit. Other programs will require phased implementation (e.g., development of a slide show for reporting illicit discharges), and still others will be developed during the middle years of the program (e.g., evaluation of any existing major flood control structures for water quality benefits). For some programs, the schedule indicates the number of ponds, structures, and sites to be considered (e.g., ongoing field screening for up to 25 new sites a year) for each year of the permit. The frequency (e.g., once a year) of monitoring and specific inspection programs are also indicated on the schedule.

<u>Program Evaluation</u>

During the term of the permit, the city, principally through the Department of Public Works, will monitor the progress of implementing the components of the comprehensive management program and the representative monitoring program. As part of this process, the city will evaluate the pollution removal/control effectiveness of the various program activities. For commercial and residential areas, the comprehensive storm water management program will be tracked and evaluated in light of the new and existing ordinances related to storm water quality. The expanded BMP data base will be monitored to assure that new data on structural BMPs are being used by the BMP reinspection program to assist in the maintenance schedule for structural controls, including major sediment removal.

Criteria for Prioritizing Basins

The primary objective of King County's watershed approach is to protect and maintain the integrity of County stream systems and to prevent their degradation to the degree possible.

King County's philosophy is that stream protection must be accomplished through the evaluation and management of land and water within the entire watershed; that erosion cannot be managed without controlling the high flows that cause erosion; that water pollution cannot be adequately reduced without controlling the runoff and sediment, by which pollutants are transported; and that aquatic habitat cannot be managed without considering all of the chemical, physical, and hydrological elements that define each habitat.

Accordingly, criteria for prioritizing watersheds were developed to give planning urgency to those basins where hazardous conditions, such as landslides and flooding, were most frequent/severe and where water quality and habitat have not been severely affected (and could yet be preserved through proactive planning).

The initial basin planning prioritization was based on a significant body of knowledge gained from the 1987 Basin Reconnaissance program, a field inventory of problems and potential solutions conducted during the rainy seasons of 1985-1986 and 1986-1987. Multidisciplinary teams noted existing problems and features in portions of 29 service area basins. These data were used directly to determine ratings for each basin in four major categories: Existing Problems, Future Problems, Existing Resources, and Urgency/Timeliness. Rating criteria were associated with each major category, as listed in Table 2-10 below.

TABLE 2-10. BASIN PLANNING PRIORITIZATION CATEGORIES AND CRITERIA*

Category	Criteria
Existing Problems	- Landslides - Erosion/Sediment - Flooding
Future Problems	- Land in Unincorporated King County - Subdivision/Plat Activity - Population Growth - Permitted Residential Units
Existing Resources	- Stream Habitat - In-Stream Resources - Wetland Value - Wetland Storage Potential - Water Quality Potential
Urgency/Timeliness	- Other Agency Interest - Opportunity to Integrate with Other Programs

*Taken verbatim from the Part 2 NPDES Storm Water Permit Application prepared by the King County Surface Water Management Division (1992)

Problem counts for each category were generated from the Technical Appendix of each Basin Reconnaissance report (included with the Part 1 permit application). For example, for the Landslides, Erosion/Sedimentation, and Flooding categories, the following ratings were applied: "0" - low (few problems), "1" - moderate (some problems), and "2" - high (many problems). For other criteria, such as Water Quality and Stream Habitat, opposite

R0038554

scores were assigned: "0" - low quality (many problems), "1" - moderate (some problems), and "2" - high quality (few problems).

Tables 2-11 through 2-14 show the final scores of each basin for each major category. Table 2-15 shows the ranking of basins according to total scores. These rankings form the basis of the proposed basin planning schedule shown in Table 2-16.

By the end of 1992, the County will have completed, or will be substantially underway, with basin plans for 12 of the 37 basins in the surface water management service area. As expected from the ranking criteria, the first basins selected for planning services were predominately rural watersheds. More recently, the Surface Water Management Division has begun the basin planning process in urban or urbanizing basins, such as Miller Creek, Seola Creek, and Salmon Creek. The planning process for these basins will incorporate many of the same management strategies applied to rural basins and will be complemented with new programs being developed and implemented as part of the NPDES program (e.g., drainage mapping, illicit discharge surveys, and source control best management practices).

5253

R0038561

This section summarizes the Part 2 storm water permit application prepared by Charlotte, North Carolina. The discussion does not mirror the planning process described in this manual, but rather presents a variation for municipalities to consider.

Step 1 — Develop Criteria to Evaluate Objective Attainment and Planning

The table below, taken verbatim from the Charlotte, North Carolina, Part 2 storm water permit application, summarizes the factors considered in each of the Charlotte Storm Water Quality Management Program (SWQMP) elements. The purpose of the table was to force full consideration of both the pros and cons of each program element and to assist the city in determining the practicability of each measure in formulation of its MEP.

TABLE 2-17. BEST MANAGEMENT PRACTICE SCREENING CRITERIA*

BMP:					
	Criteria Description	+	0	-	**Comments**
1.	Human Risk, Public Safety and Potential Liability				
2.	Environmental Risk and Implications				
3.	Ability to Control Key Targeted Pollutants				
4.	Costs to Implement and Continuing Costs				
5.	Acceptability to the Public, Stakeholders, Staff and Political Leadership				
6.	Equitability to Impacted Persons				
7.	Reliability and Consistency Over Time				
8.	Sustainability in Terms of Maintenance or Program Management				
9.	Ability to be Applied Universally Throughout the Jurisdiction or, on a Specific Watershed Basis				
10.	"Fit with other Charlotte Operations and Programs				
11.	Relationship to other Federal, State, or Local Regulatory Requirements				
12.	Amenity or Multi-use Value				
Totals					

*Excerpted verbatim from the Part 2 Storm Water Permit Application prepared by Charlotte, North Carolina (1992)

Step 2 — Develop List of Possible Control Measures (BMP's)

There are almost an infinite number of variations on programmatic, structural, and nonstructural BMPs. A candidate set of nearly 100 control measures, program elements, and other activities was developed through brainstorming sessions. A preliminary screening was done of these based on engineering judgement and knowledge of what measures were not remotely feasible. Candidate control measures and programs surviving this initial screen were subjected to a more formal consideration using the table in step 1.

Step 3 — Apply the Criteria to Screen the Measures

The criteria were generally applied (along with engineering judgement) to spotlight potential problems with the application of program elements. It was considered too premature to require the use of certain structural BMPs,

VOL 12

5254

R0038562

though a more formal technical consideration of specific design standards and incorporation into Charlotte design criteria was adopted as a program element.

Step 4 — Preliminarily Analyze a Practical Set of Control Measures

This shortened list was organized and analyzed to determine how each measure will function singularly and in conjunction with other program elements and how and by whom these elements will be implemented. Another part of this analysis is to determine ranges of BMP application to allow for development of alternative programs and to get a feel for cost sensitivity where appropriate.

Step 5 — Estimate Overall Program Costs and Pollution Reduction Effectiveness

In most cases, particularly for nonstructural BMPs, it was very difficult to assign pollution reduction numbers without better data and information. In many cases it was inappropriate. Great care and engineering judgment must then be exercised. The steps generally were to:

- Define such factors as the control measures, phases of implementation, ranges of implementation, equipment, and locations as necessary to define the program as fully as possible; consider pilot applications and data monitoring feedback loops
- Make first order estimates of program costs in each implementation stage or phase.
- Realistically allocate budgets to these programs, over the first 5-year permit period and at ultimate development as appropriate.
- Make first order estimates of the program's effectiveness by relying on the experience of other cities.

Step 6 — Obtain Feedback and Revise Program Scope to Maximize Program Cost Effectiveness

There is a need in any comprehensive program development to go back and look at the whole assembled puzzle after suitable examination of each of the pieces and after preliminary coordination with the permit writer. Adjustments were made to the program scope and schedule.

Step 7 — Describe Roles and Responsibilities to Implement the Program

After a preliminary SWQMP strategy was formulated, preliminary roles or responsibilities for each program element were identified. The local organizational structure and current program responsibilities were considered.

Step 8 — Develop Schedule for Implementation Control Program Including Management and Feedback Loops

The end result of this step is the schedule and budget for program implementation. It was considered important to evaluate the success of the programs at every step and build into each program ways to measure that success. This may be through specially designed feedback from the persons implementing the program, through data collection and monitoring, public awareness polls, or other means.

5255

EXAMPLE METHOD FOR SELECTING SOURCE CONTROL BMPs

This section summarizes the *State of California Storm Water Best Management Practice Handbook (Municipal)*, Storm Water Quality Task Force, March 1993. The discussion provides a step-by-step planning example on how to select potential source control BMPs for inclusion in a municipal Storm Water Management Program. It assumes that program goals and priorities and existing conditions (Steps 1-3) have been identified. This example illustrates how source control BMPs may be selected using the Source Control Worksheet #1.

Selection Process

The selection criteria and the scoring system below are similar to other selection processes developed around California. It is recommended, however, that the criteria and/or the scoring be modified to suit the particular community. Modification of the following selection process attributes may be considered:

- **Criteria** — Redefine some of the criteria or add/subtract criteria.
- **Scores** — Modify the scoring to a simple +,0, and -, or 1, 2, and 3.
- **Weighting** — Group the criteria into tiers reflecting their relative importance to specific SWMP goals. By multiplying the scores of the highest tier by some factor (e.g., x2), the first tier scores could be weighted more heavily than the others to reflect this importance.
- **Fatal flaw** — Provide for some fatal flaw in scoring the BMPs (e.g., the BMP is illegal or its implementation is completely unacceptable to the public) that would make implementation impossible. Scoring a fatal flaw as a 0 is one way of highlighting the flaw. Any BMP scoring a 0 against a criterion would be eliminated from consideration, regardless of its overall ranking.

Example

In the following example, municipality Anytown, California, is developing a Storm Water Management Program that includes an element for Residential/Commercial Activities. By following the steps below, the community uses Worksheet 1 to rank the BMPs according to their ability to meet the selection criteria. The worksheet shows the initial results of this hypothetical ranking.

1. The selection process involves consideration of following:
   - Table 2-18, Application of BMPs to SWMP Program Elements
   - Discussion of selection criteria
   - Worksheet 1
   - Source Control BMPs.
2. A review of Table 2-18 shows that for Residential/Commercial Activities, the storm water regulations require the SWMP to have an element addressing Roadway and Drainage Facility Maintenance. The program activity and element are listed at the top of Worksheet 1.
3. Looking across the Roadway and Drainage Facility Maintenance row in Table 2-18, two categories of source control BMPs apply, Material Use Control and Street/Storm Drain Maintenance.
4. The Material Use Control category includes two types of BMPs, Housekeeping Practices and Safer Alternative Products. These are listed on Worksheet 1.
5. Several BMPs are described within each fact sheet. These are also listed on Worksheet 1.

Water quality and BMP assessments during planning	✓	✓	✓	✓	✓	✓		✓
Site inspection and enforcement procedures	✓	✓	✓	✓	✓	✓		
Training for developers and contractors	✓							✓

*Taken verbatim from the *State of California Storm Water Best Management Practice Handbook (Municipal)*, Storm Water Quality Task Force.

6. Using the discussion of selection criteria, the BMPs are ranked against the selection criteria using the scale of 1-5.

7. For the first BMP, Distribute Public Education Materials, the following scores are recorded:
   Meets Regulatory Requirements = 3. Public education meets the intent of the storm water regulations.
   Effectiveness of Pollutant Removal = 2. Effectiveness of source control is high; however, insufficient data exist to support this claim.
   Public Acceptance = 5. Anytown believes that the public education materials are available from other municipalities and agencies to serve as models or to purchase for use as is.
   Implementable = 5. The existing department and staff may be used, and public education materials are available from other municipalities and agencies to serve as models or to purchase for use as is.
   Institutional Constraints = 4. To provide a consistent message to the public, Anytown must coordinate its public education program with the county, which already has in place a hazardous waste disposal program. The county has indicated that it will cooperate fully with Anytown to ensure that the public education material is consistent with the county's program.
   Costs = 5. Given the availability of materials to serve as models or to use directly, production should be relatively inexpensive.

8. Addition of the criteria scores across each row produces a total score, which may be compared to the other totals.

9. The process is continued for each of the source control BMP categories checked in Table 2-18.

As a result of this evaluation, Anytown, California, implemented all the BMPs in the Housekeeping Practices and Safer Alternative Products categories, as well as the maintenance BMPs in the Street/Storm Drain Maintenance category. However, the scores for the other Street/Storm Drain Maintenance BMPs indicated that further study was necessary before their implementation could be proposed. Anytown, California, also found that storm drain flushing was not allowed by the local sewer agency, so this fatal flaw removed this BMP from further consideration.

<u>A Few Points to Remember</u>

- Have several people or one of the storm water committees conduct the selection independently to get a broad perspective on the relative merits of each BMP and to help reach a consensus.
- Keep the selection system as simple as possible and use best professional judgment to interpret and to conduct a reality check on the total scores.
- Remember that differences of a few points in the total score are probably not significant.
- Use the final rankings to plan and prioritize the SWMP. For example, those BMPs with the highest scores may be implemented in the first year of the NPDES permit, while low scoring BMPs may need more time to develop, relegating their implementation to the fifth year or to further study.
- Use the exercise of working through this selection to provide the necessary data to promote the program to other departments, political leaders, regulatory agencies, and the public.

MAINE DEPARTMENT OF ENVIRONMENTAL PROTECTION BMP SELECTION MATRIX

To address storm water and nonpoint source pollution control in areas of new development, the Maine Department of Environmental Protection (ME DEP) has developed a method to select BMPs. The method is based on the following information:

- Development land use type and size
- Receiving water type (e.g., estuary, wetland, river, or stream)
- Watershed priority (either priority or nonpriority)
- Erosion and sediment control target or "level to achieve"
- Storm water quality control target or "level to achieve"
- Erosion and sediment control options and "treatment level codes"
- Storm water quality control target or "treatment level codes."

To implement the BMP selection method, ME DEP has developed a series of eight matrices. There are two matrices for each receiving water type (estuary, wetland, river, and stream). One matrix is applied to development in designated priority watersheds, and the other is applied to development in nonpriority watersheds. A priority watershed list has been developed by ME DEP based on environmental sensitivity, local support for water quality, and importance of the watershed to the State. Example matrices for priority and nonpriority estuary watersheds are shown in Tables 2-19 and 2-20.

Each matrix has two major components, which are broken down by land use type. The first is an erosion and sediment control "level to achieve," and the second is a storm water quality "level to achieve." The "level to achieve" for a given combination of land use and receiving water category is a relative, qualitative measure of the impact of storm runoff pollution. It ranges from 1 to 5, with 1 being the lowest impact and 5 being the greatest impact. For example, a multi-housing development proposed for a priority estuary watershed is given an erosion and sediment "level to achieve" of 2 and a water quality "level to achieve" of 3. By comparison, a small residential development in the same priority watershed is given an erosion control "level to achieve" of 1 and a water quality "level to achieve" of 1. In all cases, the " levels to achieve" for priority watersheds are greater than or equal to those for nonpriority watersheds.

Each matrix also addresses the types of BMPs that can be implemented for pollution control. ME DEP selected a number of BMPs and assigned each a "treatment level code" based on the expected level of pollutant removal. The "treatment level code" is a relative, qualitative measure. It is designed to indicate the relative pollutant removal expected from various BMPs. "Treatment level codes" range from 1 to 3, with 1 providing the lowest level of control and 3 providing the greatest level of control. The BMPs and their treatment level codes are shown in Table 2-21. As indicated, various designs for each BMP are given different treatment level codes. For example, a 50-foot buffer is given a treatment level code of 1, a 125-foot buffer is given a treatment level code of 2, and a 200-foot buffer is given a treatment level code of 3.

For a proposed development to be approved, the sum of treatment level codes for the proposed BMPs must be greater than or equal to the "level to achieve." For example, if a multi-housing unit development is proposed for a priority estuary (erosion "level to achieve" of 2 and water quality "level to achieve" of 3, the developer could implement erosion and sediment controls (treatment level 2) and a combination of a swale (treatment level 1) and an infiltration system (treatment level 2). Additional combinations also could be implemented as long as the total "treatment level" provided is greater than or equal to the total "level to achieve." ME DEP has also recommended that at least one vegetative BMP be implemented unless the site is already 100 percent impervious. The specified vegetative BMPs are buffers, grassed swales with level spreaders, and swales.

This BMP selection system is in its early stages of implementation. Its success will depend on the ability to establish "levels to achieve" that will adequately protect the water bodies in new developments. It will also depend on the ability of treatment level codes to quantify the effectiveness of the identified control measures. Thus, the system is a technology-based approach for erosion and sediment control, as well as for storm water pollution control.

Currently, this method is outlined in a state-wide guidance document and is not a regulatory requirement. Municipal officials can incorporate this process at their discretion in subdivision regulations. This method of BMP selection requires extensive up-front work to develop the matrices and BMP levels of treatment. Once these are developed, however, this method provides a simple and direct technology-based approach to BMP selection. It has flexibility in terms of the range of BMPs that can be selected for given types of proposed development and given site constraints.

SANTA CLARA VALLEY, CALIFORNIA, NONPOINT SOURCE CONTROL PROGRAM BMP SCREENING AND SELECTION PROCEDURE

VOL 12

Background

In 1986, the San Francisco Regional Water Quality Control Board developed a Basin Plan for San Francisco Bay that involved regulatory activities to control point and nonpoint source discharges. This was the driving force behind initiating the Santa Clara Valley Nonpoint Source Control Program. This program involves a number of local governments and county agencies and is designed to address water quality problems in Lower South San Francisco Bay. In conducting this project, a 12-step process that closely follows the process outlined in this manual was used. The 12 steps are as follows:

- Initiate Program
- Determine Existing Conditions
- Conduct Field Monitoring
- Define Program Objectives
- Develop Evaluation and Planning Criteria
- Compile Inventory of Candidate Controls
- Apply Criteria to Screen Candidate Controls
- Apply Professional Judgment to Select a Practical set of Controls
- Estimate Overall Program Cost and Effectiveness
- Revise the Previously Defined Control Programs to Balance Cost, Effectiveness, and Other Factors
- Describe the Roles of Various Agencies
- Develop an Implementation Schedule.

Development of the Nonpoint Source Control Plan began in 1986 and has continued through various stages to initial implementation and preliminary assessment of effectiveness.

5264

Watershed Description

Santa Clara County, which incorporates the entire study area, is located at the southern end of San Francisco Bay (see Figure 2-5). The watershed is approximately 690 square miles and consists primarily of the relatively flat Santa Clara Valley. Land use in the watershed is approximately 30 percent residential, 5 percent industrial (predominantly light industry associated with high technology manufacturing), and 62 percent open space. Large cities, San Jose, Sunnyvale, and Santa Clara, account for the majority of urban areas in the watershed.

Overview of Water Quality

To characterize existing water quality in Lower South San Francisco Bay, a comprehensive monitoring program was undertaken. This program included hydrologic monitoring, wet and dry weather water quality monitoring, sediment monitoring, and biological monitoring. The monitoring was conducted primarily to determine the levels of toxic pollutants, such as heavy metals and pesticides, as well as nutrients and bacteria. Data obtained through this monitoring program were incorporated into data bases and used for developing computer models. Watershed loads were estimated using the Storm Water Management Model (SWMM), which was calibrated to the observed data gathered in the monitoring program. The data were also used to compare the relative contributions of point (e.g., waste water treatment plants) and nonpoint source pollution to the bay.

Water quality monitoring results indicated that heavy metal concentrations in receiving waters increase during wet weather due to contaminated runoff as well as resuspension of contaminated sediments. The metals primarily detected were cadmium, chromium, copper, lead, nickel, and zinc. However, copper was the primary metal regularly detected at levels greater than the EPA aquatic life toxic criterion during wet weather. The criteria were

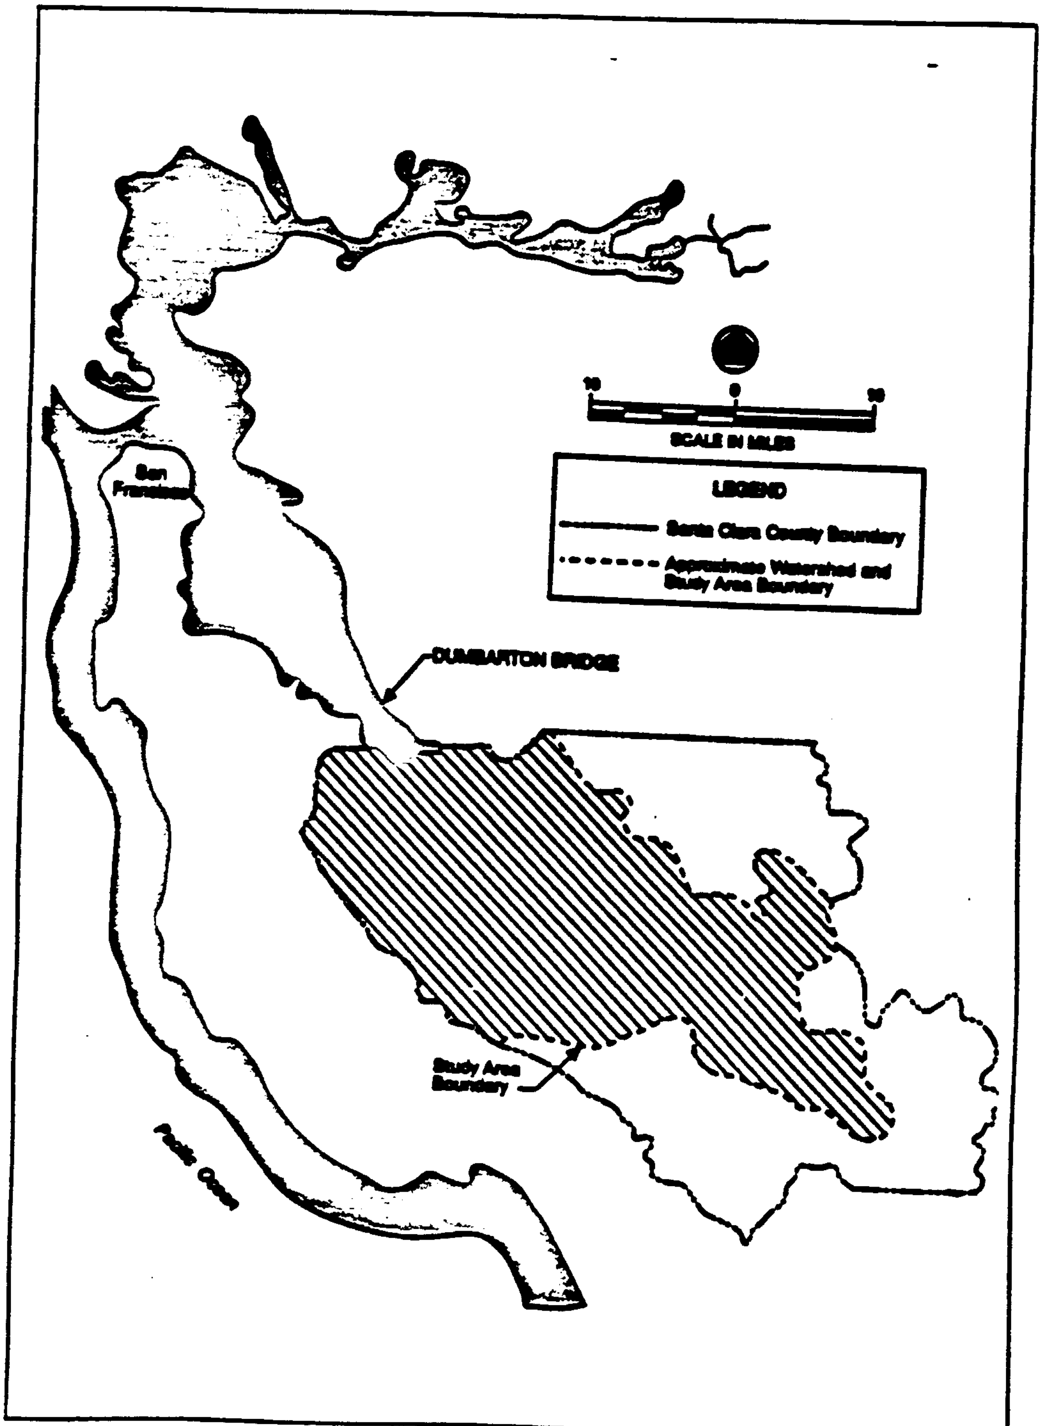

FIGURE 2-5. SANTA CLARA COUNTY

only occasionally exceeded for cadmium, lead, and zinc. Also, during wet weather, hydrocarbons and pesticides were detected in approximately 25 percent of the samples collected, while none was detected during dry weather. The limited bacteria data gathered indicated increased levels (by a factor of about 10) of fecal coliform bacteria during wet weather as compared to dry weather conditions.

In comparing point and nonpoint source contributions to water quality problems in Lower South San Francisco Bay, the monitoring results showed that point sources account for approximately 98 percent of the nutrient load. However, nonpoint sources accounted for 60 to 80 percent of the load for metals and about 98 percent of the total suspended solids on a long-term basis.

Management Practice Screening

Because of the large size of the watershed and the variety of pollutants entering the Lower South San Francisco Bay, the emphasis of the nonpoint source pollution control program was on pollution prevention measures and nonstructural controls that could be implemented across municipal boundaries. Selection of appropriate pollution controls was accomplished through a process consisting of preliminary screening followed by final control measure selection (see Figure 2-6).

To screen the extensive list of potential pollution control practices, the program team first developed a list of important criteria for the selected control measures. The criteria developed for this project were:

- **Pollutants Controlled:** Emphasis is placed on controls for metals, pesticides, oil and grease, bacteria, and sediments.
- **Effectiveness:** Each control measure should contribute enough toward the overall program pollution control to warrant its inclusion.
- **Reliability/Sustainability:** Control measures should be effective over an extended period of time and be able to be properly implemented over time.
- **Implementation Cost:** Emphasis was placed on control measures with low planning, design, land acquisition, construction, and equipment acquisition costs.
- **Continuing Costs:** Emphasis was placed on control measures with low operation, maintenance, repair, support service, and equipment replacement costs.
- **Equitability:** Controls were evaluated regarding the degree to which costs and benefits would be considered to be equitably distributed.
- **Universality:** Controls were evaluated in terms of how universally they would have to be applied to be effective.
- **Public Acceptability:** Control measures were assessed on the expected response of agencies responsible for implementation.
- **Relationship to Regulatory Requirements:** Control measures were evaluated on their consistency with existing and anticipated regulatory requirements.
- **Risk/Liability:** Control measures were evaluated in terms of the risks or liabilities that may occur in implementation.
- **Environmental Implications:** Control measures were evaluated regarding the positive and negative environmental impacts resulting from their use.

Once the control measure criteria were listed and agreed upon, the project team developed a comprehensive list of potential control measures for implementation. The inventory of potential control measures was developed through

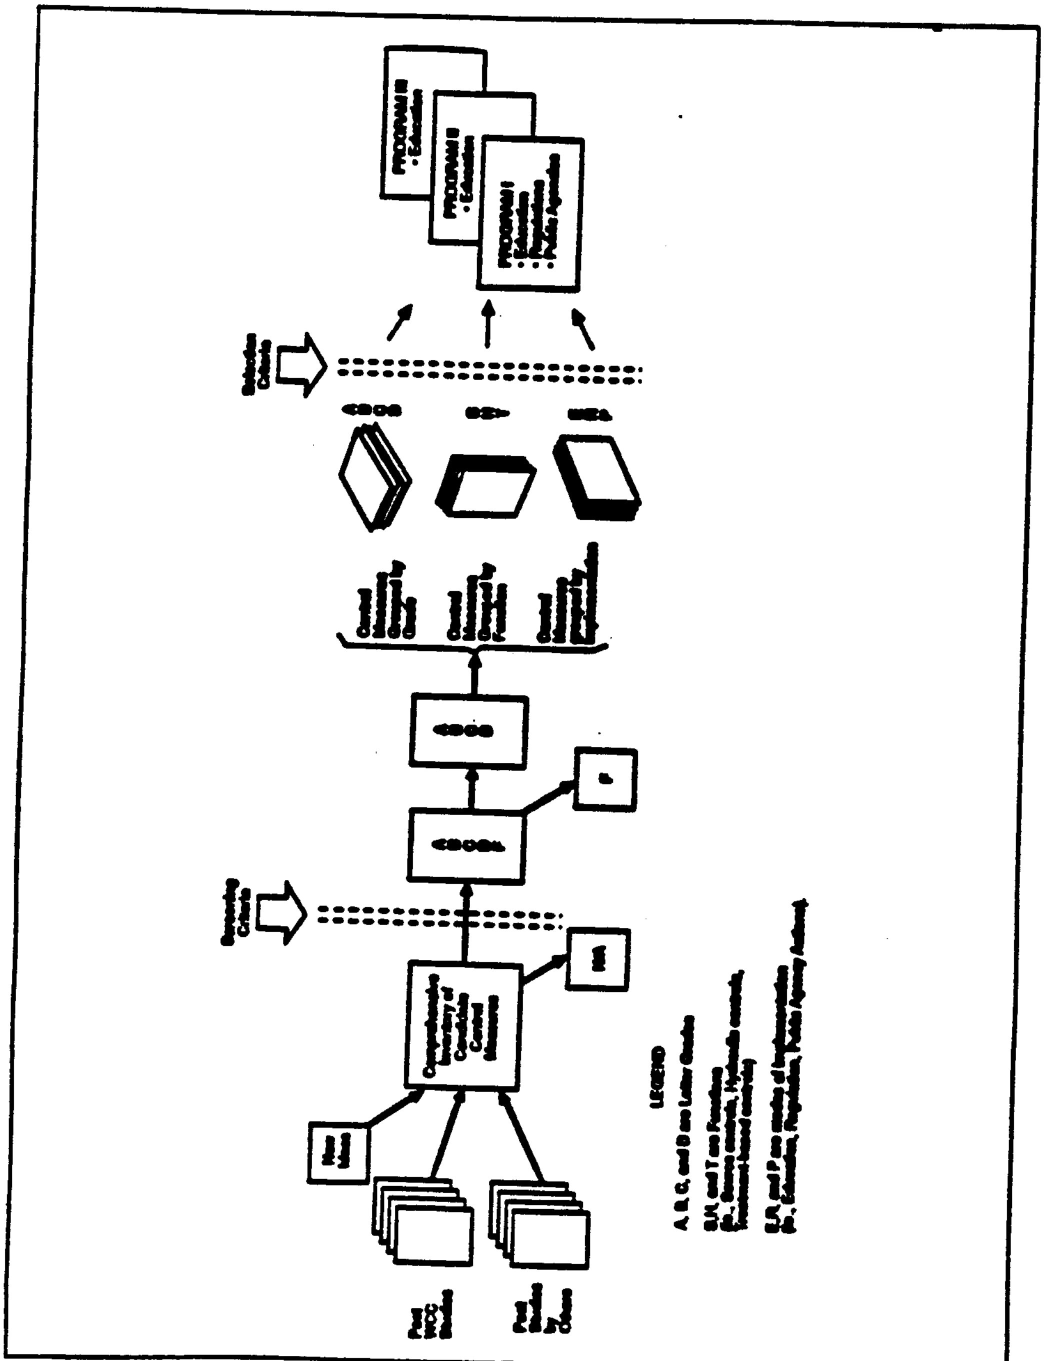

FIGURE 2-6. SELECTION OF APPROPRIATE POLLUTION CONTROLS

a review of technical literature and other nonpoint source control programs. In addition, technical and managerial personnel from other State agencies, county agencies, and city public works and planning agencies were interviewed. This review resulted in a list of more than 120 separate control measures to be screened. This initial list was developed to be comprehensive, and no consideration was given to the applicability of the measures. However, once the list had been developed, obviously inappropriate control measures were eliminated. The control measures eliminated from the list at this step were primarily those designed to address specific situations that did not exist in the watershed. This initial screening reduced the list of potential pollution controls to 92.

This list of 92 control measures was then assessed qualitatively using the criteria developed earlier in the program. This was conducted by assigning each of the control measures a letter "grade" (A through F) for its ability to meet the criteria. Those measures receiving an "A" were viewed to meet all or a large number of the assessment criteria, while those receiving an "F" were viewed to meet none or very few of the assessment criteria. In this way, each of the potential control measures was assigned to a category. The control measures that fell into the category of "F" were immediately eliminated from further consideration in the Santa Clara Valley watershed.

VOL 12

5268

The Waukegan River/Ravine system is the primary drainage for the urban areas of Waukegan. Significant point and nonpoint source discharges of storm water runoff create considerable water quality problems. Directly related to these water quality concerns are significant erosion and siltation problems occurring in various areas of the river/ravine system.

The Waukegan River/Ravine main channel and tributaries are approximately 12.5 miles. The watershed, primarily in Waukegan, is approximately 7,640 acres and receives storm water runoff from point and nonpoint discharges from an urban area with 80,000 residents. The river/ravine system has the highest population density (8.0 people per acre) of any river in Lake County. The Waukegan River discharges into Lake Michigan just east of the downtown area at a point 6,000 feet from the city's fresh water intake.

The water quality problems identified are siltation, suspended sediments, pesticides, petroleum products, and solid waste. In addition, unstable stream channels result in severe bank erosion, and damaged sewer lines along the stream channel. Stream channel instability has already broken up small sewer lines that enter the main sewer (buried in the floodplain along the stream).

In response to these problems, a number of implementation activities have occurred. The Lake County Storm Water Management Commission developed a model environmental storm water strategy and is implementing a nonpoint source pollution awareness project. This strategy is a watershed-based, multiobjective approach that considers all the environmental values associated with surface water. This comprehensive strategy includes a complete coordinated system addressing program operations, planning design, construction, finance, maintenance, and regulations. In addition, the strategy addresses prevention, remediation, and maintenance.

A specific program to restore this area includes the restoration of urban streambanks through the development of technical and legal procedures for urban stream management and training of local government employees in the bioengineering techniques of vegetative stream stabilization. Also, to improve water quality in the Waukegan River, an aerator was installed and an illicit connection program is proposed.

The purpose of the storm water pollution prevention awareness project is to increase the awareness of urban storm water pollution problems in Lake County, Illinois, through pollution prevention advertisements (e.g., messages, graphics, and photographs) on billboards, buses, and bus stops. The advertisements will address such urban runoff issues as gasoline spills on pavements, storm drains clogged by debris, sediment runoff from construction sites, erosion of urban stream banks, and runoff of phosphate detergents into storm drains. Preventive actions will include storm drain stenciling programs and recycling of motor oil.

An intensive 10-year monitoring and evaluation program has been implemented to demonstrate and evaluate the effectiveness of the storm water best management practices (BMPs) implemented in the Waukegan River watershed. This monitoring effort focuses on the impacts of the storm water pollution control program on urban fisheries and stream habitat.

VOL 12

5270

Identification of Water Quality Problems

Physical Setting

Lincoln Creek is a 9 mile high gradient warm water stream in the Milwaukee River South Watershed. The Milwaukee River drains into Lake Michigan. The creek's drainage area, the City of Milwaukee, is mostly urbanized.

Land Use

Lincoln Creek is the largest urban subwatershed in the Milwaukee River South Watershed, draining 12,600 acres. This subwatershed is entirely urban, although there are large areas of recreational and open space land, including a U.S. Army tract, the State's Havenwoods Forest Preserve and Nature Center, the Milwaukee County Lincoln Creek Parkway, and golf courses and municipal parks.

Residential lands dominate the subwatershed. High density residential areas cover 35 percent of the subwatershed and multifamily residential areas cover an additional 15 percent. Industrial areas cover 12 percent and commercial areas 7 percent of the subwatershed. Most of the subwatershed is contained within the city of Milwaukee. However, a small portion is contained within the city of Glendale and includes primarily industrial and multifamily land uses.

Project Area Size

The Lincoln Creek drainage area is about 20 square miles (12,600 acres), and the entire area is urbanized. The breakdown for some of the land uses is high density residential (35%), multifamily residential (15%), industrial (15%), and commercial (7%).

Critical Areas

Critical land uses were identified using the Source Loading and Management Model (SLAMM). Critical areas were those that had the highest annual loads of sediment and lead. Lead was considered an indicator for other toxic pollutants. High density residential, industrial, multifamily residential, and commercial land uses contributed most of the sediment and lead loads. The Lincoln Creek drainage area was the most important source of toxic pollutants in the Milwaukee South Watershed. There are 24,000 feet of eroding streambank, which produces about 430 tons of sediment each year. Construction sites are another critical source of sediments.

Water Resource Condition

The lower portion of Lincoln Creek has the potential to support a warm water sport fishery, while the upper portions have the potential to support a warm water forage fishery. All sections of the creek have the potential to support partial body contact water recreation.

However, none of the potential uses of the creek are being attained. Recent surveys of the creek have found it to be highly degraded. Only two fish species (fathead minnow and sunfish) were found in the middle portions of the creek in 1992 and both species are pollutant tolerant. Lincoln Creek should support a diverse fish community of at least 15 fish species.

Lincoln Creek is almost entirely channelized, with the channel alternating between concrete and earthen sections. Channel modifications and frequent high storm water flows contribute to the low biological activity observed in the creek.

Levels of petroleum aromatic hydrocarbons (PAHs), heavy metals, fecal coliform and suspended solids, and other pollutants increase significantly during runoff events. Some pollutants, like PAHs, reach levels high enough to exceed water quality standards. Based on EPA criteria, the bottom sediments are moderately or heavily polluted with heavy metals and PAHs.

Crayfish tissue is highly contaminated with PAHs. Mortality was observed in fathead minnows exposed to Lincoln Creek water for more than 15 days. Traditional acute and chronic bioassays did not indicate any toxicity.

Problems in the creek are caused by poor habitat, increased flows, and high levels of pollutant loading.

BMPs, such as wet detention basins, are proposed in the priority watershed plan to address these problems.

Storm water pollution control objectives for Lincoln Creek include:

1. Restore the forage and sport fish communities by improving the habitat and water quality.

2. Improve the recreational uses.

3. Reduce the loadings of pollutants to the Milwaukee River and Lake Michigan.

Watershed Plan

The implementation plan for Lincoln Creek is part of the Milwaukee River South Priority Watershed Plan, which was implemented in 1991.

One of the recommendations in the watershed plan has been implemented—the preparation of a storm water management plan. The storm water management plan provides detailed information about the management alternatives for Lincoln Creek. Critical land uses are identified by sewershed instead of the whole drainage area. A major effort is put into determining the feasibility of installing the structural practices recommended in the watershed plan and locating sites for installing the wet detention basins.

Inventory Results

Existing urban land uses, future urban land use, construction sites, and eroding streambanks were the urban sources of pollutants evaluated during the preparation of the priority watershed plan. The inventory of the urban land uses was designed to quantify the acres and the development characteristics of each land use. Existing land use categories were delineated on 1" = 400' scale, aerial photographs were digitized, quantified, and mapped by the Southeastern Wisconsin Regional Planning Commission.

Annual pollutant loadings of sediment, phosphorus, and lead were calculated for existing and planned land uses by running SLAMM. Input parameters for SLAMM included the acres of each land use and the development characteristics, such as the percent connectedness. SLAMM was also used to evaluate the effectiveness of different BMPs on the existing and future urban areas.

Lincoln Creek receives an annual lead loading of about 8,000 pounds. Major land uses contributing to the elevated lead levels are: high density residential (33%), industrial (32%), multifamily residential (14%), and commercial (14%). Future development could increase lead loads by 21 percent. These same land uses also contribute relatively large amounts of other toxicants, such as PAHs and heavy metals.

Runoff from construction sites and streambank erosion annually contribute about 6,500 tons of sediment to the stream. Sediment loads are expected to decrease as the remaining planned areas are developed.

VOL 12

5271

R0038579

Storm water flows have adverse effects on the creek. High flows cause flooding, bottom scour, and streambank erosion. The Milwaukee Metropolitan Sewage District is evaluating alternative measures for reducing flows in the creek.

Pollutant Reduction Goals

Pollutant reduction goals were based on the needs of the stream. A different approach was taken to establish the reduction goals for each type of problem.

Sediment and Phosphorus

An overall 50 percent reduction in the existing sediment loading is needed to improve the habitat in the creek. Implementation of the storm water pollution control program should reduce the sediment load from construction sites by about 75 percent.

A high reduction of phosphorus (50% to 70%) is needed to reduce the excessive aquatic plant growth in the Milwaukee River and reduce the threat to Lake Michigan.

Storm Water Pollutants

Lead is being used as an indicator pollutant for the other toxic pollutants. Although the State of Wisconsin does not currently use numeric effluent limits to regulate storm water, the pollutant reduction goals for lead were based on meeting the chronic toxicity standards in the Wisconsin Administrative Code. The average annual concentration of total lead in the Milwaukee River exceeds the chronic toxicity standard by 50 percent for surface waters. The proposed pollutant load reduction goal for lead in Lincoln Creek is 50 percent.

By combining the output of SLAMM with a Probabilistic Dilution Model for the creek, the frequency with which the chronic toxicity standard for a number of pollutants is exceeded in Lincoln Creek. The models will assist in determining the amount of reduction needed to significantly lower the probability of exceeding the chronic toxicity standards. The Probabilistic Dilution Model was developed by the EPA and is a good technique for estimating the amount of pollutant reduction needed.

Stream Flow

Specific goals will be established by the Milwaukee Sewage District; however, there are three basic hydrologic goals that must be considered.

1. Maintain baseflow in the creek as much as possible.

2. Reduce stream flows to prevent streambank erosion and bottom scour.

3. Maintain peak flow discharge for 2-year 24-hour storm at predevelopment conditions.

Bottom Sediments

Bottom sediments are heavily polluted. Although a specific reduction goal has not been determined for the bottom sediments, the watershed project has a goal of reducing the levels of pollutant in the bottom sediments.

Management Practices

BMPs are those practices identified in the Wisconsin Administrative Code and are referenced in the Milwaukee River South Watershed Plan to be the most cost-effective controls for storm water pollutants. SLAMM was used

VOL 12

5272

to evaluate the effectiveness of wet detention basins, infiltration devices, street sweeping, and roof top disconnection for both existing and future urban areas. Pollution prevention measures were also suggested for controlling construction site erosion and streambank erosion.

Following is a list of BMPs proposed in the storm water management plan.

Best Management Practice	State Cost-Share Rate
Critical Area Stabilization	70%
Grade Stabilization Structure	70%
Shoreline and Streambank Stabilization	70%
Shoreline Buffers	70%
Wetland Restoration	70%
Structural Urban Practice	70%
Street Sweeping	50%

A high level of control is needed to achieve the pollutant reduction goal for lead. All of the critical land uses in established areas would have to be controlled with structural practices, such as wet detention basins or other structural practices.

About 90 one-acre wet detention basins will be needed to treat all the critical land uses in Lincoln Creek. Street sweeping could be used as an interim practice before all the structural practices are built. About 14,000 curb miles of streets would need accelerated sweeping schedules. Twelve one-acre ponds would be needed to treat all the land uses in the planned areas.

Using structural practices in the existing and planned areas would also achieve the pollutant reduction goal for sediment. However, the watershed plan also recommends the implementation of construction site erosion and streambank protection practices. These practices will provide greater than 50 percent reduction before the structural practices are completed.

The watershed plan assumes that an effective construction erosion program will be in place for the cities to obtain cost-share dollars. Erosion control practices standards and applicability criteria should be consistent with those set forth in the *Wisconsin Construction Site Best Management Practice Handbook* (DNR, 1989). Cities in the Lincoln Creek drainage area are required to effectively administer and enforce their existing ordinances.

Control of streambank erosion will require a combination of streambank protection practices. The Cities of Milwaukee and Glendale plan to control peak flows to help protect their streambanks. The Milwaukee Metropolitan Sewage District is preparing a comprehensive stream corridor management approach for Lincoln Creek. The approach will consider flow reduction, alternative approaches for stabilizing eroding streambanks, and rehabilitation of the concrete stream sections.

Construction on the stream corridor will have the most impact on the quality of Lincoln Creek in the near future. Monitoring the proposed project will document the effectiveness of improving the stream corridor. The changes should occur over the next 3 years, while other practices will take longer to bring about significant changes in the water quality of the creek. Urban education is also a practice recommended in the watershed plan.

R0038581

VOL 12

Institutional Roles and Responsibilities

Wisconsin Department of Natural Resources

The Wisconsin Department of Natural Resources (WDNR) will have both administrative and monitoring responsibilities for the Lincoln Creek Evaluation Monitoring Project. The administrative role is defined as part of the Department's role in the Wisconsin Water Pollution Abatement Program.

Administration

Administration of the project began by following a selection process. After the project was selected, WDNR worked with Wisconsin Department of Agriculture Trade and Consumer Protection, the cities, and counties to prepare a watershed plan. Implementation of the plan is based on the guidance in the plan.

The Department is working with the Cities of Milwaukee and Glendale to develop cost-share agreements for the practices recommended in the plan. Grant requests will be reviewed by the Department. Interpretation of the State statutes, administrative rules, and watershed plans is provided by the Department.

Financial Support

Financial support for implementation of watershed projects is provided by local assistance agreements and a nonpoint source grant agreement. The cost of implementing all rural and urban practices in the Milwaukee River South Watershed Project is between $89,000,000 and $159,000,000. The State share is about $18,000,000. Installation of the structural practices in existing and future areas in Lincoln Creek will cost between $36,000,000 and $74,000,000. The State share of this cost is about $5,000,000. Total cost of street sweeping each year would be about $350,000. Development of storm water management plans for Lincoln Creek cost about $1,000,000. Most of the cost for the implementation of the watershed plan is for the structural practices. State funds are available to cover the State's share of the cost.

Project Evaluation

Project evaluation will involve the collection, analysis, and reporting of information needed to track the progress of the project. The categories of evaluation include administrative accomplishments, pollutant reduction, and water quality improvements. The local units of government will report annually on the progress of core and segmented program activities. Information will also be provided on financial expenditures and time spent on project activities.

Technical Assistance

The WDNR will provide technical assistance to the local units of government on the design and application of BMPs.

Monitoring Responsibilities

Fish, habitat, and macroinvertebrate sampling will be the responsibility of the Department. Field work will be done by crews supervised by the Department's Bureau of Research.

Stakeholders

Local Units of Government

Each local unit of government will have a number of responsibilities for the core and segmented programs.

5274

University of Wisconsin Extension

Area extension agents will provide support in developing and conducting a public information and education program.

Milwaukee Metropolitan Sewage District

Sewage districts have all the privileges and responsibilities of cities, villages, and counties when participating in the program.

Landowners and Land Operators

In some situations, private landowners will install practices on their property.

United States Geological Survey

All of the chemical and physical monitoring will be the responsibility of the U.S. Geological Survey (USGS). Peter Hughes will be the project manager for the USGS.

CHAPTER 3
GUIDANCE ON COMPLETING ADMINISTRATIVE REQUIREMENTS

INTRODUCTION

Chapters 1 and 2 summarized the municipal storm water management program regulatory requirements and guidance for municipal officials to rank storm water management activities for maximum cost effectiveness. This chapter discusses the administrative requirements of a municipal storm water management plan. These requirements include public information and participation campaigns, fiscal resources, and annual assessment reports.

Public information and public participation programs are essential to the implementation of an effective municipal storm water management plan. The key points to consider in developing this component of the plan include creating appropriate goals and objectives, targeting the proper audience, explaining and selling the program to the audience, and having the necessary equipment and staff for proper program implementation. The availability of fiscal resources is another essential component of municipal storm water management plans. Several funding options are available to municipalities: local funding mechanisms, matching fund programs, and grant programs. In addition, to implement an effective plan, an assessment of the plan must be developed annually and submitted to the permitting authority. This assessment allows the permitting authority and municipality to critique the effectiveness of the plan and to make any necessary changes.

PUBLIC INFORMATION CAMPAIGNS

Developing Goals and Objectives

The program's goals and objectives will form the framework for developing public information and participation efforts. Program goals are usually general and should include the essence of a program's purpose. They should also include some measure of the expected outcome. An example goal might be "to protect our watershed by linking and supporting citizens and organizations that are working locally for protection of wetlands and water quality."

Objectives are more specific and should identify actions or activities to be taken at the program-operations level. They focus the broad vision of the goal to something that can be accomplished through organizational resources. An example of an objective is "to publish and distribute four 12 to 16-page wetland journals by June 1, 1994."

To accomplish these goals and objectives, everyone involved in the program must be given the opportunity to participate and contribute and agree on the ideas. To ensure cooperation, the benefits should be explained. Otherwise, goals and objectives will not be important to the staff and will not be considered seriously when implementing the program. Also, because people may interpret goals differently, it is essential to develop the goals and objectives jointly with the staff through a meeting or other forum that is appropriate in your organization and to make sure that everyone understands them.

Identifying the Target Audience

When developing a public education campaign, it is critical to identify the target audience and develop materials accordingly. Target audiences are groups that have common characteristics, such as age, culture, socioeconomic background, language, and the educational level of the community or watershed. Learning more about the target audience will assist the staff in developing an effective outreach program. To reach the target audience, you must know specifically who it comprises and what common traits they share. This involves breaking groups down into subgroups that exhibit similar characteristics or traits. For example, construction contractors who are likely to have projects within your municipality or residents who change their own oil can be targeted. Some likely target audiences include:

- Members of industrial categories (e.g., landfills)
- Developers
- Construction contractors
- Auto repair/gas station owners
- Environmental groups (e.g., Adopt-a-Stream, local chapters of Sierra Club, Audubon Society)
- Community groups (e.g., churches, Boy and Girl Scouts, Jaycees)
- Non-English speaking residents
- Outdoor recreation groups (fishermen, garden clubs)
- Homeowners
- Students.

Identifying and learning about target audiences allows messages and programs to be developed in a way that will reach and influence these subgroups. The following contacts can provide more information about the target audiences in your community:

- Chamber of Commerce for information on the interests of local business people and what types of materials are most useful to them
- Other government agencies that interact with groups similar to those you will target (e.g., planning department for a list of construction contractors who have received building permits or an economic development department to learn about certain industries)
- Tax records or zoning records to find industrial and commercial facilities
- Wastewater treatment plants for a list of industry types, facility sizes, and potential pollutant sources
- Board of Education to identify ongoing school programs and methods for contributing to school programs and curricula
- Libraries to find local and State magazines and newsletters directed at specific audiences (e.g., environmental and outdoor recreation topics).

"Selling" the Storm Water Program

Educating the public about a new regulatory program and getting them involved with its implementation are among the most important factors for ensuring program success. Issues such as regulatory deadlines and implementation procedures all depend on educating both the regulated community and the public at large. A key element of the municipal storm water management plan is to help communities understand the importance of the storm water program and citizens' participation in improving water quality.

When creating public outreach materials, the storm water management program goals must be clearly communicated and the importance of accomplishing these goals explained. This is especially true in cases where municipalities intend to impose a utility fee for the storm water program. Municipalities may encounter opposition to a new fee if the benefits of the program are not understood. In such cases, it is important to obtain public and political support for the program through education.

One of the biggest political obstacles that municipalities face is that the impacts of polluted storm water runoff may not be obvious. For example, a water body that has been overloaded with sediment from an

VOL 12

5281

R0038589

upstream construction activity may look fine to the casual observer when, in fact, the fish and plant life has been harmed significantly. Once an awareness of both the sources and impacts of water pollution is created, educational programs can be developed to motivate the public to effect positive changes in their daily activities, thereby reducing the addition of pollutants to receiving waters.

Information intended to educate the target audience should include solutions as well as explanations of the issues. Simply providing people with information may not make them change their attitudes and rarely makes them change their behavior. People need to know more about the solutions and action that they can take. Education efforts, therefore, should present the reasons why the program is important and focus on actions that citizens and businesses can take to prevent increases in pollution of storm water. Examples of successful outreach materials that provide information and solutions are included at the end of this chapter.

Developing Outreach Materials

Specific education activities can include disseminating information through flyers included in residential utility bills; interactive methods, such as workshops; open houses at industrial facilities; school curricula materials; or talks or slide shows for schools and community groups. Whichever activities you use, communication should strive to be interactive and allow for feedback to those implementing the plan. For example, written materials become interactive when a telephone number to receive further information is provided. Keeping track of the number of callers and the questions they have also provides a way to judge the effectiveness of the materials. Some examples of communication methods that can be used to publicize public involvement are given in the following list:

- TV public service announcement
- TV news story
- Radio public service announcement
- Radio news story
- Newspaper advertisement
- Newsletter
- Fact sheet
- Pamphlet
- Storm drain stencils (e.g., "Dump No Waste, Drains To Lake")
- "Freebies (i.e., bumper stickers, magnets)
- T-shirts, hats, etc.
- Workshops
- Community meetings
- Church meetings
- School meetings
- One-on-one personal contact
- "Event" days
- Opinion leaders (i.e., community leaders, parents, teachers)

VOL 12 5282

R0038590

- Magazines
- Magazine advertisement
- Magazine article
- Billboard
- Fairs
- Libraries
- Books
- Transit cards (i.e., in buses).

Table 3-1 presents positive and negative characteristics of several outreach options.

Many outreach materials already exist that you may borrow ideas from or incorporate directly into your storm water management program. One particularly good source of public education materials is a guidance manual entitled, *Urban Runoff Management Information/Education Products*, developed by EPA Region 5, Water Division, and EPA Office of Wastewater Enforcement and Compliance, February, 1993. This document describes specific materials (booklets, books, bumper stickers, catalogs, citizen action guides, computer software, fact sheets, handbooks, newsletters, pamphlets, posters, slide shows, student activities, and videos) and how to obtain them. It is available from the EPA Office of Water Resources Center, (202) 260-7186.

Outreach materials should use clear, concrete language and, where possible, incorporate graphics. The goal is to design effective materials that people pay attention to, remember, and use. Effective materials should persuade people to behave in a more environmentally friendly manner and to influence others to do the same. The ideas discussed below should help you create interesting materials that will attract public attention, encourage community action, and ultimately make a positive impact on environmental conditions in your area.

When crafting outreach materials, remember to use concrete language that helps people to understand, visualize, and remember information. Here are some tips:

- Do not use jargon or technical, scientific language.
- Use anecdotes and examples. Tell a story to draw you reader in and to add more "human interest."
- Use analogies.
- Use descriptive adjectives and adverbs.

TABLE 3-1. CHARACTERISTICS OF SELECTED MEDIA

Media Format	Channel	Pros	Cons
Newsletters	Mail, handout	Can reach a large audience	Printing/mailing is costly
		Can be more technical	Staff time
			Passive, not participatory
Videotape	Workshops	Can reach a large audience	Relatively expensive
	Mail	Visually pleasing	Must be done well
	Cable TV	More participatory	
		Can show behavior	
Public Service Announcements	TV	Free	Sometimes aired at night
	Radio	Can reach a large audience	Competition for air time
		Can target audience	Very passive
			Difficult to evaluate
Mass Media	TV	Can reach a large audience	Constrained by time, space
	Radio	Good for raising awareness	Must be "newsworthy"
	Newspapers	Usually considered credible	Cannot explain complex issues
			Bad for persuasion
Presentations	Workshops	Can be participatory	Reach smaller audience
	Conferences	Good for persuasion	Staff time
	Group meetings	Can show behavior	Can be too technical
		More personal	People may not attend
Exhibits	Libraries	Can reach a large audience	Staff time
	Malls	Visually pleasing	Must be durable
	Fairs		
Freebies (i.e., bumper stickers, buttons, magnets, hats, etc.)	Fairs	Increases awareness	Very short message
	"Event" days	Inexpensive	Weak on persuasion
	Easy to produce		

VOL 12

5284

R0038592

- Use active verbs.
- Try to visualize what you are saying.
- Use graphics to illustrate and highlight what you are saying.
- Describe consequences of action (or no action) in terms of an individual, family, or business rather than using a broader term, such as "the public."

The format and layout of the materials will also influence the readers reaction to the information. Materials should be designed to help the reader find information quickly and easily. An audience that is confused or overwhelmed will be less likely to read and remember the message of the materials. Even though you may have many important points to make, try to avoid crowded pages with small type and little white space. Important information can be highlighted by using bullets, boxes, side-bars, or shading to highlight it. For example, side-bars with the following heads will capture the reader's attention: "Things You Can Do To Help" or "Where to Get More Information." An appealing layout and easy-to-read type will greatly increase the chances that your materials will be read. Special type fonts, bold, italics, or colors can be used for titles, headings, or, occasionally, extra emphasis. A medium-weight type that is large enough, usually 10 point and above, is more easily read. Selected examples of outreach materials that are easy to read are included at the end of this chapter.

Graphics can enhance the program materials by capturing attention and providing a simple visual picture of important information. A good rule of thumb is to keep graphics simple and portray images that the reader shall remember. For example, to influence people to dispose of hazardous waste properly, a person pouring oil down the storm sewer should not be used (even if the text is talking about the hazards of doing so). A picture of a person taking the waste to a proper collection site would be more effective. The following list provides further tips on using graphics effectively:

- Large illustrations are better than small ones.
- Photographs are more effective than sketches.
- If sketches are used, simple, clear, realistic ones are better than cartoons or more abstract drawings.
- A large photo at the beginning of an article draws the reader in.

VOL 12

5285

- Bright colors are useful because they attract our attention.
- Pictures grouped together have greater interest than pictures scattered throughout an article. They can also the be used to "tell a story."
- Gr:phics are especially useful for showing "how to" type information.

<u>Meeting Staffing and Equipment Needs</u>

Consider the resources allocated to your storm water management program. What kind of budget do you have to spend on production and distribution? How much time do you have? How many staff people are available and what are their skills and expertise? Is it possible to get help from citizen volunteers for development and distribution of materials? Producing your communication materials may be a major cost of your program. Make sure that you have enough resources to produce sufficient quantities of your material and to distribute them in your community.

Consider the number of people that need to be reached as a function of the amount of available money. A "cost-per-person" can be calculated by dividing the total cost of production by the number of people being targeted. This will allow comparison of different communication strategies on a cost basis.

PUBLIC PARTICIPATION PROGRAMS

Public education and participation efforts often go hand-in-hand, but public participation may require additional coordination efforts and can present unique challenges to those implementing the storm water management program. The benefits of involving the public in the implementation of the storm water program are many:

- If the public is encouraged to participate in the decisionmaking process of the program, their support for the program will likely increase.
- Large numbers of community members can watch over more of a watershed or municipality than a handful of regulators.
- The public is often the primary source of reports of illicit connections and illegal dumping to storm drains.

- Only the homeowners and residents can implement pollution prevention practices on their residential properties.

- Public volunteer efforts will save staff resources.

With proper training, citizens (e.g., community groups, local colleges, and high schools) can also be included in field screening and sampling portions of the storm water management plan. This can possibly reduce the labor required to perform a large-scale dry-weather screening program or at least locate more discharges than could be done by staff alone. In addition, dischargers would be constantly reminded that the public is watching and has access to the system, thereby encouraging compliance with the municipality's management plan. To take full advantage of the public participation watchfulness in dry-weather screening programs, municipalities can develop reporting criteria and procedures for the public to follow. The information needs to be clearly stated, public participation should be voluntary, and the city should not be liable if someone is injured in attempting to collect information. The reporting procedures can be similar to crime-watch or fraud-reporting programs and can even include a hotline for the public to report illegal dumping.

Coordination and Integration

Many water quality programs already exist at the local, State, and Federal levels. It is essential, therefore, that storm water management efforts be coordinated with these existing programs so that you are not repeating efforts. By coordinating with other agencies, non-profit groups, industry associations, chambers of commerce, and other citizen groups, you will not only save resources but will also build a coalition of supporters for the program. It may even be possible for your agency to take the lead in identifying all relevant programs and orchestrating them into an effective, comprehensive program with a focus on water quality improvement.

Resources and existing programs do not need to be strictly environmental in focus. For example, in Prince George's County, Maryland, the Police Community Relations Program will incorporate water pollution control information into their outreach program. In this way, the enforcement of water quality regulations will be enhanced through integration between police and water quality specialists.

<u>Program Components</u>

Public participation efforts contribute to the success of the storm water management program by educating other citizens and promoting responsibility for, and interest in, the preservation of water quality. This, in turn, will help generate public and political support for the storm water program. The municipality staff may save certain resources, but will have the added responsibility of communicating with other groups and programs, coordinating and training volunteers, and organizing public events. The following efforts, among others, have contributed to the success of various public participation programs:

- Partnerships with civic organizations, such as with the Boy Scouts and Girl Scouts to stencil storm drains
- Neighborhood representatives to educate their neighbors about the effects of household chemicals, such as fertilizers, herbicides, and cleaners, and alternatives homeowners can use and proper disposal methods
- Citizen watch and reporting programs
- Citizen advisory groups to help create and establish local ordinances
- Household hazardous waste collection days
- Stream and lake cleanup campaigns.

CASE STUDIES

The following pages present case studies of selected municipalities and their public information and public participation programs.

VOL 12

The overall goal of Santa Clara County's public outreach effort is to educate its target audiences about the significance of storm water pollution. The objectives of the program are to elicit public support through volunteer efforts, to encourage changes in everyday chemical usage and disposal habits, and to generate political support for the storm water management program in general. The target audiences include households, small businesses, large industries, educational institutions, private and public waste management programs and facilities, environmental groups, community/neighborhood groups, and local governmental offices. Specific education campaigns address:

- Proper disposal of pollutants that would otherwise enter storm drains and channels
- Control of leaks and spills from automobiles, trucks, and storage tanks
- The role of atmospheric emissions in generating nonpoint source pollution
- The need to promote better site runoff and sediment control.

Many of the objectives of the Santa Clara County public information and participation program will be achieved through a combination of activities that are designed to address various interest groups. A number of activities and coordination efforts have already been conducted, including the development of a public information participation plan, the establishment of a public information subcommittee, the development of program logo and stationery, and the development and distribution of a four-color general awareness brochure. Santa Clara County has also developed a storm drain stencil with instructions, a slide show, and poster and convened focus groups to coordinate a nonpoint source educational effort with existing educational programs. Specific action items include:

- Distribution of a storm drain stencil and how-to pamphlet and slide show for use with volunteer groups and general audiences
- Coordination with the Santa Clara County Household Hazardous Waste Program to develop and distribute 1) two pollutant-specific brochures to commercial and industrial audiences and 2) information guidebook for use by the jurisdictions
- Distribution a "how-to manual" explaining storm water management requirements and pollution prevention opportunities at industrial facilities
- Development of educational curriculum to teach students about the impacts of urban runoff and ways to prevent pollution
- Development of media support and advertising to promote public awareness of municipal storm water pollution and for the Santa Clara County storm water management program.

5289

The city of Seattle has implemented an education and outreach plan designed for each watershed to inform and educate the general public, businesses, and students about the fate of pollutants discharged to the storm drain system and what individuals can do to reduce pollution. The following paragraphs briefly describe some of the major components of the education program.

Schools Education Program

Seattle's extensive school education program includes field trips to an aquarium and a trout farm, videos and films, guest speakers, teachers guides, aquarium displays, and training and equipment for raising salmon in classrooms and releasing the fish into local receiving waters. Development of the program was enhanced by obtaining input from both students and teachers about what kinds of materials would be most interesting and educational.

Consumer Education

The city of Seattle has recruited more than three dozen businesses in the Pipers Creek watershed to display information about caring for the watershed and the proper use and disposal of household, yard, and automotive products. Information is presented in a series of brochures that are displayed in a colorful holder depicting a typical house and its connections to the water through the storm drain and sanitary sewer systems. Each business or service that is hosting a display is given a plaque that they in turn can display to the public.

Clean Water Business Partners

Businesses are mailed invitations to become clean water business partners. To qualify, businesses must earn a certain number of points based on their commitment to clean water. Points are earned by following sound management practices to help protect clean water, hosting information displays, and promoting community activities related to water quality. Each qualified business is presented with a plaque suitable for display certifying that they are a Clean Water Business Partner and honoring their commitment to the environment. The city will bring attention to these businesses through other educational promotions.

Storm Drain Stenciling

Volunteer school and community groups have been recruited to paint a pollution prevention message on a number of Seattle's 30,000 storm drain inlets. The message reads "Dump No Waste - Drains to Stream" and other variations depending on where the storm drain discharges. The program has been expanded through incorporation into the school education program and will likely expand further into a new "Adopt-A-Street" program. To date, more than 5,000 storm drain inlets have been stenciled in Seattle.

Motor Oil Recycling

Motor Oil Recycling is a joint project of the Seattle Drainage and Wastewater Utility (DWU) and the Seattle Solid Waste Utility. Waste oil collection tanks have been placed at 12 auto supply stores located throughout Seattle. The program is publicized by the auto store (Shucks) and by the two utilities. Spin-off programs have been initiated by other auto supply establishments in response to this program.

Waterfront Awareness Campaign

Seattle's downtown waterfront is a major tourist and recreation destination. Litter is a major problem along the waterfront, especially within the water itself. An association of waterfront businesses has initiated a cleanup campaign aimed at improving the appearance of the waterfront. The DWU has joined this partnership and has expanded the message to include the impact of litter and pollution on water quality. DWU recruited youth from the recreation centers around Seattle to paint trash receptacles colorfully with clean water and anti-pollution messages. Signs have been designed by Seattle Aquarium artists and placed along the waterfront reminding people about the effect of their actions on aquatic habitat. Posters similar to the signs will be displayed in waterfront businesses.

Bill Inserts and Citywide Direct Mailings

Seattle utilities include education and public awareness information in their bimonthly billings, which are sent to 188,000 customers. DWU's bill is shared with the Seattle Water Department and the Seattle Solid Waste Utility. The information is distributed on a variety of water quality subjects, including household hazardous waste, protection of Elliott Bay and the Duwamish River, and the school education program. A brochure has been distributed to every customer describing the storm water protection program and the role of the drainage and wastewater utility.

Television Public Service Announcements

Seattle has also developed four television public service announcements (PSAs) for broadcast on local television as part of the education video project in the schools program. The PSAs address the importance of watersheds, the difference between storm drains and sanitary sewers, nonpoint pollution, and pet waste.

Grand Traverse County, Michigan, developed a storm water control ordinance in response to the increase in development the county was experiencing. The primary reason for creating a new ordinance, rather than relying on the old system of Drain Commissioner review of drainage plans, was to establish clear, written guidelines for developers to follow for storm water management.

In writing the ordinance, the Grand Traverse County Drain Commissioner formed the Storm Water Management Advisory Committee. The committee comprised of area engineers, concerned citizens, and officials from the township, county, and state. The committee was split into two subcommittees: a technical committee and a policy committee. The technical committee wrote the technical guidelines for the ordinance and then submitted them to the policy committee for approval. The policy committee made all the final decisions on the ordinance and were assisted by a county-funded environmental planner.

After the ordinance was approved by the committee, the Drain Commissioner took the ordinance to each Township Planning Commission and Town Board for comments and approval. The county then held public hearings, particularly to communicate with some community members who thought the ordinance was unnecessary. The public hearings allowed the county to hear these skeptic's concerns and, in turn, to educate them about the potential impacts to the lakes and streams from soil erosion and additional storm water runoff. The county is convinced that the majority of people now understand the need for this ordinance. After the public hearings, the County Board of Commissioners approved the ordinance and it went into effect January 1992.

The ordinance went into effect with no major problems and has become acceptable practice throughout the community. Many developers are glad that there are finally written guidelines, which make project planning easier. Neighboring counties have been interested in adopting similar ordinances in their communities.

Grand Traverse County also established a program to educate landowners about pollution control on their property and the availability of conservation easements and tax-deductible land gifts through the Grand Traverse Regional Land Conservancy. A citizen committee and the Conservancy assist landowners in permanently protecting the wetlands, streamside greenbelts, and ground water upland recharge areas on their property. The county plans to contact every land owner within the critical areas of the watershed to discuss the various land protection programs offered by the Conservancy. The Conservancy has put together a Mitchell Creek Watershed Landowner's Handbook which covers creek protection issues, watershed care, land protection regulations, and a Mitchell Creek Watershed Map. There will also be a series of workshops to give property owners the chance to learn best management techniques "hands-on."

The county has also targeted areas with streams running through the property, including an elementary school and two golf courses. The county has worked with the Michigan State University Extension Service to assist the landowners in creating buffer zones around the stream and to reduce the amount of fertilizers and pesticides used. At the elementary school, students will participate in planting a buffer zone along the edge of the creek. Where possible, financial assistance is also provided either through public or private grants to cover the cost of planting additional vegetation. These programs are intended to protect the quality of the streams but they also provide education about storm water runoff and watershed protection.

The goal of the Prince George's County program is to educate the public about water quality, focusing on steps that people can take to improve water quality. The program will identify specific tasks for public participation in the management of water quality. Tailored to the specific community demographics and types of land use, the program may include an array of educational programs dealing with the following topics: lawn care (proper fertilizer and pesticide application), car care (car washing tips proper disposal of oil and antifreeze), recycling, composting of yard wastes, reporting of pollutant spills, landscaping to improve wildlife habitat and water quality, swimming pool care, septic system overflows, use/storage/disposal of household hazardous wastes and toxic material, and animal waste control.

The county has also proposed a number of public outreach programs to involve citizens and industries in watching over their local water resources. Along with public education programs, public outreach programs will be important in storm water pollution prevention efforts. To the extent possible, community groups will be identified to conduct and organize a number of volunteer activities, including tree planting, stream cleanups, road cleanups, biological monitoring, and environmental watch programs to report and stop illegal dumping activities. Environmental activists in communities, citizen groups and Citizen Advisory Committees, industrial coalitions, and schools will all be targeted for various programs, such as:

- Adopt-A-Stream and Adopt-A-Road projects
- Water Quality Hotline
- Water pollution contests and projects at area schools
- Recreational opportunities
- Recycling
- Co-op for organic fertilizers
- Wildlife sanctuary delineations
- Wildlife corridors
- Tree planting
- Cleanups
- Award programs
- Household hazardous waste collection.

In addition, communities and public meetings will be held to encourage reporting of illegal dumping into storm drains. The public will also be instructed to watch for industries or other entities that may be contributing unpermitted, non-storm water discharges to the storm sewer. A Water Quality Hotline number is planned that will enable the public to talk to local officials about violations and other water quality problems. This information may then be used in conjunction with local and State investigation and enforcement programs to control illicit discharges to the county's waterways.

Prince George's County has also planned a Community Liaison Service to assist in implementing the storm water management program. The program stresses non-enforcement methods to solve water pollution problems by empowerment and cooperation. County officials will coordinate with various organizations, such as business groups, community associations, environmental groups, Citizen Advisory Groups, schools, to enlist their help in implementing the storm water management program. This coordination will entail notification of programs (stream surveys, watershed surveys, complaints), training of all people interested in any program, and recruitment of volunteers for baseline water quality sampling.

VOL 12

5293

SAMPLE PUBLIC OUTREACH MATERIALS

The following pamphlets and booklets are examples of public education materials that attract attention, are easy to read, and provide steps that the public can take to help improve water quality.

PET WASTE and WATER QUALITY

PUBLISHED FOR THE WISCONSIN PRIORITY WATERSHEDS PROGRAM

Pet-Owners, Take Heed . . . When you clean up after your pet, do you dump the waste in the street or storm sewer? Do you leave it to decay on the sidewalk or on the grass near the street? If so, you may be causing pollution or health problems.

Are You Polluting Our Lakes and Streams?

Pollutants from improperly disposed pet waste may be washed into storm sewers by rain or melting snow. Storm sewers usually do not go to a sewage treatment plant. Instead, most storm sewers drain *directly* into our lakes and streams, carrying many pollutants along with the water.

Pollutants commonly found in urban lakes, streams and ponds include:

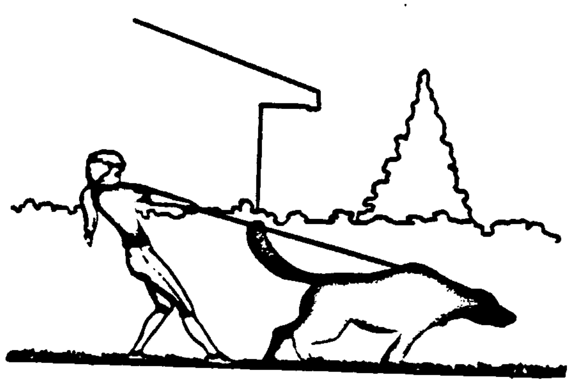
- Sediment
- Oil and antifreeze
- Pesticides and fertilizers
- Toxic chemicals
- Pet waste

When pet waste is washed into lakes or streams, the waste decays, using up oxygen and sometimes releasing ammonia. Low oxygen levels and ammonia combined with warm temperatures can kill fish.

Pet waste also contains nutrients that encourage weed and algae growth. Overly fertile water becomes cloudy and green—unattractive for swimming, boating and fishing.

Perhaps most importantly, pet waste carries diseases which make water unsafe for swimming or drinking.

About 90% of storm water samples collected recently in Wisconsin cities had very high levels of bacteria which violated water quality standards for recreational use. Common sources of bacteria include sanitary sewer overflows, pets, and urban wildlife.



Are You Risking Your Health?

When pet waste is disposed of improperly, not only water quality suffers—your health may be at risk, too. Pets, children who play outside, and adults who garden are most at risk for infection from some of the bacteria and parasites found in pet waste. Flies may also spread diseases from animal waste. Diseases that can be transmitted from pet waste to humans include:

Campylobacteriosis—A bacterial infection carried by dogs and cats that frequently causes diarrhea in humans.

Salmonellosis—The most common bacterial infection transmitted to humans by other animals. Symptoms include fever, muscle aches, headache, vomiting, and diarrhea.

Toxocariasis—Roundworms usually transmitted from dogs to humans, often without noticeable symptoms, but may cause vision loss, a rash, fever, or cough.

Toxoplasmosis—A protozoan parasite carried by cats that can cause birth defects such as mental retardation and blindness if a woman becomes infected during pregnancy; also a problem for people with depressed immune systems. Symptoms include headache, muscle aches, lymph node enlargement.

Pet waste may not be the largest or most toxic pollutant in urban waterways, but it is one of the many little sources of pollution that add up to a big problem for water quality. Fortunately, there are some simple things we can all do to help keep our water clean. See the other side for ways to keep pet waste out of local waterways.

You Can Make A Difference

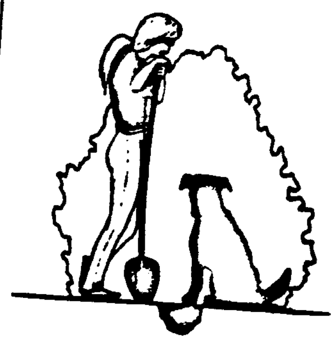
...ning up after your pet can be as simple as taking a plastic bag or pooper scooper along on your next walk. What should you do with the waste you pick up? No solution is perfect, but here are the choices:

❶ Flush it down the toilet . . .

The water from your toilet goes to a septic system or sewage treatment plant that removes most pollutants before the water reaches a lake or stream.

To prevent plumbing problems, don't try to flush debris such as rocks, stick[s] [o]r cat litter. Cat feces may be sco[oped] out and flushed down the toilet, [b]ut used litter should be put in a securely closed bag in the trash.

❷ Bury it in the yard . . .



Dig a hole or trench that is:

- About 5 inches deep;
- Away from vegetable gardens;
- Away from any lake, stream, ditch, or well.

Microorganisms in the top layer of soil will break down the waste and release nutrients to fertilize nearby plants.

Be cautious. Keep pet waste away from vegetable gardens and water supplies to prevent disease. Don't add pet waste to your compost pile. The pile won't get hot enough to kill disease organisms in pet waste.

❸ Put it in the trash . . .

This may be easy, but it is not the best solution. Waste taken to a landfill or incinerator can still cause pollution problems.

Check local ordinances. Putting pet waste in the trash is against the law in some communities.

Another option is to install an underground pet waste digester that works like a small septic tank. Before buying one from a pet store, check local laws that may restrict their use, design or location.

A Few Words of Caution

Around Your Home—If you leave pet waste to decay in your yard, be sure it does not become a problem. To prevent water pollution, clean up areas near wells, sewer inlets, ditches, and waterways. Always remove waste from areas where children play. They are the most frequent victims of diseases from pet waste. Of course, the best protection for children and adults is washing hands with soap and water.

In Your Community—Many communities have "pooper scooper" laws that govern pet waste cleanup. Some of these laws specifically require anyone who takes an animal off their property to carry a bag, shovel, or pooper scooper. Any waste left by the animal must be cleaned up immediately. Call your city or village clerk to find out more about local pet waste laws.

A publication of the University of Wisconsin–Extension, in cooperation with the Wisconsin Department of Natural Resources under funding from the Wisconsin Nonpoint Source Water Pollution Abatement Program. Be cautious. Keep pet waste away from vegetable gardens and water supplies to prevent disease. Don't add pet waste to your compost pile. The pile won't get hot enough to kill disease organisms in pet waste.

❸ Put it in the trash . . .

This may be easy, but it is not the best solution. Waste taken to a landfill or incinerator can still cause pollution problems.

Check local ordinances. Putting pet waste in the trash is against the law in some communities.

Another option is to install an underground pet waste digester that works like a small septic tank. Before buying one from a pet store, check local laws that may restrict their use, design or location.

A Few Words of Caution

Around Your Home—If you leave pet waste to decay in your yard, be sure it does not become a problem. To prevent water pollution, clean up areas near wells, sewer inlets, ditches, and waterways. Always remove waste from areas where children play. They are the most frequent victims of diseases from pet waste. Of course, the best protection for children and adults is washing hands with soap and water.

In Your Community—Many communities have "pooper scooper" laws that govern pet waste cleanup. Some of these laws specifically require anyone who takes an animal off their property to carry a bag, shovel, or pooper scooper. Any waste left by the animal must be cleaned up immediately. Call your city or village clerk to find out more about local pet waste laws.

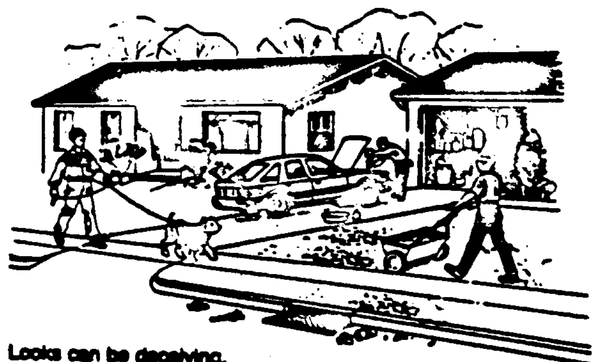
Practical Tips for Home and Yard

A SERIES OF WATER QUALITY FACT SHEETS FOR RESIDENTIAL AREAS

It's an unfortunate fact of urban life—many of our streams and lakes have been polluted. It may be a surprise, however, to learn that water pollution often starts right where you live.

In the community. Urban water pollution begins when development alters natural processes. Removing vegetation and replacing it with streets, rooftops and driveways greatly decreases the amount of water soaking into the soil. As a consequence, the amount of water running off to streams and lakes increases dramatically.

How does the water get from street to stream? Nearly every city street has storm sewer inlets, which open into a network of underground pipes. Leaves, litter, pet wastes, and other materials dumped or washed into storm sewer inlets *do not* go to a sewage treatment plant but flow *directly* to streams and lakes. Also, most storm sewer systems are designed to remove water from developed areas quickly during a storm. This allows pollutants to reach streams and lakes at a "rapid transit" pace.



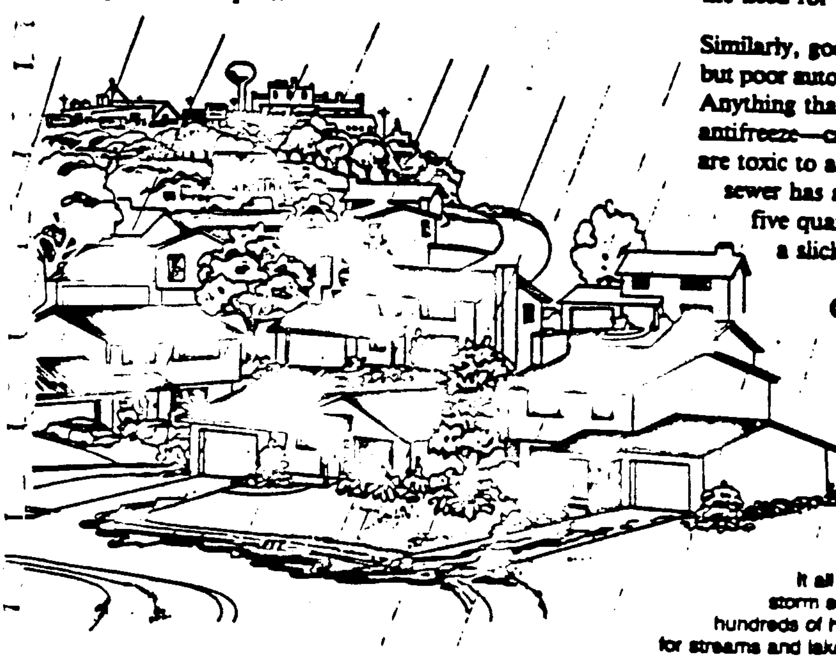
Looks can be deceiving.
Fertilizing the lawn, working on the car, walking the dog and other home activities might seem far removed from water quality. But with gutters and storm sewers, it's as if we all live on a streambank.

Around the home. Our actions around home can either help or harm water quality. For example, rain can wash improperly applied lawn fertilizer and pesticides into lakes and streams. On the other hand, careful landscaping and sound lawn care practices can reduce the need for chemicals and protect water quality.

Similarly, good auto maintenance pays in the long run, but poor auto maintenance can seriously harm our waters. Anything that drips from a motor vehicle—oil, gas, antifreeze—can wash into storm sewers. These materials are toxic to aquatic life. Dumping them into a storm sewer has almost unthinkable consequences. Just five quarts of oil in a stream or lake can create a slick as large as two football fields.

Clearly, there is a need to rethink what we're doing at home if urban waters are to be clean and usable. Fortunately, by following the tips inside, we can all contribute to cleaner water while making our homes and communities more attractive and liveable.

5298



It all adds up. Pollutants washed into storm sewers from dozens of streets and hundreds of homes can become major problems for streams and lakes in a community.

SIMPLE TIPS FOR CLEANER WATER

It really doesn't matter whether you live in the city or the country . . . whether your home is large or small . . . whether you have a lot of time and money to invest in your yard or just a little. There is something you can do to improve water quality. The following suggestions are ways that you can make a contribution to clean water and a healthy environment.

Around your home

- Mow often enough to leave grass clippings on the lawn. Alternatively, use clippings as a mulch or compost them along with leaves that might otherwise "fertilize" local waters.
- Keep fallen leaves out of the streetside gutter or ditch, using them around the yard as practical. Properly place the remainder near the curb (not in the street) just before municipal collection.
- Plant an extra tree for multiple environmental benefits, especially where it becomes part of a planting bed or "naturalized" landscape area that recycles leaves, twigs, and other yard "wastes."
- Seed bare soil and cover it with a mulch as soon as possible to minimize erosion. Disturb no more ground than necessary for a project, while preserving existing vegetation.
- Direct roof downspouts away from foundations and driveways to planting beds or lawns where water can safely soak into the ground. Consider using a rain barrel if practical.
- Use lawn and garden chemicals carefully and sparingly. Pesticides, including weed killers, should be considered a last resort—other controls come first.
- Limit the use of toxic or hazardous products in general. Keep them away from storm sewers, lakes, and streams.
- Collect oil and other automotive products preferably for recycling, or tightly seal and wrap them for proper disposal.
- Wash cars on the lawn, where soapy water can't quickly run toward the nearest storm sewer, picking up other pollutants as it goes.
- Keep cars tuned up and in good operating condition. Check especially for drips and repair leaks immediately to keep nuisance oils off pavement. Better yet, walk, bike or take the bus.
- For waterfront property, grow a "buffer strip" of dense, natural vegetation along the water's edge to filter pollutants and stabilize the shoreline.
- If using a septic tank system, maintain it properly through regular inspections and licensed pumping every two to three years.
- Monitor fuel use from any underground gas and oil tanks to make sure they are not leaking.

- Plan your landscape with environmental health in mind, reducing the area that is heavily maintained.
- Clean up pet wastes, from which nutrients and bacteria could be washed toward lakes and streams.
- Conservatively use salt in winter. Use sand or chip the ice off pavement when possible.

In your community

- Support and follow ordinances that limit soil erosion from construction sites.
- Encourage stormwater management practices that reduce runoff pollution by temporarily holding water in ponds or letting it soak into the ground.
- Encourage the safe but conservative use of salt on roads and limit application to critical areas.
- Tell public officials about your interest in cleaning up local waters and about their value to recreation and the economy.
- Support the preservation of wetlands as natural filters that protect water quality, prevent flooding, and provide vital open space.
- Promote "environmental or parkway corridors" adjacent to streams and waterways for water quality, wildlife, and multiple-use benefits alike.
- Participate in groups, projects, and events that promote conservation, waterfront recreation, or shoreline clean-ups.

Home Hot Spots for Water Quality

Around every yard are spots where your activities affect water quality. The illustration shows a few of them. Take a look around your own home with an eye toward water quality.

● Good for water quality ● Bad for water quality
● Could be good or bad, depending on your actions

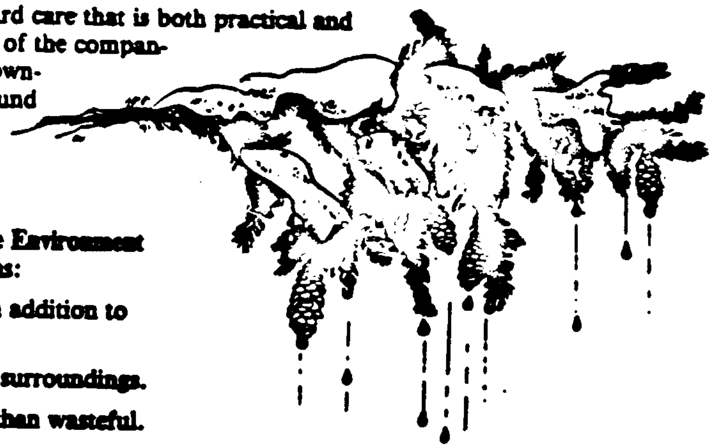
PRINCIPLES OF ENVIRONMENTALLY SOUND YARD CARE



This publication describes an approach to yard care that is both practical and environmentally sound. As a shorter version of the companion piece, *Rethinking Yard Care*, it offers down-to-earth tips for protecting water quality around your home and in your community. Look inside for information on home "hot spots" for water quality.

As stressed throughout the **Yard Care and the Environment** series, environmentally sound yard care means:

- Thinking of environmental consequences in addition to conveniences.
- Planning for greater harmony with natural surroundings.
- Being conservative and resourceful, rather than wasteful.
- Believing that small changes collectively make a big difference.
- Capitalizing on the time and cost-savings that rethinking yard care can bring.

Fact sheets in the **Yard Care and the Environment** series are designed to illustrate principles of environmentally sound yard care. They provide specific information about pesticides, fertilizers, landscaping, watering and related topics. These and other publications can be obtained from your local UW-Extension office, usually located in the county courthouse or another public building. Help is also available there regarding soil testing, pest identification, plant selection and other important items related to yard care and water quality.

(List continued on back panel)

1. *Get Involved*. Each of us pollutes ground and surface water. Each of us can help save it. Our contributions may seem small, but they join with those of others on the lake. Here are nine more ways you can help keep the lake clean.

2. *Save Water*. Saving water will help water quality by reducing the volume of water going through septic tanks. A dripping faucet wastes 20 gallons of water a day and a leaking toilet wastes 200 gallons. Use water sparingly while brushing your teeth, washing dishes, or shaving. Install a water conservation shower head and take short showers instead of baths. A bath uses 30-50 gallons of water, a short shower only 10.

3. *Soil Test for Fertilizer Application.*
Many farmers apply the same fertilizer at the same rate every year. Excessive amounts of nitrogen, phosphorus, or potassium that are not used by the crop leach through the soil and contaminate groundwater. Soil testing allows farmers to determine the exact needs of their fields. This insures optimum yields, a clean groundwater supply, and helps farmers save money by using less fertilizer.

4. *Control Soil Erosion.*
Utilize conservation practices such as conservation tillage and strip cropping to reduce soil erosion. Nutrients and pesticides bond with soil particles. When these particles are eroded into streams and rivers the chemicals are carried with them. Use filter strips near surface water areas and drainage ditches to help prevent water contamination.

5. *Practice Sensible Pest and Weed Control*. Apply pesticides and herbicides at the labelled rate. Excessive amounts will leach through the soil and can cause damage to crops and beneficial insects. Make sure the pesticide is labelled for the specific weed or insect and the crop to be treated. Do not apply in windy conditions, when rain is forecast, or to other areas as a "precaution."

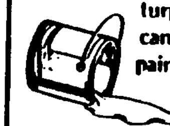
6. *Dispose of Pesticide Containers Properly*. All pesticide containers have a residue of the chemical stored in them. Triple rinsing the containers will remove over 99% of the residue. Use this rinsate in your applicator and be sure to puncture all old containers to prevent re-use. Take the rinsed containers to an approved landfill for disposal. NEVER pour rinsate on the ground!

7. *Protect Your Wellhead Area.*
Many farmers mix chemicals at or near a wellhead. Any spills near a well can easily contaminate the well water by flowing down against the well casing to the water. Always mix chemicals at least 100 feet from the well. In hilly areas make sure the mixing site is below the wellhead. A concrete pad with low curbs to catch any spills is an excellent mixing site.

8. *Manage and Utilize Animal Wastes Properly*. Concentrated animal wastes can chemically and biologically impair water supplies. Maintain lagoons and manure storage areas properly. Apply animal wastes to land to build up soil organics and lower commercial fertilizer costs. Incorporate applied wastes into the soil as soon as possible to obtain the greatest nutrient benefit. Do not apply wastes to stream banks or eroding areas.

9. *Use Equipment Service Products Wisely.*
Petroleum products, antifreeze, and battery acid contaminate water supplies just as easily as pesticides and wastes. Capture all used motor oil for disposal or re-use in lubricating chains or blades. Dispose of motor oil and antifreeze at recycling centers. Do not use gasoline as a parts cleaner or weed killer. Never pour oil or gasoline on the ground!

10. *Dispose of Household Products Carefully*. Many products under your kitchen sink or in the garbage can harm the water quality. Never pour paints, preservatives, brush cleaners, and solvents down a drain. Sewers or septic tanks do not treat these materials, and they can enter the groundwater untreated. Buy the product with the least amount of toxic material. Used turpentine and brush cleaners can be filtered and reused. Stuff paint cans and other chemical containers with newspapers before discarding.



The Lake Hartwell HUA Project is a group effort of local, state, and federal agencies. The USDA Soil Conservation Service (SCS) is assigned the overall leadership responsibility and also provides technical assistance to landowners. Financial cost sharing funds are provided by the USDA Agricultural Stabilization and Conservation Service (ASCS), and information and education assistance are coordinated by Clemson University Cooperative Extension Service.

Household alternatives for source control of heavy metals.

Often it is impossible to tell whether a product contains metals or not. Product ingredient lists are incomplete for one reason or another. Gradually this will change as the public demands "green" or environmentally sensitive products and more complete labelling information. In the meantime, research into the contents of household products is continuing, locally and nationally.

Testing conducted by the Washington Toxics Coalition of Seattle and other organizations has shown that certain products contain lower levels of metals than others. The information in this brochure is only a partial listing of products and alternatives, and will be updated and expanded from time to time.

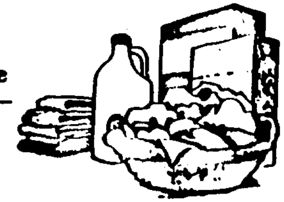
And choices don't have to be all or nothing.

Say for example that you have a favorite detergent that contains heavy metals. Try a substitute every second or fourth washload. You'll still be reducing the amount of metals by 25 to 50%—and eventually you may choose to make the substitution completely.

Garden:

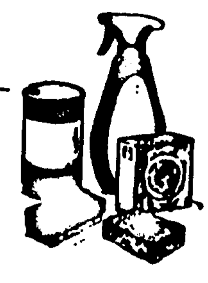
Product	Alternative
Root Killer	Crystals that are flushed down the toilet to control the growth of roots in sewer lines may contain copper. Mechanical removal may be an alternative.
Pesticides	May contain copper. Try attracting birds or introducing lady bugs or praying mantis to your garden. For small infestations, wipe leaves or use a high-pressure water sprayer and plain soap.
Weed control	Pull by hand or cover area with mulch, fabric, or plastic.
Fertilizers	Start a backyard compost bin, or use organic soil additives such as peat moss.

Laundry:



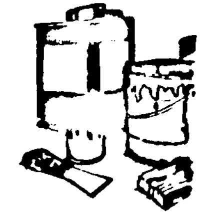
Product	Alternative
Detergents	In general, phosphate-free liquid laundry detergents contain lower levels of metals than do powdered varieties. Cheer liquid, Life Tree, Shaklee Liquid L, and White King Soap contain the lowest metals levels of products tested.
Bleach	Non-chlorine liquid bleaches are lowest in metals. Avoid bleaches containing phosphates. Try less bleach per load, with baking soda added, or presoak heavily-soiled items for 30 minutes in warm water with a half-cup washing soda.
Fabric softeners	Sheets have lower metals levels than liquids. Or add one cup vinegar or a quarter cup baking soda during final rinse.
Dishwashing Detergents	No difference between powder and liquid. An alternative is sodium hexametaphosphate, in same quantity as detergent. Hand-washing detergents have less metals than machine detergents, but do not use them as an alternative in the machines.

Household Cleaners:



Product	Alternative
Scouring Powder	Dissolve baking soda in water; or sprinkle on surface to be cleaned or on a sponge. Shaklee at Ease liquid and Soft Scrub have lowest metals levels of products tested.
General Purpose	Liquids are generally lower in metals.

Paints & Preservatives:



Product	Alternative
Paints	Avoid oil-based paints. Buy latex or water-based types. Estimate quantity carefully.
Paint removers	To remove paint from hands, massage with margarine or a few drops of baby oil. Wipe dry and then wash with soap. To strip paint, use a hook scraper, an abrasive block or sandpaper. Clean brushes right after use. Never use gasoline. Soften hard paint brushes in hot vinegar and wash with soap and water.
Preservatives	Avoid products with copper, arsenic, creosote. Use decay-resistant wood products such as redwood and cedar.
Stains	Use finishes derived from natural sources, such as shellac, tung oil, and linseed oil.

Automotive:

Product	Alternative
Used motor oil	May contain metals; never pour on land or down a sewer drain. San Jose and other cities have curbside recycling pick-up; or check with service stations/autocenters. Also, try to buy recycled oil—even for high performance autos.
Fluids	Spent antifreeze and brake fluid should be stored properly until they can be disposed of at a hazardous waste collection event.

5306

Cultivate Clean Water!

Fertilizer runoff, eroded sediments, septic wastes and pesticide residues are leading causes of water pollution.

★ Have your soil tested; use the right fertilizer at the right time, and don't use more than is needed.

★ Use pesticides only when other methods have failed—follow the manufacturer's instructions for use, storage and disposal. Buy only as much as you can use this season.

★ Help prevent erosion by planting slopes and resodding bare spots.

★ Keep your septic system running properly; keep the tank and leachfield areas clear.

★ Don't dispose of trash, lawn clippings, leaves or brush in drainage ditches or on flood control lands.

VOL 12

5307

FISCAL RESOURCES

The part 2 municipal permit application requires municipal permittees to demonstrate sufficient financial resources to meet the costs of implementing conditions of the permit. This section provides guidance on some sources of revenue available to permittees.

Selection of one or more revenue sources to fund a storm water management program depends on three factors: (1) type of organization that is operating the storm water management program, (2) amount of money that may be raised by various revenue options, and (3) political feasibility of the options.

The first consideration when choosing revenue options is to identify options that are legally authorized. This will depend on the type of local government organization used to implement the storm water program. Frequently, storm water programs are set up as storm water utilities and use a variety of revenue options. A storm water utility is an independent government entity established to design, construct, maintain, and operate a drainage system to control storm and surface water runoff. Utilities handle decisions concerning financing, personnel, and administration. These decisions are not delegated to another governmental department.

Once the legally authorized revenue options have been identified, the second consideration is the amount of money that may be raised and the activities that may be funded by each option. Each revenue source should be examined to determine if the funding is equitable to the consumers. It is critical that the revenue options chosen are able to finance all aspects of the program.

Third, the revenue options must be politically feasible. A successful capital improvement plan will select the revenue option, or package of options, that raises the required funding and is most politically feasible.

Revenue may be generated from the sectors of society that will benefit most from the replacement and expansion of the storm water infrastructure. Local governments may levy impact fees on developments for expansion and on redevelopments for upgrading the existing system. Impact fees should not be used for the replacement of facilities servicing current users. Likewise, current users should not be responsible for funding the expansion of an existing system. The revenue options chosen should be equitable in meeting the needs for replacement, upgrading, and expansion of the storm water system. Figure 3-1

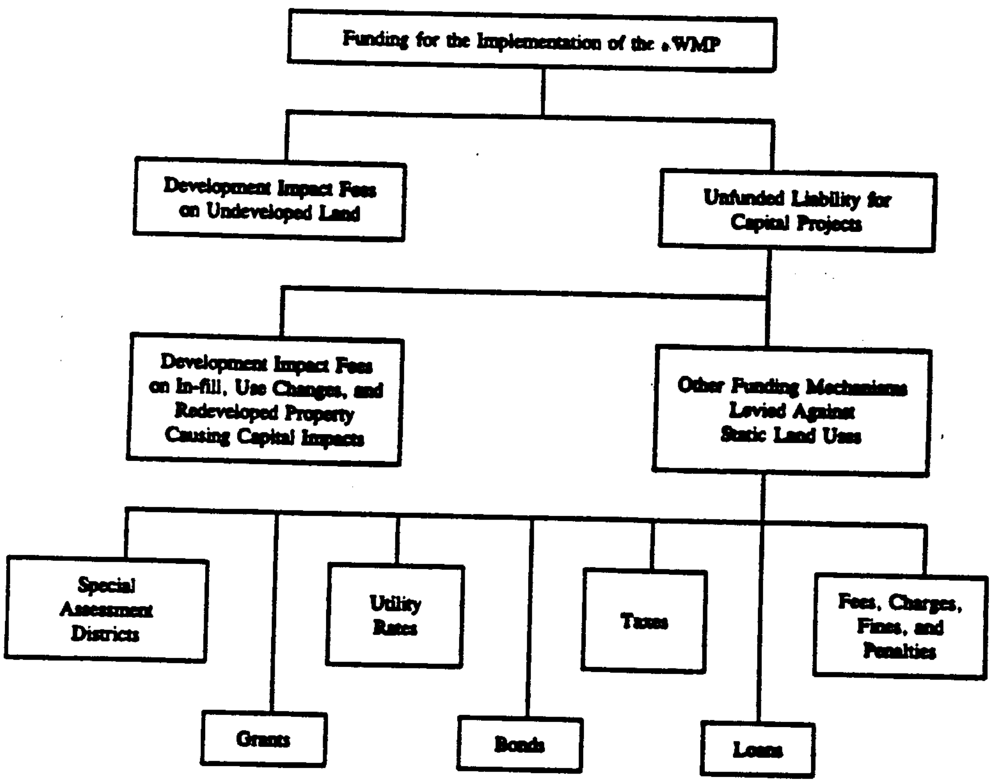

FIGURE 3-1. STORM WATER MANAGEMENT PLAN—FISCAL RESOURCES*

*This schematic is adapted from a figure in an article written by Douglas W. Ayres and Scott Thorpe titled, "Financing Capital Improvements," that was published in the *American Water Works Journal*, August 1991.

illustrates the capital and financing process. The figure shows the process by which capital projects are financed in relation to the benefits derived from the projects.

The following discussion provides an overview of the revenue options identified in Figure 3-1. In choosing a series of options to finance a storm water program, the first step is to determine whether funding is needed for replacing, upgrading, or expanding the system. If funds are needed to finance growth and expansion onto previously undeveloped land, then the authority should assess development impact fees. Development impact fees are assessed against private developers in compensation for the new capacity requirements their projects impose on public facilities.

Development Impact Fees on Undeveloped Land

A significant part of the SWMP is dictated by private development of previously undeveloped property. Additional homes and businesses require service that can only be supported by the construction of new infrastructure (including storm water BMPs). Local governments can levy development impact fees to defray the proportionate share of the infrastructure costs caused by and of benefit to the development. The capital improvement plan should contain sufficient detail to validate such fees.

Unfunded Liability for Capital Projects

Development impact fees will help finance the growth of storm water infrastructure in new developments; however, the upgrading and replacement of the system as it ages still needs to be financed. Local governments need a mechanism to finance the unfunded liabilities, other than continually drawing upon the historical funding sources. One way to help upgrade the storm water infrastructure is by including development impact fees on in-fill,[1] use changes, and property redevelopment. The funds collected can be used to help offset the cost of upgrading an existing system.

[1] In-fill is the cumulative development of single lots scattered throughout the community or the redevelopment of property that results in higher densities or increased demand on public facilities. In terms of storm water management, it includes residential to commercial use changes and an increase in the amount of impervious surface area.

Development Impact Fees on Developed Land

Levying development impact fees on properties being redeveloped, in-fill developed, or under changed use must be determined to assure current ratepayers that they are not subsidizing development. When levying development impact fees, there should be a distinct division between replacement and expansion of the system. The component of a project apportioned to replacement should be quantified. The component required for system enhancement to service new customers should be attributed to development impact fees. If the division is not made, current customers may pay for both replacing and upgrading the storm water infrastructure.

Funding of Nondevelopment-Related Project Liabilities

Portions of projects that cannot be legally or accurately charged to development should be financed by revenues paid by existing users of the capital projects. These projects may include the replacement of existing facilities or portion of an upgrade or an expanded plant that cannot be properly be apportioned to development. For example, new customers should not be expected to pay for replacing a down stream storm sewer line that has deteriorated as a result of age. Methods appropriate for use in financing storm water capital expenditures include fees, charges, fines, and penalties; taxes; utility rates; special assessment districts; debt financing (i.e., bonds and loans); and grants.

Fees, Charges, Fines, and Penalties

Municipal storm sewer operators have discovered that greater revenues may be secured with fewer complaints by separating special services and charges from general services and billing full recovery costs separately for these special operations. In addition, fines and penalties may be used to modify behavior.

Fees

Permit fees may be used to fund the portion of a storm water program that regulates activities of construction and development. Construction permits generate revenue, and they can be used to standardize the construction of new facilities and promote the use of BMPs to limit construction site runoff.

VOL 12

Charges

Special services are those requested and received by a few ratepayers. Utility services for which special fees should be charged include initiation of service, restoration of discontinued service, detection and repair of household leaks, line location, and review of construction plans.

Fines and Penalties

Fines and penalties are an important part of any effective enforcement program. These revenue sources are better suited to modifying behavior than raising revenue. As enforcement improves and the number of violations decrease, revenue from fines and penalties will decline. This is a reflection of an effective program. In some cases, especially in the early years of the program, revenue from fines and penalties are sizeable and may help to finance enforcement and related efforts.

<u>Taxes</u>

Local governments may levy a variety of taxes to fund their programs. The sales tax, property tax, business and occupation tax are the principal sources of revenue for most local governments. While all these tax sources have the potential for financing storm water management programs, in reality, few dollars are available for such programs for two primary reasons: (1) many local governments have utilized all available taxing authority provided by the State and (2) it is difficult to obtain political support to raise taxes in jurisdictions that have not exercised all of their legally authorized taxing power.

Many local governments have used all of their taxing authority and still have difficulty financing their basic programs. In these cases, it is unlikely that local governments will be able to make tax dollars available to fund storm water management programs. In jurisdictions where voters have a strong preference for minimizing local taxes, raising taxes is politically difficult. Thus, while taxing authority may be available, raising taxes to fund storm water management programs may not be a viable alternative.

If taxes are involved, then a tax analysis of the community's ability-to-pay should be performed. In such cases, the jurisdiction that has the power to levy taxes must have a clear understanding of its current and future tax sources. This will help quantify the need in terms of operational, subsidy, fixed-asset

531

replacement, or capital project purposes. With such information, specific tax sources may be identified to finance capital projects, relate benefits to payments, and indicate ability-to-pay.

Utility Rates

Municipalities may choose to form a storm water utility that is funded based upon values cf fees charged to users of the storm sewer system. A storm water utility's rate structure should finance the portions of the capital improvement plan that are not the responsibility of new or in-fill development. The portions of utility rates that will fund capital improvements are determined through detailed rate studies. Such studies are conducted to assess the proper payment level for operations and maintenance, fixed asset replacement, and system capital needs that cannot be attributed to development.

Rates are an appropriate mechanism for raising revenue for programs where there is a defined population being serviced. There are two types of rates: (1) unit charges and (2) service charges.

Unit Charges

Unit charges, the traditional types of rates, are calculated monthly and based on the quantity of a product consumed. For example, water and electricity rates are unit rates based on consumption. Utilities have traditionally levied rates in this form. Because it is difficult to measure the amount of storm water discharged by each user, however, storm water management programs do not lend themselves to levying rates based on unit charges. Increasingly, local governments turn to service charges to finance such programs.

Service Charges

Service charges are attractive when users cannot be charged according to their level of use, and services are difficult to price on a unit basis. Most service charges are structured to minimize administrative costs and to ensure that payments approximate the distribution of benefits received. As such, they are viewed as an equitable way to pay for services. Revenue from service charges is predictable and may be substantial.

The storm water service charge is determined through three commonly used methods, each based on the disruption of the natural drainage system. The first is an approximation of the percent impervious surface. Percent impervious surface is a measure of the property that does not allow water to penetrate the ground. This includes roofs, parking lots, and sidewalks. A second method is a flat rate based on the number of residents in a community. The third method assesses a service charge through a combination of percent impervious surface, type of business (SIC classification), and size of the property. Each business type is assigned a runoff factor that reflects the potential discharge of pollutants from the property and a development factor that reflects the percent impervious surface. The product of these two factors is then multiplied by the size of the property in 500 square foot increments. Once the rate is calculated, a fixed fee is added to cover administration costs. A municipality may use a combination of these methods or develop an entirely different method that better suits the characteristics of the community served.

An analysis of the service charge should be conducted annually to update needs, assure continued internal equity, and update cash flows and reserve projections. Computer models may be developed to provide annual rate updates. This type of operating system deflates potential political and financial problems by small annual rate increases instead of less frequent and more dramatic rate increases.

Special Assessment Districts

For services that cannot be categorized within a utility or fee schedules, a city, county, or utility district with the legal authority may create a special assessment district. Special assessments are levied for infrastructure installation or operations and maintenance. Normally, bonds are issued to finance capital construction that is backed by special assessments levied on district members.

Debt Financing

Financing of capital projects through public utility debt has three major advantages: (1) once the money is borrowed or a bond issued, a fixed interest rate and repayment schedule are established, and the debt is repaid over the years with dollars that are cumulatively deflating in value; (2) individuals who require and will use the facilities being built with the borrowed funds will pay for the facilities as they use them throughout debt repayment; and (3) debt financing provides large sums of money up-front to finance the capital expenditures.

Bond issues and loans are the two primary methods to acquire capital through debt financing. It is important to note that because borrowed funds must be repaid, the ultimate source for repayment of bonds

VOL 12

53/3

and loans is either taxes or rate revenue. Bonds are not suited to fund ongoing routine expenses, such as the operation of a storm water management program.

Bonds

The two types of bonds commonly used to finance capital acquisitions are general obligation and revenue bonds. General obligation bonds are backed by the full faith, credit, and taxing power of the local government issuing the bond. While a particular revenue source may be earmarked for their repayment, guarantee for repayment of the bonds is provided by the entire stream of tax revenues paid to the local government. For this reason, general obligation bonds may be considered stronger guarantees of repayment than revenue bonds.

Revenue bonds are backed by revenue from a dedicated source as a rate revenue. Because revenue bonds have far fewer statutory constraints, they have replaced general obligation bonds as the primary form of municipal financing. In theory, because this form of debt has its own guarantee (the project revenues, if any), it should not affect a locality's credit rating. In practice, however, revenue debt represents an indirect obligation of the issuing government. Because the lender has only the project revenues to depend on for repayment, interest rates are generally higher for revenue bonds than general obligation bonds.

In most cases, established utilities issuing bonds will issue revenue bonds. New utilities may not have enough history to issue revenue bonds. In these cases, general obligation bonds are issued or, alternatively, double-barreled bonds may be issued. These bonds are backed by both a dedicated revenue source and the full faith and credit of the local government.

Many small communities are unable to enter the national bond market because of poor credit ratings, little financial expertise, and relatively small capital needs. When access to the national bond market is available, small communities usually pay very high interest rates. Some States have created bond banks that enable small communities to issue bonds through the bank. This provides the small communities access to the municipal bond market at lower interest rates and with lower issuance costs.

Loans

A common loan program available within most States is the State Revolving Fund (SRF) for water pollution control planning. SRFs are intended to create a perpetual source of low cost financing. The

VOL 12

5314

funds invested in the capitalization of SRFs assist communities in meeting their needs by providing one-time loans or grants. Below market interest rates are the single most important advantage to some communities. This reduced capital cost decreased the level of user fees required to repay the project debt. The CWA requires recipients of SRF assistance to provide a dedicated source of revenue to cover loan payments. However, SRF assistance to storm water management programs is limited. To address this concern, EPA has developed a case study guidebook that presents examples of how expanded use activities can be funded under the SRF program. For more information on expanded uses, refer to EPA, Office of Water, *Funding of Expanded Use Activities by State Revolving Fund Programs: Examples and Program Recommendations*, August 1990, (EPA 43/09-90-006).

Most States have issued SRF loans at interest rates of 2 to 5½ percent below market rates. With the current interest rate being relatively low, the difference between State SRF loans and the market rate may be minimal and, therefore, not as attractive to communities. Similar to the construction grants, some States may require communities to provide a "match" prior to granting the loan. However, economically distressed communities have indicated that they would be unable to pay back a loan even at a zero percent interest rate and must rely on grants for funding.

Grants and Matching Programs

In addition to all the financial methods mentioned previously, States provide grants to communities for their wastewater quality needs. Grants can be in many forms, with or without community matches or use restrictions. Some States, for example, may provide grants to communities to be used as the prerequisite SRF match. Grants are neither a constant or consistent revenue source and should not be seen as an integral part of financing the daily operations of the storm water program. Grants are more likely to be issued for large one-time capital expenditures to assist in reducing the financial burden on the local community.

Table 3-2 lists selected Federal grant programs that can assist in the financing of storm water management needs. The list does not include grant programs available at the State level. The *Catalog of Federal Domestic* contains a comprehensive list of Federal assistance programs.

VOL 12 5315

TABLE 3-2. SELECTED FEDERAL GRANT PROGRAMS

Program Name	Economic Development—Grants for Public Works and Development Facilities
1992 Catalog of Federal Domestic Assistance Number	11.300
Administering Office or Agency	Economic Development Administration, U.S. Department of Commerce
Legislative Authority	Public Works and Economic Development Act of 1965, as amended
Objectives	To promote long-term economic development and assist in the construction of public works and development facilities needed to initiate and encourage the creation or retention of permanent jobs in the private sector in areas experiencing severe economic distress.
Types of Assistance	The basic grant rate may be up to 50 percent of the project cost. Severely depressed areas may receive supplementary grants to bring the Federal contribution up to 80 percent of the project cost; designated Native American Reservations may be eligible for up to 100-percent assistance. Additionally, redevelopment areas located within designated Economic Development Districts may, subject to the 80-percent maximum Federal grant limit, be eligible for a 10-percent bonus on grants for public works projects. On average, EDA grants cover 50 percent of project costs.
Uses and Use Restrictions	Grants can be used for public facilities, such as water and sewer systems, and infrastructure improvements. Qualified projects must fulfill a pressing need for the area and must (1) tend to improve the opportunities for the successful establishment or expansion of industrial or commercial plants or facilities, (2) assist in the creation of additional long-term employment opportunities, or (3) benefit the long-term unemployed and members of low-income families. In addition, proposed projects must be consistent with the currently approved Overall Economic Development Program for the area and for the Economic Development District, if any, in which it will be located and must have adequate local share of funds with evidence of firm commitment and availability.
Eligible Applicants	States, cities, counties, and other political subdivisions and private or public nonprofit organizations or associations representing a redevelopment area or a designated Economic Development Center are eligible to receive grants.
Information Contacts	Director, Public Works Division, Economic Development Administration, Room H7236, Herbert C. Hoover Building, Department of Commerce, Washington, DC 20230.

TABLE 3-2. SELECTED FEDERAL GRANT PROGRAMS (Continued)

Program Name	Economic Development—Support for Planning Organizations
1992 Catalog of Federal Domestic Assistance Number	11.302
Administering Office or Agency	Economic Development Administration, U.S. Department of Commerce
Legislative Authority	Public Works and Economic Development Act of 1965, as amended
Objectives	To assist in providing administrative aid to multi-county districts and redevelopment areas economic development planning and implementation capability and thereby promote effective utilization of resources in the creation of full-time permanent jobs for the unemployed and underemployed in high distress redevelopment areas.
Types of Assistance	A minimum of 25 percent must be obtained from nonfederal sources, except for grants to Native American Tribes. This may be in the form of cash and in-kind contributions. The Secretary is authorized to fund up to 100 percent planning support grants to Native American Tribes.
Uses and Use Restrictions	Grants are used to staff salaries and other planning and administrative expenses of the economic development organization.
Eligible Applicants	(1) Public bodies and other nonprofit organizations representing groups of State-delineated adjoining counties, which include at least one area designated as a redevelopment area by the Secretary of Commerce and one or more centers of growth not over 250,000 population, (2) Native American Tribes, and (3) counties designated as redevelopment areas or nonprofit organizations representing redevelopment areas or nonprofit organizations.
Information Contacts	Director, Planning Division, Economic Development Administration, Room H7023, Herbert C. Hoover Building, Department of Commerce, Washington, DC 20230.

TABLE 3-2. SELECTED FEDERAL GRANT PROGRAMS (Continued)

Program Name	Economic Development—Public Works Impact Projects
1992 Catalog of Federal Domestic Assistance Number	11.304
Administering Office or Agency	Economic Development Administration, U.S. Department of Commerce
Legislative Authority	Public Works and Economic Development Act of 1965, as amended
Objectives	To promote long-term economic development and assist in providing immediate useful work (i.e., construction jobs) to unemployed and underemployed in designated project areas.
Types of Assistance	The basic grant rate for Public Works Impact Program areas is 50 percent, except for Native American areas, where the rate can be 100 percent. Severely distressed areas may receive supplementary grant assistance to bring the Federal contribution up to 80 percent. Local matching share may be waived if appropriate entity can demonstrate that it has exhausted its effective taxing and/or borrowing capacity. On average, EDA grants more than 50 percent of project costs.
Uses and Use Restrictions	Renovation or construction of public works and development facilities to provide immediate jobs to the unemployed and underemployed in project areas.
Eligible Applicants	Eligibility is based on designation of the county or city as a redevelopment area according to the criteria under Section 401(a)(6) of the Public Works and Economic Development Act of 1965 (Public Law 89-136).
Information Contacts	Director, Public Works Division, Economic Development Administration, Room H7236, Herbert C. Hoover Building, Department of Commerce, Washington, DC 20230.

TABLE 3-2. SELECTED FEDERAL GRANT PROGRAMS (Continued)

Program Name	Water Quality Management Planning 205(j)
1992 Catalog of Federal Domestic Assistance Number	66.454
Administering Office or Agency	Office of Water, U.S. Environmental Protection Agency
Legislative Authority	Clean Water Act, Section 205(j), as amended
Objectives	To assist States (including territories and the District of Columbia), Regional Public Comprehensive Planning Organizations, and Interstate Organizations in carrying out water quality management planning.
Types of Assistance	Formula Grants. Each fiscal year, the Administrator shall reserve under Section 205(j)(1) an amount not to exceed 1 percent of the amount allotted and available for obligation or $100,000, whichever is greater, for the purposes of making grants to the States to carry out water quality management planning. Forty percent of the State's annual award must be allocated to Regional Public Comprehensive Planning Organizations and Interstate Organizations, unless EPA approves a lesser amount.
Uses and Use Restrictions	Section 205(j)(1) and Section 604(b) funds are awarded under Section 205(j)(2), to the State water quality management agencies to carry out water quality management planning. States are required to allocate 40 percent of the State's annual award to Regional Public Comprehensive Planning Organizations and Interstate Organizations. EPA may approve a State's request to pass through less than 40 percent if, after consultation with its Regional Public Comprehensive Planning Organizations and Interstate Organizations, the Governor determines that pass through of at least 40 percent will not (1) result in significant participation by Regional Public Comprehensive Planning Organizations and Interstate Organizations unless in water quality management and (2) significantly assist in development and implementation of the State's water quality management plan.
Eligible Applicants	State water quality management agencies.
Information Contacts	Contact the appropriate EPA Regional Office.

5319

ANNUAL REPORTS: ASSESSING THE EFFECTIVENESS OF THE STORM WATER PROGRAM

Purpose of Annual Reports

On the annual anniversary of permit issuance, the municipality is required to submit an annual report discussing the progress made toward achieving the specified storm water management program goals. As stated in Section 122.42(c) of the regulation:

> 40 CFR Part 122.42(c)(1)-(7)
>
> ***The report shall include -***
>
> (1) Status of implementing components of storm water management program that are established as permit conditions;
>
> (2) Proposed changes to storm water management programs that are established as a permit condition. Such changes shall be consistent with §122.26(d)(2)(iii) of this part; and
>
> (3) Revisions, if necessary, to the assessment of controls and the fiscal analysis reported in the permit application under §122.26(d)(2)(iv) and (d)(2)(v) of this part;
>
> (4) Summary of data that is accumulated throughout the reporting year;
>
> (5) Annual expenditures and budget for the year following each annual report;
>
> (6) A summary describing the number and nature of enforcement actions, inspections and public education programs;
>
> (7) Identification of water quality improvements or degradation

In developing their Part 2 municipal permit applications, applicants should have considered their strategy for preparing annual reports. While each municipality will take a different approach, in general, strategies will include identification of measures to track the long-term progress of their storm water management program goals, discussion of the role of monitoring data in assessing program effectiveness, and discussion of how the municipality plans to provide for future adjustment to this reporting strategy.

> The annual report will be used by the municipality to provide an assessment of the program performance, and guidance in establishing longer term assessment strategies.
>
> The annual report will be used by the permitting authority to monitor program compliance, and determine if the program is achieving the goal of improved storm water quality.

Benefits for Municipality

Completing annual reports is an invaluable exercise for municipalities because it allows them to gather all relevant information from the past year's storm water management activities and to assess the effectiveness of the program to date. If program goals are being met (or are in the process of being met), then the municipality can feel confident that its storm water management program has been designed and implemented in a relatively effective manner. If program goals are not being met, however, the municipality can reassess current program measures and make alterations if necessary. This annual evaluation should help permittees gauge tangible and intangible measures of progress (e.g, pollutant loadings or public awareness).

Benefits for State

Many municipalities are still in the early stages of developing storm water management programs suitable for controlling pollutants in discharges under an NPDES permit; others have relatively sophisticated programs in place. By reviewing the annual report, the State can determine whether various municipalities are developing their programs in a timely manner and can use information gathered in these reports to assess aquatic conditions on the State level.

While the annual report may be used by the States to evaluate municipal compliance with permit conditions, it also may indicate to the permitting authority where permit conditions need to be modified to address specific problems. Access to monitoring data identifying water quality improvements or degradation is important to the State for several reasons. First, it can be used to evaluate the success or failure of a management program in reducing pollutants. Second, it provides the State with information to use in a watershed data base. Third, the State can use the data to meet the informational requirements of various Federal programs. Data drawn from the annual reports will be especially useful for programs

VOL 12

5321

such as the Coastal Nonpoint Source Pollution Control Program (CZARA), the Safe Drinking Water Act Program, the Clean Lakes Program (CWA 314), and among others, which are identified in Section 1.3 of this document.

Required Elements

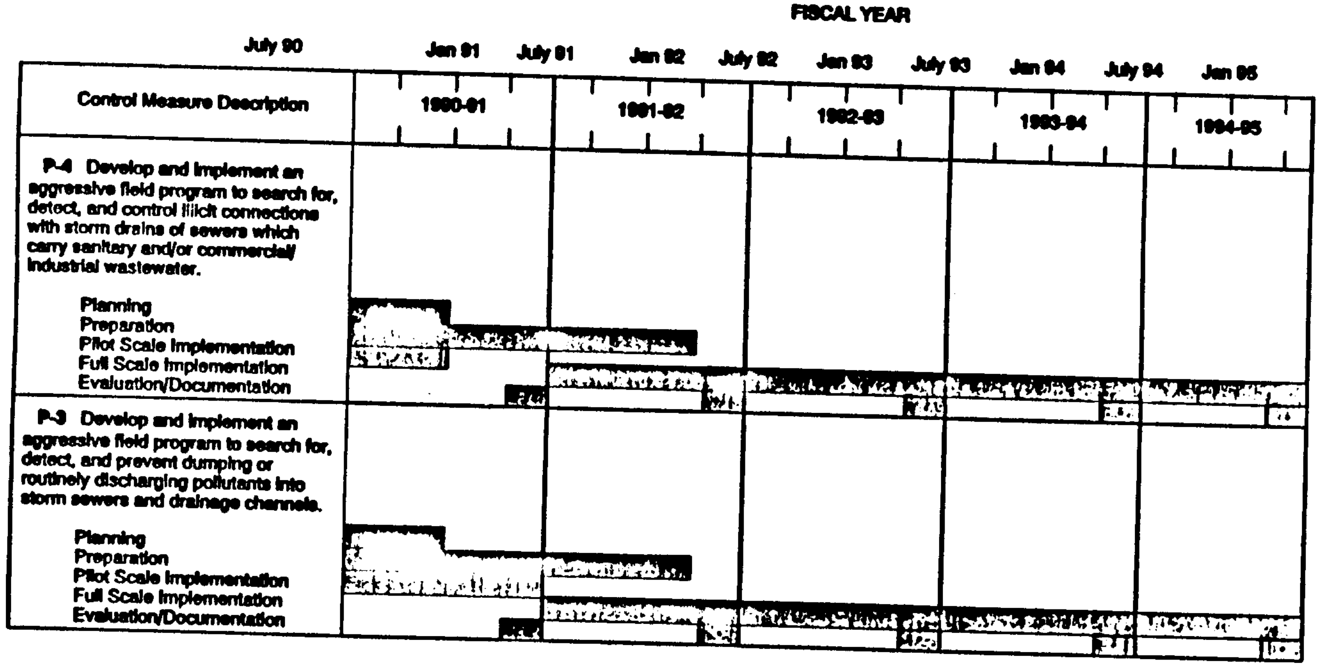
The annual report contains several requirements aimed at evaluating the accomplishments of the past year. This information can be used to evaluate the relative effectiveness of the storm water management program and to determine which elements should be continued or dropped from the plan. In some cases, the review will indicate that new methods or measures should be tried. The next several sections appear in the same order as in the permit; however, evaluating them in a slightly different order may be more productive.

Status of Implementing Components of Storm Water Management Program

This section addresses the relative degree to which storm water management program elements have been completed. Numerous approaches can be taken to accomplish this. You may want to begin by providing an overview of the program approach and history. Then, using your permit requirements as a guide, look at each component and decide whether it can be evaluated directly (e.g., pollutant removal) or indirectly (e.g., the success of a public outreach program). To complete this section, you can refer to various documents, including ordinances proposed or enacted, documentation for design or completion of structural controls, inspection reports, site assessments, and progress reports on cleanups. For components that can be directly measured, an effective way to present the information is in a matrix format, as shown in Figure 3-2.

Figure 3-2 shows activity goals versus activities accomplished. If the component you are addressing is not directly measurable, a narrative description can be given to convey its status. For example, you might describe the effectiveness of a public education program by discussing the number of meetings held to generate community awareness, the results of a post-meeting survey, any followup inquiries or letters from the meetings, or by discussing the increase in the number of citizens reporting violations.

Once you have addressed the circumstances of each program component, the status of the SWMP as a whole should be summarized.



• Submittal of annual report to RWQCB

NOTE: Schedules for tasks beyond the 1991 - 1992 fiscal year at *projected only* and will be re-evaluated and revised annually as part of the Annual Reporting Provision in the Permit. Implementation of control measures is contingent with results of planning, preparation, and pilot testing phases. Schedules for specific tasks may vary among the participants according to different conditions and considerations.

FIGURE 3-2. IMPLEMENTATION SCHEDULE FOR PROGRAM ELEMENT IV—ILLICIT CONNECTION ELIMINATION AND ILLEGAL DUMPING ELIMINATION

Proposed Changes to SWMP Established in Permit Conditions

After reviewing the effectiveness of your program components over the last year, you can determine which components require adjustments in order to meet long-term goals of water quality improvement. Among the reasons for proposing a change are:

- The existing component is not cost-effective
- The existing component has not performed as anticipated
- Physical circumstances have changed (e.g., the addition of an outfall or consolidation of existing ones)
- New technologies are available that produce better results.

When municipalities make programmatic changes, the background information used to formulate original decisions should be consulted. For example, you should be aware of the initial strategy used to develop the component, such as cost or time constraints. Consider how the initial strategy may have influenced component performance (e.g., lack of funding may have curtailed an activity before the end of the period). The next step is to explain the reason for requesting the change. A detailed description of the proposed component in terms of its impact on budget, schedule, and previously stated program goals should also be provided. For example, Santa Clara Valley's annual report included sections that described successes and shortfalls and future changes as a result of these two areas. All changes must be consistent with regulatory requirements in Section 122.26(d)(2)(iii). Requests for significant revisions to the storm water management program may require municipalities to partially resubmit their storm water permit application, as noted in Section 122.26(d)(2)(iv) and (d)(2)(v).

Revisions to the "Assessment of Controls/Fiscal Analysis" Sections of SWMP

Assessment of Controls

As part of the Storm Water Management Program, municipalities are required to provide an annual "assessment of controls," as well as a "fiscal analysis." This section should be completed only after you have reviewed and summarized the data gathered throughout the year. The municipality will compare the collected data and documented achievements of the program to the estimated data (e.g., reductions in pollutant loading and other site-specific measurements included in Parts 1 and 2 of the permit). Program components will not always meet the anticipated return value, and others may exceed

VOL 12

5324

expectations. The effectiveness of controls should be modified based on the actual values from data gathered throughout the past year.

A number of control measures cannot be evaluated in terms of direct measures, such as pollutants removed, but instead must be evaluated in terms of indirect measures. Indirect measures can often be very effective when direct measures are not appropriate or when they do not tell the whole story. For example, public education campaigns generally cannot be assessed in terms of pollutant reduction. An increase in the number of citizens participating in a cleanup program, however, would be a good indirect indicator of program effectiveness. Similarly, an increase in the rate of volunteerism within the community could indicate the relative success of a particular program. Another indirect measure might be an increase in the volume of recycling materials collected. An indirect measure of success in lowering pollutant loads would be a lowering in the number of beach closings or fishing restrictions. Be aware of the possibility of these indirect indicators as you review your records.

Table 3-3 contains control activities and possible ways to indirectly measure their effectiveness. Some of these activities may be appropriate for your situation.

TABLE 3-3. SWMP COMPONENTS AND SELECTED MEASURES

SWMP Component	Indirect Measure
Classes/art or writing contests for school aged children	Attendance records, entries received
Public hearings/discussions/seminars	Attendance records
Community cleanup programs or adopt-a-highway campaigns	Number of volunteers or truckloads of trash collected
Public education/outreach programs (e.g., print, video, audio)	Number of handouts distributed, media spots, or citizen response (e.g., phone calls or letters)
Violations reported by citizens	Number and type of violation
Public awareness	Letters, reported violations, court records indicating citizen suits against specific facilities, or a rise in recycling program participation
Household hazardous waste/used oil collection program	Number of gallons of hazardous waste or used oil collected
Industry outreach programs	Increase in the number of permit applications or articles in industry/local publications

VOL 12

5325

R0038633

Fiscal Analysis

The fiscal analysis section will also be updated based on actual figures for the year past. The information to be updated will include the existing budget, estimated operation costs necessary for the storm water management program during the term of the permit, capital available to meet these costs, and the list of available sources of funding and legal restrictions on these sources. Information for this section and the section on assessment of controls can be presented in a number of ways, including graphs, pie charts, and matrices. When the projected and actual figures differ, the permittee should also include a narrative explanation. For example, if the monitoring program exceeded its budget in a particular area, the permittee may indicate in the narrative that this was caused by the addition of several outfalls that were not included in the original list.

Summary of Data Gathered Throughout the Year

This section of your annual report is used to present an overview of the data gathered during the past year and is an important step in evaluating the effectiveness of your program to date (e.g., data may indicate that efforts to reduce a particular pollutant have been successful). This section should address, at a minimum, the results of the storm water monitoring program and the seasonal pollutant load estimates for each major outfall identified in the application.

Your municipality was required to include, in the Part 2 permit application, a proposed monitoring program for data collection from the separate storm sewer system. The permit issued to your municipality should specify the required monitoring for the permit term. The amount, type, and schedule for monitoring data collection will vary, depending on the proposed plan and on the permitting authorities need to characterize the discharge from the separate storm sewer system. The annual report should summarize the monitoring activities for the previous year indicating, at a minimum, the number of outfalls or screening points sampled, the number of times each outfall was sampled, and the location of the outfalls sampled. The annual report should also summarize the data collected in the monitoring program. The monitoring data should be organized by watershed. For example, the results of all monitoring performed on discharges to Smith Creek should be listed together in the same table. The report should include the following information for each outfall sampled:

- The date the sample was collected
- The duration and depth (in inches) of the storm event that generated the discharge

VOL 12

5326

- The form of precipitation (rainfall or snow melt)
- The type of sample collected (grab, flow weighted composite, or time weighted composite)
- The results of the analysis performed on the samples (e.g., the concentrations of the pollutants).

Monitoring data are best presented in a table or matrix format. Monitoring data can also be given in line graphs, bar charts, pie charts, or other easily understood formats.

Municipalities are also required to submit in their Part 2 applications a schedule for providing estimates of the seasonal pollutant loads and event mean concentration of any parameter detected in any sample collected for the Part 2 application requirements. The proposed schedule will be reviewed by the permitting authority and should be included in the permit conditions. The annual report should present the estimates of pollutant loads and event mean concentrations in the years specified in the permit schedule. The following information should be provided:

- Location of the major outfall
- Estimates for four seasonal pollutant loads for each parameter
- Brief description of method used to estimate the pollutant load
- Estimate of the event mean concentration of each parameter for a representative event
- Brief description of the method used to estimate the event mean concentration.

The estimates of pollutant loads and event mean concentrations should be presented in tabular format by watershed. The description of the calculation methods should indicate the extent to which the monitoring data were used. You may also include a written evaluation addressing the results.

For instance, Santa Clara Valley has a 5-year monitoring plan. This plan contains 10 monitoring sites, including 5 new sites—an industrial site, two transportation corridors, and two outfalls at a detention basin. The objectives of the plan are to:

- Gather data to determine long-term water quality trends
- Assess impacts of toxicity in storm water runoff and determine the pollutants causing the toxicity

VOL 12

5327

- Evaluate the appropriateness of the WQOs in protection aquatic life
- Determine the treatment effectiveness of an existing detention basin under different hydrologic conditions
- Assess the role of stream sediments as pollutant sinks or sources
- Describe the management implications of the findings.

Annual Expenditures and Budget for the Upcoming Year

This section addresses the coming year's proposed budget and the previous year's expenditures. An analysis of last year's budget and actual expenditures is used to determine if targeted amounts in the new budget will be adequate. Note which of your program elements will be continued, which will be dropped, and whether any new ones are to be added. Compare this list of proposed program changes to your available budget to ensure adequate funding. Once you have listed the projected cost for each item, note the source of funding and its approval status. Tracking approval status of funding for planned activities is important because the program may not be able to achieve its goals or permit compliance without funding approval. For example, the Santa Clara Valley Water District (SCVWD) is the managing agency for the municipality's budget. A management committee is appointed to decide on budget matters. The committee is chaired by the SCVWD Manager of Operations and Water Quality and includes representatives from each of the 15 co-permittee municipalities. The nonpoint source division's program manager is responsible for the administration and management of the budget program.

Summary Describing the Number and Nature of Enforcement Actions, Inspections, and Public Education Programs

This section should describe each enforcement action, educational program, or inspection conducted during the past year. This may include actions initiated by citizens, private industry, or the municipality. Refer to legal notices, court records, and newspaper articles for this information. Permittees should note the number and type of each action and, where appropriate, the number of participants or the number of materials distributed (as in the case of educational programs). When addressing enforcement actions, it may be useful to indicate the types of outcome (e.g., the names of offenders published in the local newspapers, the number of fines levied and the amounts, or the number of closures or stop work orders issued). The total number of inspections, the types of facilities inspected, and the number of violations cited due to these should also be indicated. It may be helpful to note the number of in-house training programs held for inspectors and the number of attendees. Public education programs may be assessed by noting the number of meetings or classes, subject matter, attendance figures, the number and type of media spots, printed materials distributed, etc. In evaluating program success, it may also be helpful to use some indirect measures, such as a decrease in illegal storm drain dumping, which may be attributable to storm drain stenciling. The key to Santa Clara Valley's enforcement program, for example, is the ordinance regulating industrial or other polluting activities within the municipality. The ordinance to be developed by Santa Clara Valley will include language addressing the following activities: controlling non-storm water discharges to storm drains, watercourse protection, regulation of outdoor material storage, control of improper grease disposal, and storm water management requirements for new development and redevelopment. For more specific information on how the ordinance will affect these areas, various subcommittees will develop guidance manuals on storm water controls.

Identification of Water Quality Improvements and Degradation

An important measure of the program effectiveness is the extent to which water quality has improved during the past year. In particular, municipalities should examine the water quality of the receiving waters to which the system discharges. This section should include such changes in receiving water quality and cite the reasons for them.

Municipalities were required to provide information on receiving waters and watersheds in Part 1 of the permit application. This information included a discussion of water bodies cited in State reports required by CWA Sections 305(b), 304(1), and 314(a); the State Nonpoint Source Report; and other reports identifying sensitive watersheds. To complete this section, you will need to review information gathered for these State and Federal programs during the past year and data from the required monitoring program. The municipality may have also gathered receiving water data as part of its strategy for continuing program assessment. In addition, information may be available from other Federal programs, as noted in Chapter 1. Be aware that numerical data are not the only way to determine water quality. One criterion you may use when judging water quality is how well the body of water meets its designated uses (e.g., recreational or industrial uses).

Once water quality improvement has been noted, the next step is to determine the cause for these changes. For instance, if the annual monitoring data indicate that discharge water quality and receiving water quality have improved proportionally, it may be attributable to the successful implementing of the SWMP. If monitoring data indicate an improvement in discharge quality yet receiving water quality has

VOL 12

5329

degraded over the past year, you must try to find the reasons (e.g., unforeseen weather conditions, such as flooding or drought, or sources upstream). Available computer water quality modeling programs may be helpful in completing this section.

Sample Annual Reports

An excerpt from an annual report on the Santa Clara County program is given after the summary.

SUMMARY

This chapter discussed the procedures on implementing the specific administrative requirements, which include public participation and public information programs, fiscal analysis, and annual reports. Each of these components is essential to the successful implementation of a municipal storm water management plan. Public participation and public information programs solicit public support by informing individuals of the importance of good storm water management and its effect on water quality. By conducting a thorough fiscal analysis program, a municipality examines all of the available sources of funding and selects the funding option(s) according to its specific needs. The annual report assesses the effectiveness of the management plan and allows the municipality to revise the plan based on the results of the assessment. The next chapter provides procedures for implementing an effective illicit connections detection program as a key element in the municipal storm water management plan and provides examples of programs from different municipalities.

VOL 12

SANTA CLARA COUNTY STORM WATER MANAGEMENT PLAN

Public Information/Participation Program

Provision 4b of Santa Clara County's NPDES permit requires the individual co-permittees to implement educational control measures to inform the public of and encourage participation in nonpoint source pollution control activities. Educational control measures are being implemented through a Public Information and Participation (PI/P) program.

Overview and Objectives

The main objective of the PI/P element is to implement educational control measures that provide information to the public and increase understanding of and participation in controlling nonpoint source pollution. The overall goals for FY 91-92 were to generate awareness of the program by defining the problem, inform individuals on ways to participate in solutions to the problem, and provide the means for participation. Specific industries were targeted for development of Best Management Practices (BMP) manuals, brochures, and posters. To aid in the development, publication, storage, and distribution of educational materials, the program established a PI/P Subcommittee in FY 90-91 to have primary responsibility for the implementation of this PI/P element.

Program Activities Completed and In Progress

The subcommittee produced nine types of educational material during FY 91-92. This included development and distribution of an Automotive Industry BMP manual and poster, a construction BMP poster, a "Recycle Your Used Motor Oil" poster, brochures describing how to decrease the use of toxic chemicals in the home, guidebooks, and stencils. The storm drain stencils developed in FY 90-91 were made available to co-permittees and volunteer groups to use during FY 91-92, and the remaining brochures developed in FY 90-91 were distributed to the co-permittees as needed. The co-permittees distribute them to the public through presentations, events, direct mailing, and billing inserts. In addition, the subcommittee distributes the materials to the public through presentations and events and to schools, teacher organizations, and specific businesses.

FY 92-93 Program Activities

The subcommittee will continue to be primarily responsible for implementation of this PI/P element, and to act as the central development and distribution point for all materials. The subcommittee will also be evaluating the effectiveness of the PI/P element activities of the past 2 fiscal years and developing recommendations for increasing the outreach effort. Activities planned for FY 92-93 include development of a program newsletter for nontechnical audiences with periodic distribution and development of a brochure for homeowners to use when dealing with contractors who offer potentially hazardous services (e.g., carpet cleaning, pest control). Other activities planned for FY 92-93 are creation and implementation of a distribution plan for program educational materials, translation of one brochure into Spanish, reprinting of existing materials to keep distribution points supplied, provision of funds to support other programs and for the purchase of educational materials produced by other programs in the Nation, development of a strategy for a recognition program for industry compliance efforts, and funding of the San Francisco Bay National Wildlife Refuge's Alviso Environmental Education Center.

5331

Co-Permittee Activities Completed and in Progress

The activities conducted by the subcommittee and the co-permittees for the PI/P element are summarized below. The detailed reports submitted by the subcommittee and the co-permittees are presented in the "Public Information/Participation" Program Element Report.

Infrastructure

The funding, staffing, and organizational/institutional infrastructures established by the co-permittees are summarized in Table 3-4. Of the 15 co-permittees, 6 relied wholly or partially on their general fund for funding of PI/P element activities in FY 91-92, and 10 acquired funding through related program funds, fees, or utilities. Funding for the program element was sufficient for 14 co-permittees in FY 91-92, and 1 reported that the budget was constrained. Staffing for the PI/P element was sufficient in FY 91-92 for nine co-permittees and insufficient, overextended, or limited for six co-permittees. A total of five of the six co-permittees reporting insufficient or limited staff proposed changes to resolve the problem; one indicated no changes would be made due to a hiring freeze. The 4 co-permittees who reported organizational limitations to implementation of the PI/P element identified the problems as establishment of effective communication among departments and difficulties in analysis of activities; 11 co-permittees reported that there were no organizational limitations.

Public Information and Participation Activities

The activities conducted by the co-permittees to meet the objectives of the PI/P element included storm drain stenciling; publication of articles in newspapers, community reports and newsletters, preparation of advertisements for radio and TV; direct mailing of brochures, and distribution of billing inserts (Table 3-5). Brochures and posters were distributed at presentations and special events and were made available at community centers and public office buildings. Some co-permittees provide telephone and mail service to distribute materials on request. In FY 91-92, more than 21,000 storm drains were stenciled, 76 articles and advertisements were published, 238 presentations and events were presented or attended, and more than 77,000 brochures and posters and over 82,00 billing inserts were distributed. The city of San Jose took the lead in producing bookmarks for the co-permittees to distribute to libraries for summer reading programs. Copies of San Jose's co-permittee PI/P activities are attached.

CHAPTER 4

CHAPTER 4

PROCEDURES FOR IMPLEMENTING A PROGRAM TO IDENTIFY AND REMOVE ILLICIT AND/OR INAPPROPRIATE DISCHARGES FROM STORM SEWER SYSTEMS

VOL 12

INTRODUCTION

The previous chapters presented information on municipal storm water management program regulatory requirements, guidance for municipal officials to rank storm water management activities for maximum cost effectiveness, and detailed procedures on how to implement specific administrative requirements. This chapter describes the procedures for identifying illicit discharges and implementing illicit discharge programs. Specifically, it discusses the components of an effective illicit discharge detection program, EPA's method for identifying illicit discharges, and examples of illicit discharge programs that have been or will be implemented in different municipalities.

Current interest in illicit or inappropriate connections to storm drainage systems is an outgrowth of investigations into the larger problem of determining the role of urban storm water runoff as a contributor to receiving water quality problems. Water discharge from storm water drainage systems often includes waters from many non-storm water sources. A 1987 study in Sacramento, California, found that almost half the water discharged from the storm water drainage system was not directly attributable to runoff. Illicit and/or inappropriate entries to the storm drainage system are likely sources of this discharge and can account for a significant amount of the pollutants discharged from storm drainage systems.

5341

Common sources of non-storm water entries include sanitary wastewater, automobile maintenance and operation waste products, laundry washwater, household toxic substances, accident and spill waste streams, runoff from excess irrigation, and industrial sources of cooling waters, rinse water, and other process wastewater. Although these sources can enter the storm drainage system various ways, they generally result from either direct connections (e.g., wastewater piping either mistakenly or deliberately connected to the storm drains) or indirect connections (e.g., infiltration into the storm drain system or spills collected by drain inlets). Sources can be further divided into those discharging continuously and those discharging intermittently. Table 4-1, presented in *Investigation of Inappropriate Pollutant Entries Into Storm Drainage Systems*, gives a simple overview of typical pollutant sources and their most likely characteristics. The table lists the potential sources for inappropriate pollutant entries into the storm sewer system from residential, commercial, and industrial areas.

TABLE 4-1. POTENTIAL INAPPROPRIATE ENTRIES INTO STORM DRAINAGE SYSTEMS

Potential Source	Storm Drain Entry		Flow Characteristics		Contamination Category		
	Direct	Indirect	Continuous	Intermittent	Pathogenic/ Toxic	Nuisance	Clear
Residential Areas

blank: not very likely

REQUIRED COMPONENTS OF AN ILLICIT AND/OR INAPPROPRIATE DISCHARGE DETECTION AND REMOVAL PROGRAM

The regulations under 40 CFR 122.27 require that the Storm Water Management Plans include "a description of a program . . . to detect and remove . . . illicit discharge and improper disposal into the storm sewer." The regulations further require the following components be included in the program:

- Prohibition of illicit and/or inappropriate discharges
- Field screening of outfalls within the drainage area

- Investigation of potential illicit and/or inappropriate discharges
- Spill response and prevention
- Public awareness and reporting program
- Control of infiltration of seepage from sanitary sewers to municipal separate storm sewer systems (MS4s).

Prohibition of Illicit and/or Inappropriate Discharges

Applicants must develop and implement an effective program to prohibit illicit and/or inappropriate discharges from entering MS4s. This is accomplished through the implementation of inspection procedures, local ordinances, and other legal authorities. In addition to adopting prohibition procedures, a schedule of the implementation process should be developed, and sufficient staff and resources should be allocated. The prohibition of illicit and/or inappropriate discharges should be linked to legal authority to ensure proper enforcement.

Field Screening

Applicants must propose procedures for a continued outfall field screening program. They can use the procedures from their Part 1 applications or use alternative methods. The field screening procedures in the Part 2 application should identify target areas to be examined for continued field screening and the reasons for selecting these areas. Also, any additional major outfalls recently identified should be included in the Part 2 field screening process. Of particular concern are areas of older development, areas with automobile-related industries, and areas with high concentrations of industrial facilities, among others.

This section should provide a detailed summary of the departmental responsibility for field activities, frequency of inspections, inspection procedures, inspection equipment, and documentation procedures for field activities.

Investigation of Potential Illicit and/or Inappropriate Discharges

Applicants should propose criteria to identify the parts of the MS4 that need investigation. Procedures for investigating likely locations for illicit and/or inappropriate connections include an MS4 inspection,

VOL 12

5343

R0038651

use of remote control cameras, onsite facility inspections and dye-testing, and additional monitoring to pinpoint pollutant sources. To adequately address these procedures, a checklist should be developed to ensure a comprehensive evaluation of the problem. The checklist should emphasize the use of the easiest, least expensive, and most effective methods for detecting illicit and/or inappropriate discharges. EPA suggests that a map be developed to supplement the investigation by identifying the illicit and/or inappropriate discharge locations.

Spill Response and Prevention

The purpose of spill response programs is to reduce the risk of spills to the public. These programs usually require coordination among fire, police, health, and public works departments. The municipal departments responsible for implementing the program should be identified and should address topics such as employee training, reporting procedures, spill containment, storage and disposal activities, documentation, and followup procedures. For each of these elements, particular attention should be given to good housekeeping and materials management practices. Procedures can be implemented through modification of the land use planning process and ordinance enforcement or through coordination with existing spill prevention or spill containment programs.

Public Awareness and Reporting Program

Applicants should promote, publicize, and facilitate public reporting of illicit and/or inappropriate discharges or water quality impacts associated with discharges from MS4s. The public awareness program should stress that the public is the beneficiary of this program. Typical public awareness and reporting programs may include developing a hotline number, educating school students, using inserts in utility bills, and media announcements. Effectively implementing these programs should lead to a reduction in the residential discharges noted in Table 4-1.

Proper Management of Used Oil and Toxic Materials

This program component should facilitate the proper disposal of used oil and toxic materials from households, industrial, and commercial users by establishing municipal collection sites or identifying private collection sites. This program should also include any outreach plans for handlers of used oil, as well as the general public.

VOL 12

5344

Control of Infiltration of Seepage

This program component should describe procedures that would control infiltration of seepage from sanitary sewers to MS4s. Some controls to consider for limiting seepage include inspection programs, preventive maintenance surveys, and ongoing infiltration and inflow programs for locating seepage sites. Seepage from malfunctioning septic systems should also be controlled.

EPA'S SUGGESTED METHOD FOR DETECTING ILLICIT AND/OR INAPPROPRIATE CONNECTIONS

EPA's suggested method for detecting illicit and/or inappropriate discharge connections, developed by the Office of Research and Development, is described in *Investigation of Inappropriate Pollutant Entries into Storm Drainage Systems* (user's guide), which is available from the Center for Environmental Research Information, (513) 569-7562. This method focuses on data collection and quantitative analysis to implement a proper illicit and/or inappropriate discharge connection program.

The user's guide may be used as part of a comprehensive storm water management plan that addresses all sources of storm water pollution. Correcting only the most obvious pollutant entries is unlikely to significantly improve the quality of storm water discharges or receiving waters.

A municipality planning to investigate inappropriate entries to its storm drainage system needs to base this on local conditions. This user's guide describes the issues and provides examples to facilitate the design of a local investigation.

All the applicable procedures described in the user's guide may be used to successfully identify pollutant sources. For example, attempting to reduce costs by only examining a certain class of outfalls or using inappropriate testing procedures will significantly reduce the utility of the testing program and result in inaccurate data. Cursory data analyses are also likely to result in inaccurate conclusions.

The methodology (appropriately modified) can also be applied to other types of sewerage systems, such as combined and separate sanitary sewerage, to locate inappropriate entries (e.g., untreated or toxic industrial wastewater/wastes and infiltration/inflow) into sanitary systems.

Figure 4-1 presents a simplified flow chart for the detailed methodology contained in the user's guide.

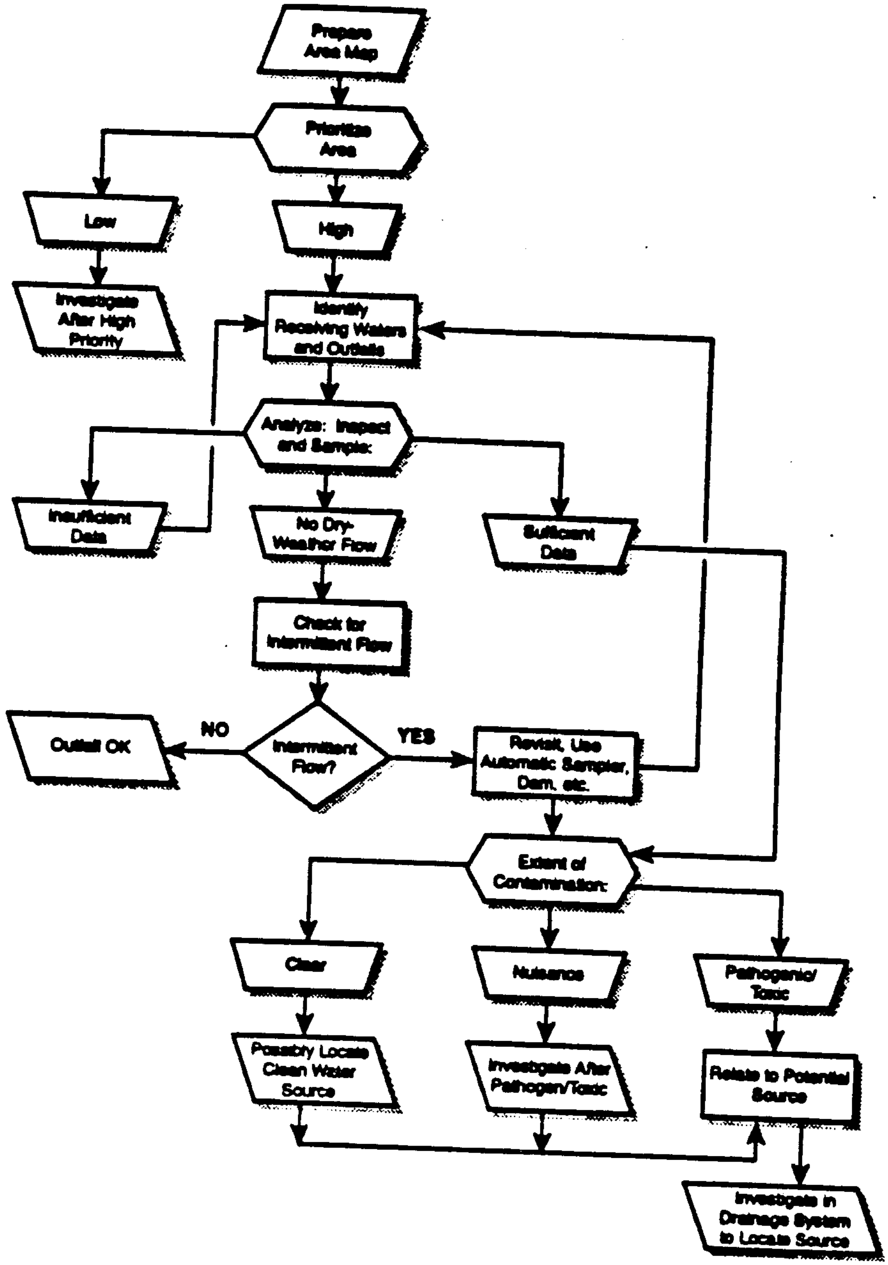

FIGURE 4-1. SIMPLIFIED FLOW CHART SHOWING THE DETAILED METHODOLOGY CONTAINED IN THE USER'S GUIDE

The initial phase of the investigative protocol includes initial mapping and surveys. These activities require minimal effort and result in little chance of missing a seriously contaminated outfall. More detailed watershed surveys are then performed to locate and correct the sources of the contamination in the identified problem areas. After corrective action has been taken, repeated outfall field surveys are required to ensure that the outfalls remain uncontaminated. Receiving water monitoring should also be conducted to analyze water quality improvements. If expected improvements are not noted, then additional contaminant sources are likely present, and additional outfall and watershed surveys are needed.

The user's guide is designed to provide information and guidance to agencies planning or implementing an investigation of illicit and/or inappropriate entries to a storm water or wastewater drainage system. This is achieved by:

- Providing a methodology to identify and describe potential sources of non-storm water pollutant entries into the storm drainage system
- Describing an investigative procedure that will allow a user first to determine whether significant non-storm water entries are present in a storm drain and then to identify the potential type of industrial, residential, or commercial sources responsible, as an aid to determining the ultimate location of the source.

Procedure

The user's guide describes the following investigation steps:

- Drainage area mapping
- Tracer identification
- Field survey and data collection
- Analyses of data collected
- Categorization of outfalls
- Investigation and remediation
- Pollution prevention program.

VOL 12

5347

VOL 12

Mapping

The mapping exercise is carried out as both a desktop operation by using existing information and with field visits to collect further data and to confirm existing information. The maps should provide complete descriptions of the drainage areas, including outfall locations, watershed boundaries for each outfall, critical land use areas (mostly commercial and industrial areas), permitted discharges to the storm drainage system, city limits, major streets, and streams. The user's guide discusses critical land use areas and lists major industries and their potential to be non-storm water entry sources.

The drainage areas are ranked in the order of their potential to cause problems. This allows priorities to be set for field investigation of the outfalls. Note that all outfalls will eventually require investigations, and the mapping stage is important because the entire investigation is based on it.

Geographical information systems (GIS) are computer-based tools that can be used to store, display, and analyze geographical information; GIS can be used by municipalities when mapping their storm sewer systems for the purpose of documenting illicit and/or inappropriate connections. The GIS system also serves as a data base to store information about the illicit and/or inappropriate connections, such as field screening and enforcement activities. If GIS is not being used or is not available to a municipality, then zoning maps, marked with important features (e.g., identification of potential discharge points) can also be used to target potential discharges for identification and further action, as necessary.

5348

Tracer Identification

To detect and identify non-storm water entries, dry-weather outfall discharges are analyzed for selected tracers (e.g., ammonia, surfactant), which are found in the potential contaminating sources. Ideally, the selected tracers should be unique for each potential non-storm water contaminating source and should exhibit the following properties:

- Significant difference in concentrations between possible pollutant sources
- Small variations in concentrations within each likely pollutant source category
- A conservative behavior (i.e., no significant concentration change due to physical, chemical, or biological processes)
- Ease of measurement with adequate detection limits, good sensitivity, and repeatability.

R0038656

The user's guide suggests tracers for common pollutant sources (e.g., sanitary wastewater, septic tank effluent, laundry wastewater, and vehicle washwater, as well as potable water and "natural waters"). A non-storm water entry investigation may need to select additional tracers specific to potential pollutant sources, especially industries, in the study area (e.g., major ions, specific heavy metals). For each selected tracer, the concentration means and standard deviations in all the potential source flows in the drainage area are needed (use of data from other drainage area investigations is not recommended).

Local data collected on tracers will be essential to identify the contamination sources in the outfall discharge. It is important that the tracer data be accurate. Guidance is provided in the user's guide on representative sampling and on the number of samples required for valid data.

Field Survey and Data Collection

Field investigations are used to locate and record all outfalls, including outfalls not previously identified from the mapping exercise. During field investigations, outfalls are physically inspected and samples are taken of any dry-weather flow for analyses. The field survey should, at a minimum, include:

- Accurately locating outfalls and assigning ID numbers
- Photographing outfalls
- Estimating outfall discharge flow rate (or identifying likely intermittent discharge)
- Physically inspecting and recording outfall characteristics, including discharge odor, color, turbidity, floatable matter (e.g., solids, oil sheen), temperature, deposits, stains, vegetation affected by pollutants, and damage to outfall structure
- Collecting dry-weather discharge samples for tracer analyses of specific conductivity (can be field measured with temperature), fluorides, hardness, ammonia, potassium, surfactants, fluorescence, and pH, as well as other samples, depending on industrial activities.

Intermittent flows will be more difficult to confirm and sample. Additional field visits, use of automatic samplers, and flow damming techniques may prove successful for obtaining samples of intermittent flows.

Analyses of Data Collected

Simple testing procedures are suggested for analyzing the tracer parameters. Except for temperature and specific conductivity measurements, the analyses should be carried out in a laboratory and not in the field to ensure consistent results. The laboratory need not be sophisticated; it can be a room or a trailer set up on a temporary basis.

The recommended analytical procedures for each tracer parameter are based on the following criteria:

- Appropriate detection limits
- Freedom from interferences
- Good analytical precision
- Low cost, good equipment durability
- Reasonable operator training requirements.

The user's guide also includes guidance on appropriate levels of analytical detection and precision (repeatability) needed to achieve acceptable results.

Categorization of Outfalls

Three levels of outfall discharges are defined: (1) pathogenic or toxic substance pollution, (2) pollution that is a nuisance or threatens aquatic life, and (3) unpolluted.

Pathogenic and toxic pollutants can cause illness upon water contact or consumption. They can cause significant water treatment problems for downstream consumers, especially if the pollutants are soluble metal and organic toxicants. These pollutants may originate from sanitary, commercial, or industrial wastewater non-storm water entries; household toxicant disposal; automobile engine degreasing; and excessive use of fertilizers and pesticides.

Nuisance and aquatic-life-threatening pollutants include laundry wastewaters, lawn irrigation runoff, vehicle washwaters, construction site dewatering, and washing of concrete ready-mix trucks. These pollutants can cause excessive algal growths, tastes, and odors in downstream water supplies, offensive coarse solids and floatables, and noticeably colored, turbid or odorous waters.

VOL 12

Clean water discharged through storm water outfalls can originate from natural springs feeding urban creeks that have been converted to storm drains, infiltrating ground water, infiltrating domestic water from watering leaks, etc.

Outfalls can be classified by comparing the collected dry-weather outfall discharge data with potential sources flow data. At the very least, outfalls with major pollutant sources should be identified for immediate remediation.

Investigation and Remediation

Drainage area investigations to locate the source(s) of non-storm water entries can take a number of forms:

- In-depth watershed evaluation (e.g., evaluate whether sources are likely to be an individual industry or an areawide problem, such as general failure of sanitary wastewater sewers)
- Drainage system upstream surveys (e.g., tracer analyses, visual inspections, smoke and dye tests, and TV surveys to trace the individual sources of the pollutant)
- Industrial and commercial site studies (e.g., identify materials/chemicals used and/or produced and whether the sites discharge to a storm drainage system).

5351

Pollution Prevention Program

The goal of eliminating all non-storm water entries will probably not be achieved completely; however, any action that prevents future entries should be promoted. Typical actions include educating the public (industrial, commercial, residential, and governmental) and developing zoning and ordinances.

Discussion

In addition to these steps, the user's guide provides background information in the form of discussions, tables, and checklists to assist the user in identifying contaminated outfall discharges and potential sources and in using the tracer data to estimate the proportion of each contaminating source flow in the outfall flow.

SUMMARY

This chapter discussed the components of an effective illicit and/or inappropriate discharge detection program. The presence of illicit and/or inappropriate connections within a storm sewer system can adversely affect water quality. By implementing an effective illicit and/or inappropriate discharge detection program, a municipality can identify the source(s) of illicit and/or inappropriate discharges and take the action necessary to eliminate the discharges. Before the development of an adequate illicit and/or inappropriate discharge detection program, however, municipalities must identify the available fiscal resources, assess the public's knowledge of water quality issues, and develop an SWMP that will successfully complement the illicit and/or inappropriate discharge program. This chapter presented the components of an effective program, EPA's method of detecting illicit and/or inappropriate discharges, and detailed examples of programs from various municipalities. The components of an effective program include a mechanism for prohibiting illicit and/or inappropriate discharges, field screening, investigation of potential illicit and/or inappropriate discharges, spill response and prevention procedures, public awareness and reporting program, used oil/toxic materials management and disposal procedures, and methods to control infiltration from sanitary sewers to storm sewers. Within these components, the use of GIS for mapping illicit and/or inappropriate connections and for maintaining a data base of information on illicit and/or inappropriate discharges throughout the municipality is essential. EPA's method for detecting illicit and/or inappropriate connections is discussed within the user's guide. This method relies on the quantitative analysis of dry weather flows to identify the pollutants within illicit and/or inappropriate discharges. This information is then used to locate the potential source(s) of the discharges.

CASE STUDIES

The following case studies provide information on the various ways illicit and/or inappropriate discharge programs can be developed and implemented. These municipalities have incorporated the components of an effective program in ways that are most effective to their specific needs.

In 1985, the Fort Worth Public Health Department (Health Department) developed and implemented a unique program for detecting illicit and/or inappropriate discharge connections to its MS4s. The program, known as the Drainage Water Pollution Control Program, focuses on empowering people to take action against illicit and/or inappropriate dischargers and places less emphasis on excessive data collection. As a result, Fort Worth's program is cost efficient and ensures corrective compliance. The four components of Fort Worth's program are:

- Problem detection
- Source investigation
- Correction of problems
- Prevention of problems.

Problem Detection

The Health Department identified three means of detecting surface water contamination: (1) a drainage water quality assessment and monitoring program, (2) a biotoxicity testing method, and (3) a program for determining the concentrations of six metals in drainage sediments.

Assessment and Monitoring

The drainage water quality assessment and monitoring program examines the types of discharges entering a receiving water body (Trinity River). To properly assess the affect these discharges have on the water body, the Health Department thinks it is essential to monitor the discharges over an extended period of time. The monitoring technique used, however, is not one of quantitative analysis but relies mostly on visual observation of the outfalls or drainage ways. From its observations, the Health Department concluded that the presence or absence of persistent features (e.g., vegetation, animal life) at an outfall are directly related to water quality. Even though persistent features are a direct indication of water quality, one has to know which features are associated with good water quality and vice versa. One indication of a healthy waterway is the presence of a variety of plant and animal life; unhealthy waterways have little or no plant and animal life.

The assessment and monitoring phase of this program is based on detecting subtle changes in the waterways from frequent observations and by the use of modified versions of conventional chemical tests. The Health Department's methodology does not readily utilize consulting firms or laboratories to determine if a problem exists; however, if exact determinations are required, then the services of the aforementioned are solicited.

The Health Department chose 24 drainage outfalls and one control site for monthly water quality monitoring to assess the presence or absence of the undesirable features in the outfalls. Undesirable features include filamentous sewage bacteria, mosquito larvae, fish kills, water color, water odor, water clarity, water pH, oil sheen, floatable solids, and positive water tests to Nessler reagent. The information gathered from the monthly monitoring is recorded on data sheets. The data are compiled from all of the sites and displayed on a table with a 45-month profile. The occurrence and persistence of undesirable features indicate the impact that outfall drainage has on the Trinity River and the effectiveness of correction and prevention measures within the program.

Biotoxicity Testing

The 24 drainage outfalls are then subjected to biotoxicity testing. The purpose of the testing is to determine the presence of toxins in the waterway, the hazard level created by the toxins, and the source of the toxins. The object of the test is not to define the properties of toxic substances. Instead of a laboratory biotoxicity test, the Health Department conducts in-situ toxicity tests. Native aquatic species are used to assess the environmental affects of the toxins on the waterway habitat. The use of native species is key because they are accustomed to the environmental characteristics of the ecological region. To test these species, the Health Department used homemade minnow buckets, which are floating, ventilated, transparent combiners used to hold test organisms. The test is also used to examine surface water contamination.

Metal Testing

In addition to biotoxicity, the 24 sampling sites are analyzed for 6 metals. Water and sediment samples are collected for the following metals: cadmium, chromium, copper, lead, nickel, and zinc. To establish a basis for comparison, three nonpolluted background sampling sites were chosen to reflect the natural occurrence of these six metals within the waterway. The samples are analyzed according to the protocol within Standard Methods for the Examination of Water and Wastewater.

Source Investigation

After the detection of a drainage source of pollution, an investigation follows to determine whether the source of the problem is known or unknown. If the source is known, then the responsible party is connected, and action is taken to stop the discharge as soon as possible. The notification is done by a pollution control officer or other designated official. Unknown sources are traced back from the detection point to the source. The Health Department has a specially trained Storm Tunnel Investigation Team to trace illicit and/or inappropriate discharges through the sewer system to the source. The Health Department uses the following tools for source investigation: Storm Tunnel Investigation Team; a safety equipment Step Van; biotoxicity testing devices; fluorescent dyes and smoke generators for obscure tunnels and leaks; water evaluation equipment; Federal, State, and local regulations; and drainage maps.

All investigative activities are documented with photographs, reports, and samples. Required sampling is done according to Standard Methods and is handled through the chain of custody procedures specified by the legal authority. Other important information recorded during the investigation include time and date of the violation and investigation, location of the violation, location of the responsible party, name and telephone number of the responsible party and witnesses, description and results of any tests conducted during the investigation, and the name(s) of the investigator(s). All of this information is recorded on a Discharge Report Form.

Correction of Problems

The Health Department's approach is to correct the problem at the source, instead of the typical "end-of-the-pipe" treatment. Correcting problems at the source is essential because the drainage way below the outfall improves and the responsibility is placed on the pollution generator and not the municipality. Fort Worth notifies the responsible party, explains the violation(s) and the need to make corrections, issues time-dated notices on when to make corrections, and checks the violator's progress. If the pollution generator refuses to make corrections, then legal enforcement agencies (e.g., EPA) are notified.

Prevention of Problems

In addition, the Health Department uses a strategy of "concentric containment." Concentric confinement includes the recognition, containment, and resolution of existing illicit and/or inappropriate connections to prevent their spread to other areas of the city. To achieve this, the Health Department conducts weekly "roving patrols" of various city sectors and critiques the development plans of new industries and businesses. Public education programs (e.g., videotapes, workshops) are also available to community groups, schools, and other regulatory organizations.

To receive more information about Fort Worth's program, contact Gene Rattan at (817) 871-5463.

In Charlotte, North Carolina, controlling illicit and/or inappropriate discharges is an important issue. In conjunction with Mecklenburg County, Charlotte is in the process of developing an extensive program for detecting and removing sources of illicit and/or inappropriate discharges. A discussion of the components of Charlotte's illicit and/or inappropriate connections program follows.

Ordinances

Presently, Charlotte does not have an ordinance prohibiting illicit and/or inappropriate discharges into storm sewers or surface waters. However, the city is proposing an ordinance that will prohibit plumbed-in connection, intermittent discharges, and the dumping of trash and wastes (hazardous and nonhazardous) into surface waters. Other aspects of the ordinance will define non-storm water discharges and address the enforcement process, penalties for violation, and due process for appeals of violations. The development effort will be coordinated with Mecklenburg County's ordinance and will occur during the first year of the permit. The cost is estimated to be about $11,300.

Field Screen

Charlotte's proposed field screening program will result in a one-time visual field screen of every outfall in the city. The program will specifically address improving the efficiency of field screening methodology; a one-time visual screen of all outfalls; field screening of problem area outfalls; continuation, support, and expansion of Mecklenburg County's Stream Walk program; and maintenance of a GIS storm water data base.

Field Screening Methodology

To improve the efficiency of the field screening methodology, Charlotte takes a two-phased approach. Phase one will utilize the observation protocol used in the Part 1 application process. Observations will be made for the presence of dry weather flow, color, turbidity, and oil sheen. Phase two will identify sources of the illicit and/or inappropriate discharges and ensure compliance with the illicit and/or inappropriate discharge ordinance. The cost of this program is $10,000.

One-Time Visual Field Screen

Charlotte is in the process of developing a storm water utility, which includes a preventive maintenance program for the storm sewer system infrastructure. The storm drainage system is currently being inventoried. As part of this inventory, the city has initiated a 2-year, one-time visual field screen for dry weather flow of all outfalls. The cost of the program is $8,000 per year.

Problem Area Outfalls

As part of field screening the problem areas, Charlotte and Mecklenburg County investigated known water quality problems throughout the municipality. The city was broken down into polygons, which represented neighborhoods, land uses, and stream segments. These polygons were then prioritized on the types and magnitudes of the problems. To address the problems identified in the investigation, the city will be divided into zones and each zone will be assigned a zone team. This will be implemented in the second year of the permit and costs $130,000.

Mecklenburg County Stream Walk Program

The Mecklenburg County Department of Environmental Protection (MCDEP) sponsors a Stream Walk program. The participants in the program are volunteers from the county, Charlotte, and other surrounding counties. The volunteers are split into teams and assigned a resource person from the MCDEP staff. They walk streams that are affected by point and nonpoint source pollution and are responsible for investigating and determining the pollutant source(s). The weaknesses of the program, to be addressed by Charlotte and MCDEP, are available personnel, volunteer motivation, volunteer training, and public education. The program will cost approximately $36,000.

GIS Data Base Maintenance Program

A GIS data base will be used to track all field screening activities. The results of initial and followup field screening will be entered into the data base and used to identify the problem areas. The program is currently in use and the estimated cost is high.

Followup Investigation

The program tries to identify and remove all sources of illicit and/or inappropriate discharges by enhancing MCDEP's current program. The only two possible improvements to the program are to add more staff and to computerize it. Charlotte will be:

- Developing followup program procedures
- Developing and implementing a training program
- Implementing the followup procedures
- Maintaining a GIS data base.

Followup Procedures Development

The followup procedures will respond to the problems identified by the visual field screenings, MCDEP's Stream Walk, MCDEP's monitoring programs, problem area investigations, and citizen complaints. The areas to be addressed will be prioritized based on the urgency and magnitude of the problem. Teams will be assigned to the problem areas and are responsible for the determination and elimination of pollutant sources. To accomplish this task, the teams have to review existing data on the area, perform field reconnaissance, locate and identify problem sources, perform source identification methods (e.g., video, smoke, and dye testing), distribute violation notices, perform other enforcement actions, and notify higher authorities when appropriate. The program will be implemented during the first year and will cost $22,200.

Training Program

The training program for the followup investigations team will be developed with the training programs for industrial and related facilities. Charlotte will also coordinate the development of this training with supervisors of MCDEP's Stream Walk and Charlotte Mecklenburg Utility Department (CMUD). The training will address the reconnaissance followup methods (e.g., observation techniques, chemical screening), detailed followup methods (e.g., closed circuit television, dye and smoke testing), and enforcement methods. Training should begin in the middle of the first year and is estimated to cost $23,100 over the 5-year period.

Followup Procedures Implementation

During field investigations, the followup teams will identify sources of illicit and/or inappropriate connections using the prioritization system and the followup procedures. This will begin in the second half of the first year and will cost $50,000 annually.

GIS Data Base Maintenance

All of the information, including information on violations, received during the followup investigations will be entered into a GIS data base. This data base will be used to track repeat offenders and to produce annual reports to be presented to the State. The data base will cost approximately $14,000 per year.

VOL 12

5356

R0038664

VOL 12

Spill Response Program

The objective of the spill response program is to prevent and respond to spills. The existing program is well developed; therefore, Charlotte will only enhance the public education and awareness aspect of the program. In Charlotte, the Fire Department is responsible for the spill response program and maintains a Hazardous Materials (HAZMAT) team. The city will review the types of spills and their causes in order to minimize the risk to storm systems and surface waters. The public education and awareness component will educate people on the illicit and/or inappropriate connections ordinance and encourage public reporting of spills. This program, which has an estimated cost of $30,000, will begin immediately.

Public Reporting Program

The objective of this program is to increase and improve public reporting of spills and improper disposal. The program will focus on public education and information to inform the public of the importance of reporting spills and illicit and/or inappropriate discharges. This program will be coordinated with other public education programs and will include information on:

- Charlotte's overall storm water management program
- The importance of the illicit and/or inappropriate connections component
- Charlotte's illicit and/or inappropriate connections ordinance
- Proper disposal and recycling programs
- The purpose of stenciling catch basins.

In addition, the program will:

- Publicize Charlotte's storm water hotline
- Encourage the public to readily report signs of illicit and/or inappropriate discharges
- Urge the public to participate in MCDEP's Stream Walk.

Information will be disseminated through public speaking, distribution of written materials at civic functions, participation of neighborhood groups and associations, and local media announcements. This program will begin immediately with an estimated cost of more than $70,000.

5357

Used Oil/Household Hazardous Waste Program

The objective of this program is to properly dispose of and manage used oil and household hazardous waste. Charlotte will address this problem with public education and changes to existing programs. The program will include used oil recycling, permanent household hazardous waste program, and a review of the current small quantity generators.

Used Oil Recycling Program

The used oil program is currently based on extensive public education. The components to revise/expand this program include:

- Review of the public and private facilities that accept used oil and a determination of additional facility locations

- Review of the existing Mecklenburg County program to determine the feasibility of expanding the program to include recycling other automotive parts

- Review of the possibility of providing curb-side pick-up of nonhazardous materials
- Inventory of used oil recycling facilities and implementation of a regular inspection program to prevent storm water pollution.

Household Hazardous Waste Program

The used oil public education program will provide information to the public and private sectors and will be coordinated with the household hazardous waste program. It will include education on:

- Illicit and/or inappropriate connections ordinance
- Negative impacts of dumping used oil into storm sewers
- Stenciling of catch basins
- Misconception that dumping in sanitary sewer is an alternative to the storm sewer
- Education of operators of recycling facilities the proper handling procedures of materials
- Economic incentives for private companies to encourage participation in used oil program.

The development of this program will begin immediately but will not be implemented until the third year. The estimated cost is $30,000 per year.

Charlotte, in conjunction with Mecklenburg County, will develop a permanent household hazardous waste turn-in program. The proposed methods of disposing of the wastes will include:

- <u>Modular Structures (Bare Bones)</u>: This is a continuous service program in which the public would bring their household hazardous wastes to a permanent site for temporary storage to be removed later by a licensed contractor. There is a minimum allocation for storage space.
- <u>Modular Structures</u>: This is the same program as above but it allows for more storage space.
- <u>Fixed Structure</u>: A continuous service program that will operate similarly to the modular structure except that it would be in a fixed place and allow for maximum storage.
- <u>Independent Fixed Structure</u>: This is the same as the fixed structure but would be located at a site different than the fixed location.
- <u>Mobile Unit</u>: This is a continuous service program in which the public would bring their household hazardous waste to a mobile unit that would move from one place to another.

Mecklenburg County currently has an educational plan which utilizes videos and brochures. This plan will be expanded by the use of utility bill inserts and media announcements. The planning of the household hazardous waste program is in progress and will be implemented in the second year. The costs for the city and county are estimated to be high.

Review of Small Quantity Generators

The purpose of the small quantity generators review is to determine what is required of the participants and how they impact storm water runoff. The data base of small quantity generators will be reviewed with HAZMAT and MCDEP to decide if any spill-related problems or contaminated site runoff have occurred in the past. As a result of this review, these facilities may included in Charlotte's inspection program for industrial facilities. The review program will begin immediately with an estimated cost of $15,000.

Infiltration and Seepage Program

Sanitary Sewer Program

The object of this program is to reduce and eliminate sanitary sewer seepage into the storm sewer system. This program should also increase city/county coordination in dealing with problems related to infiltration and seepage from sanitary sewers and septic systems to storm sewers and surface waters. Charlotte currently has city codes in place that require new and replacement sanitary and onsite waste disposal systems to be built to lessen or eliminate leakage and infiltration of floodwaters into the system and discharge from the system into floodwaters. There is also a code that allows the city to fix inoperative sanitary sewer lines on private property and requires payment from the property owner.

MCDEP responds to sanitary flow issues on a complaint basis. CMUD has a cross connection program for the sanitary sewer that requires periodic inspection for leakage and overflows. The Mecklenburg County Health Department issues septic tank permits for the inspection of new and failed septic systems within Charlotte. The Health Department also requires remediation of failed septic systems, which are usually reported by citizen complaint, an MCDEP stream walker, or government inspector.

CMUD is currently developing a dynamic sanitary system model, along with a monitoring program for sanitary system flows and rainfall. Charlotte's role in the development of this program includes:

- Coordinating the preparation of ordinances to enforce the programs
- Ascertaining whether storm water detention facilities should continue to be built over sanitary sewer lines
- Ensuring that illicit and/or inappropriate disconnections from the storm sewer will not increase connections to sanitary sewer
- Implementing a source control program that will limit the dumping of materials into the sanitary sewer that are not treatable
- Developing public education and awareness programs.

The review and coordination of the infiltration and cross connection program with CMUD will begin immediately with an estimated cost of $15,000.

Septic Tank Program

Charlotte, in conjunction with the Mecklenburg County Health Department, will review and revise the current septic tank program. The weaknesses they will address include:

- Notification/inspection procedure
- Lack of contractor supervision
- Abandoned septic tanks not required to be sealed
- Allowable construction of septic tanks in sensitive areas.

The septic tank program will also include a public education component and a data base of septic tank failures. The review and revisions will begin immediately with an estimated cost of $15,000.

The city of Seattle realizes the negative impacts of illicit and/or inappropriate discharges and currently operates a program that detects and eliminates such discharges. Public education and awareness is an important component of this program, but emphasis is also placed on enforcement.

Ordinances

Seattle's key ordinance to prevent illicit and/or inappropriate discharges is the Storm Water, Grading and Drainage Code. Other ordinances, with pollution prevention components, include the Side Sewer Ordinance, the Street Use Ordinance, and the Solid Waste Ordinance. The Storm Water, Grading and Drainage Code prohibits certain discharges into the storm drainage system, requires existing dischargers and land users to implement pollution prevention practices to minimize the pollutants entering storm water discharges, requires the city to review plans for drainage control and grading activity, regulates sediment and erosion controls for construction sites, designates responsibility for maintenance of drainage control facilities and erosion practices, and establishes enforcement procedures. The Storm Water, Grading and Drainage Control Code is enforced by the Department of Construction and Land Use (DCLU), the Department of Engineering - Street Use Section, and the Department of Engineering - Drainage and Wastewater Utility (DWU).

Metro's Key Manhole Monitoring Program

The Municipality of Metropolitan Seattle (Metro) uses a manhole monitoring program to ascertain whether or not illicit and/or inappropriate connections are present and, if so, to identify the sources. After the sources are identified, companies are brought into compliance with Metro's discharge limits and pretreatment standards. This program also requires inspections of facilities that violate the permit requirements.

Field Screening

Seattle DWU's field screening program consists of responding to citizen complaints, responding to city employees or other agency calls, and implementing source control programs and long-term monitoring of surface waters. Seattle will rely on its ordinances, the erosion control program, citizen response, and field personnel to control future illicit and/or inappropriate connections problems.

Followup Investigation Program

The objectives of Seattle's Source Control Program are to eliminate cross connections, reduce spill-related risks, promote better waste disposal, promote good housekeeping practices, provide educational materials on water quality, and require routine maintenance of storm water control facilities where new storm drains will be constructed to reduce combined sewer overflows. This program is implemented on a watershed basis and responds to the unique characteristics of that watershed. The Source Control Program is first implemented in watersheds identified by the Department of Ecology as having surface waters of concern. These are areas of concern because they are used for recreation or as a fisheries resource. The Source Control Program contains the following steps:

- Data Gathering: All the water and sediment quality data from the storm drainage system and all the basin information (e.g., size, topography, industry type) are compiled. Drainage maps and side sewer cards identify outfalls and sewer lines.

- Initial Investigation: Drainage basins are field checked. The side sewer cards are examined, industrial sites are inspected, historical information from the owner is obtained, dye testing is performed to prove connections, and a television inspection is done when necessary. Seattle's storm drain lines and catch basin maintenance schedule is evaluated and when necessary revised to improve water quality.

- Business Inspection and Education Program: Businesses with a high potential to pollute storm water discharges are visited by Source Control Water Quality Investigators. During the visit, the operator will receive a copy of the written inspection procedures. If necessary, followup visits are conducted to guarantee compliance. The operators are encouraged to implement new BMPs or improve old ones to ensure compliance. The facilities are also given information on current programs, including enforcement information. Repeat offenders are referred to the appropriate agency for enforcement action.

- Education and Outreach: Educational materials describing the negative impacts illicit and/or inappropriate discharges have on the storm sewers and surface waters are distributed within watersheds to the public and to industrial facilities. An incentive program is provided for businesses to encourage participation.

The Source Control Program approach by watershed allows for onsite visits and for pipes to be checked for illicit and/or inappropriate connections and has been very effective. Seattle also works with Metro's Industrial Waste Staff because of their authority to enforce pretreatment limits on discharges from industries.

Spill Prevention Program

As required by the Source Control Program, site inspections are performed at industries identified as significant polluters. The inspectors ensure that each facility has a spill prevention plan, including the materials to respond to a spill. The Seattle Municipal Code requires all industrial facilities to develop and implement spill prevention plans.

Seattle Fire Department - Hazardous Materials Unit

Within Seattle, the Fire Department is the main responder to spills within the city, as well as those to surface waters. The Fire Department enforces sections of the Uniform Building Code that address buildings used for storing, handling, or using hazardous wastes. Each industry that uses or stores certain amounts of hazardous wastes is required to obtain a permit from the Fire Department. Facilities are inspected when they apply for the permit and are inspected each year after permit issuance.

Seattle Police Department - Harbor Patrol Unit

The Seattle Harbor Patrol is responsible for the enforcement of oil spill regulations within the Seattle Harbor Code. The patrol investigates complaints received from a 24-hour hotline and reports from the Department of Ecology and the U.S. Coast Guard. If a pollution problem exists, the source is traced and enforcement actions taken.

Trouble Call Network

Metro runs a Trouble Call Network for public use for handling potential water quality problems, including spills. Seattle works with Metro on this project.

Public Reporting Program

DWU published literature with telephone numbers for citizen use when reporting water quality problems or for requesting information on disposal of hazardous materials.

DWU recognizes the importance of public education in relation to protecting water quality and has taken an approach that combines the following three components: public involvement, in-school education, and general public outreach.

VOL 12

Public Involvement

Citizen involvement was important in developing Seattle's storm water program, and DWU involves citizens at various levels of the decisionmaking process. The public involvement programs include the following:

- Comprehensive Drainage Plan Citizens Advisory Committee: Citizens were key in developing the DWU. The DWU is charged with developing a Comprehensive Drainage Plan to determine which areas would benefit the most from the new fees. A Citizens Advisory Committee (CAC) was created to represent the community interests. The Comprehensive Drainage Plan is the foundation of Seattle's water quality projects and will be updated in 5 years with public involvement.

- Drainage and Wastewater Utility Citizens Advisory Committee: The CAC is now the advisory committee for the ongoing activity of the DWU. The Drainage and Wastewater Utility Citizens Advisory Committee (DWUCAC) has expanded its membership to include minority communities and industrial interests that are concerned about water quality and utility services.

- Capital Project Development: When plans for new capital facilities are developed, DWU involves the public. The public interest usually focuses on the impacts of construction but may expand to include water quality and environmental improvement.

- Watershed Planning: The Puget Sound Water Quality Authority and the Department of Ecology administer a program that addresses planning for the control of nonpoint source pollution within watersheds. The watershed plans are developed by a Watershed Management Committee (WMC), which comprises members from community and business organizations and government agencies that are interested in the watershed.

Schools Education Program

These educational programs emphasize respect for water resources and encourage responsible behavior. DWU's schools program builds on existing environmental education and has reached 80 Seattle schools. The following list describes several of these programs:

- Salmon in the Classroom: DWU has provided the training and equipment for teachers in schools to raise salmon from egg to fry and then release the fry into local receiving waters. The salmon are raised in aquariums that simulate spawning stream conditions. DWU trains the teachers participating in the project and provides a manual for additional training and lesson planning. DWU also sponsors two field trips: one to obtain the eggs and the other to release the fry.

- Water Quality Field Trip: DWU sponsors a field trip every year for fourth or fifth grade students to the Seattle Aquarium to learn about aquatic species, their habitat, and the impacts of human activity on their habitat. DWU also sponsors a fishing field trip to a trout farm. Students receive a tour and learn about the impacts of nonpoint source pollution.

- Middle School Water Quality Education Video Program: "Water You Doing?" is a 35-minute educational video produced by DWU with a grant from the Department of Ecology. The video's audience is middle school students and includes a teacher's manual and field trip guide. Five video segments address five different water quality issues. The manual describes lesson planning, is a resource guide, and contains a field trip directory. DWU has given workshops on how to use the video and has distributed it to every public middle school in Seattle.

5362

- Speakers Bureau: DWU employees who work on water quality issues, community volunteers, and others are part of DWU's speakers bureau. The speakers give classroom presentations on water quality education activities sponsored by the DWU.

- Puget Sound on Wheels: DWU is sponsoring the development of a mobile educational display by the Seattle Aquarium. The display will include a truck outfitted with a walk-through exhibit describing the Puget Sound water resource, habitat, and pollution issues. The exhibit will be shown at schools and community fairs.

- Education Coordination: Other educational efforts sponsored by DWU include a teachers advisory committee that evaluates the water quality classroom and field trip activities to help DWU enhance its programs; DWU participation on Seattle's Environmental Education Committee and promotion of its programs, as well as work with other organizations; and membership in the Washington Environmental Education Committee sponsored by the State Superintendent for Public Instruction.

General Public Education Program

Many residents have an out-of-sight, out-of-mind attitude about their behaviors concerning water quality. General public education should change the negative everyday activities people perform on a regular basis. The following DWU programs encourage appropriate behavior and community initiative to protect water quality:

- Source Control Education: With a grant from the Department of Ecology, DWU has implemented a program to control nonpoint source pollution at the source. DWU accomplishes this through a three-pronged approach: Consumer Education, Clean Water Business Partners, and Targeted Education Campaigns.

- Watershed Education: DWU currently sponsors two watershed action plans in Seattle. The WMC responsible for developing the plans concluded that the people living and working within the watersheds must be educated on water quality in order to prevent further degradation of the watersheds.

- Storm Drain Stenciling: DWU uses volunteer school and community groups to paint a message on Seattle's storm drain inlets. With this program, DWU hopes to rid Seattle of the out-of-sight, out-of-mind attitude.

- Motor Oil Recycling: DWU and the Seattle Solid Waste Utility coordinate a used oil recycling program. Waste oil collection tanks are located at the 12 locations of an auto supply store in Seattle. The supply store, along with the utilities, publicizes the program.

- Waterfront Awareness Company: DWU and an association of waterfront businesses have initiated a cleanup campaign for the waterfront. DWU has also added a pollution prevention message to the effort and has recruited children to paint pollution prevention messages on trash cans.

- Seattle Aquarium Intertidal Exhibit: DWU has contributed to a new aquarium exhibit displaying an intertidal ecosystem and explaining the potential negative impacts of human activity on the ecosystem.

- Bill Inserts and Citywide Direct Mailings: DWU includes education and public awareness materials in its bimonthly billings. Customers are also mailed brochures about water quality protection and storm water management.

- Outreach to Non-English Speaking Communities: DWU is developing water quality messages in different languages for publication in community newspapers.

VOL 12

5363

- Television Public Service Announcements: DWU has developed four public service announcements for broadcast on local television. The announcements address the importance of watersheds, the difference between sanitary and storm sewers, nonpoint source pollution, and pet waste.

- Seattle Public Libraries: DWU is currently working to distribute copies of the educational videos to all branches of the public library. The video has also been made available for broadcast on the public access cable station. DWU will develop educational displays for all of the libraries.

Local Hazardous Waste Management Plan for Seattle-King County

Seattle is part of the local hazardous waste management plan and is currently developing and implementing programs for small businesses. The components of the program are to provide free onsite consultations to small businesses; organize seminars, workshops, and classes for business persons; create brochures, booklets, and other materials; create a resource library on hazardous waste issues; provide response to complaint calls and agency referrals; conduct onsite surveys of business practices; and research new treatment methods. Participating agencies include the Seattle-King County Health Department, King County, Seattle, Metro, and 29 suburban cities.

Solid Waste Utility Household Hazardous Waste Program

The Seattle Solid Waste Utility operates one permanent household hazardous waste collection site and sponsors a used motor oil collection system. The household hazardous waste component also provides educational materials to the public on alternative products, collection services, and the proper use and disposal of products.

Metro's Small Quantity Generator Program

This program provides small businesses with information and assistance on the proper use and disposal of hazardous wastes and on ways to minimize the pollutants entering storm drains and surface waters. The Waste Information Network was developed through this program and consists of private businesses, public agencies, and other groups that try to resolve waste management concerns.

Seattle-King County Department of Public Health Environmental Services Program

The health department operates a telephone information line that provides information on waste reduction and the proper storage and disposal of household hazardous wastes. The health department also operates a materials exchange, known as "Industrial Materials Exchange" (IMEX). IMEX oversees the transfer of hazardous materials from the generator to a party that can use them.

Infiltration Control Program

If infiltration from the sanitary sewer to the storm sewer occurs, the city's maintenance crew will conduct a television or walk-through inspection to locate the leak and make the necessary repairs. Storm drain maintenance activities include upgrading surface drainage facilities (e.g., inlets, catch basins, junction boxes, ditches) and removing debris from detention facilities. Sewer maintenance includes inspection, routine cleaning, and system repairs.

VOL 12

5364

Virginia Beach presently facilitates or participates in existing programs that address illicit and/or inappropriate discharges and other forms of pollution. The illicit and/or inappropriate discharge program described below will supplement the current programs for detecting and eliminating sources of illicit and/or inappropriate discharges.

<u>Ordinances</u>

The city of Virginia Beach has developed the Storm Sewer Discharge Ordinance, which authorizes the city to regulate non-storm water discharges to storm sewers and surface waters. This ordinance will supplement other codes currently in effect, specifically the building code, which requires sanitary and storm sewers of a building to be kept separate. The Department of Public Works will be responsible for implementing and enforcing the ordinance. The Storm Sewer Discharge Ordinance also grants inspection and monitoring authority, as necessary, for administration and enforcement to the Department of Public Works. An existing program conducted by Public Works through the Department of Permits and Inspections inspects construction sites for illicit and/or inappropriate discharges. Other city agencies that perform inspections are to report violations to the Department of Public Works.

<u>Ongoing Field Screening Program</u>

The purpose of this program is to test field screening points throughout the term of the permit for dry weather flows and other indications of possible illicit and/or inappropriate discharges. The program will screen points identified in the city's Part 1 application and screen new points.

Part 1 Sites

Out of the 112 field screening points with dry weather flow identified in Part 1, 30 sites were chosen for continued dry weather monitoring. The sampling results are compiled and added to the existing GIS data base. If dry weather flow continues at these sites, the possible source(s) will be investigated.

New Sites

New field screening sites will be chosen from areas with high concentrations of commercial, industrial, and older residential areas and from major highways and roads that have automotive and commercial service areas. The final selection of the new screening points will be determined by field inspection. The chosen outfalls are examined for dry weather flow. If flow is present, then a sample is taken. Twenty-five new field screening points will be evaluated during each year of the permit. The sampling data for each site will be compiled and entered into the GIS data base. If dry weather flow continues at these sites, the possible source(s) will be investigated.

<u>Investigation of the Storm Sewer System</u>

To locate the sources of illicit and/or inappropriate discharges, sections of the storm sewer will have to be investigated. Investigations will be conducted based on analysis of the data received from field screening activities and any other information the city receives concerning illicit and/or inappropriate connections. This program will emphasize public reporting to aid investigations. Investigations will occur at the problem areas and will involve mapping and evaluation, field surveys, and source identification.

Mapping and Evaluation

Each area to be investigated will be highlighted on the storm sewer map, and the drainage area will be defined. The types of land uses will also be evaluated to determine the types of residential, commercial, and industrial areas that may be potential polluters. Other areas that will receive special attention include sanitary, septic tanks, and vehicle maintenance activity sources.

Field Surveys

The city will utilize the strategy of "halving-intervals" to locate the area of the source. This method will be applied to the main trunk of the sewer system and branch lines as necessary. Investigations will occur halfway between the field screening points and the upper most headwater locations. These investigations will use the same criteria as the field screening, except only one site visit will be conducted. The Department of Public Works will perform the field surveys.

Source Identification

After the area and the probable activity have been identified, field visits will be conducted to identify the source(s). Five actions are taken to eliminate a source once it is identified: sending a letter with a questionnaire; site visit and interview; dye tests or smoke tests, if needed; noncompliance notification; and followup inspections.

- Letter with Questionnaire: The Department of Public Works will send a letter to the owner/operator of the suspected source to advise the owner/operator of the problem and to request that the owner/operator complete the attached questionnaire. The completed questionnaire should describe the industrial activities and indicate the possible sources of non-storm water discharges.

- Site Visit and Interview: After the questionnaire is received, a staff person from the Department of Public Works will conduct a site visit and interview to further pinpoint the source.

- Dye Tests and Smoke Tests: If the questionnaire, site visit, and interview do not support the field screening data, then it is necessary to perform fluorometric dye tests of plumbing fixtures and floor drains. If several sources are suspected, a smoke test may be needed to limit the number of possible sources and to allow for a more detailed analysis. These tests will be performed by the Department of Public Works.

- Notification of Noncompliance: Once the suspected source is confirmed, the owner/operator will be issued a notification of noncompliance with the Storm Sewer Discharge Ordinance and will be subject to the penalties in the ordinance.

- Followup Inspection: The Public Works staff will conduct followup inspections to ensure that corrective action was taken and the illicit and/or inappropriate discharge has been eliminated. If the negligent violation continues, the Virginia Water Control Board (VWCB) and/or the news media will be notified.

Spills Program

The spills program in Virginia Beach has two components: hazardous material spill response and inspection of sites for proper compliance with State and Federal regulations for gas, oil, and hazardous chemicals.

Spill Response Program

The city will continue to implement its Hazardous Materials Emergency Response Plan through the Virginia Beach Fire Department. The plan is structured to comply with SARA Title III, Emergency Planning and Community Right-to-Know legislation. The response plan details the proper procedures to be followed in the event of a hazardous materials spill, which could affect persons, property, or the environment. The plan also describes the roles and responsibilities of local government and private agencies when responding to hazardous materials emergencies.

The Fire Department is responsible for the command and control of activities during a spill event. The Fire Department provides initial containment, fire suppression, rescue operations, and evacuation procedures. However,

VOL 12

5366

VOL 12

5367

cleanup is the responsibility of the spiller, or owner/operator of the facility, with monitoring from the Fire Department. When necessary, the Fire Department contacts local, State, and Federal government offices. The Department of Public Works will be notified if any spills enter or have the potential to enter the storm sewer or surface waters. Public Works will then assist the Fire Department with material and equipment to prevent the spill from entering the storm sewer and/or to remove an existing spill from within the storm sewer.

Inspection Program

The VWCB is responsible for regulating waste materials for wastewater and petroleum products, and the Virginia Department of Waste Management regulates solid and hazardous wastes. Under the Hazardous Waste Management Regulations, the Virginia Department of Waste Management requires facilities that generate more than 1,000 kilograms per month of hazardous waste to develop a contingency plan and emergency procedures. The Federal Government requires a spill prevention and containment countermeasures (SPCC) plan for facilities that have the potential to discharge oil in reportable quantities to surface waters. VWCB requires facilities covered under an SPCC to develop an oil discharge contingency plan for bulk storage of 25,000 gallons or more.

- The city has an inspection program that delineates the proper methods for the storage and handling of hazardous wastes to prevent spills from entering the storm sewer or surface waters. The Fire Marshal's office inspects all commercial properties for compliance. Inspection frequency is based on the nature of the perceived hazard. New buildings and construction sites are inspected by the Permits and Inspections Division of the Department of Public Works to ensure compliance with State and Federal regulations for gas, oil, and hazardous chemicals.

Reporting of Illicit and/or Inappropriate Discharges and Water Quality Impacts

Virginia Beach has implemented various programs to address water quality issues. Public education programs in relation to storm water are coordinated through the Public Information Office at Public Works. The city's local cable television channel has shown videos on water quality, litter control, sediment and erosion control, and storm water management. The city has also distributed literature in the form of leaflets and brochures on similar topics. On a regional level, storm water public information programs are developed through the Hampton Roads Municipal Communicators (HRMC). HMRC's membership includes the cities/counties of Virginia Beach, Norfolk, Hampton, Chesapeake, James City, Newport News, Portsmouth, Suffolk, and York. Upcoming projects include stenciling storm drains and developing public service announcements for media broadcast.

Awareness and Reporting

The current programs increase public awareness of water quality issues and of potential impacts of illicit and/or inappropriate discharges. The city would like the public to increase reporting of illicit and/or inappropriate discharges. The Department of Planning within the Division of Environmental Management, along with other departments, takes reports of odor, color, turbidity, and the presence of trash in storm sewers and waterways. The following information programs will continue to increase public awareness and encourage the public to report signs of illicit and/or inappropriate discharges. These information programs include a brochure, Cityline message, and a slide show:

- Brochure: The brochure will address "what to look for" and "who to report to." The public will receive discharges. The brochure will present the options of a hotline and a mailing address for reporting. The Public Information Office will develop and distribute the brochure with funding from Public Works. The brochure will be mailed with the water/sewer bill every 2 years and be distributed to schools and community groups.

- Cityline Message: Virginia Beach has a public information service line called Cityline. A taped message concerning illicit and/or inappropriate discharges will be developed for Cityline and will include information similar to that in the brochure.

- Slide Show: A slide show with accompanying text will be developed by the Public Information Office. The target audience will be children and community groups. The slide show will be presented once a year at elementary, middle, and high schools. A copy of the slide show will also be given to the Virginia Marine Science Museum.

Proper Management and Disposal of Used Oil and Toxic Materials

The City currently participates in programs that facilitate the proper disposal of used oil and toxic materials. The Southeastern Public Service Authority (SPSA) has various recycling programs, including curbside collection and drop-off centers. SPSA produces and distributes brochures explaining the recycling program and listing the locations of the drop-off centers. Household hazardous wastes are accepted at the regional landfill and at seven transfer stations free of charge to private citizens. The State of Virginia operates a used oil recycling program through the Department of Mines, Minerals and Energy. This program recruits service stations to accept and properly dispose of used oil. A toll free number that gives the names and locations of the service stations is available to the public.

New Programs

The following new programs will be developed:

- Brochure: The Public Information Office will develop and distribute a brochure to promote and explain all programs within the city that handle the proper management activities of used oil and toxic materials. The brochure will list the telephone numbers of the various agencies with such programs. The brochure will be available at slide show presentations and mailed every 2 years with the water/sewer bill separate from the illicit and/or inappropriate discharges brochure.

- Cityline Message: A hyped message will be developed by the Public Information Office that will state the major programs and information sources that deal with the management and disposal of used oil and toxic materials.

- Slide Show: A slide show will be developed on the proper management and disposal of used oil and toxic materials. The slide show will be made available to schools, community groups, and the Virginia Marine Science Museum.

Controls to Limit Infiltration from Sanitary Sewers and Septic Systems

Sanitary Sewers

Problems with infiltration of seepage from sanitary sewers to storms sewers in Virginia Beach are rare because the storm sewer is located under the curb and the sanitary sewer is in the middle of the road. The Sewer and Water Standard Specifications and Details of the Department of Public Utilities requires consideration of design, pipe depth, and alignment to avoid conflict between the two sewer systems and to facilitate maintenance. When a leak or spill does occur from the sanitary sewer to the storm sewer, the sewage is contained in the storm sewer and pumped to the sanitary sewer or tanker trucks to prevent discharge to surface waters. If the sewage cannot be collected, Public Utilities will disinfect the site and obtain a special discharge permit from VWCB. Sanitary overflows are reported to VWCB's Tidewater Regional Office within 24 hours. A written report is also required within 5 days. Public Utilities reports any overflows to Public Works.

The Department of Public Utilities has an inspection program for locating defects within the sanitary sewer system. Television inspections for infiltration problems are performed on 80,000 feet of sewer lines per year.

Septic Systems

Subdivision regulations require every subdivision to have an adequate sanitary sewerage system cohesive with the type of development proposed. If public sewerage is not an option, then private septic tanks must be built. These individual sewerage systems must be permitted by the Virginia Beach Health District in cooperation with the Virginia State Health Department.

If the public health director determines that the area chosen for the septic system has poorly drained soils, then a land management plan must be developed by the property owner and approved by the director. The plan must contain the location of the septic tanks and a proposed drainage plan. The owner is also responsible for the construction, repair, maintenance, and operation of the system.

If septic tanks are located in the Chesapeake Bay Preservation Area, the Chesapeake Bay Preservation Area Ordinance requires the property owner to provide a reserve sewage disposal drainfield site with a capacity at least equal to the primary sewage disposal drainfield site. The same is true for septic systems located in the Southern Watersheds, as stipulated in the Southern Watersheds Management Ordinance.

VOL 12

5373

Dear Mr. President:

As required by Section 305(b) of the Clean Water Act (CWA), I am transmitting to the Congress the 1994 National Water Quality Inventory Report. This biennial report is the tenth in a series of national water quality assessments published since 1975 by the U.S. Environmental Protection Agency. On December 14, 1995, we transmitted to you the executive summary of the report and summaries of water quality conditions in each of the States and Territories; the enclosed includes the entirety of the report.

Based on surveys conducted by the States, this report indicates that, while most of the Nation's surveyed waters are of good quality, about 40 percent of the Nation's surveyed rivers, lakes, and estuaries are too polluted for basic uses, such as fishing or swimming. These results are consistent with those reported in 1992 and show that, on the whole, we have managed to hold the line or prevent further degradation, and still maintain continued population growth and growth in economic activity.

States reported that the beneficial uses that they designate for the waters in their water quality standards, such as drinking water supply, swimming, and the propagation of aquatic life, were impaired in 36 percent of surveyed river miles, 37 percent of surveyed lake acres, and 36 percent of surveyed estuarine square miles. In addition, States report that they consider some of the good quality waters threatened because they could become impaired if pollution prevention or control actions are not taken.

According to the States, the most commonly reported problem in impaired waters is polluted runoff from agricultural lands and urban streets. Pollutants include nutrients, siltation, and bacteria. Agriculture is the leading source of pollution in rivers and lakes, and ranks in the top three sources in estuaries.

It is important to recognize that, despite the remarkable accomplishments of the past two decades, significant water pollution problems remain. The cost of sewage treatment still needed is estimated to be over $100 billion. Toxic pollutants discharged by industry continue to pose a threat to humans, aquatic life, and wildlife. Runoff from agricultural operations, city streets, and construction sites also causes significant water pollution problems. Wetlands, which cleanse our waters, protect our property from floods, and provide breeding grounds for our Nation's fisheries and waterfowl, continue to be lost and degraded. For these reasons, we want to ensure that we continue the progress we have made toward cleaner water and address our remaining water pollution problems. We look forward to working with Congress in efforts leading toward this goal.

Sincerely,

Carol M. Browner

Acknowledgments

This report is based primarily on water quality assessments submitted to the U.S. Environmental Protection Agency by the States, Territories, American Indian Tribes, the District of Columbia, and Interstate Commissions of the United States. The EPA wishes to thank the authors of these assessments for the time and effort spent in preparing these reports and reviewing the draft of this national assessment. Additional thanks go to the water quality assessment coordinators from all 10 EPA Regions who work with the States, Tribes, and other jurisdictions.

The project manager and editor of this document was Barry Burgan of the Monitoring Branch, Assessment and Watershed Protection Division, Office of Wetlands, Oceans and Watersheds. Key contributions were also made by the following individuals in other EPA program offices: Roger Anzzolin and Chuck Job, Office of Ground Water and Drinking Water; Dan Weese, Mike Mundell, and David Sprague, Permits Division; Michael Plehn, Wetlands Division; Ann Beier, Nonpoint Source Control Branch; Joe Hall, Oceans and Coastal Protection Division; Susan Ratcliffe, formerly of the Watershed Branch; Wayne Davis, Office of Policy, Planning and Evaluation; Kevin Summers and Steve Paulsen, Ecological Monitoring and Assessment Program; Joseph Macknis, Chesapeake Bay Program; Larinda Tervelt, Gulf of Mexico Program; Bob Beltran, the Great Lakes National Program Office; Melissa McCullough, the Great Waters Program; Marlene Regelski, American Indian Environmental Office; Ginny Kibler, Office of Water; and Alice Mayio, Assessment and Watershed Protection Division. Additional information was provided by the U.S. Geological Survey, the Tennessee Valley Authority, the National Oceanic and Atmospheric Administration, and the National Centers for Disease Control and Prevention.

EPA would also like to thank all of the artists and photographers who contributed their work for inclusion in this document. We regret that we were unable to include all of their fine work in this document.

Contractor support was provided under Contract 68-C3-0303 with Tetra Tech, Inc. Subcontractor Research Triangle Institute (RTI) provided data analysis, technical assistance, editorial support, design, typesetting, and graphics.

Executive Summary

5388

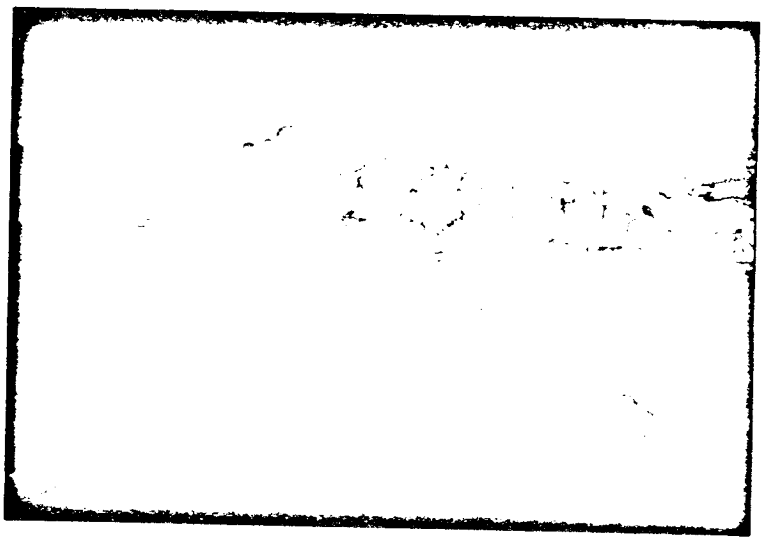
The Quality of Our Nation's Water

Introduction

The *National Water Quality Inventory Report to Congress* is the primary vehicle for informing Congress and the public about general water quality conditions in the United States. This document characterizes our water quality, identifies widespread water quality problems of national significance, and describes various programs implemented to restore and protect our waters.

The *National Water Quality Inventory Report to Congress* summarizes the water quality information submitted by 61 States, American Indian Tribes, Territories, Interstate Water Commissions, and the District of Columbia (hereafter referred to as States, Tribes, and other jurisdictions) in their 1994 water quality assessment reports. As such, the report identifies water quality issues of concern to the States, Tribes, and other jurisdictions, not just the issues of concern to the U.S. Environmental Protection Agency (EPA). Section 305(b) of the Clean Water Act (CWA) requires that the States and other participating jurisdictions submit water quality assessment reports every 2 years. Most of the survey information in the 1994 Section 305(b) reports is based on water quality information collected and evaluated by the States, Tribes, and other jurisdictions during 1992 and 1993.

It is important to note that this report is based on information submitted by States, Tribes, and other jurisdictions that do not use identical survey methods and criteria to rate their water quality. The States, Tribes, and other jurisdictions favor flexibility in the 305(b) process to accommodate natural variability in their waters, but there is a trade-off between flexibility and consistency. Without known and consistent survey methods in place, EPA must use caution in comparing data or determining the accuracy of data submitted by different States and jurisdictions. Also, EPA must use caution when comparing water quality information submitted during different 305(b) reporting periods because States and other jurisdictions may modify their criteria or survey different waterbodies every 2 years.



Paul Goetz, Cary, NC

For over 10 years EPA has pursued a balance between flexibility and consistency in the Section 305(b) process. Recent actions by EPA, the States, Tribes, and other jurisdictions include implementing the recommendations of the National 305(b) Consistency Workgroup and the Intergovernmental Task Force on Monitoring Water Quality. These actions will enable States and other jurisdictions to share data across political boundaries as they develop watershed protection strategies.

EPA recognizes that national initiatives alone cannot clean up our waters; water quality protection and restoration must happen at the local watershed level, in conjunction with State, Tribal, and Federal activities. Similarly, this document alone cannot provide the detailed information needed to manage water quality at all levels. This document should be used together with the individual Section 305(b) reports (see the inside back cover for information on obtaining the State and Tribal Section 305(b) reports), watershed management plans, and other local documents to develop integrated water quality management options.

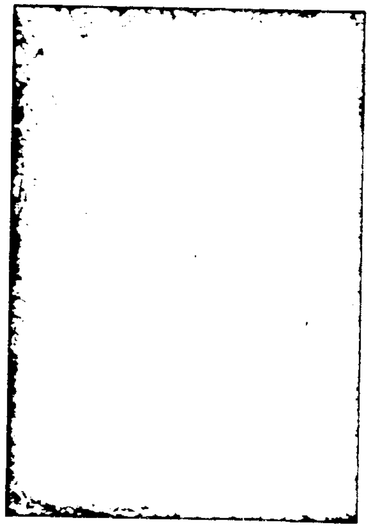
Key Concepts

Measuring Water Quality

The States, participating Tribes, and other jurisdictions survey the quality of their waters by determining if their waters attain the water quality standards they established. Water quality standards consist of beneficial uses, numeric and narrative criteria for supporting each use, and an antidegradation statement:

■ **Designated beneficial uses** are the desirable uses that water quality should support. Examples are drinking water supply, primary contact recreation (such as swimming), and aquatic life support. Each designated use has a unique set of water quality requirements or criteria that must be met for the use to be realized. States, Tribes, and other jurisdictions may designate an individual waterbody for multiple beneficial uses.

■ **Numeric water quality criteria** establish the minimum physical, chemical, and biological parameters required to support a beneficial use. Physical and chemical numeric criteria may set maximum concentrations of pollutants, acceptable ranges of physical parameters, and minimum concentrations of desirable parameters, such as dissolved oxygen. Numeric biological criteria describe the expected attainable community attributes and establish values based on measures such as species richness, presence or absence of indicator taxa, and distribution of classes of organisms.



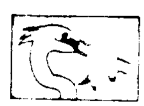
Barry Burgan, U.S. EPA

■ **Narrative water quality criteria** define, rather than quantify, conditions and attainable goals that must be maintained to support a designated use. Narrative biological criteria establish a positive statement about aquatic community characteristics expected to occur within a waterbody. For example, "Ambient water quality shall be sufficient to support life stages of all native aquatic species." Narrative criteria may also describe conditions that are desired in a waterbody, such as "Waters must be free of substances that are toxic to humans, aquatic life, and wildlife."

■ **Antidegradation statements**, where possible, protect existing uses and prevent waterbodies from deteriorating, even if their water quality is better than the fishable and swimmable water quality goals of the Act.

The CWA allows States, Tribes, and other jurisdictions to set their own standards but requires that all beneficial uses and their criteria comply with the goals of the Act. At a minimum, beneficial uses must provide for "the protection and propagation of fish, shellfish, and wildlife" and provide for "recreation in and on the water" (i.e., the fishable and swimmable goals of the Act), where attainable. The Act prohibits States and other jurisdictions from designating waste transport or waste assimilation as a beneficial use, as some States did prior to 1972.

Section 305(b) of the CWA requires that the States biennially survey their water quality for attainment of the fishable and swimmable goals of the Act and report the results to EPA. The States, participating Tribes, and other jurisdictions measure attainment of the CWA goals by determining how well their waters support their designated beneficial uses. EPA encourages the surveying of waterbodies for support of the following individual beneficial uses:

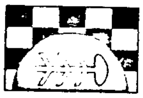


Aquatic Life Support

The waterbody provides suitable habitat for protection and propagation of desirable fish, shellfish, and other aquatic organisms.

VOL 12

5391

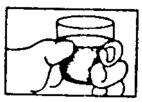


Fish Consumption

The waterbody supports fish free from contamination that could pose a human health risk to consumers.

Shellfish Harvesting

The waterbody supports a population of shellfish free from toxicants and pathogens that could pose a human health risk to consumers.



Drinking Water Supply

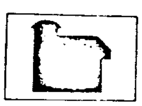
The waterbody can supply safe drinking water with conventional treatment.

Primary Contact Recreation – Swimming

People can swim in the waterbody without risk of adverse human health effects (such as catching waterborne diseases from raw sewage contamination).

Secondary Contact Recreation

People can perform activities on the water (such as boating) without risk of adverse human health effects from ingestion or contact with the water.



Agriculture

The water quality is suitable for irrigating fields or watering livestock.

States, Tribes, and other jurisdictions may also define their own individual uses to address special concerns. For example, many Tribes and States designate their waters for the following beneficial uses:

Ground Water Recharge

The surface waterbody plays a significant role in replenishing ground water, and surface water supply and quality are adequate to protect existing or potential uses of ground water.

Wildlife Habitat

Water quality supports the waterbody's role in providing habitat and resources for land-based wildlife as well as aquatic life.

Tribes may designate their waters for special cultural and ceremonial uses:

Water Quality Monitoring

Water quality monitoring consists of data collection and sample analysis performed using accepted protocols and quality control procedures. Monitoring also includes subsequent analysis of the body of data to support decisionmaking. Federal, Interstate, State, Territorial, Tribal, Regional, and local agencies, industry, and volunteer groups with approved quality assurance programs monitor a combination of chemical, physical, and biological water quality parameters throughout the country.

- Chemical data often measure concentrations of pollutants and other chemical conditions that influence aquatic life, such as pH (i.e., acidity) and dissolved oxygen concentrations. The chemical data may be analyzed in water samples, fish tissue samples, or sediment samples.
- Physical data include measurements of temperature, turbidity (i.e., light penetration through the water column), and solids in the water column.
- Biological data measure the health of aquatic communities. Biological data include counts of aquatic species that indicate healthy ecological conditions.
- Habitat and ancillary data (such as land use data) help interpret the above monitoring information.

Monitoring agencies vary parameters, sampling frequency, and sampling site selection to meet program objectives and funding constraints. Sampling may occur at regular intervals (such as monthly, quarterly, or annually), irregular intervals, or during one-time intensive surveys. Sampling may be conducted at fixed sampling stations, randomly selected stations, stations near suspected water quality problems, or stations in pristine waters.

Culture

Water quality supports the waterbody's role in Tribal culture and preserves the waterbody's religious, ceremonial, or subsistence significance.

The States, Tribes, and other jurisdictions assign one of five levels of use support categories to each of their waterbodies (Table ES-1). If possible, the States, Tribes, and other jurisdictions determine the level of use support by comparing monitoring data with numeric criteria for each use designated for a particular waterbody. If monitoring data are not available, the State, Tribe, or other jurisdiction may determine the level of use support with qualitative information. Valid qualitative information includes land use data, fish and game surveys, and predictive model results. **Monitored assessments** are based on monitoring data. **Evaluated assessments** are based on qualitative information or monitored information more than 5 years old.

For waterbodies with more than one designated use, the States, Tribes, and other jurisdictions consolidate the individual use support information into a single overall use support determination:

Good/Fully Supporting Overall Use – All designated beneficial uses are fully supported.

Good/Threatened Overall Use – One or more designated beneficial uses are threatened and the remaining uses are fully supported.

Fair/Partially Supporting Overall Use – One or more designated beneficial uses are partially supported and the remaining uses are fully supported or threatened. These waterbodies are considered impaired.

Poor/Not Supporting Overall Use – One or more designated beneficial uses are not supported. These waterbodies are considered impaired.

Poor/Not Attainable – The State, Tribe, or other jurisdiction has performed a use-attainability analysis and demonstrated that use support of one or more designated beneficial uses is not attainable due to one of six biological, chemical, physical, or economic/social conditions specified in the *Code of Federal Regulations* (40 CFR Section 131.10). These conditions include naturally high concentrations of pollutants (such as metals); other natural physical features that create

Table ES-1. Levels of Use Support

Symbol	Use Support Level	Water Quality Condition	Definition
	Fully Supporting	Good	Water quality meets designated use criteria.
	Threatened	Good	Water quality supports beneficial uses now but may not in the future unless action is taken.
	Partially Supporting	Fair (Impaired)	Water quality fails to meet designated use criteria at times.
	Not Supporting	Poor (Impaired)	Water quality frequently fails to meet designated use criteria.
	Not Attainable	Poor	The State, Tribe, or other jurisdiction has performed a use-attainability analysis and demonstrated that use support is not attainable due to one of six biological, chemical, physical, or economic/social conditions specified in the *Code of Federal Regulations*.

VOL 12

53992

unsuitable aquatic life habitat (such as inadequate substrate, riffles, or pools); low flows or water levels; dams and other hydrologic modifications that permanently alter waterbody characteristics; poor water quality resulting from human activities that cannot be reversed without causing further environmental degradation; and poor water quality that cannot be improved without imposing more stringent controls than those required in the CWA, which would result in widespread economic and social impacts.

- Impaired Waters – The sum of waterbodies partially supporting uses and not supporting uses.

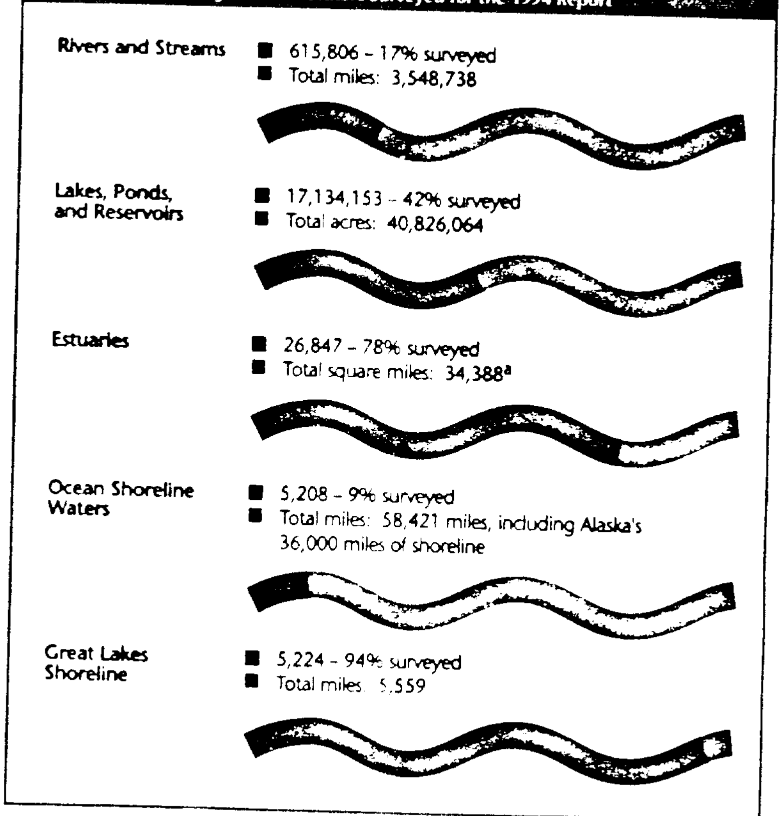
The EPA then aggregates the use support information submitted by the States, Tribes, and other jurisdictions into a national assessment of the Nation's water quality.

How Many of Our Waters Were Surveyed for 1994?

National estimates of the total waters of our country provide the foundation for determining the percentage of waters surveyed by the States, Tribes, and other jurisdictions and the portion impaired by pollution. For the 1992 reporting period, EPA provided the States with estimates of total river miles and lake acres derived from the EPA Reach File, a database containing traces of waterbodies adapted from 1:100,000 scale maps prepared by the U.S. Geological Survey. The States modified these total water estimates where necessary. Based on the 1992 EPA/State figures, the national estimate of total river miles doubled in large part because the EPA/State estimates included nonperennial streams, canals, and ditches that were previously excluded from estimates of total stream miles.

Estimates for the 1994 reporting cycle are a minor refinement of the 1992 figures and indicate that the United States has:

Figure ES-1. Percentage of Total Waters Surveyed for the 1994 Report



Source: 1994 Section 305(b) reports submitted by the States, Tribes, Territories, and Commissions.

[a] Excluding estuarine waters in Alaska because no estimate was available.

VOL 12

5393

R0038701

- More than 3.5 million miles of rivers and streams, which range in size from the Mississippi River to small streams that flow only when wet weather conditions exist (i.e., nonperennial streams)
- Approximately 40.8 million acres of lakes, ponds, and reservoirs
- About 34,388 square miles of estuaries (excluding Alaska)
- More than 58,000 miles of ocean shoreline, including 36,000 miles in Alaska
- 5,559 miles of Great Lakes shoreline
- More than 277 million acres of wetlands such as marshes, swamps, bogs, and fens, including 170 million acres of wetlands in Alaska.

Most States do not survey all of their waterbodies during the 2-year reporting cycle required under CWA Section 305(b). Thus, the surveyed waters reported in Figure ES-1 are a subset of the Nation's total waters. In addition, the summary information based on surveyed waters may not represent general conditions in the Nation's total waters because States, Tribes, and other jurisdictions often focus on surveying major perennial rivers, estuaries, and public lakes with suspected pollution problems in order to direct scarce resources to areas that could pose the greatest risk. Many States, Tribes, and other jurisdictions lack the resources to collect use support information for nonperennial streams, small tributaries, and private ponds. This report does not predict the health of these unassessed waters, which include an unknown ratio of pristine waters to polluted waters.

The Intergovernmental Task Force on Monitoring Water Quality

In 1992, the Intergovernmental Task Force on Monitoring Water Quality (ITFM) convened to prepare a strategy for improving water quality monitoring nationwide. The ITFM is a Federal/State partnership of 10 Federal agencies, 9 State and interstate agencies, and 1 American Indian Tribe. The EPA chairs the ITFM with the USGS as vice chair and Executive Secretariat as part of their Water Information Coordination Program pursuant to OMB memo 92-01.

The mission of the ITFM is to develop and aid implementation of a national strategic plan to achieve effective collection, interpretation, and presentation of water quality data and to improve the [illegible] of existing information for decisionmaking at all levels of [illegible] and the private sector. A permanent successor to the ITFM, [illegible] National Monitoring Council will provide guidelines and support for [illegible] collaboration, comparable field and laboratory methods, quality assurance/quality control, environmental indicators, data management and sharing, ancillary data, interpretation and techniques, and training.

The ITFM and its successor, the National Monitoring Council, [illegible] products that can be used by monitoring [illegible] such as an outline for a recommended [illegible] environmental indicator selection criteria, and a [illegible] assessment of State and Tribal designated uses.

For a copy of the first, second, and final ITFM reports, contact:

Pollutants and Processes That Degrade Water Quality

Where possible, States, Tribes, and other jurisdictions identify the pollutants or processes that degrade water quality and indicators that document impacts of water quality degradation. The most widespread pollutants and processes identified in rivers, lakes, and estuaries are presented in Table ES-2. Pollutants include sediment, nutrients, and chemical contaminants (such as dioxins and metals). Processes that

VOL 12

5394

degrade waters include habitat modification (such as destruction of streamside vegetation) and hydrologic modification (such as flow reduction). Indicators of water quality degradation include physical, chemical and biological parameters. Examples of biological parameters include species diversity and abundance. Examples of physical and chemical parameters include pH, turbidity, and temperature. Following are descriptions of the effects of the pollutants and processes most commonly identified in rivers, lakes, estuaries, coastal waters, wetlands, and ground water.

Low Dissolved Oxygen

Dissolved oxygen is a basic requirement for a healthy aquatic ecosystem. Most fish and beneficial aquatic insects "breathe" oxygen dissolved in the water column. Some fish and aquatic organisms (such as carp and sludge worms) are adapted to low oxygen conditions, but most desirable fish species (such as trout and salmon) suffer if dissolved oxygen concentrations fall below 3 to 4 mg/L (3 to 4 milligrams of oxygen dissolved in 1 liter of water, or 3 to 4 parts of oxygen per million parts of water). Larvae and juvenile fish are more sensitive and require even higher concentrations of dissolved oxygen.

Many fish and other aquatic organisms can recover from short periods of low dissolved oxygen availability. However, prolonged episodes of depressed dissolved oxygen concentrations of 2 mg/L or less can result in "dead" waterbodies. Prolonged exposure to low dissolved oxygen conditions can suffocate adult fish or reduce their reproductive survival by suffocating sensitive eggs and larvae or can starve fish by killing aquatic insect larvae and other prey. Low dissolved oxygen concentrations also favor anaerobic bacterial activity that produces noxious gases or foul odors often associated with polluted waterbodies.

Table ES-2. Five Leading Causes of Water Quality Impairment

Rank	Rivers	Lakes	Estuaries
1	Bacteria	Nutrients	Nutrients
2	Siltation	Siltation	Bacteria
3	Nutrients	Oxygen-Depleting Substances	Oxygen-Depleting Substances
4	Oxygen-Depleting Substances	Metals	Habitat Alterations
5	Metals	Suspended Solids	Oil and Grease

Source: Based on 1994 Section 305(b) reports submitted by States, Tribes, Territories, Commissions, and the District of Columbia.

Fish Kills

Fish kill reporting is a voluntary process; States, Tribes, and other jurisdictions are not required to report on how many fish kills occur, or what might have caused them. In many cases it is the public–anglers, and hunters, recreational boaters, or hikers–who first notice fish kills and report them to game wardens or other State officials. Many fish kills go undetected or unreported and others may be difficult to investigate, especially if they occur in remote areas. This is because dead fish may be carried quickly downstream or may be difficult to count because of turbid conditions. It is therefore likely that the statistics presented by the States, Tribes, and other jurisdictions underestimate the total number of fish kills that occurred nationwide between 1992 and 1994.

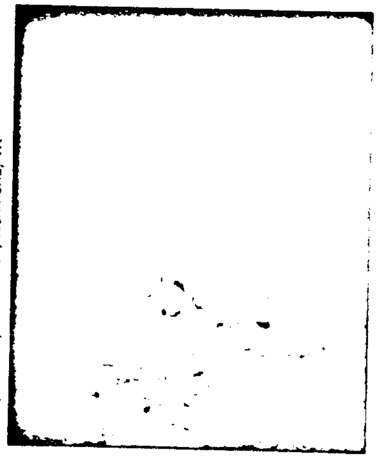
Despite these problems, fish kills are an important consideration in water quality assessments. In 1994, 32 States, Tribes, and other jurisdictions reported a total of 1,454 fish kill incidents. These States attributed 737 of the fish kills to pollution, 257 to unknown causes, 263 to natural conditions (such as low flow and high temperatures), and 229 kills to ambiguous causes. Pollutants most often cited as the cause of kills include oxygen-depleting substances, sewage, pesticides, manure and silage, oil and gas, chlorine, and ammonia. Leading sources of fish kills include agricultural activities, industrial discharges, municipal sewage treatment plant discharges, spills, runoff, and pesticide applications.

Oxygen concentrations in the water column fluctuate under natural conditions, but severe oxygen depletion usually results from human activities that introduce large quantities of biodegradable organic materials into surface waters. Biodegradable organic materials contain plant, fish, or animal matter. Leaves, lawn clippings, sewage, manure, shellfish processing waste, milk solids, and other food processing wastes are examples of oxygen-depleting organic materials that enter our surface waters.

In both pristine and polluted waters, beneficial bacteria use oxygen to break apart (or decompose) organic materials. Pollution-containing organic wastes provide a continuous glut of food for the bacteria, which accelerates bacterial activity and population growth. In polluted waters, bacterial consumption of oxygen can rapidly outpace oxygen replenishment from the atmosphere and photosynthesis performed by algae and aquatic plants. The result is a net decline in oxygen concentrations in the water.

Toxic pollutants can indirectly lower oxygen concentrations by killing algae, aquatic weeds, or fish, which provides an abundance of food for oxygen-consuming bacteria. Oxygen depletion can also result from chemical reactions that do not involve bacteria. Some pollutants trigger chemical reactions that place a chemical oxygen demand on receiving waters.

Other factors (such as temperature and salinity) influence the amount of oxygen dissolved in water. Prolonged hot weather will depress oxygen concentrations and may cause fish kills even in clean



Chesapeake Bay Foundation, Richmond, VA

waters because warm water cannot hold as much oxygen as cold water. Warm conditions further aggravate oxygen depletion by stimulating bacterial activity and respiration in fish, which consumes oxygen. Removal of streamside vegetation eliminates shade, thereby raising water temperatures, and accelerates runoff of organic debris. Under such conditions, minor additions of pollution-containing organic materials can severely deplete oxygen.

Nutrients

Nutrients are essential building blocks for healthy aquatic communities, but excess nutrients (especially nitrogen and phosphorus compounds) overstimulate the growth of aquatic weeds and algae. Excessive growth of these organisms, in turn, can clog navigable waters, interfere with swimming and boating, outcompete native submerged aquatic vegetation (SAV), and lead to oxygen depletion. Oxygen concentrations can fluctuate daily during algal blooms, rising during the day as algae perform photosynthesis, and falling at night as algae continue to respire, which consumes oxygen. Beneficial bacteria also consume oxygen as they decompose the abundant organic food supply in dying algae cells.

Lawn and crop fertilizers, sewage, manure, and detergents contain nitrogen and phosphorus, the nutrients most often responsible for water quality degradation. Rural areas are vulnerable to ground water contamination from nitrates (a compound containing nitrogen) found in fertilizer and manure. Very high concentrations of nitrate (>10 mg/L) in drinking water cause methemoglobinemia, or blue baby syndrome, an inability to fix oxygen in the blood.

Nutrients are difficult to control because lake and estuarine ecosystems recycle nutrients. Rather than leaving the ecosystem, the nutrients cycle among the water column, algae and plant tissues, and the bottom sediments. For example, algae may temporarily remove all the nitrogen from the water column, but the nutrients will return to the water column when the algae die and are decomposed by bacteria. Therefore, gradual inputs of nutrients tend to accumulate over time rather than leave the system.

Sediment and Siltation

In a water quality context, sediment usually refers to soil particles that enter the water column from eroding land. Sediment consists of particles of all sizes, including fine clay particles, silt, sand, and gravel. Water quality managers use the

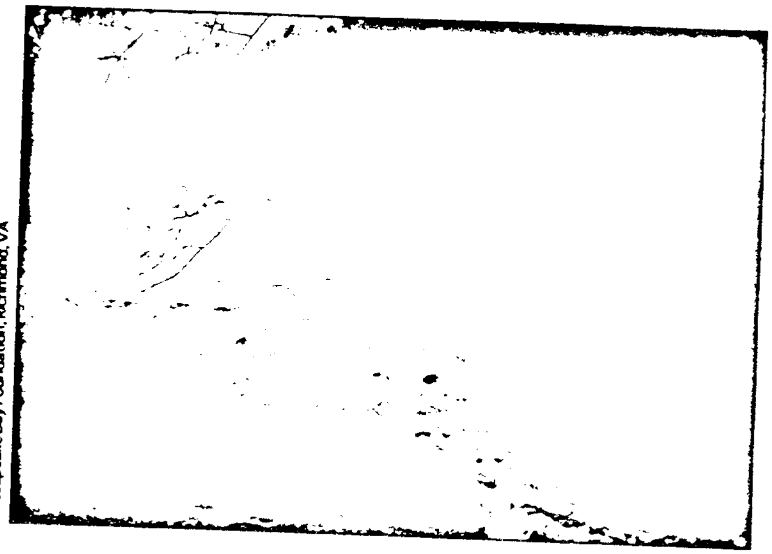
VOL 12

5396

term "siltation" to describe the suspension and deposition of small sediment particles in waterbodies.

Sediment and siltation can severely alter aquatic communities. Sediment may clog and abrade fish gills, suffocate eggs and aquatic insect larvae on the bottom, and fill in the pore space between bottom cobbles where fish lay eggs. Silt and sediment interfere with recreational activities and aesthetic enjoyment at waterbodies by reducing water clarity and filling in waterbodies. Sediment may also carry other pollutants into waterbodies. Nutrients and toxic chemicals may attach to sediment particles on land and ride the particles into surface waters where the pollutants may settle with the sediment or detach and become soluble in the water column.

Rain washes silt and other soil particles off of plowed fields, construction sites, logging sites, urban areas, and strip-mined lands into waterbodies. Eroding stream banks also deposit silt and sediment in waterbodies. Removal of vegetation on shore can accelerate streambank erosion.



Chesapeake Bay Foundation, Richmond, VA

Bacteria and Pathogens

Some waterborne bacteria, viruses, and protozoa cause human illnesses that range from typhoid and dysentery to minor respiratory and skin diseases. These organisms may enter waters through a number of routes, including inadequately treated sewage, stormwater drains, septic systems, runoff from livestock pens, and sewage dumped overboard from recreational boats. Because it is impossible to test waters for every possible disease-causing organism, States and other jurisdictions usually measure indicator bacteria that are found in great numbers in the stomachs and intestines of warm-blooded animals and people. The presence of indicator bacteria suggests that the waterbody may be contaminated with untreated sewage and that other, more dangerous organisms may be present. The States, Tribes, and other jurisdictions use bacterial criteria to determine if waters are safe for recreation and shellfish harvesting.

Toxic Organic Chemicals and Metals

Toxic organic chemicals are synthetic compounds that contain carbon, such as polychlorinated biphenyls (PCBs), dioxins, and the pesticide DDT. These synthesized compounds often persist and accumulate in the environment because they do not readily break down in natural ecosystems. Many of these compounds cause cancer in people and birth defects in other predators near the top of the food chain, such as birds and fish.

Metals occur naturally in the environment, but human activities (such as industrial processes and mining) have altered the distribution of metals in the environment. In most reported cases of metals contamination, high concentrations of metals appear in fish tissues rather than the water column because the metals accumulate in greater concentrations in predators near the top of the food chain.

pH

Acidity, the concentration of hydrogen ions, drives many chemical reactions in living organisms. The standard measure of acidity is

VOL 12

5397

pH, and a pH value of 7 represents a neutral condition. A low pH value (less than 5) indicates acidic conditions; a high pH (greater than 9) indicates alkaline conditions. Many biological processes, such as reproduction, cannot function in acidic or alkaline waters. Acidic conditions also aggravate toxic contamination problems because sediments release toxicants in acidic waters. Common sources of acidity include mine drainage, runoff from mine tailings, and atmospheric deposition.

Habitat Modification/ Hydrologic Modification

Habitat modifications include activities in the landscape, on shore, and in waterbodies that alter the physical structure of aquatic ecosystems and have adverse impacts on aquatic life. Examples of habitat modifications include:

- Removal of streamside vegetation that stabilizes the shoreline and provides shade, which moderates instream temperatures
- Excavation of cobbles from a stream bed that provide nesting habitat for fish
- Stream burial
- Excessive suburban sprawl that alters the natural drainage patterns by increasing the intensity, magnitude, and energy of runoff waters.

Hydrologic modifications alter the flow of water. Examples of hydrologic modifications include channelization, dewatering, damming, and dredging.

Other pollutants include salts and oil and grease. Fresh waters may become unfit for aquatic life and some human uses when they become contaminated by salts. Sources of salinity include irrigation runoff, brine used in oil extraction, road deicing operations, and the intrusion of sea water into ground and surface waters in coastal areas. Crude oil and processed petroleum products may be spilled during extraction, processing, or transport or leaked from underground storage tanks.

Table ES-[illegible]. Pollution Source Categories Used in This Report

Category	Examples
Industrial	Pulp and paper mills, chemical manufacturers, steel plants, metal process and product manufacturers, textile manufacturers, food processing plants
Municipal	Publicly owned sewage treatment plants that may receive indirect discharges from industrial facilities or businesses
Combined Sewers	Single facilities that treat both storm water and sanitary sewage, which may become overloaded during storm events and discharge untreated wastes into surface waters.
Storm Sewers/ Urban Runoff	Runoff from impervious surfaces including streets, parking lots, buildings, lawns, and other paved areas.
Agricultural	Crop production, pastures, rangeland, feedlots, other animal holding areas
Silvicultural	Forest management, tree harvesting, logging road construction
Construction	Land development, road construction
Resource Extraction	Mining, petroleum drilling, runoff from mine tailing sites
Land Disposal	Leachate or discharge from septic tanks, landfills, and hazardous waste sites
Hydrologic Modification	Channelization, dredging, dam construction, streambank modification

Sources of Water Pollution

Sources of impairment generate the pollutants that violate use support criteria (Table ES-3). Point sources discharge pollutants directly into surface waters from a conveyance. Point sources include industrial facilities, municipal sewage treatment plants, and combined sewer overflows. Nonpoint sources deliver pollutants to surface waters from diffuse origins. Nonpoint sources include urban runoff, agricultural runoff, and atmospheric deposition of contaminants in air pollution. Habitat alterations, such as hydromodification, dredging, and streambank destabilization, can also degrade water quality.

Throughout this document, EPA rates the significance of causes and sources of pollution by the percentage of impaired waters impacted by each individual cause or source (obtained from the Section 305(b) reports submitted by the States, Tribes, and other jurisdictions). Note that the cause and source rankings do not describe the condition of all waters in the United States because the States identify the causes and sources degrading some of their impaired waters, which are a small subset of surveyed waters, which are a subset of the Nation's total waters. For example, the States identified sources degrading some of the 224,236 impaired river miles, which represent 36% of the surveyed river miles and only 6% of the Nation's total stream miles.

"The term 'point source' means any discernible, confined, and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, or vessel or other floating craft, from which pollutants are or may be discharged. This term does not include agricultural storm water discharges and return flows from irrigated agriculture."

Clean Water Act Section 502(14)

Table ES-4 lists the leading sources of impairment related to human activities as reported by States, Tribes, and other jurisdictions for their rivers, lakes, and estuaries. Other sources cited include removal of riparian vegetation, forestry activities, land disposal, petroleum extraction and processing activities, and construction. In addition to human activities, the States, Tribes, and other jurisdictions also reported impairments from natural sources. Natural sources refer to an assortment of water quality problems:

- Natural deposits of salts, gypsum, nutrients, and metals in soils that leach into surface and ground waters
- Warm weather and dry conditions that raise water temperatures, depress dissolved oxygen concentrations, and dry up shallow waterbodies
- Low-flow conditions and tannic acids from decaying leaves that lower pH and dissolved oxygen concentrations in swamps draining into streams.

With so many potential sources of pollution, it is difficult and expensive for States, Tribes, and other jurisdictions to identify specific sources responsible for water quality impairments. Many States and other jurisdictions lack funding for monitoring to identify all but the most apparent sources degrading waterbodies. Local management priorities may focus monitoring budgets on other water quality issues, such as identification of contaminated fish populations that pose a human health risk. Management priorities may also direct monitoring efforts to larger waterbodies and overlook sources impairing smaller waterbodies. As a result, the States, Tribes, and other jurisdictions do not associate every impacted waterbody with a source of impairment in their 305(b) reports, and the summary cause and source information presented in this report applies exclusively to a subset of the Nation's impaired waters.

Rank	Rivers	Lakes	Estuaries
1	Agriculture	Agriculture	Urban Runoff/ Storm Sewers
2	Municipal Sewage Treatment Plants	Municipal Sewage Treatment Plants	Municipal Sewage Treatment Plants
3	Hydrologic/Habitat Modification	Urban Runoff/ Storm Sewers	Agriculture
4	Urban Runoff/ Storm Sewers	Unspecified Nonpoint Sources	Industrial Point Sources
5	Resource Extraction	Hydrologic/Habitat Modification	Petroleum Activities

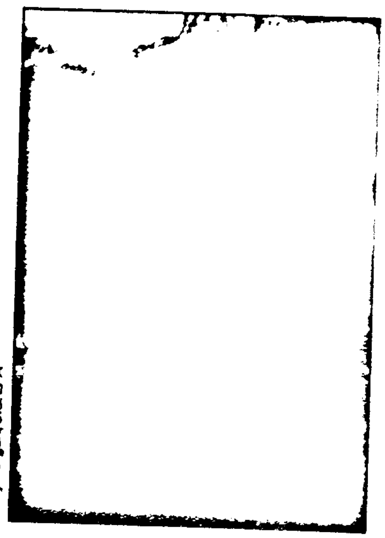
Rivers and Streams

Rivers and streams are characterized by flow. Perennial rivers and streams flow continuously, all year round. Nonperennial rivers and streams stop flowing for some period of time, usually due to dry conditions or upstream withdrawals. Many rivers and streams originate in nonperennial headwaters that flow only during snowmelt or heavy showers. Nonperennial streams provide critical habitats for nonfish species, such as amphibians and dragonflies, as well as safe havens for juvenile fish to escape from predation by larger fish.

The health of rivers and streams is directly linked to habitat integrity on shore and in adjacent wetlands. Stream quality will deteriorate if activities damage shoreline (i.e., riparian) vegetation and wetlands, which filter pollutants from runoff and bind soils. Removal of vegetation also eliminates shade that moderates stream temperature as well as the land temperature that can warm runoff entering surface waters. Stream temperature, in turn, affects the availability of dissolved oxygen in the water column for fish and other aquatic organisms.

Overall Water Quality

For the 1994 Report, 58 States, Territories, Tribes, Commissions, and the District of Columbia surveyed 615,806 miles (17%) of the Nation's total 3.5 million miles of rivers and streams (Figure ES-2). The surveyed rivers and streams represent 48% of the 1.3 million miles of perennial rivers and streams that flow year round in the lower 48 States.



Barry Burgan, U.S. EPA

Altogether, the States and Tribes surveyed 27,075 fewer river miles in 1994 than in 1992. Individually, most States reported that they surveyed more river miles in 1994, but their increases were offset by a decline of 85,000 surveyed river miles reported by Montana, Mississippi, and Maryland. For 1994, these States reported use support status for only those river miles that they surveyed in direct monitoring programs or evaluations rather than using inferences for unsurveyed waters.

The following discussion applies exclusively to surveyed waters and cannot be extrapolated to describe conditions in the Nation's rivers as a whole because the States, Tribes, and other jurisdictions do not consistently use statistical or probabilistic survey methods to characterize all their waters at this time. EPA is working with the States, Tribes, and other jurisdictions to expand survey coverage of the Nation's waters and expects future survey information to cover a greater portion of the Nation's rivers and streams.

Figure ES-2. River Miles Surveyed

Total rivers = 3.5 million miles
Total surveyed = 615,806 miles

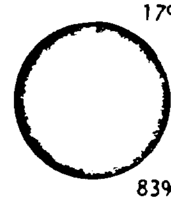


Figure ES-3. Levels of Overall Use Support—Rivers

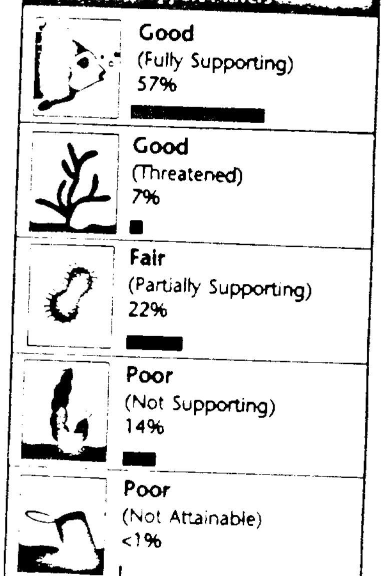


Source: Based on 1994 Section 305(b) reports submitted by States, Tribes, Territories, Commissions, and the District of Columbia

VOL 12

5400

Of the Nation's 615,806 surveyed river miles, the States, Tribes, and other jurisdictions found that 64% have good water quality. Of these waters, 57% fully support their designated uses, and an additional 7% support uses but are threatened and may become impaired if pollution control actions are not taken (Figure ES-3).

Some form of pollution or habitat degradation prevents the remaining 36% (224,236 miles) of the surveyed river miles from fully supporting a healthy aquatic community or human activities all year round. Twenty-two percent of the surveyed river miles have fair water quality that partially supports designated uses. Most of the time, these waters provide adequate habitat for aquatic organisms and support human activities, but periodic pollution interferes with these activities and/or stresses aquatic life. Fourteen percent of the surveyed river miles have poor water quality that consistently stresses aquatic life and/or prevents people from using the river for activities such as swimming and fishing.

What Is Polluting Our Rivers and Streams?

The States and Tribes report that bacteria pollute 76,397 river miles (which equals 34% of the impaired river miles) (Figure ES-4). Bacteria provide evidence of possible fecal contamination that may cause illness if the public ingests the water.

Siltation, composed of tiny soil particles, remains one of the most widespread pollutants impacting rivers and streams. The States and Tribes reported that siltation impairs 75,792 river miles (which equals 34% of the impaired river miles).

Bacteria and siltation are the most widespread pollutants in rivers and streams, affecting 34% of the impaired river miles.

Siltation alters aquatic habitat and suffocates fish eggs and bottom-dwelling organisms. Excessive siltation can also interfere with drinking water treatment processes and recreational use of a river.

In addition to siltation and bacteria, the States and Tribes also reported that nutrients, oxygen-depleting substances, metals, and habitat alterations impact more miles of rivers and streams than other pollutants and processes. Often, several pollutants and processes impact a single river segment. For example, a process, such as removal of shoreline vegetation, may accelerate erosion of sediment and nutrients into a stream.

Where Does This Pollution Come From?

The States and Tribes reported that agriculture is the most widespread source of pollution in the Nation's surveyed rivers (Figure ES-4). Agriculture generates pollutants that degrade aquatic life or interfere with public use of 134,557 river miles (which equals 60% of the impaired river miles) in 49 States and Tribes.

Twenty-one States reported the size of rivers impacted by specific types of agricultural activities:

- Nonirrigated Crop Production – crop production that relies on rain as the sole source of water.
- Irrigated Crop Production – crop production that uses irrigation systems to supplement rainwater.
- Rangeland – land grazed by animals that is seldom enhanced by the application of fertilizers or pesticides, although managers sometimes modify plant species to a limited extent.
- Pastureland – land upon which a crop (such as alfalfa) is raised to feed animals, either by grazing the animals among the crops or harvesting the crops.
- Feedlots – facilities where animals are fattened and confined at high densities.
- Animal Holding Areas – facilities where animals are confined briefly before slaughter.

The States reported that nonirrigated crop production impaired the most river miles, followed by irrigated crop production, rangeland, feedlots, pastureland, and animal holding areas.

Many States reported declines in pollution from sewage treatment

Agriculture is the leading source of impairment in the Nation's rivers, affecting 60% of the impaired river miles.

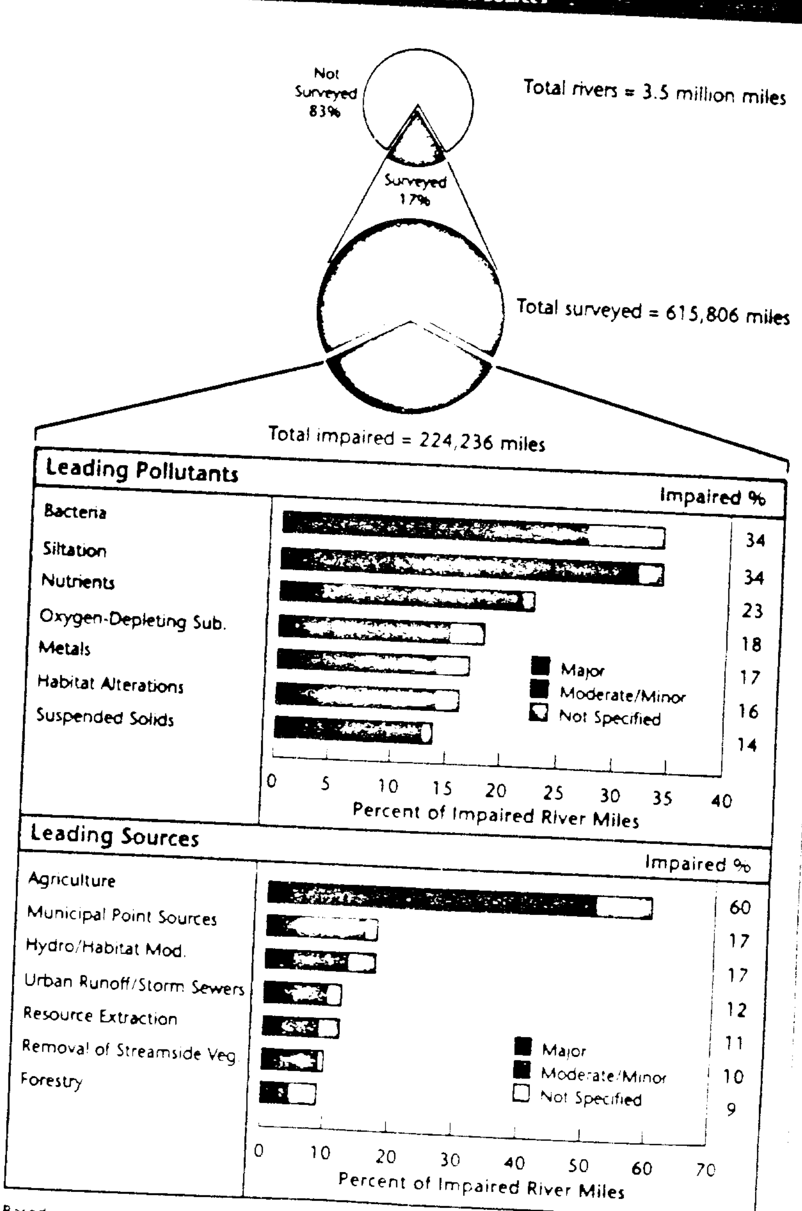
plants and industrial discharges as a result of sewage treatment plant construction and upgrades and permit controls on industrial discharges. Despite the improvements, municipal sewage treatment plants remain the second most common source of pollution in rivers (impairing 37,443 miles) because population growth increases the burden on our municipal facilities.

Hydrologic modifications and habitat alterations are a growing concern to the States. Hydrologic modifications include activities that alter the flow of water in a stream, such as channelization, dewatering, and damming of streams. Habitat alterations include removal of streamside vegetation that protects the stream from high temperatures, and scouring of stream bottoms. Additional gains in water quality conditions will be more subtle and require innovative management strategies that go beyond point source controls.

The States, Tribes, and other jurisdictions also reported that urban runoff and storm sewers impair 26,862 river miles (12% of the impaired rivers), resource extraction impairs 24,059 river miles (11% of the impaired rivers), and removal of streamside vegetation impairs 21,706 river miles (10% of the impaired rivers).

The States, Tribes, and other jurisdictions also report that "natural" sources impair significant stretches of rivers and streams. "Natural" sources such as low flow and soils with arsenic deposits, can prevent waters from supporting uses in the absence of human activities.

Figure ES-4. Impaired River Miles: Pollutants and Sources



Based on data contained in Appendix A, Tables A-4 and A-5

VOL 12

5402

R0038710

Lakes, Ponds, and Reservoirs

Lakes are sensitive to pollution inputs because lakes flush out their contents relatively slowly. Even under natural conditions, lakes undergo eutrophication, an aging process that slowly fills in the lake with sediment and organic matter (see sidebar). The eutrophication process alters basic lake characteristics such as depth, biological productivity, oxygen levels, and water clarity. The eutrophication process is commonly defined by a series of trophic states as described in the sidebar.

Overall Water Quality

Forty-eight States, Tribes, and other jurisdictions surveyed overall use support in more than 17.1 million lake acres representing 42% of the approximately 40.8 million total acres of lakes, ponds, and reservoirs in the Nation (Figure ES-5). For 1994, the States surveyed about 1 million fewer lake acres than in 1992.

The number of surveyed lake acres declined because several States separated fish tissue data from their survey of overall use support. Some of these States, such as Minnesota, have established massive databases of fish tissue contamination information (which is used to establish fish consumption advisories), but lack other types of water quality data for many of their lakes. In 1994, these States chose not to assess overall use support entirely with fish tissue data alone, which is a very narrow indicator of water quality.

The States and Tribes reported that 63% of their surveyed 17.1 million lake acres have good water quality. Waters with good quality include 50% of the surveyed lake acres fully supporting uses and 13% of the surveyed lake acres that are threatened and might deteriorate if we fail to manage potential sources of pollution (Figure ES-6).

Some form of pollution or habitat degradation impairs the remaining 37% of the surveyed lake acres. Twenty-eight percent of the surveyed lake acres have fair water quality that partially supports designated uses. Most of the time, these waters provide adequate habitat for aquatic organisms and support human activities, but periodic pollution interferes with these activities and/or stresses aquatic life. Nine percent of the surveyed lake acres suffer from poor water quality that consistently stresses aquatic life and/or prevents people from using the lake for activities such as swimming and fishing.

VOL 12

5403

What Is Polluting Our Lakes, Ponds, and Reservoirs?

Forty-one States, the District of Columbia, and Puerto Rico reported the number of lake acres impacted by individual pollutants and processes.

Thirty-seven States and Puerto Rico identified more lake acres polluted by nutrients than any other pollutant or process (Figure ES-7). The States and Puerto Rico reported that extra nutrients pollute 2.8 million lake acres (which equals 43% of the impaired lake acres). Healthy lake ecosystems contain nutrients in small quantities, but extra inputs of nutrients from human activities unbalance lake ecosystems.

In addition to nutrients, the States, Puerto Rico, and the District of Columbia report that siltation pollutes 1.8 million lake acres (which equals 28% of the impaired lake acres), enrichment by organic wastes that deplete oxygen impacts 1.6 million lake acres (which equals 24% of the impaired lake acres), and metals pollute 1.4 million acres (which equals 21% of the impaired lake acres).

Metals declined from the most widespread pollutant impairing lakes in the 1992 305(b) reporting cycle

Trophic States

Oligotrophic	Clear waters with little organic matter or sediment and minimum biological activity.
Mesotrophic	Waters with more nutrients and, therefore, more biological productivity.
Eutrophic	Waters extremely rich in nutrients, with high biological productivity. Some species may be choked out.
Hypereutrophic	Murky, highly productive waters, closest to the wetlands status. Many clearwater species cannot survive.
Dystrophic	Low in nutrients, highly colored with dissolved humic organic matter. (Not necessarily a part of the natural trophic progression.)

The Eutrophication Process

Eutrophication is a natural process, but human activities can accelerate eutrophication by increasing the rate at which nutrients and organic substances enter lakes from their surrounding watersheds. Agricultural runoff, urban runoff, leaking septic systems, sewage discharges, eroded streambanks, and similar sources can enhance the flow of nutrients and organic substances into lakes. These substances can overstimulate the growth of algae and aquatic plants, creating conditions that interfere with the recreational use of lakes and the health and diversity of native fish, plant, and animal populations. Enhanced eutrophication from nutrient enrichment due to human activities is one of the leading problems facing our Nation's lakes and reservoirs.

Acid Effects on Lakes

Increases in lake acidity can radically alter the community of fish and plant species in lakes and can increase the solubility of toxic substances and magnify their adverse effects. Twenty-eight States reported the results of lake acidification assessments. These States assessed pH (a measure of acidity) at more than 5,933 lakes and detected acidic conditions in 526 lakes and a threat of acidic conditions in 423 lakes. Most of the States that assessed acidic conditions are located in the Northeast, upper Midwest, and the South.

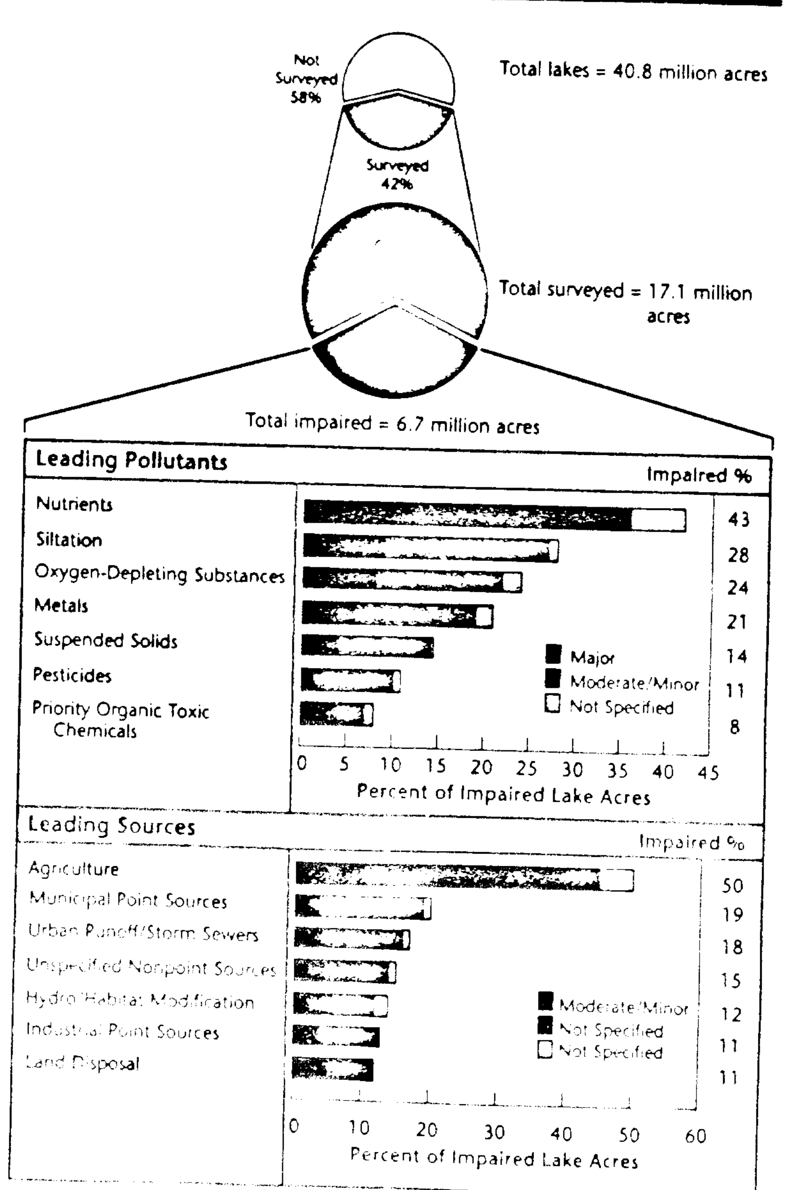
Only 11 States identified sources of acidic conditions. Maine and New Hampshire attributed most of their acid lake conditions to acid deposition from acidic rain, fog, or dry deposition in conjunction with natural conditions that limit a lake's capacity to neutralize acids. Alabama, Kansas, Maryland, Montana, Oklahoma, and Tennessee reported that acid mine drainage resulted in acidic lake conditions or threatened lakes with the potential to generate acidic conditions.

to the fourth leading pollutant impairing lakes in 1994. The decline is due to changes in State reporting and assessment methods rather than a measured decrease in metals contamination. In 1994, several States chose to no longer assess overall use support with fish contamination data alone. Much of that data consisted of measurements of metals in fish tissue. As a result of excluding these fish tissue data, the national estimate of lake acres impaired by metals fell by over 2 million acres in 1994.

More States reported impairments due to nutrients than any other single pollutant.

Forty-one States also surveyed trophic status, which is associated with nutrient enrichment, in 9,735 of their lakes. Nutrient enrichment tends to increase the proportion of lakes in the eutrophic and hypereutrophic categories. These States reported that 18% of the lakes they surveyed for trophic status were oligotrophic, 32% were mesotrophic, 36% were eutrophic, 6% were hypereutrophic, and 3% were dystrophic. This information may not be representative of national lake conditions because States often assess lakes in response to a problem or public complaint or because of their easy accessibility. It is likely that more remote lakes—which are probably less impaired—are underrepresented in these assessments.

Figure ES-7. Impaired Lake Acres—Pollutants and Sources



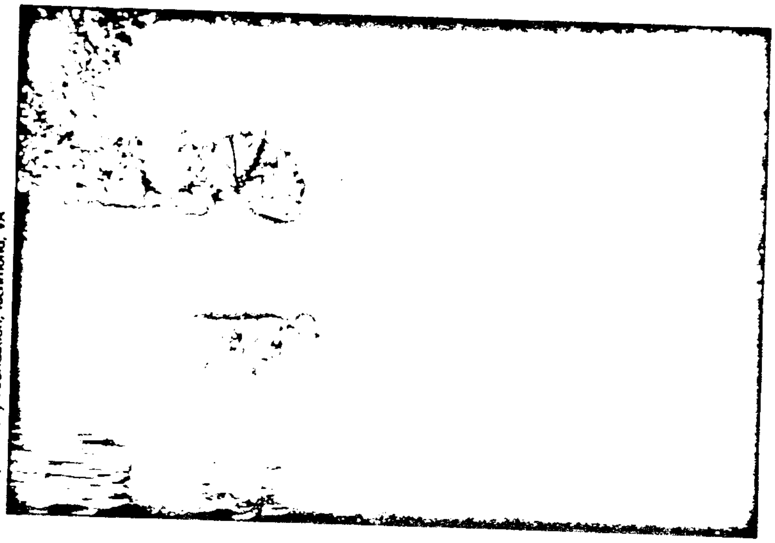
Based on data contained in Appendix B, Tables B-4 and B-5.

Where Does This Pollution Come From?

Forty-two States and Puerto Rico reported sources of pollution in some of their impacted lakes, ponds, and reservoirs. These States and Puerto Rico reported that agriculture is the most widespread source of pollution in the Nation's surveyed lakes (Figure ES-7). Agriculture generates pollutants that degrade aquatic life or interfere with public use of 3.3 million lake acres (which equals 50% of the impaired lake acres).

Agriculture is the leading source of impairment in lakes, affecting 50% of impaired lake acres.

The States and Puerto Rico also reported that municipal sewage treatment plants pollute 1.3 million lake acres (19% of the impaired lake acres), urban runoff and storm sewers pollute 1.2 million lake acres (18% of the surveyed lake acres), unspecified nonpoint sources impair 989,000 lake acres (15% of the impaired lake acres), hydrologic modifications and habitat alterations degrade 832,000 lake acres (12% of the impaired lake acres), and industrial point sources pollute 759,000 lake acres (11% of the impaired lake acres). Many States prohibit new point source discharges into lakes, but existing municipal sewage treatment plants remain a leading source of pollution entering lakes.



Chesapeake Bay Foundation, Richmond, VA

The States and Puerto Rico listed numerous sources that impact several hundred thousand lake acres, including land disposal of wastes, construction, flow regulation, highway maintenance and runoff, contaminated sediments, atmospheric deposition of pollutants, and onsite wastewater systems (including septic tanks).

The Great Lakes

The Great Lakes contain one-fifth of the world's fresh surface water and are stressed by a wide range of pollution sources, including air pollution. Many of the pollutants that reach the Great Lakes remain in the system indefinitely because the Great Lakes are a relatively closed water system with few natural outlets. Despite dramatic declines in the occurrence of algal blooms, fish kills, and localized "dead" zones depleted of oxygen, less visible problems continue to degrade the Great Lakes.

Paul Goetz, Cary, NC

Overall Water Quality

The States surveyed 94% of the Great Lakes shoreline miles for 1994 and reported that fish consumption advisories and aquatic life concerns are the dominant water quality problems, overall, in the Great Lakes (Figure ES-8). The States reported that most of the Great Lakes nearshore waters are safe for swimming and other recreational activities and can be used as a source of drinking water with normal treatment. However, only 2% of the surveyed nearshore waters fully support designated uses, overall, and 1% support uses but are threatened (Figure ES-9). About 97% of the surveyed waters do not fully support designated uses, overall, because fish consumption advisories are posted throughout the nearshore waters of the Great Lakes and water quality conditions are unfavorable for supporting aquatic life in many cases. Aquatic life impacts result from persistent toxic pollutant burdens in birds, habitat degradation and destruction, and competition

Figure ES-8: Great Lakes Shore [illegible] Surveyed

Total Great Lakes = 5,559 miles
Total surveyed = 5,224 miles

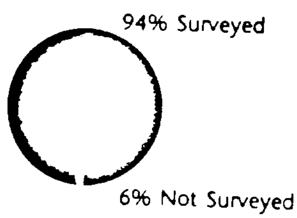


Figure ES-9: [illegible] Overall Use Support [illegible]

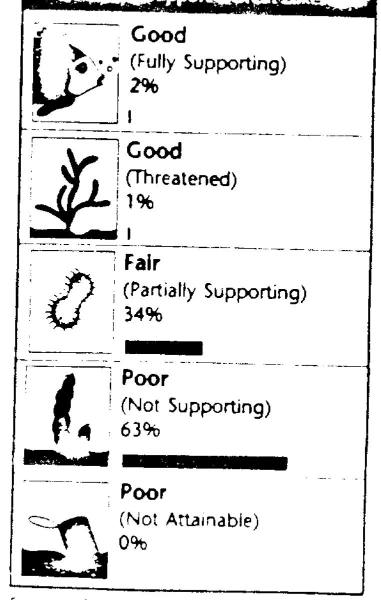


Source: Based on 1994 State Section 305(b) reports and predation by nonnative species such as the zebra mussel and the sea lamprey.

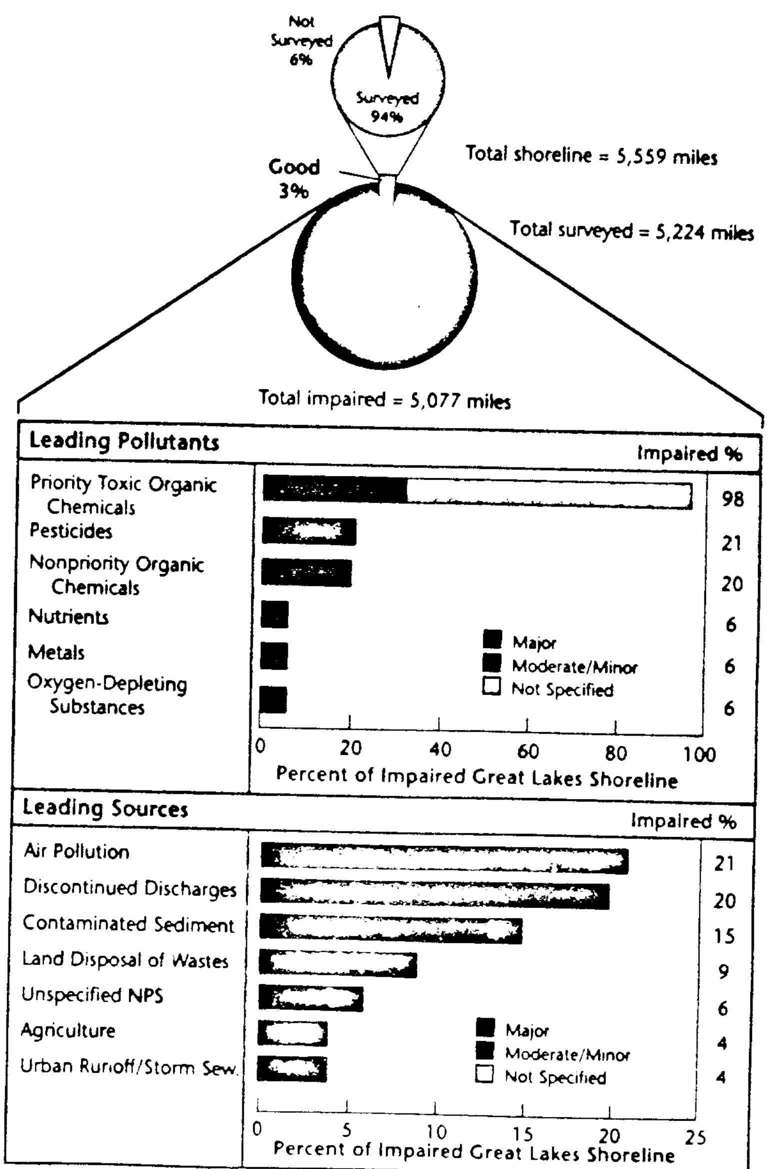
Considerable progress has been made in controlling conventional pollutants, but the Great Lakes are still subject to the effects of toxic pollutants.

These figures do not address water quality conditions in the deeper, cleaner, central waters of the Lakes.

What Is Polluting the Great Lakes?

The States reported that most of the Great Lakes shoreline is polluted by toxic organic chemicals–primarily PCBs–that are often found in fish tissue samples. The Great Lakes States reported that toxic organic chemicals impact 98% of the impaired Great Lakes shoreline miles. Other leading causes of impairment include pesticides, affecting 21%; nonpriority organic chemicals, affecting 20%; nutrients, affecting 6%; and metals, affecting 6% (Figure ES-10).

Figure ES-10. Impaired Great Lakes Shoreline: Pollutants and Sources



Based on data contained in Appendix F, Tables F-4 and F-5.

VOL 12

5408

Where Does This Pollution Come From?

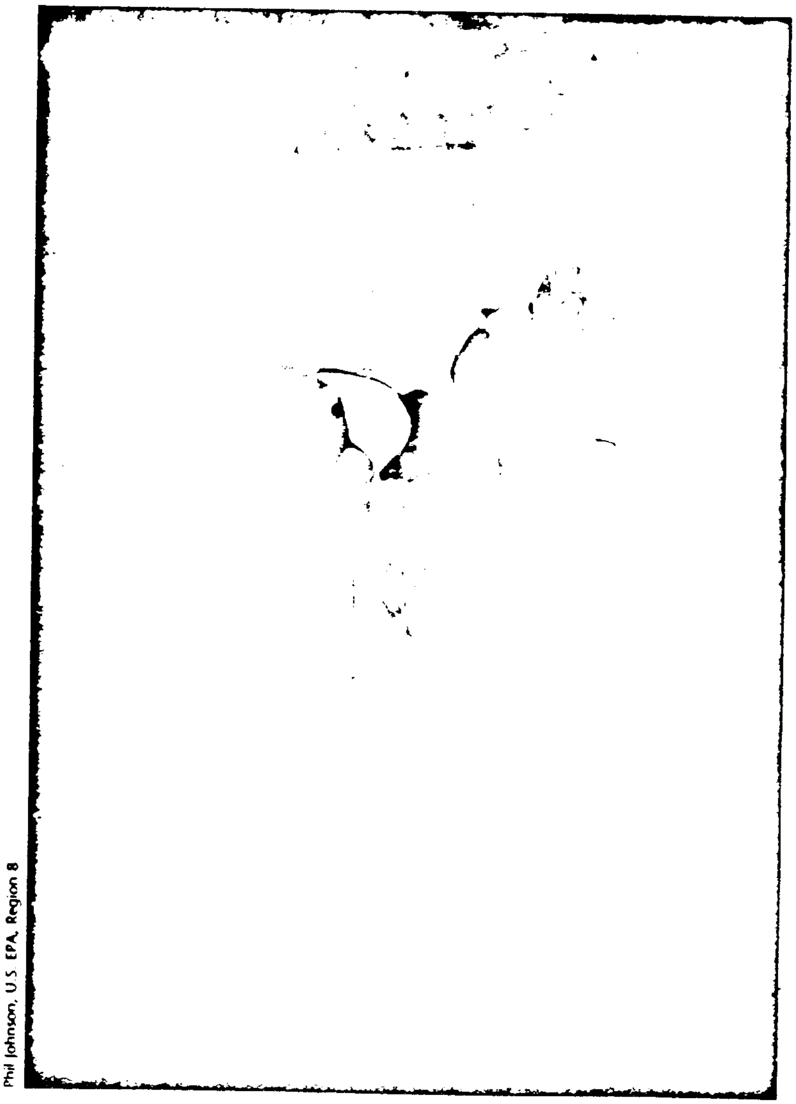
Only four of the eight Great Lakes States measured the size of their Great Lakes shoreline polluted by specific sources. These States have jurisdiction over one-third of the Great Lakes shoreline, so their findings do not necessarily reflect conditions throughout the Great Lakes Basin.

- Wisconsin identifies air pollution and discontinued discharges as a source of pollutants contaminating all 1,017 of their surveyed shoreline miles. Wisconsin also identified smaller areas impacted by contaminated sediments, nonpoint sources, industrial and municipal discharges, agriculture, urban runoff and storm sewers, combined sewer overflows, and land disposal of waste.

- Indiana attributes all of the pollution along its entire 43-mile shoreline to air pollution, urban runoff and storm sewers, industrial and municipal discharges, and agriculture.

- Ohio reports that nonpoint sources pollute 86 miles of its 236 miles of shoreline, in-place contaminants impact 33 miles, and land disposal of waste impacts 24 miles of shoreline.

- New York identifies many sources of pollutants in their Great Lakes waters, but the State attributes the most miles of degradation to contaminated sediments (439 miles) and land disposal of waste (374 miles).



Phil Johnson, U.S. EPA, Region 8

Estuaries

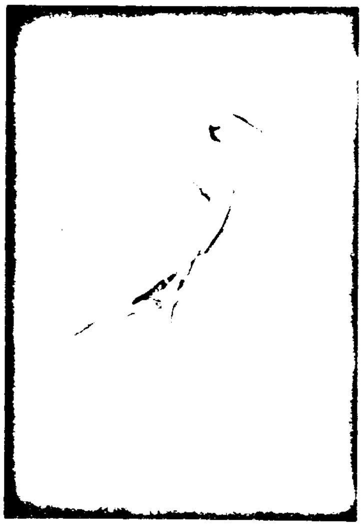
Estuaries are areas partially surrounded by land where rivers meet the sea. They are characterized by varying degrees of salinity, complex water movements affected by ocean tides and river currents, and high turbidity levels. They are also highly productive ecosystems with a range of habitats for many different species of plants, shellfish, fish, and animals.

Many species permanently inhabit the estuarine ecosystem; others, such as shrimp, use the nutrient-rich estuarine waters as nurseries before traveling to the sea.

Estuaries are stressed by the particularly wide range of activities located within their watersheds. They receive pollutants carried by rivers from agricultural lands and cities; they often support marinas, harbors, and commercial fishing fleets; and their surrounding lands are highly prized for development. These stresses pose a continuing threat to the survival of these bountiful waters.

Overall Water Quality

Twenty-five coastal States and jurisdictions surveyed 78% of the Nation's total estuarine waters in 1994 (Figure ES-11). The States and other jurisdictions reported that 63% of the surveyed estuarine waters have good water quality that fully supports designated uses (Figure ES-12). Of these waters, 6% are threatened and might deteriorate if we fail to manage potential sources of pollution.



Brian Murphy, Walnut Creek, CA

Some form of pollution or habitat degradation impairs the remaining 37% of the surveyed estuarine waters. Twenty-seven percent of the surveyed estuarine waters have fair water quality that partially supports designated uses. Most of the time these waters provide adequate habitat for aquatic organisms and support human activities, but periodic pollution interferes with these activities and/or stresses aquatic life. Nine percent of the surveyed estuarine waters suffer from poor water quality that consistently stresses aquatic life and/or prevents people from using the estuarine waters for activities such as swimming and shellfishing.

VOL 12

5410

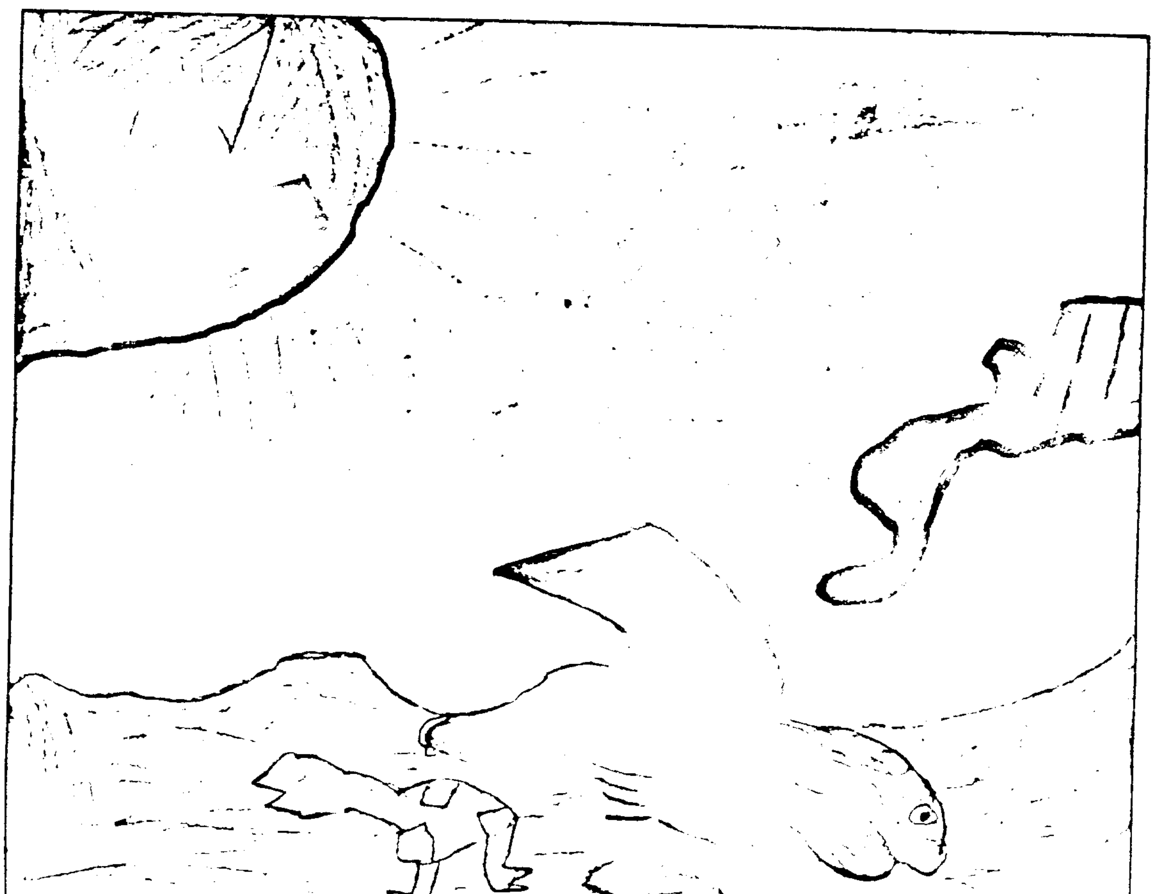
R0038718

What Is Polluting Our Estuaries?

The States identified more square miles of estuarine waters polluted by nutrients and bacteria than any other pollutant or process (Figure ES-13). Fifteen States reported that extra nutrients pollute 4,548 square miles of estuarine waters (which equals 47% of the impaired estuarine waters). As in lakes, extra inputs of nutrients from human activities destabilize estuarine ecosystems.

Twenty-five States reported that bacteria pollute 4,479 square miles of estuarine waters (which equals 46% of the impaired estuarine waters). Bacteria provide evidence that an estuary is contaminated with sewage that may contain numerous viruses and bacteria that cause illness in people.

The States also report that oxygen depletion from organic wastes impacts 3,127 square miles (which equals 32% of the impaired estuarine waters), habitat alterations impact 1,564 square miles (which equals 16% of the impaired estuarine waters), and oil and grease pollute 1,344 square miles (which equals 14% of the impaired estuarine waters.

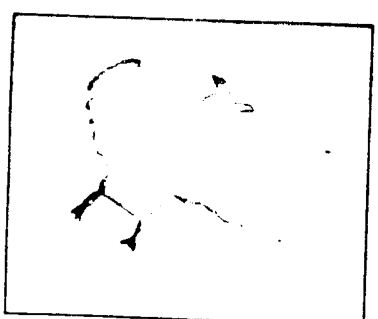


Chris Ingram, age 8, Bruner Elementary, North Las Vegas, NV

Where Does This Pollution Come From?

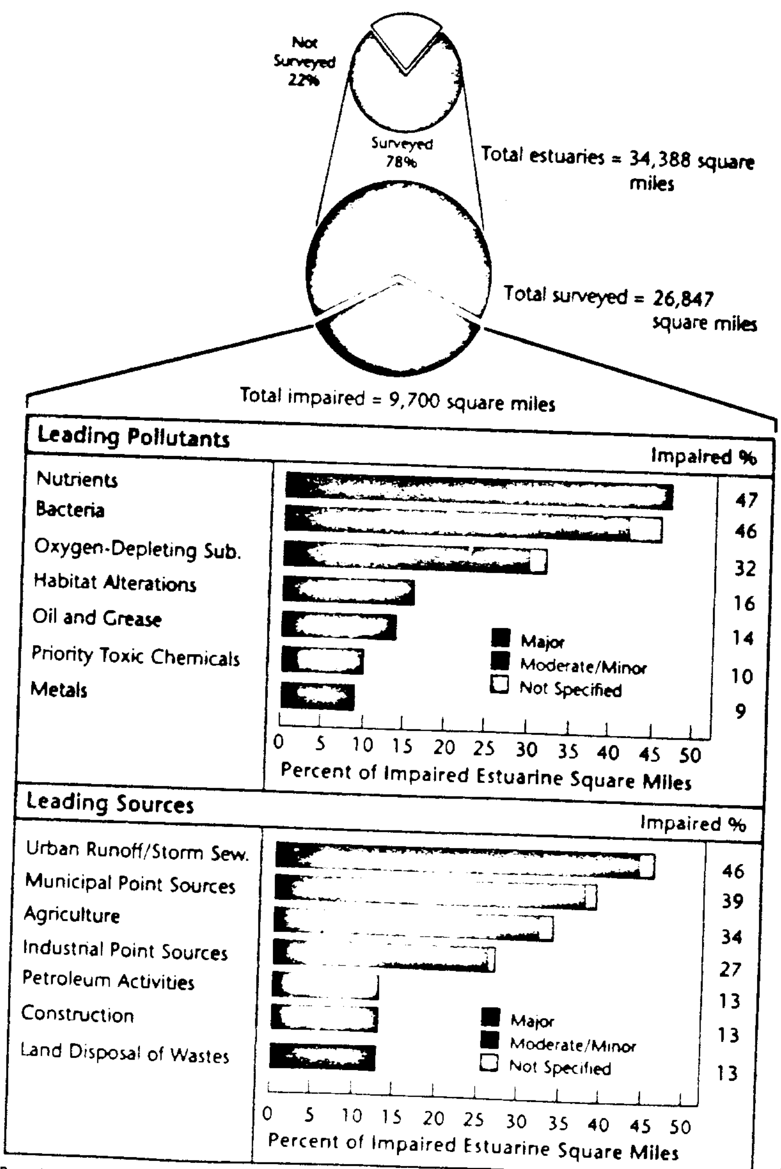
Twenty-three States reported that urban runoff and storm sewers are the most widespread source of pollution in the Nation's surveyed estuarine waters. Pollutants in urban runoff and storm sewer effluent degrade aquatic life or interfere with public use of 4,508 square miles of estuarine waters (which equals 46% of the impaired estuarine waters) (Figure ES-13).

The States also reported that municipal sewage treatment plants pollute 3,827 square miles of estuarine waters (39% of the impaired estuarine waters), agriculture pollutes 3,321 square miles of estuarine waters (34% of the impaired estuarine waters), and industrial discharges pollute 2,609 square miles (27% of the impaired estuarine waters). Urban sources contribute more to the degradation of estuarine waters than agriculture because urban centers are located adjacent to most major estuaries.



Krista Rose, age 8, Bruner Elementary, North Las Vegas, NV

Figure ES-13. Impaired Estuaries: Pollutants and Sources



Based on data contained in Appendix C, Tables C-4 and C-5

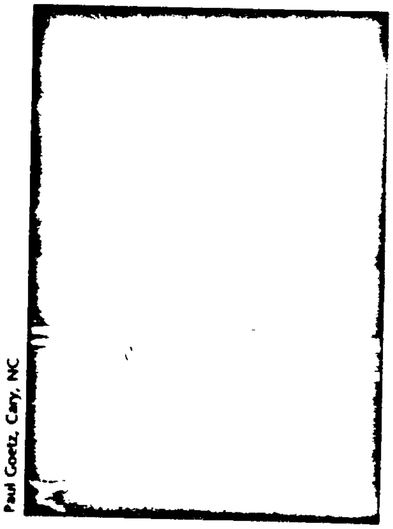
Ocean Shoreline Waters

Although the oceans are expansive, they are vulnerable to pollution from numerous sources, including city storm sewers, ocean outfalls from sewage treatment plants, overboard disposal of debris and sewage, oil spills, and bilge discharges that contain oil and grease. Nearshore ocean waters, in particular, suffer from the same pollution problems that degrade our inland waters.

Overall Water Quality

Thirteen of the 27 coastal States and Territories surveyed only 9% of the Nation's estimated 58,421 miles of ocean coastline (Figure ES-14). Most of the surveyed waters (4,834 miles, or 93%) have good quality that supports a healthy aquatic community and public activities (Figure ES-15). Of these waters, 225 miles (4% of the surveyed shoreline) are threatened and may deteriorate in the future.

Some form of pollution or habitat degradation impairs the remaining 7% of the surveyed shoreline (374 miles). Five percent of the surveyed estuarine waters have fair water quality that partially supports designated uses. Most of the time, these waters provide adequate habitat for aquatic organisms and support human activities, but periodic pollution interferes with these activities and/or stresses aquatic life. Only 2% of the surveyed shoreline suffers from poor water quality that consistently stresses aquatic life and/or prevents people from using the shoreline for activities such as swimming and shellfishing.



Paul Goetz, Cary, NC

Only six of the 27 coastal States identified pollutants and sources of pollutants degrading ocean shoreline waters. General conclusions cannot be drawn from the information supplied by these States because these States border less than 1% of the shoreline along the contiguous States. The six States identified impacts in their ocean shoreline waters from bacteria, metals, nutrients, turbidity, siltation, and pesticides. The six States reported that urban runoff and storm sewers, industrial discharges, land disposal of wastes, septic systems, agriculture, unspecified nonpoint sources, and combined sewer overflows (CSOs) pollute their coastal shoreline waters.

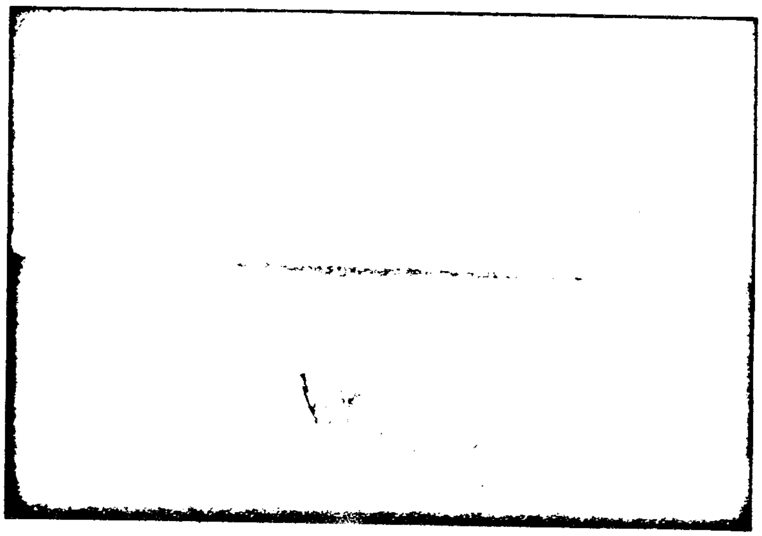
Wetlands

Wetlands are areas that are inundated or saturated by surface water or ground water at a frequency and duration sufficient to support (and that under normal circumstances does support) a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands, which are found throughout the United States, generally include swamps, marshes, bogs, and similar areas.

Wetlands are now recognized as some of the most unique and important natural areas on earth. They vary in type according to differences in local and regional hydrology, vegetation, water chemistry, soils, topography, and climate. Coastal wetlands include estuarine marshes; mangrove swamps found in Puerto Rico, Hawaii, Louisiana, and Florida; and Great Lakes coastal wetlands. Inland wetlands, which may be adjacent to a waterbody or isolated, include marshes and wet meadows bottomland hardwood forests, Great Plains prairie potholes, cypress-gum swamps, and southwestern playa lakes.

In their natural condition, wetlands provide many benefits, including food and habitat for fish and wildlife, water quality improvement, flood protection, shoreline erosion control, ground water exchange, as well as natural products for human use and opportunities for recreation, education, and research.

Wetlands help maintain and improve water quality by intercepting surface water runoff before it reaches open water, removing or retaining nutrients, processing chemical and organic wastes, and reducing sediment loads to receiving waters. As water moves through a wetland, plants slow the water, allowing sediment and pollutants to settle out. Plant roots trap sediment and are then able to metabolize and detoxify pollutants and remove nutrients such as nitrogen and phosphorus.



Audrey Moore, U.S. EPA, Region 2

Wetlands function like natural basins, storing either floodwater that overflows riverbanks or surface water that collects in isolated depressions. By doing so, wetlands help protect adjacent and downstream property from flood damage. Trees and other wetlands vegetation help slow the speed of flood waters. This action, combined with water storage, can lower flood heights and reduce the water's erosive potential. In agricultural areas, wetlands can help reduce the likelihood of flood damage to crops. Wetlands within and upstream of urban areas are especially valuable for flood protection because urban development increases the rate and volume of surface water runoff, thereby increasing the risk of flood damage.

Wetlands produce a wealth of natural products, including fish and shellfish, timber, wildlife, and wild rice. Much of the Nation's fishing and shellfishing industry harvests wetlands-dependent species. A national survey conducted by the Fish and Wildlife Service (FWS) in 1991 illustrates the economic value of some of the wetlands-dependent products. Over 9 billion pounds of fish and shellfish landed in the United States in 1991 had a direct, dockside value of $3.3 billion. This served as the basis of a seafood processing and sales industry that generated total expenditures of $26.8 billion. In addition, 35.6 million anglers spent $24 billion on freshwater and saltwater fishing. It is estimated that 71% of commercially valuable fish and shellfish depend directly or indirectly on coastal wetlands.

Overall Water Quality

The States, Tribes, and other jurisdictions are making progress in developing specific designated uses and water quality standards for wetlands, but many States and Tribes still lack specific water quality criteria and monitoring programs for wetlands. Without criteria and monitoring data, most States and Tribes cannot evaluate use support. To date, only nine States and Tribes reported the designated use support status for some of their wetlands. Only one State used quantitative data as a basis for the use support decisions.

EPA cannot derive national conclusions about water quality conditions in all wetlands because the States used different methodologies to survey only 3% of the total wetlands in the Nation. Summarizing State wetlands data would also produce misleading results because two States (North Carolina and Louisiana) contain 91% of the surveyed wetlands acreage.

What Is Polluting Our Wetlands and Where Does This Pollution Come From?

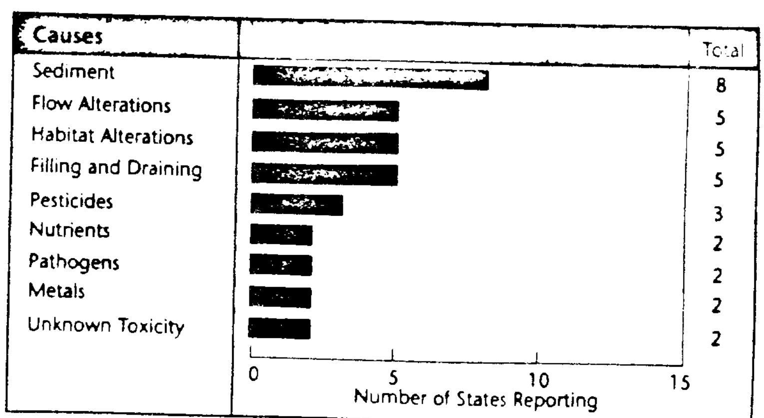
The States have even fewer data to quantify the extent of pollutants degrading wetlands and the sources of these pollutants. Although most States cannot quantify wetlands area impacted by individual causes and sources of degradation, 12 States identified causes and 13 States identified sources known to degrade wetlands integrity to some extent. These States listed sediment as the most widespread cause of degradation impacting wetlands, followed by flow alterations, habitat modifications, and draining (Figure ES-16). Agriculture topped the list of sources degrading wetlands, followed by urban runoff, hydrologic modification, and municipal point sources (Figure ES-17).

Wetlands Loss: A Continuing Problem

It is estimated that over 200 million acres of wetlands existed in the lower 48 States at the time of European settlement. Since then, extensive wetlands acreage has been lost, with many of the original wetlands drained and converted to farmland and urban development. Today, less than half of our original wetlands remain. The losses amount to an area equal to the size of California. According to the U.S. Fish and Wildlife Service's *Wetlands Losses in the United States 1780's to 1980's*, the three States that have sustained the greatest percentage of wetlands loss are California (91%), Ohio (90%), and Iowa (89%).

According to FWS status and trends reports, the average annual loss of wetlands has decreased over the past 40 years. The average annual loss from the mid-1950s to the mid-1970s was 458,000 acres, and from the mid-1970s to the mid-1980s it was 290,000 acres. Agriculture was responsible for 87% of the loss from the mid-1950s to the mid-1970s and 54% of the loss from the mid-1970s to the mid-1980s.

Figure ES-16. Causes Degrading Wetlands Integrity (12 States Reporting)



Based on data contained in Appendix D, Table D-2.

VOL 12

5415

A more recent estimate of wetlands losses from the National Resources Inventory (NRI), conducted by the Natural Resources Conservation Service (NRCS), indicates that 792,000 acres of wetlands were lost on non-Federal lands between 1982 and 1992 for a yearly loss estimate of 70,000 to 90,000 acres. This net loss is the result of gross losses of 1,561,300 acres of wetlands and gross gains of 768,700 acres of wetlands over the 10-year period. The NRI estimates are consistent with the trend of declining wetlands losses reported by FWS. Although losses have decreased, we still have to make progress toward our interim goal of no overall net loss of the Nation's remaining wetlands and the long-term goal of increasing the quantity and quality of the Nation's wetlands resource base.

The decline in wetlands losses is a result of the combined effect of several trends: (1) the decline in profitability in converting wetlands for agricultural production;
(2) passage of Swampbuster provisions in the 1985 and 1990 Farm Bills that denied crop subsidy benefits to farm operators who converted wetlands to cropland after 1985; (3) presence of the CWA Section 404 permit programs as well as development of State management programs; (4) greater public interest and support for wetlands protection; and (5) implementation of wetlands restoration programs at the Federal, State, and local level.

Nineteen States listed sources of recent wetlands losses in their 1994 305(b) reports. Residential development and urban growth were cited as the leading sources of current losses. Other losses were due to commercial development; construction of roads, highways, and bridges; agriculture; and industrial development. In addition to human activities, a few States also reported that natural sources, such as rising lake levels, resulted in wetlands losses and degradation.

Ground Water

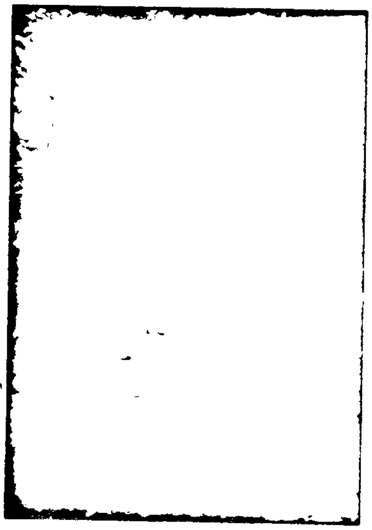
Ninety-five percent of all fresh water available on earth (exclusive of icecaps) is ground water. Ground water–water found in natural underground rock formations called aquifers–is a vital natural resource with many uses. The extent of the Nation's ground water resources is enormous. At least 60% of the land area in the conterminous United States overlies aquifers that may be susceptible to contamination. Usable ground water exists in every State.

Aquifers can range in size from thin surficial formations that yield small quantities of ground water to large systems such as the High Plains aquifer that underlies eight western States and provides water to millions. Although the Nation's ground water is of good quality, it is recognized that ground water is more vulnerable to contamination than previously reported and that an increasing number of pollution events and contamination sources are threatening the integrity of the resource.

Ground Water Use

Nationally, 51% of the population relies to some extent on ground water as a source of drinking water. This percentage is even higher in rural areas where most residents rely on potable or treatable ground water as an economical source of drinking water. Eighty-one percent of community water systems are dependent on ground water. Seventy-four percent of community water systems are small ground water systems serving 3,300 people or less. Ninety-five percent of the approximately 200,000 noncommunity water systems (serving schools, parks, and other small facilities) are ground water systems.

Ground water provides drinking water for 51% of the population.



Jeff Reynolds, Raleigh, NC

Irrigation accounts for approximately 63% of national ground water withdrawals. Public drinking water supplies account for approximately 19% of the Nation's total ground water withdrawals. Domestic, commercial, livestock, industrial, mining, and thermoelectric withdrawals together account for approximately 18% of national ground water withdrawals.

Ground Water Quality

Although the 1994 Section 305(b) State Water Quality Reports indicate that, overall, the Nation's ground water is of good quality, many local areas have experienced significant ground water contamination. The sources and types of ground water contamination vary depending upon the region of the country. Those most frequently reported by States include:

- **Leaking underground storage tanks.** Approximately 1.2 million federally regulated underground storage tanks are buried at over 500,000 sites nationwide. An estimated 139,000 tanks have leaked and impacted ground water quality.
- **Agricultural activities.** Seventy-seven percent of the 1.1 billion pounds of pesticides produced annually in the United States is applied to land in agricultural production, which usually overlies aquifers.
- **Superfund sites.** More than 85% of all Superfund sites have some degree of ground water contamination. Most of these sites impact aquifers that are currently used, or potentially may be used, for drinking water purposes.
- **Septic tanks.** Approximately 23 million domestic septic tanks are in operation in the United States. These tanks impact ground water quality through the discharge of fluids into or above aquifers.

The most common contaminants associated with these sources include petroleum compounds, nitrates, metals, volatile organic compounds (VOCs), and pesticides.

States are reporting that ground water quality is most likely to be adversely affected by contamination in areas of high demand or stress.

VOL 12

To combat these problems, States are developing programs designed to evaluate the overall quality and vulnerability of their ground water resources, to identify potential threats to ground water quality, and to identify methods to protect their ground water resources. Thirty-three States indicate that they have implemented statewide ground water monitoring programs.

Ground water monitoring programs vary widely among the States, depending upon the special needs of each of the States. For example, some States choose to monitor ground water quality in specific areas that are especially vulnerable to contamination, whereas other States may choose to monitor ground water quality on a statewide basis. When it comes to selecting chemicals to test for in the ground water, some States monitor for a large suite of chemicals, whereas other States limit monitoring to one or two specific chemicals that are a definite threat to ground water quality.

Ground water monitoring provides a great deal of information about the nature and quality of our Nation's ground water resources. Still, there is much we do not know about how human activities influence ground water quality. Our continued quest for information about the status of our ground water will help protect and preserve this vast and vulnerable resource. Through a greater understanding of how human activities influence ground water quality, we can better ensure the long-term availability of high-quality water for future generations.

VOL 12

54/8

Water Quality Protection Programs

Although significant strides have been made in reducing the impacts of discrete pollutant sources, our aquatic resources remain at risk from a combination of point sources and complex nonpoint sources, including air pollution. Since 1991, EPA has promoted the watershed protection approach as a holistic framework for addressing complex pollution problems.

The watershed protection approach is a place-based strategy that integrates water quality management activities within hydrologically defined drainage basins—watersheds—rather than areas defined by political boundaries. Thus, for a given watershed, the approach encompasses not only the water resource (such as a stream, lake, estuary, or ground water aquifer), but all the land from which water drains to the resource. To protect water resources, it is increasingly important to address the condition of land areas within the watershed because water carries the effects of human activities throughout the watershed as it drains off the land into surface waters or leaches into the ground water.

Under the Watershed Protection Approach (WPA), a "watershed" is a hydrogeologic area defined for addressing water quality problems. For example, a WPA watershed may be a river basin, a county-sized watershed, or a small drinking water supply watershed.

Mike Steuart, Minnesota Pollution Control Agency

EPA's Office of Water envisions the watershed protection approach as the primary mechanism for achieving clean water and healthy, sustainable ecosystems throughout the Nation. The watershed protection approach enables stakeholders to take a comprehensive look at ecosystem issues and tailor corrective actions to local concerns within the coordinated framework of a national water program. The emphasis on public participation also provides an opportunity to incorporate environmental justice issues into watershed restoration and protection solutions.

In May of 1994, the EPA Assistant Administrator for Water, Robert Perciasepe, created the Watershed Management Policy Committee to coordinate the EPA water program's support of the watershed protection approach. During 1995, EPA's water program managers, under the direction of the Watershed Management Policy Committee, evaluated their programs and identified additional activities needed to support the watershed protection approach in an action plan.

EPA's Office of Water will continue to promote and support the watershed protection approach at local, State, Tribal, Territorial, and Federal levels. The Office of Water recognizes that the watershed protection approach relies on active participation by local governments and citizens who have the most direct knowledge of local problems and opportunities in their watersheds. However, the Office of Water will look to the States, Tribes, and Territories to create the framework for supporting local efforts because most EPA programs are implemented by the States, Tribes, and Territories.

The Clean Water Act

A number of laws provide the authority to develop and implement pollution control programs. The primary statute providing for water quality protection in the Nation's rivers, lakes, wetlands, estuaries, and coastal waters is the Federal Water Pollution Control Act of 1972, commonly known as the Clean Water Act.

The CWA and its amendments are the driving force behind many of the water quality improvements we have witnessed in recent years. Key provisions of the CWA provide the following pollution control programs.

Water quality standards and criteria - States, Tribes, and other jurisdictions adopt EPA-approved standards for their waters that define water quality goals for individual waterbodies. Standards consist of designated beneficial uses to be made of the water, criteria to protect those uses, and antidegradation provisions to protect existing water quality.

Effluent guidelines - The EPA develops nationally consistent guidelines limiting pollutants in discharges from industrial facilities and municipal sewage treatment plants. These guidelines are then used in permits issued to dischargers under the

The Watershed Protection Approach (WPA)

Several key principles guide the watershed protection approach:

- **Place-based focus** – Resource management activities are directed within specific geographical areas, usually defined by watershed boundaries, areas overlying or recharging ground water, or a combination of both.
- **Stakeholder involvement and partnerships** – Watershed initiatives involve the people most likely to be affected by management decisions in the decision making process. Stakeholder participation ensures that the objectives of the watershed initiative will include economic stability and that the people who depend on the water resources in the watershed will participate in planning and implementation activities. Watershed initiatives also establish partnerships between Federal, State, and local agencies and nongovernmental organizations with interests in the watershed.
- **Environmental objectives** – The stakeholders and partners identify environmental objectives (such as "populations of striped bass will stabilize or increase") rather than programmatic objectives (such as "the State will eliminate the backlog of discharge permit renewals") to measure the success of the watershed initiative. The environmental objectives are based on the condition of the ecological resource and the needs of people in the watershed.
- **Problem identification and prioritization** – The stakeholders and partners use sound scientific data and methods to identify and prioritize the primary threats to human and ecosystem health within the watershed. Consistent with the Agency's mission, EPA views ecosystems as the interactions of complex communities that include people; thus, healthy ecosystems provide for the health and welfare of humans as well as other living things.
- **Integrated actions** – The stakeholders and partners take corrective actions in a comprehensive and integrated manner, evaluate success, and refine actions if necessary. The watershed protection approach coordinates activities conducted by numerous government agencies and nongovernmental organizations to maximize efficient use of limited resources.

National Pollutant Discharge Elimination System (NPDES) program. Additional controls may be required if receiving waters are still affected by water quality problems after permit limits are met.

Total Maximum Daily Loads– The development of Total Maximum Daily Loads, or TMDLs, establishes the link between water quality standards and point/nonpoint source pollution control actions such as permits or Best Management Practices (BMPs). A TMDL calculates allowable loadings from the contributing point and nonpoint sources to a given waterbody and provides the quantitative basis for pollution reduction necessary to meet water quality standards. States, Tribes, and other jurisdictions develop and implement TMDLs for high-priority impaired or threatened waterbodies.

Permits and enforcement – All industrial and municipal facilities that discharge wastewater must have an NPDES permit and are responsible for monitoring and reporting levels of pollutants in their discharges. EPA issues these permits or can delegate that permitting authority to qualifying States or other jurisdictions. The States, other qualified jurisdictions, and EPA inspect facilities to determine if their discharges comply with permit limits. If dischargers are not in compliance, enforcement action is taken.

Grants – The EPA provides States with financial assistance to help support many of their pollution control programs. These programs include the State Revolving Fund program for construction and upgrading of municipal sewage treatment plants; water quality monitoring, permitting, and enforcement; and developing and implementing nonpoint source pollution controls, combined sewer and stormwater controls, ground water strategies, lake assessment, protection, and restoration activities, estuary and near coastal management programs, and wetlands protection activities.

Nonpoint source control – The EPA provides program guidance, technical support, and funding to help the States, Tribes, and other jurisdictions control nonpoint source pollution. The States, Tribes, and other jurisdictions are responsible for analyzing the extent and severity of their nonpoint source pollution problems and developing and implementing needed water quality management actions.

The CWA also established pollution control and prevention programs for specific waterbody categories, such as the Clean Lakes Program. Other statutes that also guide the development of water quality protection programs include:

- **The Safe Drinking Water Act**, under which States establish standards for drinking water quality, monitor wells and local water supply systems, implement drinking water protection programs, and implement Underground Injection Control (UIC) programs.

- **The Resource Conservation and Recovery Act**, which establishes State and EPA programs for ground water and surface water protection and cleanup and emphasizes prevention of releases through management standards in addition to other waste management activities.

- **The Comprehensive Environmental Response, Compensation, and Liability Act (Superfund Program)**, which provides EPA with the authority to clean up contaminated waters during remediation at contaminated sites.

- **The Pollution Prevention Act** of 1990, which requires EPA to promote pollutant source reduction rather than focus on controlling pollutants after they enter the environment.

VOL 12

5421

Protecting Lakes

Managing lake quality often requires a combination of in-lake restoration measures and pollution controls, including watershed management measures:

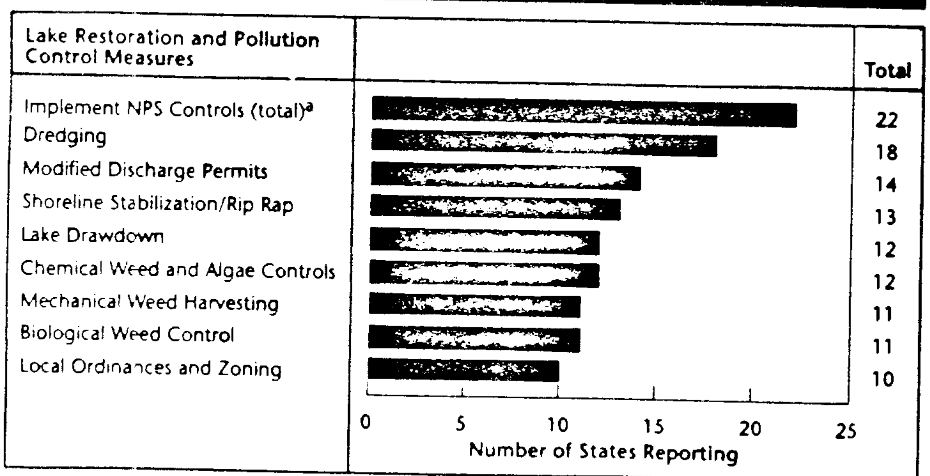
Restoration measures are implemented to reduce existing pollution problems. Examples of in-lake restoration measures include harvesting aquatic weeds, dredging sediment, and adding chemicals to precipitate nutrients out of the water column. Restoration measures focus on restoring uses of a lake and may not address the source of the pollution.

Pollution control measures deal with the sources of pollutants degrading lake water quality or threatening to impair lake water quality. Control measures include planning activities, regulatory actions, and implementation of BMPs to reduce nonpoint sources of pollutants.

During the 1980s, most States implemented chemical and mechanical in-lake restoration measures to control aquatic weeds and algae. In their 1994 Section 305(b) reports, the States and Tribes report a shift toward nonpoint source controls to reduce pollutant loads responsible for aquatic weed growth and algal blooms (Figure ES-18). Twenty-two States reported that they implemented best management practices to control nonpoint source pollution entering more than 171 lakes. The States reported that they implemented agricultural practices to control soil erosion, constructed retention and detention basins to control urban runoff, managed animal waste, revegetated shorelines, and constructed or restored wetlands to remove pollutants from runoff. Although the States reported that they still use in-lake treatments, the States recognize that source controls are needed in addition to in-lake treatments to restore lake water quality.

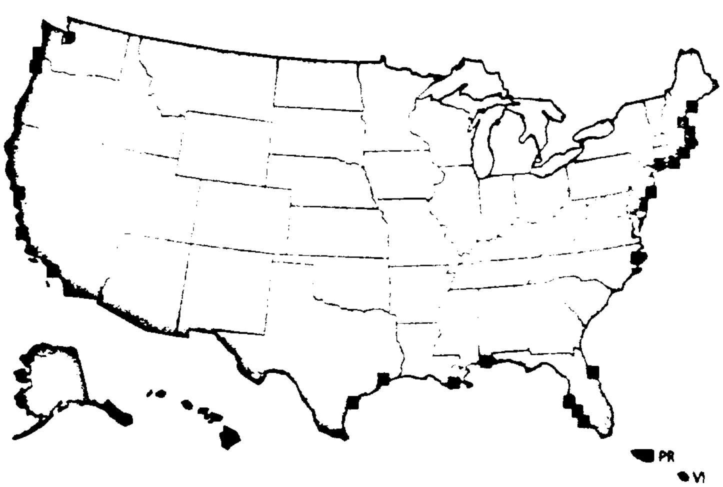
Successful lake programs require strong commitment from local citizens and cooperation from natural resource agencies at the local, State, and Federal levels.

Figure ES-18



[a]Includes best management practices, such as conservation tillage, sediment detention basins, vegetated buffers, and animal waste management.

Figure ES-19.--Locations of National Estuary Program Sites



The National Estuary Program

Section 320 of the Clean Water Act (as amended by the Water Quality Act of 1987) established the National Estuary Program (NEP) to protect and restore water quality and living resources in estuaries. The NEP adopts a geographic or watershed approach by planning and implementing pollution abatement activities for the estuary and its surrounding land area as a whole.

The NEP embodies the ecosystem approach by building coalitions, addressing multiple sources of contamination, pursuing habitat protection as a pollution control mechanism, and investigating cross-media transfer of pollutants from air and soil into specific estuarine waters. Under the NEP, a State governor nominates an estuary in his or her State for participation in the program. The State must demonstrate a likelihood of success in protecting candidate estuaries and provide evidence of institutional, financial, and political commitment to solving estuarine problems.

If an estuary meets the NEP guidelines, the EPA Administrator convenes a management conference of representatives from interested Federal, Regional, State, and local governments; affected industries; scientific and academic institutions; and citizen organizations. The management conference defines program goals and objectives, identifies problems, and designs strategies to control pollution and manage natural resources in the estuarine basin. Each management conference develops and initiates implementation of a Comprehensive Conservation and Management Plan (CCMP) to restore and protect the estuary.

The NEP currently supports 28 estuary projects.

The NEP integrates science and policy by bringing water quality managers, elected officials, and stakeholders together with scientists from government agencies, academic institutions, and the private sector. Because the NEP is not a research program, it relies heavily on past and ongoing research of other agencies and institutions to support development of CCMPs.

With the addition of seven estuary sites in July of 1995, the NEP currently supports 28 estuary projects (see Figure ES-19). These 28 estuaries are nationally significant in their economic value as well as in their ability to support living resources. The project sites also represent a broad range of environmental conditions in estuaries throughout the United States and its Territories so that the lessons learned through the NEP can be applied to other estuaries.

VOL 12

5424

> Shortly after coming into office, the Clinton Administration convened an interagency working group to address concerns with Federal wetlands policy. After hearing from States, developers, farmers, environmental interests, members of Congress, and scientists, the working group developed a comprehensive 40-point plan for wetlands protection to make wetlands programs more fair, flexible, and effective. This plan was issued on August 24, 1993
>
> The Administration's Wetlands Plan emphasizes improving Federal wetlands policy by
>
> - Streamlining wetlands permitting programs
> - Increasing cooperation with private landowners to protect and restore wetlands
> - Basing wetlands protection on good science and sound judgment
> - Increasing participation by States, Tribes, local governments, and the public in wetlands protection.

Protecting Wetlands

A variety of public and private programs protect wetlands. Section 404 of the CWA continues to provide the primary Federal vehicle for regulating certain activities in wetlands. Section 404 establishes a permit program for discharges of dredged or fill material into waters of the United States, including **wetlands**.

The U.S. Army Corps of Engineers (COE) and EPA jointly implement the Section 404 program. The COE is responsible for reviewing permit applications and making permit decisions. EPA establishes the environmental criteria for making permit decisions and has the authority to review and veto Section 404 permits proposed for issuance by the COE. EPA is also responsible for determining geographic jurisdiction of the Section 404 permit program, interpreting statutory exemptions, and overseeing Section 404 permit programs assumed by individual States. To date, only two States (Michigan and New Jersey) have assumed the Section 404 permit program from the COE. The COE and EPA share responsibility for enforcing Section 404 requirements.

The COE issues **individual** Section 404 permits for specific projects or **general** permits (Table ES-5). Applications for individual permits go through a review process that includes opportunities for EPA, other Federal agencies (such as the U.S. Fish and Wildlife Service and the National Marine Fisheries Service), State agencies, and the public to comment. However, the vast majority of activities proposed in wetlands are covered by Section 404 general permits. For example, in FY94, over 48,000 people applied to the COE for a Section 404 permit. Eighty-two percent of these applications were covered by general permits and were processed in an average of 16 days. It is estimated that another 50,000 activities are covered by general permits that do not require notification of the COE at all.

General permits allow the COE to permit certain activities without performing a separate individual

Table ES-5 Federal Section 404 Permits

General Permits (streamlined permit review procedures)				Individual Permits
Nationwide Permits	Regional Permits	Programmatic Permits		
		State Programmatic Permits	Others	
• Cover 36 types of activities that the COE determines to have minimal adverse impacts on the environment	• Developed by COE District Offices to cover activities in a specified region	• COE defers permit decisions to State agency while reserving authority to require an individual permit	• Special Management Agencies • Watershed Planning Commissions	• Required for major projects that have the potential to cause significant adverse impacts • Project must undergo interagency review • Opportunity for public comment • Opportunity for 401 certification review

permit review. Some general permits require notification of the COE before an activity begins. There are three types of general permits:

- Nationwide permits (NWPs) authorize specific activities across the entire Nation that the COE determines will have only minimal individual and cumulative impacts on the environment, including construction of minor road crossings and farm buildings, bank stabilization activities, and the filling of up to 10 acres of isolated or headwater wetlands.

- Regional permits authorize types of activities within a geographic area defined by a COE District Office.

- Programmatic general permits are issued to an entity that the COE determines may regulate activities within its jurisdictional wetlands. Under a programmatic general permit, the COE defers its permit decision to the regulating entity but reserves its authority to require an individual permit.

Currently, the COE and EPA are promoting the development of State programmatic general permits (SPGPs) to increase State involvement in wetlands protection and minimize duplicative State and Federal review of activities proposed in wetlands. Each SPGP is a unique arrangement developed by a State and the COE to take advantage of the strengths of the individual State wetlands program. Several States have adopted comprehensive SPGPs that replace many or all COE-issued nationwide general permits. SPGPs simplify the regulatory process and increase State control over their wetlands resources. Carefully developed SPGPs can improve wetlands protection while reducing regulatory demands on landowners.

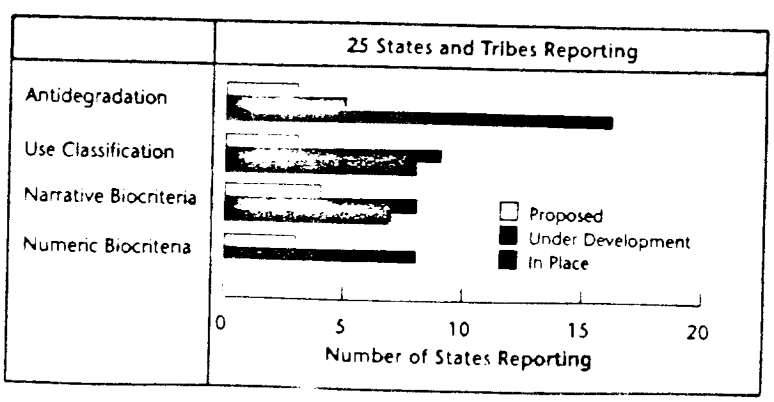
Water quality standards for wetlands ensure that the provisions of CWA Section 303 that apply to other surface waters are also applied to wetlands. In July 1990, EPA issued guidance to States for the development of wetlands water quality standards. Water quality standards consist of designated beneficial uses, numeric criteria, narrative criteria, and antidegradation statements. Figure ES-20 indicates the State's progress in developing these standards.

Standards provide the foundation for a broad range of water quality management activities under the CWA including, but not limited to, monitoring for the Section 305(b) report, permitting under Section 402 and 404, water quality certification under Section 401, and the control of nonpoint source pollution under Section 319.

States, Territories, and Tribes are well positioned between Federal and local government to take the lead in integrating and expanding wetlands protection and management programs. They are experienced in managing federally mandated environmental programs, and they are uniquely equipped to help resolve local and regional conflicts and identify the local economic and geographic factors that may influence wetlands protection.

Section 401 of the CWA gives States and eligible American Indian Tribes the authority to grant, condition, or deny certification of federally permitted or licensed activities that may result in a discharge to U.S. waters, including wetlands. Such activities include discharge of dredged or fill material permitted under CWA Section 404, point source discharges permitted under CWA Section 402, and Federal Energy Regulatory Commission's

Figure ES-20. Development of State Water Quality Standards for Wetlands



VOL 12

5425

hydropower licenses. States review these permits to ensure that they meet State water quality standards.

Section 401 certification can be a powerful tool for protecting wetlands from unacceptable degradation or destruction especially when implemented in conjunction with wetlands-specific water quality standards. If a State or an eligible Tribe denies Section 401 certification, the Federal permitting or licensing agency cannot issue the permit or license.

Until recently, many States waived their right to review and certify Section 404 permits because these States had not defined water quality standards for wetlands or codified regulations for implementing their 401 certification program into State law. Now, most States report that they use the Section 401 certification process to review Section 404 projects and to require mitigation if there is no alternative to degradation of wetlands. Ideally, 401 certification should be used to augment State programs because activities that do not require Federal permits or licenses, such as some ground water withdrawals, are not covered.

State Wetlands Conservation Plans (SWCPs) are strategies that integrate regulatory and cooperative approaches to achieve State wetlands management goals, such as no overall net loss of wetlands. SWCPs are not meant to create a new level of bureaucracy. Instead, SWCPs improve government and private-sector effectiveness and efficiency by identifying gaps in wetlands protection programs and identifying opportunities to improve wetlands programs.

States, Tribes, and other jurisdictions protect their wetlands with a variety of other approaches, including permitting programs, coastal management programs, wetlands acquisition programs, natural heritage programs, and integration with other programs. The following trends emerged from individual State and Tribal reporting:

- Most States have defined wetlands as waters of the State, which offers general protection through antidegradation clauses and designated uses that apply to all waters of a State. However, most States have not developed specific wetlands water quality standards and designated uses that protect wetlands' unique functions, such as flood attenuation and filtration.

- Without specific wetlands uses and standards, the Section 401 certification process relies heavily on antidegradation clauses to prevent significant degradation of wetlands.

- In many cases, the States use the Section 401 certification process to add conditions to Section 404 permits that minimize the size of wetlands destroyed or degraded by proposed activities to the extent practicable. States often add conditions that require compensatory mitigation for destroyed wetlands, but the States do not have the resources to perform enforcement inspections or followup monitoring to ensure that the wetlands are constructed and functioning properly.

- More States are monitoring selected, largely unimpacted wetlands to establish baseline conditions in healthy wetlands. The States will use this information to monitor the relative performance of constructed wetlands and to help establish biocriteria and water quality standards for wetlands.

Although the States, Tribes, and other jurisdictions report that they are making progress in protecting wetlands, they also report that the pressure to develop or destroy wetlands remains high. EPA and the States, Tribes, and other jurisdictions will continue to pursue new mechanisms for protecting wetlands that rely less on regulatory tools.

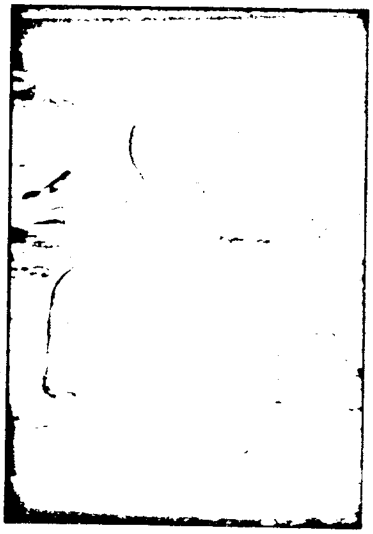
Protecting the Great Lakes

Restoring and protecting the Great Lakes requires cooperation from numerous organizations because the pollutants that enter the Great Lakes originate in both the United States and Canada, as well as in other countries. The International Joint Commission (IJC), established by the 1909 Boundary Waters Treaty, provides a framework for the cooperative management of the Great Lakes. Representatives from the United States and Canada, the Province of Ontario, and the eight States bordering the Lakes sit on the IJC's Water Quality Board. The Water Quality Board recommends actions for protecting and restoring the Great Lakes and evaluates the environmental policies and actions implemented by the United States and Canada.

The EPA Great Lakes National Program Office (GLNPO) coordinates Great Lakes management activities conducted by all levels of government within the United States. The GLNPO also works with nongovernmental organizations to protect and restore the Lakes. The GLNPO provides leadership through its annual *Great Lakes Program Priorities and Funding Guidance*. The GLNPO also serves as a liaison to the Canadian members of the IJC and the Canadian environmental agencies.

The 1978 Great Lakes Water Quality Agreement (as amended in 1987) lay the foundation for ongoing efforts to restore and protect the Great Lakes. The Agreement committed the United States and Canada to developing Remedial Action Plans (RAPs) for Areas of Concern and Lakewide Management Plans (LaMPs) for each Lake. Areas of Concern are specially designated waterbodies around the Great Lakes that show symptoms of serious water quality degradation. Most of the 42 Areas of Concern are located in harbors, bays, or river mouths entering the Great Lakes. RAPs identify impaired uses and examine management options for addressing degradation in an Area of Concern. LaMPs use an ecosystem approach to examine water quality issues that have more widespread impacts within each Great Lake. Public involvement is a critical component of both LaMP development and RAP development.

EPA advocates pollution prevention as the most effective approach for achieving the virtual elimination of persistent toxic discharges into the Great Lakes. The GLNPO has funded numerous pollution prevention grants throughout the Great



Julie Fountain, Youngsville, NC

Lakes Basin during the past 3 years. EPA and the States also implemented the 38/50 Program in the Great Lakes Basin, under which EPA received voluntary commitments from industry to reduce the emission of 17 priority pollutants by 50% by the end of 1995. In addition, EPA, the States, and Canada are implementing a virtual elimination initiative for Lake Superior. The first phase of the initiative seeks to eliminate new contributions of mercury.

The Great Lakes Water Quality Initiative is a key element of the environmental protection efforts undertaken by the United States in the Great Lakes Basin. The purpose of the Initiative is to provide a consistent level of protection in the Basin from the effects of toxic pollutants. In 1989, the Initiative was organized by EPA at the request of the Great Lakes States to promote consistency in their environmental programs in the Great Lakes Basin with minimum requirements.

Initiative efforts were well under way when Congress enacted the Great Lakes Critical Programs Act of 1990. The Act requires EPA to publish proposed and final water quality guidance that specifies minimum water quality criteria for the Great Lakes System. The Act also requires the Great Lakes States to adopt provisions that are consistent with the EPA final guidance within 2 years of EPA's publication. In addition, Indian Tribes authorized to administer an NPDES program in the Great Lakes Basin must also adopt provisions consistent with EPA's final guidance.

To carry out the Act, EPA proposed regulations for implementing the guidance on April 16, 1993, and invited the public to comment. The States and EPA conducted public meetings in all of the Great Lakes States during the comment period. As a result, EPA received over 26,500 pages of comments from over 6,000 commenters. EPA reviewed all of the comments and published the final guidance in March of 1995.

The final guidance prioritizes control of long-lasting pollutants that accumulate in the food web—bioaccumulative chemicals of concern (BCCs). The final guidance includes provisions to phase out mixing zones for BCCs (except in limited circumstances), more extensive data requirements to ensure that BCCs are not underregulated due to a lack of data, and water quality criteria to protect wildlife that feed on aquatic prey.

Publication of the final guidance is a milestone in EPA's move toward increasing stakeholder participation in the development of innovative and comprehensive programs for protecting and restoring our natural resources.

The Chesapeake Bay Program

In many areas of the Chesapeake Bay, the quality is not sufficient to support living resources year round. In the warmer months, large portions of the Bay contain little or no dissolved oxygen. Low oxygen conditions may cause fish eggs and larvae to die. The growth and reproduction of oysters, clams, and other bottom-dwelling animals are impaired. Adult fish find their habitat reduced and their feeding inhibited.

Many areas of the Bay also have cloudy water from excess sediment in the water or an overgrowth of algae (stimulated by excessive nutrients in the water). Turbid waters block the sunlight needed to support the growth and survival of Bay grasses, also known as submerged aquatic vegetation (SAV). Without SAV, critical habitat for fish and crabs is lost. Although there has been a recent resurgence of SAV in some areas of the Bay, most areas still do not support abundant populations as they once did.

The main causes of the Bay's poor water quality and aquatic habitat loss are elevated levels of the nutrients nitrogen and phosphorus. Both are natural fertilizers found in animal wastes, soil, and the atmosphere. These nutrients have always existed in the Bay, but not at the present elevated concentrations. When the Bay was surrounded primarily by forests and wetlands, very little nitrogen and phosphorus ran off the land into the water. Most of it was absorbed or held in place by the natural vegetation. As the use of the land has changed and the watershed's population has grown, the amount of nutrients entering the Bay has increased tremendously.

Now in its twelfth year, the Chesapeake Bay Program is a regional partnership of Federal, State, and local participants that has directed and coordinated restoration of the Bay since the signing of the historic 1983 Chesapeake Bay Agreement. Maryland, Pennsylvania, Virginia, the District of Columbia, the Chesapeake Bay Commission, EPA, and advisory groups form the partnership. The Chesapeake Executive Council provides leadership for the Bay Program and establishes program policies to restore and protect the Bay and its living resources. The Council consists of the governors of Maryland, Virginia, and Pennsylvania, the mayor of the District of Columbia, the administrator of EPA, and the chairperson of the Chesapeake Bay Commission.

Considered a national and international model for estuarine restoration and protection programs, the Chesapeake Bay Program is still a "work in progress." Since 1983, milestones in the evolution of the program include the 1987 Chesapeake Bay Agreement and the 1992 amendments to the Agreement. The 1987 Agreement set a goal to reduce the quantity of nutrients entering the Bay by 40% by the year 2000. In the 1992 amendments to the Agreement, the partners reaffirmed the 40% nutrient reduction goal, agreed to cap nutrient loadings beyond the year 2000, and agreed to attack nutrients at their source by applying the 40% reduction goal to the 10 major tributaries of the Bay. The amendments also stressed managing the Bay as a whole ecosystem. The amendments also spell out the importance of reducing atmospheric sources of nutrients and broadening regional interstate cooperation.

Protection and restoration of forests is a critical component of the Chesapeake Bay Program because scientific data clearly show that forests are the most beneficial land cover for maintaining clean water, especially forests alongside waterbodies in the riparian zone. Through the Chesapeake Bay Program, unique partnerships have been formed among the Bay region's forestry agencies, forest managers, and interested citizen groups. Since 1990, the U.S. Forest Service has assigned a Forestry Program Coordinator to the Chesapeake Bay Program to assist both the EPA and Bay Program committees in developing strategies and projects that will contribute to the Bay restoration goals. A Forestry Work Group, formed under the Nonpoint Source Subcommittee, raises and addresses issues related to forests and the practice of forestry in the watershed.

In addition, State foresters and local governments have developed and implemented numerous programs and projects aimed at the protection and restoration of forests.

VOL 12

5428

Forestry incentive programs in all of the Bay States have resulted in the planting of millions of trees, the restoration of nearly 50 miles of riparian forest, the development of stewardship plans, and forest enhancement projects on thousands of acres within the Bay watershed.

On the positive side, the extent of Bay grasses has increased by 75% since 1978. The current extent of SAV attains 64% of the goal established by the Chesapeake Bay Program. Striped bass, or rockfish, have made a remarkable recovery over the past decade due to improved reproduction and better control of the harvest. There has been a modest increase in the number of American shad returning to the Bay to spawn. Controls on the harvest of American shad, creation of fish passages at blockages, stocking programs, and habitat restoration are expected to yield increases in the American shad population and similar fish species that inhabit the Bay during part of their life cycle.

Phosphorus levels continue to decline and, after many years of increasing nitrogen concentrations, most of the Bay's tributaries are showing a leveling off of this trend. Some tributaries are showing declining trends in nitrogen concentrations. These trends indicate that both point and nonpoint source pollution abatement programs are working.

Despite the promising trends in nutrient concentrations, oxygen concentrations are still low enough to cause severe impacts or stressful conditions in the mainstem of the Bay and several larger tributaries. Prospects for the Bay's oyster populations remain poor. Overharvesting, habitat loss, and disease have severely depleted oyster stocks. New management efforts have been developed to improve this situation.

Chesapeake Bay Foundation, Richmond, VA

The blue crab is currently the most important commercial and recreational fishery in the Bay. There is growing concern about the health of the blue crab population due to increasing harvesting pressures and relatively low harvests in recent years. Both Maryland and Virginia have recently implemented new regulations on commercial and recreational crabbers to protect this important resource.

Overall, the Chesapeake Bay still shows symptoms of stress from an expanding population and changes in land use. However, conditions in the Chesapeake Bay have improved since the Chesapeake Bay Program was launched, and continuation of the Program promises an even brighter future for the Bay.

The Gulf of Mexico Program

The Gulf of Mexico Program (GMP) was established in 1988 with EPA as the lead Federal agency in response to signs of long-term environmental damage throughout the Gulf's coastal and marine ecosystem. The main purpose of the GMP is to develop and help implement a strategy to protect, restore, and maintain the health and productivity of the Gulf. The GMP is a grass roots program that serves as a catalyst to promote sharing of information, pooling of resources, and coordination of efforts to restore and reclaim wetlands and wildlife habitat, clean up existing pollution, and prevent future contamination and destruction of the Gulf. The GMP mobilizes State, Federal, and local government; business and industry; academia; and the community at large through public awareness and information dissemination programs, forum discussions, citizen committees, and technology applications.

A Policy Review Board and the Management Committee determine the scope and focus of GMP activities. The program also receives input from a Technical Advisory Committee and a Citizen's Advisory Committee. The GMP Office, eight technical issue committees, and the operations and support committees coordinate the collection, integration, and reporting of pertinent data and information. The issue committees are composed of individuals from Federal, State, and local agencies and from industry, science, education, business, citizen groups, and private organizations.

The issue committees are responsible for documenting environmental problems and management goals, available resources, and potential solutions for a broad range of issues, including habitat degradation, public health, freshwater inflow, marine debris, shoreline erosion, nutrient enrichment, toxic pollutants, and living aquatic resources. The issue committees publish their findings in Action Agendas.

On December 10, 1992, the Governors of Alabama, Florida, Louisiana, Mississippi, and Texas; EPA; the Chair of the Citizen's Advisory Committee; and representatives of 10 other Federal agencies signed the Gulf of Mexico Program Partnership for Action agreement for protecting, restoring, and enhancing the Gulf of Mexico and adjacent lands. The agreement committed the signatory agencies to pledge their efforts, over 5 years, to obtain the knowledge and resources to:

- Significantly reduce the rate of loss of coastal wetlands
- Achieve an increase in Gulf Coast seagrass beds
- Enhance the sustainability of Gulf commercial and recreational fisheries
- Protect human health and food supply by reducing input of nutrients, toxic substances, and pathogens to the Gulf
- Increase Gulf shellfish beds available for safe harvesting by 10%
- Ensure that all Gulf beaches are safe for swimming and recreational uses
- Reduce by at least 10% the amount of trash on beaches
- Improve and expand coastal habitats that support migratory birds, fish, and other living resources
- Expand public education/outreach tailored for each Gulf Coast county or parish
- Reduce critical coastal and shoreline erosion.

Beginning in 1992, the GMP also launched Take-Action Projects in each of the five Gulf States to demonstrate that program strategies and methods could achieve rapid results. The Take-Action Projects primarily address inadequate sewage treatment, pollution prevention, and habitat protection and restoration. Several projects aim to demonstrate the effectiveness of innovative sewage treatment technologies to control pathogenic contamination of shellfish harvesting areas. Other projects aim to restore wetlands, sea grass beds, and oyster reefs. The Take-Action Projects are designed to have Gulf-wide application.

Take-Action Projects in the five Gulf States primarily address sewage treatment, pollution prevention, and habitat protection and restoration.

Since 1992, EPA has streamlined and restructured its management scheme for the GMP to increase Regional involvement and better meet the needs of the 5-year environmental challenges. The GMP has also expanded efforts to integrate Mexico and the Caribbean Islands into management of the Gulf. These activities include technology transfer and development of international agreements that prohibit the discharge of ship-generated wastes and plastics into waters of the Gulf and Caribbean Sea.

Ground Water Protection Programs

The sage adage that "An ounce of prevention is worth a pound of cure" is being borne out in the field of ground water protection. Studies evaluating the cost of prevention versus the cost of cleaning up contaminated ground water have found that there are real cost advantages to promoting protection of our Nation's ground water resources.

Numerous laws, regulations, and programs play a vital role in protecting ground water. The following Federal laws and programs enable, or provide incentives for, EPA and/or States to regulate or voluntarily manage and monitor sources of ground water pollution:

- The Resource Conservation and Recovery Act (RCRA) addresses the problem of safe disposal of the huge volumes of solid and hazardous waste generated nationwide each year. RCRA is part of EPA's comprehensive program to protect ground water resources through the development of regulations and methods for handling, storing, and disposing of hazardous material and through the regulation of underground storage tanks—the most frequently cited source of ground water contamination.

- The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) regulates the restoration of contaminated ground water at abandoned hazardous waste sites.

- The Safe Drinking Water Act (SDWA) regulates subsurface injection of fluids that can contaminate ground water.

- The Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) controls the use and disposal of pesticides, some of which have been detected in ground water wells in rural communities.

- The Toxic Substances Control Act (TSCA) controls the use and disposal of additional toxic substances, thereby minimizing their entry into ground water. Other Federal laws establish State grants that may be used to protect ground water.

- Clean Water Act Sections 319(h) and (i) and 518 provide funds to State agencies to implement EPA-approved nonpoint source

Comprehensive State Ground Water Protection Programs

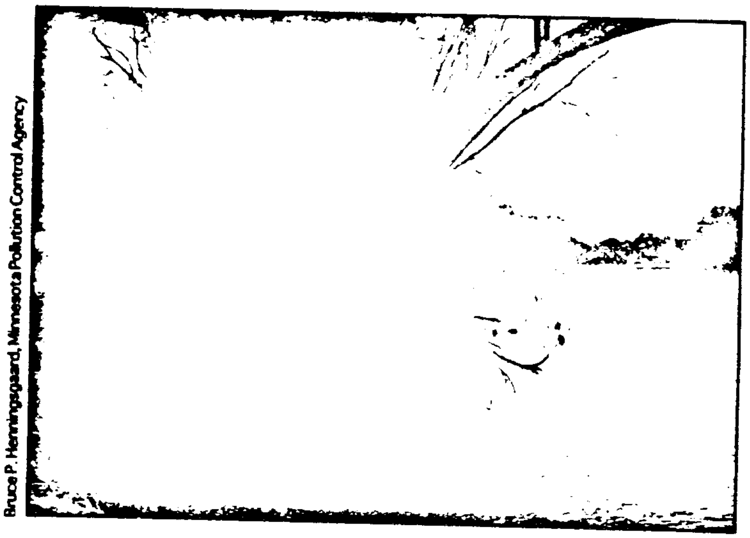
A Comprehensive State Ground Water Protection Program (CSGWPP) is composed of six "strategic activities." They are:

- Establishing a prevention-oriented goal
- Establishing priorities, based on the characterization of the resource and identification of sources of contamination
- Defining roles, responsibilities, resources, and coordinating mechanisms
- Implementing all necessary efforts to accomplish the State's ground water protection goal
- Coordinating information collection and management to measure progress and reevaluate priorities
- Improving public education and participation

management programs that include ground water protection activities. Several States have developed programs that focus on ground water contamination resulting from agriculture and septic tanks.

- The Pollution Prevention Act of 1990 allows grants for research projects to demonstrate agricultural practices that emphasize ground water protection and reduce the excessive use of fertilizers and pesticides.

Comprehensive State Ground Water Protection Programs (CSGWPPs) attempt to combine all of the above efforts and emphasize contamination prevention.



Bruce P. Henningsgaard, Minnesota Pollution Control Agency

Comprehensive State ground water protection programs support State-directed priorities in resource protection.

CSGWPPs improve coordination of Federal, State, Tribal, and local ground water programs and enable distribution of resources to established priorities.

Another means of protecting our Nation's ground water resources is through the implementation of Wellhead Protection Plans. EPA's Office of Ground Water and Drinking Water is supporting the development and implementation of Wellhead Protection Plans at the local level through many efforts. For example, EPA-funded support is provided through the National Rural Water Association Ground Water/Wellhead Protection programs. At the conclusion of the first 4 years of this program, over 2,000 communities in 26 States were actively involved in protecting their water supplies by implementing wellhead protection programs. These 2,000 communities represent almost 4 million people in the rural areas of the United States who will have better-protected water supplies.

Recognizing the importance and cost-effectiveness of protecting our Nation's ground water resources, States are participating in numerous activities to prevent future impairments of the resource. These activities include enacting legislation aimed at the development of comprehensive State ground water protection programs and promulgating protection regulations. More than 80% of the States indicate that they have current or pending legislation geared specifically to ground water protection. Generally, State legislation focuses on the need for program development, increased data collection, and public education programs. In addition, States also may mandate strict technical controls such as discharge permits, underground storage tank registrations, and protection standards.

All of these programs are intended to provide protection to a valuable, and often vulnerable, resource. Through the promotion of ground water protection on both State and Federal levels, our Nation's ground water resources will be safeguarded against contamination, thereby protecting human health and the environment.

What You Can Do

Federal and State programs have helped clean up many waters and slow the degradation of others. But government alone cannot solve the entire problem, and water quality concerns persist. Nonpoint source pollution, in particular, is everybody's problem, and everybody needs to solve it.

Examine your everyday activities and think about how you are contributing to the pollution problem. Here are some suggestions on how you can make a difference.

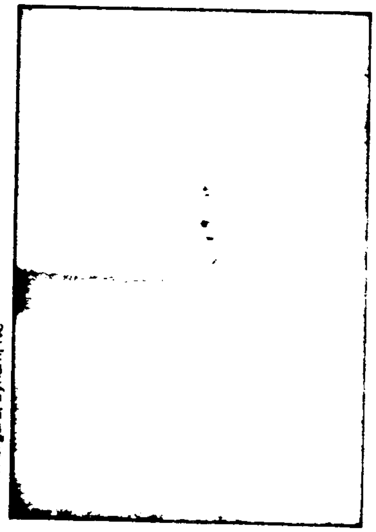
Be Informed

You should learn about water quality issues that affect the communities in which you live and work. Become familiar with your local water resources. Where does your drinking water come from? What activities in your area might affect the water you drink or the rivers, lakes, beaches, or wetlands you use for recreation?

Learn about procedures for disposing of harmful household wastes so they do not end up in sewage treatment plants that cannot handle them or in landfills not designed to receive hazardous materials.

Be Responsible

In your yard, determine whether additional nutrients are needed before you apply fertilizers, and look for alternatives where fertilizers might run off into surface waters. Consider selecting plants and grasses that have low maintenance requirements. Water your lawn conservatively. Preserve existing trees and plant new trees



John Theilgard, Bynum, NC

and shrubs to help prevent erosion and promote infiltration of water into the soil. Restore bare patches in your lawn to prevent erosion. If you own or manage land through which a stream flows, you may wish to consult your local county extension office about methods of restoring stream banks in your area by planting buffer strips of native vegetation.

Around your house, keep litter, pet waste, leaves, and grass clippings out of gutters and storm drains. Use the minimum amount of water needed when you wash your car. Never dispose of any household, automotive, or gardening wastes in a storm drain. Keep your septic tank in good working order.

Within your home, fix any dripping faucets or leaky pipes and install water-saving devices in shower heads and toilets. Always follow directions on labels for use and disposal of household chemicals. Take used motor oil, paints, and other hazardous household materials to proper disposal sites such as approved service stations or designated landfills.

Be Involved

As a citizen and a voter there is much you can do at the community level to help preserve and protect our Nation's water resources. Look around. Is soil erosion being controlled at construction sites? Is the community sewage plant being operated efficiently and correctly? Is the community trash dump in or along a stream? Is road deicing salt being stored properly?

Become involved in your community election processes. Listen and respond to candidates' views on water quality and environmental issues. Many communities have recycling programs; find out about them, learn how to recycle, and volunteer to help out if you can. One of the most important things you can do is find out how your community protects water quality, and speak out if you see problems.

Volunteer Monitoring: You Can Become Part of the Solution

In many areas of the country, citizens are becoming personally involved in monitoring the quality of our Nation's water. As a volunteer monitor, you might be involved in taking ongoing water quality measurements, tracking the progress of protection and restoration projects, or reporting special events, such as fish kills and storm damage.

VOL 12

5433

Volunteer monitoring can be of great benefit to State and local governments. Some States stretch their monitoring budgets by using data collected by volunteers, particularly in remote areas that otherwise might not be monitored at all. Because you are familiar with the water resources in your own neighborhood, you are also more likely to spot unusual occurrences such as fish kills.

The benefits to you of becoming a volunteer are also great. You will learn about your local water resources and have the opportunity to become personally involved in a nationwide campaign to protect a vital, and mutually shared, resource. If you would like to find out more about organizing or joining volunteer monitoring programs in your State, contact your State department of environmental quality, or write to:

Alice Mayio
Volunteer Monitoring
Coordinator

Fish Consumption Advisories

States issue fish consumption advisories to protect the public from ingesting harmful quantities of toxic pollutants in contaminated fish and shellfish. Fish may accumulate dangerous quantities of pollutants in their tissues by ingesting many smaller organisms, each contaminated with a small quantity of pollutant. This process is called bioaccumulation or biomagnification. Pollutants also enter fish and shellfish tissues through the gills or skin.

Fish consumption advisories recommend that the public limit the quantity and frequency of consumption of fish caught in specific waterbodies. The States tailor individual advisories to minimize health risks based on contaminant data collected in their fish tissue sampling programs. Advisories may completely ban fish consumption in severely polluted waters, or limit fish consumption to several meals per month or year in cases of less severe contamination. Advisories may target a subpopulation at risk (such as children, pregnant women, and nursing mothers), specific fish species, or larger fish that may have accumulated high concentrations of a pollutant over a longer lifetime than a smaller, younger fish.

The EPA fish consumption advisory database tracks advisories issued by each State. For 1994, the database listed 1,531 fish consumption advisories in effect in 49 States. Fish consumption advisories are unevenly distributed among the

Chesapeake Bay Foundation, Richmond, VA

States because the States use their own criteria to determine if fish tissue concentrations of toxics pose a health risk that justifies an advisory. States also vary the amount of fish tissue monitoring they conduct and the number of pollutants analyzed. States that conduct more monitoring and use strict criteria will issue more advisories than States that conduct less monitoring and use weaker criteria. For example, 62% of the advisories active in 1994 were issued by the States surrounding the Great Lakes, which support extensive fish sampling programs and follow strict criteria for issuing advisories.

Most of the fish consumption advisories (73%) are due to mercury. The other pollutants most commonly detected in elevated concentrations in fish tissue samples are polychlorinated biphenyls (PCBs), chlordane, dioxins, and DDT (with its byproducts).

Many coastal States report restrictions on shellfish harvesting in estuarine waters. Shellfish–particularly oysters, clams, and mussels–are filter-feeders that extract their food from water. Waterborne bacteria and viruses may also accumulate on their gills and mantles and in their digestive systems. Shellfish contaminated by these microorganisms are a serious human health concern, particularly if consumed raw.

States currently sample water from shellfish harvesting areas to measure indicator bacteria, such as total coliform and fecal coliform bacteria. These bacteria serve as indicators of the presence of potentially pathogenic microorganisms associated with untreated or undertreated sewage. States restrict shellfish harvesting to areas that maintain these bacteria at concentrations in sea water below established health limits.

In 1994, 15 States reported that shellfish harvesting restrictions were in effect for more than 6,052 square miles of estuarine and coastal waters during the 1992-1994 reporting period. Six States reported that urban runoff and storm sewers, municipal wastewater treatment facilities, nonpoint sources, marinas, industrial discharges, CSOs, and septic tanks restricted shellfish harvesting.

R0038745

Introduction

Purpose

The *National Water Quality Inventory Report to Congress* is the primary vehicle for informing Congress and the public about general water quality conditions in the United States. This document characterizes whether waters are meeting water quality standards, identifies widespread water quality problems of national significance, and describes various programs implemented to restore and protect our waters.

This document, the tenth in a series published since 1975, satisfies reporting requirements in Section 305(b) of the Clean Water Act (CWA), formally known as the Federal Water Pollution Control Act Amendments of 1972 (Public Law 92-500). Section 305(b) requires that States and other jurisdictions survey the health of their surface waters every 2 years and submit biennial reports describing their water quality conditions to the U.S. Environmental Protection Agency (EPA). Section 305(b) also requires that EPA summarize the reports submitted by the States, Tribes, and other jurisdictions and convey the information to Congress on a biennial schedule.

The *National Water Quality Inventory Report to Congress* is a compilation of information reported by States, Tribes, and other jurisdictions. As such, this report identifies water quality issues of concern to the States, Tribes, and other jurisdictions, not just the issues of concern to EPA. This report summarizes the water quality assessment information submitted by 61 States, American Indian Tribes, Territories, Interstate Water Commissions, and the District of Columbia in their 1994 Section 305(b) reports. Most of the survey information in the 1994 Section 305(b) reports is based on water quality information collected and evaluated during 1992 and 1993.

It is important to note that the States, Tribes, and other jurisdictions do not use identical survey methods and criteria to rate their water quality. They favor flexibility in the 305(b) process to accommodate natural variability in their waters, but there is a tradeoff between flexibility and consistency. Without consistent survey methods in place, EPA cannot compare data submitted by different States and jurisdictions or determine the quality and accuracy of their data. Also, EPA must use caution when comparing water quality information submitted during different 305(b) reporting periods because States and other jurisdictions may modify their criteria or survey different waterbodies from one reporting period to the next.

For more than 10 years, EPA has pursued a balance between flexibility and consistency in the Section 305(b) process that could generate data of known quality and accuracy. Recent joint actions by EPA, the States, Tribes, and other

Meghan Minshew, age 8, Bruner Elementary, North Las Vegas, NV

VOL 12

5438

R0038746

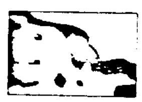
jurisdictions include implementing the recommendations of the National 305(b) Consistency Workgroup and the Intergovernmental Task Force for Monitoring Water Quality, revising EPA's *Guidelines for Preparation of the 305(b) Reports*, and beginning to implement monitoring recommendations in the *State Section 106 Grant Guidelines*. The 1996 305(b) Guidelines recommend moving toward a goal of comprehensively characterizing waters of every State every 5 years using a variety of monitoring techniques targeted to the condition of, and goals for, the water. These actions will improve consistency and accuracy in the Section 305(b) data, which will enable States and other jurisdictions to share data across political boundaries as they develop watershed protection strategies.

The Section 305(b) information, which focuses on attainment of water quality standards adopted by States, Tribes, and other jurisdictions, complements the water quality data contained in the *National Water Summary 1990-91 – Hydrologic Events and Stream Water Quality*, in which the U.S. Geological Survey (USGS) applied statistical analysis methods to a nationally consistent water database. Congress, EPA, and the public can use the summary information in this report and the *National Water Summary* to develop national goals and strategies for restoring and protecting our waters.

EPA recognizes that national initiatives alone cannot clean up our waters; water quality protection and restoration must happen at the local watershed level, in conjunction with State and Federal activities. Similarly, this document alone cannot provide the detailed information needed to manage water quality at all levels. This document should be used together with the individual Section 305(b) reports (see the inside back cover for information on obtaining Section 305(b) reports), watershed management plans, and other local documents to develop integrated water quality management options.

Background

Integrated water quality management begins with a basic understanding of how water moves through the environment, comes into contact with pollutants, and transports and deposits pollutants. The water cycle depicted in the highlight on page 15 illustrates the general links between the atmosphere, soil, surface waters, ground waters, and plants. Additional links between surface waters and ground waters are described below.



Rivers and Streams

Rivers and streams are characterized by flow. **Perennial** rivers and streams flow continuously, all year round. **Nonperennial** rivers and streams stop flowing for some period of time, usually due to dry conditions or upstream withdrawals. Many rivers and streams originate in nonperennial headwaters that flow only during snowmelt or heavy showers. Nonperennial streams provide critical habitats for nonfish species, such as amphibians and dragonflies, as well as safe havens for juvenile fish to escape from predation by larger fish. (See note on page 25 regarding the national estimate of total stream miles almost doubling from 1.8 million miles in 1990 to more than 3.5 million miles in 1994.)

The health of rivers and streams is directly linked to habitat integrity on shore and in adjacent wetlands. Stream quality will deteriorate if activities damage shoreline (i.e., riparian) and wetlands vegetation, which filter pollutants from runoff and bind soils. Removal of vegetation also eliminates shade that moderates stream temperature as well as the land temperature that can warm runoff entering surface waters. Stream temperature, in turn, affects the availability of dissolved oxygen in the water column for fish and other aquatic organisms.

Lakes, Reservoirs, and Ponds

Lakes, reservoirs, and ponds are depressions that hold water for extended periods of time. These waterbodies may receive water carrying pollutants from rivers and streams, melting snow, runoff, or ground water discharge areas. Lakes may also receive pollution directly from the air.

Pollutants become trapped in lakes, reservoirs, and ponds because water exits these waterbodies at a slow rate. Therefore, they are especially vulnerable to additional inputs of pollutants from human activities in lake watersheds. Even under natural conditions, sediment, nutrients, and organic materials accumulate in lakes and ponds as part of a natural aging process called eutrophication. Unnatural sources of nutrients (such as point source discharges and agricultural runoff) overload lake systems and accelerate eutrophication. Algae blooms, depressed oxygen concentrations, and aquatic weeds are symptoms of cultural eutrophication from unnatural sources of nutrients.

The Great Lakes

The Great Lakes—Superior, Michigan, Huron, Erie, and Ontario—are the largest system of fresh surface water on earth, by area. They contain approximately 18% of the world's fresh water supply. The Great Lakes basin is currently home to one-tenth of the population in the United States and one-quarter of the population of Canada.

Despite their large size, the Great Lakes are sensitive to the effects of a broad range of contaminants that enter the Lakes from polluted air, ground water, surface water, and overland runoff. Even dilute quantities of toxic chemicals can have adverse effects on water quality in the Great Lakes because many toxic chemicals persist in the environment and concentrate in organisms, including fish.

Overall, scientists estimate that atmospheric deposition contributes 35% to 50% of current annual inputs of a variety of chemicals entering the Great Lakes. In wet deposition, precipitation events (such as rain or snow) remove pollutants from the atmosphere. Dry deposition occurs when particles settle out of the air directly on a lake surface or within the extensive land basin draining into a lake. It is difficult to manage atmospheric sources of pollutants entering the Great Lakes because these pollutants

> Lakes are vulnerable to inputs of pollutants from human activities because water exits lakes at a very slow rate.

VOL 12

5440

may originate in the Great Lakes basin or hundreds of miles away.

For Lake Superior, the largest of the Great Lakes, available data indicate that volatilization (i.e., evaporation) and other processes remove far greater quantities of polychlorinated biphenyls (PCBs) than are introduced to it from atmospheric deposition and river inflow combined. Atmospheric deposition, nevertheless, is the largest source of new PCBs to the lake system and serves to significantly retard the PCB stripping process. Meanwhile, contributions from the reservoir of already contaminated sediments remains the overwhelming source of total PCBs to the water column and biota.

Estuaries

Rivers meet the oceans, Gulf of Mexico, and the Great Lakes in coastal waters called estuaries. Estuarine waters include bays and tidal rivers that serve as nursery areas for many commercial fish and most shellfish populations, including shrimp, oysters, crabs, and scallops. Most of our Nation's fish and shellfish industry relies on productive estuarine waters and their adjacent wetlands to provide healthy habitat for some stage of fish and shellfish development. Recreational anglers also enjoy harvesting fish that reproduce or feed in estuaries, such as striped bass and flounder.

Pollutants from both local and distant sources tend to accumulate in estuaries. Most pollutants that enter rivers migrate toward the coast. As rivers approach the coast, their mouths broaden and flow decreases. The low flow and fluctuating tides, typical of estuarine waters, reduce flushing and trap nutrients and pollutants in estuarine waters. This natural trapping process lays the foundation for rich estuarine ecosystems but also makes estuaries vulnerable to excessive loads of nutrients and pollutants.

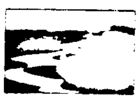
Historic development patterns have amplified natural trapping functions and overloaded estuaries on all our coasts. Historically, industrial development and population centers clustered around estuarine bays with access to shipping and an adjacent waterbody for waste disposal. Now, many coastal cities must address contaminated sediments and develop alternative disposal systems for their outdated combined sewer systems.

Wetlands

In general, wetlands are a transition zone between land and water where the soil is occasionally or permanently saturated with water. Wetlands are populated by plants that are specially adapted to grow in standing water or saturated soils. There are many different types of wetlands, including marshes, bogs, fens, swamps, mangroves, prairie potholes, and bottomland hardwood forests. Wetlands may not always appear to be wet. Many wetlands dry out for extended periods of time. Other wetlands may appear dry on the surface but be saturated beneath the surface.

Saltwater wetlands fringe estuaries; freshwater wetlands border rivers, lakes, and the Great Lakes or occur in isolation. In general, wetlands improve water quality, provide critical habitat for a wide variety of fish and wildlife, provide storage for flood waters, and stabilize shorelines. Wetlands filter sediment and nutrients (from both natural and unnatural sources) out of the water before they enter adjacent waterbodies and underlying ground water aquifers. Wetlands also provide storage for floodwaters and reduce the velocity of overland runoff. Reduced velocity translates into less damage from flood waters.

Wetlands can be physically destroyed by filling, draining, and dewatering, or wetlands can be damaged by the same pollutants that degrade other waterbodies, such as toxic chemicals and oxygen-demanding substances.



Ocean Shoreline Waters

Our ocean shoreline waters provide critical habitat for various life stages of commercial fish and shellfish (such as shrimp), provide habitat for endangered species (such as sea turtles), and support popular recreational activities, including sport fishing and swimming. Despite their vast size and volume, oceans are vulnerable to impacts from pollutants, especially in nearshore waters that receive inputs from adjoining waterbodies, ground water seeps, and land surfaces. Beach closures due to elevated bacterial concentrations are one of the most visible symptoms of water quality degradation in ocean shoreline waters resulting from activities onshore. Wastes disposed of offshore may also impact nearshore waters, as was demonstrated in the late 1980s when trash and medical wastes disposed of at sea washed ashore on the East Coast. Oil spills from tankers or offshore extraction facilities can also generate persistent adverse impacts on ocean shoreline waters.

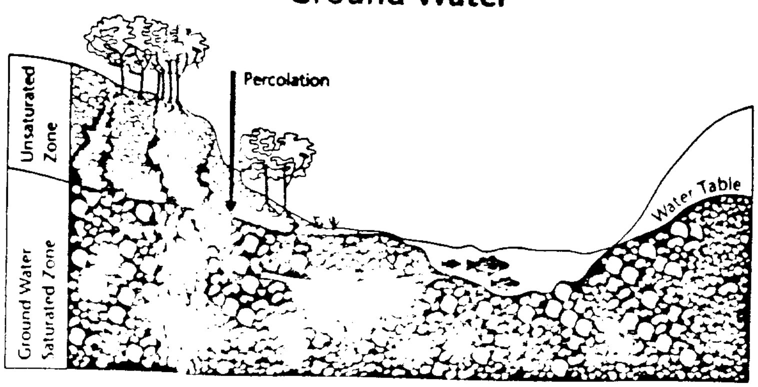
Ground Water

Beneath the land's surface, water resides in two general zones, the saturated zone and the unsaturated zone (Figure 1-1). The unsaturated zone lies directly beneath the land surface, where air and water fill in the pore spaces between soil and rock particles. Water saturates the pore spaces in the saturated zone beneath the unsaturated zone in most cases. The term "ground water" applies to water in the saturated zone. Surface water replenishes (or recharges) ground water by percolating through the unsaturated zone. Therefore, the unsaturated zone plays an important role in ground water hydrology and may act as a pathway for ground water contamination.

Ground water can move laterally and emerge at discharge sites, such as springs on hillsides or seeps

Figure 1-1

Ground Water



VOL 12

5442

The Clean Water Act of 1972

. . . it is the national goal that, wherever attainable, an interim goal of water quality which provides for the protection and propagation of fish, shellfish, and wildlife and provides for recreation in and on the water, be achieved by July 1, 1983 . . .

Water quality standards consist of:

- *Designated beneficial uses*
- *Numeric criteria for biological, chemical, and physical parameters*
- *Narrative criteria for biological, chemical, and physical parameters*
- *Antidegradation policy*

in the bottoms of streams, lakes, wetlands, and oceans. Therefore, ground water affects surface water quantity and quality because polluted ground water can contaminate surface waters. Conversely, some surface waters, such as wetlands, contain flood waters and replenish ground waters. Loss of wetlands reduces ground water recharge.

The Clean Water Act

The Clean Water Act still guides Federal, State, and some Tribal water pollution control programs more than 20 years after it was enacted by Congress. In 1972, the CWA launched a national objective to "restore and maintain the chemical, physical, and biological integrity of the Nation's waters." The Act set two goals to achieve this objective:

- Eliminate the discharge of pollutants into navigable waters by 1985

- Achieve an interim water quality level that protects and propagates fish, shellfish, and wildlife and supports recreation in and on the water, where attainable.

As it became evident that the Nation could not eliminate pollutant discharges by 1985, Congress amended the CWA to stress achieving the interim water quality levels, which came to be known as "the fishable and swimmable goals of the Act."

The EPA measures national progress in achieving the CWA interim water quality levels by summarizing attainment of State and Tribal water quality standards. Water quality standards consist of designated beneficial uses, numeric and narrative criteria sufficient to protect each use, and an antidegradation statement:

- **Designated beneficial uses** are the desirable uses that water quality should support. Examples are drinking water supply, primary contact recreation (such as swimming), and aquatic life support. Each designated use has a unique set of water quality requirements or criteria that must be met for the use to be realized. States, Tribes, and other jurisdictions may designate an individual waterbody for multiple beneficial uses.

- **Numeric water quality criteria** establish the minimum physical, chemical, and biological parameters required to support a beneficial use. Physical and chemical numeric criteria may set maximum concentrations of pollutants, acceptable ranges of physical parameters such as flow, and minimum concentrations of desirable parameters, such as dissolved oxygen. Numeric biological criteria describe the expected attainable community attributes and establish values based on measures such as species richness, presence or absence of indicator taxa, and distribution of classes of organisms.

- **Narrative water quality criteria** define, rather than quantify, conditions and attainable goals that must be maintained to support a designated use. Narrative biological criteria establish a positive statement about aquatic community characteristics expected to occur within a waterbody. For example, "Aquatic life shall be as it naturally occurs," or "Ambient water quality shall be sufficient to support life stages of all

VOL 12

5443

indigenous aquatic species." Narrative criteria may also describe conditions that are desired in a waterbody, such as, "Waters must be free of substances that are toxic to humans, aquatic life, and wildlife."

- Antidegradation statements, where possible, protect existing uses and prevent waterbodies from deteriorating even if their water quality is better than the fishable and swimmable goals of the Act.

The CWA allows States, Tribes, and other jurisdictions to set their own standards but requires that all beneficial uses and their criteria comply with the goals of the Act. At a minimum, beneficial uses must provide for "the protection and propagation of fish, shellfish, and wildlife" and provide for "recreation in and on the water" (i.e., the fishable and swimmable goals of the Act), where attainable. The Act prohibits States and other jurisdictions from designating waste transport or waste assimilation as a beneficial use, as some States did prior to 1972.

Survey Methodology

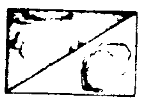
Section 305(b) of the CWA requires that the States biennially survey their water quality for attainment of the fishable and swimmable goals of the Act and report the results to EPA. The States, participating Tribes, and other jurisdictions measure attainment of the CWA goals by determining how well their waters support their designated beneficial uses. EPA encourages States, Tribes, and other jurisdictions to survey waterbodies for support of the following individual beneficial uses:

Aquatic Life Support

The waterbody provides suitable habitat for protection and propagation of desirable fish, shellfish, and other aquatic organisms.

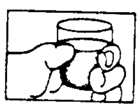
Fish Consumption

The waterbody supports fish free from contamination that could pose a human health risk to consumers.



Shellfish Harvesting

The waterbody supports a population of shellfish free from toxicants and pathogens that could pose a human health risk to consumers.



Drinking Water Supply

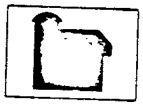
The waterbody can supply safe drinking water with conventional treatment.

Primary Contact Recreation - Swimming

People can swim in the waterbody without risk of adverse human health effects (such as catching waterborne diseases from raw sewage contamination).

Secondary Contact Recreation

People can perform activities on the water (such as boating) without risk of adverse human health effects from ingestion or contact with the water.



Agriculture

The water quality is suitable for irrigating fields or watering livestock.

States, Tribes, and other jurisdictions may also define their own individual uses to address special concerns. For example, many Tribes and States designate their waters for the following beneficial uses:

Ground Water Recharge

The surface waterbody plays a significant role in replenishing ground water, and surface water supply and quality are adequate to protect existing or potential uses of ground water.

Wildlife Habitat

Water quality supports the waterbody's role in providing habitat and resources for land-based wildlife as well as aquatic life.

Tribes may designate their waters for special cultural and ceremonial uses:

Culture

Water quality supports the waterbody's role in Tribal culture and preserves the waterbody's religious, ceremonial, or subsistence significance.

The States, Tribes, and other jurisdictions assign one of five levels of use support categories to each of their waterbodies (Table 1-1).

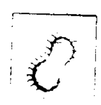
If possible, the States, Tribes, and other jurisdictions determine the level of use support by comparing monitoring data with numeric criteria for each use designated for a particular waterbody. If monitoring data are not available, the State, Tribe, or other jurisdiction may determine the level of use support with qualitative information. Valid qualitative information includes land use data, fish and game surveys, and predictive model results. **Monitored assessments** are based on recent monitoring data collected during the past 5 years. **Evaluated assessments** are based on qualitative information or monitored information more than 5 years old.

Overall Use Support

For waterbodies with more than one designated use, the States, Tribes, and other jurisdictions consolidate the individual use support information into a single overall use support determination:

Good/Fully Supporting Overall Use – All designated beneficial uses are fully supported.

Good/Threatened Overall Use – One or more designated beneficial uses are threatened and the remaining uses are fully supported.



Fair/Partially Supporting Overall Use – One or more designated beneficial uses are partially supported and the remaining uses are fully supported or threatened. These waters are considered impaired.

Poor/Not Supporting Overall Use – One or more designated beneficial uses are not supported. These waters are considered impaired.

Poor/Not Attainable – The State, Tribe, or other jurisdiction has performed a use-attainability analysis and demonstrated that use support of one or more designated beneficial uses is not attainable due to one of six biological, chemical, physical, or economic/social conditions specified in the *Code of Federal Regulations* (40 CFR Section 131.10). These conditions include naturally high concentrations of pollutants (such as metals); other natural physical features that create unsuitable aquatic life habitat (such as inadequate substrate, riffles, or pools); low flows or water levels; dams and other hydrologic modifications that permanently alter waterbody characteristics; poor water quality resulting from human activities that cannot be reversed without causing further environmental degradation; and poor water quality that cannot be improved without imposing more stringent controls than those required in the CWA that would result in widespread economic and social impacts.

- **Impaired Waters** – The sum of waterbodies partially supporting uses and not supporting uses.

Total Surveyed Waters

Most States do not assess all of their waterbodies during the 2-year reporting cycle required under CWA Section 305(b). Thus, the surveyed waters reported in Figure 1-2 are a subset of the Nation's total waters. In addition, the summary information based on surveyed waters may not represent general conditions in the Nation's total waters because States, Tribes, and other jurisdictions often focus on surveying major perennial rivers, estuaries, and public lakes with suspected pollution

Table [illegible] Levels of Use Support

Symbol	Use Support Level	Water Quality Condition	Definition
	Fully Supporting	Good	Water quality meets designated use criteria.
	Threatened	Good	Water quality supports beneficial uses now but may not in the future unless action is taken.
	Partially Supporting	Fair (Impaired)	Water quality fails to meet designated use criteria at times.
	Not Supporting	Poor (Impaired)	Water quality frequently fails to meet designated use criteria.
	Not Attainable	Poor	The State, Tribe, or other jurisdiction has performed a use-attainability analysis and demonstrated that use support is not attainable due to one of six biological, chemical, physical, or economic/social conditions specified in the *Code of Federal Regulations*

VOL 12

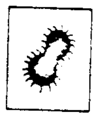
5446

problems in order to direct scarce resources to areas that could pose the greatest risk. Many States, Tribes, and other jurisdictions lack the resources to collect use support information for nonperennial streams, small tributaries, and private ponds. This report does not predict the health of these unassessed waters, which include an unknown ratio of pristine waters to polluted waters.

SAMPLE

Little River

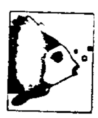
Little River is designated for aquatic life use and primary contact recreation. The State examines dissolved oxygen data and notes that 15% of the samples contain dissolved oxygen concentrations below the aquatic life use criterion of 5 parts per million (ppm). Bacterial indicators do not exceed the contact recreation criterion. Therefore, the waterbody partially supports aquatic life use and fully supports contact recreation use. The waterbody partially supports overall uses based on monitored data.



SAMPLE

Turkey Lake

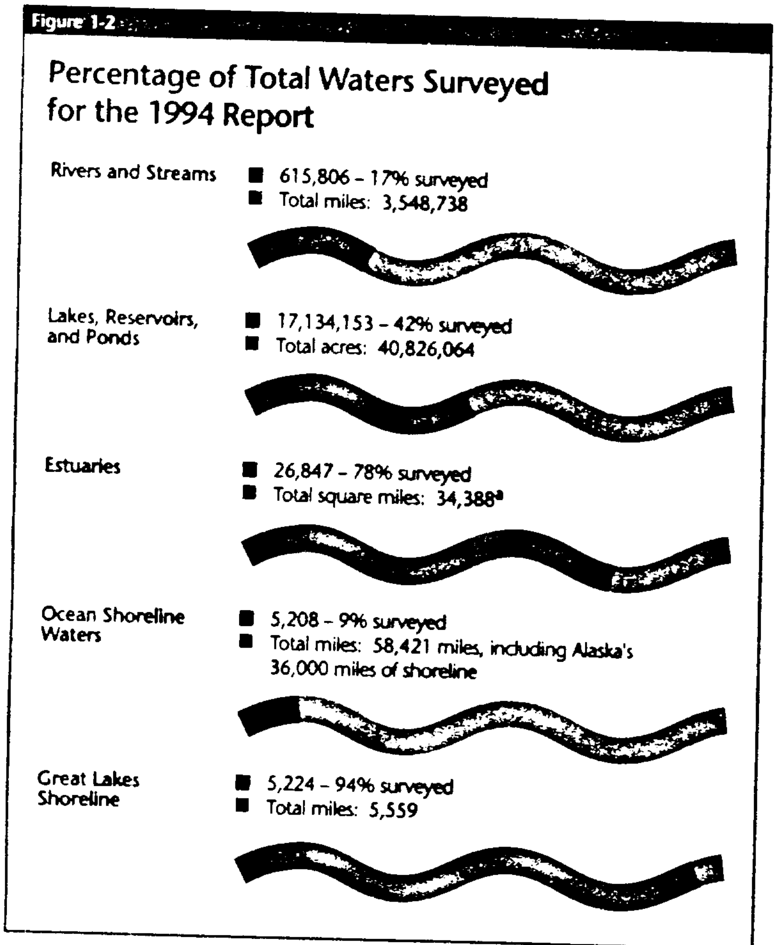
Turkey Lake is also designated for aquatic life use and primary contact recreation. However, the State has never sampled chemical and physical parameters, such as dissolved oxygen, in the lake. The State did perform a biological survey of the lake and noted the presence of desirable fish species and insect larvae. The survey also revealed a probable source of sewage contamination upstream. The lake appears to fully support aquatic life use but may only partially support contact recreation use due to sewage contamination. The waterbody partially supports overall uses based on evaluated information (the suspected source of sewage contamination).



Pollutants That Degrade Water Quality and Sources of Impairment

Where possible, States, Tribes, and other jurisdictions identify the pollutants causing water quality impairments and the sources of pollutants degrading their waterbodies. **Causes of impairment** are pollutants or processes that violate numeric or narrative use support criteria. Causes of impairment include chemical contaminants (such as PCBs, dioxins, and metals), physical parameters (such as temperature), and biological parameters (such as aquatic weeds) (see Highlight on page 16).

Sources of impairment generate the pollutants that violate use support criteria (Table 1-2). Point sources discharge pollutants directly into surface waters from a conveyance. Point sources include industrial facilities, municipal sewage treatment plants, and combined sewer overflows. Nonpoint sources deliver pollutants to surface waters from diffuse origins. Nonpoint sources include urban runoff, agricultural runoff, and atmospheric deposition of contaminants in air pollution. Habitat alterations, such as hydromodification, dredging, and streambank destabilization, can also degrade water quality.



Source: 1994 Section 305(b) reports submitted by the States, Tribes, Territories, and Commissions.

[a]Excluding estuarine waters in Alaska because no estimate was available.

Throughout this document, EPA rates the significance of causes and sources of pollution by the percentage of surveyed waters impaired by each individual cause or source (obtained from the Section 305(b) reports submitted by the States, Tribes, and other jurisdictions). Note that the cause and source rankings do not describe the condition of all waters in the United States because the States identify the causes and sources degrading some of their impaired waters, which are a small subset of surveyed waters, which, in turn, are a subset of the Nation's total waters. For example, the States identified sources degrading some of the 224,236 impaired river miles, which represent 36% of the surveyed river miles and only 6% of the Nation's total stream miles.

Table 1-2. Pollution Source Categories Used in This Report

Category	Examples
Industrial	Pulp and paper mills, chemical manufacturers, steel plants, metal process and product manufacturers, textile manufacturers, food processing plants
Municipal	Publicly owned sewage treatment plants that may receive indirect discharges from industrial facilities or businesses
Combined Sewers	Single facilities that treat both stormwater and sanitary sewage, which may become overloaded during storm events and discharge untreated wastes into surface waters.
Storm Sewers/ Urban Runoff	Runoff from impervious surfaces including streets, parking lots, buildings, lawns, and other paved areas
Agricultural	Crop production, pastures, rangeland, feedlots, other animal holding areas
Silvicultural	Forest management, tree harvesting, logging road construction
Construction	Land development, road construction
Resource Extraction	Mining, petroleum drilling, runoff from mine tailing sites
Land Disposal	Leachate or discharge from septic tanks, landfills, and hazardous waste sites
Hydrologic Modification	Channelization, dredging, dam construction, streambank modification

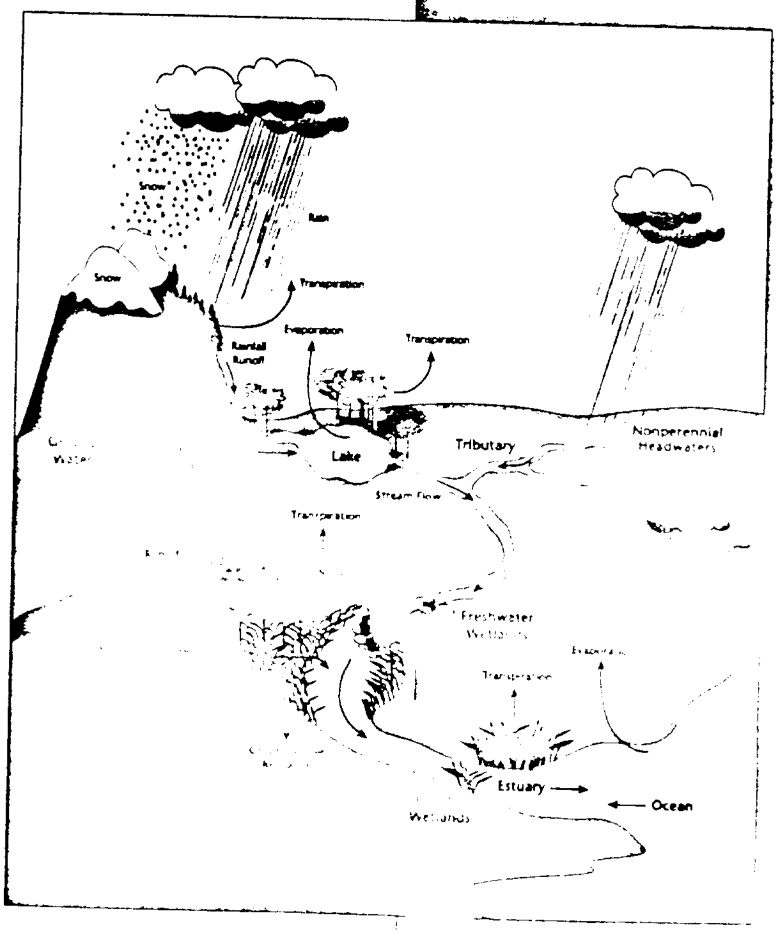
HIGHLIGHT HI HIGHLIGHT

The Water Cycle

The water cycle describes how water moves through the environment and identifies the links between ground water, surface water, and the atmosphere (see figure). For convenience, discussions of the water cycle usually begin and end in the atmosphere. Water in the atmosphere condenses and falls onto the earth in the form of rain or snow. The rain or snow can contain contaminants from air pollution. The rain and snow may fall directly onto surface waters, be intercepted by plants or structures, or fall onto the ground. Intercepted water evaporates directly back into the atmosphere or drips onto the ground.

On the ground, rainfall and melting snow percolate deeper into the ground, saturating the soil and recharging ground water aquifers. Trees and other plants take up water in the upper soil zone through their roots and return the water to the atmosphere in a process called transpiration. Ground water below the root zone may migrate many miles and emerge (or discharge) into a distant surface water.

When rainfall or melting snow saturates soils, water runs off the ground into surface waterbodies (such as lakes, streams, wetlands, and coastal waters). Runoff may dislodge soil particles and pollutants and carry them into surface waterbodies. Surface waters may evaporate back into the atmosphere, percolate into the underlying ground water, or flow into other surface waters until reaching the ocean. From the ocean, water evaporates back into the atmosphere, completing the cycle.



HIGHLIGHT HIGHLIGHT HIGHLIGHT

Pollutants and Processes That Damage Water Quality

This highlight describes individual pollutants and processes separately. In reality, water quality usually suffers from the combined effects of several pollutants and processes. EPA encourages water quality managers and the public to use a holistic approach to managing our integrated water quality problems.

Low Dissolved Oxygen

Dissolved oxygen is a basic requirement for a healthy aquatic ecosystem. Most fish and beneficial aquatic insects "breathe" oxygen dissolved in the water column. Some fish and aquatic organisms (such as carp and sludge worms) are adapted to low oxygen conditions, but most desirable fish species (such as trout and salmon) suffer if dissolved oxygen concentrations fall below 3 to 4 mg/L (3 to 4 milligrams of oxygen dissolved in 1 liter of water, or 3 to 4 parts of oxygen per million parts of water). Larvae and juvenile fish are more sensitive and require even higher concentrations of dissolved oxygen, ranging from 5 to 8 mg/L.

Many fish and other aquatic organisms can recover from short periods of low dissolved oxygen availability. However, prolonged episodes of depressed dissolved oxygen concentrations of 2 mg/L or less can result in "dead" waterbodies. Prolonged exposure to low dissolved oxygen conditions can suffocate adult fish or reduce their reproductive survival by suffocating sensitive eggs and larvae or can starve fish by killing aquatic insect larvae and other prey. Low dissolved oxygen concentrations also favor anaerobic bacterial activity that produces noxious gases or foul odors often associated with polluted waterbodies.

Oxygen concentrations in the water column fluctuate under natural conditions, but severe oxygen depletion usually results from human activities that introduce large quantities of biodegradable organic materials into surface waters. Biodegradable organic materials contain plant, fish, or animal matter. Leaves, lawn clippings, sewage, manure, shellfish processing waste, milk solids, and other food processing wastes are examples of biodegradable organic materials that enter our surface waters.

In both pristine and polluted waters, beneficial bacteria use oxygen to break apart (or decompose) organic materials. Pollution-containing organic wastes provide a continuous glut of food for the bacteria, which accelerates bacterial activity and population growth. In polluted waters, bacterial consumption of oxygen can rapidly outpace oxygen

VOL 12

5451

R0038759

replenishment from the atmosphere and photosynthesis performed by algae and aquatic plants. The result is a net decline in oxygen concentrations in the water.

Often, water quality managers measure the biological oxygen demand (or BOD) of pollution or natural organic materials in water. BOD is a measure of how much oxygen is consumed by bacteria while they decompose different mixtures of organic materials. Toxic pollutants can indirectly elevate BOD by killing algae, aquatic weeds, or fish, which provides an abundance of food for oxygen-consuming bacteria. Oxygen depletion can also result from chemical reactions that do not involve bacteria. Some pollutants trigger chemical reactions that place a chemical oxygen demand (or COD) on receiving waters.

Other factors, such as temperature and salinity, influence the amount of oxygen dissolved in water. Prolonged hot weather will depress oxygen concentrations and may cause fish kills even in clean waters because warm water cannot hold as much oxygen as cold water. Warm conditions further aggravate oxygen depletion by stimulating bacterial activity and respiration in fish, which consumes oxygen. Removal of streamside vegetation eliminates shade, thereby raising water temperatures, and accelerates runoff of organic debris. Under such conditions, minor additions of pollution-containing organic materials can severely deplete oxygen.

Nutrients

Nutrients are essential building blocks for healthy aquatic communities, but excess nutrients (especially nitrogen and phosphorus compounds) overstimulate the growth of aquatic weeds and algae. Excessive growth of these organisms, in turn, can clog navigable waters, interfere with swimming and boating, outcompete native submerged aquatic vegetation (SAV), and lead to oxygen depletion. Oxygen concentrations can fluctuate daily during algae blooms, rising during the day as algae perform photosynthesis, and falling at night as algae continue to respire, which consumes oxygen. Beneficial bacteria also consume oxygen as they decompose the abundant organic food supply in dying algae cells.

Lawn and crop fertilizers, sewage, manure, and detergents contain nitrogen and phosphorus, the nutrients most often responsible for water quality degradation. Rural areas are vulnerable to ground water contamination from nitrates (a compound containing nitrogen) found in fertilizer and manure.

VOL 12

5452

HIGHLIGHT HIGHLIGHT HIGHLIGHT

Very high concentrations of nitrate (>10 mg/L) in drinking water cause methemoglobinemia, or blue baby syndrome, an inability to fix oxygen in the blood.

Nutrients are difficult to control because lake and estuarine ecosystems recycle nutrients. Rather than leaving the ecosystem, the nutrients cycle among the water column, algae and plant tissues, and the bottom sediments. For example, algae may temporarily remove all the nitrogen from the water column, but the nutrients will return to the water column when the algae die and are decomposed by bacteria. Therefore, gradual inputs of nutrients tend to accumulate over time rather than leave the system.

Sediment and Siltation

In a water quality context, sediment usually refers to soil particles that enter the water column from eroding land. Sediment consists of particles of all sizes, including fine clay particles, silt, sand, and gravel. Water quality managers use the term "siltation" to describe the suspension and deposition of small sediment particles in waterbodies.

Sediment and siltation can severely alter aquatic communities. Sediment may clog and abrade fish gills, suffocate eggs and aquatic insect larvae on the bottom, and fill in the pore space between bottom cobbles where fish lay eggs. Silt and sediment interfere with recreational activities and aesthetic enjoyment at waterbodies by reducing water clarity and filling in waterbodies.

Sediment may also carry other pollutants into waterbodies. Nutrients and toxic chemicals may attach to sediment particles on land and ride the particles into surface waters where the pollutants may settle with the sediment or detach and become soluble in the water column.

Rain washes silt and other soil particles off of plowed fields, construction sites, logging sites, urban areas, and strip-mined lands into waterbodies. Eroding streambanks also deposit silt and sediment in waterbodies. Removal of vegetation on shore can accelerate streambank erosion.

Bacteria and Pathogens

Some waterborne bacteria, viruses, and protozoa cause human illnesses that range from typhoid and dysentery to minor respiratory and skin diseases. These organisms may enter waters through a number of routes, including inadequately treated sewage, storm water drains, septic systems, runoff from livestock pens, and sewage dumped overboard from recreational boats. Because it is impossible to test waters for every possible disease-causing organism, States and other jurisdictions usually measure indicator bacteria that are found in great numbers in the stomachs and intestines of warm-blooded animals and people. The presence of indicator bacteria suggests that the waterbody may be contaminated with untreated sewage and that other, more dangerous, organisms may be present. The States, Tribes, and

VOL 12

5453

HIGHLIGHT HIGHLIGHT HIGHLIGHT

other jurisdictions use bacterial criteria to determine if waters are safe for recreation and shellfish harvesting.

Toxic Organic Chemicals and Metals

Toxic organic chemicals are synthetic compounds that contain carbon, such as PCBs, dioxins, and DDT. These synthesized compounds often persist and accumulate in the environment because they do not readily break down in natural ecosystems. Many of these compounds cause cancer in people and birth defects in other predators near the top of the food chain, such as birds and fish.

Metals occur naturally in the environment, but human activities (such as industrial processes and mining) have altered the distribution of metals in the environment. In most reported cases of metals contamination, high concentrations of metals appear in fish tissues rather than the water column because the metals accumulate in greater concentrations in predators near the top of the food chain.

pH

Acidity, the concentration of hydrogen ions, drives many chemical reactions in living organisms. The standard measure of acidity is pH, and a pH value of 7 represents a neutral condition. A low pH value (less than 5) indicates acidic conditions; a high pH (greater than 9) indicates alkaline conditions. Many biological processes, such as reproduction, cannot function in acidic or alkaline waters. Acidic conditions also aggravate toxic contamination problems because sediments release toxicants in acidic waters. Common sources of acidity include mine drainage, runoff from mine tailings, and atmospheric deposition.

Habitat Modification/ Hydrologic Modification

Habitat modifications include activities in the landscape, on shore, and in waterbodies that alter the physical structure of aquatic ecosystems and have adverse impacts on aquatic life. Examples of habitat modifications include:

- Removal of streamside vegetation that stabilizes the shoreline and provides shade, which moderates instream temperatures
- Excavation of cobbles from a stream bed that provide nesting habitat for fish
- Burying streams
- Excessive development sprawl that alters the natural drainage patterns by increasing the intensity, magnitude, and energy of runoff waters.

Hydrologic modifications alter the flow of water. Examples of hydrologic modifications include channelization, dewatering, damming, and dredging.

VOL 12

5454

HIGHLIGHT HIGHLIGHT HIGHLIGHT

Tribal Water Quality

Tribal lands span the United States and are diverse in climate, habitat, and water usage. Water quality is one of the top environmental priorities for the majority of Tribes throughout the United States. Over the past 7 years, approximately 100 Tribes have developed or have begun developing water quality programs, including water quality criteria and standards, through grants from Section 106 of the Clean Water Act. This number represents close to 40% of all Tribes in the contiguous United States that are eligible for Section 106 grants, a number that reflects the importance of this effort by Tribes. Tribes are also establishing water quality programs with General Assistance Program (GAP) grants, which can be used to develop general multimedia environmental programs on reservations.

Phil Johnson, EPA Region 8

As Tribes expand their interest in administering water quality programs on Tribal lands, their technical capabilities and desire to monitor those waters over which they have jurisdiction also grows. Some Tribes have special concerns about water quality because they acquire a large portion of their food or income from water resources and/or water plays a significant role in their traditional ceremonies and cultural heritage.

Tribes are interested in developing water quality management options and assessments in all of the areas described in this report. Some Tribes are conducting water quality monitoring programs for surface and ground waters and assembling databases of biological, chemical, physical, and bacteriological analyses. Others are working toward adopting standards involving biological criteria and ecosystem preservation. Still others are developing nonpoint source assessment and management programs and establishing their own laboratory capability for monitoring waters and

HIGHLIGHT HIGHLIGHT HIGHLIGHT

training staff to perform monitoring. Joint Tribal consortia, intertribal councils, and other collaborative efforts have been established to examine entire watersheds. All of these efforts reiterate the common goal shared by communities throughout the country to acquire the data needed to preserve and restore water quality for generations to come. Tribes will continue to make water quality a priority as they develop and expand their capacity to contribute information to the *National Water Quality Inventory Report to Congress.*

EPA's Office of Wetlands, Oceans, and Watersheds (OWOW), in conjunction with the Section 305(b) Consistency Workgroup (which includes 3 Tribal members and 25 State members), developed flexible guidance to assist Tribes in reporting water quality information for inclusion in the 1996 *National Water Quality Inventory Report to Congress.* This guidance describes a level of reporting that may be appropriate for most Tribes' first 305(b) reports.

In 1995, OWOW also produced a booklet, *Knowing Our Waters: Tribal Reporting Under Section 305(b),* to encourage all Tribes to monitor, assess, and report on their water quality. The goal of Tribal reporting is to document the status of water quality and identify water quality improvements needed on Tribal lands. The 305(b) report is a good vehicle for recommending actions to EPA to protect Tribal waterbodies and achieve the objectives of the Clean Water Act. EPA encourages Tribes to use the 305(b) process as a mechanism for sharing their ideas, concerns, and information with State and Federal water quality managers.

Water Quality Assessments

Barry Burgan, U.S. EPA

Rivers and Streams

Forty-eight States, three Interstate River Commissions, one Territory, and the District of Columbia (hereafter collectively referred to as States), and six American Indian Tribes rated river water quality in their 1994 Section 305(b) reports (see Appendix A, Table A-1, for individual State and Tribal information). These States and Tribes surveyed conditions in 615,806 miles of rivers and streams; most of the surveyed rivers and streams are perennial waterbodies that flow all year. The surveyed rivers and streams represent 48% of the 1.3 million miles of perennial rivers and streams in the lower 48 States, or 17% of the estimated 3.5 million miles of all rivers and streams in the country, including nonperennial streams that flow only during wet periods (Figure 2-1).

Altogether, the States and Tribes surveyed 27,075 fewer river miles in 1994 than in 1992. Individually, most States reported that they surveyed more river miles in 1994, but their increases were offset by a decline of 85,000 surveyed river miles reported by Montana, Mississippi, and Maryland. For 1994, these States reported use support status for only those river miles that they surveyed in direct monitoring

Note: In comparison to 1990, it appears that the States and Tribes assessed a smaller percentage of the Nation's rivers in 1994. However, in 1994, most States and Tribes included intermittent streams, canals, and ditches that were excluded from the 1990 estimates of total stream miles. As a result, the national estimate of total stream miles almost doubled from 1.8 million miles in 1990 to more than 3.5 million miles in 1994.

programs or evaluations rather than using inferences for unsurveyed waters. Previously, Montana and Maryland assumed that rivers of unknown quality were surveyed and in good condition. Mississippi assumed that conditions in evaluated rivers represented conditions in upstream tributaries.

The changes made by Montana, Mississippi, and Maryland are examples of the numerous modifications the States made to their water quality survey methods between 1992 and 1994 as a result of the many Federal and State partnership efforts to improve monitoring in the Nation. Due to these changes, the summary data presented herein should not be compared with summary data presented in the 1992 Report to Congress.

The summary information presented in this chapter applies strictly to the portion of the Nation's rivers surveyed by the States and Tribes. EPA cannot make generalizations about the health of all of our Nation's rivers based on data extracted from the 305(b) reports because most States and Tribes rate their waters with information obtained from water monitoring programs designed to detect degraded waterbodies. Very few States or Tribes select water sampling sites with a statistical design to represent a cross section of water quality conditions in their jurisdiction. Instead, many States and Tribes direct their limited monitoring resources toward waters with suspected problems. As a result, the surveyed rivers reflect conditions of targeted waters rather than a representative sampling of all waters.

In the future, increased use of statistically based programs will enable EPA and the States and Tribes to report more comprehensively on the general health of the Nation's waters. Examples of statistically based programs include probability designs implemented by Delaware and Maryland, EPA's Environmental Monitoring and Assessment Program (EMAP), and EPA's Regional Environmental Monitoring and Assessment Program (R-EMAP). EMAP is a long-term monitoring program with a unique approach that combines a probability-based sampling strategy with ecological indicators (quantifiable expressions of an environmental value) to assess the overall condition of ecological resources. R-EMAP applies the concepts, methods, and approach developed by EMAP to resolve specific environmental issues of importance to the EPA Regions and the States.

National data from other Federal agencies, such as the U.S. Geological Survey (USGS) and the National Oceanic and Atmospheric Administration (NOAA), and private organizations, such as the Nature Conservancy, will also clarify national water quality trends. (See Chapter 13 for additional information about monitoring and assessment programs.)

Overall Water Quality

The States and Tribes rate whether their water quality is good enough to fully support a healthy community of aquatic organisms and human activities, such as swimming, fishing, and drinking. The States designate individual rivers for specific activities, termed "individual designated uses." EPA and the

VOL 12

5460

States use the following terminology to rate their water quality:

■ **Good/Fully Supporting**: Good water quality supports a diverse community of fish, plants, and aquatic insects, as well as the array of human activities assigned to a river by the State.

■ **Good/Threatened**: Good water quality currently supports aquatic life and human activities in and on the river, but changes in factors such as land use threaten water quality, or data indicate a trend of increasing pollution in the river.

■ **Fair/Partially Supporting**: Fair water quality supports aquatic communities with fewer species of fish, plants, and aquatic insects, and/or occasional pollution interferes with human activities. For example, runoff during severe thunderstorms may temporarily elevate fecal coliform bacteria densities and indicate that swimming is not safe immediately following storms.

■ **Poor/Not Supporting**: Poor water quality does not support a healthy aquatic community and/or prevents some human activities on the river. For example, persistent PCB contamination in river sediments (originating from discontinued industrial discharges) may contaminate fish and make the fish inedible for years.

■ **Poor/Not Attainable**: The State has performed a use-attainability analysis and demonstrated that use support of one or more designated beneficial uses is not attainable due to one of six specific biological, chemical, physical, or economic/social conditions (see Chapter 1 for additional information).

Most States and Tribes rate how well a river supports individual uses (such as swimming and aquatic life habitat) and then consolidate individual use ratings into a general water quality rating termed "overall use support." A river receives a poor overall rating if water quality consistently fails to support any one human activity or a healthy aquatic community (see Chapter 1 for a complete discussion of use support).

Forty-three States, six Tribes, three Interstate Commissions, Puerto Rico, and the District of Columbia reported overall use support status for rivers and streams in their 1994 Section 305(b) reports (see Appendix A, Table A-2, for individual State and Tribal information). Another five States reported individual use support status but did not report overall use support status. In such cases, EPA used aquatic life use support status to represent overall water quality conditions in the State's rivers and streams.

Altogether, 64% of the 615,806 surveyed river miles have good water quality. Of these waters, 57% fully support designated uses and 7% have good water quality that fully supports uses but is threatened and might deteriorate if we fail to manage potential sources of pollution (Figure 2-2).

Some form of pollution or habitat degradation prevents the remaining 36% of the surveyed river miles from fully supporting a healthy aquatic community or human activities all year round. Twenty-two percent of the surveyed river miles have fair water quality that partially supports designated

uses. Most of the time, these waters provide adequate habitat for aquatic organisms and support human activities, but periodic pollution interferes with these activities and/or stresses aquatic life. Fourteen percent of the surveyed river miles suffer from poor water quality that consistently stresses aquatic life and/or prevents people from using the river for activities such as swimming and fishing.

Individual Use Support

Individual use support information provides additional detail about water quality problems in our Nation's surface waters. The States are responsible for designating their rivers and streams for State-specific uses, but EPA requests that the States rate how well their rivers support six standard uses so that EPA can summarize the State data.

- **Aquatic life support** – Is water quality good enough to support a balanced community of aquatic organisms, including fish, plants, insects, and algae?
- **Fish consumption** – Can people eat fish caught in the river or stream?
- **Primary contact recreation (swimming)** – Can people make full body contact with the water without risking their health?
- **Secondary contact recreation** – Is there a risk to public health from recreational activities on the water, such as boating, that expose the public to minor contact with the water?
- **Drinking water supply** – Can the river or stream provide a safe water supply with standard treatment?
- **Agricultural uses** – Can the water be used for irrigating fields and watering livestock?

Only eight States did not report individual use support status of their rivers and streams (see Appendix A, Table A-3, for individual State and Tribal information). The reporting States and Tribes surveyed the status of aquatic life and swimming uses most frequently and identified more impacts on aquatic life and swimming uses than on the other individual uses (Figure 2-3). These States and Tribes reported that fair or poor water quality impacts aquatic life in 161,367 stream miles (31% of the 527,269 miles surveyed for aquatic life support). Fair or poor water quality conditions also impair

VOL 12

5462

swimming activities in 92,058 miles (23% of the 394,528 miles surveyed for swimming use support).

Many States and Tribes did not rate fish consumption use support because they have not codified fish consumption as a use in their standards. Some of these States consider fishing use as a component of aquatic life use–rivers and streams that provide a healthy habitat for fish support fishing activities even though anglers may not be able to eat their catch in these States. EPA encourages the States to designate fish consumption as a use in their waterbodies to promote consistency in future reporting.

Water Quality Problems Identified in Rivers and Streams

Figures 2-4 and 2-5 identify the pollutants and sources of pollutants that impair (i.e., prevent from fully supporting designated uses) the most river miles, as reported by the States and Tribes. The two figures are based on the same data (contained in Appendix A, Tables A-4 and A-5), but each figure provides a different perspective on the extent of impairment attributed to individual pollutants and sources. Figure 2-4 compares the impacts of the leading pollutants and sources in all surveyed rivers. Figure 2-5 presents the relative impact of the leading pollutants and sources in impaired rivers, a subset of surveyed rivers with identified water quality problems.

The following sections describe the leading pollutants and sources of impairment identified in rivers. It is important to note that the information about pollutants and sources is incomplete because the States cannot identify the pollutant or source of pollutants responsible for every impaired river segment. In some cases, a State may recognize that water quality does not fully support a designated use, but the State may not have adequate data to document that a specific

pollutant or process is responsible for the impairment. Sources are even more difficult to identify than pollutants and processes.

Pollutants Impacting Rivers and Streams

Fifty-five States and Tribes reported the number of river miles impacted by individual pollutants and processes, such as invasions by exotic species (see Appendix A, Table A-4, for individual State and Tribal information). EPA ranks the pollutants and processes by the geographic extent of their impacts on aquatic life and human activities (i.e., the number of river miles impaired by each pollutant or process) rather than actual pollutant loads in rivers and streams. This approach targets the pollutants and processes causing the most harm to aquatic life and public use of our waters, rather than the most abundant pollutants in our rivers and streams.

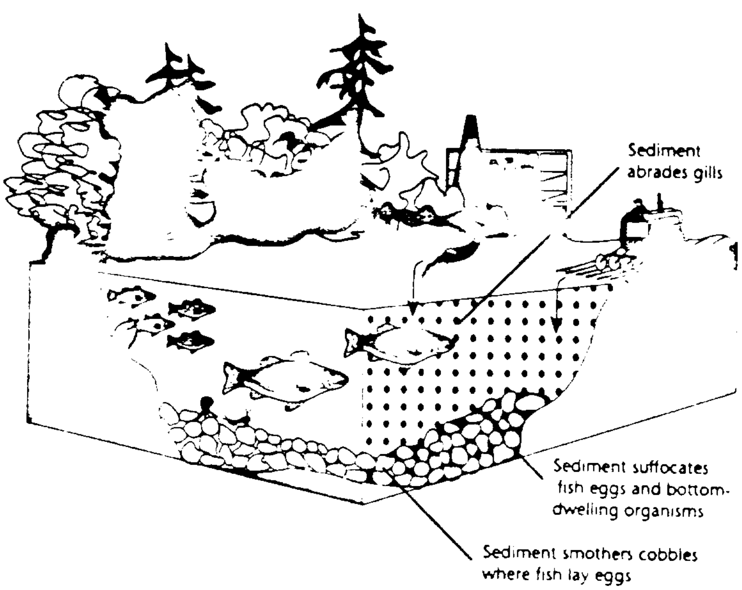
The States and Tribes report that bacteria pollute 76,397 river miles (which equals 12% of the surveyed river miles). Bacteria provide evidence of possible fecal contamination that may cause illness if the public ingests the water. States use bacterial indicators to determine if rivers are safe for swimming and drinking. Bacteria commonly enter surface waters in inadequately treated sewage, fecal material from wildlife, and runoff from pastures, feedlots, and urban areas.

Siltation, composed of tiny soil particles, remains one of the most widespread pollutants impacting rivers and streams (Figure 2-6). The States and Tribes reported that siltation impairs 75,792 river miles (which equals 12% of the surveyed river miles). Siltation alters aquatic habitat and suffocates fish eggs and bottom-dwelling organisms. Aquatic insects live in the spaces between cobbles, but their habitat is destroyed when silt fills in these spaces. The loss of aquatic insects adversely impacts fish and other wildlife that eat these insects. Excessive siltation can also interfere with drinking water treatment processes and recreational use of a river. Sources of siltation include agriculture, urban runoff, construction, and forestry.

In addition to siltation and bacteria, the States and Tribes also

Figure 2-6

The Effects of Siltation in Rivers and Streams



Siltation is one of the leading pollution problems in the Nation's rivers and streams. Over the long term, unchecked siltation can alter habitat with profound adverse effects on aquatic life. In the short term, silt can kill fish directly, destroy spawning beds, and increase water turbidity resulting in depressed photosynthetic rates.

VOL 12 5466

R0038774

reported that nutrients, oxygen-depleting substances, metals, and habitat alterations impact more miles of rivers and streams than other pollutants and processes. Often, several pollutants and processes impact a single river segment. For example, a process, such as removal of shoreline vegetation, may accelerate erosion of sediment and nutrients into a stream. In such cases, the States and Tribes count a single mile of river under each pollutant and process category that impacts the river mile. Therefore, the river miles impaired by each pollutant or process do not add up to 100%.

Most States and Tribes also rate pollutants and processes as major or moderate/minor contributors to impairment. A major pollutant or process is solely responsible for an impact or predominates over other pollutants and processes. A moderate/minor pollutant or process is one of multiple pollutants and processes that degrade aquatic life or interfere with human use of a river.

Currently, EPA ranks pollutants and processes by the geographic extent of their impacts (i.e., the number of miles impaired by each pollutant or process). However, less abundant pollutants or processes may have more severe impacts on short stream reaches. For example, a toxic chemical spill can eliminate aquatic life in a short stream while widely distributed bacteria do not affect aquatic life but occasionally indicate a potential human health hazard from swimming. The individual State and Tribal 305(b) reports provide more detailed information about the severity of pollution in specific locations.

Sources of Pollutants Impacting Rivers and Streams

Fifty-two States and Tribes reported sources of pollution related to human activities that impact some of their rivers and streams (see Appendix A, Table A-5, for individual State and Tribal information). These States and Tribes reported that agriculture is the most widespread source of pollution in the Nation's surveyed rivers. Agriculture generates pollutants that degrade aquatic life or interfere with public use of 134,557 river miles (which equals 22% of the surveyed river miles) in 49 States and Tribes (Figures 2-4 and 2-5).

Twenty-one States reported the size of rivers impacted by specific types of agricultural activities:

- Nonirrigated Crop Production – crop production that relies on rain as the sole source of water.

- Irrigated Crop Production – crop production that uses irrigation systems to supplement rainwater.

- Rangeland – land grazed by animals that is seldom enhanced by the application of fertilizers or pesticides, although land managers sometimes modify plant species to a limited extent.

- Pastureland – land upon which a crop (such as alfalfa) is raised to feed animals, either by grazing the animals among the crops or harvesting the crops. Pastureland is actively managed to encourage selected plant species to grow, and fertilizers or pesticides may be applied more often on pastureland than rangeland.

VOL 12

5467

R0038775

Kings Park Elementary. 3rd Grade, Springfield, VA

■ Feedlots are generally facilities where animals are fattened. By EPA's definition, feedlots are large sites where many animals are confined at high densities.

■ Animal Holding Areas – facilities for confining animals briefly before slaughter. By EPA's definition, animal holding areas confine fewer animals than feedlots.

Nonirrigated crop production leads the list of agricultural activities impacting rivers and streams, followed by irrigated crop production, rangeland, feedlots, pastureland, and animal holding areas (Figure 2-7). Runoff from irrigated and nonirrigated cropland may introduce commercial fertilizers (that contain nitrogen and phosphorus), pesticides, and soil particles into rivers and streams. Manure applied to cropland as a fertilizer may also wash off of irrigated and nonirrigated fields and prevent rivers and streams from fully supporting designated uses.

Animal waste runoff from feedlots and animal holding areas can introduce pathogens, nutrients (including phosphorus and nitrogen), and organic material to nearby rivers and streams. Rangeland may generate both soil erosion and animal waste runoff. Pastureland usually has good ground cover that protects the soil from eroding, but pastureland can become a source of animal waste runoff if animals graze on impermeable frozen pastureland during winter.

The States and Tribes also report that municipal sewage treatment plants pollute 37,443 river miles (6% of the surveyed river miles), hydrologic modifications and habitat alterations degrade 37,080 river miles (6% of the surveyed river miles), urban runoff and storm sewers pollute 26,862 river miles (4% of the surveyed river miles), resource extraction pollutes 24,059 river miles (4% of the surveyed river miles), and industrial discharges pollute 16,348 river miles (3% of the surveyed river miles).

The States and Tribes also report that "natural" sources impair many miles of rivers and streams in the absence of human activities. "Natural" sources include soils with natural deposits of arsenic or salts that leach into waterbodies, waterfowl (a source of nutrients), and low-flow conditions and elevated water temperatures caused by drought. The total size of rivers impaired by "natural" sources is probably exaggerated because some States may automatically attribute water quality impairments to "natural" sources if the State cannot identify a human activity responsible for a water quality problem.

Other sources, such as mining and forestry activities, can play a more significant role in degrading water quality at a regional or local level than at the national level. For example, resource extraction (including acid mine drainage) contributes to the degradation of 39% of the impaired river miles in the coal belt States of Kentucky, Maryland, Ohio, Pennsylvania, and West Virginia. These States report that resource extraction impairs about 7,590 miles of rivers and streams. Yet, at the national level, resource extraction contributes to the degradation of only 11% of all the impaired river miles in the Nation. At the local level, streams impacted by acid mine drainage are devoid of fish and other aquatic life due to low pH levels and the smothering effects of iron and other metals deposited on stream beds. The primary sources of acid mine drainage are abandoned coal refuse disposal sites and surface and underground mines.

In the Pacific Northwest States of Oregon and Washington, States identify forestry activities as responsible for almost half (46%) of the impaired river miles, but, at the national level, States report that forestry activities contribute to the degradation of only 9% of the Nation's total impaired river miles. Forestry activities include harvesting timber, constructing logging roads, and stand maintenance. California, Florida, Montana, and Wisconsin also report that forestry activities degrade over 1,000 miles of streams in each State.

Many States reported declines in pollution from sewage treatment plants and industrial discharges since enactment of the Clean Water Act in 1972. The States attributed improvements in water quality conditions to sewage treatment plant construction and upgrades and permit controls on industrial discharges. Despite the improvements, municipal sewage treatment plants remain the second most common source of pollution in rivers because population growth increases the burden on our municipal facilities.

Several States reported that they detected more subtle impacts from nonpoint sources, hydrologic modifications, and habitat alterations as they reduced conspicuous pollution from point sources. Hydrologic modifications and habitat alterations are a growing concern to the States. Hydrologic modifications include activities that alter the flow of water in a stream, such as channelization, dewatering, and damming of streams. Habitat alterations include removal of streamside vegetation that protects the stream from high temperatures and scouring of stream bottoms. Additional gains in water quality conditions will be more subtle and require innovative management strategies that go beyond point source controls.

Figure 2-7

Agricultural Impairment: Rivers and Streams
(21 States Reporting)
