As described by the amendment's sponsor in a floor statement on CZARA, the additional management measures provide a "second tier of pollution control efforts" and "are targeted to those coastal land uses that are recognized to cause or contribute to water quality problems generally." See 136 Cong. Rec. E. 3590, October 27, 1990. In addition, the legislative history describes the additional management measures provision as also requiring "the identification of important coastal areas -- as contrasted to individual land uses under paragraph (1) [section 6217(b)(1)] -- that need additional measures to protect against anticipated pollution problems. Unlike paragraph (1), the imposition of additional measures are not contingent upon identified water quality problems, and are to be established as a preventative step to avoid water quality problems that might otherwise develop." Id.

For program approval, states will need to do the following:

1. identify coastal waters that are not attaining or maintaining applicable water quality standards or protecting designated uses, or that are threatened by reasonably foreseeable increases in pollution loadings from new or expanding sources;

2. identify land uses that individually or cumulatively cause or threaten water quality impairments in those coastal waters;

3. identify critical coastal areas;

4. develop a process for determining whether additional measures are necessary to attain or maintain water quality standards in the waters identified above;

---

[11] For purposes of section 6217(b), the definitions for water quality standards and designated uses are those found in section 303 of the Clean Water Act and in 40 C.F.R. Part 131.

5. describe the additional management measures the state will apply to the identified land uses and critical coastal areas; and,

6. develop a program to ensure implementation of the additional management measures within the time frame described in section IV.D.

These elements are discussed in greater detail in the following sections.

III.D.1. Identification of coastal waters that are not attaining or maintaining water quality standards

For program approval, states must, at a minimum, identify the following as threatened or impaired waters:

a. coastal waters identified in a state's most recent report under section 305(b) of the CWA as "partially meeting" or "not meeting" designated uses or as "threatened";

b. coastal waters listed by a state in accordance with the requirements of section 303(d)(1)(a) of the CWA requiring Total Maximum Daily Load calculations if listing is due at least in part to nonpoint sources;

c. coastal waters listed by a state under CWA section 304(l) as impaired by nonpoint source pollution;

d. coastal waters identified by a state as impaired or threatened by nonpoint source pollution in an assessment submitted to EPA under section 319 of the CWA or in any updates of the assessment.

States should also consider the results of water quality monitoring associated with assessing the effectiveness of the (g) measures in attaining and maintaining water quality standards when identifying impaired or threatened waters.

States should also identify coastal waters for which existing dilution calculations or predictive models indicate nonattainment of water quality standards. Other organizations and groups should be actively solicited for research they may be conducting or reporting. For example, volunteer monitoring organizations, university researchers, the USDA, NOAA, USGS, and the U.S. Fish and Wildlife Services and a wide variety of state agencies can be good sources of field data. In addition, states should examine waters for which coastal water quality problems have been reported to the state by local, state or Federal agencies, members of the public, or academic institutions.

States should use the most current data available, including information generated in evaluating the effectiveness of the (g) measures, and must describe the validity of the data used to determine threatened or impaired waters. States should consider the following in evaluating the validity of the data:

a. whether the assessments are based on monitored or evaluated data;

b. the limits on the availability of water quality information for coastal wetlands, estuaries and groundwater resources that affect coastal waters; and,

c. the difference between each coastal waterbody's current condition and the condition needed to support the designated uses that the state has identified in its water quality standards. (See Appendix F for examples of designated uses and support levels).

NOAA and EPA require each state to identify its impaired and threatened coastal waters in order to evaluate both the adequacy of the state's identification of land uses required by section 6217(b)(1) and the critical coastal areas required by section 6217(b)(2), and the adequacy of its determination that additional management measures need to be implemented. As part of the threshold review process (see section IV.B.), NOAA and EPA will work with the state to evaluate the state's water quality information. If the information is incomplete, the state may be asked to develop reasonable additional information on water quality impairments. States are encouraged to complete water quality assessments for coastal waters and estuaries. In addition, states are encouraged to adopt water quality standards for marine waters and for common nonpoint source pollutants such as nutrients.

III.D.2. Identification of land uses causing or threatening water quality impairments

Once threatened and impaired coastal waters have been identified, as described in section III.D.1, states must then identify those land uses that individually or cumulatively cause or contribute to coastal water quality impairments. The land uses should include the general nonpoint sources categories and subcategories described in the (g) guidance and other land uses not mentioned in the (g) guidance that are or may be sources of runoff and infiltration to coastal waters such as landfills and certain mining operations. States should use the most current land use information available (local and state land use maps, Geographic Information Systems, etc.) to identify these land uses. NOAA and EPA encourage states to use maps to display identified land uses.

Water quality impacts may occur where a land use involves: (1) substantial disturbance to the land or water resource; (2) substantial treatment, introduction, or creation of a nonpoint source pollutant; or (3) a substantial temporary or permanent change to the hydrology or other natural characteristics of a land area or water resource.

Once general land use patterns and potential water quality impacts have been identified, states should consider more specific land use characteristics to help determine whether current or future uses are likely to cause or contribute to water quality impairments. State should consider the biological and physical impacts of these land uses within the watershed adjacent to the impaired or threatened waterbody or segment. States should consider physical characteristics such as: topography/slope; soil characteristics (erodibility, etc.); shoreline erosion characteristics; hydrology, in particular groundwater linkages to coastal waters and high water tables; and the presence of forest and other vegetated areas that may provide natural buffers or nutrient sinks. States should also consider habitat and other biological impacts that may be caused by specific land uses.

The preferred source of information on the relationship between land uses and water quality is "refereed" technical journals. However, other sources often will be needed to fill gaps caused by a shortage of information relating land use to nonpoint source impacts. Additional sources could include Federal and state publications, generally accepted models (e.g., loading coefficients), and similar information. Sources used by the state in identifying and evaluating the land uses should be cited in its coastal nonpoint program.

III.D.3. Identification of critical coastal areas

For program approval, a state must also identify and map critical coastal areas -- as contrasted to individual uses identified under paragraph (1) of section 6217(b) -- that need additional measures to protect against current and anticipated nonpoint pollution problems. See section 6217(b)(2). The establishment of critical coastal areas should focus on those areas in which new or substantially expanding land uses may cause or contribute to the impairment of coastal water quality.

States have flexibility in their approach to delineating critical coastal areas. The following two examples illustrate approaches for the establishment of critical coastal areas.

Under the first approach, a state could establish the critical coastal area as a strip of land along the portion(s) of the shoreline adjacent to threatened or impaired coastal waters. Some states have programs that specify a land area along the shoreline of a waterbody and that extend inland a uniform distance from the shoreline or from landward boundaries of wetlands or heads of tides. Within this area, special controls such as setbacks and low density zoning can be employed to protect coastal waters.

In establishing a critical coastal area along the shoreline, a state may omit areas where recent water quality assessments demonstrate that the coastal waterbody is neither impaired nor threatened, and where a state can demonstrate that new land uses or expansions of existing land uses will not contribute to a future threat or impairment of the waterbody. For example, shoreline segments could be omitted if: (1) a state can demonstrate that its coastal area is predominantly in Federal or state conservancy, the use of which will not threaten coastal water quality, and that changing or expanding land uses are not a concern; or (2) existing ordinances for an adjacent area effectively manage new or expanding land uses (e.g., by controlling the extent of impervious surfaces and/or the density of development along the coastal waters).

Under a second approach, a state could rely on site specific evaluations to determine the extent of a critical coastal area. The critical coastal area could be established on an ecosystem basis for the impaired or threatened coastal waters.[12] Under this approach, states may include broader geographic areas in the critical area designation, starting with shoreline segments adjacent to threatened or impaired coastal waters, and extending inland to encompass significant coastal features or resources further inland. These broader areas may include entire watersheds or portions of watersheds adjacent to coastal waters, and may encompass significant biological features such as wetlands.

In selecting an approach, states should consider the following factors:

- The nature of the coastal water quality problem(s) caused by nonpoint sources.
- The extent to which the nonpoint sources are located adjacent to the waterbodies as opposed to further inland.
- The physical and biological characteristics of the adjacent lands, such as those described in the previous section on land use, that will affect the extent to which uses of these lands will cause nonpoint source pollution problems. (See section III.D.2.).
- Important biological features that should be included as a whole in critical coastal areas, e.g. wetlands.
- The type(s), density and characteristics of the new or expanding land uses that are anticipated and their expected effect(s) on water quality.

[12] Ecosystem is defined as a biological community whose environment functions as an ecological unit.

VOL 12

- The extent to which the above effects can be prevented or reduced by implementation of (g) management measures and/or the additional management measures for land uses.

NOAA and EPA also encourage states to consider including other previously designated areas within the critical coastal areas under this program. Such areas may include: areas of particular concern designated as part of state coastal zone management programs; National Estuarine Research Reserves; National Marine Sanctuaries; and, significant watershed areas within National Estuaries designated by EPA under section 320 of the CWA. NOAA and EPA expect that this approach will help to fully integrate and coordinate this new coastal nonpoint program with other existing programs.

III.D.4. Process to implement additional management measures

Once the land uses and critical coastal areas, described above, have been identified, states must describe additional management measures applicable to those land uses and areas in order to address the sources of nonpoint pollution. <u>See</u> section 6217(b)(3). States will also need to develop a continuing process, including milestones, for implementing, evaluating and, as necessary, revising the additional measures.

6497

NOAA and EPA expect that it may be necessary for a state to provide for the implementation of some additional management measures immediately and others only if implementation of the (g) measures are shown to be insufficient to protect and restore water quality. The two categories of additional management measures are:

1. **Immediate Implementation**: For the waterbodies identified in section III.D.1., states should evaluate the relative contributions from point and nonpoint sources. Where a threat or impairment of a particular water or waterbody segment is due to nonpoint sources, the state should determine whether existing pollution prevention activities and/or the implementation of the (g) measures will be adequate to address the threat or impairment. If existing information indicates that the implementation of the (g) measures will not be adequate to attain or maintain water quality standards of the coastal waters or waterbody segment due to contributions from nonpoint sources, then the state program must specify, at the time of program submission, additional management measures applicable to the appropriate land uses and critical coastal areas. Implementation of these additional measures should begin at the time program approval is granted. Two instances where additional management measures are most likely to be needed immediately are: (1) where the (g) measures (or their equivalents) are already being implemented under existing nonpoint source programs but water quality is still impaired due to identifiable nonpoint sources; and (2) where states have identified critical coastal areas pursuant to the description in III.D.3. because new

or expanding land uses threaten or impair coastal waters notwithstanding existing nonpoint source controls.

2. **Implementation based on performance of (g) measures:** States should also specify a continuing process for identifying, implementing, and revising, as necessary, additional management measures after the program's (g) measures have been implemented. As the (g) measures are implemented, the states should monitor their effectiveness and should verify whether water quality standards are being attained or maintained and designated uses protected. If a state determines that nonpoint sources contribute in whole or in part to water quality impairment even after implementation of the (g) measures, then the state will need to provide for the implementation of additional management measures. As discussed in section IV.D. (Schedule for Program Implementation), additional measures under these circumstances must be fully implemented within eight years of Federal approval of the coastal nonpoint program. The additional management measures also must be monitored to assess their effectiveness in attaining and maintaining water quality standards and protecting designated uses. Further refinements to these management measures, the use of other additional measures, or enforcement action may be necessary if water quality goals are still not met.

III.D.5. Selection of additional management measures

Having determined the need for additional management measures under III.D.4., states will then need to select the additional measures to be implemented. Like the (g) measures, these measures can include a broad range of structural and nonstructural nonpoint source controls. Unlike the (g) measures, the additional measures need not apply to all similar land uses throughout the 6217 management area. Rather, the additional management measures apply only to those identified land uses and critical coastal areas where further nonpoint source controls are necessary to ensure that coastal water quality standards are attained or maintained and designated uses are protected.

For program approval, states are expected to provide the following information on the additional management measures that will be implemented:

a. a discussion of the measure and the land uses and pollutants it is designed to address;

b. evidence of the anticipated effectiveness of the measure in reducing nonpoint pollution to meet water quality standards; and,

c. a process for evaluating the effectiveness of the measures once they are implemented, and a schedule for revising such measures, as necessary, to meet water quality standards.[13]

A number of alternatives are available to states in selecting the additional management measures.

- States can select management measures not specified in the (g) guidance. Under this alternative, states or local governments could develop very specific additional management measures that could include buffer zones, low density zoning, cluster development ordinances, conservation zoning, or other land use measures best developed at the local level.

- States can apply the measures specified in the (g) guidance more intensively (e.g., require a wider stream-side management area for certain forestry operations than that necessary to achieve the (g) guidance measures for stream-side management).

- States can apply the measure specified in the (g) guidance more stringently (e.g., require a higher removal rate for suspended solids for new urban development than that specified in the (g) guidance measure).

- States can provide management measures for land and water uses not identified in the (g) guidance, or for sources excluded under the process described in section III.C.1.

- States can employ innovative approaches as additional management measures. For example, where there is adequate information, states could consider the use of pollution trading for discharges from nonpoint and point sources or among nonpoint sources in watersheds in order to attain or maintain water quality standards in coastal waters and to protect designated uses.

Given the focused nature of additional management measures and the opportunity to tailor the measures to local conditions, the requirement provides an excellent opportunity to use local land use measures to control nonpoint source pollution. Thus states are encouraged to work closely with local governments to develop and implement these measures.

---

13 EPA and NOAA will establish a schedule for evaluating the need for management measures revision, which may be tied to 305(b) biennial water quality assessments. If these assessments indicate that water quality is not improving, the additional management measures already in place will need to be revised.

VOL 12

III.D.6. Using Innovative Pollutant Trading Techniques

One innovative approach that states could consider as they develop additional management measures is pollutant trading. Pollutant trading is a concept that enables one or more sources to meet less stringent treatment levels in exchange for other sources meeting more stringent treatment levels than the levels they would otherwise be required to meet. In appropriate situations, trading can result in more cost-effective pollutant control.

There are two types of nonpoint source trades that are possible:

(1) Point-nonpoint source trading. A point source that has complied with its technology-based requirements may be able to avoid or lessen more stringent water-quality-based treatment requirements by obtaining the requisite (water-quality driven) reductions from nonpoint sources.

(2) Nonpoint-nonpoint source trading. A nonpoint source may apply more stringent treatment than another one, and together the sources obtain the requisite reductions.

Pollutant trading, to date, has been used only sparingly under the Clean Water Act. Point-nonpoint trades have been approved in the Dillon Reservoir, Colorado (for phosphorus) and for North Carolina's Tar-Pamlico watershed (for nitrogen).

The following factors, developed at a recent EPA conference on pollutant trading, should be considered before considering the use of trading techniques[14]:

1. Trading is a potentially valuable tool, but its usefulness has not been fully demonstrated.

2. Trading cannot be applied uniformly nationwide; it is site-specific and local in nature.

3. Cause and effect water quality data, improved predictive modeling, and definitive information on nonpoint source control effectiveness are all crucial technical elements for trading.

4. Education and monitoring are both essential to the success of any trading program.

6500

[14] A summary of that conference, "Administrator's Point/Nonpoint Source Trading Initiative Meeting" (August 1992) is available from EPA.

Despite the formidable technical and administrative difficulties, EPA and NOAA continue to believe that trading offers some potential water quality benefits and will work to help state and local governments identify opportunities for beneficial trades and to implement such trades.

III.E. Technical Assistance

For program approval, state coastal nonpoint programs will be required to provide for technical and other assistance to local governments and the public for implementing the additional management measures (section 6217(b)(4)). This may include "assistance in developing ordinances and regulations, technical guidance, and modeling to predict and assess the effectiveness of such measures, training, financial incentives, demonstration projects, and other innovations to protect coastal water quality and designated uses." States are also encouraged to provide assistance to local governments and the public on the implementation of the (g) measures.

In order to tailor the type and scale of their technical assistance activities, states should identify those aspects of the program requiring implementation at the regional or local level and the situations where regional entities or localities may need additional expertise and/or experience. In designing the assistance program, NOAA and EPA expect that states will consult with regional and local governments regarding their concerns about implementation, and with the public about its needs and concerns. For certain management measures, training sessions and certification programs conducted by the state for regional and local officials may be appropriate. For others the financing of demonstration projects may be an effective means of enhancing implementation. NOAA and EPA will provide support to states in the implementation of this technical assistance, as requested.

The statute states that technical and other assistance shall be provided to the public as well as to local governments. The technical assistance to the public should include help in solving individual problems and information on how citizen groups can participate in the development and implementation of state programs (e.g., monitoring).

At a minimum, the state coastal nonpoint program should discuss the types of technical assistance that will be provided to support implementation of additional management measures for each of the major land use categories identified in a state's program. States should identify the agency that will provide the technical assistance, the intended recipients of the assistance, and a schedule of when such assistance will be available.

NOAA and EPA are committed to providing technical assistance to the states in the development and implementation of their coastal nonpoint programs. EPA has assembled a great deal of technical information during development of the (g) guidance, and is continuing to add to this collection. This information will be available to the states in a variety of formats, including bibliographies and summaries, both in hard copy and by electronic bulletin board. NOAA and EPA will hold a series of national and regional meetings with state and local officials to discuss their technical assistance needs. Throughout the development and implementation of the coastal nonpoint programs, NOAA and EPA will maintain a dialogue with the states and will provide technical assistance whenever possible. NOAA and EPA will also work with other Federal agencies and will encourage them to use their expertise to assist the states in the development and implementation of the state programs.

III.F. Public Participation

For program approval, states must provide opportunities for public participation in all aspects of the program (section 6217(b)(5)). Congress intended the public to have the opportunity to be extensively involved in the development and implementation of the state coastal nonpoint programs, calling not only for public participation, but also for public education.

As an integral part of the coastal nonpoint program, the goals of the public involvement and education program should be defined by the state before it begins to develop its coastal nonpoint program. The public will need to be involved as early as possible in the development and implementation of the coastal nonpoint program, and the process should seek to promote and maintain the public's long-term commitment to the program. Each state must demonstrate that its coastal nonpoint program has undergone public review and comment prior to submittal to NOAA and EPA. Specifically, a state will need to demonstrate that it has provided opportunities for public comment prior to determining which management measures will be used, what enforceable policies and mechanisms should be employed to ensure implementation of the identified measures, the geographic scope of the coastal nonpoint program, the identification of land uses and critical coastal areas, and the selection and implementation of additional management measures. Depending on the type of threshold review a state selects, there may also need to be public participation as part of that process (see section IV.B.).

The public involvement and education program should include a schedule for initial public contact and education activities, and milestones for further involvement throughout the development and implementation of the coastal nonpoint program. These milestones will need to address public participation, particularly in the development phase, and public education, particularly in the implementation phase. The coastal nonpoint program should also describe how the state expects to fund the public involvement and education programs, including both program development and implementation activities (e.g., Federal funds, state and local funds, or the innovative use of private sector dollars).

As part of the public participation and education programs, states should describe how they will periodically evaluate the effectiveness of these programs.

Public education programs are expected to target several types of audiences, including those regulated or affected by the program (e.g., farmers, building contractors, and marina operators) and those that can assist with program implementation (e.g., conservation organizations and county extension agents). In the implementation phase of the coastal nonpoint program, volunteers may be a very valuable source of assistance. For example, Federal and state funds often are limited for water quality monitoring programs, but volunteers can help to fill the gap. While clearly supplemental to professional data collection, a number of states have successfully used volunteers in their programs. Although costs will be incurred for training volunteers and supporting staff time to coordinate the volunteer efforts, studies and reports demonstrate that volunteers can effectively provide accurate, useful long-term water quality monitoring data.

III.G. Administrative Coordination

For program approval, the coastal nonpoint program must include administrative coordination mechanisms (section 6217(b)(6)). At a minimum, the coastal nonpoint program must include a list of state, regional and local agencies that will play a role in developing and implementing the state nonpoint program. The list should describe the mission, structure and operation of the agencies as they relate to nonpoint source pollution control, and identify the specific role to be played by each agency in the coastal nonpoint program.

A variety of mechanisms can be used to improve coordination among the agencies involved in the coastal nonpoint program and to ensure that the various programs are fulfilling their responsibilities to implement the applicable provisions of the program. These mechanisms include, but are not limited to:

- Memoranda of Agreement/Understanding describing specific agency roles and points of coordination
- Joint permitting processes
- Formal interagency comments during other agencies' permitting processes
- Cross training of staff in other agencies' programs
- Temporary assignment of staff to other agencies, e.g., Intergovernmental Personnel Agreements

- Interagency task forces (e.g., those associated with national estuary programs)
- Interagency advisory committees
- Regularly scheduled interagency staff meetings
- State statutes/regulations describing expectations for interagency cooperation and coordination

The mechanisms selected to ensure coordination among participating agencies should be in place when the coastal nonpoint program is submitted to NOAA and EPA for review and approval. The coastal nonpoint program should also explain how the state will measure the effectiveness of program coordination and should provide a schedule for periodic evaluation and reporting of the results to NOAA and EPA.

NOAA and EPA will work with other Federal agencies at the national level to ensure their understanding and cooperation in the development of the coastal nonpoint programs. NOAA and EPA will also work to assist in resolving conflicts that may occur between states and Federal agencies during the development and implementation of the state coastal nonpoint program.

III.H. Enforceable Policies and Mechanisms

Section 306(d)(16) of the CZMA states that, "[b]efore approving a management program submitted by a coastal state, the Secretary shall find the following: ... [t]he management program contains enforceable policies and mechanisms to implement the applicable requirements of the Coastal Nonpoint Pollution Control Program of the State required by section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990." The Act further provides that, "[e]ach State which submits a management program for approval under section 306 of the Coastal Zone Management Act of 1972, as amended by this subtitle (including a State which submitted a program before the date of enactment of this Act), shall demonstrate to the Secretary -- ... that the program complies with section 306(d)(16) of that Act by not later than 30 months after the date of publication of final guidance under section 6217(g) of this Act."

The statute includes a definition of "enforceable policy" in section 304(6a) of the CZMA: "[t]he term "enforceable policy" means State policies which are legally binding through constitutional provisions, laws, regulations, land use plans, ordinances, or judicial or administrative decisions, by which a State exerts control over private and public land and water uses and natural resources in the coastal zone."

NOAA interprets the term "applicable requirements" in section 306(d)(16) of the CZMA to include the implementation, at a minimum, of: (1) management measures in conformity with the guidance developed under section 6217(g) in order to protect coastal waters generally, and (2) such additional management measures applicable to land uses and critical areas identified in the program as are necessary to maintain or restore coastal water quality and protect designated uses.

States can design a coastal nonpoint program that uses a variety of effective regulatory and/or non-regulatory approaches in order to meet the requirement for enforceable policies and mechanisms. Non-regulatory approaches must be backed by enforceable state authority which ensures that the management measures will be implemented. States are expected to demonstrate that they have the authority to take enforcement actions where incentive or other programs do not result in implementation of management measures, or where significant harm to coastal waters is found or threatened. The selection and design of enforceable policies can be tailored to specific state or local circumstances. The approaches states choose should take into account the nature of the activity and existing institutions and authorities. States may also want to evaluate the costs and benefits of various approaches. States may include existing and/or new enforceable polices and mechanisms in their coastal nonpoint programs. Whatever enforceable policies and mechanisms a state uses, they must meet the threshold test in section 306(d)(16) of ensuring implementation of the applicable requirements, (e.g., management measures as described above).

Enforceable policies may be established through state, regional or local authorities. Where implementation occurs at the regional or local levels, the state must be able to exert or retain authority to ensure local implementation in accordance with the federally approved coastal nonpoint program.

As reflected in the section 6217(g) management measures guidance, a state may need to develop different approaches or requirements for new and existing sources. For example, the (g) guidance specifies separate management measures for the installation of new onsite disposal systems and for the operation of existing onsite disposal systems. States may want to consider these differences in designing enforceable policies and mechanisms for implementing the various management measures to restore and protect coastal waters.

To ensure the effective implementation of the enforceable policies and mechanisms, states should educate the public about the importance of the management measures and should provide technical assistance to local governments and the affected interests. While public education and technical assistance programs alone may not be used to fulfill the requirement for enforceable policies and mechanisms (except as noted below), these programs can enhance the success of both regulatory and non-regulatory programs.

Although the (g) guidance includes educational programs as practices under a number of management measures, only the measures for urban pollution prevention and marina public education require educational programs as part of the management measures itself. For these measures, a demonstration that the state will conduct educational activities will be adequate, and, therefore the state programs need not include enforceable policies and mechanisms for these two measures.

Similarly, the guidance contains management measures which call for the state to promote the restoration of wetlands and riparian areas, and the use of engineered vegetated treatment systems such as constructed wetlands or filter strips. A demonstration that the state will promote these efforts will be adequate to respond, and the state will not be required to include enforceable policies and mechanisms in its coastal nonpoint program for these two measures.

The next two subsections describe examples of the various approaches that a state might consider in developing enforceable policies and mechanisms. The presence in a state coastal nonpoint program of enforceable policies and mechanisms identical to the examples does not necessarily guarantee approval of these approaches because NOAA and EPA will need to evaluate a state's enforceable policies and mechanisms in the context of that state's complete coastal nonpoint program.

III.H.1. Regulatory approaches

One way to implement the requirement for enforceable policies and mechanisms in the coastal nonpoint program is the traditional regulatory approach. Examples of regulatory approaches include permit programs, local zoning, or direct requirements contained in state statutes.

Permit programs

If a state chooses a permitting approach, it has flexibility in the type of permits it uses: individual and general. An individual permit is written for a specific entity. For example, states and localities can issue individual permits for onsite sewage disposal systems prior to home construction. These permits can require implementation of the management measures related to the siting, design, installation, operation, inspection, and maintenance of new systems. These permits also may be renewed periodically to ensure that the system continues to operate properly and/or is pumped out at specified intervals. Implementation of the management measures for the operation of onsite sewage disposal systems can be accomplished through these permit renewals. Other types of individual permits such as coastal development, building, or grading permits can be used to ensure that a number of the urban management measures are implemented.

A state can also issue general permits for specific source categories. These permits prescribe management measures that must be adopted by all entities that meet the category definition. The state would conduct an education program to notify the targeted entities that they must comply with the conditions of the general permit. Individual permits may be issued or penalties imposed for non-compliance.

For example, a general permit can require farmers to adopt management measures for various facets of their operation: e.g., nutrient management, pesticide management, and livestock management. Farmers would choose site-specific management practices from technical guidance provided by the state.

In another example, general permits are currently allowed for certain storm water discharges under section 402(p), e.g., construction activities. Persons engaged in construction activities would have to undertake certain sediment and erosion control practices as conditions of a general permit. If recipients of a general permit fail to meet conditions of the permit by not adopting the management measures, they may face enforcement actions or could be required to apply for an individual permit containing more detailed management, reporting, and inspection requirements.

Local zoning

Many local governments already use zoning ordinances to set conditions on development. For example, local zoning ordinances may restrict the siting of marinas to protect sensitive areas such as shellfish beds, and could, therefore, be used to implement the management measures for marina siting. States could provide oversight of these local decisions by setting the standards by which the zoning ordinances are adopted and by retaining appeal of local decisions if they do not meet the state standards. In addition, local zoning may be an effective mechanism to implement additional management measures. For example, a state may direct local governments to adopt provisions restricting land uses in critical coastal areas to protect and restore water quality.

Direct state statutory requirements

A state may adopt laws that directly require or prohibit certain activities in certain areas as a way to implement some of the management measures. While not requiring a permit per se, state forest practices acts can require forest operators to maintain streamside management areas as part of their plans of operation. This mechanism could provide a way to implement a number of forestry management measures.

Enforcement of Regulatory Approaches

Enforcement under the regulatory approach could be triggered for failure to obtain or comply with a permit, zoning ordinance, or direct statutory requirement. Enforcement actions may include cease and desist orders, administrative orders, fines, or in certain cases, criminal penalties. Fines can be punitive or can be based on the economic benefit an entity gained from not implementing the management measures or the cost of restoring the environment from harm caused by the noncompliance. Enforcement may be triggered when inspections or monitoring programs show that operators are failing to implement the (g) measures or the additional management measures.

III.H.2. Non-regulatory approaches

Although regulatory approaches may be well suited for certain nonpoint sources, they may be difficult to design and implement for other sources. In addition, efforts to control some nonpoint sources historically have relied almost solely on non-regulatory programs. Accordingly, a state has the flexibility to employ economic incentive, disincentive, or innovative approaches to address these types of sources, provided that the state can ensure such approaches will result in the necessary implementation of the (g) management measures and additional management measures. States will have to include back-up enforcement authority for voluntary programs. Such back-up authority could include sunset provisions for incentive programs. For example, a state could provide that if too few operators participate in a tax incentive program, the state would develop additional incentives or mandatory requirements to achieve the necessary implementation of management measures.

Non-regulatory approaches may use financial mechanisms to encourage or discourage certain behaviors. State tax credits, tax deductions, tax rebates, cost-share programs, performance bonds, or loan programs are economic incentives that are often used to encourage changes in behavior. Economic disincentives include increased taxes, fees, or pricing structures. There are a variety of economic tools that states can use; however, each state should analyze the relative effectiveness of the tools in implementing the management measures before applying them in a given situation.

Economic incentives

State economic incentives can be used to provide financial support to guarantee mplementation of some management measures. For example, as a condition of the ·eceipt of state agricultural cost-share funds, farmers can be required to fully mplement specific management measures (e.g., sediment and erosion control, nutrient nanagement, pesticide management). Cost-share funds can also be used to ensure that some of the forestry management measures are implemented (e.g., road construction/reconstruction, road management, revegetation of disturbed areas).

State tax credits, deductions, or rebates could be granted or pricing structures created to encourage the adoption of water efficiency measures to implement urban management measures for onsite disposal systems (e.g., marginal cost water pricing to encourage conservation of water, installation of low-flow plumbing fixtures). States could set up grant or low interest loan programs to help individuals finance capital expenditures associated with management measures such as replacing failing onsite disposal systems, installing animal waste controls, stabilizing eroding shorelines using vegetative methods, or constructing pumpout facilities for marinas.

Although economic incentive programs can be very effective in many cases, states should recognize their limitations. Incentive programs can be very expensive for a state to administer and implement, and state revenues will be required to support them. In addition, if such approaches are used alone, it may be difficult to establish the rate of cost-share or tax credits at a level that guarantees widespread adoption of the management measures. As a state raises the level of financial support, the costs of the incentive program will increase.

Economic disincentives

States can also develop economic disincentive programs to implement some management measures. Fees, taxes, or price increases on specific items can be used to reach the level specified in the management measures. For example, increased prices may be used to stimulate water conservation (or modifications to pricing structures that inadvertently encourage high consumption). Similarly, taxes or fees may be levied on products to discourage their inefficient use.

States also should recognize the limitations on the effectiveness of disincentive programs. The success of these approaches depends on the level of the tax or fee relative to the price of the good. If a tax or fee is too high, it may change behavior more than is necessary to meet the management measure. If a tax or fee is too low, it may not change behavior sufficiently to adequately implement the management measures. However, a fee could be supplemented by other approaches to meet the measure. Despite these limitations, the use of mechanisms such as taxes and fees has the advantage of generating program revenues.

Other innovative approaches

States also may use more innovative approaches to encourage management measure implementation. Trading of pollution control requirements among point and nonpoint sources or among nonpoint sources may be a useful tool in implementing additional management measures to meet water quality standards in a particular waterbody. (See discussion in section III.D.6.)

States may require that performance bonds be posted before an entity engages in an activity requiring management measure implementation. For example, prior to authorizing a channelization project, a state could require a developer to post a bond to ensure that proper design and construction activities occur. When the developer complies with the practices, the bond will be returned. If not, the bond will be forfeited to the state. Bonds can also be used to ensure that proper operation and maintenance activities occur.

As mentioned earlier, states may enhance the success of these non-regulatory approaches through education programs. For example, as part of an existing pesticide applicators' licensing program, states may require that applicators be educated on management measures and appropriate practices and may require certification of course attendance.

In conclusion, NOAA and EPA expect that states will employ a range of approaches in crafting enforceable policies and mechanisms to implement the (g) management measures and additional management measures. A state coastal nonpoint program should indicate clearly what approaches and authorities the state will rely on to meet the requirement for enforceable policies and mechanisms and should describe how the approaches will ensure the necessary implementation of the management measures.

IV. PROGRAM SUBMISSION, APPROVAL AND IMPLEMENTATION

The legislative history of section 6217 states that "coastal nonpoint pollution control programs are not intended to supplant existing coastal zone management programs and nonpoint source management programs. Rather, they are to serve as an update and expansion of existing programs." Id. See also section 6217(a)(2). The legislative history indicates that the central purpose of section 6217 is to strengthen the links between Federal and state coastal zone management and water quality programs and to enhance state and local efforts to manage land use activities that degrade coastal waters and coastal habitats.

The sections below describe several aspects of the approval process. States may elect to undertake "threshold reviews" with NOAA and EPA. Under certain circumstances, NOAA and EPA may grant "conditional approvals" for state coastal nonpoint programs. The last step in the process is "final approval" by NOAA and EPA. When a state coastal nonpoint program receives final approval, it will automatically be incorporated into the state's coastal management and nonpoint source programs.

IV.A. Program Submission and NOAA/EPA Review

Within 30 months after the publication of EPA's (g) guidance, states must submit their coastal nonpoint programs to NOAA and EPA for approval. Appendix G contains a listing of the information that needs to be included in the state's submission.

The statute requires the Secretary of Commerce to make a determination whether the portions of the state's program under the Secretary's authority meet the requirements of section 6217, and likewise, the Administrator of the EPA must make a determination whether the portions under the Administrator's authority meet the requirements of section 6217. If both officials determine that the requirements of section 6217 have been met and each agency official concurs with the other's determination, then the program will be approved. As stated previously, NOAA and EPA have determined as a matter of policy that neither agency will approve a state's coastal nonpoint program until the program meets all the Federal approval requirements as determined by both agencies. NOAA and EPA (including both headquarters and regional offices) will coordinate their review of the coastal nonpoint program.

IV.B. Threshold Review

A state may request that NOAA and EPA conduct a threshold review of its proposed coastal nonpoint program. The threshold review is an initial review by NOAA and

EPA of a state's approach to specific elements of its coastal nonpoint program. The review would address key issues and decision points (e.g., identification of sources, geographic scope, alternative management measures) that a state may wish to discuss prior to drafting its coastal nonpoint program. The intent of this early review is twofold. First, the process would allow the state, NOAA and EPA to discuss the state's approach to certain program elements before the state invests substantial resources in program development. Second, it would help states set priorities and focus early on the final program, particularly on elements, such as enforceable policies and mechanisms, that may take time to adopt. Threshold reviews may take the form of informal consultations or a more formal process. The requirements for each type of review are discussed below.

Informal Review

The first type of threshold review would be an informal consultation between a state and NOAA and EPA. The informal threshold review should occur as early in the program development process as is practical.

A state would initiate the threshold review by developing a threshold review package that briefly describes how it expects to address the requirements for the coastal nonpoint program. NOAA and EPA will provide additional information for states to use in preparing for the threshold review.

NOAA and EPA will review the information and will work with the state coastal and nonpoint agencies to refine the state's approach, as necessary. Public participation in an informal threshold review is not required; however, states may decide to involve the public in some aspects of the process.

Formal Review

States may wish to undertake a more formal review of specific program elements prior to submitting their final program. NOAA and EPA may issue preliminary findings on the approvability of elements of the program. The purpose of these findings would be to increase the predictability of the final review process, although these findings would still be subject to the outcome of review of the program in its entirety.

As with the informal review, a more formal review is optional. However, if a state wishes to take advantage of this form of threshold review, it should submit, at a minimum, the following information: a description of the portion(s) of the coastal nonpoint program which the state wishes to have reviewed, an analysis of how that portion(s) meets the program requirements, the specific management measures addressed by that portion(s) of the program, a description of opportunities for public review and comment, and to the extent possible, how that portion(s) would fit in with and relate to the remainder of the program.

Unlike the informal threshold review, the formal review process must include opportunities for public participation and review. Prior to seeking formal review, the state must provide a minimum period of 30 days in which the public is given the opportunity to review and comment upon all portions of the program being submitted to NOAA and EPA for their preliminary findings. The public notice for the review period must indicate that the state is seeking such findings from the Federal agencies on the specific portions of its coastal nonpoint program. It must also include a description of the submitted portions and how they address the 6217 requirements. NOAA and EPA also expect the state to consider any comments received prior to finalizing the submitted portion(s) of the program.

NOAA and EPA will review the submissions and determine, as a preliminary matter, whether they meet the specified program requirements. NOAA and EPA will provide the state with written preliminary findings. Elements that have received preliminary findings would still be subject to the final approval process, including public participation, as part of the state's submission of its final coastal nonpoint program.

IV.C. Conditional Approvals

States are expected to submit a coastal nonpoint pollution control program that meets all the requirements of section 6217 at the time of the statutory deadline for program submission. However, NOAA and EPA recognize that in limited situations, a state might submit a program for which all state enforceable policies and mechanisms necessary to implement the applicable program requirements are in place, but that will require further development of state, regional, or local authorities, or administrative mechanisms, to ensure close coordination with existing plans and programs as required by 6217(a)(2). In other cases, a state might have a substantial majority of the required state enforceable policies and mechanisms in place, but need additional time to develop other state enforceable policies and mechanisms to ensure implementation of all applicable program requirements.

In either situation, NOAA and EPA may elect to exercise their discretion and grant conditional approval of the state coastal nonpoint program. Final approval of the program would be conditioned upon the state's ability to demonstrate that all necessary enforceable policies and mechanisms are in place. It should be noted, however, that a conditional approval will not postpone the date by which NOAA and EPA expect full implementation of the (g) measures. As discussed in section IV.D. below, these measures are to be fully implemented within three years of the first Federal approval action regardless of whether that approval is final or conditional.

Conditional approval of the program will be granted only in situations where the state can demonstrate its ability to ensure adoption of the necessary regulations or local ordinances or obtain state authorities for the remaining portions of the program. NOAA and EPA will consider the following factors in evaluating a state's submittal for conditional approval:

- Scope and significance of nonpoint sources addressed and the geographic coverage for the enforceable policies and mechanisms already in place;

- Status of efforts to date to obtain the remaining enforceable policies and mechanisms;

- The state's plan and reasonable timetable for obtaining the remaining enforceable policies and mechanisms; and,

- The presence, in the submitted program, of enforceable policies and mechanisms for additional management measures to be implemented immediately to protect and improve coastal water quality.

In cases in which NOAA and EPA grant conditional approval of a state's program, the state and local enforceable policies or mechanisms necessary to satisfy the conditions will be required to be adopted within one year from the date of conditional approval. Under very limited circumstances, NOAA and EPA may grant a state an additional year to obtain the required enforceable policies and mechanisms. If the state is able to satisfy the conditions within the required period, final approval of the program will be granted. Conditional approval does not alter the program implementation schedule described in section IV.D. below.

If NOAA and EPA find that a state fails to submit an approvable program or fails to meet the conditions for full approval, both section 319 and section 306 funds will be withheld according to the schedule described below.

IV.D. Schedule for Program Implementation

NOAA and EPA expect states to fully implement management measures, including alternative measures in conformity with the measures specified in the (g) guidance, within three years of Federal approval of the program and to fully implement additional measures within eight years of that Federal approval.[15] That is, if state

[15] "Federal approval" as used in this section means the first Federal approval action, whether final or conditional. For states receiving conditional approval, the implementation schedule begins to run at the time that conditional, rather than final, approval is granted.

programs are submitted in July, 1995 and approved by NOAA and EPA in January, 1996, the (g) measures must be fully implemented by January, 1999 and the additional measures by January, 2004. The period for implementation of additional measures includes a two year period for evaluating the implementation of the (g) measures and a three year period for implementing the additional management measures.

Under the statute, the purpose of the states' coastal nonpoint programs is to protect and restore coastal waters. This purpose is advanced by establishing a schedule that requires management measure implementation as soon as possible. In addition, NOAA and EPA believe that states should begin implementing certain additional management measures at the time of program approval to ensure that the statutory goal of attaining and maintaining coastal water quality standards is achieved. However, it is recognized that it may be necessary to defer implementation of other additional management measures until the (g) measures are in place and their effectiveness is monitored. The statute also requires continuing revision of the additional management measures to ensure that water quality standards are met.

For new sources, NOAA and EPA interpret full implementation to mean that new sources within each identified nonpoint source category or subcategory would be subject to the management measures at the time of Federal approval. Full implementation of management measures for existing sources (e.g., existing agricultural operations or existing urban development) means that each identified category and subcategory of existing sources is expected to implement the management measures to which they are subject not later than three years after Federal approval.

The state coastal nonpoint program should include milestones established at appropriate intervals within the three year implementation period, by which progress toward full implementation can be assessed in terms of management measures in place and water quality protection achieved. This schedule should ensure that sources having the most significant impact on coastal waters are addressed first. NOAA and EPA will monitor progress of state implementation as part of program and grant reporting requirements under section 319 of the CWA, section 306 of the CZMA, and regular program evaluations under section 312 of the CZMA. States not making satisfactory progress in meeting their milestones may be subject to loss of funds awarded under section 319, as well as to sanctions imposed under section 312 of the CZMA.

State coastal nonpoint programs must also include a schedule and milestones for implementation of additional measures. Implementation of additional management measures for critical areas and for those land uses (sources) for which state authorities already require management measures in conformity with the (g) management measures but where coastal water quality is still threatened or impaired, should begin at the time of Federal approval.

IV.E. Program Approval Standards, Implementation and Penalties

Both EPA and NOAA will base their review of a state's coastal nonpoint program on whether the state has met the requirements of the statute. NOAA and EPA will perform their review consistent with the interpretation set forth in this guidance. NOAA and EPA will consult with the states during the six month review period above. The states will have an opportunity to amend their submission, if necessary, subject to the public participation requirements and time constraints.

If either NOAA or EPA determines that a state has failed to submit an approvable coastal nonpoint program, the relevant penalties will be levied both on section 306 coastal management grants and section 319 nonpoint source grants. The penalties start at 10% in fiscal year 1996, and increase to 15% in FY 1997, 20% in FY 1998, and 30% in FY 1999 and each fiscal year thereafter. In the case of the coastal zone management program, the penalty is based upon the grants otherwise available to a state in the current fiscal year. In the case of the section 319 nonpoint source management program, the penalty is based on the grant amount awarded to the state for the preceding fiscal year. Given the joint approval process, no state will experience penalties to only one program. Funds withheld by NOAA and EPA will be made available to states with approved coastal nonpoint programs.

APPENDICES

VOL 12

6517

APPENDIX A: Section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990

P.L. 101-508

SEC. 6217. PROTECTING COASTAL WATERS.

(a) IN GENERAL.–

(1) PROGRAM DEVELOPMENT.–Not later than 30 months after the date of the publication of final guidance under subsection (g), each State for which a management program has been approved pursuant to section 306 of the Coastal Zone Management Act of 1972 shall prepare and submit to the Secretary and the Administrator a Coastal Nonpoint Pollution Control Program for approval pursuant to this section. The purpose of the program shall be to develop and implement management measures for nonpoint source pollution to restore and protect coastal waters, working in close conjunction with other State and local authorities.

(2) PROGRAM COORDINATION.–A State program under this section shall be coordinated closely with State and local water quality plans and programs developed pursuant to sections 208, 303, 319, and 320 of the Federal Water Pollution Control Act (33 U.S.C. 1288, 1313, 1329, and 1330) and with State plans developed pursuant to the Coastal Zone Management Act of 1972, as amended by this Act. The program shall serve as an update and expansion of the State nonpoint source management program developed under section 319 of the Federal Water Pollution Control Act, as the program under that section relates to land and water uses affecting coastal waters.

(b) PROGRAM CONTENTS.–Each State program under this section shall provide for the implementation, at a minimum, of management measures in conformity with the guidance published under subsection (g), to protect coastal waters generally, and shall also contain the following:

(1) IDENTIFYING LAND USES.–The identification of, and a continuing process for identifying, land uses which, individually or cumulatively, may cause or contribute significantly to a degradation of–

(A) those coastal waters where there is a failure to attain or maintain applicable water quality standards or protect designated uses, as determined by the State pursuant to its water quality planning processes; or

(B) those coastal waters that are threatened by reasonably foreseeable increases in pollution loadings from new or expanding sources.

(2) IDENTIFYING CRITICAL COASTAL AREAS.–The identification of, and a continuing process for identifying, critical coastal areas adjacent to coastal waters referred to in paragraph (1)(A) and (B), within which any new land uses or substantial expansion of existing land uses shall be subject to management measures in addition to those provided for in subsection (g).

(3) MANAGEMENT MEASURES.–The implementation and continuing revision from time to time of additional management measures applicable to the land uses

and areas identified pursuant to paragraphs (1) and (2) that are necessary to achieve and maintain applicable water quality standards under section 303 of the Federal Water Pollution Control Act (33 U.S.C. 1313) and protect designated uses.

(4) TECHNICAL ASSISTANCE.–The provision of technical and other assistance to local governments and the public for implementing the measures referred to in paragraph (3), which may include assistance in developing ordinances and regulations, technical guidance, and modeling to predict and assess the effectiveness of such measures, training, financial incentives, demonstration projects, and other innovations to protect coastal water quality and designated uses.

(5) PUBLIC PARTICIPATION.–Opportunities for public participation in all aspects of the program, including the use of public notices and opportunities for comment, nomination procedures, public hearings, technical and financial assistance, public education, and other means.

(6) ADMINISTRATIVE COORDINATION.–The establishment of mechanisms to improve coordination among State agencies and between State and local officials responsible for land use programs and permitting, water quality permitting and enforcement, habitat protection, and public health and safety, through the use of joint project review, memoranda of agreement, or other mechanisms.

(7) STATE COASTAL ZONE BOUNDARY MODIFICATION.–A proposal to modify the boundaries of the State coastal zone as the coastal management agency of the State determines is necessary to implement the recommendations made pursuant to subsection (e). If the coastal management agency does not have the authority to modify such boundaries, the program shall include recommendations for such modifications to the appropriate State authority.

(c) PROGRAM SUBMISSION, APPROVAL, AND IMPLEMENTATION.–

(1) REVIEW AND APPROVAL.–Within 6 months after the date of submission by a State of a program pursuant to this section, the Secretary and the Administrator shall jointly review the program. The program shall be approved if–

(A) the Secretary determines that the portions of the program under the authority of the Secretary meet the requirements of this section and the Administrator concurs with that determination; and

(B) the Administrator determines that the portions of the program under the authority of the Administrator meet the requirements of this section and the Secretary concurs with that determination.

(2) IMPLEMENTATION OF APPROVED PROGRAM.–If the program of a State is approved in accordance with paragraph (1), the State shall implement the program, including the management measures included in the program pursuant to subsection (b), through–

(A) changes to the State plan for control of nonpoint source pollution approved under section 319 of the Federal Water Pollution Control Act; and

(B) changes to the State coastal zone management program developed under section 306 of the Coastal Zone Management Act of 1972, as amended by this Act.

(3) WITHHOLDING COASTAL MANAGEMENT ASSISTANCE.–If the Secretary finds that a coastal State has failed to submit an approvable program as required by this section, the Secretary shall withhold for each fiscal year until such

a program is submitted a portion of grants otherwise available to the State for the fiscal year under section 306 of the Coastal Zone Management Act of 1972, as follows:

(A) 10 percent for fiscal year 1996.
(B) 15 percent for fiscal year 1997.
(C) 20 percent for fiscal year 1998.
(D) 30 percent for fiscal year 1999 and each fiscal year thereafter.

The Secretary shall make amounts withheld under this paragraph available to coastal States having programs approved under this section.

(4) WITHHOLDING WATER POLLUTION CONTROL ASSISTANCE.–If the Administrator finds that a coastal State has failed to submit an approvable program as required by this section, the Administrator shall withhold from grants available to the State under section 319 of the Federal Water Pollution Control Act, for each fiscal year until such a program is submitted, an amount equal to a percentage of the grants awarded to the State for the preceding fiscal year under that section, as follows:

(A) For fiscal year 1996, 10 percent of the amount awarded for fiscal year 1995.

(B) For fiscal year 1997, 15 percent of the amount awarded for fiscal year 1996.

(C) For fiscal year 1998, 20 percent of the amount awarded for fiscal year 1997.

(D) For fiscal year 1999 and each fiscal year thereafter, 30 percent of the amount awarded for fiscal year 1998 or other preceding fiscal year.

The Administrator shall make amounts withheld under this paragraph available to States having programs approved pursuant to this subsection.

(d) TECHNICAL ASSISTANCE.–The Secretary and the Administrator shall provide technical assistance to coastal States and local governments in developing and implementing programs under this section. Such assistance shall include–

(1) methods for assessing water quality impacts associated with coastal land uses;

(2) methods for assessing the cumulative water quality effects of coastal development;

(3) maintaining and from time to time revising an inventory of model ordinances, and providing other assistance to coastal States and local governments in identifying, developing, and implementing pollution control measures; and

(4) methods to predict and assess the effects of coastal land use management measures on coastal water quality and designated uses.

(e) INLAND COASTAL ZONE BOUNDARIES.–

(1) REVIEW.–The Secretary, in consultation with the Administrator of the Environmental Protection Agency, shall, within 18 months after the effective date of this title, review the inland coastal zone boundary of each coastal State program which has been approved or is proposed for approval under section 306 of the Coastal Zone Management Act of 1972, and evaluate whether the State's coastal zone boundary extends inland to the extent necessary to control the land and water uses that have a significant impact on coastal waters of the State.

(2) RECOMMENDATION.–If the Secretary, in consultation with the

Administrator, finds that modifications to the inland boundaries of a State's coastal zone are necessary for that State to more effectively manage land and water uses to protect coastal waters, the Secretary, in consultation with the Administrator, shall recommend appropriate modifications in writing to the affected State.

(f) FINANCIAL ASSISTANCE.–

(1) IN GENERAL.–Upon request of a State having a program approved under section 306 of the Coastal Zone Management Act of 1972, the Secretary, in consultation with the Administrator, may provide grants to the State for use for developing a State program under this section.

(2) AMOUNT.–The total amount of grants to a State under this subsection shall not exceed 50 percent of the total cost to the State of developing a program under this section.

(3) STATE SHARE.–The State share of the cost of an activity carried out with a grant under this subsection shall be paid from amounts from non-Federal sources.

(4) ALLOCATION.–Amounts available for grants under this subsection shall be allocated among States in accordance with regulations issued pursuant to section 306(c) of the Coastal Zone Management Act of 1972, except that the Secretary may use not more than 25 percent of amounts available for such grants to assist States which the Secretary, in consultation with the Administrator, determines are making exemplary progress in preparing a State program under this section or have extreme needs with respect to coastal water quality.

(g) GUIDANCE FOR COASTAL NONPOINT SOURCE POLLUTION CONTROL.–

(1) IN GENERAL.–The Administrator, in consultation with the Secretary and the Director of the United States Fish and Wildlife Service and other Federal agencies, shall publish (and periodically revise thereafter) guidance for specifying management measures for sources of nonpoint pollution in coastal waters.

(2) CONTENT.–Guidance under this subsection shall include, at a minimum-

(A) a description of a range of methods, measures, or practices, including structural and nonstructural controls and operation and maintenance procedures, that constitute each measure;

(B) a description of the categories and subcategories of activities and locations for which each measure may be suitable;

(C) an identification of the individual pollutants or categories or classes of pollutants that may be controlled by the measures and the water quality effects of the measures;

(D) quantitative estimates of the pollution reduction effects and costs of the measures;

(E) a description of the factors which should be taken into account in adapting the measures to specific sites or locations; and

(F) any necessary monitoring techniques to accompany the measures to assess over time the success of the measures in reducing pollution loads and improving water quality.

(3) PUBLICATION.–The Administrator, in consultation with the Secretary, shall publish–

(A) proposed guidance pursuant to this subsection not later than 6 months after the date of the enactment of this Act; and

(B) final guidance pursuant to this subsection not later than 18 months after such effective date.

(4) NOTICE AND COMMENT.–The Administrator shall provide to coastal States and other interested persons an opportunity to provide written comments on proposed guidance under this subsection.

(5) MANAGEMENT MEASURES.–For purposes of this subsection, the term "management measures" means economically achievable measures for the control of the addition of pollutants from existing and new categories and classes of nonpoint sources of pollution, which reflect the greatest degree of pollutant reduction achievable through the application of the best available nonpoint pollution control practices, technologies, processes, siting criteria, operating methods, or other alternatives.

(h) AUTHORIZATIONS OF APPROPRIATIONS.–

(1) ADMINISTRATOR.–There is authorized to be appropriated to the Administrator for use for carrying out this section not more than $1,000,000 for each of fiscal years 1992, 1993, and 1994.

(2) SECRETARY.–(A) Of amounts appropriated to the Secretary for a fiscal year under section 318(a)(4) of the Coastal Zone Management Act of 1972, as amended by this Act, not more than $1,000,000 shall be available for use by the Secretary for carrying out this section for that fiscal year, other than for providing in the form of grants under subsection (f).

(B) There is authorized to be appropriated to the Secretary for use for providing in the form of grants under subsection (f) not more than-

(i) $6,000,000 for fiscal year 1992;

(ii) $12,000,000 for fiscal year 1993;

(iii) $12,000,000 for fiscal year 1994; and

(iv) $12,000,000 for fiscal year 1995.

(i) DEFINITIONS.–In this section–

(1) the term "Administrator" means the Administrator of the Environmental Protection Agency;

(2) the term "coastal State" has the meaning given the term "coastal state" under section 304 of the Coastal Zone Management Act of 1972 (16 U.S.C. 1453);

(3) each of the terms "coastal waters", and "coastal zone" has the meaning that term has in the Coastal Management Act of 1972;

(4) the term' "coastal management agency" means a State agency designated pursuant to section 306(d)(6) of the Coastal Zone Management Act of 1972;

(5) the term "land use" includes a use of waters adjacent to coastal waters; and

(6) the term "Secretary" means the Secretary of Commerce.

VOL 12

6522

APPENDIX B: National Pollutant Discharge Elimination System

A. Urban Runoff

Historically, there have always been overlaps and ambiguity between programs designed to control urban runoff nonpoint sources and those designed to control urban stormwater point sources. For example, runoff may often originate as a nonpoint source but ultimately be channelized and become a point source. Two statutory requirements have resulted in additional confusion about program applicability. Section 402(p) of the Clean Water Act, establishes permit requirements for certain municipal and industrial storm water discharges, and Section 6217 of CZARA, which requires EPA to promulgate and States to implement management measures to control nonpoint pollution in coastal waters. The discussion below is intended to clarify the relationship between these two programs and describe the scope and applicability of the coastal nonpoint program to urban runoff in coastal areas.

B. The Storm Water Permit Program

The storm water permits program is a two-phased program enacted by Congress in 1987 under section 402(p) of the Clean Water Act. Under Phase I, National Pollutant Discharge Elimination System (NPDES) permits are required to be issued for municipal separate storm sewers serving large or medium-sized populations (greater than 250,000 or 100,000 people, respectively), and for storm water discharges associated with industrial activity. Permits are also to be issued, on a case-by-case basis, if EPA or a State determines that a storm water discharge contributes to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States. EPA published a rule implementing Phase I on November 16, 1990.

Under Phase II, EPA is to prepare two reports to Congress which assess remaining storm water discharges; determine, to the maximum extent practicable, the nature and extent of pollutants in such discharges; and establish procedures and methods to control storm water discharges to the extent necessary to mitigate impacts on water quality. Then, EPA is to issue regulations which designate storm water discharges, in addition to those addressed in Phase I, to be regulated to protect water quality, and EPA is to establish a comprehensive program to regulate those designated sources. The program is required to establish (A) priorities, (B) requirements for State storm water management programs, and (C) expeditious deadlines.

These regulations were to have been issued by EPA not later than October 1, 1992. However, due to the numerous discharges to be covered by the studies and regulations, EPA has not yet issued these regulations.

C. Scope of Urban Runoff in Coastal Nonpoint Pollution Control Programs

As discussed above, Congress enacted section 6217 of CZARA in late 1990 to require that States develop coastal nonpoint pollution control programs that are in conformity with the management measures guidance published by EPA. Although EPA's management measures guidance includes measures to address certain urban runoff, EPA is excluding from coverage under this Section 6217(g) guidance all storm water discharges that are covered by Phase I of the NPDES storm water permit program. Thus EPA is excluding any discharge from a municipal separate storm sewer systems serving a population of 100,000 or more; any point source discharge associated with a permitted industrial activity; any discharge which has already been permitted; and any discharge for which EPA or the State makes a determination that the storm water discharge contributes to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States. All of these activities are clearly addressed by the storm water permit program and thus are excluded from the coastal nonpoint pollution control program.

EPA is adopting a different approach with respect to other (non-Phase I) storm water discharges. At present, EPA has not yet promulgated its regulations that would designate additional storm water discharges, beyond those regulated in Phase I, that will be required to be regulated in Phase II. It is thus not possible to determine at this point which additional storm water discharges may be regulated by the NPDES program and which will not. Furthermore, due to the great number of such discharges, it is likely that it would take many years to permit all of these discharges, even if EPA allows for relatively expeditious State permitting approaches such as the use of general permits.

Therefore, to give effect to Congressional intent that coastal waters receive special and expeditious attention from EPA, NOAA, and the States, discharges that potentially may be ultimately covered by Phase II of the storm water permits program are covered by the management measures guidance and will be addressed by the coastal nonpoint pollution control programs. Any storm water discharge that ultimately is issued an NPDES permit will become exempt from this guidance and from the coastal nonpoint pollution control program at the time that the permit is issued.

In addition, we note that some other activities are exempt from the NPDES permit requirements and thus are covered by the coastal nonpoint pollution control program. Most important, construction activities on sites less than five acres, which are not currently covered by the NPDES Phase I stormwater application requirements, are covered by the coastal nonpoint pollution control program.[1] Similarly, discharges from wholesale, retail, service or commercial activities, including gas stations, which are not covered by Phase I of the NPDES stormwater program, are covered instead by the

[1] The provision exempting construction activities on sites less than five acres from the NPDES permit requirements is currently being reviewed by EPA in response to a recent court decision.

VOL 12

6524

coastal nonpoint pollution control program. Further, on-site disposal systems, which are generally not covered by the stormwater permit program, are covered by the coastal nonpoint pollution control program.

Finally, EPA emphasizes that while different legal authorities may apply to different situations, the goals of the NPDES and CZARA programs are complementary. Many of the techniques and practices used to control urban runoff are equally applicable to both programs. Yet, the programs do not work identically. In the interest of consistency and comprehensiveness, States have the option to implement the CZARA section 6217(g) management measures throughout the State's coastal zone, including Phase I stormwater areas, as long as the NPDES requirements are met for areas subject to NPDES requirements. In general, States are encouraged to develop consistent approaches to addressing urban runoff throughout their coastal zones.

D. Marinas

Another specific overlap between the stormwater program and this coastal nonpoint source program occurs in the case of marinas. EPA intends that the management measures guidance for marinas and recreational boating apply only to sources that are not currently required to apply for and receive an NPDES permit. In the (g) guidance, EPA has attempted to avoid addressing marina activities that are clearly regulated point source discharges. Any stormwater discharge that is ultimately issued an NPDES permit will become exempt from this guidance and from the coastal nonpoint pollution control program at the time that the permit is issued.

Marinas contributing stormwater runoff to municipal sewer systems serving a population of 100,000 or more are a part of the municipal NPDES permit and are not covered by the coastal nonpoint source program. Marinas are also required to obtain permits for those portions of the marina that are involved in vehicle maintenance (including vehicle rehabilitation, mechanical repairs, painting, fueling, and lubrication) and equipment cleaning operations. However, many marinas are not currently required to apply for and receive NPDES permits. The (g) management measures are applicable to marinas and the parts of marinas that are not required to apply for NPDES permits.

E. Other Point Sources

Overlapping areas between the point source and nonpoint source programs occur in addition to storm water and marinas. For example, concentrated animal feeding operations that meet particular size or other criteria are defined and regulated as point sources under the section 402 permit program, while other confined animal feeding operations are not currently regulated as point sources. Overlaps may occur with respect to aspects of mining operations, oil and gas extraction, land disposal, and other activities.

EPA intends that the coastal nonpoint pollution control programs to be developed by the States apply only to sources that are not currently required to apply for and receive an NPDES permit, and that the management measures similarly apply only to sources that are not required to apply for and receive an NPDES permit. In the (g) guidance, EPA has attempted to avoid addressing activities that are regulated point source discharges.

APPENDIX E: Overview of Existing National Efforts to Control Nonpoint Source Pollution

Section III.G of this document describes the statutory requirement for administrative coordination. It also describes EPA's and NOAA's expectation that state coastal nonpoint source programs build on and complement, rather than duplicate and conflict with, other Federal statutory requirements and state-implemented programs. The following section describes several existing and on-going efforts to control nonpoint source pollution. State coastal zone and nonpoint source agencies are encouraged to work with these programs in implementing their coastal nonpoint programs.

EPA Programs

1. Clean Water Act Section 319 - Nonpoint Source Program

A number of local, state and Federal programs have been implemented over time to address nonpoint source pollution. However, the first national program to authorize Federal funding for the control of nonpoint sources began in 1987 when Congress passed the Water Quality Act of 1987, enacting section 319 of the Clean Water Act, which established a national program to control nonpoint sources of water pollution. Section 319 requires that, in order to be eligible for federal funding, states develop an assessment report detailing the extent of nonpoint pollution, and a management program specifying nonpoint source controls. Section 319 authorizes EPA to issue grants to states to assist them in implementing their nonpoint source management programs or portions of management programs that have been approved by EPA.

As of August 1992, all states and territories had approved nonpoint source assessments and management programs or portions of management programs. Congress appropriated $40 million in section 319 FY 1990 and $51 million in FY 1991 funds to assist States in implementing their management program.

2. Clean Water Act Section 320 - National Estuary Program

EPA also administers the National Estuary Program under section 320 of the Clean Water Act. This program focuses on point and nonpoint pollution in geographically targeted, high-priority estuarine waters. Under this program, EPA assists state, regional and local governments in developing estuary-specific comprehensive conservation and management plans that recommend corrective actions to restore and maintain estuarine water quality and to protect fish populations and other designated uses of these targeted waters. To date, seventeen estuaries have been designated as part of the National Estuary Program.

3. **Near Coastal Waters Program**

The Near Coastal Waters (NCW) Program serves as a primary vehicle for implementing environmental protection in coastal areas under a variety of programs and authorities. It is also the framework for coastal regions for carrying out Agency directives, strategic themes, and other initiatives not specifically related to distinct program issues. Examples of these cross-cutting themes include geographic targeting for management attention; pollution prevention; and setting priorities based on the expected efficacy of preventive measures as well as the magnitude of ecological or human health risks. Specific objectives include:

- directing and focusing EPA's coastal activities within priority geographic areas;
- promoting linkages among programs;
- encouraging a comprehensive approach to problem assessment and management; and
- maximizing environmental results.

The NCW Program is implemented through two basic components: specific national activities which provide direction, support, and oversight; and Regional development of NCW Strategies that serve to implement the Program within EPA's Regions and that are carried out through activities described in annual work-plans.

4. **Ground Water Protection Programs**

EPA has a number of programs, in addition to section 319, to control nonpoint source pollution of ground water. Since at least 1984, ground water protection programs have provided technical and financial assistance to states for the development of state ground-water strategies and, more recently, Ground Water Protection Programs. Under the Safe Drinking Water Act, EPA may designate sole source aquifers. These are aquifers that are the sole or principal of drinking water source for an area. At EPA's discretion, no commitment for federal funds can be made for projects that will contaminate these aquifers. In addition, the 1986 amendments to the Safe Drinking Water Act established a Wellhead Protection program. This program was created to protect ground waters that supply wells and wellfields that contribute to public drinking water supply systems. USDA and EPA are also cooperating under a program to assess private drinking water wells on farmsteads.

VOL 12

6533

5. **Pesticides Program**

EPA's pesticides program under the Federal Insecticide, Fungicide, and Rodenticide Act addresses some forms of nonpoint pollution. Among other things, this statute authorizes EPA to control pesticides that may threaten ground water and surface waters. In determining the appropriate regulatory approach for specific pesticides, EPA uses the following step-by-step approach:

1) EPA determines the pesticide's potential for leaching into ground and surface water; 2) if there is such potential, EPA considers whether establishing national label restrictions (enforceable under FIFRA) would adequately address leaching concerns (included in these restrictions can be classification of the pesticide as "restricted-use," which requires application by a trained, certified applicator; requirements for certain methods of application, safe handling, storage, and disposal; etc); 3) if these restrictions are not adequate to address the potential problem, EPA will determine whether providing states with the opportunity to develop Pesticide State Management Plans for the chemical will effectively address the unreasonable risk from pesticide contamination. In the event that Pesticide State Management Plans could not sufficiently reduce the risks to human health and the environment (i.e., an unreasonable risk remains), then EPA would resort to national cancellation of the pesticide.

Pesticide State Management Plans will be developed by state agriculture, water/environment, and health agencies and will prescribe pesticide application measures to protect ground water that is vulnerable to pesticide contamination. Required components of these Plans will include: state philosophy and goals, state roles and responsibilities, legal authority, resources, assessment and planning, monitoring, prevention, response, enforcement, public awareness and participation, information dissemination, and records and reporting.

Since areas to be managed under State Pesticides Management programs and coastal nonpoint programs may overlap in developing the coastal nonpoint programs' management measures for agricultural pesticides, state coastal zone and nonpoint source agencies should work with the State Lead Agency for Pesticides (or the state agency that has a lead role in developing and implementing the State Management Plan). Such coordination is necessary to ensure that program efforts and pesticide management measures and practices to protect ground and surface water, complement and are not in conflict with the pesticide label and with requirements in the Pesticide State Management Plans. (For instance, if a Pesticide State Management Plan prescribes a moratorium on pesticide use in one are, the coastal nonpoint program should not allow pesticide use in that area). In states where Pesticide State Management Plans have not been developed, planning efforts for the two programs should be closely coordinated.

6. Wetlands Protection Program

EPA's wetlands program also has undertaken a number of projects to increase awareness of the relationship between the protection and restoration of wetlands and nonpoint source control. In 1990, the agency developed guidance to encourage coordination of nonpoint sources and wetlands programs, both within EPA and the states, to attain water quality goals shared by the two programs. In addition, EPA has released guidance on how to ensure effective application of water quality standards to wetlands. Projects in this area include:

Efforts with other Federal Agencies: The Wetlands Division is working with several agencies to develop methods and transfer information on protecting and restoring wetlands in ways which can be expected to provide nonpoint source abatement benefits:

- The Wetlands Division is working with members of the Interagency Task Force on Floodplain Management and the Association of State Floodplain Managers to better protect and enhance the natural and beneficial values of the Nation's floodplain by promoting the concept of comprehensive or multi-objective river corridor management. Managing river corridors for multiple uses provides the opportunity for communities to simultaneously address nonpoint source pollution, water quality, flooding, recreation, habitat and any number of needs and challenges.

- The Wetlands Division is initiating a pilot project with USDA, the Fish and Wildlife Service, and non-profit groups to encourage landowner participation in USDA's Wetland Reserve Program. By working cooperatively, these groups will help landowners identify wetland restoration sites that will improve water quality as well as enhance other wetland values.

Development of technical and outreach materials: The Wetlands Division has worked with a number of other EPA offices and regions to develop materials that can increase awareness of the important role wetlands play in improving water quality.

- Publications include: "Livestock Grazing on Western Riparian Areas"; "Summary of Section 319(h) Wetlands and Riparian Projects for Fiscal Years 1990 and 1991"; and "Beyond the Estuary: The Importance of Upstream Wetlands to Estuarine Processes" which focuses on the beneficial effects that upstream wetlands have on the downstream water quality in estuaries.

- EPA has released technical guidance to States on how to ensure effective application of water quality standards to wetlands. The development of standards provides the foundation of a broad range of water quality management activities including, but not limited to, monitoring under Section 305(b), permitting under

Sections 402 and 404, water quality certification under Section 401, and control of nonpoint pollution under Section 319.

- The Wetlands Division is developing a manual on best management practices to protect wetlands from excessive stormwater runoff and to avoid overloading their water quality improvement functions.

Criteria to address nonpoint source pollution: EPA is providing support for the development of criteria to address the many types of nonpoint source pollutants including nutrients, clean sediment, and organic contaminants (e.g., pesticides). The Wetlands Division is assisting in the development of wildlife criteria applicable to all waterbody types and biological criteria for wetlands.

Wetlands Regional Contacts: For more information regarding regional or state initiatives, contact the EPA regional wetlands coordinator.

NOAA Programs

Coastal Zone Management Program

The Coastal Zone Management Act of 1972 established a program for states and territories to voluntarily develop comprehensive programs to protect and manage coastal resources. In order to receive Federal approval and implementation funding, states and territories must demonstrate that they have programs, including enforceable policies that are sufficiently comprehensive and specific to regulate land uses, water uses, and coastal development; and to resolve conflicts among competing uses. In addition, they must have the authority to implement the enforceable policies. The programs operates within a coastal zone bound any which includes coastal waters and those which have a direct one significant impact on coastal waters.

There are currently 29 federally approved state and territorial programs. Despite institutional differences, each program must protect and manage important coastal resources, including: wetlands, estuaries, beaches, dunes, barrier islands, coral reefs, and fish and wildlife and their habitats. Resource management and protection is accomplished in a number of ways through state laws, regulations, permits, and local plans and zoning ordinances.

While water quality protection is integral to the management of many coastal resources, it was not specifically cited as a purpose or policy of the original statute. The Coastal Zone Act Reauthorization Amendments of 1990 specifically charged state coastal programs, as well as state nonpoint source programs, with addressing nonpoint source pollution affecting coastal water quality.

USDA Programs

The U.S. Department of Agriculture's Agricultural Stabilization and Conservation Service (ASCS), Soil Conservation Service (SCS) and Extension Service administer a number of programs that contribute to reducing nonpoint pollution from agricultural production.

Agricultural Conservation Program

The Agricultural Conservation Program, administered by ASCS, provides cost-share funds to farmers and ranchers to install conservation practices. The program has several goals including: conserving soil and water, improving water quality, protecting and maintaining productive farm and ranch land, and preserving and developing wildlife habitat.

ASCS also administers the Conservation Reserve Program (CRP), designed to protect the nation's most highly erodible land and to protect and improve water quality. Under the CRP, farmers are reimbursed for retiring highly erodible and environmentally sensitive croplands from production under ten year contracts. Water quality improvements occur as lands are taken out of production because of lower fertilizer and pesticide applications and because reductions in soil erosion decrease sediment loadings to water. Land enrolled in the reserve program also provides habitat and other environmental benefits.

Criteria for the conservation reserve program have been expanded to include environmentally sensitive lands such as filter strips, wetlands and wellhead protection areas.

Soil Conservation Service

The Soil Conservation Services (SCS) is the technical arm of USDA. SCS provides technical assistance to conservation districts throughout the U.S. Under the President's Water Quality Initiative, started in 1989, SCS is focusing some of its technical assistance on a number of demonstration projects to address water quality problems. SCS staff are also located in many of EPA's Regional Offices to provide technical assistance and support to the States and EPA. SCS is also providing accelerated technical assistance to multi-state, regional projects such as the Chesapeake Bay Program, the Gulf of Mexico, the Great Lakes National Program, Land and Water 201, and the National Estuary Program.

Nonpoint Source Hydrologic Unit Areas

In selected agricultural watersheds and aquifer recharge areas, SCS, Extension Service, and cooperating federal, state and local agencies will provide technical assistance and conservation planning to help farmers and ranchers meet state water quality goals without undue economic hardship. These hydrologic units are selected based on: significance of the agricultural sources of pollution, relative predominance of pollutants such as pesticides, nutrients, and animal wastes, and conformance with other water quality efforts. Findings on the water quality effects of selected conservation practices will provide a basis for expanding applications of such practices to other areas with similar water quality problems.

Forest Service

The Forest Service managers 191 million acres of public forest and range land for multiple use purposes. These lands comprise the National Forest System. EPA and the Forest Service held a joint technical workshop in Oregon this past winter on sediment and water quality. This meeting reflects the increased concern regarding the potential impacts of sediment production from forest management activities on water quality and aquatic life.

President's Water Quality Initiative

In 1989, President Bush launched an initiative to protect ground and surface water from contamination of fertilizers and pesticides. Congress has funded the initiative in the past several years. USDA, EPA, USGS, and NOAA are all working together on this initiative through a series of work groups. Through this initiative, a number of watershed projects have begun to address fertilizer and pesticides problems. The agencies are tracking the implementation progress in these watersheds.

U.S. Geological Survey

EPA and the U.S. Geological Survey have signed a memorandum of understanding (MOU) pledging cooperation and collaboration on water quality monitoring and assessment activities. Both agencies expend much effort on monitoring and assessment activities and the MOU is a tool to coordinate these efforts.

APPENDIX F: Designated Uses and Support Levels

DESIGNATED USES

Wildlife	Fish and wildlife
Fishery	Warmwater Fishery Coldwater Fishery
Shellfishery	Shellfish protection
Drinking water	Domestic water supply
Agriculture	Agriculture Irrigation Livestock watering
Industry	Industrial
Recreation	Recreation Primary contact Secondary contact Noncontact
Navigation	Navigation
High Quality	High Quality Nondegradation

SUPPORT LEVELS

Fully Supported	= all uses supported
Partial Support	= one use not supported
Non-support	= 2 or more uses not supported
Threatened	= all uses supported, but one or more uses may not be fully supported in the future (unless additional management measures are implemented) because of anticipated new or expanded sources

VOL 12

6540

APPENDIX G: State Coastal Nonpoint Program Submission

1. DESCRIBE PROGRAM GOALS AND OBJECTIVES

The introduction should include a description of the magnitude and distribution of sources of nonpoint pollution in the 6217 management area.

2. DESCRIBE OVERALL PROGRAM COMPONENTS

a. **§6217 Management Area**
Respond to NOAA's boundary recommendation.
[§6217(b)(7); Program Guidance, p.9]

b. **Coordination Mechanisms**
Describe the mechanisms which have been established to coordinate among the state, regional, and local agencies responsible for implementing portions of the program. [§6217(b)(6); Program Guidance, p.33]

c. **Public Participation**
Describe the process used to ensure full public participation in the development and implementation of the program. [§6217(b)(5); Program Guidance, p.32]

d. **Technical Assistance**
Describe the state program for technical assistance to localities and the public. [§6217(b)(4); Program Guidance, p.31]

e. **Water Quality Monitoring**
Describe activities to monitor the effectiveness of management measures (see Chapter 8 of the (g) Guidance). States may choose to design specific monitoring programs for individual source categories.

3. DESCRIBE MANAGEMENT MEASURES "in conformity with" (g) GUIDANCE

State programs should address each management measure identified in the (g) Guidance for the six source categories: agriculture, forestry, urban, marinas, hydromodification, wetlands and riparian areas. The following information should cover each management measure, but may be provided by source category, subcategory, or individual management measure.

a. **Covered Sources**
Identify nonpoint source categories and subcategories in the 6217 management area. Identify the categories or subcategories specified in the (g) Guidance which 1) do not exist in the 6217 management area or 2) may be excluded based on Program Guidance criteria, p.13.

b. **Management Measures**
Identify the (g) Guidance measure or alternative measure to be implemented. Alternative measure must include technical documentation. [Program Guidance, p.15]

c. **Management Practices**
Describe state practices to implement measure or the process for selecting practices to meet site-specific conditions. Include operation and maintenance practices where appropriate.

d. **Lead Agency**
Identify the lead agency and cooperating agencies responsible for implementation of the management measure. Identify available resources (staff, funding, etc.)

e. **Enforceable Policies and Mechanisms**
Cite state and local authority to ensure implementation of the management measure, including inspection and monitoring provisions. If the program relies on local or regional authorities, cite state oversight authority to ensure implementation. [§306(d)(16); Program Guidance, p.34]

f. **Schedule**
Describe schedule, including milestones, to ensure implementation of management measures for existing sources within three years of program approval or conditional approval. New sources are subject to management measures at time of program approval. [Program Guidance, p.44]

4. DESCRIBE ADDITIONAL MANAGEMENT MEASURES

Describe the implementation of additional management measures including the following information:

a. **Impaired and Threatened Coastal Waters**
Identify impaired and threatened coastal waters using existing water quality assessments. [§6217(b)(1)(a); Program Guidance, p.23]

b. **Land Uses**
Identify land uses in the 6217 management area which individually or cumulatively may cause or contribute to a degradation of coastal waters. Use(g) Guidance source categories as a starting point and add others appropriate to state conditions. [§6217(b)(1); Program Guidance, p.24]

c. **Critical Coastal Areas**
Identify and map, critical areas adjacent to impaired and threatened coastal waters. [§6217(b)(2); Program Guidance, p.25]

d. **Additional Management Measures**
Describe measures that will be implemented at time of program approval 1) in critical areas and 2) in cases where (g) Guidance measures (or their equivalent) are fully implemented for certain source categories or subcategories, but water quality threats or impairments persist.

Describe process for determining the need for additional measures to meet water quality standards even after implementation of (g) Guidance measures. Describe process for revising measures.

e. **Enforceable Policies and Mechanisms**
Cite state and local authority to ensure implementation of the management measure, including inspection and monitoring provisions. [§306(d)(16); Program Guidance, p.34]

f. **Schedule**
Describe schedule, including milestones, to ensure implementation of management measures for existing sources within three years of program approval or conditional approval. [Program Guidance, p.44]

Appendix H: Demonstrated Benefits of Trading

I. SIGNIFICANT TECHNICAL DOCUMENTS

A. Emissions Trading: An Exercise in Reforming Pollution Policy, 1985. T.H. Tietenberg.

In Emissions Trading: An Exercise in Reforming Pollution Policy, Tietenberg references studies that show that trading may be used in lieu of command-and-control approaches to limit biological oxygen demand in water. The studies demonstrate that trading can lower costs by factors of 1.12 to 3.13 without affecting benefits. Tietenberg also discusses a variety of air emission studies that illustrate that trading can lower the costs of achieving environmental objectives by factors ranging from 1.07 to 22.

B. "Financial Cost Effectiveness of Point and Nonpoint Source Nutrient Reduction Technologies in the Chesapeake Bay Basin," 1991. R. Camacho.

Trading can offer very large cost savings to sources while achieving quality goals. In order to offer gains to all market participants, incremental costs of pollution control must differ between sources. Camacho demonstrates this in "Financial Cost Effectiveness of Point and Nonpoint Source Nutrient Reduction Technologies in the Chesapeake Bay Basin." The article states that for nitrogen and phosphorus, the cost effectiveness of controls differs by as much as a factor ten. This differential provides the necessary economic incentive for trading to be effective.

C. The Private Use of Public Interest, 1975. C. Schultze

Schultze presents trading programs as a means of harnessing the private incentives of polluters for public purpose in The Private Use of Public Interest. Trading programs allow sources with low control costs to undertake additional abatement efforts in exchange for compensation from high-cost sources. More pollution abatement is therefore undertaken where it is cheapest, and less is undertaken where it is costly. Such a trading scheme minimizes the total cost of achieving loading reductions.

D. "Incentive Analysis for Clean Water Act Reauthorization: Point Source/Nonpoint Source Trading For Nutrient Discharge Reductions," 1992. USEPA.

"Incentive Analysis for Clean Water Act Reauthorization: Point Source/Nonpoint Source Trading For Nutrient Discharge Reductions" provides an assessment of trading potential for nutrient discharges to surface waters. The report states that

VOL 12

6543

over 900 water quality-limited waterbodies could potentially benefit from trading under current conditions, and that the best opportunities are for trading nutrient allocations.

E. "Point Nonpoint Source Trading of Pollution Abatement: Choosing the Right Trading Ratio," 1992. A. Malik.

The question of the right trading ratio for trades between point sources and nonpoint sources has been addressed by Malik et. al. in "Point Nonpoint Source Trading of Pollution Abatement: Choosing the Right Trading Ratio." Two types of uncertainty are recognized: the effectiveness of nonpoint source controls, and NPS loadings reductions attributable to weather. Uncertainty in the effectiveness of nonpoint source controls would justify higher trading ratios, which imply expected net reductions in loadings. The uncertainty attributable to weather, however, may justify lower ratios.

II. NOTABLE CASE STUDIES

A. Dillon Reservoir, Colorado

The Dillon Water Quality Management Plan established the nation's first point/nonpoint source phosphorus trading program. The program is driven by the reservoir's phosphorus limit and a perceived need to offset new nonpoint sources of phosphorus with phosphorus removals elsewhere in the watershed. A 2:1 trading ratio was established in which point sources received a credit of one additional pound of phosphorus above their allocation for every 2 pounds of phosphorus removed from a nonpoint source that existed before 1984. This ratio establishes a safety margin and has also been used in two trades to offset increased loadings from new nonpoint source discharges to the reservoir.

B. Tar-Pamlico, North Carolina

A point/nonpoint source trading program was developed as part of the overall nutrient management strategy of the Tar-Pamlico River Basin. Under the established rules of this trading program, it is anticipated that trading will achieve equivalent or better water quality than would have been achieved under originally proposed effluent limits. The trading program allows a coalition of point source discharges (the Basin Association) to fund less expensive nonpoint source controls, thus avoiding high compliance costs associated with major facility upgrades. Monies generated by trading go into a fund where they are subsequently allocated by the Division of Soil and Water Conservation for nonpoint source control implementation.

VOL 12

6544

VOL 12

C. Cherry Creek, Colorado

Several years ago, the citizens of Cherry Creek Reservoir in Colorado anticipated a significant population increase as a result of development pressure. It was determined that this growth would result in an exceedance of the reservoir's phosphorus budget by 1990. The Cherry Creek trading program will allow the reservoir to accommodate growth by permitting municipal wastewater treatment plants to gain waste load allocation credits in exchange for the implementation of nonpoint source controls. Because the greatest amount of phosphorus loading comes from nonpoint sources, the trading program will go into effect only after urban nonpoint sources reduce their loading by 50 percent.

Acknowledgments

The authors gratefully acknowledge the dedication and hard work of many individuals throughout the country whose efforts during the past 15 years have greatly increased the scientific, technical, and institutional knowledge of urban runoff problems and their management. This work forms the basis for this manual and is referenced throughout.

The authors also acknowledge the support of Tom Davenport, U.S. Environmental Protection Agency, Region 5, whose continuing dedication to solving urban runoff management problems led to the Chicago conference and this manual.

Finally, the authors thank Bobbi Shulman for editing this manual and converting the technical writing into a readable and understandable format.

Produced under the direction of Lura T. Svestka, edited by Roberta F. Shulman, and designed and typeset by Jessica A. Johnson.

Dedication

This manual is dedicated to the memory of an individual who, for many years, carried the banner of resource protection through scientific study and analysis. D. Earl Jones, who passed away in 1991, was a leader in water resources research and a friend. We need more such individuals if our efforts to protect and maintain water quality are to be successful.

The background material for this publication was produced under U.S. Environmental Protection Agency (EPA) cooperative agreement number CX820957 with the Terrene Institute. The manual was finalized under EPA grant number X995046. Points of view expressed in this publication do not necessarily reflect the views of the Terrene Institute nor of any of the contributors to its publication. Mention of trade names and commercial products does not constitute endorsement of their use.

Introduction

This manual departs from the traditional urban runoff management design manual—in addition to providing technical information, the manual offers an in-depth discussion of institutional issues.

Traditional urban runoff management design manuals from states, regional authorities, and local governments present best management practices (BMPs) or pollution prevention practices. However, they normally offer little guidance on the institutional structure or framework necessary to ensure that BMPs are implemented and continue to function. In this manual—designed for program managers, engineers, technical staff, biologists, and others who have urban runoff management responsibility—even the technical chapters stress the program aspects of urban runoff management.

To engender support from elected officials, industry, and the general public, professionals need background information on urban runoff quantity, pollutant sources, and their associated impacts. Professionals need to ensure that decisionmakers understand the serious nature of the urban runoff problem so that the problem receives the priority and attention it deserves.

Historically, our society has lived and worked in a narrowly defined environment, only aware of relationships affecting us individually. In today's era of global communication and travel and with our increased understanding of the impacts of our activities, we can no longer ignore our effects on aquatic and terrestrial resources. Our awareness obligates—or should obligate—us to address the problems our actions cause. Information in this manual is intended to explain the impacts that urban land uses have on our receiving systems.

After presenting the fundamentals of urban runoff hydrology and the impacts of urban land use in Part I, Part II presents guidance on the various types of runoff control measures and practices available. In addition to the more traditional structural measures, the manual also presents nonstructural strategies and practices. These nonstructural practices, based largely on ordinary common sense, can both enhance the performance and longevity of more complex structural measures and, at times, even replace them. This integrated presentation of structural and nonstructural practices is only one example of the dynamic, interactive approach to urban runoff management the manual encourages.

But all these practices and best intentions will not succeed unless we work to establish an infrastructure that provides the overall framework to implement programs. Because the programmatic considerations are as important as the actual urban runoff management practices themselves, half of this manual is devoted to program-related issues.

The manual's recommendations are based on the authors' experience in the technical and programmatic aspects of urban runoff management, with a strong interaction between research and program implementation.

The manual is a summary of materials distributed at a workshop in Chicago in June 1992. This information is valuable for individuals who implement runoff requirements under the National Pollutant Discharge Elimination System, Coastal Zone Act Reauthorization Amendments, or section 319 of the Clean Water Act. Any opinions rendered are those of the authors and do not necessarily reflect the opinions of either the U.S. Environmental Protection Agency or the Terrene Institute.

Since *all* of us contribute to the decline in our natural resources, all will need to alter our daily habits if we are to significantly improve our resource values. Native Americans demonstrate a reverence for the land worthy of emulation if true resource protection efforts are to be successful. In Delaware, the Nanticoke Indians demonstrate this reverence in their daily lives. The following quote shows how our attitudes must change if we are to succeed in addressing our environmental problems:

To the Native American people, Mother Earth is a living, breathing entity.
The rocks and coal in the soil are her bones.
The rivers and oceans are her blood.
The trees and plants are her hair, and the wind is her breath.
All living creatures are her children, they are our brothers and sisters.
If we fail to protect our brothers and sisters, we do not respect our Mother Earth.
Each step upon the Earth is a sacred dance.

CHAPTER 1

Hydrologic Impacts of Land Use Change

Urban runoff is a by-product of the land's interaction with rainfall. Since, by definition, urban runoff remains on and moves along the land's surface, it is the most visible of the many forms into which rainfall is converted. This chapter provides the technical fundamentals of the rainfall-runoff and soil erosion processes. It also describes ways that land development alters these processes and quantifies some of the adverse impacts.

The amount or volume of runoff produced by a rain event and the rates, depths, and velocities at which it flows during and after the event depend on several factors. They include the amount and rate of the rainfall and the amount of other forms into which rain is converted. These "conversions" are related to several land characteristics, including depth, slope, and permeability of both the surface and subsurface soils; the extent and character of any surface vegetation; and the degree of moisture already present in the soil. Other important factors typically encountered when the land undergoes a use change, or development, include the extent of impermeable surfaces covering the soil and the presence and efficiency of any conveyance system created through natural processes or constructed through human processes to drain runoff from the land.

Runoff directly affects the surface it flows within and across. These effects are most readily seen as erosion and sediment, as the forces created by runoff moving along the ground surface—as well as the initial impact of the raindrops themselves—dislodge and transport surface particles downstream to slower velocity areas. When runoff velocities can no longer transport the heavy particles, they drop out of the flow and back onto the surface.

Similar to the rainfall-to-runoff process, the amount of erosion and the character of the eroded material depend on several factors, including the flow volume, rate, duration, and the character of the surface material. Soil erosion has several major consequences:

- The original sites of the eroded material are degraded, therefore, potential productivity is lessened;
- The sites of soil particle deposition are altered physically, chemically, and hydrologically; and
- The chemical and physical nature of the transporting water system is affected.

From this information, three key aspects of urban runoff now come into focus:

- Since the amount and rate of urban runoff from a given storm event depend not only on the rainfall but also on the characteristics of the land on which runoff falls, changing the land characteristics can increase the runoff amount and/or rate, sometimes with disastrous results.
- An increase in runoff amount and rate can also increase the erosion of land surfaces and stream channels and change the quality of the runoff.
- The fundamental characteristics of the rainfall-runoff and erosion-sedimentation processes are not mysterious. With the information and references presented in this chapter and some logical thinking, those involved in developing urban runoff management programs at *all levels* can base their efforts on a sound understanding of the hydrologic processes at the core of the program.

VOL 12

6560

This first chapter will provide all readers—from novices to veterans of urban runoff management—fundamental technical information on urban runoff, soil and channel erosion, and the quantitative impacts of land development. The chapter also highlights some of the unknowns and uncertainties of both processes, to the extent of our current understanding. It also discusses various computational methods and models typically used to supply quantitative answers. The chapter concludes with advice and insights into the technical aspects of developing a runoff management program.

This broad approach will not only help the reader understand the technically complex urban runoff management topics presented in later chapters, it will also help ensure that decisions on a specific runoff management program will be founded on an informed understanding of runoff fundamentals. The chapter also provides a list of recommended textbooks and other references from a large body of technical material currently available. Because of the chapter's broad scope and focus on "learning the fundamentals first," readers should use the reference material to expand their knowledge beyond the manual's pages.

Throughout this chapter, the technical information regarding urban runoff hydrology is presented not as an end in itself but to assist in developing urban runoff management programs. This style, which varies somewhat from more traditional textbooks, should make the technical information more understandable to readers unaccustomed to a traditional approach. In addition, the style also allows the more experienced reader to view the technical aspects of urban runoff hydrology from a different perspective.

Finally, while melting snowfall also produces runoff, the complexities of the melting process are beyond the technical scope of this chapter. Therefore, discussion of runoff will be limited to rain events.

Real Versus Design Conditions

In technical subject matter, important differences exist between "real" and "design" conditions. This distinction is important when establishing a technology-based regulatory program. The "real" process that actually occurs during a storm event can be extremely complex, not only in its physical or mechanical behavior, but also in the numerous and highly variable external factors and conditions influencing it.

In the case of urban runoff hydrology, for example, the mechanics of evapotranspiration are extremely complex. They are strongly influenced by numerous external factors such as rainfall amount and intensity, antecedent moisture conditions, the character and condition of the vegetation, ambient air temperature, humidity, and wind speed—all of which can vary greatly from storm to storm. This inherent complexity of the mechanical processes—and the conditions under which they function—makes it difficult to precisely compute the runoff volume from a real storm event. Determining the exact level or value of all the influencing factors that exist when a storm event occurs is overwhelming.

On the surface, this inability to precisely analyze real storm events does not bode well for a regulatory program intended to manage the resulting runoff. Fortunately, differences can be predicted using simplifications between real and "design" events—i.e., hypothetical or future events. To deal with hypothetical events, we can preset all the external factors and conditions that will exist when the future storm event occurs. We can even decide that certain factors have no significant effect. We can also assume that the actual mechanical process will not be as complicated in our design world as in the real world. These simplifications will certainly make our analysis easier. But how can we be sure that it remains accurate and workable?

To achieve simplicity, accuracy, and usable design parameters, we must be able to make simplifying assumptions that are conservative or safe. This means that the predicted results of these assumptions will be on the safe side of the real answer, if we could compute it. For example, suppose our regulatory program required temporary storage of increased runoff from a land development site, as many do. A safe assumption for the value of any influencing factor would be one that would compute a runoff volume greater than what would actually occur. This will ensure that the constructed runoff storage facility will be larger and presumably safer than what will be required.

To consistently make safe assumptions, we must understand, at least qualitatively, how the real process works and what factors influence it. If dense vegetation covering the ground results in less runoff volume, then to be safe, our analysis might assume that only a thin stand of vegetation exists. Or if the degree of soil moisture before the storm event affects runoff volume, for safety we might assume that this moisture level is greater than average conditions.

We cannot be sure that our assumptions—and, therefore, our programs—are safe unless we understand the technical aspects of urban runoff hydrology well enough to identify all pertinent factors and understand their effect. This is a sound argument for learning the fundamentals first.

To gain a firm understanding of the fundamentals of urban runoff hydrology, we might ask, "How safe is safe?" and, perhaps more importantly, "How safe is too safe?" As our theoretical knowledge and analytical abilities improve, we may learn that the safe assumptions that simplified our computations have resulted in conservative program measures whose size, cost, or management needs are impractical and/or unaffordable. Therefore, the urban runoff management benefits they provide may simply not be worth the expense.

Those with a cursory knowledge of urban runoff hydrology can, in time, learn to make unquestionably safe analytical assumptions. However, only those with an in-depth understanding can consistently make program assumptions and decisions with the right combination of safety, cost, and practicality. To be truly effective, an urban runoff management program must possess large doses of all three.

The Rainfall-Runoff Process

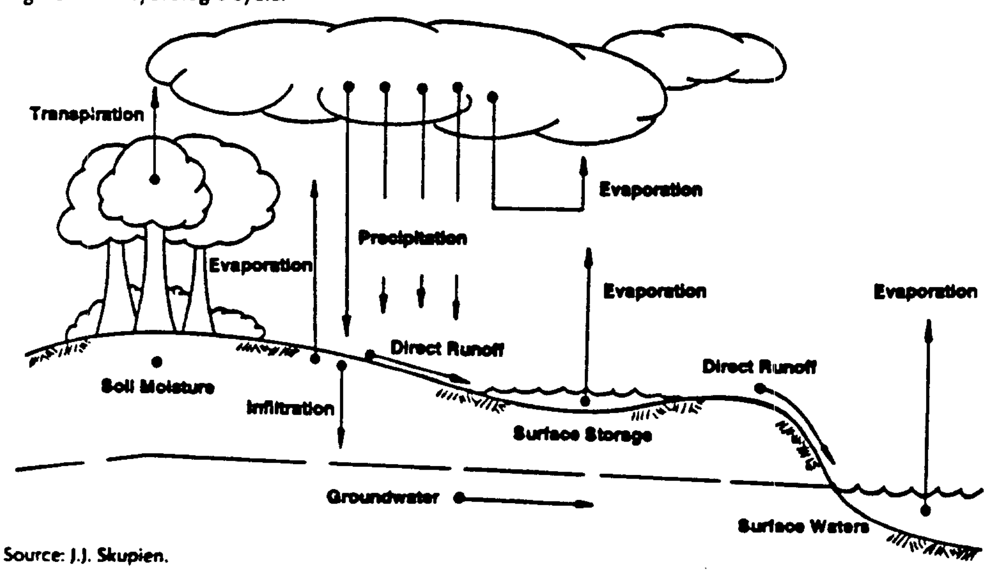
The Hydrologic Cycle

As previously explained, runoff represents a byproduct of the land's interaction with rainfall. While appropriately describing an individual storm event, this conversion process is only one of many that water goes through as it continually moves over, through, or above the land. Therefore, the rainfall-runoff process is an integral part of a cyclical process—the hydrologic cycle—that the earth's water supply continually experiences.

The hydrologic cycle shows the primary components or forms that water can take (Figure 1.1). The figure represents the earth's entire surface and atmosphere, including various forms of water that exist in the atmosphere such as water vapor measured as humidity near the ground surface, clouds comprised of tiny droplets of water condensed from that vapor, and forms of precipitation—created by large droplets too heavy to remain suspended in the clouds.

After arriving on the earth's surface, water follows one of several possible routes. It is absorbed by surface soils, intercepted by vegetation, directly impounded in numerous surface features from small depressions to large lakes and oceans, or infiltrated through the surface and subsurface soils into the groundwater. Another route taken by some water falling as precipitation is runoff.

Figure 1.1—Hydrologic cycle.



Source: J.J. Skupien.

The hydrologic cycle has two important aspects. First, the path of water movement is only half the story. Water also moves from the earth to the atmosphere, primarily through evaporation from surface waterbodies such as the oceans and evapotranspiration by vegetation. In fact, the rates of both movements over time are exactly equal. If they were not, the skies would get *very* cloudy or inland property owners would eventually have ocean or lakeside views. Although we can, and will in coming sections, focus on a single rain storm as a localized, temporary imbalance in this water transfer between the earth and its atmosphere, such a storm event is only one component of a much larger and complex process continually occurring around the planet.

Second, the hydrologic cycle is not easily broken into separate, discrete components. The cyclical process demands that the places water can be and the routes it takes between them are interrelated. Depending on conditions, the water that becomes part of the surface runoff from a parking lot may join the elevated flow in a nearby stream, or the moisture in the soil surrounding the lot, or—if it moves vertically through the soil—the groundwater moving below the lot. In fact, the water that was originally parking lot runoff and then became groundwater beneath it may eventually become streamflow, although well after the initial flooding has passed.

How do we make enough sense of this very common but complex cycle to develop a regulatory process to manage it? By defining the process by (1) the location on the ground that we may affect; (2) the land size and characteristics from which runoff will flow (or drain) to that location; and (3) the time period for which we analyze the continuously operating hydrologic cycle. To assist us, we rely on simplified design conditions to overcome unknowns or uncertainties in the real process that we must quantify in some manner. Finally, we rely on our knowledge of hydrologic fundamentals to ensure that our assumptions are safe, reasonable, and affordable. The following sections present details of these steps.

Runoff Estimation—Typical Parameters

In the previous description of routes that rainfall may follow, runoff was listed last. That is because runoff is the last form or by-product of precipitation used in most runoff estimation techniques for ungaged drainage areas after all the other processes—infiltration by soil, interception by vegetation—have been quantified. That is, we often estimate runoff produced by a given amount of rainfall by subtracting from the total rainfall those portions or percentages likely to become something other than runoff. The remainder is the estimated runoff.

The preceding paragraph uses the term "ungaged drainage area" to qualify the statement concerning runoff estimating techniques. If we were fortunate enough to have some type of gage or metering device to measure the actual runoff over an extended time period, our computations would be more direct and our interest in other aspects of the rainfall-runoff process, including rainfall itself, would be incidental at best. Using this flow data and the knowledge that runoff, like rainfall, is a random event, we could use standardized statistical and probability techniques to estimate the runoff volume, peak rate, duration, and other characteristics for runoff events of various frequencies.

For example, individuals concerned with flooding and flood plain delineation and management could choose a 100-year flood frequency event, technically defined as an event with a 1 percent chance of being equaled or exceeded in any given year. Others concerned with erosion could develop estimates of the two- or five-year flood—having a 50 or 20 percent chance, respectively. While the magnitudes are not as great as the 100-year event, they possess the right combination of frequency and magnitude to define natural channel banks and cause considerable erosion. Finally, individuals concerned with urban runoff quality and the impacts of nonpoint source pollution would probably be most interested in one-year and even more frequent events, since these have the most severe, acute, and chronic water quality effects. A 2.5 year, 24-hour flood is the most frequently used design.

However, while many streams and rivers have been equipped with flow gages by local, state, or federal agencies—including the U.S. Geological Survey (USGS)—gages are primarily meant to address flooding and water supply on a large scale. In contrast, urban runoff management must address localized issues such as construction site runoff and small stream erosion. Even if flow gages were practical on a small scale, we would need several years of actual runoff measurements before we could accurately predict future possibilities.

VOL 12

6563

The shear impracticality of installing, operating, and analyzing runoff gages at the scale required for urban runoff management, in addition to some inherent limitations of gaged flow analysis, means that instead of focusing on runoff directly, we must focus on it indirectly by analyzing the rainfall that creates it. We must study the rainfall-runoff process closely and use the runoff byproduct approach previously described.

Most runoff estimation methods use some of the following factors or parameters. They each, therefore, require at least some quantitative estimate of their effects on the final product—runoff.

Rainfall. As the most significant parameter in any runoff estimation process, rainfall is the primary input value. Actual rainfall amounts measured at gages in or near the drainage area are used to analyze real or historic rainfall events. Hypothetical rainfall amounts and intensities are typically used for design or regulatory purposes. Data collected from an actual storm event of appropriate magnitude, if available, can be used to check the design or even serve as the design storm itself. Finally, as computer and data resources increase, real, long-term data—considered the most accurate approach to estimating runoff—is increas-

VOL 12

6564

ingly being used and accepted in continuous rainfall-runoff simulation models.

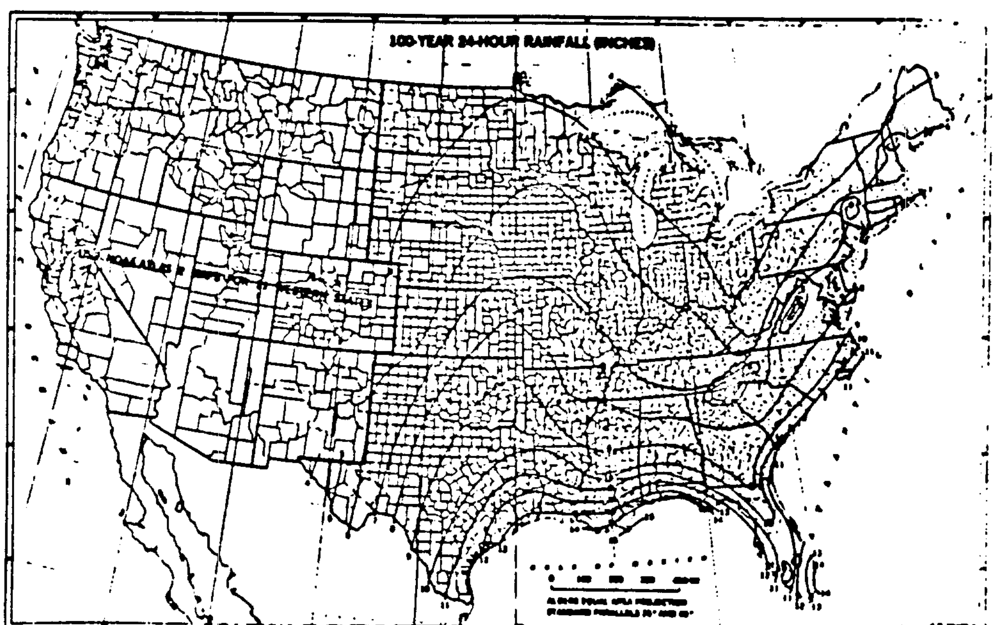
Rainfall data for hypothetical or design events is obtained from statistical compilations and extrapolations of real data collected over a statistically significant time period. Figures 1.2 and 1.3 present two such compilations. Figure 1.2 shows rainfall intensity-duration-frequency curves developed from data collected over a 62-year period at the rainfall gage in Trenton, New Jersey. The curves predict the expected average rainfall intensity for a given frequency storm event over a user-selected time period. For example, the expected five-year average rainfall intensity for a hypothetical rainfall period lasting 30 minutes is approximately 2.8 in (7.1 cm)* per hour. Thus, the total rainfall during the half-hour period will be 1.4 in (3.6 cm).

The curves in Figure 1.3 also show rainfall intensity-duration-frequency relationships, but with some significant differences. Data is presented for the entire United States east of the Rocky Mountains and is expressed for only one duration (24 hours) and frequency (100 years). The rainfall is expressed as a total amount over the time period, rather than as an intensity or rate. Using simple arithmetic, we can compute the average rainfall intensity over 24 hours. The curves in Figure 1.3 are part of a larger set for numerous storm frequencies and durations originally published in *Rainfall-Frequency Atlas of the United States (TP-40)* by the (then) U.S. Weather Bureau. Although TP-40 is out of print, the curves are reproduced in *Urban Hydrology for Small Watersheds (TR-55)*, published by the USDA Soil Conservation Service (USDA SCS). This publication has become a current standard for estimating runoff. This chapter will provide additional information on TR-55 and the USDA SCS hydrologic methodology on which it is based.

To use rainfall data such as that shown in Figures 1.2 and 1.3, the user must select not only the

* Note: Throughout this manual, English measurements are presented first with SI (metric) conversions in parenthesis, except where dual measurements would be confusing, inaccurate, or redundant or where no comparable measurement exists.

Figure 1.3—100-year 24-hour rainfall (inches).



Source: U.S. Dep. Agric. 1986.

rainfall frequency pertinent to the analysis but also the rainfall duration. The element of time or duration is vital to any rainfall-runoff analysis and will be discussed in greater detail later. But for now, the time runoff takes to collect and flow to the point of concern on the ground surface—located at the lowest end of the area draining to that point—is key to selecting the appropriate rainfall duration.

Regarding the element of time, while the data in the figures and in similar charts are based on real storm events, they are not meant to imply any total storm duration or amount. For example, while Figure 1.2 indicates that the five-year rainfall intensity of 2.8 in (7.1 cm) per hour will last for 30 minutes, it gives no indication of the actual storm length. Instead, Figure 1.2 shows a 20 percent chance (the probability of a five-year event) exists that any rain event of at least 30 minutes will contain a 30-minute period that will produce 1.4 in (3.6 cm) of rain—i.e., rain falling at an average rate of 2.8 in (7.1 cm) per hour over a half-hour period. The figures indicate nothing about how the rain fell during the selected time period—they only indicate the total amount that fell. That is why we use the word "average" whenever we discuss rainfall rates.

As analysts, we may be required to select critical rainfall intensities and durations within an overall storm event. The specific runoff characteristic we seek (e.g., peak flow rate versus total volume) will help determine whether or not we need to select a total storm event duration.

Our rainfall discussion would not be complete without mentioning the rain that has fallen during prior storms. While the runoff from this rain may have long since drained from the watershed, some may still be present as soil moisture or stored in surface depressions. Referred to as antecedent rainfall, runoff, or moisture condition, this helps characterize a watershed's potential to produce runoff from a new storm event by describing how wet conditions are from previous storms.

Antecedent runoff conditions are particularly critical when recreating real or historic storm events and when analyzing real or hypothetical storms involving fairly small amounts of total rainfall. For simplicity, many runoff estimating techniques assume that average antecedent conditions are present in the watershed prior to the start of the storm in question. The more sophisticated techniques allow the analyst to vary the input data to reflect some other antecedent condition. Readers should keep antecedent conditions in mind when reviewing discussions of initial abstraction, surface depressions, and soil infiltration.

▌*Time.* The time element plays a critical role in both the real rainfall-runoff process and the methods used to estimate the runoff. This is not surprising, since gravitational, thermodynamic, and other natural forces involved in producing both precipitation and runoff are intrinsically dynamic and constantly changing with, and therefore influenced by, time. This chapter presents a simplified description of how time affects runoff estimates. The reader should further explore the time element through the publications referenced here and the many other excellent ones available.

Two fundamental measures or lengths of time are important when performing runoff estimates, whether for an existing or future condition. The first measure is the response time of a drainage area to a rainfall input. This response time indicates how quickly runoff drains to the bottom of the watershed and how quickly the runoff rate, created by a certain rainfall, will change as the rainfall rate changes. To a lesser degree, this response time may also help determine the runoff volume produced by the rainfall.

Several terms and definitions quantify this response time; most are applicable to a particular runoff estimating technique or method. The most common definition of watershed response is time of concentration (TC), which the USDA SCS and others define as the time runoff—once it has begun—takes to flow from the most distant point in the watershed to the point of interest at the bottom. Numerous procedures, equations, charts, and graphs can help estimate TC, including those presented in Chapter 3 of TR-55.

Remember that TC or any other watershed response time definitions are only conceptual values. A watershed's actual response time is not only affected by numerous and complex factors, it is also constantly changing in length throughout a storm. Therefore, any computed TC estimate is *only* an estimate. The reason is not only because we use simplified data and equations to compute the TC, but also because we assume that a single time represents the watershed throughout the entire storm event. This assumption is critical to remember when computing entire runoff hydrographs.

Regardless of the definition or estimating technique adopted, the most important aspect of the watershed response time is its direct effect on the rate of runoff flow. Since response time determines how quickly the runoff produced throughout a watershed can flow to the bottom or outlet, it determines how much *time* runoff will take to *concentrate* at the bottom. Therefore, whether we seek just the peak runoff rate from a storm event or an estimate of all the various runoff rates during and after a storm period—known as a hydrograph—we must compute a reasonable time estimate. In addition, the shorter the response time, the greater the flow rate for a given runoff volume amount. Or, we can analyze further to determine how an existing runoff rate will be changed if the watershed's response time is altered. More information regarding the impacts of such alterations from land development is presented later.

Since watershed response time also indicates how quickly the runoff rate will change due to changes in rainfall rate or intensity, response time helps us determine the length of rainfall increments needed in a runoff analysis to assure accurate results. Or, stated differently, we learn how short a time period is needed to safely assume an average rainfall rate. For example, a watershed whose outlet takes several hours to respond to the rainfall within it will show little change in runoff rate from a change in rainfall intensity lasting only a few minutes. As a result, we would waste time and effort if we based our analysis on rainfall increments of less than 15 minutes. This aspect of watershed response time helps determine the appropriate time increment for other time-dependent runoff computations such as detention basin, reservoir, and channel/flood plain routings. It can also help us select appropriate sampling and recording intervals required for runoff field studies.

The second fundamental measure or length of time in rainfall-runoff analyses is the total event time. It not only includes the total time for rain to fall, but it frequently includes the time required after the rainfall for a watershed to fully respond. For example, if we wished to compute the total runoff volume from a certain frequency rainfall, we would need to know both the average intensity and total duration. This differs from the peak rate example given in the preceding paragraph. There, we only needed to know the rainfall that fell during the time period, equal to the watershed response time, that produced the peak rate. In addition, if we need this estimate of total runoff volume to design an urban runoff detention or other storage facility at the watershed outlet, then we must extend the total event time to include the additional time the facility prolongs or delays the watershed's response time. This additional time, known as the "interevent dry period" between rain events (Wanielista and Yousef, 1993), has become increasingly important as the use of extended runoff storage times for urban runoff quality grows in popularity and the storage times increase in length.

▌*Drainage Area.* The drainage area or watershed concept is fundamental to any rainfall-runoff analysis. As such, we must determine and evaluate several key drainage area characteristics to perform runoff estimates. The first and most obvious characteristic is the drainage area size. This is usually determined by using topographic or other area maps upstream from the point of interest and actual field reconnaissance to verify available map data and supplement missing data.

Most runoff estimating techniques assume a linear relationship between drainage area size and runoff volume. Therefore, a 20 percent error in estimating the drainage area size will, among other impacts, result in a similar error in estimating runoff volume. This relationship is important when determining the required accuracy of drainage area computations and the amount of time and effort to spend achieving it. The percent of a particular drainage area that contributes runoff during a storm event will vary by antecedent moisture content, size of the storm event, and duration.

Two important drainage area characteristics, particularly for estimating runoff rates, are the shape of the drainage area and its various slopes. The previous discussion of watershed response time shows that a watershed with steep surfaces and channels allows runoff to drain to its outlet more quickly. This creates a greater peak flow than a flat watershed of similar total area. Similarly, an elongated drainage area with a longer distance from its upper reaches to its outlet may have a longer response time than a rounded one of equal size and, therefore, a lower peak runoff rate.

The term "may" conveys reservations about over-generalizing drainage area shape and slope and their effects on runoff rate, particularly for complex watersheds with major branches or tributaries. Each drainage area or watershed has its own unique shape, slope, and complexity, and each factor has a direct effect on response time and resultant runoff. Therefore, the representative response time required by the selected runoff estimating method should be computed as accurately as possible for each watershed under study and should consider all these unique characteristics.

The slope of localized areas within a watershed, particularly those that create surface depressions and other low areas, can have a direct effect on the watershed's response time and volume of runoff, especially at the rainfall onset. If the surface depressions are large relative to the rainfall volume, they can capture and store the beginning runoff, delaying its flow downstream.

This delay, combined with such effects as soil infiltration and interception by vegetation, helps produce the "initial abstraction"—the amount of rainfall converted into something other than runoff during the earliest part of the storm event. In estimating runoff, the initial abstraction is the amount of rain that must fall before runoff begins. Depending on the watershed's surface, soils, and vegetation, and the amount of rainfall analyzed, the initial abstraction can significantly affect the results. It should not be overlooked, particularly when analyzing small, frequent storm events in largely pervious watersheds.

■ *Soils*. Since several soil characteristics in a watershed have a direct effect on the rainfall-runoff process, they are included in most runoff estimating techniques. These include soil layer thickness, permeability or infiltration rate, and the degree of moisture in the soil before the rain event. The greater the soil permeability—the ability to infiltrate rainfall to its lower strata—the less remains to become runoff. The same can be said for soil thickness, particularly above bedrock or an impermeable subsurface layer, and the degree of moisture present in the voids between the individual soil particles.

If a storm occurs in an undeveloped watershed whose soil is saturated from previous rainfalls and incapable of storing additional water, the runoff amount could be the same as that produced in a watershed completely covered with impervious surfaces such as roofs, parking lots, and roadways. This fact is particularly critical in many parts of the country in spring, when extended wet weather and prolonged snowmelt keep soil levels nearly or completely saturated. This saturation causes a high threat of flooding, since extreme flow rates and flood levels can even be caused by small storms with high probabilities or frequencies.

Soil infiltration rate and thickness data is found in numerous sources, including laboratory tests of soil samples taken from various watershed locations, borings, and other subsurface samples. USDA SCS county soil surveys are reliable sources for general soil information. Depending on drainage area size, degree of accuracy required, and importance of soil characteristics to the runoff estimating method, the data may need some degree of field verification.

As in surface depressions, the delaying effects of initial soil wetting and infiltration help to produce initial abstraction. This can significantly affect the rainfall-runoff analysis result and should be considered, when analyzing small, frequent storm events in pervious watersheds.

■ *Vegetative Cover.* The vegetative cover directly affects the rainfall-runoff process and is an important parameter in many runoff estimating techniques. Vegetation characteristics include various types, canopies, and densities; extent of coverage; degree of residue or natural litter at the base; and degree of surface roughness. These characteristics affect the amount of rainfall that becomes runoff and the length of time the watershed takes to fully respond. For example, according to data in TR-55, sheet flow—runoff that occurs during the critical first stages of runoff movement—has an average velocity 10 times slower across a wooded area than it does across a comparable bare soil or asphalt-paved area. These effects must be considered in estimating peak runoff rates.

Vegetation data sources, frequently used in combination, include field reconnaissance and aerial photographs and satellite imagery, particularly to study large watersheds using computerized geographic information systems (GIS).

Vegetation's delaying effects of rainfall interception also help produce initial abstraction, which can significantly affect the results of a rainfall-runoff analysis in largely pervious watersheds.

■ *Impervious Cover.* Impervious cover means that virtually all rain will become runoff. Under most conditions, impervious cover is the last factor created in a watershed. As mentioned previously, the sheet flow velocity of runoff over a smooth, impervious surface such as a road or parking lot is about 10 times faster than over a vegetated surface. These strong impacts on runoff volume and rate make impervious cover the most critical characteristic in most runoff estimating techniques. In fact, the British Road Research Laboratory (BRRL) Method considers only the impervious portions of a watershed or drainage area.

Sources of impervious cover data required for rainfall-runoff analyses range from field reconnaissance to aerial photographs to satellite imagery, particular for GIS-based studies.

Runoff Estimation—Common Methods

In this manual, most techniques used to analyze the rainfall-runoff process and estimate runoff volumes, peak rates, and hydrographs are classified into two general types, distinguished by how each uses time in its computations.

▮ *Steady State Methods.* These methods assume that key parameters remain steady or constant throughout the rainfall duration. Therefore, these methods use uniform rainfall intensities, soil infiltration rates, and representative watershed response times. Rather than merely a shortcut, steady state conditions are a reasonably accurate way to estimate peak runoff rates from high to moderate frequency storms in small watersheds with relatively short response times. As a result, steady state techniques, such as the rational method, are widely accepted for such watersheds. This relative accuracy may be caused by the short response time, resulting in a short time period over which steady or constant conditions are assumed (Wanielista and Yousef [1993] recommends limiting rational method use to drainage areas with a maximum TC of 20 minutes). Unfortunately, these same assumptions limit steady state methods, such as the rational method, to computing peak runoff rates. They are less effective in estimating total event runoff volumes and hydrographs.

A modified form of the rational method estimates runoff volumes from a series of hypothetical rainfall events of similar frequency but different duration. The method is primarily used to design smaller runoff detention and other storage facilities. Unfortunately, urban runoff management is expanding beyond traditional flood control and drainage needs to address aspects such as runoff quality, nonpoint source pollution, and aquatic habitat management. These uses require more accurate estimates of total runoff volumes and hydrographs, in particular, than the methods using steady state assumptions can reliably produce. Nevertheless, their simplicity and proven—if limited—accuracy means that steady state estimating still retains a firm position in urban runoff hydrology.

▮ *Variable State Methods.* These methods allow such parameters as rainfall intensity, soil infiltration, and watershed response time to vary with time. As such, these methods can more accurately compute runoff characteristics from rainfalls of varying intensities in single or even multiple storm events. This makes them more suitable to compute event runoff volumes and hydrographs and more capable of accurately recreating runoff from past or historic rainfall events. These methods, then, can be more readily calibrated and verified, further improving their accuracy.

Specific runoff estimating methods based somewhat on variable state assumptions include the USDA SCS runoff equation, which assumes a nonlinear soil infiltration rate to estimate runoff volumes; and methods based on either unit hydrograph theory, originally developed by L.K. Sherman in 1932 (Sherman, 1940), or the more recent kinematic wave theory to distribute runoff volume into runoff hydrographs.

In general, to consider variations in parameters, the methods divide the rainfall event into small time periods and use separate estimates of each parameter sequentially during each time period. To be accurate, a variable state method should consider the effects of previous parameter values from preceding time periods in each current time period. Most standard methods currently available do so, at least for some parameters.

In using variable state methods, the closer resemblance to the "real" rainfall-runoff process and, consequently, the greater accuracy, broader applicability, and potentially greater benefits do not come without additional cost. These methods need more input data (e.g., an initial value for each parameter and a technique for varying it throughout the event) and more computations. This normally requires appropriate computer programs and more user knowledge and experience to maintain an acceptable level of accuracy and safety. These requirements can limit the use of some methods and the effectiveness of the regulatory programs based on them.

In developing or expanding an urban runoff management program, we must balance regulatory effectiveness and technical accuracy. But because of the current demands to manage runoff and the continued growth of hydrologic tools and techniques, all urban runoff management programs should encourage technical growth and be capable of updating their own regulations.

Runoff Estimation—Computer Models

The amount and complexity of the data and computations are overwhelming. And as the scope and complexity of urban runoff management grows, linking data and computed hydrologic results with hydraulic, structural, economic, and even demographic analyses is increasingly important. As a result, we must have quick computerized runoff models and other enhanced computational tools, particularly to study large, complex watersheds. Fortunately, numerous urban runoff management programs are available.

The terms computer "program" and "model" can be confusing. The runoff models described here are computer programs since they are written in a computer language and are run (or executed) on a computer. However, the term "model" implies a specialized type of computer program that simulates or models a physical process. The user must both provide input data and make informed decisions about data values, such as soil infiltration rates or extent of vegetative cover.

The model differs, then, from a simple computer program, which may perform complex arithmetic, but uses input data requiring little or no user discretion; for example, a program that computes the mean or standard deviation or that computes the closure error on a land survey. According to this definition, various estimating techniques used in urban runoff management analyses and labeled "methods" are also considered models in scientific and engineering terms. We will, therefore, refer to the computerized versions of these methods as computer models.

▌*Single Event Models.* These models allow the user to analyze or simulate the rainfall-runoff process during a single event. The user must not only select the rainfall to analyze but also the conditions and factors in the watershed immediately prior to its onset. The models then estimate the resulting runoff characteristics such as volumes, peak rates, and entire hydrographs.

To develop and use a single event model, the user need only know the initial values of the factors in the runoff estimating method and how they will change over time in response to the selected rainfall. The user does not need to know how the factors will continue to change during any drying period following the selected rainfall and preceding the next one, since the model is only intended to analyze a single event. This makes these computer models ideally suited to analyze individual historic storm events and design urban runoff detention and other short-term urban runoff storage facilities primarily influenced by individual storms.

Some popular single event computer models available include HEC-1 Flood Hydrograph Package, developed by the Hydrologic Engineering Center (HEC) of the U.S. Army Corps of Engineers (1990); USDA Technical Release 20 (TR-20), developed by the USDA SCS (1992); and the U.S. EPA Stormwater Management Model (SWMM) (Huber and Dickinson, 1988); along with numerous others. The first two models can only be used for estimating quantitative aspects of runoff such as volumes, rates, and hydrographs. SWMM can also be used to estimate runoff quality characteristics such as pollutant concentrations and masses. References at the end of the chapter provide detailed descriptions of the models.

▌*Continuous Models.* Unlike single rainfall-runoff models, these models analyze the rainfall-runoff process for a series of storm events over an extended time period—several years or even decades. Models must account for changes in watershed factors and parameters during the time *between* storms (interevent dry periods) as well as *during* storms. Such factors as temperature, relative humidity, surface evaporation and evapotranspiration, and groundwater levels and movement, all of which may significantly affect runoff response to the next rainfall in the analysis or simulation, must be considered. These factors require a similar increase in data needs and user knowledge and experience.

The additional effort and expense are often well spent, particularly to analyze or design agricultural, urban runoff management, or water supply facilities that respond slowly to rainfall and, therefore, are influenced by a long series of storm events. Single event analyses are of limited value for these facilities, since they are part of a larger, more complex picture. Also of limited value are such problems as long-term, cumulative pollutant loadings and their effects on streams, lakes, and estuaries. These phenomena occur slowly and are continuously influenced by rainfall events. Using continuous models may not only be justified, but in many instances mandatory.

One of the most familiar continuous models is Storage, Treatment, Overflow, and Runoff Model (STORM), originally developed by the U.S. Army Corps of Engineers in 1974.

Runoff Estimation—An Example

To highlight the rainfall-runoff concepts, parameters, and methods previously discussed, we have selected a sample method of a single event presented in TR-55 to estimate runoff volumes, peak rates, and entire hydrographs. The methodology first uses the USDA SCS runoff equation—a mathematical model of the real rainfall-runoff process—to estimate the runoff volume, expressed as a uniform depth in inches over the watershed, that would result from a specified rainfall depth. We assume that this rainfall depth falls over a 24-hour period in a hypothetical pattern developed by USDA SCS from the rainfall depth-frequency-duration data originally published in TP-40 (U.S. Dep. Commerce, 1961). The resultant runoff volume is then distributed over time using a synthetic unit hydrograph for the watershed to estimate the peak runoff rate. If we desire, we can estimate the entire hydrograph that would result from the day-long rainfall. The synthetic unit hydrograph is based on the principles and assumptions of unit hydrograph theory and, in part, on an estimate of the watershed's TC.

This is a complicated mix of theories, assumptions, and calculations. However, the USDA SCS runoff equation, synthetic storm distributions, and synthetic unit hydrographs included in the methodology are based on extensive field data, research, and experience. They are, therefore, consistent with the concepts and cautions discussed earlier for real versus design conditions. As a result, the USDA SCS hydrologic methods, including those in TR-55, have gained widespread acceptance among engineers, planners, and regulators. Details regarding USDA SCS methodology in the following example are in TR-55 as well as USDA SCS's National Engineering Handbook Section Four— Hydrology (NEH-4) (U.S. Dep. Agric. 1972).

As described in these publications, the USDA SCS runoff equation is

$$Q = \frac{(P - Ia)^2}{(P - Ia) + S} \qquad [1]$$

where:
- Q = Runoff depth (inches)
- P = Rainfall depth (inches)
- S = Potential maximum retention once runoff begins (inches)
- Ia = Initial abstraction (inches)

As previously explained, the initial abstraction is the amount of rainfall that must fall before runoff begins and represents all other routes rain can take (e.g., infiltration into the soil) or forms it will assume (e.g., depression storage) during the earliest part of the storm. While the actual initial abstraction can be highly variable, USDA SCS has developed the empirical equation $Ia = 0.2S$. This eliminates Ia as an independent variable in equation 1 and results in the following:

$$Q = \frac{(P - 0.2S)^2}{(P + 0.8S)} \qquad [2]$$

The parameter S is a measure of how much rainfall the watershed soils and the materials covering them can potentially hold once the initial abstraction is overcome and runoff begins. No mention is made of the rainfall amount required to reach this limit because S is related to the actual soils and covers through a runoff curve number (CN) by the equation

$$S = \frac{1000}{CN} - 10 \qquad [3]$$

TR-55 and NEH-4 have several tables of CNs for numerous ground covers and land uses in various hydrologic conditions, including lawns, meadows, woodland, impervious surfaces such as roads and roofs, and even bare soil. These tables present four CNs for each cover/use/condition. USDA SCS has classified most soils into hydrologic soil groups (HSG) based on their minimum infiltration capabilities. Soils in HSG A have the highest infiltration rates, while HSG D soils have the lowest. Conversely, HSG A soils have the lowest runoff potential while HSG D soils have the highest. The recommended CNs in the TR-55 and NEH-4 tables are also based on the assumption of average antecedent runoff conditions at the start of rainfall.

Graphic solutions to equation 2 (i.e., the USDA SCS runoff equation for $Ia = 0.2S$) for a range of CNs is presented from TR-55 in Figure 1.4. A summary of recommended CNs for various land uses/covers, conditions, and hydrologic soil groups taken from the extensive listings in TR-55 (Tables 2-2a and 2-2c) is presented in Table 1.1. TR-55 also contains rainfall depth-frequency-duration maps originally published in TP-40 to allow the user to select the appropriate 24-hour rainfall amount.

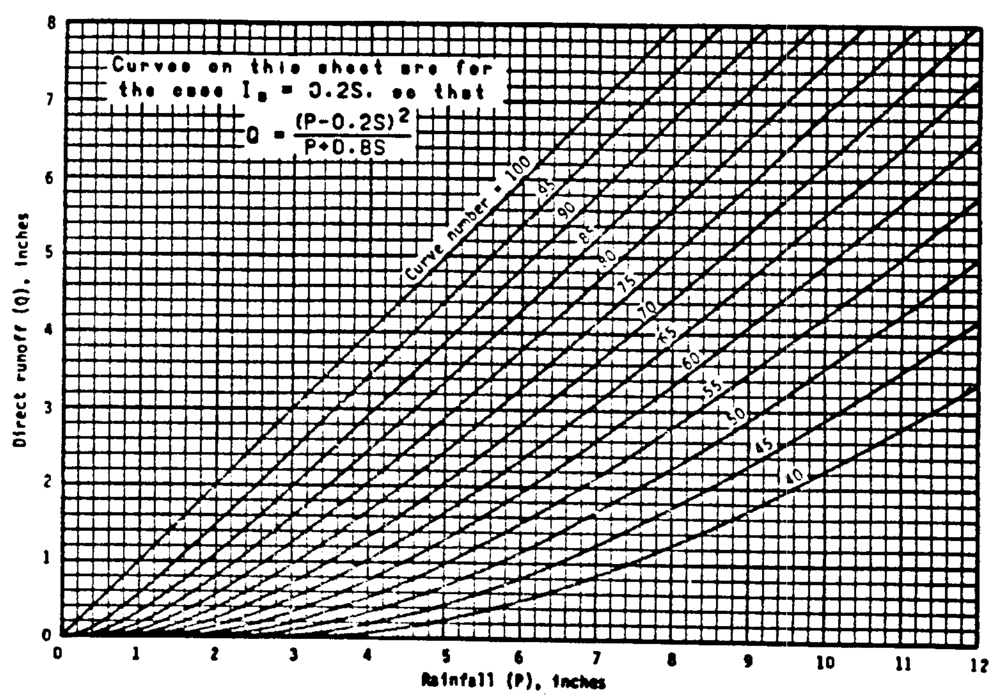
For example, assume a wooded, 20-acre (8.1-ha) drainage area around Chicago with good leaf cover and other natural litter on the ground. Using the previous equations and the CNs from Table 1.1, we can estimate the volume of runoff expected for a 2-year, 10-year, and 100-year storm event lasting 24 hours. We will base the computations on two alternative soil types—HSG B and D—and compare the results.

Table 1.1—Summary of recommended SCS runoff curve number for average antecedent runoff conditions.

COVER TYPE/LAND USE	HYDROLOGIC CONDITION	HYDROLOGIC SOIL GROUP A	B	C	D
Woods	Poor–no forest litter Good–litter and brush	45 30	65 55	77 70	83 77
Meadow	—	30	58	71	78
Lawns/open space	Good–full grass cover	39	61	74	80
Bare soil	—	77	86	91	94
½ acre residential (25% impervious)	—	54	70	80	85
Commercial/business (85% impervious)	—	89	92	94	95
Roofs/paved roads, drives, and parking	—	98	98	98	98

Note: Summary values are presented for example only. Refer to complete SCS tables and texts for actual CN use.
Source: U.S. Dep. Agric. 1986.

Figure 1.4—Graphic solution of Soil Conservation Service runoff equation.



Source: U.S. Dep. Agric. 1986.

From the description and information from Table 1.1, we can safely assume that the wooded area is in "good" hydrologic condition and a CN of 55 can be used if the soils belong to HSG B. Similarly, a CN of 77 is recommended if the soils belong to HSG D. We can now perform some preliminary computations using these values, equation 3, and the USDA SCS assumption that Ia is equal to 20 percent of S:

PARAMETER	SOIL GROUP B	SOIL GROUP D
CN	55	77
S (inches)	8.18	2.99
Ia (inches)	1.64	0.60

From these computations, we can make some comparisons between the two soils right away, even before the rain begins. For instance, we have estimated that a drainage area comprised of HSG B soils can potentially retain 8.18 in (20.8 cm) of rainfall, once the initial abstraction of 1.64 in (4.2 cm) is used up and runoff begins. This is almost three times greater than if the drainage area were comprised of HSG D soils. In addition, the HSG B drainage area requires a greater amount of rainfall to overcome the initial abstraction and for runoff to begin than the HSG D drainage area.

To complete the computations, we use 24-hour rainfall values for the general Chicago area for 2-year, 10-year, and 100-year storm events from Figure 1.3 (from TR-55, Appendix B: Figures B-3, B-5, and B-8). Using these values, the preliminary computations, and equation 2, we can compute the following estimates of runoff volume:

STORM FREQ. (years)	24-HOUR RAINFALL (inches)	ESTIMATED RUNOFF (inches)	
		B SOIL	D SOIL
2	2.8	0.14	0.93
10	4.0	0.53	1.81
100	5.8	1.40	3.30

The estimated runoff volumes from equation 2 are expressed in inches, which does not exactly meet the mathematical definition of volume. Actually, these volumes are meant to represent average runoff depths over the entire drainage area where the CN has been computed (the USDA SCS runoff equation does not have an explicit term for drainage-area size). To compute the various runoff volumes in more traditional measurement units, we can multiply the average runoff depths produced by equation 2 by the 20-acre drainage area (making sure of our units) to produce several different versions of estimated volumes:

STORM FREQ. (years)	ESTIMATED RUNOFF (inches)		ESTIMATED RUNOFF (cubic feet)		ESTIMATED RUNOFF (acre-feet)	
	B SOIL	D SOIL	B SOIL	D SOIL	B SOIL	D SOIL
2	0.14	0.93	10,019	67,518	0.23	1.55
10	0.53	1.81	38,333	131,551	0.88	3.02
100	1.40	3.30	101,495	239,580	2.33	5.50

All previous estimates for each storm frequency and HSG represent the same runoff volume—they only represent different units. Referring to runoff volumes in inches of average depth over the entire watershed or in units of acre-feet is often easier than in cubic feet.

In comparing the two HSGs, the HSG D drainage area would produce 2-year, 10-year, and 100-year runoff volumes that are 6.6, 3.4, and 2.4 times greater than those from the HSG B drainage area. This confirms our suspicions from the preliminary computations. While the HSG D runoff volumes are greater than those for HSG B in all storm frequencies analyzed, the percentage difference decreases as the storm frequency—or, more precisely, the rainfall amounts—increases. However, the USDA SCS runoff equation uses both a fixed initial abstraction value for a given CN (i.e., it does not vary with rainfall) and an exponential infiltration rate (note the squared numerator in equations 1 and 2). We will explore this important aspect of urban runoff hydrology later.

Some interesting relationships exist within each HSG. For example, in the HSG B drainage area, the estimated 2-year runoff volume represents only 5 percent of the total 2-year rainfall. This percentage increases first to 13 percent and then to 24 percent for the HSG B drainage area as the storm frequency/rainfall amount increases to the 10-year and 100-year levels. A similar relationship between event frequencies exists for the HSG D drainage area.

The following is a summary of the percentages for both HSGs:

STORM FREQ.	24-HOUR RAINFALL	ESTIMATED RUNOFF (inches)		RUNOFF AS PERCENT OF RAINFALL	
(years)	(inches)	B SOIL	D SOIL	B SOIL	D SOIL
2	2.8	0.14	0.93	5%	33%
10	4.0	0.53	1.81	13%	45%
100	5.8	1.40	3.30	24%	57%

These relationships show the effects of both the initial abstraction and nonlinear (i.e., exponential) infiltration rate assumptions from the USDA SCS runoff equation. The percentages also show the strong effect of soil characteristics on runoff volume from a given amount of rainfall. The data show that a much greater percentage of rain falling on the HSG D drainage area will likely become runoff than the percentage on the HSG B drainage area. For example, while we estimate that only 5 percent of the 2-year rainfall on the HSG B drainage area will become runoff, 33 percent of the same rain falling on the HSG D drainage area (with the same ground cover) will become runoff. Therefore, this hypothetical switching of HSGs clearly shows why soil characteristics are such an important parameter in runoff computations. The remaining percentage of rain that does not become runoff in either drainage area represents the sum of all the other rainfall by-products.

We can extend this example to include estimates and comparisons of peak rates at which the various runoff volumes might flow from each drainage area. We will assume that the 24-hour rainfall will fall throughout that 24-hour period in accordance with a hypothetical USDA SCS storm distribution known as Type II. This hypothetical or "design" storm is one of four 24-hour distributions that USDA SCS has developed for various parts of the United States, with Type II recommended for the Chicago area, the location of the 20-acre drainage area in our example (TR-55, Appendix B, contains a detailed description of these distributions).

Assuming a Type II storm and an estimated TC of 0.5 hours, we use Figure 1.5 to estimate the various peak runoff rates for the different storm frequencies and soil groups (TR-55, Chapter 3, contains one of the most complete and concise presentations of both the concept and computation of TC presently available).

Figure 1.5 presents various values of the parameter, unit peak discharge (qu), expressed in units of cubic feet per second per square mile of drainage area per inch of runoff (csm/in), for various drainage area TCs and Type II storm distribution. Multiplying the appropriate unit peak discharge value by the drainage-area size (expressed in square miles) and the estimated runoff volume (expressed in inches) will yield an estimate of peak runoff rate in units of cubic feet per second (cfs). Figure 1.5 also contains one additional value, Ia/P—the ratio of the drainage area's initial abstraction to the total storm rainfall—that must be determined before estimating a peak rate (TR-55, Chapter 4, contains more instruction and insight into estimating peak runoff rates).

Summaries of the resulting computations for the 20-acre (8.1 ha; 0.03 mi^2) drainage area with a 0.5 hour TC for both HSGs follow:

FOR HYDROLOGIC SOIL GROUP B

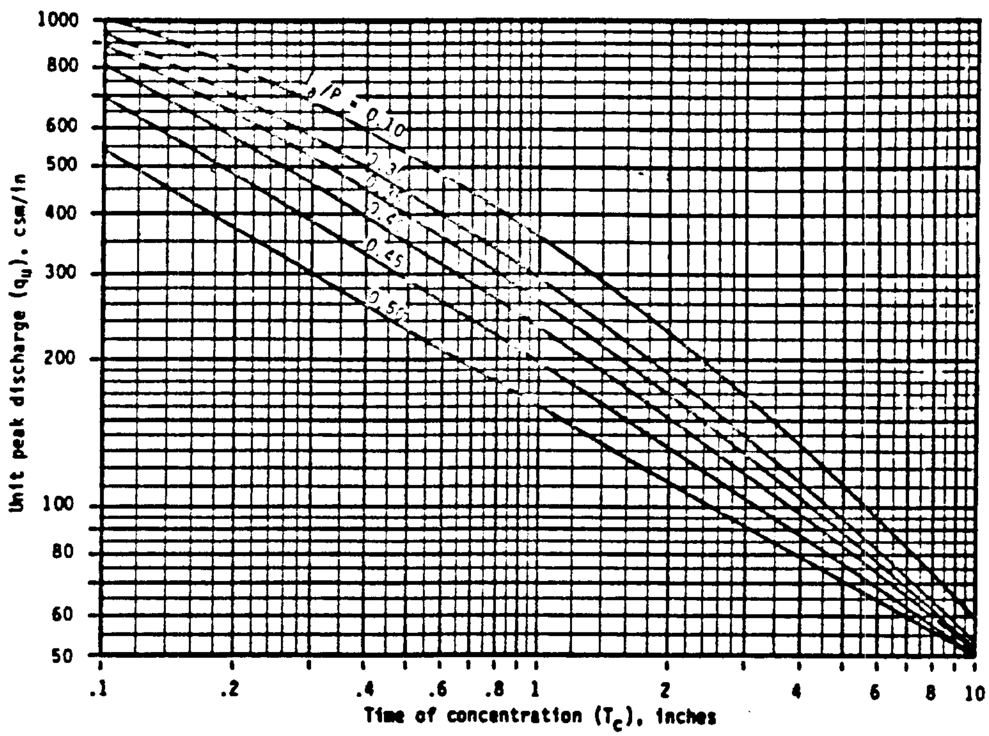
STORM FREQUENCY (years)	ESTIMATED RUNOFF (inches)	Ia/P	qu (csm/in)	ESTIMATED PEAK DISCHARGE (cfs)
2	0.14	0.59	230	1.0
10	0.53	0.41	340	5.6
100	1.40	0.28	450	19.7

FOR HYDROLOGIC SOIL GROUP D

STORM FREQUENCY (years)	ESTIMATED RUNOFF (inches)	Ia/P	qu (csm/in)	ESTIMATED PEAK DISCHARGE (cfs)
2	0.93	0.21	470	13.7
10	1.81	0.15	505	28.6
100	3.30	0.10	530	54.7

In the HSG B and D tables, we note that while the estimated peak runoff rates for the HSG D drainage area are greater than those for the

Figure 1.5—Unit peak discharge (qu) for Soil Conservation Service Type II storm.



Source: U.S. Dep. Agric. 1986.

HSG B, the ratio or percentage difference between the peak rates is greater than between the volumes. For example, the HSG D volume estimate for the 10-year frequency storm is 3.4 times greater (1.81 inches divided by 0.53 inches) than the HSG B volume. However, the HSG D peak rate estimate for the same 10-year frequency storm is 5.1 times greater (28.6 cfs divided by 5.6 cfs) than the HSG B peak rate. Similar increases for the 2-year and 100-year events show the same decreasing trend for increasing rainfall amounts. This further difference between the two HSGs is the result of several factors. These include the HSG D soil's lower initial abstraction, which results in an earlier start of runoff and has a lower Ia/P ratio and higher qu value; the variable shape of the Type II storm distribution, in which the most intense rainfalls occurs near the middle of the 24-hour duration; and the exponential character of the USDA SCS runoff equation.

The examples confirm the following points. First, the amount of runoff produced by rainfall varies nonlinearly. Consequently, as the rainfall amount increases, the amount of runoff volume will increase even more. This relationship is also true for peak runoff rates. Second, a change in drainage area or watershed runoff characteristics, as demonstrated by hypothetically varying the soils from HSG B to HSG D, can complicate both the runoff volume and rate. Finally, while we can generalize on a drainage area's rainfall/runoff relationship, we can only determine specific estimates of resultant runoff through mathematical analysis based on sound assumptions and the appropriate amount and quality of data. We will explore these relationships and the effects of drainage area changes in discussing hydrologic impacts of land development.

The Soil Erosion Process

Concepts and Theories

As previously stated, both rainfall and the runoff it produces—or is converted into—affect and are affected by the land surfaces they contact. For rainfall, this contact occurs only at the instant the raindrops strike the ground. For runoff, the contact period normally lasts considerably longer. Nevertheless, the forces exerted briefly by raindrops and longer by runoff combine to dislodge and transport soil particles, commonly known as sediment.

Chapter 2 discusses in detail the impacts of sediment on surface water quality, biota, and habitat, presenting the theoretical and technical fundamentals of the soil erosion process. A sound understanding of these fundamentals will prepare readers for the more detailed presentations to follow and will enable them to better develop and manage a comprehensive urban runoff management program. The soil erosion fundamentals are largely based on Appendix A1 of the *Standards for Soil Erosion and Sediment Control in New Jersey* (1987). The publication is one of many excellent sources for theoretical and practical information on soil erosion and its control.

Soil erosion is a three-part process, beginning the instant raindrops strike the ground surface, sometimes at velocities up to 30 mi (48.3 km) an hour. The impact force is often sufficient to dislodge soil particles from bare ground surface and begin their movement down slope. This initial stage of the soil erosion process primarily from raindrop impact is known as sheet erosion. In the sheet erosion stage, significant quantities of soil particles are mobilized from the enormous number of raindrop impacts over an area.

The exact amount of sediment produced during sheet erosion depends on several factors, including the size, mass, and texture of the soil particles; the size and slope of the ground surface; the type and degree of surface cover; and the intensity and duration of the rainfall. The shear forces created by runoff flowing across the impacted area from upslope portions of the drainage area can also dislodge soil particles from the ground surface. This increases the total quantity of sediment produced during sheet erosion.

Once the soil particles are detached from the surface, runoff primarily keeps them mobilized during the next stage of soil erosion—downslope transport. During this stage, runoff transports the sediment across the ground surface, along small rills and gullies, and through larger swales and channels. The extent of the sediment movement also depends on a large number of factors, including the volume, rate, and duration of the runoff; the size, mass, and shape of the displaced soil; and the shape, slope, and roughness of the various surfaces over which the runoff-borne sediment is moving. As previously explained, runoff moving across the ground surface also further displaces soil particles by mobilizing previously attached material. This runoff movement can create enormous amounts of additional sediment, particularly in highly erodible stream channels.

The final stage of the soil erosion process is the deposition stage, when the runoff can no longer carry the sediment and deposits it back on the ground some distance from where it originated. This can occur anywhere in the watershed—from upland surfaces, to channels, to lake bottoms. The watershed is then left with depleted upper soil layers in some portions and new soil layers in others.

The soil erosion process is extremely complex and dynamic. All three stages can and do occur continually, to varying degrees, throughout the rainfall/runoff event—which is also complex and dynamic. Since sediment produced by the soil erosion process can come from anywhere in the watershed, we must carefully manage and protect each portion and component.

Estimating Sheet and Rill Erosion

Despite the complexities of measuring sediment, research and experience have developed various methods and techniques to estimate the amount of soil loss from sheet and rill erosion. The Universal Soil Loss Equation (USLE) is generally accepted as the standard technique to estimate the effectiveness of various erosion control practices and measures. Appendix A of the *Standards for Soil Erosion and Sediment Control in New Jersey* (1987) contains a detailed presentation.

The USLE is an empirical equation used to estimate the annual amount of soil lost by sheet and rill erosion on a given parcel of land:

$$E = (R)(K)(L)(C)(P) \qquad [4]$$

where:

E = Estimated Annual Soil Loss due to sheet erosion (in tons/acre/year).

R = Rainfall Factor or Rainfall Erosion Index—a measure of the erosive force of rainfall occurring over the study area during a normal year. Figure 1.6 presents typical values of R for various portions of New Jersey.

VOL 12 6576

R0039884

Figure 1.6—Rainfall erosion index (R) for New Jersey counties.

TABLE 1.2—Universal Soil Loss Equation soil erodibility (K) classes and ranges.

ERODIBILITY CLASS	RANGE OF K
Low	0.17 – 0.24
Medium	0.28 – 0.37
High	0.43 – 0.49

Source: New Jersey Dep. Agric. 1987.

K = Soil Erodibility Factor—a measure of the erodibility of soils in the study area based on field tests of fallow ground with standardized slope and length. Table 1.2 presents ranges of K for various soil erodibility classes.

L = Slope Length Factor—allows adjustments to be made to K to account for the actual slopes and lengths in the study area that vary from the standardized test values.

C = Cover Index—allows adjustments to be made to K to account for the actual ground cover in the study area other than the standard fallow condition. Table 1.3 present typical values of C for various ground covers.

P = Erosion Control Practice Factor—a relative measure of the effects of various surface conditions in the study area. Table 1.4 presents typical values of P for various surface conditions found particularly at construction sites.

The USLE uses additional factors to produce estimates for periods of time less than one year and for individual storm events of specified frequency.

The USLE is a fairly simple mathematical equation. The estimated soil loss is a function of the erosive properties of a given soil (K), as determined through standardized tests, which are then modified by a number of pertinent factors—such as rainfall and ground slope, cover, and surface character—to reflect the actual conditions in which the soil exists. In addition, the mathematical relationship between all input factors and the final result are linear—a certain percentage change in any input variable results in an identical change in the result.

The actual sheet and rill erosion process, however, is not simple and the various input factors do not behave in a simple, linear fashion. The USLE's apparent simplicity masks the complexity of the actual sheet erosion process and the difficulty of mathematical modeling. Users need to exercise caution when applying the USLE and its estimates.

The most important aspects of the USLE that relate to urban runoff management programs are the cover index (C) and the erosion control practice factor (P). These are the factors that designers, constructors, and regulators can control. For example, placing straw mulch on bare ground at the

Table 1.3—Universal Soil Loss Equation typical cover index (C) values.

GROUND COVER	APPLICATION RATE (tons/acre)	SLOPE (%)	TYPICAL C
None	—	All	1.00
Straw or hay	1.0	0 – 10	0.20
	1.5	0 – 10	0.12
	2.0	0 – 10	0.06
	2.0	11 – 15	0.07
Crushed stone (0.25–1.50")	135	0 – 15	0.05
	240	0 – 15	0.02
Woodchips	7	0 – 15	0.08
	12	0 – 15	0.05
	25	0 – 15	0.02
Temporary seeding and straw mulch (first 6 weeks)	No mulch	—	0.70
	Mulch @ 1.0	—	0.20
	Mulch @ 1.5	—	0.12
	Mulch @ 2.0	—	0.06
	No mulch	—	0.10
	Mulch @ 1.0	—	0.07
	Mulch @ 1.5	—	0.05
	Mulch @ 2.0	—	0.05
Permanent seeding (after 2 years) and sod	—	—	0.01

rate of 1 ton per acre will result in an 80 percent reduction of the C value in the USLE (in Table 1.3, from 1.0 to 0.2). The USLE's linear nature can produce a similar reduction in the estimated soil lost through sheet erosion from those surfaces. Proper surface conditions, demonstrated in the typical P values in Table 1.4, can achieve more limited results.

Table 1.4—Universal Soil Loss Equation typical Practice Factor (P) values.

SURFACE CONDITION WITH NO COVER	TYPICAL P
Compacted and smooth Machine scraped along slope	1.3
Compacted and smooth Machine raked along slope	1.2
Compacted and smooth Machine scraped across slope	1.2
Compacted and smooth Machine raked across slope	0.9
Rough and irregular Random machine tracks	0.9
Loose and smooth Deeper than 12 inches	0.9
Loose and rough Deeper than 12 inches	0.8

Source: New Jersey Dep. Agric. 1987.

The second aspect of the USLE and sheet erosion is the time the erosive condition is allowed to exist in the field. Regardless of the ground cover, surface conditions, or any other USLE sheet erosion factor, limiting erosion to the shortest practical exposure time attains the least soil loss. Chapter 4 recommends techniques and regulations to minimize losses.

USDA is in the process of replacing the USLE with the Water Erosion Prediction Program (WEPP). Currently, the Revised Universal Soil Loss Equation (RUSLE) is being adopted nationwide. RUSLE is based on updated rainfall cover index and erosion control practice factors.

Estimating Channel Erosion

The sediment created by sheet erosion is only part of the soil erosion process. Once the runoff across the ground surface exceeds a certain depth, gravity moves the runoff toward collection in progressively larger conveyance devices. These range from small rills to large gullies and finally to stream and river channels. As gravity forces runoff to flow downslope, it creates further erosion and collects additional sediment from the soils on the banks and bottoms.

Whether runoff causes such erosion and how much sediment it creates depends on a number of interrelated and dynamic factors. These include the velocity and duration of flow; weight, shape, and location of the soil particles; the degree of sediment already suspended in the runoff; and the channel's shape, length, slope, and irregularity.

Although estimating soil losses due to channel erosion is beyond the scope of this and most similar manuals, the rate of channel erosion is partly a function of the channel's flow velocity. While all velocities do not cause erosion, a channel is generally considered to be stable up to some conceptual flow velocity, called the maximum permissible velocity. This flow velocity should be thought of as the channel erosion equivalent of time of concentration—that is, a conceptualization that can be practically used.

Once this maximum permissible velocity is exceeded, erosion of soil particles on the channel banks and bottom will begin and continue as long as the velocity is maintained. As the flow velocity increases, the rate of erosion will also increase. While we cannot determine an upper limit on the erosion rate, the quantity of sediment produced by channel erosion can be enormous, as an inspection of natural stream channels immediately following a major flood event can show.

Impacts of Land Development

Impacts on Urban Runoff

Typically, a land development project in a drainage area or watershed involves replacing or modifying at least some of the existing surface cover with roads, roofs, driveways, and other impervious material. Since the existing cover material is usually more permeable, particularly if it existed naturally, this change will result in a greater percentage of rainfall becoming runoff. We can use the USDA SCS runoff equation (equation 2) and the recommended runoff curve numbers (CNs) from Table 1.1 to quantify this.

We will assume that the 20-acre (8.1-ha) wooded drainage area in the earlier example has

Table 1.5—Comparison of runoff volume between undeveloped and developed conditions.

PARAMETER	UNDEVELOPED CONDITIONS	DEVELOPED CONDITIONS
CN	55	70
S (inches)	8.18	4.29
Ia (inches)[1]	1.64	0.86

STORM FREQUENCY (years)	24-HOUR RAINFALL (inches)	ESTIMATED RUNOFF (inches)	
		Undeveloped	Developed
2	2.8	0.14	0.60
10	4.0	0.53	1.33
100	5.8	1.40	2.64

STORM FREQUENCY (years)	24-HOUR RAINFALL (inches)	ESTIMATED RUNOFF (inches)		RUNOFF AS PERCENT OF RAINFALL	
		Undevel.	Devel.	Undevel.	Devel.
2	2.8	0.14	0.60	5%	21%
10	4.0	0.53	1.33	13%	33%
100	5.8	1.40	2.64	24%	46%

now been converted into half-acre residential lots with an average impervious coverage of 25 percent and, for simplification, contains soils in HSG B. According to values from Table 1.1, the CN would increase from 55 in the wooded state to 70 when the homes, lots, and roads are constructed and the lawns and other landscaped areas are fully established. Equations 2 and 3 produce the results shown in Table 1.5.

The increase in impervious coverage has reduced the drainage area's initial abstraction by nearly a half—from 1.64 in (4.2 cm) to 0.86 in (2.2 cm)—and less rainfall is needed to produce runoff from the drainage area. This results in a greater amount of runoff from storms that already produced runoff from the drainage area and an increase in the total number of future runoff-producing storms. Among other impacts, this increase in runoff means decreased amounts of rain infiltrating into the soil. This can produce lower groundwater levels and diminished or totally eliminated dry weather or base flows in streams.

The increased impervious coverage further increases runoff volume by increasing the runoff production rate once the initial abstraction is overcome and runoff begins. We see this clearly by comparing the estimated percentages of rainfall that becomes runoff in undeveloped and developed conditions. The 2-year storm percentage increases fourfold—from 5 percent to 21 percent. The 10-year and 100-year percentages also increase, with the 10-year nearly tripling and the 100-year almost doubling. This indicates, however, that land development impacts on runoff volume will be more acute for the smaller, more frequent storm events—a problem for channels and streams, which are sensitive to these storm events.

Another effect of land development is a decrease in the drainage area's response time or TC. This effect results from the faster flow of runoff across the impervious surfaces and the installation of more efficient (i.e., faster) conveyance measures—gutters, storm sewers, and impermeably lined channels—replacing the natural measures present prior to development. If these measures resulted in a new TC for the 20-acre (8.1-ha) drainage area of 0.25 hours, we can use charts and data from TR-55 to estimate the following changes to the peak runoff rates from the drainage area:

UNDEVELOPED CONDITIONS
Woods in Good Hydrologic Condition

STORM FREQUENCY (years)	ESTIMATED RUNOFF (inches)	Ia/P	qu (csm/in)	ESTIMATED PEAK DISCHARGE (cfs)
2	0.14	0.59	230	1.0
10	0.53	0.41	340	5.6
100	1.40	0.28	450	19.7

DEVELOPED CONDITIONS
Half-Acre Residential

STORM FREQUENCY (years)	ESTIMATED RUNOFF (inches)	Ia/P	qu (csm/in)	ESTIMATED PEAK DISCHARGE (cfs)
2	0.60	0.31	620	11.6
10	1.33	0.22	660	27.4
100	2.64	0.15	710	58.6

These estimates indicate that the peak runoff rates from the drainage area increase because of development activity, with the estimated 2-year, 10-year, and 100-year peak rates increasing by factors of approximately 10, 5, and 3, respectively. The impacts of these peak flow increases include increased depths in the streams and rivers downstream, which can aggravate existing flood problems and create new ones in previously safe areas.

As shown in the previous chart, land development impacts on the rainfall-runoff process typically include an increase in the volume of urban runoff created by a given amount of rain, a decrease in the time it takes for runoff to drain from the land, and consequently, an increase in peak rate. These increases can produce more frequent and deeper flood depths, threatening the safety and property of those residing and working downstream. In addition, the increased volume of runoff typically means a decrease in groundwater levels and base flows in the streams and rivers, which also threatens aquatic organisms and their habitats and water supply resources.

Impacts on Soil Erosion

The impacts of land development activity on soil erosion can be devastating. Soil erosion can accelerate to levels higher than geologic norms. These impacts begin during the construction phase, primarily in the form of sheet erosion, and often persist after construction. Increases in sheet erosion during construction are caused by removing natural vegetation during site clearing, exposing surface soils to the impacts from raindrops, and the shear forces of the resultant runoff.

For example, a typical C value for grass cover ranges from approximately 0.10 for temporary grass cover after six weeks of growth to 0.01 for established grass cover or sod (Table 1.3). However, the C value for bare ground is 1.00—10 to 100 times larger. Since the USLE considers the average annual soil loss (E) from an area linearly related to C, the soil lost to sheet erosion during construction can be as much as 100 times greater than from the natural, undisturbed area. This makes up to 100 times more sediment available for runoff to transport into downstream waterways.

However, this estimate does not include the effects of bare soil in increasing the volume and rate of runoff that can dislodge and transport even more sediment. In Table 1.1, the CN for bare soil

VOL 12

6580

in HSG B is 86, greater than the CN of 70 that reflects final developed conditions in the drainage area. Therefore, the construction phase of land development not only increases the quantity of erodible sediment but also the rate and volume of runoff to transport it.

The increased rate and volume of runoff from development activity can also aggravate existing or create new channel erosion, initiating additional sediment loadings. For the more frequent 2-year and 10-year storms, greater impervious coverage and a shorter drainage area response time produce peak runoff rates 5 to 10 times greater after development. These increased peak runoff rates will, in turn, produce higher peak runoff velocities in the downstream waterways. If these increased velocities exceed a certain critical level, channel erosion will likely occur in previously stable, undisturbed channels. For channels already experiencing erosion, these increased velocities will increase the problem.

Sediment is typically deposited in a flatter, slower reach of the waterway or at the bottom of a wetland, lake, or estuary. Sediment recovery in the lower reaches can also have devastating effects. Chapter 2 discusses the qualitative effects of the erosion and sedimentation process.

Summary and Conclusions

The chapter's purpose is to enable those developing urban runoff management programs to make informed decisions about their programs and increase their effectiveness and applicability.

The chapter's key messages are

1. The rainfall-runoff and soil erosion processes are dynamic and complex. No perfect analytical models or methods can exactly reproduce past runoff or erosion events or predict future ones.

2. Because urban runoff management must consider the quantitative impacts of land development on runoff quality, its complexity significantly increases. These impacts exacerbate any weaknesses or inaccuracies in the analytical models and methods.

3. Through research and a sound understanding of the fundamentals, we can make simplifying assumptions about these hydrologic processes that enable us to produce reasonable, practical, and safe runoff and soil erosion estimates.

4. Everyone involved in developing an urban runoff management program must understand the fundamentals of urban runoff hydrology. Experienced professionals in the field must be included in the development process, particularly in selecting technical standards, methodologies, and measures.

5. The growth of computer resources and capabilities has increased the accuracy and applicability of methods and models and the effectiveness of urban runoff management programs. However, the need for more comprehensive data and expanded user knowledge has increased likewise, further highlighting the importance of technical knowledge and experience.

6. While general information can be a useful guide, the complexity of the hydrologic processes demands site-specific data and methods to identify, define, and/or address urban runoff management problems or concerns.

7. The interrelationships of the rainfall-runoff and soil erosion processes emphasize the need for a comprehensive, watershed approach to all aspects of urban runoff management, ranging from individual site designs to comprehensive regulatory programs.

Recommended Reading

The following publications were influential in developing this chapter. We strongly recommend them to readers wishing to expand their knowledge of the rainfall-runoff and soil erosion processes.

CHAPTER 2

Water Quality Impacts of Urban Land Use

Urban runoff carries with it a wide variety of pollutants from diverse and diffuse sources. Representing all recognized classes of water pollutants, these runoff contaminants originate not only from land activities in the drainage catchment where runoff is collected but also from atmospheric deposition as either "dryfall" or "wetfall." Moreover, surface and groundwaters can exchange. This chapter focuses on water quality by examining the characteristics, sources, and patterns of urban runoff pollutants and discusses assessment techniques.

Contaminants originating below ground (e.g., landfill leachate, effluent from failing septic systems) can enter surface runoff, while runoff can enter groundwater through sinkholes or drainage wells. Pollutants originating on the surface can also percolate through the soil and contaminate groundwater.

These general sources of urban runoff pollution on, above, and below the surface represent a complex set of watershed conditions. They determine the effects that drainage from the watershed will have on a natural receiving water, and represent a challenge for management. Figure 2.1 illustrates the relationships between watershed activity and its consequences in the receiving water. The complex of watershed conditions determines the characteristics of the habitats that will develop in the receiving waterbody. For example, if the base geological material is relatively insoluble and erosion resistant, a stream draining that area will likely have a substrate of relatively large cobbles, or even bedrock, and a low level of nutrition. The aquatic biota evolve in direct response to the types of habitats produced by the watershed conditions. In this example, the biota will likely consist of diatoms at low biomass levels among the attached algae. Populations of invertebrates and fish, though probably quite diverse, are likely to be relatively small in both numbers and sizes of the individual organisms. The dashed arrow at the top of Figure 2.1 shows that living organisms do have some ability to modify their environment.

The lower portion of Figure 2.1 links watersheds in which humans are active to the systems to which they drain. Numerous pollutants in the watershed, here represented by only two, can stress organisms and interact to varying degrees. This interaction can either reinforce or reduce the stress of the participating agents. Water pollution is not the only condition in the watershed that causes stress. Chief among other stresses is modified hydrology from increased wet weather flow volumes and peak rates discharged from altered landscapes. Conversely, stress can come from decreased dry weather base flows resulting from reduced groundwater recharge in urban areas.

In Figure 2.1, water pollutants go through various kinds of processing before they create some effect on an aquatic organism. During their transport on land and in water, losses such as sedimentation can reduce the total stress burden on water column organisms, although the reduction may not be permanent (e.g., sediments can resuspend). Of course, organisms dwelling among the sediments often become more affected by these processes. Physical, chemical, or biological processes can also cause transformations to different physical (particulate versus dissolved) or chemical forms. Transformation can cause enhanced or reduced stress potential.

Finally, the biota, or receptors, are affected by the various stresses in whatever form they ar-

rive. A receptor will have an easier time dealing with a few rather than many stressors, especially when they reinforce each other. Of course, populations of aquatic organisms do not live in isolation but interact with other species, especially in predator-prey relationships. This relationship is represented by the arrow linking the two receptors in the simple system. These interactions have many implications for the ecosystem. For example, the loss of one species from a pollution problem will likely result in the decline or elimination of a major predator of that species.

This illustration sets the stage for discussions in this chapter and in Chapter 3, Aquatic Biological Impacts of Urban Land Use. Substantial complexities exist at every level of the system from pollutant generation to ultimate effects on aquatic ecosystems. Therefore, predicting the result of a particular event or action in the watershed is problematic. However, by carefully tracing the progression of problems and their interrelationships, we can make some judgments to improve our success in ecosystem protection. While this chapter focuses on water quality, Chapter 3 discusses the water quality and hydrologic stresses that disrupt habitats and harm aquatic life.

Characteristics of Urban Runoff Pollutants

Substances In Urban Runoff

Table 2.1 lists pollutant categories commonly found in urban runoff that can harm receiving wa-

VOL 12

6584

ters and the specific measures that express them. Pollutants other than solids and pathogens are found in either a solid or dissolved state. In urban runoff, most pollutants occur as solids or are associated with soil or other natural particulates. This condition differs among the specific pollutants. For example, depending on overall chemical conditions, each metal differs in solubility. For instance, lead (Pb) is relatively insoluble, while zinc (Zn) is in solution form. The nutrients phosphorus (P) and nitrogen (N) typically differ substantially from one sample to another in dissolved and particulate forms.

Table 2.1—Urban runoff pollutants.

CATEGORY	SPECIFIC MEASURES
Solids	Settleable solids (SS) Total suspended solids (TSS) Turbidity (Turb)
Oxygen-demanding substances	Biochemical oxygen demand (BOD) Chemical oxygen demand (COD) Total organic carbon (TOC)
Phosphorus (P)	Total phosphorus (TP) Soluble reactive phosphorus (SRP) Biologically available phosphorus (BAP)
Nitrogen (N)	Total nitrogen (TN) Total Kjeldahl nitrogen (TKN) (ammonia + organic) Ammonia-nitrogen (NH_3-N) Nitrate + nitrite-nitrogen (NO_3+NO_2-N)
Metals	Copper (Cu), lead (Pb), zinc (Zn), cadmium (Cd), arsenic (As), nickel (Ni), chromium (Cr), mercury (Hg), selenium (Se), silver (Ag)
Pathogens	Fecal coliform bacteria (FC) Enterococcus bacteria (Ent) Viruses
Petroleum hydrocarbons	Oil and grease (O + G) Total petroleum hydrocarbons (TPH)
Synthetic organics	Polynuclear aromatic hydrocarbons (PNAs) Phthalates Pesticides Polychlorobiphenols (PCBs) Solvents

Source: R.R. Horner.

Besides these pollutants, other water quality characteristics affect the behavior and fate of materials in water. These characteristics include

- Temperature (Temp);
- pH—an expression of the relative hydrogen ion concentration on a logarithmic scale of 0-14, with 0-6.99 representing a preponderance of hydrogen relative to hydroxyl ions (acidic conditions), 7.00 being neutral, and 7.01-14 representing a preponderance of hydroxyl ions (basic conditions);
- Dissolved oxygen (DO);
- Alkalinity (Alk)—the capacity of a solution to neutralize acid of a standard pH, usually the result of its carbonate and bicarbonate ion content, but conventionally expressed in terms of calcium carbonate equivalents;
- Hardness—an expression of the relative concentration of divalent cations, principally calcium (Ca) and magnesium (Mg), also conventionally expressed in terms of calcium carbonate equivalents; and
- Conductivity (Cond)—a measure of a water's ability to conduct an electrical current as a result of its total content of dissolved substances (often expressed as salinity in estuarine and marine waters).

These characteristics affect pollutant behavior in several ways. Metals generally become more soluble as pH drops below neutral and hence more available—bioavailable—to harm organisms. Depleted dissolved oxygen can also make some metals more soluble. Anaerobic conditions in the bottom of lakes release phosphorus from sediments, as iron changes from the ferric to the ferrous form. Elements creating hardness work against the toxicity of many heavy metals. Water quality standards take this relationship into account by varying the permitted level as a function of hardness.

Quantifying Water Pollutants

Water pollutants are quantified by concentrations and loadings. Concentration is the mass of pollutant per unit volume of water sample, usually expressed as mg/L or µg/L. It is a measure of the pollutant content at the instant the sample is taken. If the pollutant level is higher than an aquatic organism can tolerate, the concentration represents an acute effect that could be lethal or affect the performance of some physiological function as long as the concentration persists. The effects of pollutant concentrations have been established through bioassays exposing test organisms in standard laboratory procedures. However, these simple, static tests completely omit the dynamic patterns and other complexities associated with urban runoff.

Loading is the mass of pollutants delivered to a waterbody over a period of time and is usually given on an annual basis as kg/year (kg/y) or lbs/y. When ascribed to a particular land use, loading—sometimes termed yield or export—is stated per unit area of the land use (kg/ha-y or lbs/acre-y). It represents the cumulative burden over the extended period and hence the potential chronic effects on receptor organisms. With few exceptions (e.g., phosphorus loading to lakes), testing has not established the biological significance of loadings and the way they are delivered to a waterbody. Thus, loading is mainly used to

VOL 12

6586

make relative comparisons, for example, of total pollutant burden before and after development or with and without a certain control strategy.

Table 2.2 presents concentration statistics on several pollutants in general urban and highway runoff and water quality criteria to protect aquatic life. While concentrations generally range widely, the mean values tend to be low. Highway runoff is similar to urban drainage, but means and maximums are generally higher. Urban runoff usually does not exceed water quality criteria with reasonable dilution in the receiving water, but it could. These criteria stem from laboratory testing and represent continuous flow discharges, such as industrial and municipal sewage treatment plant effluents, better than runoff.

Table 2.3 presents typical loadings for a number of pollutants and land uses. Although this table presents no ranges or statistics on the possible dispersion of these numbers when measurements are made, the variation is always substantial from place-to-place in the same land use and from year-to-year at the same place. The general order of loading production, from highest to lowest is

Industrial and commercial > freeway > higher-density residential > lower-density residential > open land.

However, the construction phase can produce far higher loadings of solids and pollutants in soil, like phosphorus, than any finished land use. These data, however, were derived from 10-year-old studies and should be used with caution. For example, substantial evidence indicates that the values for lead have considerably declined in urban runoff with the much reduced use of leaded gasoline.

Metals and synthetic organics are of particular interest because of their potential for toxicity to human consumers of water and to aquatic life. They make up most of EPA's priority pollutants list. Table 2.4 lists the priority pollutants most frequently detected in samples collected during EPA's Nationwide Urban Runoff Program (NURP) in the early 1980s. Three metals (lead, zinc, and copper) were found in almost all samples, and four additional metals were detected in approximately half. Phthalate, the most common synthetic organic, was found in only 22 percent of the samples. Present in 10 to 19 percent were three chlorinated hydrocarbons (two pesticides and a wood preservative) and four polynuclear aromatic hydrocarbons (PNAs).

Table 2.3—Typical pollutant loadings (lbs/acre-y) from urban land uses.

LAND USE	TSS	TP	TKN	NH_3-N	NO_2-N	BOD	COD	Pb	Zn	Cu

Sources of Urban Runoff Pollutants

Table 2.5 summarizes urban runoff pollutant sources and shows that most pollutant categories have diverse sources. Likewise, the major sources emit contaminants in most pollutant categories. The atmosphere also contributes some pollution to runoff. Thus, urban runoff is a multifaceted and complex problem to manage.

Synthetic organics represents an exceptionally large and diverse category of chemicals. They include hundreds of specialized products for industrial and commercial uses and compounds produced incidentally through chemical reactions. Examples of the latter group are the PNAs, by-products of fossil fuel combustion, that appear in vehicle exhausts and lubricants and smokestack emissions. New chemicals also form through environmental reactions after the release of a material.

Stormwater management can also be the source of pollutants. During large flows, poorly maintained facilities—like catch basins, conveyance systems, sedimentation ponds, and belowground vaults—can release surges of sediments trapped during small storm events. Galvanized pipes and other parts of drainage systems, commonly used to convey runoff, can also add zinc, a ubiquitous metal in the environment.

Urban Runoff Water Quality Patterns

While pollutant magnitudes in urban runoff follow characteristic patterns over short and long time spans, they vary greatly over space and time. The short term spans a period of hours during one or a sequence of storm events. Measurements at discrete points through such a period often reveal a pattern of pollutant concentration similar to that illustrated in Figure 2.2. During the first minutes, first flush of runoff contains a relatively high concentration of contaminants. The concentration then drops substantially and fluctuates at a lower level for the remainder of the runoff event. The first flush sometimes does not appear, or is less pronounced, when rainfall is not intense or follows soon after an earlier storm that cleans the surfaces. A secondary spike can appear if a sudden burst of intense rain drives material off surfaces not completely cleaned by the initial runoff. Runoff concentrations assume an almost infinite variety of patterns depending on rainfall intensity, antecedent period length and conditions, deposition during the antecedent period, and surface characteristics.

The event concentration-time graph (Figure 2.2) shows the stress created by a single pollutant on a receptor organism. The concentrations represent a series of acute stresses, the most significant of which is the maximum concentration often reached during the first flush. Experts do not fully understand the consequences of a short-duration elevated concentration, even one above water quality criteria, and of the fluctuating stress-filled environment of runoff receiving waters on their resident organisms.

Because of the difficulty in characterizing pollutant concentrations during dynamic flow

Source: R.R. Horner.

conditions, the expense of sampling, and the analysis required to produce even a partial picture, the accepted practice is to determine an event-mean concentration (EMC). This value is found by analyzing a single sample composited from a series of samples taken at points throughout the runoff event and combined in proportion to the flow rate existing at the time of sampling (termed a flow-proportional composite sample). In addition to its expediency, basing impact assessment on the EMC is justified from a biological standpoint. This will be further explored in Chapter 3.

The flow pattern of an event is customarily pictured on a hydrograph—a graph of flow rate (water volume per unit time) versus time. The integrated area under the curve is the total event runoff volume; the product of volume and EMC is the pollutant loading for the event. The sum of loadings for all events in an interval (e.g., a year) represents the cumulative pollutant burden during that time.

Analysis of climatological data in a number of U.S. locations reveals that most of the total annual runoff is produced by numerous small storms and the initial runoff from large storms. For example, Livingston and Roesner (in press) used Cincinnati data to show that the first 0.5 in (1.27 cm) of runoff from all storms represents more than 90 percent of the total annual runoff volume and encompasses all but four or five events in an average year. Theoretical reasons and some empirical demonstrations indicate that the majority of pollutant loadings is also generated by these smaller flow volumes. Hydrologic criteria for runoff treatment system design are based on these patterns. For example, a pond needs sufficient volume to treat the first 0.5 or 1 in (1.27 or 2.54 cm) of runoff, or the runoff associated with the six-month return frequency, 24-hour duration precipitation event.

Urban Runoff Water Quality Estimation

We need a quantitative estimate of water quality to assess impacts from development actions or to predict the benefits of a management plan. This estimation process is called water quality modeling, although this term is sometimes restricted to the more sophisticated approaches. Assessments are based on annual pollutant loading estimates, although short-term loadings or concentrations are sometimes needed. Long-term loadings tend to diminish the large fluctuations to which short-term phenomena, like instantaneous or event-mean concentrations, are subject. Therefore, we can estimate long-term loading with more assurance than concentrations.

Estimating Concentrations

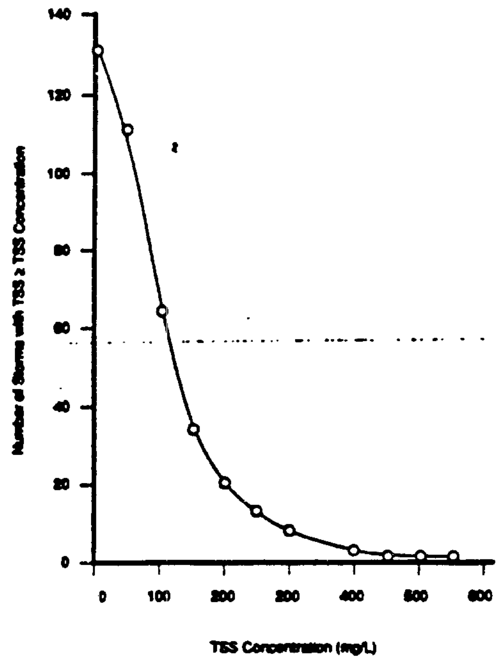
Since concentrations have a high variation level, they must be estimated based on probability—i.e., the ability to state the probability of exceeding any selected concentration. Estimating the probability of concentrations can theoretically be used to estimate maximum (or any other level), but it is usually restricted to the EMC. To estimate even the EMC, we need a large data set to establish the underlying probability distribution for the locale or an assumption of the distribution and a smaller local data set to fit the distribution.

NURP and other data conclusively demonstrated that urban runoff pollutant concentrations fit a log-normal probability distribution—i.e., their logarithms are normally distributed. This is the characteristic distribution of data like those in Table 2.2, where the distribution range is much higher than the mean, and most values are in the lower portion. Figure 2.3, taken from highway runoff data in Washington State, illustrates such a distribution. It shows that the concentration of total suspended solids (TSS EMC) reached as high as 550 mg/L, but exceeded 300 mg/L in less than 10 of more than 130 storms.

Figure 2.4 graphs a highway runoff lead distribution (untreated) on a log-probability plot. The horizontal probability axis expresses the chance of exceeding any concentration selected from the vertical axis. For example, the probability of exceeding 0.12 mg/L in untreated, undiluted runoff is 50 percent, and the chance of surpassing 0.24 mg/L is 10 percent. Treatment or dilution capable of reducing the concentration by 50 percent would decrease the probability of exceeding 0.12 mg/L to 10 percent. Adding the water quality criteria permits performing the analysis from a regulatory perspective. For example, if the receiving water is a drinking water source, the concentration must be reduced by 90 percent to have no more than a 0.5 percent chance of violating the then current standard (the standard is lower now).

NURP produced graphs like Figure 2.4 for each pollutant to determine the EMCs at each site and the EMC medians from all sites nationwide (U.S. Environ. Prot. Agency, 1983). These plots

Figure 2.3—Cumulative frequency distribution of TSS concentrations in runoff from a Washington State interstate highway site.



Source: Little et al. 1983.

can help estimate concentration exceedance probabilities at other locations. Such estimates are best made with data from a site with climatological, land use, geological, and other characteristics similar to those of the location of interest. Using the nationwide plot of median values is less satisfactory.

Estimating Loadings

We can estimate cumulative (usually annual) pollutant loadings for a catchment in five ways, from the least to the most complex method:

1. Using published yield values;
2. Using a simple empirical model;
3. Using published regression equations;
4. Computing from site-specific or modeled flow data and either local or published concentrations; and
5. Using a computerized, mechanistic model.

▮ *Method 1—Published Yield Values.* This simple method is least likely to give accurate results because of the general lack of fit between the catchment of interest and the data collection lo-

cation(s). To apply this method, consult a reference like Table 2.3, select the areal loading rate for each land use, multiply by the areas in each use, and sum:

$$L = \sum a_i \cdot l_i \quad [1]$$

where: L = Total loading;
a_i = Area in land use i;
l_i = Areal loading from land use i.

We can improve this method by producing some measure of uncertainty or error in the estimates. To do so, we establish ranges of areal loadings from the literature, estimate maximum and minimum and mean or median values of L, and then evaluate to determine if uncertainty or error could change the conclusions. For example, uncertainty makes little difference in managing a watershed if we are assessing to identify critical pollutant source areas, and one or more clearly stand out in magnitude.

Table 2.6 presents loading rate ranges compiled by Horner (1992). The author drew values from the general literature and data collected in the Pacific Northwest. The regional data provided values for total phosphorus and total nitrogen for most land uses and all pollutants in road runoff, except fecal coliforms. Accordingly, the regional data have narrower ranges than the remainder. This table should be as discriminately used as others, especially since most pollutants are generally lower in Pacific Northwest runoff than elsewhere. Horner found that ranges estimated from this table

Table 2.6—Pollutant loading ranges[a] for various land uses.

6592

almost always bound estimates made independently by Hydrologic Simulation Program-Fortran (HSPF) computer modeling (see Method 5).

▮ *Method 2—Simple Empirical Model.* The best example of this method is Schueler's Simple Model (1987):

$$L = 0.23 \cdot P \cdot Pj \cdot Rv \cdot C \cdot A \qquad [2]$$

where:
- L = Loading (lbs);
- 0.23 = Conversion factor;
- P = Precipitation depth (inch) over the desired time interval;
- Pj = Factor that corrects for storms that produce no runoff;
- Rv = Runoff coefficient;
- C = Pollutant EMC;
- A = Area of the contributing catchment (acres).

For annual loading estimation, P is the area's average annual precipitation. Schueler recommends using 0.9 for Pj for annual and seasonal loading calculations. He uses NURP and Washington, D.C., area data to derive a regression equation ($r^2 = 0.71$) for Rv:

$$Rv = 0.05 + 0.009 \cdot I \qquad [3]$$

where: I = Percentage of the catchment area that is impervious.

Relative to C, Schueler notes that NURP data analysis finds no statistically significant differences in EMCs among sites and no correlations between EMCs and storm volume or intensity. Therefore, for rough estimates, these national NURP average EMCs can be used:

Total phosphorus	0.46 mg/L
Total soluble phosphorus	0.16 mg/L
Total nitrogen	3.31 mg/L
Total Kjeldahl nitrogen	2.35 mg/L
Nitrate-nitrogen	0.96 mg/L
Chemical oxygen demand	90.8 mg/L
Biochemical oxygen demand	11.9 mg/L
Zinc	0.176 mg/L
Lead	0.180 mg/L
Copper	0.047 mg/L

Of course, EMCs from local measurements should yield superior estimates. Data from other sources (like Table 2.2) can supplement this listing. A recent comparison of several West Coast watersheds found that Simple Model loading estimates usually agreed, within a factor of two, with estimates made by much more involved and expensive modeling procedures. Either approach will produce the same management conclusions (Chandler, 1993).

▮ *Method 3—Published Regression Equations.* The regression method is best represented by an extensive compilation made by the USGS using its own and NURP data (Driver and Tasker, 1990). This analysis produced multiple regression equations for three national regions for runoff volume and pollutant loadings and concentrations as functions of several independent variables. Independent variables include various meteorological, land use, and other characteristics. Standard errors for the equations were provided as a measure of uncertainty. For a detailed reference, refer to Driver and Tasker's large and complex tables.

▮ *Method 4—Site-Specific or Modeled Flow Data.* To use this method conveniently, arrange the calculations on computerized spreadsheets. Depending on local data, calculations can be performed in several ways. The best situation is to have continuously recorded local flow data and a series of representative local EMC readings. Assuming a log-normal distribution of EMCs, calculate the mean of the EMCs (a) using a statistical equation appropriate for the distribution (Marsalek, 1990). First, take the natural logs (ln) of the EMC values and compute the mean (μ) and variance (s^2) of the natural logs. Then

$$a = e^{(\mu + s^2/2)} \qquad [4]$$

where: e = Base of natural logarithms.

Calculate the confidence interval (C.I.) of the mean EMC estimate using the following equation:

$$C.I. = a \cdot e^{\pm \theta \cdot [s^2/n + 2 \cdot (s^2)^2/(n-1)]^{0.5}} \qquad [5]$$

where:
- + Is used for upper confidence limit;
- − Is used for lower confidence limit;
- θ = 1.96 for 95% confidence interval and 1.69 for 90%;
- n = Number of EMC values used to find μ.

Consult a flow record to obtain the total flow volume for the loading estimate period. Multiply that volume by the mean EMC to get the loading; then multiply it by the upper and lower confidence limits to get the estimate bounds.

Lacking a flow record, use a hydrologic model to estimate (see Chapter 1). One option is to use Schueler's formula for the runoff coefficient, $P_j = 0.9$, and the average precipitation for the period, demonstrated in Method 2. This method can also be used with a flow record but no local concentration data by using NURP or other published average EMC values.

■ *Method 5—Mechanistic Model.* This method includes comprehensive computerized models like the Storage, Treatment, Overflow, and Runoff Model (STORM) created by the U.S. Army Corps of Engineers; Storm Water Management Model (SWMM) and Hydrologic Simulation Program—Fortran (HSPF), both sponsored by U.S. EPA; and Illinois Urban Drainage Area Simulation (ILLUDAS) developed by the Illinois State Water Survey. Detailed coverage of these models is beyond this manual's scope, but the manual does describe their general elements. The models contain hydrologic and water quality components and have mathematical algorithms that represent the mechanisms generating and transporting runoff and contaminants. The hydrologic components of both SWMM and HSPF stem from the Stanford Watershed Model, first introduced almost 25 years ago, and produce continuous hydrograph simulations.

The models structure the water quality components on a mass balance framework that represents the rate of change in pollutant mass as the difference between pollutant additions and losses. Additions, considered to be pollutant deposition, are computed as a linear function of time. Soil erosion is usually calculated according to the Universal Soil Loss Equation (see Chapter 1). Losses are represented by a first-order washoff function (i.e., loss rate is considered to be a function of pollutant mass present); other losses are modeled in mathematically similar ways. For example, both organic matter decomposition and bacterial die-off are considered first-order reactions.

Some models, like SWMM, have both a receiving water and runoff component. These models treat some of the transformation processes that can occur in water (e.g., dissolved oxygen depletion according to the Streeter-Phelps equation). However, no model can comprehensively represent these numerous and complex processes.

These models require substantial local data to set variable parameters in the calibration step and to verify them for the intended application. They also require considerable skill and commitment from personnel. Therefore, only agencies prepared to commit the resources for database development and expertise should embark on using these models. Agencies that need to estimate urban runoff water quality should determine their objectives and select the most appropriate method.

Aquatic Sediment Impacts

At some point in their life cycle, many aquatic organisms have their principal habitat in, on, or near sediment. Sediments also hold pollutants introduced by urban runoff. Pollutants enter sediments in several ways. The most direct path is the settling of solids—this physically changes sediment quality and carries along other pollutants that change sediment chemistry or biology. Dissolved pollutants also move out of solution and into sediments by such mechanisms as adsorption of metals and organics at the sediment surface; ion exchange of heavy metals in water with native calcium, magnesium, and other minerals in sediments; and precipitation of phosphorus.

Most aquatic sediments have a large capacity to receive such contaminants through these processes. Also, many of the pollutants are conservative—once in sediments, they do not decompose or significantly change form. These conservative pollutants include refractory organic chemicals relatively resistant to biodegradation and all metals. Consequently, these types of pollutants progressively accumulate in sediments. Over the long term, discharge of even modest quantities of pollutants can result in sediment concentrations several orders of magnitude higher than in the overlying water. These contaminant reservoirs can be toxic to aquatic life to which they come in direct contact, and can also contaminate reservoirs far beyond the benthic (bottom-dwelling) organisms by biomagnification through the food web.

Historically, water quality has received more attention than sediment contamination. In the past 10 to 15 years, this view has changed because of mounting evidence of environmental degradation in areas that meet water quality criteria. However, sediment toxicity investigations are limited because we do not understand the factors that control contaminant bioavailability and we lack accepted testing methods. The result is an approach that emphasizes bioassay exposure techniques either in situ or in the laboratory along-with chemical analysis of the sediments, overlying water, and/or sediment interstitial water (see Chapter 5).

CHAPTER 3

Aquatic Biological Impacts of Urban Land Use

A wide array of pollutants entering aquatic ecosystems along with urban runoff causes numerous potential biological effects. These substances often change in transport. Other stresses often associated with hydrologic changes also accompany urbanization. These different stressors interact, and the receptor organisms under stress can interact with one another. How an urban runoff discharge might affect the biota in a receiving water is thus very complex, imperfectly understood, and hard to forecast with assurance.

This chapter focuses on the most numerous, complex, and difficult-to-manage aquatic ecosystem impacts. Table 3.1 provides a general summary of impacts and their causes. The table shows that impacts include chemical effects such as degraded water quality; physical effects such as altered hydrology, degraded habitat, and sediment transport; and biological effects such as altered biotic interactions and death of organisms.

Chapter 3 presents illustrations that cover key issues and the complex, interdisciplinary nature of aquatic biological impacts. Subjects covered include hydrologic and related physical impacts, the role of urban runoff in lake eutrophication, metals and their effects on aquatic organisms, thermal impacts of urbanization and urban runoff management, and fish habitat impacts and managing for habitat protection.

Water quality criteria are a regulatory attempt to avoid adverse impacts on aquatic systems by setting limits on concentrations of specific chemical pollutants that can reach receiving waters. However, relying on these criteria to manage urban runoff is often not an effective strategy, because biological damage can occur even when chemical water quality criteria have been met.

Several factors can explain this dilemma. Based in conventional toxicity, criteria do not represent the variable exposure pattern related to urban runoff or the cumulative effects of pollutant loadings over time. They also cannot account for transformations between release and the point of impact or for the many potential interactions in an ecosystem.

As previously noted, pollutant concentrations are often not high enough in urban runoff, which is diluted in receiving waterbodies, to directly or rapidly harm aquatic organisms. However, continued runoff drainage with relatively low contaminant levels can eventually cause biological damage in two ways:

- Cumulative water quality stress can result in chronic effects; and
- Pollutant accumulations in aquatic sediment can especially affect organisms that inhabit or spend considerable time in or on the streambed or lake bottom.

While this chapter does not cover sediment toxicity and its effects, Chapter 5 discusses both sediment monitoring and using monitoring results to assess biological effects. In addition, Burton (1991) has published an extensive review of information on assessing toxicity of freshwater sediments.

Hydrologic and Related Physical Impacts

Although water quality deterioration from urban runoff is often considered the leading cause of ecological damage, this is not always true.

Urbanization alters the hydrologic regime of surface waters by changing the way water cycles through a drainage basin. In a natural setting, precipitation is intercepted or delayed by the forest canopy and ground cover. Vegetation, depressions on the land, and soils provide extensive storage capacity for precipitation. Water exceeding this capacity travels via shallow subsurface flow and groundwater and eventually discharges gradually to surface waterbodies. In a forested, undisturbed watershed, direct surface runoff occurs rarely or not at all because precipitation intensities do not exceed soil infiltration rates.

Urbanization effects are multifaceted. Tree removal reduces or eliminates interception storage and the water reservoir in soils. Loss of vegetation and duff from the understory takes away another storage reservoir. Regrading eliminates natural depressions. Impervious surfaces, of course, stop any infiltration and produce surface runoff. Even when surfaces remain pervious, building often removes, erodes, or compacts topsoil. The exposed soil retards infiltration and offers much less storage capacity. Development replaces natural drainage systems with hydraulically efficient pipe or ditch networks that shorten the travel time of runoff to the receiving water.

Adjacent to waterbodies, floodplain encroachment eliminates another storage zone needed to diminish high flows. Clearing bank vegetation removes the wood supply that helps slow down the flow and often helps prevent bed and bank erosion. Clearing also eliminates shade, refuge, and food supply. Urban residents and high stream flows remove remaining wood, further decreasing the stream's opportunity to dissipate energy without flooding or damaging the channel.

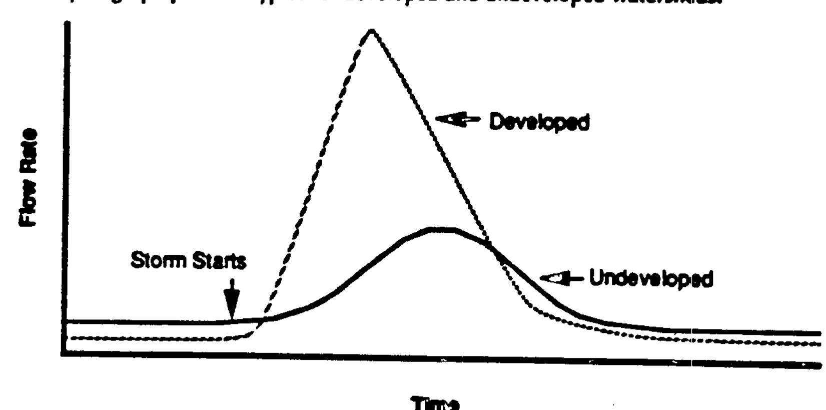
An extensive study comparing an urban and a nonurban stream in western Washington State found that hydrologic changes from urbanization were the principal reasons that the urban stream failed to match its nonurban counterpart in diversity and size of salmonid fish populations and other biological indices (Richey, 1982).

In the Pacific Northwest, the importance of hydrologic alteration and its effects on stream habitats and the salmonid resource is widely recognized. A significant share of the urban runoff management effort goes into controlling runoff water quantity to retain predevelopment hydrologic patterns. In most other U.S. urbanized areas, with respect to resource protection, less attention is paid to controlling quantity to maintain stream channel integrity and more is paid to quality control. Yet, the same hydrologic modification problems have been noted elsewhere; e.g., Mississippi (Wilson, 1967), Long Island (Seaburn, 1969), and Maryland (Hammer, 1972).

The many changes brought on by urbanization tend to alter stream flow patterns in characteristic ways. Figure 3.1 illustrates typical hydrographs (flow rate versus time) for a stream before and after watershed urbanization. The hydrograph emphasizes the higher peak flow rate of urbanized settings compared to preurban conditions. A two-to-five-fold increase is common (Leopold, 1968), although some streams show even greater rises, especially in arid areas.

When the channel cannot contain the greater flow, flooding results. If the flow is largely

Figure 3.1—Hydrograph patterns typical of developed and undeveloped watersheds.



Source: R.R. Horner.

VOL 12 6598

R0039906

contained, high flow rates within the same area increase velocities. This can cause large shear stresses that erode streambeds and banks. Shear stress roughly increases proportionately to the square of the velocity (Hynes, 1970). The doubling of velocity could, for example, increase the erosion potential by approximately four. Loss of the stabilizing wood previously in the channel magnifies the effect of flow magnitude.

The hydrograph also indicates the urban stream's faster response to precipitation. Less obvious is the greater total volume, represented by the integrated area under the urban stream curve. When watersheds urbanize, a common runoff volume increase for any given storm is at least 50 percent (Leopold, 1968). Thus, changes in watershed hydrology not only create more friction on the stream channel materials at any instant in time, but that stress also exists for a longer period while the greater volume passes downstream. Runoff quantity control efforts to hold total volumes within predevelopment levels can only be achieved with infiltration equivalent to that in the undeveloped watershed. If storage volume and outlet are sized properly, detention can restrict peak flow rates to those levels, but it will not maintain lower volumes without the needed infiltration. Therefore, even the best quantity control programs often cannot avoid stream channel damage.

The left side of Figure 3.1 shows that while urban streams usually have higher flows during and following rain storms, they also commonly have lower baseflows between storm events. In urban landscapes, baseflow decrease is a consequence of water's rapid transport downstream before it can recharge the groundwater that supplements streams in dry periods. During droughts, baseflow deficit can have an especially severe ecological impact.

These are short-term hydrologic patterns. Urbanization impacts with longer time frames are even more evident. The frequency of recorded high flows increases even more than the flow levels. In one Washington State stream, the flow rate that had been reached only once in 10 years on average before development increased in frequency to about every two years after urbanization (Scott, 1982).

A computer model capable of continuous simulation was applied to another western Washington basin (Booth, 1991). It compared a fully forested basin with a developed 40 percent impervious area. The model predicted that the predevelopment discharge, which occurs only once in five years, would occur in 39 of 40 years after development. Moreover, the model forecasted that in an average year, this discharge level could be reached five times, separated by less than one month in the wet season. The model estimated that the predevelopment five-year discharge could occur bimonthly following development. This 60-fold frequency increase dwarfs the 3.5 times increase predicted for 10-year peak flow rates.

A Long Island study revealed the extent of seasonal hydrologic shifts in urban streams. In several predevelopment streams, baseflow constituted 95 percent of the annual discharge; that proportion dropped to 20 percent after development (Simmons and Richard, 1982).

Some studies have measured urbanization levels that cause significant hydrologic changes. In a study of several Maryland watersheds, Klein (1979) found hydrologic alteration evident with 12 percent impervious area and severe with 30 percent.

Ecological Consequences of Hydrologic Changes

Along with extensive hydrologic modifications, the ecological effects of urbanization on water quantity are also significant. These effects come mostly from habitat damage accompanying hydrologic alteration.

The most basic change is from erosion of the stream channel that sweeps away various habitats and expands the channel, increasing both width and depth. While these increases can be steady and gradual, they frequently occur abruptly in response to particular storms (Hammer, 1972; Leopold, 1973; Booth, 1991). Even in areas where the stream has been stable for years, massive changes in channel dimensions can occur in the first large storm after urbanization, affecting the stream's entire course and profile. The regular meander and pool-riffle patterns of streams not in highly confining substrates will be modified as erosion and deposition increase in magnitude and speed.

Rapid, nearly uncontrolled downcutting, known as incision, can be especially dramatic (Booth, 1990). Incision results when increased flow and loss of the woody debris that dissipates energy occur in relatively steep channels with an easily erodible substrate. While all channel damage is ecologically harmful, incision is especially problematic because it removes virtually all habitat and supplies great quantities of sediment that do further damage downstream.

Research in several humid locations suggests that flows larger than the five-year frequency discharge are sufficient to create large-scale channel disruption (Carling, 1988; Sidle, 1988). More than anything else, the greatly increased incidence of these flows explains the ecological vulnerability of urban streams.

Even without the spectacular phenomenon of incision, habitats are still damaged by complex physical effects from elevated urban stream flows. Impacts can include the following:

- Sediment deposits on gravel substrates where fish spawn and rear young and where algal and invertebrate food sources live;
- Sediment that fills pools where fish feed, take refuge from predators, and rest;
- Direct effects of suspended sediment on aquatic organisms, like abrading gills and other sensitive tissues, reducing light for photosynthesis, reducing visibility for catching food and avoiding predators, and transporting metallic, organic, oxygen-demanding, bacterial, and nutrient pollutants;
- Loss of riparian vegetation, as banks erode, along with the loss of shade and refuge it provides; and
- Loss of the protective qualities of the large woody debris.

Reduced baseflow produces its own set of impacts. Summer temperatures increase because less water absorbs heat, and dissolved oxygen declines from the lower oxygen solubility of warmer water. Less dilution of pollutants results in higher concentrations, and shallower flow can interfere with fish migrations and localized movements.

In the Washington State comparison of urban and nonurban streams, Kelsey Creek, an urban stream, experienced twice the bed scour of its nonurban counterpart, Bear Creek (Scott, 1982). As a consequence, sediment transport was three times as great in Kelsey Creek (Richey, 1982), and fines were twice as prevalent in its substrates (Scott, 1982). The invertebrate communities in different benthic locations produced 14 to 24 taxa in Bear Creek but only six to 14 in Kelsey Creek (Pedersen, 1981; Richey, 1982).

Salmonid fish diversity also differed. Bear Creek had four salmonid species of different age classes, whereas Kelsey Creek had only one non-anadromous species mainly represented by the 0- to 1-year age class (Scott, 1982; Steward, 1983). While both creeks generally met water quality criteria that protect aquatic life from toxicity, differences still occurred. Although we cannot explicitly determine the relative roles of hydrology and water quality, much evidence shows that hydrologic alteration and the related sediment transport were most responsible for the biological effects (Richey, 1982).

King County (Washington) Surface Water Management Division (unpublished data) has examined various aspects of urban hydrology's influence on the valued salmon. Data show a significant decrease in young salmon survival in both large and small streams when events occur that are equal to or larger than the five-year frequency discharge. Since the frequency of events increases tremendously after urbanization, salmonids experience great difficulty even in relatively clean urban streams.

The King County investigations also pointed out the relationship between urbanization level and biological integrity. The study rated channel stability along numerous stream reaches and related it to the proportion of the watershed's impervious areas. Stability was significantly lower with more than 10 percent imperviousness (Booth and Reinelt, 1993). The study rated habitat quality along 87 miles (140 km) of streams in two basins according to four standard measures. Marked habitat degradation occurred at 8 to 10 percent impervious area. Population data on cutthroat trout and less tolerant coho salmon from streams draining nine catchments did not show a distinct threshold. They indicated, however, that population shifts are measurable with just a few percent of impervious area and become substantial beyond 10 to 15 percent (Lucchetti and Fuerstenberg, 1993).

King County also studied urbanization impacts on freshwater wetlands. Gage readings determined mean water level fluctuations (WLF), and a geographic information system related them to various watershed variables. Biological measures were analyzed using mean WLF. The richness (species representation) of both plants and amphibians significantly decreased when mean WLF exceeded 20 cm (7.8 in). WLF depends on various watershed and wetland morphological conditions, but typically surpasses 20 cm when impervious areas are around 10 percent (Taylor, 1993).

Information consistently indicates that placing impervious surface on some 10 percent of a watershed creates significantly negative hydrologic, habitat, and ecological responses. To complicate the picture, development located immediately adjacent to rather than away from a waterbody changes the circumstances. Nonetheless, information of this type provides a basis for protective watershed management through planning and zoning.

Urban Runoff in Lake Eutrophication

Eutrophication is the process through which algal biomass increases overall—especially during "bloom" periods—from increased loading of the nutrient that had previously been in shortest supply relative to need (limiting nutrient). The limiting nutrient in lakes around the world is usually either phosphorus or nitrogen, but is most often and most consistently phosphorus (P) in freshwater lakes. In addition to promoting larger quantities of algae, enrichment typically changes the composition of the algal community. One-celled diatoms give way to filamentous green forms, followed by blue-green forms with a larger nutrient supply.

Eutrophication degrades lake ecosystems in several ways. The filamentous algae are poorer food than diatoms to herbivores because of their structure and, sometimes, bad taste and toxicity. Filamentous algae clog water intakes and boat propellers and form odorous masses when they wash up on beaches. They also reduce water clarity, making swimming unpleasant. When a large biomass dies at the end of the bloom, its decomposition by bacteria creates high oxygen demand. In summer, eutrophic lakes that thermally stratify usually have little or no oxygen in the bottom stratum of water.

As discussed in Chapter 2, urban areas have a number of nutrient sources, and nutrient loadings increase with the development level. The following hypothetical case study discusses the potential of urbanization to change the trophic status of a lake. It compares the lake's trophic state at 10, 50, and 75 percent watershed urbanization. The case assumes the following conditions:

Lake area—100 ha (271.1 acres)

Lake mean depth—3 m (9.84 ft)

Lake water residence time—1 year

Watershed area—5 km^2 (12.36 acres)

Walker (1987) developed a regression equation ($r^2 = 0.69$, standard error = 24) from Minnesota watersheds relating P export to urbanization:

$$\text{P export (kg/km}^2) = 1.02 \cdot \text{(percent urban)} + 2.92$$

Although this equation is quite simplified and omits impervious area and other specifics of the urbanization type, it gives a rough indication of urbanization effects. This example refers to a lake originally in an oligotrophic state. Actual lakes differ in their trophic states even without anthropogenic effects.

The export for the different urbanization levels can be estimated and expressed in terms of its distribution over the lake area, as summarized in Table 3.2. Vollenweider and Dillon (1974) categorized trophic status using data from a number of lakes. They found that boundaries between oligotrophic (relatively unenriched) and mesotrophic (moderately enriched) systems, and between mesotrophic and eutrophic systems (highly enriched), could be drawn by considering the relationship between P loading over the lake area and the ratio of mean depth/water residence time (Figure 3.2).

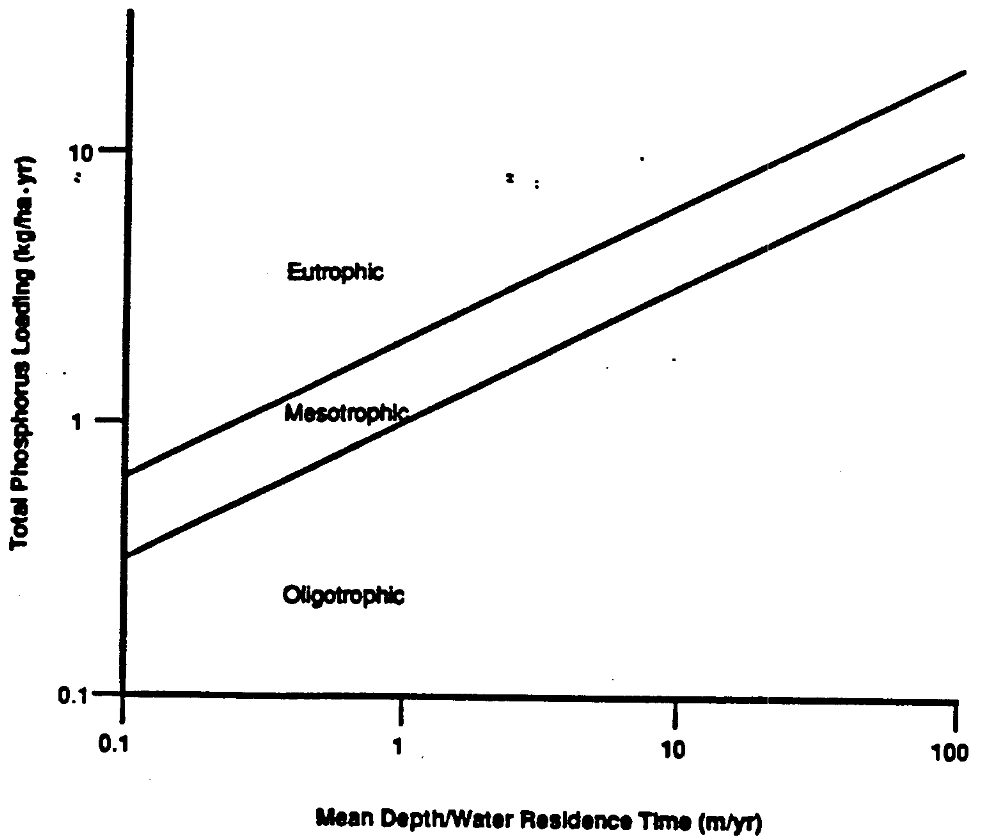
Table 3.2—Phosphorus loadings associated with hypothetical case study conditions.

% URBAN	ANNUAL TOTAL (kg/y)	DISTRIBUTION OVER LAKE AREA (kg/ha · y)
10	50	0.5
50	250	2.5
75	375	3.75

The graph, tabulated data, and mean depth/water residence time ratio of 3 can be used to see that 10 percent urbanization, which would be equivalent to a few percent impervious area, keeps the lake safely in the oligotrophic region. Urbanization at the 50 percent level places the lake in the mesotrophic zone. The highest level of urbanization takes the lake into the eutrophic area.

The exercise can be extended to consider how much P loading control would have to be provided in some way to reach certain lake water quality protection objectives. The typical P loading of a 75 percent urban watershed would need to be reduced 47 percent to keep the lake from passing from its position of 10 percent urban land use into the mesotrophic zone. To keep it more safely in the oligotrophic area—for example, at a loading of 1.5 kg/ha · y—a 60 percent reduction would be needed. This efficiency is very hard to achieve with urban runoff treatment practices (see Chapter 8). Even with this level of control, how-

Figure 3.2—Lake trophic state in response to phosphorus loading.



Source: Vollenweider and Dillon, 1974.

ever, the loading would still be three times the amount at 10 percent urbanization.

A version of this analysis was performed for Lake Sammamish, Washington, using pollutant loading coefficients mostly derived from local data instead of the regression equation. Also, a model was developed to simulate the lake's response to P loading and calibrated with data taken in the lake itself (Welch et al. 1985; Shuster et al. 1986). Planning agencies estimated that urbanization would increase from 16 percent of the watershed in 1975 to 46 percent in 2000, in the form of single- and multiple-family residential and commercial land uses. On the basis of median values of the loading coefficients, P loading per unit area of the lake surface was projected to rise from 4.3 to 7.5 kg/ha · y in that time—a 74 percent increase. These levels are higher than those in the hypothetical case because the watershed of the main tributary to Lake Sammamish has relatively high natural soil sources of P. Nevertheless, the lake's mean depth of 17.7 m (58.1 ft) and water residence time of 1.8 years give it a ratio sufficient to place it low in the mesotrophic zone (Figure 3.2) in 1975. Increased urbanization would send it into the eutrophic area. The projections were used to devise strategies for P source control and runoff treatment.

The Effects of Metals on Aquatic Organisms

Metals are the toxic contaminants most commonly found in urban runoff. Because the exposure patterns of runoff differ from the standard laboratory procedures traditionally used to gage toxicity, metals' role in causing toxic reactions in aquatic organisms is unclear. Different types of experiments are needed to develop a clearer picture and, eventually, more appropriate water quality criteria for waters affected by urban runoff.

For now, clues come from some completed experiments. Davies (1986) summarized a series of experiments with rainbow trout. Although the focus was on mining discharges, results provide some useful insights to consider toxicity in urban runoff. The following account of the findings contains remarks on the significance for urban runoff, which appear in italics.

Note: LC_{50} (96 h) means the concentration lethal to 50 percent of the test organisms in a 96-hour exposure.

Metals Toxicity to Fish

1. Increases in pH, alkalinity, and hardness decrease metal toxicity.

HARDNESS (mg/L as $CaCO_3$)	ALKALINITY (mg/L as $CaCO_3$)	RAINBOW TROUT LC_{50} (96 h) (mg Zn/L)
315	227	7.21
102	81	1.00
23	20	0.56

Hardness (Ca^{+2} and Mg^{+2}) antagonizes toxic metal uptake at the gill surface by competing for uptake sites. Alkalinity plays a role in bioavailability by providing bicarbonate and carbonate ligands under pH control to complex metals in either soluble or insoluble form, removing them from the toxic ionic state. In alkaline waters, metals are not acutely toxic until enough are present to overwhelm the bicarbonate-carbonate buffering system that precipitates lead carbonate complexes. Organic ligands may also form complexes of low toxicity, a subject that has not been well studied. Particulate metals and those adsorbed to particles are relatively nontoxic.

Therefore, runoff discharge to well-buffered waters with most metals in the solid state creates less toxic reactions than dissolved metal discharge to soft waters.

2. Metal toxicity generally increases as temperature increases because of increased chemical activity and metabolism.

TEMPERATURE (°C)	RAINBOW TROUT LC_{50} (96 h) SOFT WATER (mg Zn/L)
6	0.83
10	0.41
15	0.24

Therefore, runoff discharge in the winter and runoff to shaded or groundwater-fed waters in the summer create less toxic reactions than into warm waters.

3. Smaller, younger organisms are more sensitive to metals, and fish are generally more sensitive than macroinvertebrates.

Therefore, runoff discharge during rearing periods creates more toxic reactions than during adult stages.

4. If exposed during the embryonic stage in soft water, fish can acclimate to metals and are less sensitive to higher exposures later. Rainbow trout were approximately four times more sensitive to both cadmium (Cd) and zinc (Zn) when not exposed embryonically, compared to fish that were exposed (chronic effect/no-effect concentrations of approximately 1 μg Cd/L and 50 μg Zn/L for unexposed fish, compared to approximately 4 and 200 for exposed trout). Acclimation ability was confirmed by two-week and one-year experiments in a zinc-contaminated reservoir. However, acclimation does not appear to occur with lead (Pb) and silver (Ag), nor in hard water.

Therefore, relatively low continuous exposures throughout life can somewhat insulate fish from periodic elevated exposures in runoff.

5. Metal toxicity increases as exposure period lengthens.

EXPOSURE (DAYS)	RAINBOW TROUT LC_{50} SOFT WATER (mg Pb/L)
4	1.17
14	0.20

Therefore, fish can better tolerate a high exposure for a short interval than continuous delivery. This observation, however, says nothing about the potential reaction to repeated, periodic exposures, as with urban runoff discharge.

6. The apparent mechanism of acute (one to four days) metal toxicity in fish is gill irritation by the ionic metal, causing mucus secretion and internal destruction of gill epithelium, resulting in suffocation. Chronic (one-week to one-year) toxicity can negatively affect reproduction, growth, physiological and behavioral development, and/or cause death through the breakdown in metabolic or other biochemical functions.

7. "Free" metals include the most toxic ionic forms, as well as other labile forms. Most or all metals present can be free in soft waters but can be a small fraction of total metals in hard waters, thus allowing fish in hard waters to withstand much higher total metals in acute exposure. However, toxicity of free metals is similar in soft and hard water.

HARDNESS (mg/L as $CaCO_3$)	RAINBOW TROUT LC_{50} (96 h) (mg Pb/L) TOTAL	FREE
290	471	1.47
385	542	1.32
32	1.17	1.17

8. Chronic toxicity exhibits trends similar to acute toxicity with respect to free and total metals, but at much lower levels.

WATER	EFFECT/NO-EFFECT PHYSIOLOGICAL ABNORMALITY (µg Pb/L) FREE	TOTAL
Hard	18.2–31.6	120.0–360.0
Soft	7.2–14.6	7.2– 14.6

9. Complexation, which reduces the more toxic free metals, is not instant (e.g., two days for cadmium to come to equilibrium), and mortality increases in tests with unaged water.

   Urban runoff dynamics do not allow time to complete complexation, and therefore buffering is a smaller benefit with intermittent than with continuous releases.

10. "Toxic" concentrations are frequently measured in natural water samples, but fish still live. This contradiction probably stems partly from acclimation and partly from comparing a standard meant for continuous exposure with a condition that is only intermittent. However, the contradiction is also a function of using acid to preserve samples, which frees metals from soils and other particles, and from using the nonselective atomic absorption technique.

11. The use of a dissolved metals measurement can only approximate the toxic forms because some are solubilized over time. "Potentially dissolved" metals can be determined in runoff by waiting to filter for 8 to 96 hours after acidifying the sample, but this method has not been well tested.

   Realistic water quality criteria for waters affected by urban runoff require considering duration and frequency of exposures, chemical forms, and species.

Aquatic Invertebrate Response to Zinc Exposure

Horner (in press) performed experiments with the invertebrate amphipod *Hyalella azteca* that further clarify the observations in points 4 and 5, summarized in Figure 3.3. Organisms were given two types of zinc exposures—continuous and intermittent (three times for 24 hours each)—at the same concentration. Total loadings were close (122 mg with continuous and 90 mg with intermittent). The number of organisms in the continuously exposed community declined gradually at first but stabilized by the end of the 18-day experiment, with a mean survival for individuals of 11.3 days. The concentration was lower than the chronic aquatic life criterion. In contrast, the periodically exposed community declined in steps with each exposure and went extinct by the end (mean survival was 8.5 days).

The same type of experiment was run with a higher loading level (approximately 210 mg) produced by either continuous exposure at 65 µg/L or intermittent exposure in the same pattern as the first experiment at 350 µg/L. The continuously exposed community reacted much as in the first experiment, although the higher concentration caused a more rapid initial die-off that reduced mean survival to 9.6 days. Still, the surviving number was about the same as in the first experiment, despite the higher concentration and loading. The intermittent exposure caused extinction after the second treatment, and mean survival was only 5.0 days.

These results clearly indicate that organisms in the same species tolerate metal toxicity differently. Stronger organisms can survive continuous

VOL 12

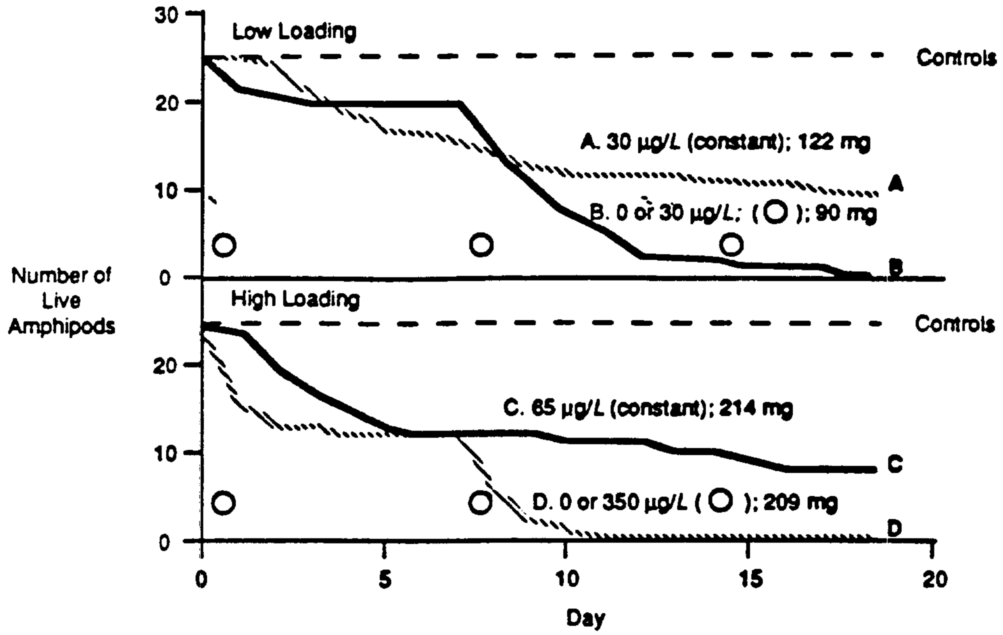
Figure 3.3—Responses of *Hyalella azteca* to constant and intermittent exposures to zinc.



NOTE: Zinc exposures were delivered either at constant concentrations (given in the units µg/L) or intermittently for a 24-hour period on the day, indicated by the circular symbol. The mass values (given in the units mg) represent the total zinc loadings for the entire experimental period.

Source: R.R. Horner.

exposure to concentrations that kill others. In the first experiment, inability to tolerate the same concentration, if intermittent, suggests that, when a threatening condition continues, acclimation defenses may develop over time. Once past the initial period, these defenses probably allow stronger organisms to continue to survive and stabilize the community. Response to the first intermittent exposure in the second experiment shows that, even if the effect to some is severe, the remaining organisms can persist. However, they cannot withstand a second episode of severe shock.

These experiments demonstrate that the important factor is not necessarily pollutant loading but how it is delivered. The findings have substantial implications for urban runoff management—criteria should specify both maximum concentrations for several lengths of exposure, as they do now, and maximum lower concentrations not to be repeated more than once in certain intervals. However, much more work is needed to arrive at the appropriate criteria. A second implication is that the common practice of managing by trying to restrict loading increases may not be successful if we do not develop and incorporate our knowledge of how loading is generated.

Thermal Impacts of Urban Runoff

Aquatic life forms have characteristic temperature preferences and tolerance limits. Fish of interest to humans, like trout and salmon, and their preferred invertebrate food sources have lower ranges and maximums than others. In summer, urban runoff can warm receiving waters to the detriment of these organisms because of lower oxygen concentration in the water. The warmer the water, the less dissolved oxygen can be absorbed by the water and be available to the fish. Urban runoff management facilities can further aggravate the situation when they hold water for an extended time in hot weather. These conditions exist in most of the nation, excluding a narrow band along the Pacific coast west of the Sierra and Cascade Mountains. The Metropolitan Washington Council of Governments (Galli, 1991) investigated the local thermal impacts of urban runoff and its management and reached the following conclusions:

1. Air temperature was the strongest influence on stream water temperature.
2. Average stream temperature increased linearly with impervious area percentage.
3. Some temperature criteria violations occurred with 12 percent impervious area; they increased in severity and frequency with more imperviousness.
4. All structural treatment practices tested that had a surface discharge caused some violations of temperature criteria under both baseflow and storm runoff conditions.
5. The order of the practices in both raising receiving water temperatures and causing violations, from least to most serious, was

   Infiltration basins < extended-detention wetlands < extended-detention dry ponds < wet ponds.
6. Based on the findings from a literature review, the investigators concluded that the thermal conditions produced by urban runoff and treatment facilities could cause algal succession from cold-water (mainly diatoms) to warm-water filamentous green and blue-green species, as well as severe impacts on cold-water invertebrates and fish, where they exist.
7. The findings have important implications for facility selection and design, especially to shade pools and outlets.

Fish Habitat Impacts and Habitat Protection

Effective, comprehensive management of any natural resource has several prerequisites:

1. Setting clear objectives for the effort;
2. Understanding what chemical and physical (including habitat) characteristics organisms need to meet the objectives;
3. Understanding what can disrupt these characteristics; and
4. Understanding what can cause these disruptions and how to overcome the problems.

The following case study illustrates points two and three, summarizing habitat requirements of trout and salmon and citing limits tolerated by various organisms. While salmon are located in only a small area of the nation, trout are prevalent and valued throughout the northern portion and higher altitude, cooler areas farther south. Protecting diversity in aquatic systems requires knowledge of the variation in species requirements. Chapters 2 and 3 discuss causes of reduced diversity; other chapters deal with strategies to overcome these problems (point 4).

Life Cycle Characteristics

Managers must pay attention to organisms' life cycles, which can differ significantly even among closely related species. Table 3.3 summarizes the life-cycle characteristics of six ocean-going Pacific salmon species. Different fish carry out their migrations, reproduction, and rearing at different times and have freshwater stages of various lengths. Management must ensure that the sensitive young fish have the conditions they need at the right time and that barriers to migration do not bar passage of either the returning adults or sea-running young.

Habitat Requirements

Following is a summary of physical and chemical requirements of various salmonid species and life stages that define their habitat requirements, drawn from Bjornn and Reiser (1991), except as noted. As with life cycle characteristics, substantial differences exist among species.

For migration of anadromous adults

Temperature maximum: 15.6°C, except for chinook (dependent on seasonal run—13.3°C spring, 20.0°C summer, 19.4°C fall).

Depth minimum: 0.18 m, except for chinook (0.24 m).

Velocity maximum (sustainable for 5-8 minutes/sustainable in extended cruising, both in meters/seconds) (after Kerr Wood Leidal Associates Ltd. and D. B. Lister and Associates Ltd., 1980):

Coho	3.2/2.7
Chinook (fall)	3.3/2.7
Sockeye	3.1/1.0
Steelhead	4.2/1.4

Dissolved oxygen minimum: Reduced performance when below saturation; sharply reduced when below 6.5-7.0 mg/L; lower limit 5.0 mg/L.

Table 3.3—Life cycle characteristics of anadromous salmonid fish.

SPECIES	ADULT MIGRATION	SPAWNING	EMERGENCE	FRESHWATER STAGE	DIET	JUVENILE MIGRATION
Coho	September–November	October–December	April–May	1 year	Insects Fish fry	May–June
Chinook (fall)	September–October	October–November	March–April	2–3 months	Insects	May–July
Sockeye	August–September	September–October	April–May	1 year (lake)	Zooplankton	April–June
Pink	August–September	September–October	April–May	None	In sea	April–May
Chum	September–December	October–January	April–May	None	In sea	April–May
Steelhead	All months	January–May	June–July	2–3 years	Insects Fish fry	April–June

Source: Kerr Wood Leidal Assoc. and D.B. Lister Assoc. 1980.

Barriers: Ideal falls height to pool depth = 1:1.25; maximum falls height 2.1-2.4 m, except for steelhead (3.4 m) (0.8 m for nonanadromous brown trout).

For spawning adults

Stream flow: Weighted usable (spawning) area (WUA) is a function of depth, velocity, and substrate and is related to discharge by In-stream Flow Incremental Methodology (IFIM) species models.

Dissolved oxygen minimum: 7 mg/L (Welch 1980).

Temperature maximum:
Anadromous: coho and steelhead—9.4°C, sockeye—12.2°C, chum and pink—12.8°C, chinook—13.9°C.
Nonanadromous: brown trout—12.8°C, cutthroat trout—17.2°C, rainbow trout—20.0°C.

Redd area/spawning pair: Dependent on species and space availability; ranges from order 0.1-1.0 m^2 for nonanadromous trout, to 1-10 m^2 for steelhead and smaller salmon, to 10-20 m^2 for chinook.

Depth minimum:
Anadromous: sockeye and pink—15 cm, coho and chum—18 cm, steelhead and chinook—24 cm (except 30 cm for summer chinook).
Nonanadromous: cutthroat trout—6 cm, rainbow trout—18 cm, brown trout—24 cm.

Velocity range:
Anadromous: generally 20-40 cm/s minimum to approximately 1 m/s maximum.
Nonanadromous: cutthroat trout—11-72 cm/s, brown trout—21-64 cm/s, rainbow trout—48-91 cm/s.

Substrate size range:
Anadromous: 1.3-10.2 cm (except 0.6 cm minimum for steelhead).
Nonanadromous: rainbow trout—5.2 cm maximum, brown trout—7.6 cm maximum, cutthroat trout—10.2 cm maximum (0.6 cm minimum in each case).

For egg incubation

Temperature maximum:
Anadromous: 13.3°C, except for chinook (14.4°C) (Welch, 1980, recommended 12.8°C for all salmon and trout).

Substrate size minimum: Data show that embryo survival declines from near 100 percent with near 0 percent fines < 6.35 mm, to approximate 50 percent with 20-40 percent fines (species dependent—order 20 percent for cutthroat, 30 percent for rainbow, 40 percent for chinook and steelhead), to near 0 percent with > 50-60 percent fines.

Dissolved oxygen minimum: Percent survival exhibits a linear relationship with DO for some species (e.g., steelhead); percent survival drops below 50 percent when DO < 8-9 mg/L and low DO reduces size and a threshold relationship for others (e.g., coho, where the threshold is approximately 8-9 mg/L).

For Juvenile rearing

Temperature preferences:
Anadromous: 12-14°C, except for steelhead (10-13°C).
Nonanadromous: 14-16°C for brook trout.

Dissolved oxygen minimum: Data show a threshold relationship generally exists, with the threshold at approximately 4 mg/L and a very rapid decline in survival below that level.

Space minimum: Depends on age and size; anadromous fish with a short freshwater rearing period need 0.01-0.1 m^2/fish and those with an extended freshwater rearing period need 0.5-5 m^2/fish; nonanadromous fish need 5-100 m^2/fish.

Streamflow: IFIM models also exist for rearing.

Depth range: Highly variable; mostly in range 30-75 cm.

Velocity maximum: Variable with few data showing preferences above 40 cm/s.

Substrate size minimum: Embedding large substrate with fines (< 6 mm) reduces juvenile densities (faster in winter than in summer); density decreased to about half of maximum with about 30 percent embeddedness in winter for steelhead and chinook.

Cover: Cutthroat trout biomass exhibited an exponential decline with cover loss in one study; in another study steelhead and chinook biomass was higher with more diversity in cover types and benefited most with increased amounts of side overhang and brush.

Examples of Management Strategies

1. Culverts are a common impediment to fish movements. Considerations are depth, length and velocity in relation to the fish's ability to swim against the velocity long enough to pass through the culvert, and vertical drop at the downstream end. For example, smaller, slower-swimming sockeye salmon adult migrants would need a lower velocity and smaller vertical jump than steelhead. Table 3.3 also shows that favorable conditions would have to be maintained at different times (late summer for sockeye and throughout the year for steelhead).

2. A frequent mistake in protecting and restoring fisheries habitat is to underestimate the space needed for a pair to spawn and each juvenile to rear. Successful spawning for larger fish and those with a longer residency requires that substantial suitable bed space be created or protected. For example, to provide for spawning and rearing of brown trout, 0.1-1.0 m^2 of substrate with 0.6-7.6 cm material must be provided for each spawning pair. The water should be no warmer than 12.8°C, at least 24 cm deep, and have at least 7 mg/L DO and velocity in the range 21-64 cm/s. Each juvenile would need much more space (5-100 m^2), however, at comparable conditions (except lower velocity). Anadromous fish would need more territory for spawning but less for rearing.

CHAPTER 4

Water Quality Monitoring

To obtain conclusive data on urban runoff and its effects on the watershed is difficult and expensive. Therefore, monitoring programs that collect data must be carefully designed to be cost-effective. This chapter suggests a general process for designing water quality monitoring programs, whether the monitoring subject is water quality, sediments, or biological organisms.

This process comes mainly from research to improve monitoring program design in urban runoff and other nonpoint source fields. Consult Reinelt, Horner, and Castensson (1992); Reinelt, Horner, and Mar (1988); Mar et al. (1986); and other references and sources for more details. Guidance on sediment and biological monitoring programs follow in subsequent chapters.

The suggested analytical process has five steps:

1. Specify monitoring program objectives;
2. Determine the level of effort to devote to the analysis;
3. Perform a systematic analysis appropriate to the problem and objectives;
4. Use the analysis results to tentatively specify monitoring program elements; and
5. Evaluate the tentative monitoring program for cost-effectiveness and finalize according to evaluation results.

Monitoring Program Design Steps

1. Specify monitoring program objectives

Establishing objectives is essential, even though they cannot always be specified in great detail. The most thoughtful statements, agreed upon by all stakeholders, should guide the monitoring program design and conduct. Objectives stem from the nature of the problem or decisionmaking need that requires data collection. Urban runoff management problems include the following:

- Defining the water quality status of a discharge or waterbody;
- Identifying problem areas, their sources, or both;
- Selecting locations to apply problem abatement strategies;
- Evaluating alternative abatement strategies both prior to and after implementing control techniques;
- Calibrating and verifying runoff simulation models; and
- Researching (e.g., to identify ways that contaminants affect organisms).

Every monitoring program should, if possible, formulate objectives at two levels—general and specific. General objectives describe what must be accomplished to solve the overall problem or meet the need. For example

- Obtaining a baseline definition of the effect a proposed development will have on water quality in a lake.
- Determining long-term trends in sediment accumulation of metals in a poorly flushed bay.

VOL 12

6610

- Finding the contamination source that has closed a shellfish bed to harvesting.

Specific objectives relate directly to measurements and produce results to meet the general objectives. Some examples related to the third general objective—finding the contamination source—are

- Determining the annual fecal coliform loadings contributed by agricultural, septic drain field, and urban runoff sources.

- Identifying the three largest sources of fecal coliform loading to the shellfish bed area.

These objectives can be stated in more detail and more specifically, particularly regarding measurements (e.g., zinc and chromium as the specific metals; percent Ephemeroptera [mayflies] + Plecoptera [stoneflies] + Trichoptera [caddisflies] as the macroinvertebrate measure) when step 3 of the general design process is completed. Using this process ensures careful decisionmaking at each step and counters the tendency to use a generic monitoring strategy that may not relate to the program goals. Exercising discipline to make careful assessments is the best way to be cost-effective in monitoring.

2. Determine the level of effort

A monitoring program can range from simple and inexpensive to thorough and costly, depending on the objectives for the particular program. The effort expended depends on the quantity and type of information available, the detail of additional information needed, the resources of the designers, and the urgency to begin monitoring.

Available information can help target new monitoring and substantially reduce costs. Therefore, designers should incorporate this information in their analysis, using techniques in this manual. Some problems may not be worth extensive effort, while others demand it. For example, merely determining whether a problem exists at a particular place is often straightforward and may not need extensive analysis. On the other hand, monitoring to allocate resources for solving problems in a large, complex watershed may require a substantially greater level of analysis.

Even if little guidance information exists, and the designer has limited time and resources, at least the basic analytical process should be applied. After developing a preliminary information base, the designer can always review the systematic analysis of the problem and objectives in more detail later.

3. Perform a systematic analysis

As the core of the process, step 3 represents the most effort. The analyst should give priority to key factors causing the problem.

This systematic analysis is often referred to as a watershed analysis. The term watershed broadly signifies an area, large or small, that drains a land surface to a point of interest. While a watershed can be a small catchment with a simple drainage system, for now we will consider a watershed as a landscape of some size and complexity draining through a network of artificial and natural conveyances to a natural waterbody. Thus, the analysis involves surveying watershed characteristics, identifying the most critical potential problems and sources, and highlighting the most critical places, times, and biological units that manifest the problems.

A watershed inventory involves collecting the appropriate level of data according to the needs of the project. While the level of detail may vary, your inventory should include developing a basin map; identifying such features as land uses, soils, topographic information, and hydrologic data; and identifying potentially critical problem source locations (e.g., earth-moving activity, industrial areas, major traffic concentrations) or areas potentially sensitive to problems (e.g., fisheries and other productive resource areas, rare or endangered resources, stream reaches vulnerable to major channel damage). Obtaining any available data on these features and field reconnaissance are key tasks in a watershed inventory.

Identifying critical problems and sources should be a systematic process of formulating a broad list and then narrowing it by prioritizing items, with the level of effort chosen in step 2 dictating the scale of the analysis. For example, to find the principal sources of water quality deterioration in a river draining a large watershed, we may suspect that certain areas and activities need our attention. However, this judgment should be tested by some quantified, comparative estimates of pollution quantities like those models suggested in Chapter 2. Although such a model may be overly generalized, simplified, and not calibrated locally, its purpose is not to reach a final decision, but to guide the design of a monitoring program. Even with a small effort level, the simplest model can often bring objectivity and rigor to the analysis.

VOL 12 6 / / /

Identifying critical places, times, and receptor organisms presents a more difficult problem. We must at least conceptualize the relationship between problem occurrence and timing and the potential damage for habitats, species, and life stages. While models can sometimes help, they are usually too simple or inconvenient. Ideally, the specialists (e.g., water quality engineer, hydrologist) will work closely with an ecologist familiar with the waterbody, its ecology, and natural history to judge these critical factors.

Reviewing the original objectives for their continued appropriateness is a good practice. Objectives will likely need to be modified or made more specific with the increased knowledge.

4. Specify monitoring program elements tentatively

If performed properly, the systematic analysis of step 3 will provide sufficient information to give tentative shape to the monitoring program. In designing the program, determine

- What to sample;
- Where to sample;
- When to sample;
- How many samples to take on each occasion (replicates);
- How to sample; and
- What to analyze in samples.

The design should set objectives, identify potentially critical problems, and target the monitoring program, considering cost-effectiveness. Thus, the objectives and analytical findings should dictate the media to be sampled, the locations and times of sampling, and the analyses to be performed. This philosophy rejects working from prescribed sampling scopes and frequencies and standard lists of analytical measures. It advocates tailoring the program to a specific level of effort to meet stated objectives developed from a systematic analysis—all to advance program cost-effectiveness. The tentative decisions on monitoring program design are further evaluated in step 5 before they are finalized.

Deciding when to sample includes planning and scheduling a number of visits to each sampling location. Use careful judgment to select the initial number of visits rather than automatically specifying periodic intervals (e.g., biweekly or monthly). Natural phenomena do not occur at evenly spaced intervals. Most places, for example, have seasonal differences in the type, amount, and/or intensity of precipitation. Accordingly, stratify sampling to consider these events. For instance, visits might be scheduled for times of highest runoff when pollutant delivery is greatest and at lowest flow when pollutants concentrate most. Transitional periods would get less coverage.

How to sample is discussed in the guidance following step 5.

5. Evaluate the tentative monitoring program and finalize

Evaluate the step 4 tentative monitoring program according to its number of samples. The sample numbers and the analyses specified are factors that directly determine the program's cost and probable effectiveness. Monitoring programs frequently fail to provide the desired information, even when performed flawlessly, because the samples are insufficient to achieve an accepted level of statistical assurance. This failure results from the high variability in runoff and natural aquatic systems. For example, variability prevents us from attaining a high level of statistical confidence that an average water quality condition meets a criterion or that a new discharge creates a change in a biological community.

Sources of variability include spatial differences in a landscape or waterbody, differences over time (temporal variability), and measurement error. Measurement errors can be reduced by using better techniques, if they exist. Otherwise, collecting replicate samples quantifies the measurement error component. Increasing sample numbers can overcome natural spatial and temporal variability, unless they are enormous; but that strategy raises cost.

The basic task is to determine the number of samples (stations, occasions, and replicates) needed to meet the objectives, considering variability and budget limits. Using the optimal number of samples to reach a conclusion will produce the maximum confidence level for a set budget, or a minimum cost for a set assurance level. These options, representing two ways to maximize the monitoring program's cost-effectiveness, can only be applied if some data are already available to give statistical measures of central tendency (e.g., mean or median) and variance. In that case, statistical methods can be applied to the optimization

VOL 12

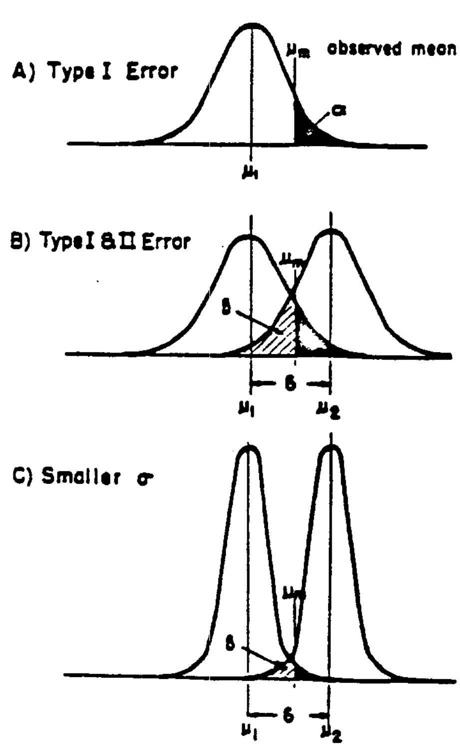
6 6 / 2

problem. Mar et al. (1986) reviewed the following appropriate methods for common situations in monitoring program designs.

Determining a Mean Value

Determining a mean value applies, for example, when an average water quality condition is compared to a regulatory criterion. In basic statistics, t-distribution defines the confidence interval for the mean of a normal population (set of values) as estimated from a data set. The t-distribution is used to determine sample numbers if the data are demonstrated or assumed to have a normal probability distribution (Figure 4.1A), or if they can be transformed (e.g., by taking their logarithms) to yield a normal distribution.

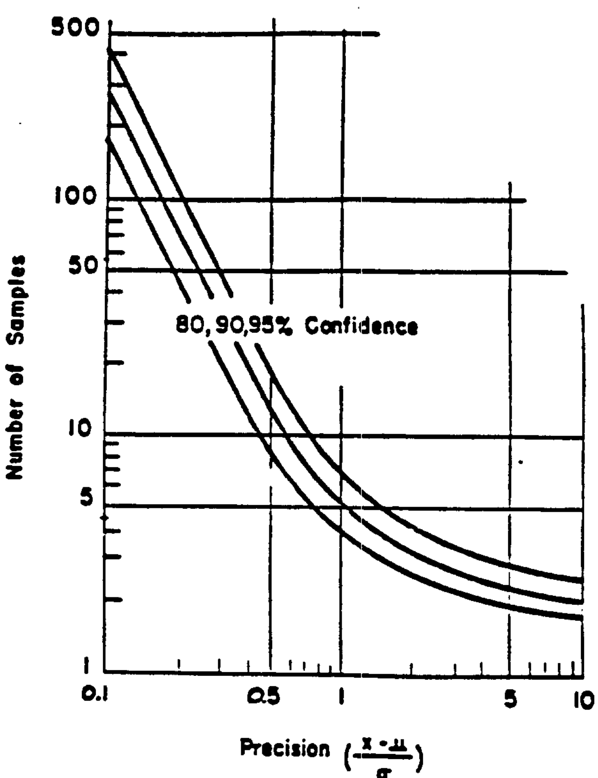
Figure 4.1—Hypothesis-testing fundamentals. μ_1 and μ_2 are the means of two populations of measurements; their difference represents a change—delta. Alpha and beta are the probabilities of the Type I and Type II error, respectively.



Source: Mar et al. 1986.

Figure 4.2 shows an analysis result based on the t-distribution for three confidence levels. The curves show the number of samples required as a function of precision. Precision is the ratio of the difference in the estimated and actual mean (the error that will be accepted) to the standard deviation (the variation or noise in the data). To use the graph, the monitoring program designer consults available data to get estimates of the mean and standard deviation and decides on the acceptable error and confidence level. For the case of an acceptable error equal to the standard deviation (precision = 1) and an 80 percent confidence, four samples are needed. But demanding a precision of 0.1 requires hundreds of samples.

Figure 4.2—Number of samples versus precision for three confidence levels. Precision is the ratio of the allowable error to the standard deviation of the population of measurements.



Source: Mar et al. 1986.

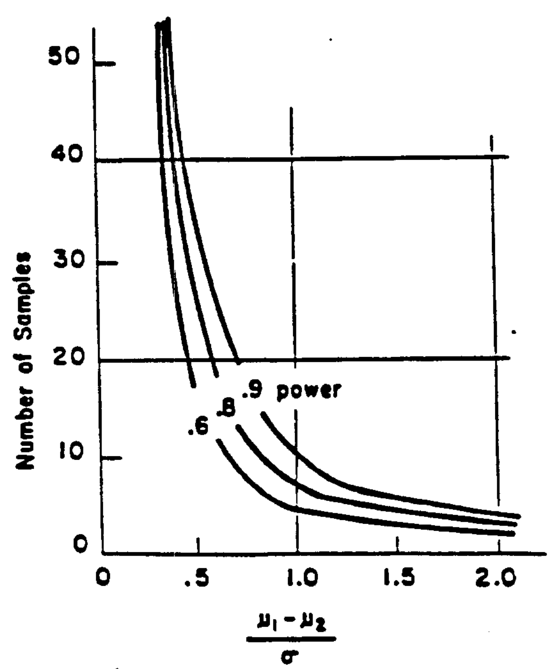
Detecting Change

Detecting change applies, for example, when the size or composition of a biological community is evaluated at two different points in time. Programs designed to detect change require different statistics than those that simply identify means. This type of problem is phrased as a statistical hypothesis test in which the null hypothesis (H_0) is that the populations at the two times are from the same distribution; the alternative hypothesis (H_1) is that they are from different distributions.

Figure 4.1 illustrates terminology needed for this type of evaluation. The shaded area of Figure 4.1(A) represents the probability (alpha) of a Type I error (H_0 was rejected when it was, in fact, true). Figure 4.1(B) shows distributions at both points in time, in which the difference in means represents an apparent change of magnitude (delta). The hatched area represents the probability (beta) of a Type II error (H_0 was accepted when it was, in fact, false). The quantity (1-beta) is termed the power of a statistical hypothesis test. Figure 4.1(C), in comparison to the other two graphs, illustrates the variation effect, as represented by the standard deviation, on power. For a given change, delta, the power increases as the standard deviation decreases.

Figure 4.3 provides a graphic way to establish the number of samples needed to detect change. To use the graph, the monitoring program designer consults any available data to estimate the standard deviation and decides on the magnitude of change to be detected (delta = $\mu_1 - \mu_2$) and the power. This plot shows that to detect changes to less than 50 percent of the standard deviation, the program requires a large number of samples.

Figure 4.3—Power curves relate number of samples to change to be detected. Sigma is standard deviation.



Source: Mar et al. 1986.

Monitoring Costs

The statistical methods previously illustrated show how to measure the program effectiveness value of added information in the form of more samples. However, to optimize the program, cost estimation must accompany these methods. Given the cost and value of added data, a trade-off analysis can be performed to obtain the most cost-effective program within the existing constraints. Costs are accounted as follows:

$$TC = C_o + T \cdot C_t + S \cdot T \cdot C_s + R \cdot S \cdot T \cdot C_r \quad [1]$$

where:
- TC = Total cost;
- C_o = Fixed overhead cost;
- C_t = Fixed cost for each sampling occasion;
- C_s = Cost associated with visiting each sampling station;
- C_r = Cost to collect and analyze each sample;
- T = Number of sampling occasions;
- S = Number of sampling stations; and
- R = Number of replicates on each occasion at each station.

Note that $R \cdot S \cdot T$ = the total number of samples. For a given total, the three quantities can be varied so long as their product remains the same. If measurement error is larger than natural variation, then adding replicates would reduce uncertainty more than adding stations or occasions. However, if spatial or temporal variation dominates, adding stations or occasions, respectively, would be a better strategy.

Optimization Example

Suppose three variables—A, B, and C—are monitored to establish their means with 90 percent confidence. Table 4.1 gives the measurement and variability costs of each. Considering three bases to design the monitoring program illustrates optimizing for a given budget (Designs 1 and 2) and a given level of assurance (Design 3):

▮ *Design 1.* Three samples will be collected for each variable (fixed cost of \$333). What is the minimum error that can be attained in each case?

▮ *Design 2.* Four samples will be collected for each variable (fixed cost of $444). What is the minimum error that can be attained in each case?

▮ *Design 3.* A fixed error of 24 percent of the mean is required for each variable. What design (sample numbers) provides this level of certainty at the minimum cost?

Table 4.1 summarizes the evaluation. Design 2, as compared to Design 1, indicates that an increased but equal number of samples would only slightly improve the estimate of the mean for each variable, and the estimate for variable B would still be uncertain relative to the others. However, as shown by Design 3, allocating more samples to the variable with the greatest variation, and where the most improvement results per dollar spent, provides a more cost-effective design.

In most actual cases, a simple analysis like this is insufficient since uncertainties can result from several factors, including measurement errors and spatial and temporal variability. Then, a sensitivity analysis should be performed to investigate each cost and variance component and its effect on the design in order to allocate the effort among sampling locations, occasions, and replicates. Mar et al. (1986) gives an example of such an analysis.

Table 4.1—Monitoring program optimization example.

INPUT DATA	VARIABLE		
	A	B	C
Cost per sample	$100	$ 1	$10
Standard deviation (percent of mean)	10	100	20

DESIGN 1 (3 samples of each variable)

VARIABLE	COST	PRECISION[a]	ERROR[b] (% OF MEAN)
A	$300	2.4	24
B	3	2.4	240
C	30	2.4	48
TOTAL	$333		

DESIGN 2 (4 samples of each variable)

VARIABLE	COST	PRECISION[a]	ERROR[b] (% OF MEAN)
A	$400	2.2	22
B	4	2.2	22[illegible]
C	40	2.2	44
TOTAL	$444		

DESIGN 3 (fixed allowable error of 24 percent of the mean for each variable)

VARIABLE	ERROR (% OF MEAN)	PRECISION[c]	NO. SAMPLES[a]	COST
A	24	2.4	3	$300
B	24	1.2	5	50
C	24	0.24	56	56
			TOTAL	$406

[a] From Figure 4.2 for 90 percent confidence.
[b] Error = Precision X standard deviation.
[c] Precision = Error/standard deviation.
Source: Mar et al. 1986.

Additional Considerations

Stratification of sampling, as discussed under step 4, can help reduce the variability that complicates monitoring. Values will fit in tighter bounds within a single season if all values are lumped for the entire year. The analysis can be performed separately for the respective seasons and sampling occasions allocated accordingly.

If no data are available, monitoring program designers have several choices. They can conduct a pilot program to obtain a limited data set; however, this would require spending time and money. A second choice is to use data from a similar location or estimate values using professional judgment. Either course has obvious drawbacks in accuracy, but both may be superior to making an educated guess of the sample number with qualitative, but no quantitative, analysis. Even that option is better, though, than blindly choosing the number of sampling occasions without any analysis.

In some cases, uncontrollable natural variability will be too great to achieve confidence in some program element with any feasible budget. The designer must then either delete the element or reduce costs in other areas to direct resources to the element. The options, illustrated by the cost equation, are to reduce the number of sampling stations, the analyses prescribed, the various cost functions representing program elements, or some combination. This decision is often unpalatable because it can demand, for example, cutting geographic coverage or not analyzing for a water quality measure traditionally included. However, the designer must choose and target the program according to objectives and circumstances, rather than conducting a program that gives inconclusive or misleading answers.

Water Quality Monitoring Program Guidance

Flow Measurement

Measuring Flow in Uncontrolled Open Channels

Flow, or discharge, is a basic hydraulic characteristic affecting morphological development of stream channels, flooding behavior, bed and bank erosion, and sediment deposition. A flow measurement is needed to estimate pollutant mass flux—the product of pollutant concentration and flow. Flow is measured manually or by continuously recording automatic instruments. Recording instruments require a controlled section such as a pipe, weir, or flume (see following section).

The common manual methods of flow measurement in uncontrolled channels are current meter surveys, staff gages, and float and tracer surveys (U.S. Dep. Inter. 1977). The current meter technique involves determining flow for a cross section of the channel. Current velocity and depth data from several points along the cross section are summed to obtain total flow. A staff gage provides an instant reading of water stage (i.e., level of water surface relative to a known point or datum). A stage-discharge curve must be developed to estimate flow from the staff gage reading. The curve is developed by correlating flows determined from current meter surveys with stages over a range of flow conditions. Estimating flow from timed float travel measurements can be inaccurate. Using this method should be limited to low or high flow conditions when the current meter cannot be employed. Tracers include biodegradable dyes and salts detectable by photometric and conductometric measurements, respectively. Tracer surveys are less convenient and more time consuming in natural waters than current meter methods.

▮ *Site Selection Criteria.* Select a representative location to establish a station for monitoring flow. Proper site selection improves the accuracy of flow measurements at all discharge levels. Consider the following criteria when establishing a discharge measurement station. However, all criteria listed can rarely be met. Be aware of the site's limitations and possible effects on measurement.

The station should be located in a channel reach (i.e., longitudinal section) with the following characteristics:

- The channel should be straight for 328 ft (100 m) upstream and downstream of the staff gage station.
- Flow should be confined to one channel at all discharge stages (i.e., the channel should contain no surface or subsurface bypasses).
- The bed should be subject to minimal scour and relatively free of plant growth.
- Banks should be stable, high enough to contain maximum flows to be measured, and free of brush.

VOL 12

6 6 / 6

- The station should be located a sufficient distance upstream so that flow from tributaries and tides does not affect stage/discharge measurements.
- All discharge stages should be measurable within the reach, but low and high flows at the identical cross section need not be measured.
- The site should be readily and safely accessible.

The cross section in which a station is located within a channel reach should have the following characteristics:

- Banks should be relatively high and stable.
- The channel should be straight with parallel banks.
- Depth and velocity must meet minimum requirements of the method and instruments used.
- The bed should be relatively uniform with minimal boulders and without heavy aquatic growth.
- Flow should be uniform and free of eddies, slack water, and excessive turbulence.
- Sites should not be located downstream of areas with rapid changes in stage or velocity.

Measurement Procedure Using a Current Meter

1. Extend a measuring tape at right angles to the direction of flow and measure the width of the cross section. Record measurements on a data sheet. Leave the tape strung across the stream.
2. Divide the width into segments using at least 20 points of measurement. If previous flow measurements have shown uniform depth and velocity, fewer points may be used; smaller streams may also require fewer points. Measuring points should be closer together where depths or velocities are more variable. Cross sections with uniform depth and velocity can have equal spacing.
3. Record the distance from the initial starting bank and the depth.
4. Record the current velocity at each measuring point. Horizontal (from left to right bank) and vertical (top to bottom) variation of stream velocity may influence streamflow measurements. To correct for vertical differences, hydrologists have determined depths that can yield acceptable estimates of the mean velocity over a vertical profile. If the depth exceeds 0.8 m (2.5 ft), velocities should be measured at 20 percent and 80 percent of full depth and averaged to estimate mean velocity. In the depth range 0.1 to 0.8 m (0.3 to 2.5 ft), take the velocity at 60 percent of the full depth (measured from the surface) as an estimate of the mean over the profile. Measuring velocity in water shallower than 0.1 m (0.3 ft) is difficult with conventional current meters. If much of the reach of interest is very shallow, or flow is too slow for current meter measurement, consider installing a control section and V-notch weir.
5. Calculate flow as a summation of flows in partial areas (Figure 4.4) using the following equation:

$$q_n = v_n d_n \frac{(b_{n+1} - b_{n-1})}{2} \qquad [2]$$

where:

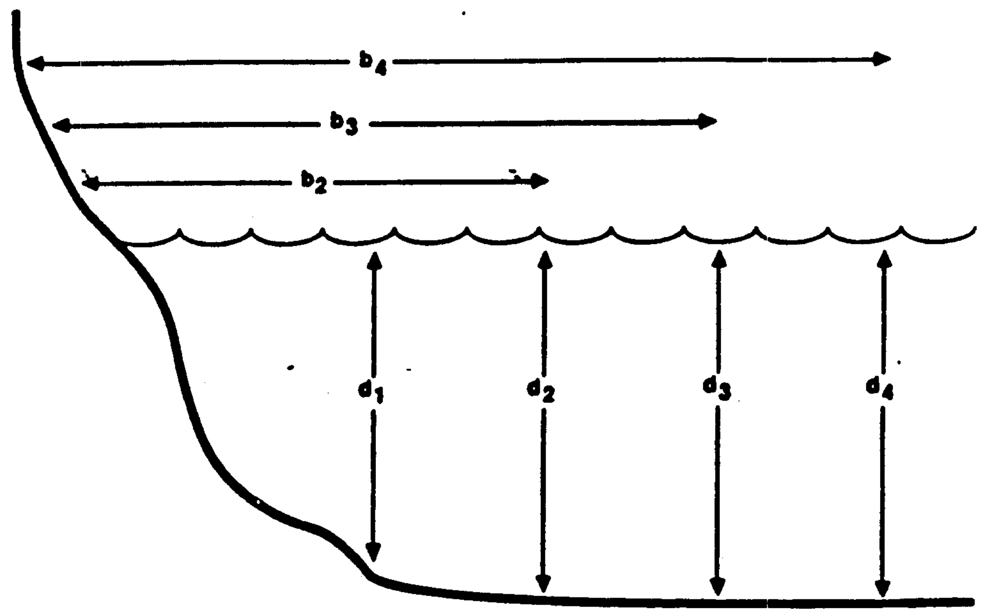
b_{n-1} = Distance from initial point to the preceding point (m [ft]);
b_{n+1} = Distance from initial point to the following point (m [ft]);
d = Mean depth of partial area n (m [ft]);
v = Average current velocity in partial area n (m/sec [ft/sec]); and
q = Discharge in partial area n (m^3/sec [ft^3/sec]).

Measuring Flow in Controlled Open Channels

An open channel is any conveyance where flow is not constrained or under pressure. Therefore, closed pipes and culverts can be open channels if they are not flowing full, a normal situation in runoff conveyance systems. When the channel geometry is regular and absolutely stable, it is termed controlled, as in pipes, culverts, many lined ditches, and channels where a weir or flume can be installed. In those situations, a recording automatic flow meter can be used.

Flow meters measure in several different ways. The most common way to measure runoff is to sense flow depth and convert to flow rate by some known relationship. Other techniques are electronic and ultrasonic.

Figure 4.4—Variables used to calculate stream discharge using the current meter method.



Source: R.R. Horner.

Among the most common means of sensing depth is by releasing a regularly spaced stream of air bubbles at the channel invert and detecting the back pressure resisting the bubble release—a function of depth. The bubble tube must be installed exactly as the manufacturer prescribes to get reliable measurements. How the depth measurement is converted to flow rate depends on the conduit. Standard weirs and flumes have well-established equations to simply compute flow rate from geometry and depth. Without a primary control device such as a weir or flume, flow rate must either be related to depth through a calibration using a current meter or, more commonly, by the standard equation of open channel flow—Manning's equation:

$$Q = A \cdot R^{0.67} \cdot s^{0.5}/n \qquad [3]$$

where:
- Q = Flow rate (m^3/s);
- A = Channel cross-sectional area (m^2);
- R = Hydraulic radius (m) = A/wetted perimeter;
- s = Water surface slope (m/m); and
- n = Manning's roughness coefficient (dimensionless).

In the English system of units, a multiplier of 1.49 on the right side of the equation gives Q in ft^3/s if geometry is in ft and ft^2.

Because of uncertainties in estimating slope, depth, and n—the latter of which comes from tables—the accuracy obtained from using Manning's equation is not as great as with a weir or flume. When using the equation, place the depth sensor in the channel where

- The cross section is uniform;
- The slope and roughness are constant;
- The channel is free of rapids, bends, abrupt falls, contractions, expansions, and backwater; and
- The channel is straight for at least 200 ft (60 m) upstream.

Modern recording automatic flow meters can make depth-to-flow rate conversions, accumulate a continuous flow-rate record, and provide the total flow volume over a period. The operator programs the appropriate flow conversion equation in the meter—using a weir or flume equation, Manning's equation, or a calibration equation derived from empirical data. These flow meters can also control an automatic sampler to collect flow-proportional composite samples.

Water Sampling Guidelines

The essential tasks in sampling natural waters and runoff are to obtain a sample that meets the program requirements and to prevent its deterioration and contamination before and during analysis. Water can be collected either as discrete or composite samples. Discrete samples are collected at a specific point in time and space; composite samples are made by combining a number of samples taken at different locations and/or different times. For flowing water sampling, flow-proportional composited samples better represent average water conditions than discrete samples or multiple samples taken at different times and composited without regard to flow.

Integrated samples refer to spatial composites. While composites can be taken over any dimension, compositing over depth is most common. In variable-depth composites, a series of grab samples are combined in proportion to flow velocities over the depth profile.

Sampling can be performed manually or with automatic collectors that collect a series of discrete samples, time-proportional, or flow-proportional composites. Flow measurements, required to produce flow-proportional composites, can be performed manually or with a continuously recording meter. Simple manual depth-integrating samplers approximately adjust for velocity differences as the sampler is lifted through the water column.

Manual Grab Sampling

The principal problem is obtaining a sample that represents the conditions being investigated. The guidelines for obtaining representative samples differ for flowing and standing water. Further information concerning lake sampling is available in Cooke et al. (1993) and Vollenweider (1974).

Water Sample Handling

To avoid mistakes, label a sample bottle with an indelible marker before going into the field. Sample labels must include station designation, date, collector's name, and any preservative added. The label can also include analyses to be performed and any pertinent remarks.

A tracking record for each sample registers possession as the sample travels from collection through analysis, making misplaced samples easier to find. Samples involved in litigation may require formal sample tracking, or chain-of-custody records.

Samples must be preserved and analyzed within a certain period to avoid deterioration. Recommended preservation methods and holding times, given in Table 4.2 were derived from American Public Health Association (APHA) and U.S. EPA (1983).

Water Quality Analytical Methods

Analytical methods and detection limits for commonly analyzed variables are given in Table 4.3. These methods are covered in both the American Public Health Association (1992) and U.S. EPA (1983) manuals.

Select an analytical laboratory carefully. A good laboratory will advise and help with aspects of the program beyond the analyses, such as sample container preparation and labeling. If an accreditation program is in effect, use a laboratory accredited for water analyses. Write detailed specifications on sample handling procedures, methods, detection limits, and quality assurance/quality control (QA/QC) requirements, using this chapter's recommendations.

Quality Control

The effectiveness of any monitoring effort depends on its quality control (QC) program. The QC program provides quantitative measurements of the "goodness" of the data. For some variables, QC involves calibrating instruments with known standards. To obtain accuracy and precision, QC also further involves analyses of blanks, replicate samples, control samples, and spiked samples. QC definitions of terms are included in this chapter.

Table 4.4 gives QC guidelines. State specific QC requirements explicitly in any contract, and conduct discussions among project managers and field and laboratory personnel concerning the QC project requirements before a contract is signed. Requirements differ among projects — a project involving enforcement actions or litigation can have more stringent QC requirements than one involving routine ambient monitoring. More information is available in U.S. EPA (1979) and American Public Health Association (1992).

Definitions Used in QC Practice

- ***Field replicates.*** Separate samples collected simultaneously at the identical source location and analyzed separately. Field replicates assess total sample variability (i.e., field plus analytical variability).

Table 4.2—Recommended sample sizes, containers, preservation techniques, and holding times for measurement of water quality variables.

VARIABLE	MINIMUM SAMPLE SIZE (mL)[a]	CONTAINER[b]	PRESERVATION	HOLDING TIME[c] RECOMMENDED	HOLDING TIME[c] MAXIMUM
Temperature	1,000[d]	P, G	None	Zero[e]	Zero[e]
Conductivity	100	P, G	Cool, 4°C[f]	28 days	28 days
Dissolved oxygen	300	G (BOD bottle)	Fix with reagents, store in dark	8 hours	8 hours
pH	25[g]	P, G	None	Zero[e]	Zero[e]
Alkalinity	100	P, G	Cool, 4°C[f]	24 hours[h]	14 days
Total hardness	100	P, G	HNO_3 to pH < 2	6 months	6 months
Total suspended solids	1,000[i]	P, G	Cool, 4°C[f]	7 days	7 days
Turbidity	100	P, G	Cool, 4°C[f]	24 hours	48 hours
Ammonia-nitrogen	125	P, G	H_2SO_4 to pH < 2 Cool, 4°C[f]	24 hours	28 days
Nitrate + nitrite - nitrogen	125	P, G	H_2SO_4 to pH < 2 Cool, 4°C[f, j]	24 hours	28 days
Total phosphorus	50	P, G	H_2SO_4 to pH < 2 Cool, 4°C[f]	48 hours	28 days
Orthophosphate-phosphorus	50	P, G	Filter onsite Cool, 4°C[f]	24 hours	48 hours
Fecal coliform bacteria	125	P, G[k]	Cool, 1-4°C[f]	6 hours	30 hours
Metals	1	P[m]	High-purity HNO_3 to pH < 2	6 months	6 months

[a] Recommended field sample size for one laboratory analysis of the given variable.
[b] P = polyethylene, polypropylene, or fluoropolymer; G = glass.
[c] Analyze within the recommended time if possible, but in all cases within the maximum. The holding times given are for routine monitoring work.
[d] Measuring directly in waterbody is preferred.
[e] Analyze immediately.
[f] Holding at 4°C implies holding in the dark.
[g] Increase the volume to rinse the pH electrodes several times, especially in low-alkalinity waters.
[h] Some agencies prefer to analyze low-alkalinity waters in the field, while the greater analytical control available in the laboratory is preferred in other agencies.
[i] Volume given is the maximum needed to filter for analysis of low concentrations. A smaller quantity (100-250 mL) is adequate for most samples.
[j] If nitrate-nitrogen data are needed, a separate, nonacidified sample is required. The nonacidified sample must be analyzed for nitrite-nitrogen within 48 hours. Nitrate-nitrogen is determined by subtracting nitrite-nitrogen from nitrate + nitrite-nitrogen.
[k] Container must be able to withstand autoclaving at 121°C for 20 minutes.
[l] Depends on number of metals to be analyzed and the analytical method. 2 liters is sufficient to analyze all EPA priority metals by atomic absorption (AA), while inductively coupled plasma (ICP) would require less.
[m] Fluoropolymer preferred.

■ *Laboratory replicates.* Repeated analyses of a variable performed on the contents of a single sample. Laboratory replicates assess analytical precision. Duplicate analyses usually suffice for well-proven procedures in the laboratory.

■ *Calibration samples.* Samples from distilled-deionized water that contain a known concentration of a specific substance or will produce a known instrument response. Calibration samples analyzed during an analytical run are often re-

Table 4.4.—Calibration and quality control guidelines for water quality variables.

VARIABLE	GUIDELINES[a]
Temperature	Check thermometer against a thermometer certified by American Society for Testing and Materials or National Institute of Standards and Technology.
Conductivity[b]	Calibrate in the laboratory with two standard KCl solutions representing the expected conductivity range of the samples. Check calibration using one standard KCl solution (with conductivity in the sample range) per batch in the laboratory or whenever the meter is set up in the field.
Dissolved oxygen[b]	For the azide-modified Winkler method, run one 100 percent saturated calibration sample/batch. For studies where low DO concentrations are expected, a calibration sample containing zero DO may be used. For the membrane-electrode method, calibrate with a sample of known DO concentration (determined using the azide-modified Winkler method) and with a sample containing zero DO. Calibration is required prior to the start of every series of measurements and whenever the meter is moved or turned off.
pH[b]	Calibrate with two buffers and check with a third every three hours. Use neutral, acid, and basic buffers (e.g., pH 4.0, 7.0, and 10.0) prepared according to National Bureau of Standards Special Publication 260-53.
Alkalinity[b]	Calibrate pH meter as above. Check titrant normality with self-prepared and U.S. EPA standard solutions (one check/batch).
Total hardness[b]	Check titrant molarity with self-prepared and U. S. EPA standard solutions (one check/batch) and run one blank/batch. Run one spiked sample/batch if interference is suspected.
Total suspended solids[b]	Check balance calibration monthly and oven temperature daily. Balances should have annual preventive maintenance checks.
Turbidity[b]	Calibrate with commercial standard in same range as samples. Recalibrate with every range change.
Manual nutrients[b]	Run calibration curve with a blank and standards at 0.2, 0.35, 0.5, 0.75, and 1.0 cu[c]. Entire range of sample concentrations must be included in the calibration curve. Run control samples at 0.2 and 0.9 cu with each batch. Run two blanks/batch and one spiked sample/batch.
Automated nutrients[b]	Run calibration curve with a blank and standards at 0.2, 0.5, and 1.0 cu. Entire range of sample concentrations must be included in the calibration curve. Run control samples at 0.2 and 0.9 cu with each batch. Run two blanks/batch and one spiked sample/batch.
Fecal coliform bacteria	Run a transport blank. Randomly split 10 percent of the samples for analysis at another laboratory. Field and laboratory replicates should both be included at a frequency of 10 percent.

[a] A batch is a group of no more than 20 samples.
[b] Field replicate samples should be collected and analyzed at a frequency of 5 to 10 percent. Laboratory replicates should be analyzed at a frequency of 5 to 10 percent.
[c] cu = Upper limit of expected concentration range.
Source: Tetra Tech et al. 1988.

ferred to as control samples or check standards. The distilled-deionized water used in calibration samples should meet Type 1 water quality criteria specified by American Public Health Association (1992) Method 107.4.

■ *Blanks.* Samples prepared from distilled water, perhaps with reagents added, to represent zero concentration of a specific substance or to produce an instrument response indicating zero concentration.

VOL 12

6622

R0039930

A transport blank is required for fecal coliform bacteria studies and may be useful in nutrient studies. A transport blank is transported to the sampling location and treated like a sample thereafter.

- ***Spiked samples.*** Samples prepared by adding known concentrations of a specific substance.

- ***Accuracy.*** The agreement between the measurement of a variable in a sample and its true value. The term "error" is used when the discrepancy between the measured and true values is expressed in the units of the measured variable. Relative error is when the error is expressed by the percentage deviation from the true value.

- ***Precision.*** The agreement among replicate laboratory measurements. Precision is measured by the standard deviation when using the units of the measured variable. Relative standard deviation is when the standard deviation is expressed as a percent of the mean of the replicate values.

Sample Container Cleaning

Avoiding sample contamination requires careful cleaning of sample bottles and laboratory equipment. Some general guidelines for cleaning are presented here. Additional requirements for certain individual variables are covered in the methods sections for those variables. The recommended procedures should be applied to sample containers and all laboratory glassware and implements that will come into direct contact with samples during collection, storage, or analysis.

Laboratory equipment should always be washed with detergent, rinsed with tap water, and rinsed an additional three times with ultrapure deionized water. Detergents must be selected considering the analyses to be performed (e.g., use phosphorus-free detergent when performing phosphorus analysis). An ultrasonic cleaner can minimize the need for hand scrubbing. Following the water rinses, perform acid washing with sulfuric acid on equipment involved with nutrient analyses. After acid washing, rinse equipment completely at least six times with ultrapure deionized water.

If QC criteria are not met, thoroughly review the cleaning operation to determine if inadequate cleaning procedures could be causing contamination.

Criteria for Acceptance of QC Results and Corrective Actions

While this chapter contains general guidelines for accepting QC results and corrective actions, more detailed information is available in U. S. EPA (1979). Control limits for accuracy and precision are established in every laboratory, and these limits may vary among laboratories.

CHAPTER 5

Sediment Monitoring

Traditional point sources of pollution typically discharge effluents of uniform, known quality, at continuous design flow, making them relatively easy to assess, model, and control. Point source assessments have relied on water column chemistry monitoring. However, urban runoff and other nonpoint sources of pollution—because of their intermittent, diffuse, land-use-specific nature—are highly variable in effluent quality and environmental effects. Of greatest environmental concern is the cumulative impact of runoff and nonpoint sources (NPS) of pollution on a waterbody within a watershed.

This chapter discusses sediment monitoring and assessment—an area of monitoring that is typically ignored yet is especially important in the assessment and management of urban runoff and other nonpoint sources. This chapter also reviews and discusses the activities undertaken in Florida to develop and implement coastal sediment sampling, analysis, and environmental assessment techniques.

Water quality managers often do not understand or know how to cope with runoff and NPS pollution. Problems include

- Discriminating anthropogenic loadings from natural watershed loadings of metals and nutrients;
- Assessing intermittent, shock loadings of pollutants;
- Assessing cumulative impacts of multiple sources;
- Comparing waterbodies and establishing priorities for management actions;
- Distinguishing actual or potential problems from perceived problems; and
- Establishing cost-effective ways to assess pollution trends and understand overall watershed pollution.

Most runoff pollutants accumulate over time in sediments, not in the water column. Therefore, assessing cumulative effects of watershed runoff and NPS pollution sources on aquatic systems should include evaluation of sediments and the organisms that reside there. Alternative assessment methods are needed to determine the actual environmental effects of runoff and to assess the effectiveness of control measures. This manual presents two alternative methods. Sediment monitoring is reviewed in this chapter and biological monitoring in Chapter 6.

Assessing Sediments Contamination

Traditionally, concerns about managing aquatic resources have focused on water quality. However, recently we have become more aware of the importance of sediments in determining the fate and effects of numerous contaminants. While evaluations of sediment quality are often used to address site-specific management needs, sediment quality is also a sensitive indicator of overall environmental quality.

Sediments influence the environmental fate of many toxic and bioaccumulative substances in

VOL 12

6624

aquatic ecosystems. Specifically, sediment quality is important because many toxic contaminants found in only trace amounts in water can accumulate to elevated levels in sediments. As such, sediments serve both as reservoirs and as potential contaminant sources to the water column. Sediments tend to integrate contaminant concentrations over time and may represent long-term sources of contamination. Sediment-associated contaminants can also directly affect benthic and other organisms. In addition to the physical and chemical relationships between sediments and contaminants, sediments provide benthic communities with suitable habitats for essential biological processes (e.g., spawning, incubation, rearing).

Sediments provide an essential link between chemical and biological processes. By understanding this link, environmental scientists can develop assessment tools and conduct monitoring programs to more accurately evaluate the health of aquatic systems. Therefore, sediment quality data provide essential information for evaluating ambient environmental quality conditions in waters. Additionally, information about the amount and quality of sediments within runoff management systems, storm sewers, and other conveyances can help track pollution sources and prioritize areas for implementing control measures.

Assessment of sediments to determine whether urban runoff pollutants are causing or contributing to ecological problems within a waterbody is increasingly performed. Consequently, sediment monitoring and assessment procedures are being developed. Before sediments can be reliably used to assess the effects of contaminants on aquatic systems, three issues must be addressed:

- Accurate, reliable sediment sampling and laboratory analysis techniques;
- Interpretive techniques to determine whether contaminants (especially metals) found in sediments are natural or from human activity; and
- Sediment quality assessment guidelines correlating sediment contaminant concentrations with biological effects. These guidlines assess whether amounts of sediment likely to adversely affect water quality and living resources could recycle to the water column or through food chains.

The Florida Example

Natural versus Anthropogenically Enriched Sediments

Florida has an extensive coastline—approximately 11,000 mi (17,699 km)—and an unusual diversity of estuarine types.* Its many estuary conditions range from nearly pristine to localized severe degradation. Metals are of particular concern in protecting and rehabilitating estuaries because of their potential toxic effects and because high metal concentrations can signal the presence of other pollution. Natural metal concentrations vary widely among Florida estuaries, presenting special difficulties in comparing estuarine systems statewide and in making consistent, scientifically defensible management decisions.

In the past, determining whether estuarine and coastal sediments were anthropogenically enriched with metals was a difficult process requiring comprehensive site-specific assessments. However, a recently developed practical approach for assessing metals contamination in coastal sediments relies on normalization of metal concentrations to a reference element. In Florida, normalization of metal concentrations to aluminum concentrations in estuarine sediments provided the most promising method of comparing metal levels regionally. In Florida and Washington State, early research indicates that other elements (e.g., lithium) may be an appropriate reference element for assessing coastal sediments.

To understand this assessment tool, one must generally understand geochemical processes that govern the behavior and fate of metals in estuaries and marine waters. Natural estuarine sediments are predominantly composed of river-transported debris from continental weathering. Acids formed in the atmosphere or from the breakdown of organic matter (e.g., carbonic, humic, fulvic acids) mix with water and form leaching solutions. These leaching solutions break down rocks and carry away the products in solution or as solid debris. This debris is chiefly composed of chemically resistant minerals, such as quartz and clay minerals, which are the alteration products of other aluminosilicate minerals. The general formula $M\text{-}AlSiO_4$ represents the aluminosilicate clay minerals

** The material in this and the following two sections was adapted from Fla. Dep. Environ. Prot. 1988.*

VOL 12

6625

where: M = naturally occurring metal that can substitute for aluminum in the aluminosilicate structure
Al = aluminum
Si = silicon
O = oxygen

The metals are tightly bound within the aluminosilicate lattice.

The weathering solution also contains dissolved metals leached from the parent rock. Because of their low solubilities, however, the transporting solution (e.g., rivers) contains low amounts of metals. Most metals transported by rivers are tightly bound in the aluminosilicate solid phases. As a consequence, weathering causes little fractionation between the naturally occurring metals and aluminum.

In general, when dissolved metals from natural or anthropogenic sources come in contact with saline water, they quickly adsorb to particulate matter and go from the water column to bottom sediments. Thus, metals from both natural and anthropogenic sources are ultimately concentrated in estuarine sediments, not the water column. Since much of the natural component of metals in estuarine sediments is chemically bound in the aluminosilicate structure, the metals are generally immobile; however, the adsorbed anthropogenic or pollutant component is more loosely bound. Metals in the anthropogenic fraction, therefore, may be more available to estuarine biota and may be released to the water column in altered forms when sediments are disturbed (e.g., by dredging or storms).

The tool for interpreting metal concentrations in estuarine sediments is based on demonstrated, naturally occurring relationships between metals and aluminum. Specifically, natural metal/aluminum concentration relationships were used to develop guidelines to distinguish natural from contaminated sediments for several metals commonly released to the environment from anthropogenic activities. Aluminum was chosen as a reference element to normalize sediment metals concentrations for several reasons:

- After silicon, aluminum is the most abundant naturally occurring metal;
- Aluminum is highly refractory;
- The proportions of metals and aluminum in crustal materials are relatively constant; and
- Aluminum concentration is rarely influenced by anthropogenic sources.

So that the information used to develop the interpretive tool represented diverse Florida sediments, uncontaminated sediments from around the state were examined for their metal content, and the natural variability of metal/aluminum relationships was statistically assessed (Fla. Dep. Environ. Prot. 1988). Sediment samples from 103 stations in uncontaminated estuarine/coastal areas were collected and analyzed for aluminum and other environmentally and geochemically important metals. The areas sampled encompassed various sediment types ranging from terrigenous, aluminosilicate-rich sediments in northern Florida to biogenic, carbonate-rich sediments in southern Florida. These "clean" sites were selected subjectively, based on their remoteness from known or suspected anthropogenic metal sources.

To ensure that divers retrieved undisturbed sediment samples at each station, they collected sediments in cellulose-acetate-butyrate cores. Sediment for metals analyses was taken from the upper 5 cm (nearly 2 in) of each core. Duplicate samples taken at each station were analyzed for nine metals—aluminum, arsenic, cadmium, chromium, copper, mercury, nickel, lead, zinc. Particular care was taken to ensure total digestion of sediment samples as required by the project quality assurance plan.

Simple linear regressions for each metal on aluminum were performed on log-transformed data and 95 percent prediction limits were calculated. Significant correlations were obtained for arsenic, cadmium, copper, lead, nickel, and zinc. The plotted regression lines and prediction limits (Figures 5.1 to 5.7) form the basis for interpreting metal concentrations in sediments. The results indicate that aluminosilicate minerals have a major influence on metal concentrations in Florida's natural sediments. Furthermore, sediment metal/aluminum relationships provide a basis for interpreting metals data from Florida coastal sediments. The effectiveness and utility of this sediment assessment tool has been tested in a variety of regional studies (Hanson and Evans, 1991; Schropp et. al. 1989; Pardue et al. 1992).

To determine whether estuarine sediments are enriched with metals, we calculate a mean value of each metal (derived from replicate or triplicate samples) and plot points representing corresponding metal and aluminum values. The sediment is judged to be natural or metal enriched, depending on where the points lie relative to the regression lines and prediction limits. If a point falls within the prediction limits, then the sediment metal concentration is within the expected natural range. If a point falls above the upper prediction limit, then the sediment is considered to be metal-enriched. Before we determine enrichment, we should confirm the accuracy of the analytical results, since an unusual point can indicate procedural errors. Since the results are interpreted with respect to the 95 percent prediction limit, some points from clean stations will lie outside the prediction limit. The farther from the prediction limit, the greater the likelihood that the sample does indeed come from a metal-enriched sediment. The greater the distance above the prediction limit, the greater the degree of enrichment.

Figures 5.1 through 5.7 show the blank metal/aluminum figures derived from the statistical analyses of sediment samples from 103 stations in Florida's uncontaminated estuarine/coastal areas. Extrapolated portions of the lines are represented by dashed lines. Metals data can be plotted on these figures to assess metals enrichment of estuarine sediments (Fla. Dep. Environ. Prot. 1988).

Figure 5.1.—Arsenic/aluminum regression line with 95 percent prediction limits.

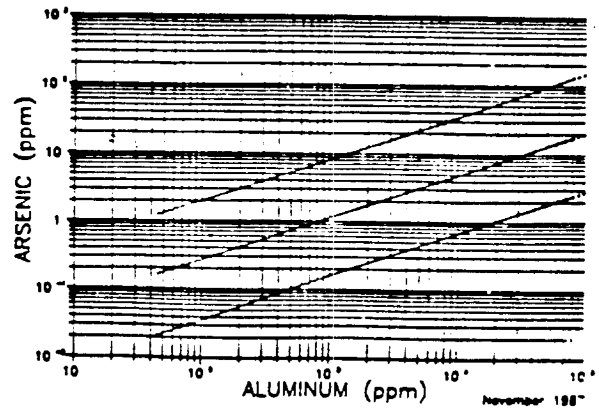

Figure 5.2—Cadmium/aluminum regression line with 95 percent prediction limits.

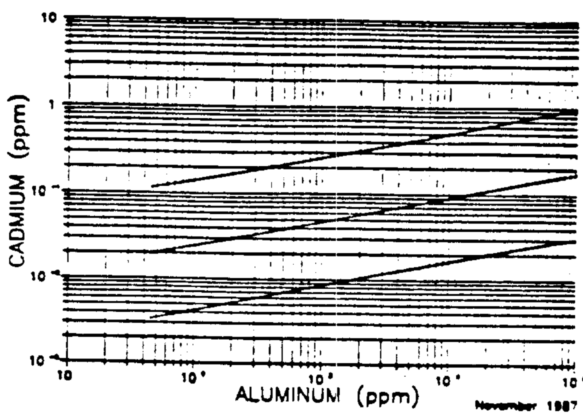

Source: Figures 5.1 – 5.7 from Fla. Dep. Environ. Prot. 1988.

Applying the Interpretive Tool

The interpretive tool, using metal and aluminum relationships, allows results of sediment chemical analyses to be used for a variety of environmental information needs, including

- **Distinguishing natural versus enriched metals concentrations in coastal sediments.** The degree of enrichment can also be estimated by the deviation from the expected natural range.

- **Comparing metal concentrations within an estuary.** Absolute metal concentrations in coastal sediments will vary depending on many factors, including sediment grain size, mineralogy, and anthropogenic metal sources. Normalizing metals to the reference element—aluminum—allows comparisons of metal concentrations among sites within an estuary.

- **Comparing investigative results from different estuaries.** By normalizing metal concentrations to aluminum, we can assess relative metal enrichment levels and rank estuaries according to specific metal enrichment problems.

- **Tracking the influence of a pollution source.** In some cases, we can determine the extent of metal-enriched sediments. This delineation focuses attention on real, rather than perceived, problems.

- **Monitoring trends in metal concentrations.** By periodically examining sediments at permanent sampling stations or along known pollution gradients, the technique may provide a much-needed device for cost-effective monitoring of the overall estuary pollution climate and the effectiveness of watershed control measures.

VOL 12
6627

R0039935

Figure 5.3—Chromium/aluminum regression line with 95 percent prediction limits.

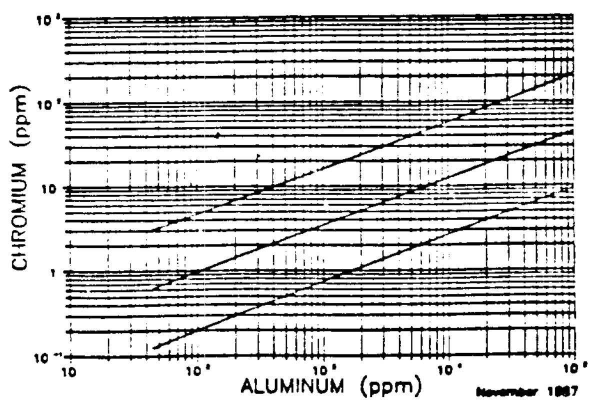

Figure 5.4—Copper/aluminum regression line with 95 percent prediction limits.

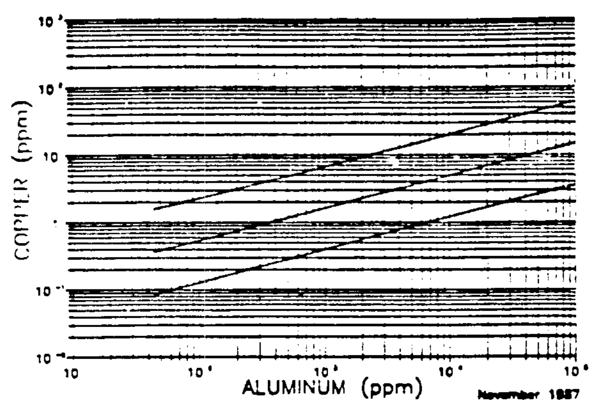

- **Determining procedural or laboratory errors.** The location of points on the metal/aluminum figures can signal possible errors, including sample contamination in the field or laboratory and analytical or reporting errors.

- **Screening tool to promote cost-effective use of tests.** A variety of tests (e.g., elutriate, bioassay) demonstrate potential release to the water column or toxicity of metals in sediments. This interpretive tool can reduce the time and cost of testing by screening sediments and selecting for further testing only those whose metal concentrations exceed expected natural ranges.

Interpretive Tool Limitations

This approach provides an interpretive tool to evaluate metals concentrations in estuarine sediments. Funding limitations in Florida have prevented collecting and analyzing sediment samples from freshwater systems to see if the tool can be used in those aquatic systems. However, such sampling is now being done in Washington State and was completed in Illinois. Tool use requires knowing local conditions and applying professional judgment and common sense. Consider the following points when using this tool:

1. The interpretive tool is useless without reliable data; results from single, nonreplicated samples should never be used. Ideally, collect sediment samples in triplicate. If budget constraints dictate analysis of only duplicate samples, archive the third sample. If a disparity in the results of the replicate analyses occurs, retrieve and analyze the archived sample to resolve the problem.

2. Carefully analyze sediment metals using techniques appropriate for saline conditions and capable of providing adequate detection limits. Because naturally occurring aluminum and other metals are tightly bound within the sediment's crystalline structure, the metals analyses methods must include complete sediment digestion. If aluminum is not completely released by a thorough digestion, metal-to-aluminum ratios may appear to be unusually high. Complete digestion requires the use of hydrofluoric (HF) acid during the digestion process.

3. Mercury presents special problems, both in the laboratory and in interpretating the results. Since mercury is more volatile than the other metals, use a different digestion procedure employing a lower temperature. Natural mercury concentrations are very near routine analytical detection limits, reducing precision and accuracy. Furthermore, mercury's apparent weak inverse relationship with aluminum precludes using aluminum as a reference element.

   To analyze mercury, the Florida Department of Environmental Protection (DEP) assumed that the maximum mercury value in the clean sediment data set (0.21 ppm mercury) represents the maximum mercury concentration found in Florida's natural sediments. To evaluate sediment samples, consider those containing less than 0.21 ppm mercury as typical of clean sediments. Samples with greater than 0.21 ppm mercury should be suspected as being enriched and should be interpreted similarly to other metals that fall outside the 95 percent prediction limits.

4. Aluminum concentrations in the data set from which these guidelines were prepared ranged from 47 to 79,000 ppm. The data set, to the extent possible, represents various natural clean sediments found in Florida estuaries. The majority of samples recovered from Florida estuarine sediments will have aluminum concentrations within this range. Some clay-rich sediments, especially in northwest Florida, may contain aluminum concentrations exceeding 79,000 ppm. Kaolinite, illite (muscovite), montmorillonite, and chlorite—four commonly occurring marine clays—contain aluminum concentrations of approximately 21 percent, 20 percent, 15 percent, and 10 percent, respectively.

   Theoretically, the maximum aluminum concentration in a natural marine sediment is about 210,000 ppm (21 percent) if the sediment is composed of pure kaolinite. Since sediments are not pure clay, the aluminum concentration in estuarine sediment samples should be considerably less than this theoretical maximum; in only a few instances should aluminum concentrations exceed 100,000 ppm (10 percent aluminum). Carefully examine any samples containing greater than 100,000 ppm aluminum for evidence of contamination or analytical error.

5. During the construction of the "trimmed clean" data set, some points containing low aluminum values were removed from the cadmium, lead, nickel, and zinc data. Since the lowest overall aluminum value was 47 ppm, the regression lines and prediction limits for these four metals have been extrapolated down to an aluminum value of 47 ppm.

6. At stations where a metal concentration exceeds the 95 percent prediction limit, the metal must be considered enriched. We cannot immediately assume, however, that a finding of enrichment indicates a problem. Some samples from natural clean sediments may contain metal concentrations that exceed the 95 percent prediction limit. Interpretation of metal concentrations, using these metal-to-aluminum relationships, must also consider sediment grain size, mineralogy, coastal hydrography, and proximity to sources of metals.

Figure 5.5—Nickel/aluminum regression line with 95 percent prediction limits.

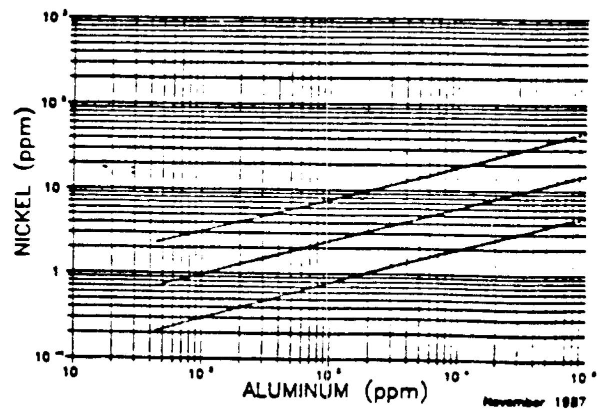

Figure 5.6—Lead/aluminum regression line with 95 percent prediction limits.

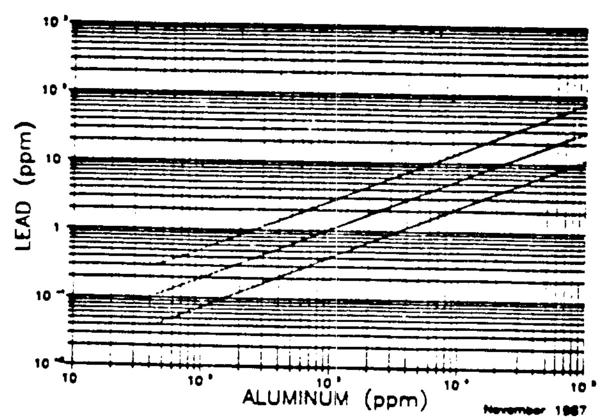
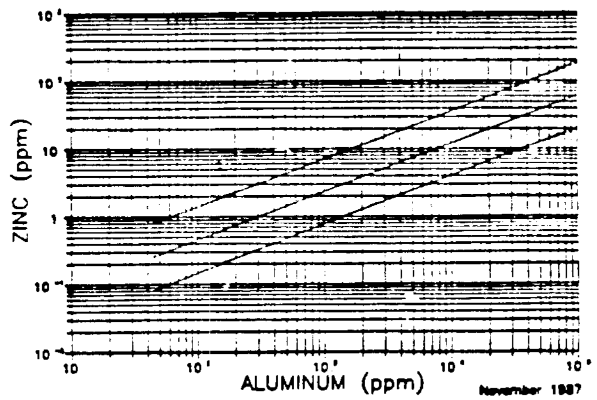


Determining the Ecological Significance of Enriched Sediments

Sediment chemistry data alone do not provide an adequate basis to identify or manage potential sediment quality problems. After determining that

Figure 5.7—Zinc/aluminum regression line with 95 percent prediction limits.



sediments are anthropogenically enriched with pollutants, we must next determine whether these sediment-bound pollutants are harmful to the environment. Biologically-based sediment quality assessment guidelines (SQAGs) also are required to interpret the ecological significance of sediment chemistry data. Numerical SQAGs support assessing the potential effects of sediment-associated contaminants.

Various approaches help formulate sediment quality guidelines (SQGs) (Chapman, 1989; Persaud et al. 1989; Beak, 1987 and 1988; U.S. Environ. Prot. Agency, 1989a,b; Sediment Criteria Subcommittee, 1989 and 1990; and MacDonald et al. 1991). The major approaches by which SQGs are developed are

- Sediment background approach (SBA);
- Spiked sediment bioassay approach (SSBA);
- Equilibrium partitioning approach (EqPA);
- Tissue residue approach (TRA);
- Screening level concentration approach (SLCA);
- Sediment quality triad approach (SQTA);
- Apparent effects threshold approach (AETA); and
- National status and trends program approach (NSTPA).

To date, no effects-based SQAGs apply directly to Florida conditions. While effects-based SQAGs have been developed specifically for a few regions of the country (i.e., Puget Sound is using an apparent effects threshold approach), the EPA Science Advisory Board (SAB) cautions against using these guidelines outside the areas for which they were developed (Sediment Criteria Subcommittee, 1989). The SAB has also questioned the validity of the sediment quality criteria that EPA is currently developing (i.e., using the equilibrium partitioning approach). These SAB evaluations suggest that SQAGs under development in other jurisdictions will not likely address Florida's immediate requirement for sediment assessment tools.

Ideally, SQAGs should be developed from dose-response data that describe acute and chronic toxicity of individual contaminants to sensitive life stages of resident aquatic organisms. These data should be generated in controlled laboratory studies, where the influences of important environmental variables—such as total organic carbon (TOC), acid volatile sulfide (AVS), salinity, and others—are identified, quantified, and compared to the values predicted by appropriate models (e.g., EqP models). Finally, the results of these studies should be validated in field trials to ensure that guidelines derived from these data will apply to a broad range of locations. Understanding the factors that influence toxicity also supports site-specific sediment quality assessments by evaluating and modifying the preliminary guidelines.

Unfortunately, data are insufficient to derive numerical SQAGs using the ideal approach. Currently, only a limited number of controlled laboratory studies (i.e., spiked-sediment bioassays) have been conducted to assess the effects of sediment-associated contaminants on estuarine and marine organisms. In spite of this limitation, other data are routinely collected that clarify the toxic effects of these contaminants. Specifically, a variety of whole sediment toxicity tests have assessed the biological significance of contaminant concentrations in sediments from specific geographic locations. Toxicity tests were performed on benthic organisms (e.g., bivalve mollusks, shrimp, amphipods, polychaetes, nematodes, chironomids and other arthropods) and on pelagic organisms (e.g., *Daphnia*, oyster larvae, luminescent bacteria [Microtox]). Numerous field studies also assessed the diversity and abundance of benthic infaunal species (e.g., bivalve mollusks, arthropods, amphipods) and epibenthic organisms (e.g., echinoderms, crustaceans). Many of these studies collected matching data on the contaminant concentrations in sediments. Studies that report matching sediment chemistry and biological effects data provide highly relevant information to the SQAGs derivation process.

A suitable strategy for deriving SQAGs for Florida recognizes the limitations of the existing database to evaluate the potential biological effects of sediment-associated contaminants. In addition, the strategy must address the immediate requirement for defensible SQAGs and the long-term requirement for increased reliability and applicability of these guidelines (i.e., guidelines that account for the environmental characteristics influencing the bioavailability of sediment-associated contaminants).

To provide Florida with a sediment assessment tool, the Florida DEP Contaminated Sediment Management Unit, in association with MacDonald Environmental Sciences, reviewed the preceding approaches to identify those applicable to Florida's coastal conditions. Selecting an appropriate procedure to derive guidelines for Florida's coastal waters necessitates evaluating each approach in light of the state's specific needs. As such, criteria were established to objectively evaluate the approaches and select a relevant strategy to derive these guidelines. The primary considerations in selecting a strategy were practicality, cost-effectiveness, scientific defensibility, and broad applicability to sediment quality assessment. These include the following considerations:

1. Practicality is a central consideration in developing SQAGs. Numerical SQAGs must be easy to use and understandable. The immediate need for these assessment tools necessitates selecting an approach that can be quickly implemented.

2. As in most states, Florida has limited resources to support SQAG development and implementation. Financial and personnel limitations make collecting significant quantities of additional data improbable. Therefore, the approach must develop numerical SQAGs with the current data, and it must be amenable to reevaluation as new data become available.

3. For SQAGs to be effective in Florida, they must be effects-based (i.e., consider biological effects) and scientifically defensible. Key evaluation criteria to assess various approaches include their potential to consider factors that control the bioavailability of sediment-associated contaminants, to establish cause-and-effect relationships, and to apply to all classes of chemicals and mixtures of contaminants that can occur in Florida. In addition, they must be compatible with other tools, such as the metals tools discussed previously. Potential approaches should explicitly consider data from Florida and elsewhere in the southeastern United States and provide a way to account for site-specific environmental conditions.

4. The inherent uncertainty associated with each approach requires guidelines to support identifying ranges of contaminant concentrations that may have high, moderate, and low probabilities of adverse biological effects.

5. SQAGs must address the specific needs of the agencies that manage environmental quality. For example, SQAGs should be relevant to the design, implementation, and evaluation of environmental quality monitoring programs by identifying contaminants and sites likely to cause adverse biological effects. This information would help identify the need for further investigations at sites with specific contaminant concentrations that exceed the SQAGs. Guidelines should also help identify areas that need remediation; however, they would not necessarily be used to establish clean-up levels. Furthermore, guidelines should contribute to regulatory programs by evaluating source control measures and/or the need for further biological and chemical testing to support regulatory decisions.

Each approach has deficiencies that limit its direct application in Florida. For this reason, an integrated strategy for deriving numerical SQAGs was recommended for the state of Florida (MacDonald, 1993). This strategy provides relevant near-term assessment tools and a basis to refine these guidelines as the necessary data become available.

Using the recommended approach, numerical SQAGs were developed for 25 priority contaminants in Florida coastal waters (MacDonald, 1993) using a modification of the National Status and Trends Program approach (Long and Morgan, 1990). The guidelines, from numerous investigations of sediment quality conducted throughout North America, are based on a weight-of-evidence linking contaminant concentrations and adverse biological effects. The guidelines represent a cost-effective response to a practical need for assessment tools. However, these guidelines are preliminary and will likely be revised or refined with results from field validation and other related studies conducted in Florida and else-

VOL 12

6631

where in North America. The guidelines should be used with other interpretive tools to conduct comprehensive and reliable assessments.

Effects-based SQAGs help assess the potential for biological effects associated with various contaminant concentrations. MacDonald (1993) derived no observed effects levels (NOELs) and probable effects levels (PELs) to define three ranges of contaminant concentrations: the probable effects range, the possible effects range, and the no effects range.

The probable effects range is the range of specific contaminant concentrations in sediment within which biological effects are usually or always observed (probable effects range ≥ PEL). Sediments with contaminant concentrations within the probable effects range *represent significant and immediate hazards to exposed organisms*. Sites with concentrations of one or more contaminants that fall within the probable effects range should be given the highest priority in implementing sediment quality management options. However, direct biological assessment is required to determine the nature and extent of effects that could be manifested.

The possible effects range is the concentration range of a specific sediment contaminant with uncertain adverse biological effects (NOEL < possible effects range < PEL). This range is likely to be dependent on factors, such as bioavailability, that may influence the toxicity of the substance. Sediment-associated contaminants *represent potential hazards to exposed organisms* when concentrations fall within this range. Sediments with contaminant concentrations within this range may require further assessment to determine the biological significance of the contamination. In general, further assessment would be supported by biological tests designed to evaluate the biological significance of sediment-associated contaminants to key species of aquatic biota.

The no effects range is the range of sediment contaminant concentrations where biological effects are rarely or never observed (no effects range ≤ NOEL). Sediments with concentrations of contaminants within the no effects range are *of acceptable quality* for those contaminants. In general, further investigations of sediment quality conditions within the no effects range are relatively lower priority. However, biological testing may be required to validate the results of the initial potential assessment for adverse biological effects, particularly in sediments with low levels of TOC, AVS, and/or other variables that could influence the bioavailability of sediment-associated contaminants.

Figure 5.8—Framework for conducting site-specific assessments of sediment quality.

Assessing Sediment Quality in Florida

MacDonald (1993) developed a framework (Figure 5.8) for the Florida DEP for future use of sediment quality assessment guidelines and related tools. This framework identifies essential considerations to address in conducting site-specific sediment quality assessment programs. The following elements comprise the framework:

- Collect historical land and water use information;
- Collect and evaluate existing sediment chemistry data;
- Collect supplemental sediment chemistry data;
- Conduct preliminary assessment of the potential for biological effects of sediment-associated contaminants;

- Evaluate natural versus anthropogenic sources of sediment-associated contaminants;
- Conduct biological assessment of sediment quality; and
- Implement management of sediment quality.

This framework consistently assesses sediment quality in marine and estuarine areas. However, the framework is not intended to replace accepted sediment testing protocols, such as those developed for the ocean disposal of dredged material. Instead, it provides general guidance to support the sediment quality assessment process.

Step 1. Collect Historical Land and Water Use Information

The first phase of a site-specific sediment quality assessment involves collecting and reviewing the site's pertinent historical information. Information required includes the types of industries and businesses that operate or have operated in the area, the location of wastewater treatment plants, land use patterns in upland areas, runoff management systems, residential developments, and other historic, ongoing, and potential activities within the area. These data help to identify sources that could contaminate aquatic ecosystems. Information on the chemical composition of wastewater effluent discharges, contaminants likely to be associated with nonpoint sources, and physical/chemical properties of those substances helps to develop an initial list of chemical concerns.

Information should also be collected that helps define the site's environmental management goals. Environmental management goals in estuarine and marine systems may be based on protecting the whole ecosystem, maintaining viable populations of sport and commercial fish species, protecting human health (e.g., swimmable and fishable), or a variety of other considerations (e.g., seagrass restoration, reestablishment of shellfish, regional runoff management). As such, information on existing site uses helps make decisions on the level of investigations that should be conducted.

Step 2. Collect and Evaluate Existing Sediment Chemistry Data

Collecting and evaluating existing sediment chemistry data is critical to the site-specific sediment quality assessment process. Sediment chemistry data typically are generated under various environmental programs. Collect relevant data to support a preliminary assessment of sediment quality. These data should be fully evaluated to determine their applicability. This evaluation should cover the overall quality of the data set and the degree to which the data represent current site conditions.

Assessment of sediment quality also requires information that adequately represents the site's contemporary environmental conditions. Therefore, knowing the age of the chemistry data is essential to determine the data's applicability. Natural degradative processes in the environment can lead to reduced concentrations of sediment-associated organic contaminants. Major events, such as storms, can transport sediments between sites, and industrial developments and/or regulatory activities can alter the sources and composition of contaminants released into the environment. Thus, assessments of sediment quality should be undertaken with the most recent data available.

In addition to temporal variability, the chemistry of bed sediments varies spatially as well. Therefore, a single sample likely represents only a small proportion of the geographic area. For this reason, data from a number of stations are required to represent a site's sediment quality conditions. The actual number of stations required depends on the size of the area, the concentrations of sediment-associated contaminants, and the variability of contaminant concentrations.

Another important factor to consider in evaluating existing sediment quality data is the variables analyzed. The list of analyses must reflect potential contaminant sources from area land and water use activities. For example, in harbors, variables such as pentachlorophenol (used to preserve pilings), tributyltin (used in antifouling paints for ships), and copper (used in antifouling paints for pleasure crafts) should be measured. Similarly, highly elevated concentrations of polycyclic aromatic hydrocarbons and lead are often associated with urban runoff discharges. In agricultural areas, persistent pesticides and nutrients should be considered in sediment quality assessments.

If the results of the data evaluation indicate that sediment chemistry data are acceptable, we can proceed with the preliminary assessment of the potential for biological effects. However, if the sediment chemistry data are of unacceptable quality or do not adequately represent the site, additional data may be required to complete the assessment.

Step 3. Collect Supplemental Sediment Chemistry Data

The third stage in assessing sediment quality involves generating supplemental sediment chemistry data. Additional testing may be required when data are insufficient to support the assessment of sediment quality at a site. The initial list of chemical concerns provides a defensible way to identify potential analyses for the sediment quality monitoring program.

Sampling programs should delineate temporal and spatial and vertical and horizontal variability in sediment contamination and explicitly identify quality assurance/quality control measures to implement. Collection, handling, and storage of sediment samples should follow established protocols, and analytical methods and detection limits should be appropriate. Total digestion of sediment samples with a strong acid (e.g., hydrofluoric) is required. A focused, well-designed monitoring program ensures that the resulting data will support a defensible sediment quality assessment.

Step 4. Conduct Preliminary Assessment of the Potential for Biological Effects of Sediment-Associated Contaminants

Sediment chemistry data alone are not adequate to assess the hazards posed by sediment-associated contaminants to aquatic organisms. Interpretive tools can determine if these contaminants are present at concentrations that could impair the designated uses of the aquatic environment. Effects-based guidelines to assess sediment quality provide a scientifically defensible way to evaluate the potential effects of sediment-associated contaminants on aquatic organisms. The three ranges of contaminant concentrations were discussed previously.

Step 5. Evaluate Natural Versus Anthropogenic Sources of Sediment-Associated Contaminants

Interpretation of environmental metals data is difficult because absolute metal concentrations in coastal sediments are influenced by various factors, including sediment mineralogy, grain size, organic content, and anthropogenic enrichment. These factors result in metals levels that can vary over several orders of magnitude at uncontaminated sites in Florida (Schropp et al. 1990). While numerical, effects-based sediment quality assessment guidelines provide essential information to evaluate sediment-associated metals, they should not be used alone to evaluate the quality of marine and estuarine sediments. Instead, assessments of sediment quality should evaluate the potential for adverse biological effects and the degree of anthropogenic enrichment. Using this approach, metals concentrations would be considered a serious concern when they exceed the biological effects-based guidelines and are anthropogenically enriched.

In the past, determining whether estuarine and coastal sediments were anthropogenically enriched with metals was difficult, requiring comprehensive, site-specific assessments. However, as discussed previously under "Assessing Sediments Contamination," Florida has developed a practical approach to assess metals contamination in coastal sediments. This procedure relies on normalization of metal concentrations to a reference element aluminum.

Step 6. Conduct Biological Assessment of Sediment Quality

Biological testing is essential in assessing sediment quality. The nature and extent of available information creates significant uncertainty in predicting the biological significance of sediment-associated contaminants (i.e., most of the data used do not support a cause-and-effect relationship). Therefore, biological testing—generally a suite of biological tests—is required to provide reliable information on the toxicity of bed sediments and to confirm the results of the preliminary sediment quality assessment.

In Florida, further biological testing supports three distinct aspects of sediment quality assessment. First, biological testing may assess sediment toxicity at sites where the concentrations of one or more contaminants fall within the probable and possible effects range. Second, biological testing may assess toxicity sediments likely to contain unmeasured substances. Third, biological data assess whether the recommended SQAGs are applicable to Florida coastal waters. Additional biological testing determines the systematic differences between the sensitivities of species represented in the Biological Effects Data System (BEDS) (MacDonald, 1993) compared to the sensitivities of species that reside in Florida coastal waters. In addition, ancillary biological testing determines the systematic differences between the toxicity—as affected by bioavailability and other factors—of a substance in sediments represented in BEDS compared to Florida sediments. In

VOL 12

6634

some cases, biological testing will require site-specific SQAGs to assess the potential effects of sediment-associated contaminants.

The biological testing program should address whole sediment toxicity, but it may also consider potential effects in the water column. Evaluation of whole sediment toxicity is a key component of the sediment quality assessment process in regulatory and management applications. Biological tests that assess potential water column effects are generally more applicable, for example, in programs concerned with regulating disposal of dredged materials.

A number of tests can evaluate the biological significance of sediment contamination. These tests may be as simple as short-term bioassays on a single contaminant using a single species or as complex as microcosm studies investigating the long-term effects of contaminant mixtures on ecosystem dynamics. In addition, tests may be designed to assess the toxicity of whole sediments (solid phase), suspended sediments, elutriates, sediment extracts, or pore water. Organisms routinely tested include microorganisms, algae, aquatic macrophytes, invertebrates, and fish.

Other biological information can assess sediment quality. For example, comparing biological indicators, such as the diversity and abundance of benthic invertebrate communities, at test sites and appropriate ecoregion reference sites provides a means of assessing the relative toxicity of test sediments. Various statistical procedures can help identify contaminants associated with observed biological effects using adequate sediment chemistry data. In addition, spiked-sediment bioassays can establish cause-and-effect relationships for specific substances or contaminant mixtures. Further, tests to evaluate pore water toxicity provide information that can identify the toxic elements of contaminated sediments. Information on contaminant level in aquatic biota and on bioaccumulation help determine contaminant levels in sediments to protect the health of humans and of wildlife that consume aquatic organisms.

Step 7. Implement Management of Sediment Quality

The objective of the sediment quality assessment process is to provide information that supports environmental quality management. Management decisions will depend on various factors, including the nature and severity of the contamination, the potential for exposure of aquatic organisms, management goals for the site, availability of remediation technology, costs associated with remediation, and public expectations. By integrating information on these factors, managers and others can make defensible decisions on remediating, preventing, and monitoring contamination.

We can make several sediment quality management decisions using information available from the environmental assessment. At some sites, no additional action is warranted. Other sites may require monitoring for trends in sediment quality. Seriously contaminated sites may require some remedial action to achieve environmental management goals. These remedial actions could include removing and treating toxic materials, isolating or capping contaminated sediments, implementing source control measures, or no action at all (i.e., permit natural degradation and sedimentation to mitigate contaminant effects).

MacDonald (1993) stresses the importance of combining the effects-based guidelines and the metals interpretive tool. MacDonald examines data on levels of sediment-associated lead from two geochemically distinct systems, Biscayne Bay and Apalachicola Bay, to illustrate the integrated sediment quality assessment framework. Figure 5.9 shows a summary of the available data (Fla. Dep. Environ. Prot. 1993) on the levels of sediment-associated lead in the Miami area. The data, sorted by increasing concentration, were assigned sample numbers from 1 to 108. Evaluation using the SQAGs suggests that approximately 15 percent of the samples fall within the probable effects concentration range (exceed the PEL of 160 mg/kg). Another 20 percent fall within the possible effects range (between NOEL and PEL). Therefore, comparing sediment chemistry data with numerical SQAGs suggests a relatively high probability of observing adverse biological effects. Further examination of the data using the metals interpretive tool (Figure 5.10) demonstrates that sediments from this area are clearly anthropogenically-enriched with lead. Roughly 90 percent of the samples exceed the 95 percent prediction limits established for clean sites. Concordance between the effects-based and the geochemically based tool suggests that the Miami area should have priority in further investigations to evaluate sediment toxicity.

In Apalachicola Bay, roughly 20 percent of the samples had levels of lead that exceeded the NOEL of 21 mg/kg (Figure 5.11). Comparison of the ambient lead levels in Apalachicola Bay with SQAGs suggests possible adverse biological effects at a significant number of sites. However, fur-

ther evaluation using the metals interpretive tool indicates that aluminum-normalized lead level is indicative of those measured in clean sediments in Florida (Figure 5.12). While the effects-based tool predicts the possibility of adverse effects at some sites, the geochemical tool demonstrates that lead concentrations in Apalachicola Bay occur naturally and, as such, should not be considered hazardous to aquatic organisms. This system does not require further investigations to evaluate the extent of sediment toxicity.

Recommended Sediment Assessment Approach Limitations

Sediment quality assessment guidelines using the recommended approach are preliminary values and should be refined as new information becomes available. This approach has several limitations and considerations:

- The approach determines the potential for sediment-associated contaminants to induce biological effects. We cannot infer direct cause-and-effect relationships when comparing chemical data to the recommended guidelines.

- The SQAGs apply to marine and estuarine waters only, not to freshwater systems.

- The SQAGs are not expressed as factors thought to control the bioavailability of sediment-associated contaminants (i.e., total organic carbon for nonpolar organics and acid volatile sulfide for divalent metals).

- The data used to derive the SQAGs consist primarily of acute toxicity study results. Few data exist on the chronic responses of aquatic organisms to contaminants associated with sediments.

- The recommended guidelines should be used with other assessment tools and protocols, such as the Florida Department of Environmental Regulations metals interpretive tool and the Green Book (U.S. Environ. Prot. Agency and Army Corps Eng. 1991) to provide comprehensive evaluations of sediment quality.

- The recommended guidelines were developed using information from various North American locations. These data may not represent Florida's diverse sediment types. For this reason, exercise caution in using these guidelines, particularly in carbonate-dominated sediments.

Sediment Quality Assessment Guideline Applications

The recommended sediment quality assessment strategy should provide consistency in evaluating Florida's sediment quality. While the SQAGs represent an integral element of this strategy, they should be used with other assessment tools to efficiently and cost-effectively evaluate ambient sediment quality conditions. In this context, these SQAGs may be used to

- Interpret the results of sediment quality monitoring data. SQAGs may assess the potential adverse biological effects of specific concentrations of sediment-associated contaminants.

- Support the design of sediment quality monitoring programs. SQAGs may evaluate existing sediment chemistry data and rank areas and chemicals of concern according to their potential association with adverse biological effects. As such, monitoring priorities may be more clearly and effectively identified.

- Identify the need for site-specific investigations to support regulatory or watershed management decisions, including source controls and regional urban management sites. SQAGs can evaluate existing data to determine if additional testing (e.g., sediment toxicity bioassays) is needed.

- Evaluate the hazards associated with increased contaminant levels at specific sites. SQAGs may act as early-warning tools for watershed management or regulatory action before contaminant levels become problematic.

- Support a preliminary assessment of the applicability of EPA's developing sediment quality criteria. The SQAGs can assess the protection level these criteria afford to aquatic organisms.

- Facilitate multijurisdictional agreements on sediment quality issues and concerns. SQAGs can establish site-specific sediment quality objectives to help define governmental responsibilities in preventing and remediating sediment contamination.

These guidelines provide a consistent way to evaluate sediment quality in Florida. However, they are preliminary and their application is limited. Therefore, SQAGs should not be used

- In lieu of water quality criteria. However, these guidelines may be used in regulatory programs to evaluate effectiveness and identify the need for more stringent regulations;
- To define uniform values for sediment quality statewide (i.e., they should not be used as sediment quality criteria). Ambient environmental conditions may influence the applicability of these guidelines at specific locations;
- As criteria to dispose of dredged material or to replace formal assessment protocols established to dispose of dredged material; or
- Directly as numerical clean-up levels at severely contaminated sites (e.g., Superfund sites).

CHAPTER 6

Biological Community Assessments

Traditionally, monitoring surface waters to assess their health and the effects of pollution discharges has relied upon chemical and physical measurements of the water column. While this approach assesses the effects of continuous discharges—such as wastewater treatment plants and industrial sources—it cannot accurately determine environmental impairments from intermittent sources such as urban runoff. This chapter discusses the development and use of biological community assessments to detect the effect of nonpoint source pollution on aquatic life.

Intermittent discharges create shock loadings to a waterbody, and the ecological effects depend on many variables and complex interactions. Moreover, many runoff pollutants become attached to sediment particles or settle quickly, exerting detrimental effects over a long period. Furthermore, urban runoff degrades habitat (e.g., channel and bank erosion) and causes tremendous siltation, neither of which are detected by water chemistry sampling.

Monitoring biological communities is an additional approach that can enhance surface water quality assessment and management. While chemical data reflect short-term conditions that exist when a particular sample is collected, biological communities accurately indicate overall environmental health because they continuously inhabit receiving waters and react to various long-term chemical and physical influences. Aquatic organisms also integrate a variety of environmental influences—chemical, physical, and biological.

Biological assessment involves integrated analyses of functional and structural components of the aquatic communities. Bioassessments are best used to detect aquatic life impairments and assess their relative severity. Once an impairment is detected, additional chemical and biological toxicity testing can identify the causative agent and its source. Both biological and chemical methods are critical in successful pollution control and environmental management programs. They are complementary, not mutually exclusive, ways to enhance overall program effectiveness.

Some advantages of bioassessments are that

- Biological communities reflect overall ecological integrity (chemical, physical, and biological).
- Over time, biological communities integrate the effects of different stressors, providing a measure of fluctuating environmental conditions.
- By assessing the integrated response to highly variable pollutant inputs, biological communities provide a practical approach for monitoring runoff source impacts and the effectiveness of best management practices.
- Routine monitoring of biological communities can be relatively inexpensive, particularly when compared to the cost of assessing toxic substances.
- The public is highly interested in the status of biological communities as a measure of environmental health.
- Biological communities offer a practical way to evaluate habitat degradation typically associated with urban runoff discharges.

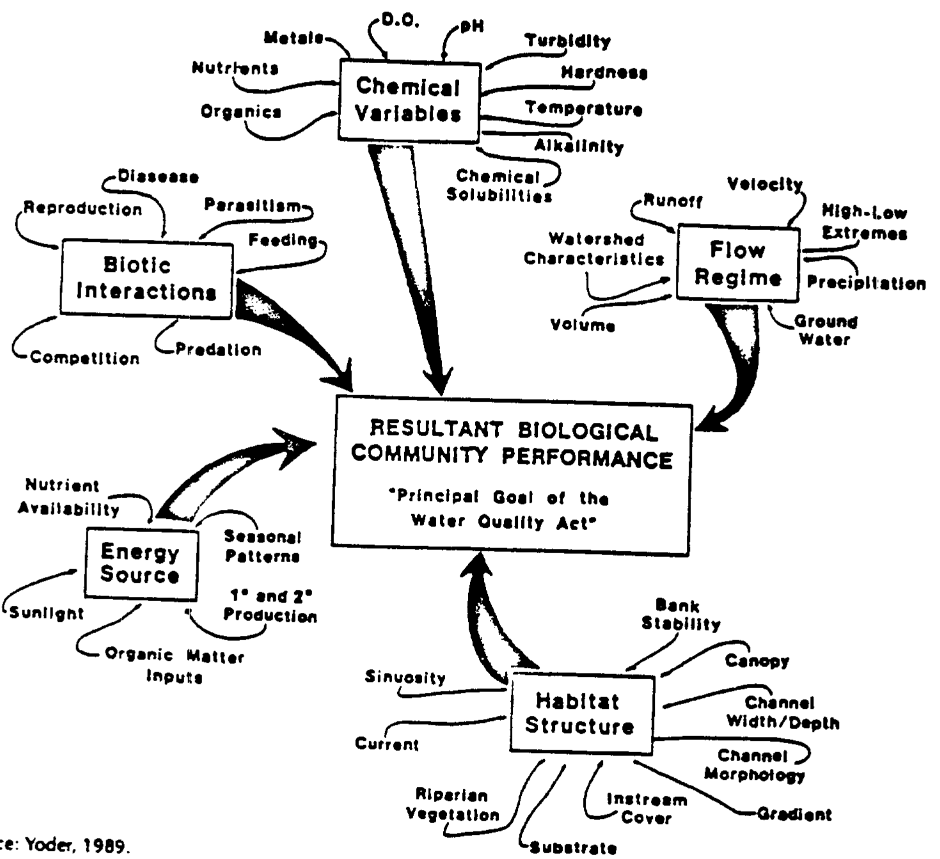
Biological Integrity

Karr et al. (1986) grouped environmental factors affecting most aquatic ecosystems into five major classes: chemical variables, biotic interactions, flow regime, habitat structure, and energy source. These factors interact to determine the integrity of water resources reflected by the resident aquatic life (Figure 6.1). Alterations to the physical, chemical, or biological processes can adversely affect the aquatic biota and, therefore, the biological integrity of the waterbody. Efforts to protect and restore waters by using only one or two of the five factors will likely fail if other factors are involved (Karr et al. 1986). Monitoring methods integrating all five classes are necessary to maintain and improve surface water quality and aquatic life resources.

Recent advances in computer technology and, more important, in biological assessment techniques make the current approach more practical. Advances include geographic information systems and available digitized databases, refined laboratory and field methods, standard assessment techniques, a practical and useful definition of biological integrity, and the regional reference site concept. These advances provide a framework to incorporate biological community assessments and "biocriteria" into surface water management programs.

Although the principal goal of the Clean Water Act is to restore and maintain the chemical, physical, and biological integrity of the nation's waters, difficulties in defining an ecological approach to assessing biotic integrity has led regulatory agencies to rely primarily on chemical

Figure 6.1—Important chemical, physical, and biological factors that influence and determine biological community performance in surface waters.



Source: Yoder, 1989.

VOL 12

6641

R0039949

measurements. However, Karr and Dudley (1981) define biotic integrity as "the ability of an aquatic ecosystem to support and maintain a balanced, integrated, adaptive community of organisms having a species composition, diversity and functional organization comparable to that of the natural habitats within a region." This definition is based on measurable characteristics of aquatic communities and comparisons to a regional reference site.

Despite the many recent advances in bioassessment techniques, state-specific ecoregions, methods to delineate reference sites, and rapid bioassessment (RBA) methods are badly needed. These techniques offer the best means of accurately assessing the impacts of urban runoff and other nonpoint sources of pollution. Conducting this essential development work requires special expertise, adequate funding, and time.

To date, ecoregion reference sites have been selected and sampled, and RBA techniques have been developed and refined only for riverine systems. Work is just beginning to refine and test RBA methods for lakes, and little progress has been made on developing RBA methods for estuaries. These aquatic systems need standard assessment techniques and quantitative biocommunity evaluation criteria.

Ecoregions and Reference Sites

Spatial frameworks can profoundly influence the effectiveness of research, assessment, and management of many water resource problems, especially those caused by urban runoff and nonpoint sources. Traditionally, we have relied on spatial frameworks based on political boundaries, watersheds, hydrologic units, or physiographic regions. However, these areas do not correspond to patterns in vegetation, soils, land surface form, land use, climate, rainfall, or other characteristics that control or reflect spatial variations in surface water quality or aquatic organisms.

Water quality management is slowly moving beyond the technology-based, uniform national standards approach that is point source oriented. The new approach recognizes land/water interactions, nonpoint sources, and regional variations in attaining water quality. Water quality assessments need a regional framework to

- Compare regional land and water patterns;
- Compare ecological similarities and differences;
- Compare habitat similarities and differences;
- Establish realistic, achievable chemical and biological standards;
- Assess the effects of all pollution sources within a watershed, especially intermittent discharges;
- Predict the effectiveness of management practices;
- Prioritize assessment and management efforts;
- Locate monitoring and special study sites; and
- Extrapolate site-specific information to larger areas.

Omernik (1987) proposed using spatial frameworks based on ecological regions (ecoregions) to assess the health of aquatic systems. Ecoregions reflect similarities in the type, quality, and quantity of water resources and the conditions affecting them. Therefore, regional patterns of environmental factors reflect regional patterns in surface water quality.

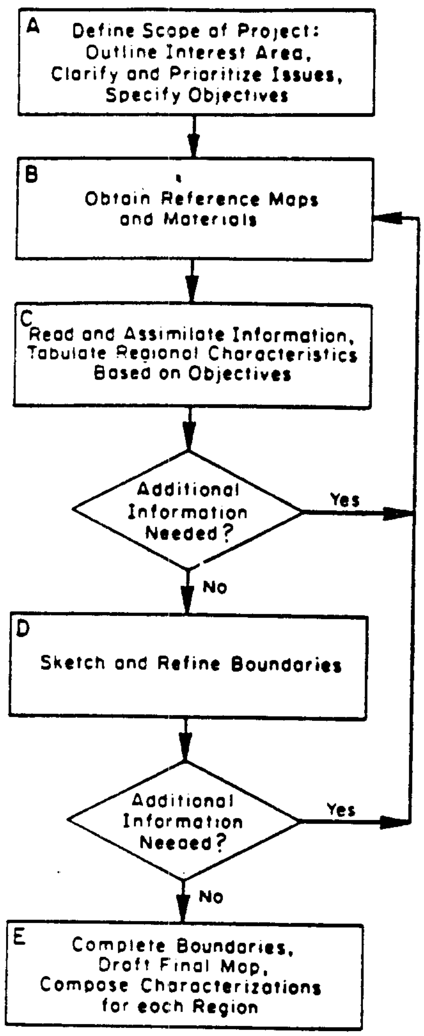
Using an ecoregional framework, we can sort out spatial variability in the environmental characteristics that we wish to manage. Delineating ecoregions requires collecting and examining reference material to understand the area. This includes determining what the ecoregion looks like, its dominant environmental features, the kinds of natural and human impacts influencing resource quality, and the characteristics supporting the regional delineation. Different environmental features drive each ecoregion. In some parts of the country, land-surface form dominates vegetation, soil formation, and land use; annual precipitation more strongly affects these characteristics in other areas.

Defining, delineating, describing, and depicting ecoregions involves a systematic collection and analysis of diverse environmental information (Figure 6.2). This process is described completely in *Regionalization as a Tool for Managing Environmental Resources* (U.S. Environ. Prot. Agency, 1989a). Ecoregions are defined at hierarchical levels for the conterminous United States (Figure 6.3). More detailed subregions have been developed for Arkansas, Colorado, Minnesota, Ohio, and Oregon. Continued subregion

VOL 12

6542

Figure 6.2—Steps to develop regionalization.



Source: U.S. Environ. Prot. Agency, 1989a.

development is underway in Alabama, Florida, and Appalachia. Additionally, subregions are being planned in other states, largely because of biological criteria development and enhanced assessment and management of nonpoint sources.

Once ecoregions are delineated and field verified, ecoregion reference sites should be selected. An essential component of the management framework, these sites allow us to evaluate the environmental health of a locale by comparing it to a known reference site. This is a key concept in Karr and Dudley's (1981) definition of biotic integrity, which compares site evaluations to the aquatic community of "natural habitats within a region." Ecoregion reference sites used in water resources management must have two essential components: They must represent the ecoregion and have ecological conditions reasonably attained, given current background conditions.

Selecting ecoregion reference sites allows us to approximate attainable quality by measuring the physical, chemical, and biological quality of streams draining watersheds that represent the region's natural environmental characteristics and have received the least amount of human influence. Select sites according to the following steps (U.S. Environ. Prot. Agency, 1989a):

1. Specify environmental characteristics affecting water quality such as soil type; vegetative cover; amount, intensity, and timing of annual or seasonal precipitation; topography and slope; and occurrence of natural geologic deposits.

2. Map areas that share similar characteristics.

3. Select watersheds from within those areas.

4. Eliminate watersheds where access is prohibited.

5. Eliminate watersheds affected by human influence. Since this will likely leave an insufficient number of watersheds, add those subject to the least anthropogenic influences. Unfortunately, in many parts of the country, pristine watersheds do not exist. However, given regional land use practices, the least affected watersheds should identify reasonable expectations in the region.

6. Verify the site's suitability to ensure the accuracy of mapped information and to eliminate inappropriate watersheds. Site visits are essential. Make use of local expert opinion.

7. Collect physical, chemical, and biological data to generate reference data that define the range of regionally achievable quality. Use this data to compare the quality of other sites. The next section discusses the type of and ways to collect biological data.

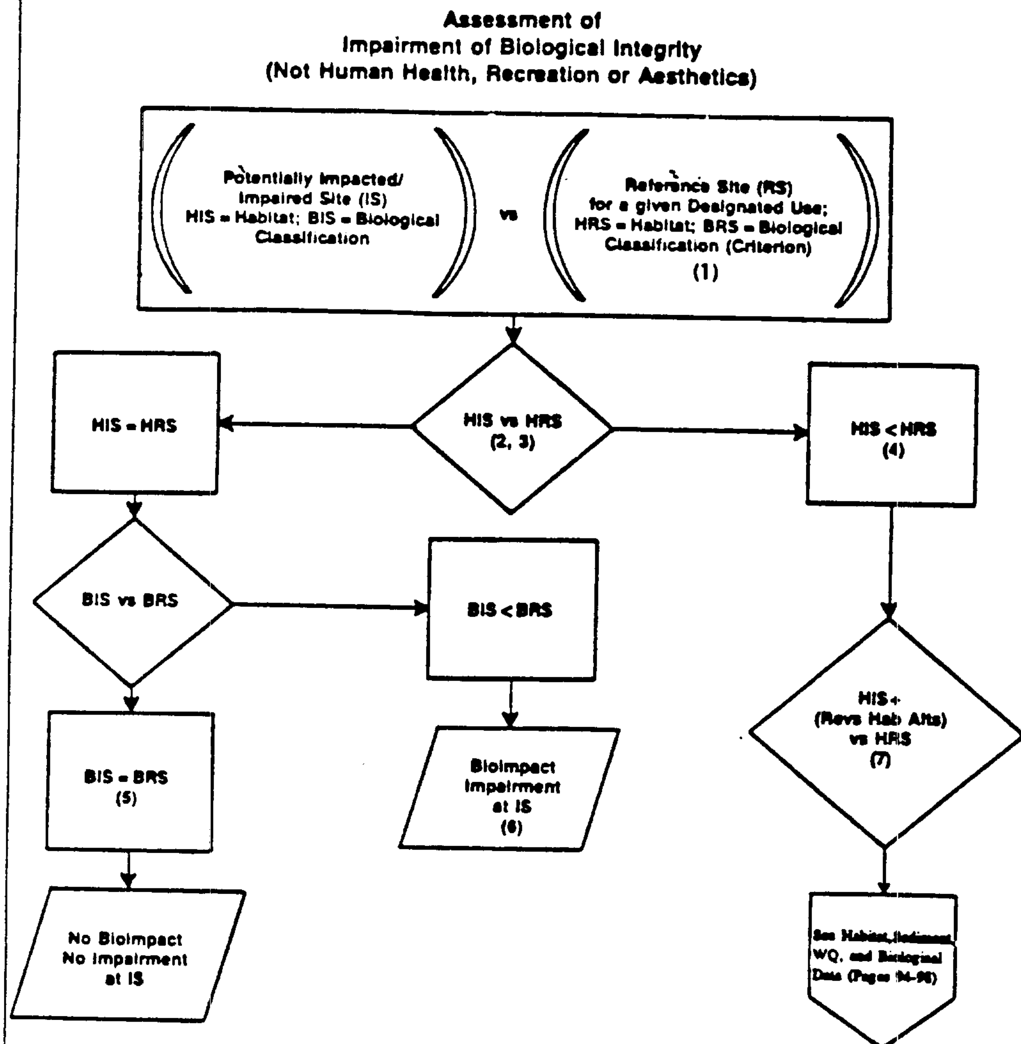
Rapid Bioassessment Protocols

In 1985, U.S. EPA conducted a survey to identify states that routinely perform biological assessments and evaluate their field methods. A workgroup of state and EPA biologists reviewed existing methods and refined protocols for monitoring benthic macroinvertebrates. Incorporating comments from state and staff, EPA also developed a set of fish protocols. *Rapid Bioassessment Protocols for Use in Streams and Rivers* (U.S. Environ. Prot. Agency, 1989b) contains a more comprehensive discussion of this topic.

The rapid bioassessment protocols (RBPs)—also known as community bioassessment protocols—advocate an integrated assessment, comparing habitat (physical structure and flow regime) and biological measures with empirically defined reference conditions (Figure 6.4). Reference conditions are established through systematic monitoring of actual sites (ecoregion reference sites) that represent the natural range of variation in "least disturbed" water chemistry, habitat, and biological condition.

Of these three components of ecological integrity, ambient water quality may be the most difficult to characterize because of the complex array of chemical constituents that affect it. Therefore, the implementation framework presented in Figure 6.4 first describes the development of an empirical relationship between habitat quality and biological condition and then refines this relationship for a given region. As additional information is obtained from systematic monitoring of potentially impacted and site-specific control sites, the predictive power of the empirical relationship is enhanced. Once the relationship between habitat and biological potential is understood, water quality impacts can be objectively discriminated from habitat effects, and management efforts can focus on the most important source of impairment.

Figure 6.4—Bioassessment decision matrix (numbers in parenthesis refer to numbered Explanatory Notes).



Source: U.S. Environ. Prot. Agency, 1989b.

Figure 6.4—Explanatory Notes

1. The reference site (RS) should represent a database consisting of the best attainable physical habitat, water/sediment chemistry, and biological parameters for specific environmental conditions. Acceptable ranges for the habitat and biological parameters of concern are based on this reference database.

   In the RBP assessment scheme, selected parameters are integrated to define generic habitat categories and bioclassifications. The integrated characterizations describe important attributes of the designated use and represent criteria for attainment/nonattainment of the designated use. Figure 6.4 also illustrates how designated uses and criteria may be established or refined as ambient monitoring activities proceed and how new data are incorporated into the reference database.

   Considerable effort may be required initially to identify reference sites and the habitat and biological characteristics of a specified aquatic life use.

Figure 6.4—Explanatory Notes continued

Alternatively, data required to define new or refined use characterizations and assessment criteria could be collected through implementation of an effective ambient monitoring program. However, when the *initial* reference database includes a spectrum of least disturbed habitats and concomitant biotic conditions, the need for site-specific controls may be greatly reduced. The value of a comprehensive reference database becomes more evident with progression through the implementation framework.

2. The purpose of the habitat assessment is to determine whether the impaired site (IS) has the potential to support a biological community comparable to that of the reference (see note 6).

3. Applicable ranges for several important habitat characteristics are generally incorporated into the habitat assessment field sheets, and the habitat evaluation can be made quickly onsite. However, preliminary reconnaissance is especially helpful when impaired site habitat (HIS) proves to be much lower in quality than reference habitat (HRS) and an evaluation of reversible habitat alterations (attainability) may also be necessary. Reconnaissance information allows planning for the additional work needed to characterize more appropriate reference sites.

4. In the early stages of developing assessment criteria for a given aquatic life use, HIS may often appear degraded relative to the HRS database. The likelihood of such an outcome is proportional to the richness of the initial HRS database. As more potentially impacted stations are assessed, however, certain stations will be shown to support

   - Biological communities equivalent to the reference sites despite apparent habitat deficiencies. Information from such sites will enrich the reference database and broaden the applicability of the use designation.

   - A relatively degraded community limited by intrinsic or irreversible habitat constraints. In this case, the original use is not attainable, and data collected from such a site should be used to revise the use designation.

5. The robustness of the comparison between the biological condition at the impaired site (BIS) and that at the reference (BRS) is limited by the rigor of the assessment procedure used (e.g., many versus few replicates) and the scope of the overall assessment (i.e., the number of biological community segments actually evaluated). The comparison of BIS and BRS is useful to detect or confirm *appreciable* impact to the biotic community and may be insensitive to certain subtle and/or threshold effects.

6. If BIS equals BRS, no detectable impairment occurs. This conclusion assumes no overriding limitations on the biological potential of IS relative to RS that are not accounted for by the previous habitat comparison (see note 2). Factors that could uniquely affect IS are discussed in station siting. For example, stations RS and IS may be located on a first order stream with primary organic inputs from a coniferous forest. In this situation, certain characteristics of the benthic community, such as taxa richness, may actually increase with organic enrichment from point source discharges rather than decrease as otherwise expected. This atypical situation should be assessed as if HIS plus reversible habitat alterations) is less than HRS (note 7).

7. The HIS plus reversible habitat alterations versus HRS comparison amounts to a simplistic use attainability analysis (UAA) that only considers habitat. The comparison involves scaling up the observed habitat parameter values to the extent that they might be feasibly improved. For example, bank stability, bank vegetation, and streamside cover could be greatly enhanced by fencing a pasture and planting trees, whereas other parameters may be unalterable. This mini-UAA can help to assess site-specific potential in the determination of actual impairment. If HIS and HRS are *potentially* equivalent, then use impairment can be appropriately assessed regarding resident biota. If HIS and HRS are not equivalent even when reversible habitat alterations are considered, biological effects may not be independent of habitat constraints. These potential scenarios are discussed in more detail in the section on integration of habitat, sediment, water quality, and biological data.

VOL 12 6546

The following are major steps in using EPA's rapid bioassessment protocols along with a brief discussion of some key considerations:

1. **Assessment of the structural/compositional and functional characteristics of the benthic macroinvertebrate community.**

   ■ **Seasonality for benthic collections.** Optimum biological sampling will correspond to invertebrates recruitment cycles, which vary with climate.

   ■ **Methods for benthic collections.** Considerations include natural versus artificial substrates; single versus multiple habitat sampling; and sampling coarse particulate organic material such as leaves, twigs, and bark.

   ■ **Benthic sample processing and enumeration.** Handling samples consistently is important because detailed comparisons are made among stations and sites.

   ■ **Benthic environmental tolerance characterizations.** Assessment of biological condition is based on the calculation of several metrics. Certain metrics rely on classifying benthic taxa according to their relative sensitivity to pollution. However, the meaning of pollution tolerance varies around the country, requiring each state to adapt established tolerance classification systems.

2. **Assessment of the structural/compositional and functional characteristics of the fish community.**

   ■ **Seasonality for fish collections.** The preferred sampling season is middle to late summer, when stream flows are less variable and more moderate.

   ■ **Methods for fish collections.** Electrofishing, seines, and rotenone are the most commonly used collection methods. Each has advantages and disadvantages.

   ■ **Sampling representative habitats.** The sampling station should represent the stream reach, incorporating at least one riffle, run, and pool if these habitats are typical. Sampling is most effective near shore and cover, such as macrophytes, boulders, snags, and brush.

   ■ **Fish sample processing and enumeration.** Standardized processing of fish samples should include identification of species, recording incidence of external abnormalities, and weighing (if biomass data are desired).

3. **Assessment of the structural/compositional and functional characteristics of the algal community.**

   ■ Note: See *Rapid Bioassessment Protocols* (U.S. Environ. Prot. Agency, 1989b) for a discussion of the advantages of using benthic macroinvertebrates, fish, and algae.

4. **Assessment of habitat type occurrence and quality.**

   ■ **Habitat, as affected by in-stream and surrounding topographical features.** This assessment largely determines aquatic community potential. Both the habitat's quality and quantity affect the structure and composition of its biological communities. Consider both physical characteristics and water quality parameters in assessing habitat.

   ■ **Physical characteristics.** These include estimating watershed land uses and their associated pollutant discharges/loadings; stream characteristics such as width, flow, and depth (in riffles, runs, and pools); substrate types; sediment odors, oils, and extent of deposits; extent of canopy cover; and human alterations such as dams, channelization, bottom scouring, channel stability/erosion, or modified shorelines.

   ■ **Water quality observations.** These should include recent and current weather conditions, temperature, dissolved oxygen, pH, conductivity, turbidity, and water odors or surface oils.

5. **Integration of benthic macroinvertebrate, fish, and habitat assessments using quantitative indices.**

   ■ **Species richness.** This figure should reflect the health of a community by measuring the variety of organisms present (total number of genera or species).

   ■ **Modified Hilsenhoff biotic index.** This index summarizes the overall pollution tolerance of the benthic arthropod community.

   ■ **Scraper and filtering collector functional group ratio.** This ratio provides

VOL 12

6647

R0039955

insight into potential disturbance factors. Predominance of a particular feeding type may indicate an unbalanced community responding to an overabundance of a particular food source.

- **EPT (Ephemeroptera, Plecoptera, Trichoptera) and Chironomidae abundance ratio.** The relative abundance of these four major invertebrate groups is used as a measure of community balance.
- **Percent contribution of the numerically dominant taxon to the total number of organisms.** This indicates community balance at the lowest positive taxonomic level.
- **EPT index.** This summarizes taxa richness within the insect orders that are generally pollution sensitive.
- **Community similarity indices.** These are used to compare biological communities at impacted sites and reference sites.
- **Ratio of shredder functional feeding group and total number of individuals collected.** This compares the shredder community at an impacted site and at a reference site.
- **Index of Biotic Integrity (IBI).** This broad index is grounded in fisheries community ecology that incorporates zoogeography, ecosystem, community, population, and individual perspectives.

6. **Careful choice of sampling locations to ensure that generally comparable habitats exist at each station.**
   - **Consider community differences.** Otherwise, differences attributable to a degraded habitat will be difficult to separate from those attributable to water quality degradation.
   - **Avoid locally modified sites.** These include small impoundments and bridge areas.
   - **Consider entering waters.** Avoid sampling near the mouths of tributaries entering large waterbodies, since these areas will have habitats more indicative of larger waterbodies.
7. **Use effective quality assurance and quality control procedures to ensure the usefulness of environmental monitoring data.**
   - **Develop a QA project plan.** It should describe the specific objectives, procedures, and methods for all staff working on the project.
   - **Training.** Train staff conducting the assessments consistently to ensure complete and standardized assessments.
   - **Achieve consistency.** Each agency must define its specific sampling methods, laboratory procedures, and analytical and validation techniques (e.g., replicate samples).
   - **Consider subjective habitat characterization.** Take special care in conducting the evaluation. Appropriate training and periodic cross-checks are essential.
   - **Routinely calibrate all field instruments.**

EPA (U.S. Environ. Prot. Agency, 1989b) presents five rapid bioassessment protocols—three for benthic invertebrates and two for fish. The appropriate bioassessment approach depends on the study objectives. RBPs I and IV are screening tools to help determine if biological impairment exists. Benthic RBP I and fish RBP V are more rigorous and provide more objective and reproducible evaluations than RBPs I and IV. RBPs II, III, and V are semiquantitative and use an integrated analysis technique to provide continuity in evaluating impairment among sites and seasons. Each of the RBPs is summarized briefly.

- **Rapid Bioassessment Protocol I—Benthic Macroinvertebrates and Rapid Bioassessment Protocol IV—Fish.** These RBPs provide a screening mechanism to identify biological impairment. They are not intended to quantify the degree of impairment nor provide definitive data to establish cause-and-effect relationships. They allow a cursory assessment, using cost and time efficiencies to evaluate a large number of sites, identify major water quality problems, and help plan and develop management strategies.

- **Rapid Bioassessment Protocol II—Benthic Macroinvertebrates.** This RBP provides information to rank sites as severely or moderately impaired so that additional study or regulatory/management action can be planned. Like RBP I, this protocol can be used as a screening tool and allows agencies to evaluate a large number of sites with relatively little time and effort. The more documented procedures and integrated metrics of

RBP II promotes better consistency and allows better comparison among sites.

- **Rapid Bioassessment Protocol III—Benthic Macroinvertebrates and Rapid Bioassessment Protocol V—Fish.** These two RBPs provide a consistent, well-documented biological assessment. Like RBP II, they provide information for ranking site impairment and a way to compare repeatable results over time (trend monitoring). These RBPs include taxonomic identifications to the lowest practical level, thereby providing information on population as well as community level effects. They include an integrated assessment of metrics and can be used to develop biocriteria.

Habitat, Sediment, Water Quality, and Biological Data

Relationship between Habitat Quality and Biological Condition

An overall assessment of ecological condition first evaluates habitat quality, then analyzes the biological components in light of these data.* If adverse effects are likely, then sediment and water chemistry sampling and evaluating potential pollution sources within the watershed should be undertaken. As the principal determinant of biological potential, habitat sets the context for interpreting biosurvey results. Along with sediment quality, habitat can be used as a general predictor of biological condition. Routine water chemistry can also help to characterize certain impacts.

In RBPs I and IV, which involve minimal biological sampling, habitat evaluation carries considerable weight in the final assessment. However, in RBPs II, III, and V, the biological evaluations are more rigorous and take precedence. The habitat assessment plays a supporting role within these protocols. It identifies obvious constraints on the site's attainable potential, helps select appropriate sampling stations, and provides basic information for interpreting biosurvey results. Sediment assessment, as discussed in Chapter 5, should be added to this methodology.

A site's attainable biological potential is determined primarily by habitat quality. The relationship between habitat quality and biological condition can be seen as a sigmoid curve (Figure 6.5), with community response varying with habitat quality. In the upper segment of the curve, good quality habitat (supporting or comparable) will often support high quality communities. Responses to minor alterations in habitat will be subtle and inconsequential. However, as habitat quality declines, discernible biological impairment results. In the absence of confounding water quality effects, this relationship is roughly linear.

In areas of severe habitat degradation, predicting the degree of biological impairment is more difficult. Community structure depends less on habitat diversity, which is usually simplified by degradation, and more on the opportunistic colonization strategies of a relatively few tolerant species. These opportunists have adapted to environmental conditions unfavorable to most other species. In the absence of competition, they thrive—or at least survive—in these marginal conditions. Therefore, biological measures, particularly those used in the RBPs, are relatively insensitive to habitat variations in this range. A nonsupporting characterization may correspond to either a moderately or severely impaired biological condition, depending on the specific site.

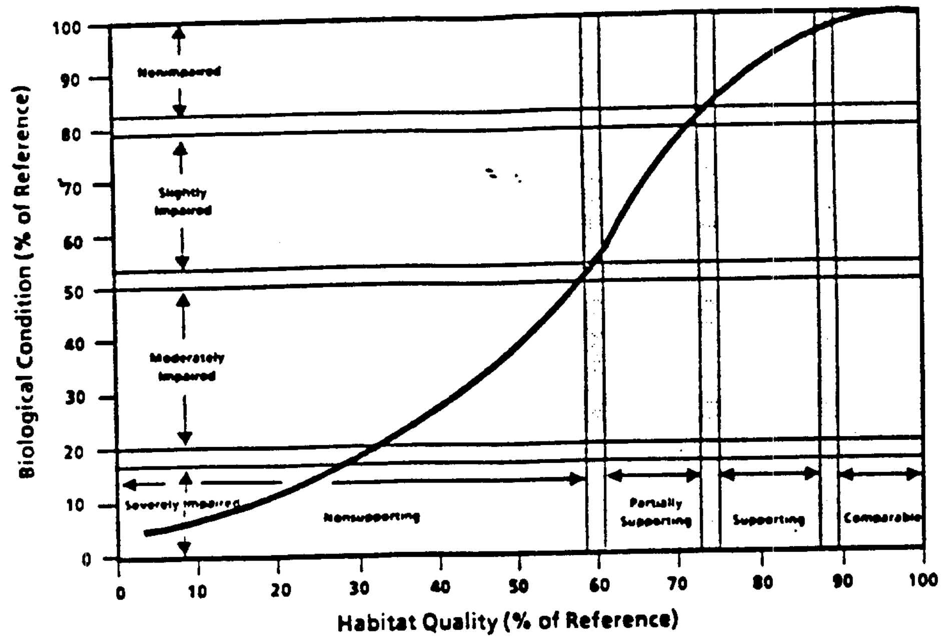
When habitat, sediment, and biological data are systematically collected together, empirical relationships can be quantified and subsequently used for screening impact sites, scoping field activities, and discriminating water quality impacts from habitat degradation. By acquiring a multiple-site database, confidence bounds can be established for the habitat/indigenous community relationship.

A theoretical relationship of habitat quality and biological condition as affected by water quality problems (organic or toxic loadings) can also be hypothesized (Figure 6.6). Curve II indicates the general relationship of biological condition to habitat quality in the absence of water quality/sediment effects. Curve II may resemble a sigmoid curve as illustrated in Figure 6.6. Curve III represents a situation where organic pollution or toxicants will adversely affect biological condition regardless of the habitat quality.

In areas of good or excellent habitat, biological communities reflect degraded conditions when water quality/sediment effects are present. However, as habitat degrades to a poor condition from water quality/sediment problems, community response may be less dramatic because of the presence of tolerant and generally opportunistic species. Curve I represents a situation indicative of nutrient enrichment, which will artificially sus-

* *Material in this section was adapted from U.S. Environ. Prot. Agency, 1989b.*

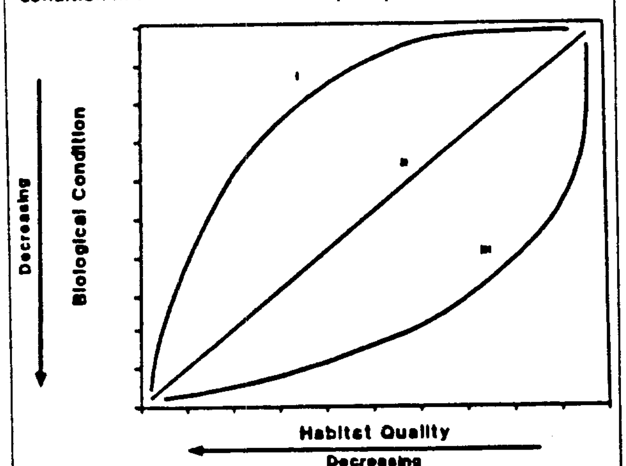
Figure 6.5—Relationship between habitat and biological condition.



Source: U.S. Environ. Prot. Agency, 1989b.

tain a more diverse fauna than dictated by the habitat quality. However, at some point along the curve as habitat degradation proceeds, nutrient enrichment will no longer support a diverse community, resulting in a drastic decrease in biological condition.

Figure 6.6—Relationship of habitat quality and biological condition in the context of water quality.



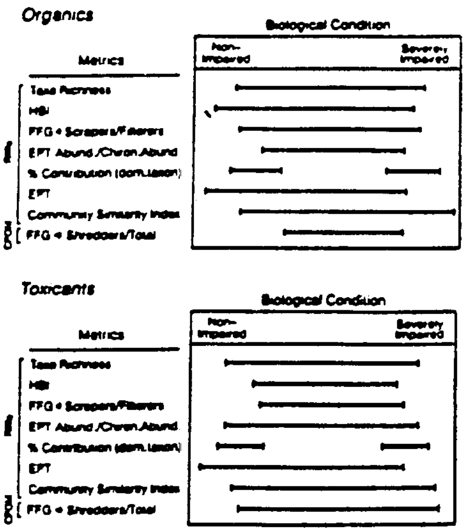
Source: U.S. Environ. Prot. Agency, 1989b.

Bioassessment Technique

Biological assessment components are evaluated using eight metrics (measurements) for benthic RBPs II and III and 12 metrics for fish RBP V. The pollution sensitivity range exhibited by each metric differs among metrics (Figures 6.7 and 6.8). Some are sensitive to a broad range of biological conditions; others only to some conditions. Sensitivity of metrics may also vary depending on whether organic or toxic impacts are being evaluated (Figure 6.7). The considerable overlap in the sensitivity ranges helps reinforce final conclusions regarding biological condition, while metrics that can better differentiate responses at the impairment range extremes enable a more complete bioassessment. This integrated analysis approach thus allows a broader assessment of condition than an analysis using any single metric. However, information from individual metrics enhances overall data interpretation.

Certain metrics are designed to be better estimators of either organic or toxic effects. For exam-

Figure 6.7—Range of sensitivities of RBP II and III benthic metrics in assessing biological condition in response to organics and toxicants.



Source: U.S. Environ. Prot. Agency, 1989b.

ple, the Hilsenhoff Biotic Index—a macroinvertebrate index—uses a tolerance classification scheme based on organic pollution effects. Functional group representation can be altered by either organics or toxicants (Figure 6.7). Although toxicants somewhat affect scrapers and filter/feeders, their ratio can best be used to assess organic enrichment. A reduction in the value obtained for scrapers and filter feeders can indicate a reduction in the quality of the periphyton as a food source and/or an increase in the suspended fine particulate organic matter (FPOM). Filter feeders are also affected by FPOM contaminated by toxicants.

The relative abundance of shredders in the benthic community is a good indicator of toxic problems. Vegetation sprayed with pesticides eventually becomes a coarse particulate organic matter (CPOM) food source for shredders. Therefore, depending on toxicant concentrations, CPOM may affect shredders. The ratio of the abundances of EPT taxa and chironomids may also function as a toxicant indicator.

The 12 IBI metrics, used in fish protocol V, also represent differing sensitivities (Figure 6.8). For example, municipal wastewater discharges typically affect total abundance and trophic structure (Karr et al. 1986), while unusually low total abundance generally indicates a toxic effect. However, some nutrient deficient environments support a limited number of individuals, and an increase in abundance may indicate organic enrichment. Bottom dwelling species that depend on benthic habitats for feeding and reproduction are particularly sensitive to the effects of siltation and benthic oxygen depletion and are good indicators of habitat degradation.

For the benthic and fish biosurveys and habitat assessment, scores are assigned to each metric or parameter based on a decision matrix. For habitat assessment, parameter quality is evaluated through visual observation. The score assigned to each habitat parameter is a function of a range of scores and is weighted by its contribution to the total habitat quality. The scores assigned to the benthic and fish metrics are based on computed values of the metrics and a station comparison, where the regional or stream reference station serves as the highest attainment criterion. Comparing the total score computed for the metrics or parameters with the reference station score provides a judgment about impairment of biological condition.

Effects indicated by the aquatic community need to be evaluated in a habitat quality context.

A poor habitat for riparian vegetation, bank stability, or stream substrate would not favorably support a well-balanced community structure. Habitat quality constraints may prohibit attaining a higher quality biological condition.

An Integrated Assessment Approach

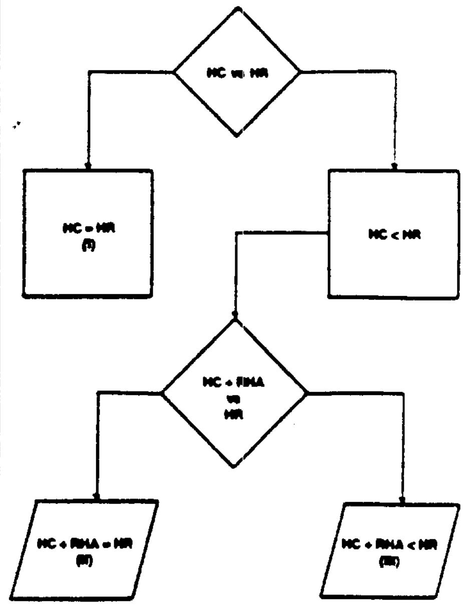
Assessing sediment, characterizing watersheds, and mapping pollution sources can be used to determine potential hot spots in watersheds and subbasins. Bioassessment and water chemistry sampling can then assess the aquatic system's actual health in these locations. A bioassessment should initially focus on habitat quality. Based on a regional reference, the habitat at an impacted site may be equal to or less than the desired quality for that particular system. If the habitat and reference are equal, then we can make a direct comparison of biological conditions as discussed in Figure 6.4. If the habitat is lower in quality than the reference, the first step is to evaluate the habitat potential. A site-specific control may be more appropriate than a regional reference for assessing an impact site. If so, select an appropriate site-specific reference site to ensure that its habitat and sediment characteristics represent the area. Once the appropriate reference site type is determined, possible outcomes of the bioassessment are

- No biological effects;
- Effects due to habitat degradation;
- Effects due to sediment or water quality; or
- Effects due to a combination of sediment, water quality, and habitat degradation.

After habitat problems are identified, separating the impairment cause from sediment or water quality problems is usually difficult. Figure 6.9 illustrates the approach to assessing biological effects. Selecting an appropriate station of comparison to evaluate biological impact begins with an evaluation of habitat at the potential control station. This comparison assumes that a regional reference database is available for the site being studied. Reference data used for comparison may be obtained from a single reference site. However, a reference database derived from numerous sites is much preferred and strongly recommended.

Scenario I depicts the situation where the habitat quality at the control station (HC) is equivalent to that at the regional reference (HR). If the control station habitat is degraded relative to that at the reference site, it becomes necessary to consider the effect that reversible habitat alterations (RHA) may have on habitat quality (Scenarios II and III). Reversible habitat alterations are those habitat parameters that can potentially be altered by remedial action (i.e., bank stabilization, bank vegetation, streamside cover).

Figure 6.9—Evaluation of habitat at a site-specific control relative to that at a regional reference.



Key:
HC = Habitat quality at control station
HR = Regional reference
RHA = Reversible habitat alterations

Source: U.S. Environ. Prot. Agency, 1989b.

If habitat quality at the control station (HC) is equivalent to that at the regional reference station (HR) as in Scenario I, then a biological assessment can be used to evaluate the potential water quality effects at the control site (Figure 6.10).

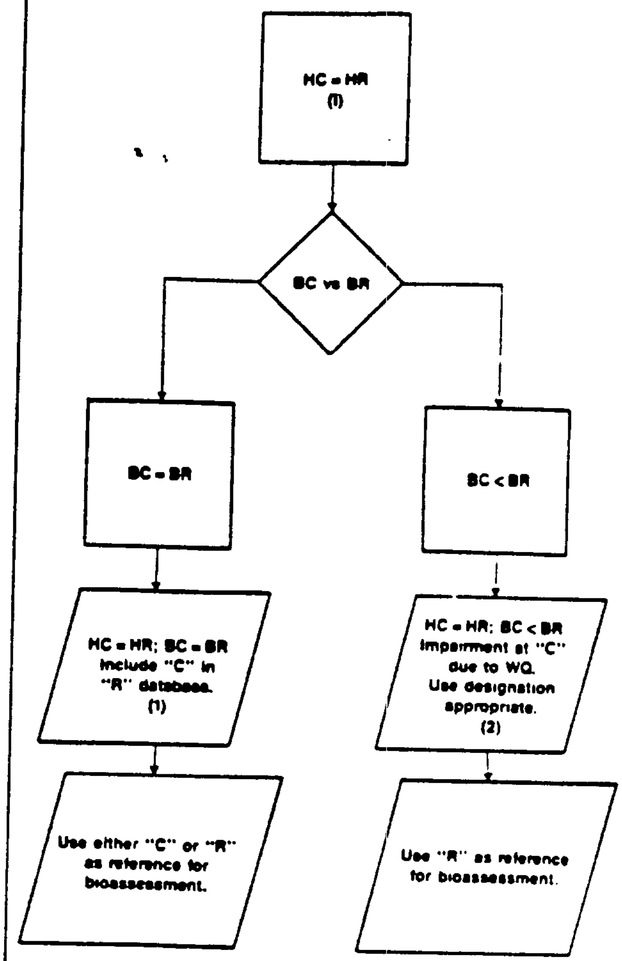
1. If impairment is not detected in a comparison of biological condition at the control station (BC) to biological condition at the reference station (BR), then C should be included in the R database; either C or R may be used as a reference for biological assessment at the impact

site (I). C would be the best indicator of a site-specific situation and would be more appropriate for use in determining water quality effects of point source pollutants, since it would be located on the same waterbody and would integrate all other background sources of impairment, other than the point source being evaluated. The reference would be more appropriate in an assessment of intermittent or nonpoint sources, since finding a nearby site-specific control that would not be impacted by the impact sources being assessed is virtually impossible. If R is based on an extensive database, then using R as a reference would provide a better estimate of acceptable variation in a data set.

2. If biological impairment is detected at C relative to R, the impairment may be attributed to water quality or sediment effects. The use designation at C is probably appropriate, but R should be used as the bioassessment reference site because of the impairment at C.

Specific approaches to evaluate environmental health for differing combinations of habitat conditions, biological condition, water quality, and sediment quality are discussed in section 8.3 of *Rapid Bioassessment Protocols for Use in Streams and Rivers* (U.S. Environ. Prot. Agency, 1989b).

Figure 6.10—Evaluation of water quality effects. (numbers in parenthesis refer to points of discussion in text).



U.S. Environ. Prot. Agency, 1989b.

Biocriteria

To implement water quality standards under the Clean Water Act, EPA requires states to include biological criteria in addition to water chemistry criteria. However, for various reasons, states have relied primarily on surrogate chemical criteria and narrative biological criteria (e.g., concentrations shall not cause imbalances of flora and fauna) to measure the health of biological communities. This situation is changing as EPA places increased emphasis on more quantitative biological criteria and as states begin assessing and managing urban runoff and nonpoint sources.

Yoder (1991) emphasizes five major needs to derive and establish scientifically defensible numeric biological criteria (biocriteria):

1. An operational definition of biological integrity. Karr and Dudley (1981) provide a workable, practical definition: "The ability of an aquatic community to support and maintain a structural and functional performance comparable to the natural habitat of a region."

2. The establishment of ecoregions and ecoregion reference sites.

3. The development and refinement of multimetric community measures such as the Index of Biotic Integrity, the Index of Well-Being (Iwb), and the Invertebrate Community Index (ICI).

4. Standardized, thorough, and cost-effective biological assessment techniques such as the RBPs discussed previously.

5. Trained, experienced, and knowledgeable staff.

In recent years, the Ohio Environmental Protection Agency (EPA) incorporated biocriteria into its water quality standards regulations. These biocriteria are based on a system of tiered aquatic life uses. The five classes include coldwater habitat, warmwater habitat, exceptional warmwater habitat, modified warmwater habitat, and limited resource waters. Ohio has defined these designations qualitatively in ecological terms and established quantitative or narrative chemical criteria for each.

Ohio derived numerical biocriteria for rivers and streams for three classes of waters—warmwater habitat, modified warmwater habitat, and exceptional warmwater habitat—based on in-stream fish and macroinvertebrate communities. Sampling conducted at more than 300 "least impacted" reference sites provided the ecoregional framework and established attainable, baseline expectations for each region and for the individual use classes.

Ohio EPA used three biological indices—IBI, I_{wb}, and ICI—to establish its biocriteria. Criteria for each index are defined by organism group, biological index, site type (fish), ecoregion, and aquatic life use designation. Modified I_{wb} and IBI criteria were defined for each of the five Ohio ecoregions for three site types: headwaters (drainage areas – 20 mi^2 [51.8 km^2]), wading sites (streams sampled with wading methods, usually 20-300 mi^2 [51.8-777 km^2]) and boat sites (streams sampled with boat methods, usually 200-6,000 mi^2 [518-15,540 km^2]). The calibration of the indices and the resultant biocriteria consider the effect of stream size and sampling gear selectivity.

Ohio established ecoregional biocriteria for the warmwater habitat class at the 25th percentile value of the reference site data for each ecoregion index. It set criteria for the exceptional warmwater habitat class at the 75th percentile, based on a statewide—not ecoregion—assessment of data from reference streams. In addition, Ohio established modified warmwater habitat criteria for some streams with physical habitat so altered that the expected warmwater habitat use could not be realistically attained but could support some semblance of a warmwater habitat community. The two biocriteria (25th percentile values) established for this class were for sites in the Huron/Erie Plain and for sites in the rest of the habitat.

Ohio EPA also established a process to determine the use attainment of Ohio's lotic surface waters. Attainment is assessed primarily based on biological monitoring and the ability to achieve the use class biocriteria. Nonattainment depends on the magnitude of departure from the ecoregional biocriteria (e.g., within four IBI units of the ecoregion criteria) and the distance downstream over which the departure is sustained. Generally, attainment is achieved by meeting all three numeric indices. Attainment is considered partial if at least one organism group index does not meet expectations but is no lower than a fair narrative rating, and the other organism group exhibits attainment. Nonattainment occurs if none of the indices meet ecoregional biocriteria or if one organism group gets a poor or very poor narrative rating, even if the other group exhibits attainment.

EPA (U.S. Environ. Prot. Agency, 1989a) presents an example of how Ohio EPA uses these biocriteria to assess waterbody impairment. A warmwater habitat stream, located in the Erie/Ontario Lake Plain ecoregion, receives point source discharges. Each graph in Figure 6.11 indicates various levels of attainment of each index, with the lines tracing the longitudinal profile of the index values along the stream. In this case, above the pollution sources, the stream attains its regional warmwater habitat biocriteria—40 for the IBI, 8.0 for the I_{wb}, and 36 for the ICI). Each index shows impairment below the discharges, followed by movement toward recovery. Each index responds somewhat differently.

This biological assessment framework accurately assesses the environmental health of surface waters as seen by a comparison of Ohio's use attainment conclusions (Table 6.1).

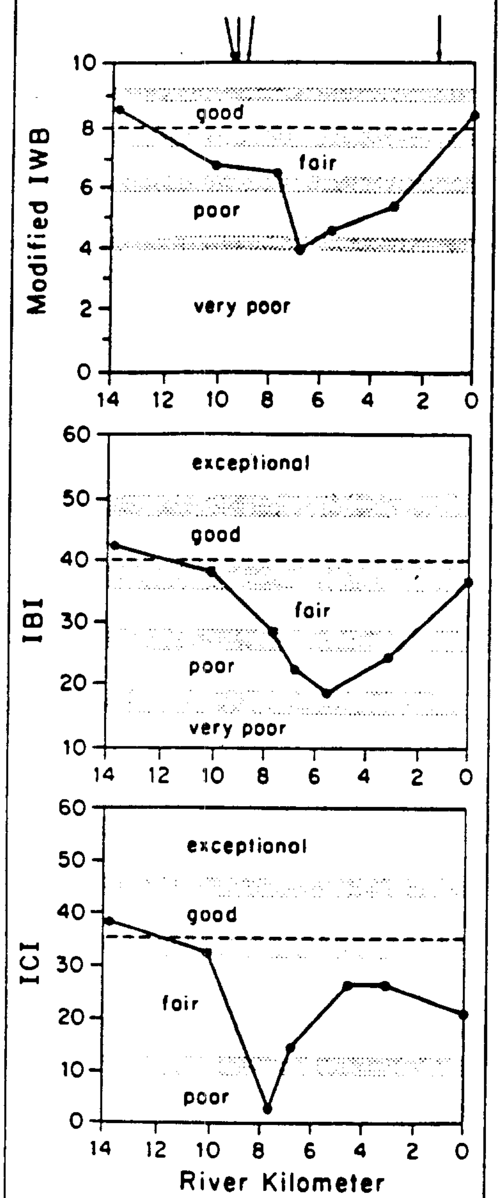
Table 6.1—Comparison of percent of stream segments attaining aquatic life uses, based on biosurvey and in-stream chemical data.

CHEMICAL ATTAINMENT	BIOSURVEY ATTAINMENT			
	FULL	PARTIAL	NON	TOTAL
Full	17	18	17	52
Partial	2	1	6	9
Non	4	6	28	39
Total	23	25	52	

Note: Rows indicate full attainment, partial attainment, or nonattainment based on in-stream water chemistry; columns indicate attainment based on biosurveys.

Source: U.S. Environ. Prot. Agency, 1989a.

Figure 6.11—The Ohio Environmental Protection Agency uses biocriteria to interpret the significance of environmental impacts. Pollution discharges are indicated by the arrows at the top of the figure; applicable biocriteria are indicated by the dashed lines.



Source: U.S. Environ. Prot. Agency, 1989a.

Conclusions drawn from Table 6.1 include

- Based on chemical data, 52 percent of the segments fully attained aquatic life uses;
- Based on biosurvey data, only 23 percent achieved full attainment;
- Both assessments agreed on full attainment in 17 percent of the cases, with overall agreement on 46 percent; and
- In 35 percent of the cases, chemical data indicated full attainment, but biosurvey data indicated partial or nonattainment. In nearly half of these cases, impairments were due to habitat, flow modifications, or siltation.

CHAPTER 7

Erosion Prevention and Sediment Control

In considering urban runoff control during construction, erosion prevention and sediment control must be considered individually. However, for effective site control, these efforts are linked. Erosion prevention reduces the amount of sediment generated from the land. Once erosion occurs, sediment control practices are necessary to limit the downstream movement of the sediment. This chapter examines erosion prevention and sediment control and offers specific recommendations for management.

For many years, erosion and sediment control during construction has been recognized as a major component of an urban runoff management program. Local sediment control programs generally date back to the early 1970s. The USDA SCS published an excellent pamphlet entitled "Conquest of the Land through 7,000 Years" (U.S. Dep. Agric. 1978). This document discusses the fall of several civilizations as a result of poor soil stewardship.

The economic impacts of off-site sedimentation are defined by several barometers, including dredging costs for local reservoirs or shipping channels, drainage channel maintenance by local departments of public works, cost of water treatment, and the cost to remove sediments from water intake structures. Not only is the removal of sediments expensive, but the transport and final disposition may be the single most costly item of the entire maintenance operation. Depending on the land use of the watershed draining to the area where sediment is being removed, the sediments may need testing for toxicity. Consideration must be given to where the spoil material can be safely placed.

Visibility makes sediment more easily identified than other pollutants. Visually inspecting streams after a storm can easily document the problem—water, by nature, is not brown. Sediments in streams, rivers, reservoirs, and estuaries mostly result from accelerated erosion because of societal impacts. Geologic erosion does occur, but mostly in arid areas where vegetation struggles to establish itself and survive. In areas with rainfall adequate to maintain dense stands of vegetation, sediment in streams generally comes from accelerated erosion resulting from lack of effective ground cover.

Design Considerations

Erosion Prevention

Erosion prevention requires reducing the amount of land that is disturbed to decrease sediment detachment and mobilization. Urban runoff management considerations reflect a similar philosophy to that contained in the Coastal Zone Act Reauthorization Amendments of 1990 (CZARA) and National Pollutant Discharge Elimination System (NPDES) stormwater guidances. The first consideration should be pollution prevention and source reduction.

Soil should not be considered a waste product but rather a resource to be protected. Minimizing areas subject to disturbance reduces the amount of work that the more traditional structural erosion and sediment controls must accomplish. Unless the land was actively engaged in another use, the site's native vegetation prior to development probably provided more effective ground cover than any proposed vegetation.

When land is disturbed, phasing of construction projects and rapid revegetation and stabilization of exposed areas must be considered. Phasing of a project limits the area exposed at any one time. It also assists the land developer in determining how to develop the site. Too often, an entire site is disturbed and left unstabilized for a long period.

Once an area has been disturbed, the single most important erosion control practice is stabilization with the intended ground cover. When the intended ground cover cannot be immediately provided, apply a temporary ground cover such as seed and straw mulch.

Sediment Control

Even with effective, timely site stabilization, a construction site generates sediments. Sediment control functions primarily as perimeter control, although interior site controls could also reduce the work (trapping need) that perimeter controls must perform. The type of runoff that is intercepted prior to sheet or concentrated flow dictates the type of sediment controls.

In sheet flow, the initial form that overland flow takes, runoff travels at a uniform depth over the ground. Generally, sheet flow will exit from a maximum slope length of about 100 ft (30.48 m). Once flow exceeds that length, areas of concentrated flow form small rivulets and channels. Sediment control practices designed for areas of sheet flow construct barriers so that water ponds or accumulates and filters through the barriers. Straw bale dikes and silt fences, the two most commonly used sheet flow practices, are effective only when sheet flow transports sediment.

Once flow is concentrated, sediment trapping practices are the only effective way to control sediment. These controls consist of two elements: a means to convey or divert runoff such as diversion berms or swales, and the actual trapping practice. Diversion dikes or swales travel across slopes and direct sediment laden runoff into trapping devices. Designs are cited in most state and local sediment control handbooks. Trapping devices include sediment traps and basins. The two practices function identically—their main difference being the size of drainage area—relying exclusively on settling. Sediment traps are used for smaller drainage areas. Sediment basins are used for larger drainage areas and, as such, must be designed and constructed to prevent overtopping or failure. This could pose downstream safety hazards. Retention time is determined by the practice's holding capacity. Around the country, most jurisdictions use .5 in (1.27 cm) of runoff storage per acre draining to the practice. These practices hold the sediment-laden water long enough for the sediment to drop to the bottom and then discharge the runoff. The amount of holding time depends on the discharge volume (.5 in per acre) and sediment particle composition.

Sediment traps function for smaller drainage areas, generally under 5 acres (2.02 ha). Traps are simpler to design and construct, even through their storage volumes are identical to sediment basins. A failed trap generally has a minor impact.

Historical Problem Areas

While most states have sediment control laws, most laws are ineffective, weak, or for the most part ignored. An effective program requires laws that are equitable and consistently applied throughout a jurisdiction. Programs not having well-defined criteria and review and inspection procedures will not be successful. A major problem, unique to erosion and sediment control, is that control practices are temporary. Therefore, a land developer may perceive that not implementing and maintaining needed practices saves money.

That perception is not totally accurate. Accelerated soil erosion also incurs costs. Topsoil loss requires fertilizers to stabilize the final site; the loss of fill material on elevated sites, such as highway embankments, requires replacement for final site elevation—all at a cost.

Despite the economic tradeoffs, many land developers fear that implementing good site sediment control practices are an economic burden when they must compete with others who do not implement such controls. Erosion and sediment controls, uniformly mandated and enforced, would place all developers on a equal footing.

Therefore, the driving mechanism for an effective erosion and sediment control program is a clearly defined uniform law defining responsibilities and enforcement options. The law should mandate the review and approval requirements before site clearing and enforcement options if control measures are inadequate. These requirements must have a solid legal basis, as they will surely be tested.

Another problem involves public construction. Public works agencies, highway agencies, and other public construction programs are generally not required to meet the same restrictions as private construction. When included, public construction frequently does not meet acceptable levels of performance. Enforcement mechanisms such as stop work and civil or criminal penalties are not considered viable options because they lead to cost overruns financed by the public. To achieve an effective control program, all agencies must comply with the laws and regulations.

Utility construction can also cause significant problems. A sewer, electric, cable, gas, or other utility contractor may cut through diversion dikes or other controls put in place by the general contractor. In these situations, responsibility for repair can be difficult to determine.

Plan Review

Local agencies should require a plan review before construction begins. Plans must define criteria and standards before receiving final approval. On small sites, normally reviewed as a general permit, the land developer might agree to implement needed practices such as straw bales or silt fences. Larger sites, where concentrated runoff flow exists or is expected, need detailed individual reviews to ensure that adequate practices are included. Requiring a developer to have only a pollution prevention plan on site, without a detailed plan review and approval procedure, will not provide downstream resource protection.

From a staffing standpoint, the number of plans estimated per year will determine how many individuals are required for plan review. The average plan reviewer can review two to six plans a day, depending on the plan's complexity. The larger a site and the more movement of earth, the greater is the degree of review and the time required. In addition, the reviewer can expect over 50 percent of the original submissions to be incomplete or contain errors in the site control approach. This will require modifications and another review. However, this number will decrease as the program grows and developers gain experience. Each subsequent review takes time and reduces the staff's ability to tackle new projects.

The review and approval time frame is another area of confusion and controversy that limits program success. In many areas, local jurisdictions have approved development plans without requiring erosion and sediment controls—often years before projects are built. Time limits should be set for previously approved projects to be resubmitted for approval.

Inspection

Inspectors are the backbone of any erosion and sediment control program; regular inspection of construction activities is the mark of a successful program. A site review program ensures that controls are implemented and maintained. An inspector, who can normally inspect from three to five sites a day, should visit each site frequently enough to ensure adequate site control throughout construction. To ensure proper site control, Maryland and Delaware *require that active construction sites be inspected about once every two weeks.* Rarely, however, does a local program have adequate inspection staff even in states with aggressive program implementation.

Inspectors should complete and provide to the owner/developer a site inspection form that discusses site conditions, details areas requiring improvement, and establishes a time frame for corrective actions. Consistency and follow-up inspections are critical to good site control and maintenance. Failure to inspect the site for corrections at the appropriate time may cause the contractor to reduce efforts to control sediment or prevent erosion.

Implementation

The effectiveness of the initial implementation of erosion and sediment control depends on the contractor's experience and the thoroughness of the approved plans. Plans should include adequate legal authorization to stop work and apply penalties if necessary. Site conditions often call for control modifications. In highway construction, for example, controls are often based on final site conditions rather than initial runoff patterns. Since these controls may not function until the final stages of the project, interim plans and measures are needed.

Maintenance

Proper maintenance of erosion and sediment controls is often difficult. While many contractors may meet requirements to implement erosion and sediment controls, they often do not include the costs of maintaining those controls in their initial bids. Because maintenance costs reduce a contractor's profit, compliance after erosion and sediment control facilities are installed requires more aggressive enforcement.

Another problem occurs when a contractor clears an entire site for grading and development, leaving the site bare throughout construction. A better practice is to phase clearing to maintain existing ground cover until disturbance is necessary.

Filled sediment traps or basins present another maintenance problem. Material removed from periodic cleaning is often placed in an area that lacks sediment control. Inspections determine when sediment trapping devices should be cleaned and where the spoil material should be placed—generally upstream of the sediment traps.

Measuring Success

Measuring the success of any preventive program is difficult since programs are based on preventing resource degradation rather than on measurable improvements. This is particularly true in erosion and sediment control, where no practice is 100 percent effective in totally preventing adverse impacts to downstream resources. Documented case studies have shown that miles of stream reaches can be affected for years. Therefore, resource degradation should be limited to the shortest possible time frame and the shortest possible distance downstream.

Science

Many practices—such as temporary stabilization and phasing of controls—are beneficial, but actual performance data are lacking. Other practices, such as sediment trapping devices, are documented but more information is needed to adequately predict expected performance. Other controls recognized as being needed—phasing of development, vegetative practices and temporary stabilization—are qualitative in their design and performance.

Controlling erosion and sediment in arid areas is different from control in "water rich" areas, and additional research on this subject is needed. Once erosion and sediment control practices are installed, the character of sediment discharges changes dramatically. The offsite impact of these practices has not been documented.

Recommended Approach

Inadequate site control during construction can devastate downstream resources more than any action other than a release of chemicals. The extent of the devastation depends on the rainfall characteristics of a given area. Therefore, implementing a site control program is essential for an overall program to succeed.

While the adverse impacts from land developing activities is well documented, our implementation of control programs is lacking. More control programs must be developed to ensure that all construction activities, private and public, are required to implement control practices.

Erosion Control

A number of items could be established as erosion control criteria:

1. Site phasing could be used to limit the total area of bare soil that is exposed at any one time. For example, Delaware sediment and stormwater regulations permit no more than 20 acres (8 ha) of land to be cleared at a time. Once land grading is initiated on that parcel, a developer may remove stumps, roots, brush, and organic material from a second 20-acre parcel. Actual clearing or grading of that second parcel may not proceed, however, until the first parcel has been either temporarily or permanently stabilized.

   Certain types of activities require flexibility to clear land in excess of 20 acres. These activities include highway interchanges, shopping malls, and other large projects. However, the land developer should make a written request stating why the 20-acre limit causes an undue hardship.

   The selection of 20 acres as a clearing limit is arbitrary. Any reasonable limit can be used as long as the land developer considers the site's development and limits soil exposure.

2. Revegetation must be required and its time frame specified. In arid regions, revegetation requirements should be related to predevelopment geologic erosion rates or seasons.

   Since rainfall patterns vary seasonably in many areas, these variations should be considered in setting a revegetation timetable. For example, seeding could be deferred until seasonal conditions allow for vegetative growth, but mulching for temporary stabilization would be required. Mulches can include organic materials such as straw or wood fiber, stone, matting, or chemical stabilizers.

   Policies for timing revegetation also vary. Delaware selected a 14-day time frame based on its ability to inspect sites approximately every two weeks and the frequency of expected rainfall. This policy requires the land developer to pay prompt attention to stabilization once a grading operation has been completed. Also, a number of states, such as Maryland and Delaware, require temporary or permanent stabilization if an area remains exposed and no site work is planned for a period of time.

Sediment Control

Several items could be considered for sediment control:

1. While sediment control is less effective than erosion control, it still must be considered to deal with overland flow. Two common mechanisms used to remove a particle in suspension are filtration and sedimentation. Practices effective for sheet flow include filtration controls such as straw bale dikes and silt fences. Effective lengths of slope prior to the onset of concentrated flow is approximately 100 ft (30.5 m). In general, flow lengths greater than 100 ft should have sedimentation practices such as sediment traps or basins.

2. Interior and perimeter controls are important considerations for sediment controls. A number of jurisdictions will allow a reduction in sizing of perimeter controls if interior controls, such as temporary stabilization of selected areas, traps, or filtration practices, are used. However, since the effectiveness of sedimentation practices rely on detention time, undersizing perimeter sediment controls can prevent adequate functioning of the perimeter trap or basin. These practices must be designed to handle the total expected flow. One effective way to reduce their size is to divert clean water away from the disturbed areas, thereby reducing the expected flow to the control.

3. The size of control practices depends somewhat on a region's rainfall. However, most states use a simple method to compute trap or basin size—they are sized equally—based on a set amount of storage per acre of drainage entering the trap or basin. Since the early 1970s, Maryland's Soil Conservation Service has recommended a volume of 1,806 ft^3 (51.2 m^3) of storage per acre, based on a silt loam soil and a desire to reduce suspended solids by 70 percent.

   Delaware uses a size criterion of 3,600 ft^3 (102 m^3) per acre draining to a control practice. This figure provides peak control of a two-year storm for a disturbed site condition, using predevelopment considerations. It also improves the sediment trapping ability of the control practice. The 3,600 ft^3 per acre size is not considered excessive for urban runoff management regulations and has not proven controversial. Other jurisdictions, like South Carolina, use an individual approach requiring hydrological analysis of each site to achieve a specified treatment level.

   Choosing one approach over another depends on monitoring results and ease of implementation. In general, control strategies and practices should be kept simple—the more complex a program, the more potential for error.

4. When implementing erosion and sediment control, consolidate efforts to reduce total costs. Permanent runoff basins, for example, can easily function to control sediment during construction with several modifications to the outlet structure. When the construction phase is complete, follow these guidelines to ensure an appropriate transition:

   - The sediment basin should be dewatered and the accumulated material spread, stabilized, or otherwise removed from site.
   - The pond bottom should be regraded to design requirements and the outlet structure altered to meet the approved design.
   - The pond area should be stabilized with vegetation runoff. If the runoff pond is a constructed wetland, the plants should be placed after the entire construction site and pond area are stabilized to reduce turbidity and prevent excessive sedimentation within the basin or on the plant community.

Programmatic Considerations

Education

Education may be the single most important program component, especially in light of limited resources. Education should be targeted to specific audiences and prioritized, with initial efforts directed toward the regulated community such as developers and contractors.

Delaware and Maryland require contractors to send a representative to a certification program. The three-and-a-half hour program educates contractors on the need for runoff management and their responsibilities under the program. As of 1987, Maryland has certified over 10,000 individuals. Since Delaware's program began in 1991, over 2,000 individuals have been certified. These programs continue to be popular with contractors.

Educational efforts also should be directed at plan designers and plan reviewers, inspectors, and the general public. Educational programs increase the visibility of the sediment control program which, in turn, increases its acceptance by the regulated community and the general public. In a time of diminishing resources, public acceptance often translates into political support to minimize funding reductions.

Staffing

The erosion and sediment control plan should be implemented by a defined program staff. Relying on building plan reviewers and building inspectors to implement the program reduces the program's effectiveness, with the inspection and enforcement component suffering most. Delaware has implemented an innovative approach to inspection and enforcement through its Certified Construction Reviewer (CCR) program.

The state or local plan approval agency may require that the developer provide a CCR to inspect the site weekly and submit an inspection form to the developer, contractor, and the responsible inspection agency. To qualify, the CCR attends a 32-hour training course that covers such topics as water quantity and quality, soils, vegetation, site inspection procedures, and laws and regulations. Upon passing a final examination, the individual receives certification. The CCR must submit accurate, weekly reports but is not required to initiate enforcement action. The public agency must still conduct periodic inspections and initiate enforcement, but the CCR program represents a means to reduce public inspection requirements.

Consistency

A regulatory program requires consistency to be successful. Submission requirements should be based on site conditions, with basic standard items required in every case. Inspection and enforcement requirements should mandate site control implementation and maintenance. Erosion and sediment control requirements should be supported through an effective and consistent enforcement mechanism. Helpful documentation can include check lists for plan review and inspection forms for site review. Above all, a coherent policy of progressive enforcement is essential.

Consistent policy is also necessary for public agency compliance. Expect governmental agencies to resist additional regulatory requirements. A common response is compliance with the intent of the law but not with submission and approval requirements. Field implementation and maintenance of controls will be poor unless all parties agree to accept authority and commitment to implementation.

Recommended Reading

The following resources contain excellent information on erosion and sediment control processes and strategies. They will also provide assistance to jurisdictions considering establishing a design or construction handbook. Most of these documents must be purchased.

CHAPTER 8

Urban Runoff Treatment Practices

Urban runoff management in its broadest and most comprehensive form involves controlling both the quantity and quality of runoff. Control options are commonly called best management practices (BMPs).

Quantity control practices regulate the peak flow rate and sometimes the total volume from precipitation. Water quality control practices prevent the initial release of pollutants into urban runoff, or once they are released, reduce the quantities that enter surface or groundwaters. Completely recapturing released pollutants is impossible, and the expense increases for higher and higher levels of recapture. Prevention is more efficient and cost-effective. This chapter examines the principles of runoff quantity and quality control and details a number of treatment practices.

Control practices are categorized in a number of ways. One system is as follows:

- **Quantity control practices.** Methods of detaining runoff to regulate its rate of release to receiving waters or to infiltrate runoff into the ground so that it does not become surface flow.
- **Management practices.** Ways of doing business to prevent pollutant releases.
- **Source control practices.** Specific actions taken at potential sources to prevent pollutants from contacting precipitation or runoff.
- **Erosion and sediment control practices.** A variety of techniques used to control areas that have been bared from construction in progress or have not been revegetated after construction or other activities.
- **Treatment practices.** Facilities that remove pollutants already in runoff.

These practices are often divided into structural and nonstructural groups. Nonstructural practices mainly embrace preventive actions that do not require building anything, such as management and source control practices. Many erosion and sediment control practices are also preventive, although some—like filter fabric fences and sedimentation ponds—treat runoff containing eroded sediments and involve construction or hardware installation. While quantity control can be nonstructural (e.g., policies to retain natural soil and vegetation cover), it generally involves building a facility such as a detention pond or an infiltration device. Treatment practices are usually structural.

This chapter covers permanent structural quantity control and treatment practices. Chapter 14 provides specific criteria for inspecting these facilities after construction and periodically thereafter to determine maintenance needs. Chapter 12 covers management and source control practices. Erosion and sediment control practices are covered in Chapter 7 and their inspection in Chapter 14.

Structural quantity control and treatment practices can also be grouped in various ways, one of which is the following:

- **Storage practices**
  - Ponds—wet ponds, extended-detention dry ponds, and dry ponds
  - Vaults and tanks
  - Oil separators
- **Vegetative practices**
  - Swales
  - Filter strips
  - Wetlands—natural and constructed
  - Landscape management (i.e., urban forestry)

VOL 12

6665

R0039973

- **Infiltration practices**
  - Basins
  - Trenches
  - Perforated pipes
  - French drains
  - Porous pavements
- **Filtration practices**
  - Sand filters
  - Leaf compost filters
  - Catch basin filters (various media)

The ponds, vaults, and tanks under storage practices can benefit quantity control, quality control, or both. However, dry ponds drain too quickly to provide any substantial runoff treatment. Enclosed vaults and tanks are limited in biological activity and are usually too small to function well in water quality control. Therefore, these devices are only effective for quantity control. Wetlands and all infiltration options can also supply quantity and quality control. The remaining practices are largely treatment devices.

In a number of instances, one mode of operation (storage, vegetative treatment, or infiltration) predominates but the practice incorporates other modes. For example, wetlands involve both storage of water and vegetative action. Also, most ponds infiltrate some water unless they are lined.

The trend is to combine the capabilities of two or more options by establishing "treatment trains" arranged in series, a strategy discussed at the end of this chapter.

Practice Selection

Success in applying any management practice initially depends on selecting the appropriate option for the site's control objectives and conditions. The objectives must be clearly delineated at the outset and conditions investigated in enough detail to match the practice to the site. Objectives might include whether quantity control, quality control, or both are to be provided; what pollutants are to be treated; and what, if any, side benefits are to be produced. Conditions that determine a practice's relevance include service area, soils, hydrogeologic conditions, and circumstances of the receiving water and nearby properties.

The British Columbia Research Corporation (1992) developed charts that incorporate these considerations, adapting and extending earlier work by Schueler (1987) and the Washington Department of Ecology (1992). Figures 8.1 and 8.2 and Tables 8.1 through 8.4 present these charts as aids in practice screening.

The recently issued California Storm Water Best Management Practice Handbooks (Camp, Dresser, McKee et al. 1993) refined the process of practice selection further with several recommendations (Municipal Handbook, Section 3), one of which was the following evaluation criteria:

- Ability to meet regulatory requirements;
- Effectiveness in pollutant reduction;
- Public acceptance;
- Ability to be implemented;
- Institutional constraints; and
- Cost.

The handbook recommends assigning a rank of 1 to 5 to each practice for each criterion. Each criterion can be weighted differently by assigning a weighting multiplier.

Principles of Runoff Quantity Control

Purpose and Goals

Controlling runoff quantities is important because, as discussed in Chapter 3, hydrologic change can produce extensive ecological impacts in small-scale aquatic systems where much valuable habitat for fish and other biota is located. The possible role of hydrologic changes in degrading valued salmon resources and recent flooding have stimulated efforts to improve quantity control programs and facilities, especially in the Pacific Northwest.

This chapter does not fully discuss design for quantity control, but it does present the key principles that should be applied. These principles are currently being integrated into some of the older runoff management manuals developed in the Northwest. New versions of manuals by Washington Department of Ecology (1992) and King County Surface Water Management Division (1990) will likely integrate these principles. Several texts present the current state of the art in some detail, including Bedient and Huber (1988), Urbonas and Stahre (1993), Wanielista (1990), and Wanielista and Yousef (1993).

The goal of quantity control in runoff system design is to maintain the predevelopment hydrograph—the maximum runoff rate, dynamics, and total volume—after a change in the watershed. This means replacing the depression and below-ground storage removed or bypassed in development. Maintaining the predevelopment hydrograph requires replacing all of the lost depression and soil storage. This is done only through extensive new infiltration opportunities or with large detention volumes that hold water while the slow processes of evaporation and infiltration operate. Matching predevelopment peak rate alone means recovering one-third to two-thirds of the lost storage. Even this less restrictive criterion generally requires much larger detention volumes than customarily demanded in existing regulations.

Analysis and Control

Effective runoff quantity control depends on substantial hydrologic analysis, only now being established. The analysis depends on

- Obtaining and properly using precipitation records for the place and time to be controlled;
- Good estimates of peak runoff flow rates and volumes of critical conditions;
- Relating water movement through and beyond the quantity control device with the effect of temporary storage in the device ("routing"); and
- Using this information to set the size of the storage volume and design the outlet structure, which controls the release rate.

The first two steps pose difficult problems. Precipitation records generally lack geographic coverage, length, frequency of recording, and accuracy. Two options to estimate peak runoff are to use models based on selected precipitation events (e.g., the 25-year frequency, 12-hour duration rainfall) or a computerized continuous simulation model.

Excluding the rational method—which is completely inadequate for this purpose—the most common event-based models are the USDA SCS' curve number method and its derivatives. These models have several liabilities, such as the arbitrariness of the selected events. Because they have no way to represent depression and soil storage of runoff, they tend to overpredict the peak runoff rate before development occurs, when the storage potential is significant. Consequently, while the objective is to match the predevelopment rate, the target is set too high. To compensate for this shortcoming, base the design on a selection of events or apply a safety factor to flow rate or storage volume size and discharge rate estimates.

Another problem with event-based models is their inability to deal with unpredictable storm dynamics. If a second storm arrives before the first one drains, the facility could overflow. To compensate for this fault, select as the basis events of longer duration and some of the less frequent, larger events. In the Pacific Northwest where winter rains are frequent and prolonged, the solution is to use a seven-day event duration, which produces larger storage facilities.

Continuous simulation models—EPA's Storm Water Management Model (SWMM) or Hydrologic Simulation Program-Fortran (HSPF)—have some important advantages over event-based models. These computer models consider such complexities as soil storage and infiltration. Given sufficient input data and proper use, they can simulate a range of conditions spanning many years—critical conditions like rain-on-snow and closely spaced storms that could cause a basin to overflow. On the other hand, these models require more and better precipitation data than are often available; additional data to represent soils, topography, and vegetation; and considerable expertise.

The Pacific Northwest is also developing "runoff files" for the HSPF model. Runoff files are unit area hydrographs for limiting precipitation conditions and site characteristics. The user merely specifies those characteristics and the location. A routing routine provides pond size and release rate.

Another Northwest strategy deals with the potential impacts of greater total volumes caused by development, even if peak rates do not increase. As pointed out previously, real volume control can result onl· ··om replacing lost depression and soil storage. However, limiting peak flow to a rate lower than before development can at least partially compensate for the additional stress on stream channels from extra volume. One possibility is to limit the two-year peak release rate after development to half of the predevelopment peak release rate associated with the two-year, 24-hour event.

Treatment Practices

Pollution Removal Mechanisms

To properly specify, design, and operate treatment practices, one needs to understand the mechanisms that can operate to prevent pollutants from entering receiving waters. Table 8.5 lists all the principal mechanisms that can capture, hold, and transform various classes of contaminants in

VOL 12

6670

R0039978

urban runoff and the factors that promote the operation of each mechanism to improve water quality.

A factor to consider in the functioning of all mechanisms is time. The effectiveness of settling a solid particle is directly related to the time provided to complete sedimentation at the particle's characteristic settling velocity. Time is also a crucial variable to determine the degree that chemical and biological mechanisms operate. Characteristic rates of chemical reactions and biologically mediated processes must be recognized to obtain treatment benefits. For all of these reasons, water residence time is the most basic variable to apply effective treatment practice technology.

The information in Table 8.5 can also be arranged by features that promote specific pollutant control objectives. The following features fulfill the most common objectives:

- **Features that help achieve any objective**
  - Increasing hydraulic residence time
  - Low turbulence
  - Fine, dense herbaceous plants
  - Medium-fine textured soil
- **Features that help achieve specific objectives**
  - Phosphorus control
    - High soil exchangeable aluminum and/or iron content
    - Addition of precipitating agents
  - Nitrogen control
    - Alternating aerobic and anaerobic conditions
    - Low toxicants
    - Circumneutral pH
- **Metals control**
  - High soil organic content

Table 8.5—Summary of pollutant removal mechanisms.

MECHANISM	POLLUTANTS AFFECTED	PROMOTED BY
Physical sedimentation	Solids, BOD, pathogens; particulate COD, P, N, metals, synthetic organics	Low turbulence
Filtration	Same as sedimentation	Fine, dense herbaceous plants; constructed filters
Soil incorporation	All	Medium-fine texture
Chemical precipitation	Dissolved P, metals	High alkalinity
Adsorption	Dissolved P, metals, synthetic organics	High soil Al, Fe high soil organics (met.); circumneutral pH
Ion exchange	Dissolved metals	High soil cation exchange capacity
Oxidation	COD, petroleum hydrocarbons, synthetic organics	Aerobic conditions
Photolysis	Same as oxidation	High light
Volatilization	Volatile petroleum hydrocarbons and synthetic organics	High temperature and air movement
Biological microbial decomposition	BOD, COD, petroleum hydrocarbons, synthetic organics	High plant surface area and soil organics
Plant uptake and metabolism	P, N, metals	High plant activity and surface area
Natural die-off	Pathogens	Plant excretions
Nitrification	NH_3-N	Dissolved oxygen > 2 mg/L, low toxicants, temperature > 5-7°C, circumneutral pH
Denitrification	NO_3+NO_2-N	Anaerobic, low toxicants, temperature > 15°C

High soil cation exchange capacity
Circumneutral pH

- **Organics control**
  Aerobic conditions
  High light
  High soil organic content
  Low toxicants
  Circumneutral pH

These features differ in what degree of control the treatment system designer and operator have over the operation. Fortunately, several features that promote all favorable mechanisms (possibly excluding the soil) are under a high degree of control. Features that promote more specific objectives require more intervention, such as developing some desired soil condition.

Sources of Detailed Information

The main treatment practices, the principles that govern their operation, and the primary design considerations are featured in a number of government manuals and other texts. These sources are valuable in planning, design, plan review, construction, and operational activities. The primary reference, however, should be the manual of the jurisdiction where the site is located. In addition to the material presented in this chapter and the listed sources, Chapter 14 includes inspection checklists and diagrams that provide details on design configurations and operations.

Storage Practices

Wet Ponds

Ponds reduce runoff pollutants by settling solids and allowing a variety of physical, chemical, and biological mechanisms to capture or transform dissolved pollutants. Settlement of fine solids and the soluble pollutant removal mechanisms all require time in quiescent or pool storage—from several days to as many as three weeks for maximum performance. Therefore, wet ponds, which have a permanent storage pool, offer substantially greater treatment advantages than ponds that dry out between storms. Unless they are lined, most ponds infiltrate some water to the soil and are often referred to as retention/detention ponds.

Figure 14.9 illustrates a typical wet pond, showing a number of the design recommendations discussed in the following paragraphs.

▮ *Sizing Calculations and Expected Performance.* Unlike in the design of wastewater treatment plants, knowledge is insufficient as yet to design runoff ponds to obtain a specific level of treatment. However, EPA's Nationwide Urban Runoff Program (NURP) included a comprehensive investigation of pond design and associated performance at 13 locations. The investigation concluded that performance could best be related statistically to the "volume ratio." This is the ratio of pool storage volume to "mean storm volume," a statistical measure expressing the runoff volume associated with the long-term average rain storm quantity (U.S. Environ. Prot. Agency, 1986).

EPA produced total suspended solids removal curves for different climatological regions. Figure 8.3, for example, shows the curve for all of the United States east of the 96th meridian, approximately along the western Minnesota border. Reductions of other pollutants were related to total suspended solids (TSS), as illustrated in Figure 8.4. Generally, a volume ratio of about 2.5 is necessary to achieve 75 percent TSS reduction, where corresponding phosphorus removal is approximately 50 percent. Each incremental increase of the ratio above 2.5 yields decreasing benefits, reflecting the fact that the pollutants easiest to capture are removed first. The results indicate that pollutants with significant amounts in dissolved forms cannot be reduced by more than 50 to 60 percent in a wet pond.

In the phosphorus example, reduction of 60 percent is approached only as the volume ratio grows toward 5. Ponds of this size generally provide two to three weeks of pool storage hydraulic residence time and consume 3 to 7 percent of the contributing catchment, depending on impervious area, slopes, rainfall characteristics, and other factors (Walker, 1987; Hartigan, 1989; Kulzer, 1989). Further improvement in phosphorus removal can be achieved in several ways, although all have practical limitations (Walker, 1987). They include

- Deepening the pond, although a practical limit of perhaps 2.5 m (about 8 ft) is imposed by the possibility that the bottom waters may become anaerobic;
- Infiltrating more water;
- Enhancing the plug-flow characteristics by design features;
- Installing certain aquatic plants, perhaps coupled with regular harvesting; or
- Chemical treatment.

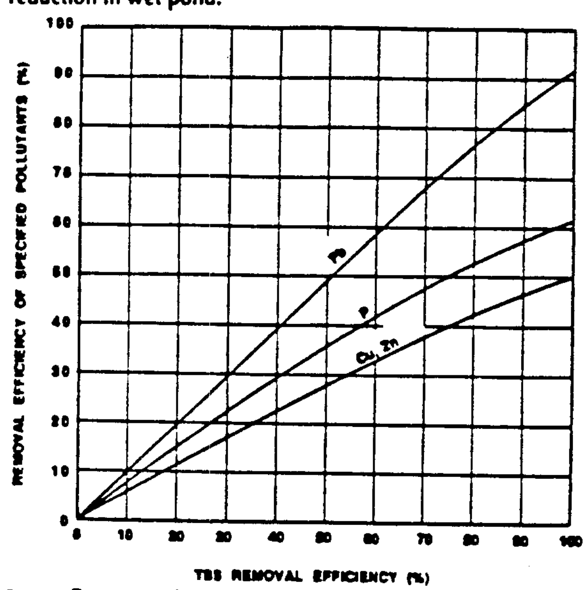
Figure 8.4—Reductions of lead (Pb), phosphorus (P), copper (Cu), and zinc (Zn) in relation to total suspended solids (TSS) reduction in wet pond.



Source: Dorman et al. 1988.

A number of agencies have adopted the NURP pond guidelines as a design basis, including the Metropolitan Washington Council of Governments (Schueler, 1987), the Federal Highway Administration (Dorman et al. 1988), and the state of California (Camp, Dresser, McKee et al. 1993). The guidelines help set performance objectives for pollutants of interest and calculate the pool storage volume from the graph and climatological statistics for the region to reach those objectives.

Other agencies have specified either a certain runoff quantity or a precipitation event as the design basis. For example, treating the first 1 in (2.5 cm) of runoff provides treatment to most storms and total runoff volume in an average year. The Washington Department of Ecology (1992) selected the six-month, 24-hour rainfall event as the "water quality design storm." The treatment system (the pool storage in a wet pond) should provide sufficient volume to hold runoff from this storm. In Seattle, this event produces about 1.2 in (3.05 cm) of rain. With a mean rain storm of 0.48 in (1.22 cm) at this location, the NURP volume ratio is thus approximately 2.5 for any runoff coefficient.

▮ *Design Recommendations.* Better performance can be expected by enlarging the surface area to gain volume as opposed to deepening the pond. A large surface area-to-volume ratio shortens the solids' settling distance and allows better aeration and light penetration to promote biological pollutant removal mechanisms.

Other design features are also important to performance. Features that reduce the tendency of water to short circuit, which raises actual hydraulic residence times toward the theoretical values, include the following (Schueler, 1987; Horner et al. 1989; Kulzer, 1989):

- Two or more distinct cells to promote plug flow;
- Effective length-to-width ratio of at least 5:1, preferably, and at least 3:1 at a minimum;
- Inlet and outlet remote from each other or shielded by baffling;
- Low inlet velocity;
- Uniform flow distribution across the inlet pond; and
- Discharging water with minimum turbulence from mid-depth rather than near the bed or surface.

Other safety features that should be incorporated in wet pond designs include the following:

- Side slopes of at least three horizontal to one vertical;
- An emergency overflow weir stabilized to avoid erosion and possible failure during high flow;
- A shallow "safety bench" at least 10 ft (3 m) wide at the toe of the slope surrounding the perimeter;
- A buffer planted to discourage young children from approaching the pond;
- An outlet structure placed out of reach to children; and
- Fencing to protect children from any remaining dangerous areas.

Extended-Detention Dry Ponds

With insufficient time to operate dissolved pollutant removal mechanisms, sedimentation is the main means to reduce pollutants in extended-detention basins. This method is especially good for capturing solids or other contaminants connected with particulates. In fact, Kuo et al. (1988) showed that extended detention was more cost-effective compared to dry or wet ponds or infiltration. This practice can also be the best choice where water is insufficient or too unreliable to sustain a wet pond or constructed wetland.

▮ *Sizing Calculations and Expected Performance.* Like wet ponds, extended-detention dry ponds are usually sized to capture a particular fraction of the runoff. In addition, this type of pond drains within a set period when filled with the design runoff volume, typically 24 to 40 hours.

Four NURP extended-detention ponds in Washington, D.C., with detention times of four to 18 hours offered at least 70 percent TSS removals with at least six hours of detention, and long-term total phosphorus reductions ranging from 13 to 56 percent (Schueler and Helfrich, 1989). Based on these somewhat conflicting results, Schueler (1987) estimated the upper limit of possible phosphorus reduction at 40 to 50 percent after 48 hours. Others, however, view the reliable efficiency to be much lower, perhaps 20 to 33 percent (Gibb et al. 1991). Schueler et al. (1992) now appear to agree with that assessment, quoting 10 to 30 percent. Stahre and Urbonas (1990) analyzed the available estimates of long-term efficiencies for various pollutants with a 40-hour detention time, as follows:

TSS	50 to 70%
chemical oxygen demand	20 to 40%
total phosphorus and total nitrogen	10 to 20%
lead	75 to 90%
zinc	30 to 60%
hydrocarbons	50 to 70%
bacteria	50 to 90%

▮ *Design Recommendations.* Extended-detention pond performance generally benefits from the same design features as wet ponds to prevent short circuiting. Schueler (1987) recommends incorporating the removal capabilities of plants by managing part of the basin as a shallow wetland. Schueler and Helfrich (1989) suggest an extended-detention wet pond, with a relatively small permanent pool that expands temporarily.

Oil Separators

Oil separators, devices that separate dispersed oil and water, are limited to capturing free or unemulsified oil. The two basic types are the Ameri-

VOL 12

6674

can Petroleum Institute (API) separator and the coalescing plate (CP) separator. The API separator is a baffled tank that separates large volumes of free oil. The CP device separates free oil in much smaller volumes because it provides a large surface area for oil collected by the corrugated plate pack. Various spill-control devices are sometimes included in this type of treatment practice. The unit is used to catch small spills—it is not capable of separating dispersed oil. Figure 8.14 illustrates three oil separators.

API and CP separators were developed for industrial wastewater treatment. This wastewater is generally much higher in oil than most urban runoff, flow rates are more uniform, and the unit can get more operator attention. The separators are best used when discharge concentrations of oil and grease are higher than usually measured in general urban runoff. These concentrations are usually below 20 mg/L—often far below, unless an oil spill has occurred. Even the best CP separators cannot reduce concentrations below 10 mg/L, however. Therefore, these devices should be used mainly where petroleum products are handled, where vehicle traffic is heavy (e.g., trucking bases), and possibly where automobiles frequently come and go (expanding and contracting engine seals leak more oil than when engines run continuously). Otherwise, vegetated treatments can handle the usual relatively low concentrations. Spill control units should be installed anywhere slugs of oil could enter runoff, including residential areas where individual automotive maintenance is common.

▮ *Sizing Calculations and Expected Performance.* Following are procedures to size the two basic types of separators:

API SEPARATOR

1. Find oil drop rising velocity (V_p, cm/s):

$$V_p = (G/18 \cdot \mu) \cdot (d_p - d_c) D^2 \qquad [1]$$

where: μ = Dynamic viscosity of oil at coldest service temperature (use 0.015 poise at 5°C if no other information is available);

$d_p - d_c$ = Density difference between oil and water (use 0.1 g/cc if no other information is available);

D = Oil drop diameter (use 0.006 cm if no other information is available).

Convert V_p to ft/s by dividing by 30.48 cm/ft.

2. Find depth (d, ft):

$$d = (60 \cdot Q/2 \cdot V_h)^{0.5} \qquad [2]$$

where: Q = Design flow rate (cfs);

V_h = Horizontal velocity (3 ft/min or 15 times V_p, whichever is smaller; 0.5 ft/min is recommended if no other information is available).

Recommended range = 2 to 8 ft.

3. Set width in the range 2 to 3.33 times the depth.

Recommended range = 4 to 16 ft.

4. Find length (L, ft):

$$L = (d/V_p) \cdot V_h \qquad [3]$$

where: V_p = 0.033 ft/min is recommended if no other information is available.

5. Set baffle height-to-depth ratios at 0.85 for top baffles and 0.2 for bottom baffles.

CP SEPARATOR

1. Find V_p as above.
2. Find effective separation area = Q/V_p.
3. Select a unit from a manufacturer's catalog that provides at least the needed effective separation area.

A CP separator is theoretically capable of capturing free oil droplets down to 5 µm in diameter, although that performance requires a large unit. In contrast, the API type is practically limited to removing drops with diameters no smaller than 150 µm. How each reduces concentration depends on oil characteristics. CP separators can generally produce an effluent in runoff having no more than 10 mg/L oil and grease.

▮ *Design Recommendations.* A CP separator is marketed both with plates horizontal and at an angle. Angled plates are less prone to clogging by solids. The normal placement is 45 to 60 degrees from horizontal. Plates should be closely spaced to minimize oil rise distance without confining the flow so much as to raise velocity to a high level and create excessive turbulence; 3/4 in (1.90 cm) is a common spacing. Specific recommendations to improve success with API and CP units are the following:

- Exclude runoff from roofs and other areas not likely to contain oil;
- Place any pump being used downstream so as to prevent mechanical emulsification;

VOL 12

6675

R0039983

- Avoid detergent use upstream to prevent chemical emulsification;
- Provide a forebay sized at 20 ft^2 (1.86 m^2) of surface area per 10,000 ft^2 (929.0 m^2) of drainage area; and
- Provide an afterbay in which to place absorbents.

Vegetative Practices

Swales and Filter Strips

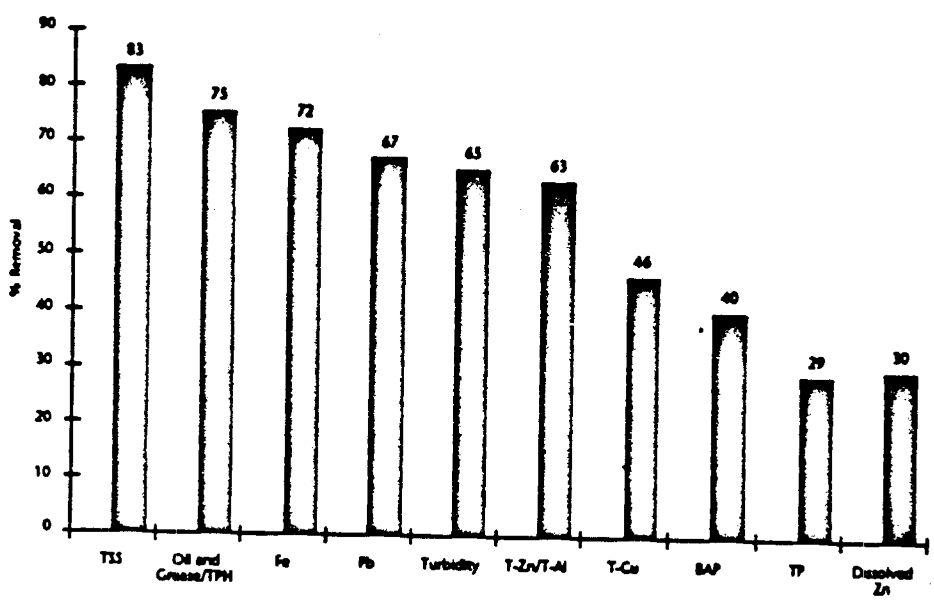
Treatment practices that use terrestrial grasses and other fine herbaceous plants are sometimes called biofiltration. These plants can be installed in a channel in which water flows at some depth—a swale—or on a broad surface area that has sheet flow—a filter strip. Biofilters can also have wetland plants in areas with the hydrology to sustain them.

A vegetated treatment strives for a plant stand that serves as a good filter. Ideal characteristics are dense, uniform growth of fine-stemmed plants tolerant of the area's water and climatological, soil, and pest conditions. Native plants generally combine the best properties. Plants serve mainly as filters; pollutant uptake is not a very important removal mechanism. Therefore, a number of species and mixes appropriate to the area will work equally well.

■ *Sizing Calculations and Expected Performance.* The results of a performance investigation of a grass swale, recently completed in the Puget Sound area of Washington (Municipality Metro. Seattle, 1992), refined a previously developed design procedure and recommended design features consistent with good performance. The report details the full design procedure, criteria, and guidelines that are excerpted here.

Figure 8.5, which summarizes the performance results, shows that the swale was relatively effective in capturing solids, oils, and the least soluble metals. The swale was less effective for more soluble metals, especially their dissolved fractions, and less yet for phosphorus. Nitrogen (not shown) exhibited little if any removal; fecal coliform's capture was inconsistent. Therefore, biofilters should generally be considered the sole

Figure 8.5—Average pollutant removal over six storms in a grass swale with an average hydraulic residence time of nine minutes.



TPH = total petroleum hydrocarbons
T = total

Source: Municipality of Metro. Seattle, 1992.

VOL 12

6676

treatment only to reduce solids and oil. In fact, they are a better choice than oil separators to remove low concentrations of oil and grease from urban runoff. Vegetation can reduce concentrations to even lower levels, while no feasible separator can decrease them below 10 mg/L. The vegetation option is also much cheaper. One theory suggests that biofilters reduce nutrients considerably better if growth is carefully mowed and removed before it dies and releases phosphorus and nitrogen; however, that hypothesis is unproven.

The design procedure uses Manning's equation of open channel flow to obtain a swale width for a given flow and slope and selected water depth. The velocity resulting in this size channel is then compared to a criterion, and the length is calculated using a hydraulic residence time criterion. A key study result is that a residence time of nine minutes is needed to achieve the highest and most reliable performance. Performance began to deteriorate noticeably when residence time fell below five minutes, recommended as the absolute minimum. A filter strip design is handled in the same general way but with a more shallow flow depth. Steps are as follows:

1. Determine the design flow rate (Q, cfs) by appropriate hydrologic analysis. Use as a basis continuous simulation with a computer model, a design rainfall event (e.g., six-month, 24-hour storm), or a set fraction of total runoff (e.g., first inch).

2. Determine slope (s, ft/ft) and select vegetation, design vegetation height, and shape if a swale. Normally, swales are parabolic or trapezoidal to avoid erosion in sharp corners of rectangular or V shapes. The trapezoidal shape is easier to construct and will tend to assume a parabolic shape over time.

3. Set design flow depth (y, ft). A grass swale's depth should not exceed one-third of the grass height in infrequently mowed swales, or one-half of the grass height in regularly mowed swales, up to a maximum of 3 in (7.62 cm). In swales with wetlands vegetation, the depth should be at least 2 in (5.08 cm) below the height of the shortest species. A filter strip's depth should be no more than 0.5 in (1.27 cm).

4. Solve Manning's equation for the width, using the conditions established in steps 1 through 3.

$$Q = 1.49 \cdot A \cdot R^{0.67} \cdot s^{0.5}/n \quad [4]$$

where: A = cross-sectional area (ft^2);
R = Hydraulic radius (ft) = A/wetted perimeter;
n = Manning's roughness coefficient.

The Puget Sound study used experiments to determine a value of n for flow below the full height of a local common grass mix. The recommended values are, unless other information is available, 0.20 in (0.5 cm) for grass biofilters to be mowed regularly and those with herbaceous wetland plants and 0.24 in (0.6 cm) for infrequently mowed swales.

Solutions of Manning's equation for two configurations follow:

TRAPEZOIDAL SWALE

$$b = Q \cdot (n/1.49) \cdot y^{1.67} \cdot s^{0.5} - Z \cdot y \quad [5]$$

$$T = b + 2 \cdot y \cdot Z \quad [6]$$

FILTER STRIP

$$T = Q \cdot (n/1.49) \cdot y^{1.67} \cdot s^{0.5} \quad [7]$$

where: T = Top width (ft);
b = Bottom width (ft);
Z = Side slope (ft/ft; should be no steeper than 3 horizontal to 1 vertical).

The bottom width of a swale should be no less than 2 ft (0.61 m) if it will be mowed and no more than 8 ft (2.44 m), unless it will be hand finished to get a completely level bottom. If b does not fit into this range, investigate how Q can be reduced by splitting flow, or set b = 8 ft (2.44 m) and proceed with the analysis, or specify hand finishing.

5. Compute A for the configuration:

TRAPEZOIDAL SWALE

$$A = b \cdot y + Z \cdot y^2 \quad [8]$$

FILTER STRIP

$$A = T \cdot y \quad [9]$$

6. Find flow velocity (V, ft/s): V = Q/A. If V is greater than 0.9 ft/s, which will knock over most grass and reduce settling of finer particles, investigate how Q can be reduced, or change the width and/or depth.

7. Compute length (L, ft):

$$L = V \cdot t \cdot 60 \text{ s/min} \quad [10]$$

VOL 12

6677

R0039985

where: t = Hydraulic residence time (min); t should be at least nine min, preferably, and no less than five min.

For swales, L should be at least 100 ft (30.38 m), a length below which flow short circuiting is more likely. If the length in a straight configuration cannot be fit to the site, investigate using a wide-radius curved path, reducing Q or changing the width and/or depth.

8. If flows larger than Q can enter the biofilter, the grass probably will be knocked over and provide no treatment until it becomes upright again. Therefore, flow regulation upstream or a bypass are recommended. If one of these measures is not provided, the velocity and depth with the largest flow rate must be calculated. If the velocity is above a level known to be erosive, the facility must be enlarged to accommodate it (use 3 ft/s maximum, if other information is lacking). The calculation procedure is standard and covered in open channel discussions in fluid mechanics texts, as well as in the previously cited report.

9. If the biofilter is a swale, once the maximum possible depth of flow is established, specify the swale's final depth. It should be at least 6 in (15.24 cm) deeper than the maximum possible flow depth.

Design Recommendations. The following features maximize the success in establishing biofilters and in their performance:

- Locate the biofilter away from building and tree shadows to avoid poor plant growth from lack of sunlight.
- If the longitudinal slope is less than 2 percent or the water table can reach the root zone of vegetation, plant water-resistant vegetation to survive standing water or install an underdrain system to assist drainage. However, underdrains may not be practical with a large filter strip.
- If the longitudinal slope is in the 4 to 6 percent range, provide check dams approximately every 50 to 100 ft (15.24 to 30.48 m) to reduce velocity. However, check dams may not be practical on a larger filter strip.
- If the slope on which a swale is installed exceeds 6 percent, place swale to traverse the slope so that no slopes reach more than 4 percent, or 6 percent with check dams.
- Make the lateral slope entirely uniform to avoid any tendency for the flow to channelize.
- Introduce the flow so that entrance velocity is dissipated quickly, flow is distributed uniformly, and erosion is avoided (e.g., by using a riprap pad or some means of level spreading).

Natural Wetlands

Wetlands naturally regulate both water quality and quantity. In recent years, natural wetlands have been used for both purposes, sometimes with engineering changes such as modified inflow and outlet structures. This practice has been legally uncertain, since wetlands are classified as "waters of the United States" under the Clean Water Act (CWA). Using such waters to transport and treat waste is generally prohibited. However, some interpretations of the CWA allow the practice under limited circumstances. EPA's policy is not to use natural wetlands to treat urban runoff. Of course, wetlands treat water by default when they happen to receive runoff from an urbanized watershed.

Therefore, some attention has been paid to managing wetlands receiving urban runoff to learn how negative impacts can be avoided or minimized. The Puget Sound Wetlands and Stormwater Management Research Program is a long-term (1986-1996) comprehensive effort to follow ecological developments in wetlands through the urbanization process and learn what causes degradation and how it might be avoided. The program has produced preliminary management guidelines (King County Resour. Plann. Sec. 1993), with continued refinement as more information becomes available. The following summary excerpts key guideline provisions. Specifics pertain to freshwater-palustrine wetlands in the Pacific Northwest, but these limits would likely be appropriate in similar communities.

Management Guidelines. Hallmarks are to

- Manage on a watershed or subbasin scale and context, so that the values of all water resources are considered and all alternatives for solving water quality and quantity problems are evaluated.
- Emphasize practices, such as source controls, that prevent the development of problems. Back up those approaches with measures that reduce the effects of problems before wetlands or other water

VOL 12

6678

resources are involved, such as pretreatments.

The guidelines are presented here as an example of a state strategy for managing wetlands. The guidelines, consistent with legal interpretations made by EPA Region 10 and the Washington Department of Ecology, state the conditions under which natural wetlands can be used for improving runoff quality:

- Situations must be analyzed case by case;
- Restoration or enhancement of a previously degraded wetland is warranted, and other wetland functions can be upgraded along with benefiting runoff water quality;
- Source control and treatment practices are applied in accordance with specific guideline recommendations, and any prevailing water quality standards are met; and
- The wetland is not one of certain rare or otherwise valuable types—estuarine, forested, peatland, or otherwise designated by recognized heritage and preservation programs—and does not provide habitat for rare, threatened, or endangered species.

The law is even less clear about the status of wetlands proposed for use only for runoff storage or incidentally affected by urban runoff. Of course, since all runoff contains contaminants, any distinction is artificial. Still, potential hydrologic effects are distinct from water quality impacts. In fact, the Puget Sound research has found that hydrologic change has more implications than water quality for wetland ecosystems where runoff is relatively low in pollutants. This program has devoted considerable effort to quantifying these hydrologic impacts—keying especially on plant and amphibian communities—and devising guidelines to overcome them. The following hydrologic guidelines specify limits on the wetland's hydroperiod—the depth (stage), frequency, duration, and pattern of inundation.

1. Depth limits—all wetlands, all year

Limit postdevelopment increase in annual maximum depth to 11.81 in (30 cm) (for 1.01-to-100-year return interval rainfall events).

Limit postdevelopment average monthly water level fluctuation (WLF) to

- An increase of 1.97 in (5 cm) if predevelopment WLF is greater than or equal to 5.9 in (15 cm);
- A maximum of 7.9 in (20 cm) if predevelopment WLF is less than 5.9 in (15 cm).

Note: WLF = Maximum depth – average depth in a time period.

2. Frequency and duration limits

These guidelines envision a fluctuating stage over time before development that could fluctuate more, both higher and lower; after development, these greater fluctuations are called "excursions." The guidelines set limits on the amount of the excursions and the total time, over one or more episodes, that can occur in a given period.

All wetlands—February 1 – May 31

- Limit postdevelopment stage excursions of up to 3.14 in (8 cm) above the predevelopment stage to a total duration of 24 hours in any 30-day period.

All wetlands—June 1 – September 30

- Limit postdevelopment stage excursions above or below the predevelopment stage to no more than 11.81 in (30 cm).
- Limit postdevelopment stage excursions of up to 5.9 in (15 cm) above or below the predevelopment stage to a total duration of 72 hours in any 30-day period.
- Limit postdevelopment increase or decrease in dry period—when pools dry down to the soil surface everywhere in the wetland—to two weeks.

Peat wetlands—bogs and fens (as more specifically defined by the Washington Department of Ecology)

- Limit postdevelopment stage excursions above the predevelopment stage of any amount to no more than once a year.
- Limit postdevelopment stage excursions of up to 5.9 in (15 cm) above or below the predevelopment stage to a total duration of 24 hours.

Forested wetlands and zones—wetlands or zones with at least 30 percent cover of trees at least 20 ft (6.1 m) tall

- Limit postdevelopment stage excursions of up to 7.9 in (20 cm) above the predevelopment stage to a total duration of 48 hours in any seven-day

VOL 12

6679

R0039987

period during March 1 to May 31 and to 96 hours over the full growing season, March 1 to August 31.

- Avoid sediment accumulation of more than 7.9 in (20 cm) in any year.

Sedge meadows—wetlands or zones with at least 20 percent cover by *Carex, Eleocharis, Scirpus*, and/or *Dilichium*

- Avoid sediment accumulation of more than 5.9 in (15 cm) in any year.

These guidelines are fairly complex to apply. Establishing predevelopment conditions requires either monitoring water levels or accurate hydrologic modeling. Postdevelopment conditions can only be established by predictive modeling. Monitoring need not be done with continuously recording instruments; simple crest-stage and staff gages are adequate. However, a continuous simulation by computer model is almost necessary for postdevelopment analysis.

The guidelines are also difficult to observe; peak runoff rate control alone is not enough, and total runoff volumes must also be controlled to prevent hydroperiod changes in a storage basin like a wetland. As pointed out in the previous discussion of quantity control, volume control is accomplished only through infiltrating excess runoff produced by urban landscapes.

Constructed Wetlands

Wetlands specifically constructed to capture pollutants from runoff draining urban and agricultural areas are gaining attention as versatile treatment options. Several major works have recently covered constructed wetland treatment, including Hammer (1989), Strecker et al. (1992), Olson (1992), and Schueler (1992). Horner (1992a) assembled a short course manual incorporating findings and recommendations from these various sources. This discussion draws on these resources and should provide a concise summary of the current state of urban runoff treatment by constructed wetlands and how to proceed in developing projects.

From a legal and regulatory standpoint, constructed wetlands are designed, built, and continuously maintained to treat waste. Thus, under the CWA they are not regarded as "waters of the United States." While no regulations control water quality within, discharge is regulated in the same way as any treatment system.

This designation contrasts with wetlands built for such purposes as mitigation of wetland losses under CWA section 404 or to develop waterfowl habitat, known as "created wetlands." These systems have the same legal protections as natural wetlands, including prohibition against conveying or treating waste. They usually have multiple functions, with water quality improvement only incidental; entering water must be managed to prevent damage to intended functions. A constructed wetland also differs in purpose and legal status from a wetland restoration, which returns a degraded system with reduced acreage or functional ability to the condition preceding its degradation. If the wetland is not completely restored but one or more functions are increased, it is termed an enhanced wetland. Restored and enhanced wetlands also have the same legal protections as natural wetlands.

The principal advantages of constructed wetlands over other treatments are

- More diversity in structure, which offers potential for relatively effective control of most pollutants;
- Wider range of potential side benefits;
- Relatively low maintenance costs; and
- Wider applicability and more reliable service than infiltration.

The disadvantages of constructed wetlands include

- Larger land requirements for equivalent service than wet ponds and other systems, especially if intended to serve quantity as well as quality control purposes;
- Relatively high construction costs;
- Delayed efficiency until plants are well established;
- Uncertainty in design, construction, and operating criteria is a drawback actually plaguing competitive methods as well; and
- Public concern about nuisances that can develop with runoff constructed wetlands if care is not taken in siting, design, construction, and operation.

Sizing Calculations and Expected Performance. Strecker et al. (1992), in a full literature review of both natural and constructed wetlands to control runoff pollution, considered more than 140 papers and reports and assembled detailed information on 18 U.S. locations. Median pollu-

VOL 12

5580

tant removals in constructed wetlands were 80.5 percent for total suspended solids (TSS), 44.5 percent for ammonia-nitrogen (NH_3-N), 58.0 percent for total phosphorus (TP), 83.0 percent for lead (Pb), and 42.0 percent for zinc (Zn). Coefficients of variation (ratio of the standard deviation to the mean) for these contaminants ranged from 27.7 to 56.1 percent, showing both substantially higher and lower performance than the median levels. Pollutant reductions in constructed wetlands overall were higher than in natural ones, attributed to the specific design features and more intensive management.

Schueler (1992) recommends wetlands designs based on the overall literature. He estimates the performance of wetlands designed as he recommends as shown in Table 8.6. He considers these efficiencies to be provisional pending monitoring of the new systems.

Table 8.6—Projected long-term pollutant removal rates for wetlands constructed.

POLLUTANT	REMOVAL RATE (%)[a]
TSS	75
TP	45[b]
TN	25[c]
BOD, COD, TOC	15
Pb	75
Zn	50
FC	2 orders of magnitude

[a] Lower by an unknown amount for pocket wetlands.
[b] 65 percent in pond/marsh system.
[c] 40 percent in pond/marsh system.
Source: Schueler, 1992.

Several ways to arrange constructed wetlands, based on runoff quality and quantity control requirements, are to

- Place a runoff quantity control device on-line and a constructed wetland off-line to treat all runoff up to a certain volume;
- Construct a wetland with a permanent pool zone for treatment and a fluctuating storage zone and discharge control sized for peak runoff rate control; and
- Construct a wetland only for treatment in situations where quantity control is not required.

The first arrangement benefits from the fact that most pollutant mass loading over time is transported by runoff from the more frequent, smaller storms, and the first flush from the less frequent, larger storms. This arrangement is recommended where runoff quantity control is required because (1) the relatively shallow depths needed to maintain wetlands are somewhat inconsistent with the large storage volume needed for quantity control, and (2) large surges of water can damage the wetland.

Basic sizing decisions involve the pool storage volume (V_P), surface area, depth contouring (plus fluctuating storage volume, if runoff quantity control will be provided)—the same dimensions required in sizing a wet pond. At this point, constructed wetland technology has established no procedures to determine volume based on desired performance efficiencies and pollutant removal mechanisms. Accordingly, pool storage volume should be sized the same for wet ponds (see previous explanation).

Schueler (1992) illustrates four design concepts to configure constructed wetlands in the Mid-Atlantic area. To establish the wetland surface area (A_W), start by selecting a trial mean depth (D) from the following approximate ranges (after Schueler, 1992):

Shallow marsh	0.30-0.45 m
Pond/marsh	0.60-0.85 m
Extended-detention wetland	
permanent pool	0.25-0.30 m
extended-detention zone	1.0 m
Pocket wetland	0.15-0.40 m

Using the trial mean depth, calculate surface area by $A_W = V_P/D$.

After determining satisfactory basic dimensions, allocate depths to the different wetland zones according to the design concept. Schueler (1992) recommends the following zones to obtain diversity in structure and treatment capabilities:

Deep areas —30-180 cm deep, no emergent vegetation—forebay, micropools, deep water pools and channels
Low marsh—15-30 cm below normal pool
High marsh—0-15 cm below normal pool
Irregularly inundated zone—above normal pool

Schueler also supplies approximate depth allocations for the various zones and design concepts.

VOL 12 6681

Design Recommendations. Identify and adopt a natural wetland that performs water quality control well and use it as a reference model. Natural wetlands control water quality because of their structure. Therefore, the elements of this natural structure must be recreated in a wetlands. Natural wetlands tend to have a more complex structure than do most runoff treatment systems. This complexity allows a range of mechanisms to operate and diverse pollutants to be treated. The result is relatively high efficiencies, compared to competing alternatives. Structural complexity can be created with high marsh peninsulas and islands.

A structurally complex system is more expensive and difficult to construct than a simple one. In some cases, we may need to dispense with a few features of an ideal system. In addition, a complex design may not be faithfully constructed. Therefore, design personnel should be in the field to interpret the design and guide construction.

A constructed wetland must have enough time to develop before it is put in full service. Attempts to short-circuit ecological processes by over-management will probably fail.

1. Site Selection

Evaluate a prospective site carefully before making a selection. Table 8.7 summarizes the major considerations that should be analyzed. While an analysis requires gathering significant data, it is essential.

A viable constructed wetlands depends on an adequate and steady water supply. A water budget should be carefully constructed to ensure that water is available and inputs at least balance outputs throughout the year:

$$I + P + D + S > O + E + R \qquad [11]$$

where:
- I = Surface inflow;
- P = Precipitation;
- D = Groundwater discharge;
- S = Wetland storage at beginning of calculation period;
- O = Surface outflow;
- E = Evapotranspiration; and
- R = Groundwater recharge.

(All units are in terms of volume or water depth over the wetland surface.)

Table 8.7—Considerations in selecting constructed wetlands sites.

CATEGORY	CONSIDERATIONS
Land use and general	Land availability Existing site use and value Site problems (e.g., previous dumping, utility lines) Adjacent land use and value Connection to wildlife corridors and potential for adjacent areas to be biological donors Public opinion Accessibility for construction and maintenance Ability to control public access according to project objectives
Environmental and regulatory	Federal, state, and local laws and regulations Avoidance of archaelogical and cultural resources Avoidance of critical wildlife habitat areas
Hydrology and water quality	Water supply reliability Low potential for disruptive flooding Water supply of adequate quality to sustain biota Low potential for adverse effects on downstream waterbodies and adjacent properties and their water supplies Need for lining to retain water or avoid groundwater contamination
Geology	Flat or gently sloped topography Adequate soil development Sufficient depth to bedrock Soil characteristics consistent with pollution control objectives Suitability of site materials for construction

Source: R.R. Horner.

VOL 12

6682

Estimate the water budget during site selection and check it after the preliminary design. In areas with pronounced seasonal drought (e.g., most of the western United States), calculate the balance for the dry period. Groundwater terms are difficult to establish, but a hydrogeologist familiar with the location should estimate them as closely as possible. Since natural wetlands often dry below the soil surface, permanent standing water is not necessarily needed to have a viable wetland. Washington State research has found that plant community richness declines substantially when drying extends longer than two months, compared to wetlands with shorter dry periods (Azous, 1991). Hence, the water balance should at least confirm that drying will not exceed two months.

2. Vegetation

Experience with wetlands creation, restoration, and construction projects shows that the plant community develops best when the soils harbor substantial vegetative roots, rhizomes, and seed banks. Development is enhanced when volunteer vegetation can enter from nearby donor sites. However, volunteers cannot be relied upon completely and should be supplemented by transplanting. While vigorous resident and volunteer stock may provide most of the vegetation, transplanting is still a wise strategy, as confirmed by most of the literature.

Hydric soils that contain vegetative plant material used to establish new wetlands are called wetland mulch. Ample use of this mulch enhances diversity and speeds plant establishment, but its content is somewhat unpredictable and donor sites are limited. Also, guidelines for extracting, handling, and storing the material are limited. In addition, exotic, opportunistic species might overtake more desirable natives—watch for this problem when obtaining material.

Potential donor sites include wetland soils removed during maintenance of highway ditches, swales, sedimentation ponds, retention/detention ponds, and clogged infiltration basins; during dredging; or from natural wetlands scheduled to be filled under permit—although these soils are best used for mitigating the loss. The upper 5.9 in (15 cm) of donor soils are best obtained at the end of the growing season and should be kept moist until installation. Establishing repositories for mulch reclaimed in maintenance operations is being explored. Despite the potential of wetland mulch and volunteer recruitment, transplanting is still the most reliable method and provides instant partial cover.

Wetland plant nurseries have sprung up recently in many places in the nation to provide material. The following list of general selection principles was compiled from Garbisch's (1986) recommendations for creating wetlands and from the comprehensive constructed wetlands literature:

- Base selections more on the prospects for success than on specific pollutant uptake capabilities. Plant uptake is an important mechanism only for nutrients, much of which are released upon the plants' death; nutrient removal is more the result of chemical and microbial processes than of plant uptake.
- Select native species; avoid natives that invade vigorously.
- Use a minimum of species adaptable to the various elevation zones; diversification will occur naturally.
- Select mostly perennial species; give priority to those that establish rapidly.
- Select species that are adaptable to the broadest ranges of depth, frequency, and duration of inundation (hydroperiod).
- Match the environmental requirements of plant selections to site conditions. Consider especially hydroperiod and light requirements.
- Give priority to species used successfully in constructed wetlands and commercially available species.
- Avoid specifying only species foraged by wildlife expected to use the site.
- Establish woody species to follow herbaceous species.
- Plant to achieve objectives other than pollution control.

Although selection based on pollution control capabilities is not recommended, considerable information on pollution control has been compiled. Kulzer's (1990) summary of plant capabilities for pollutant removal suggests that the most versatile genera, with species throughout the country, are *Carex*, *Scirpus*, *Juncus*, *Lemna*, and *Typha*.

VOL 12

6683

Specific guidance for constructing wetlands is contained in Schueler (1992) and for creating wetlands in Garbisch (1986). The course manual by Horner (1992a) also incorporates this guidance on constructed wetlands.

3. Design Features

While size alone does not guarantee good performance, adequate size is necessary. If the layout permits water to traverse the wetland too fast, the theoretical hydraulic residence provided by the volume will not be achieved. The following features will help keep the flow from short circuiting the wetland.

Shape and configuration

- Create at least two distinct cells by restricting the flow to a narrow passageway between high marsh features.
- Make the wetland relatively wide at the inlet to help distribute the flow.
- Maximize the distance between the inlet and outlet.
- The effective length-to-width ratio should preferably be 5:1, and 3:1 at a minimum.
- The longitudinal slope—parallel to the flow path—should be less than 1 percent.
- The wetland should be carefully constructed to have no lateral slope—perpendicular to the flow path—to avoid concentrating the flow in preferred channels, which reduces actual residence time and risks erosion.
- Side slopes should be gradual (e.g., 5:1 to 12:1, horizontal to vertical) as in natural wetlands. In no place should the side slope be greater than 3:1.

Forebay

- Specify a relatively deep (3.93 to 5.9 ft/ 1.2 to 1.8 m) zone placed where influent water discharges. This forebay traps coarse sediments, reduces incoming velocity, and helps to distribute runoff evenly over the marsh. The forebay should be a separate cell set aside by high marsh features.
- Provide maintenance access for heavy equipment (14.76 ft/4.5 m wide and maximum 5:1 slope) directly to the forebay. The forebay bed should be hardened to prevent disturbance during clean out.

Flow channeling

- Create sheet flow to the maximum extent possible.
- Where flow must be channeled, use multiple, meandering channels rather than a single straight one.
- Open water areas should be interspersed with marsh rather than connected along the flow path.
- Minimize velocity in channels to prevent erosion.

Outlet area

- Place a micropool 3.93 to 5.9 ft (1.2 to 1.8 m) deep at the outlet.
- Install a reverse-sloped pipe 11.81 in (30 cm) below the permanent pool elevation. This outlet design avoids the clogging characteristic of constructed wetlands (Schueler, 1992).
- Install a drain capable of dewatering the wetland in 24 hours to allow for maintenance. Control the drain with a lockable, adjustable gate valve. Place an upward-facing inverted elbow on the end of the drain to extend above the bottom sediments.

Soils

- Medium-fine textures—such as loams and silt loams—work best to establish plants, capture pollutants, retain surface water, and permit groundwater discharge.
- Circumneutral pH (approximately 6 to 8) works best to support microorganisms, insects, and other aquatic animals.
- A relatively high content of highly decomposed organics (muck) is favorable for plant and microorganism growth and metal and organic pollutant adsorption. Muck soils are better than peats (less decomposed organics), which produce somewhat acidic conditions, are low in plant nutrients, and offer plants relatively poor anchoring support.
- Vegetation becomes established more quickly and effectively in constructed wetlands when soils contain seed banks or rhizomes of obligate and facultative wetland plants. Obtain soils that offer these resources.

VOL 12 6684

R0039992

- Soil characteristics recommended for specific pollution control objectives are
  - *Control of metals*—high cation exchange capacity; and
  - *Control of phosphorus*— high exchangeable aluminum and/or iron.

Liner

- An impermeable liner is required when infiltration is too rapid to sustain permanent soil saturation, when there is a substantial potential of groundwater being contaminated by percolating runoff, or both. Infiltration losses are small at most sites with USDA SCS class B, C, and D soils. Also, sediment deposition is likely to seal the bottoms of constructed wetlands. Therefore, a liner will likely be needed only in class A soils.

Emergency spillway

- An emergency spillway is required when the wetland will be used for runoff quantity control and for any other situation in which runoff might enter from a larger storm than the largest storm the facility is sized to handle.

Buffer

- A buffer should be provided around the wetland both to separate the treatment area and the human community and, if wildlife habitat is an objective, to reduce the animals' exposure to light, humans, pets, and other factors.

- The minimum buffer width should be 26.25 ft (8 m), measured from the maximum water surface elevation, plus 16.4 ft (5 m) to the nearest structure.

- If possible, preserve existing forest in the buffer area. At least 75 percent of the buffer should be forested to repel geese and provide better protection and habitat.

Avoiding Problems

- Mosquitoes, a rare but potential problem, can be prevented with diverse habitats that support predatory insects. Mosquitofish (*Gambusia*) can control mosquitoes in permanent ponds, but use caution in introducing the fish in non-native areas. Check with the state fish and wildlife agency before taking any action.

- Avoid aesthetic problems by carefully establishing construction and with vegetation. The buffer and tall emergent vegetation conceal water level fluctuation, films on the water, and other factors.

- Constructed wetlands are inherently safer than deep ponds, but deep zones may still be a hazard to children. Avoid this danger by creating gradual side slopes, a shallow marsh safety bench (16.4 ft/5 m wide) where the toe of the side slope meets any deep pool, concealing outlet piping and locking access. Fencing should only be needed on the embankment above large outfalls.

- Discourage nuisance waterfowl by maintaining the buffer largely in forest (at least 75 percent) and avoiding turf grass around the wetland. Maintain a variety of depths, especially high marsh not favored by geese and mallards, and educate citizens by placing signs to discourage feeding.

- Undesirable plant monocultures can be limited through structural diversity and a range of depths, especially in shallow areas. Plant a diverse native selection shortly after constructing the wetland.

- Metals and organics in toxicant accumulations are tightly bound in sediments and do not become mobilized over long periods. However, maintenance creates the problem of spoils disposal. Spoils that pass hazardous waste tests can be safely land-applied or placed in a landfill (Schueler, 1992). Applying spoils on-site saves disposal costs.

Landscape Management

Landscape management (Schueler [1987] uses the term urban forestry) signifies such practices as preserving trees during construction, replanting trees, and landscaping helpful to urban runoff management. One aspect of landscape management, maintaining vegetated buffers adjacent to waterbodies, advances the principle of minimizing the impervious area directly connected (by "hard" drainage facilities) to receiving waters.

Areas established using landscape management techniques can produce runoff volumes 30 to 50 percent less than conventionally developed sites (Schueler, 1987). Evidence suggests that

VOL 12 5685

R0039993

even low density residential development can produce runoff rivaling impervious areas when lawns replace natural vegetation and topsoil is removed close to relatively impermeable underlying layers.

The effectiveness of vegetated areas in capturing pollutants depends on the water's residence time before it enters the receiving water. Buffers and other landscape management spaces are often too small to provide the nine-minute residence time specified in the earlier discussion of biofilters, considered a minimum for water quality control. Of course, landscape management can still provide significant benefits, even without the ideal residence time.

While a riparian buffer guidance handbook by Heraty (1993) also provides recommendations for landscape management forestry programs, complete guidance is not yet available.

Infiltration Practices

Infiltration is the only structural technique that reduces both the peak runoff rates and runoff volumes from urban development. Infiltration reduces contaminants in runoff when runoff percolates in a soil column in which physical and chemical mechanisms operate. Infiltration devices that receive runoff at the surface also treat water through plant uptake and processes in surface soils. Unfortunately, these practices have the highest failure rates among all alternatives. Success requires great care in site selection, design, operation, and maintenance. Types of infiltration devices are

- Infiltration basins, also known as retention ponds;
- Infiltration trenches;
- Perforated pipes;
- French drains, also termed downspout infiltration systems; and
- Porous pavements.

An infiltration basin (see Figure 14.10) impounds water in a surface pond until it infiltrates the soil. Excess runoff discharges on the surface. An infiltration trench receives runoff in a shallow excavated trench that has been backfilled with stone to form a below-grade reservoir. Water then enters the underlying subsoil according to its infiltration rate. A perforated pipe, or underground trench, distributes runoff into the subsoil. French drains, consisting of pervious material such as gravel, disseminate inflowing water into the surrounding soil. These drains are usually used in small-scale applications, such as roof drains from homes and other small buildings. Porous pavements permit precipitation to drain through coarse-graded concrete, asphalt, or specially cast paving blocks with a pervious opening. The coarse-graded pavements can be used on roads, although they are subject to clogging; paving blocks are appropriate only for paved areas with very light or no traffic.

Recent studies and observations have documented extensive infiltration system failures. Schueler et al. (1992), in reviewing Mid-Atlantic region reports, found that 50 to 100 percent of infiltration basins had failed within five years of construction; up to 50 percent had failed almost immediately. The five-year failure rates for trenches and porous pavements were approximately 50 and 75 percent, respectively. Overwhelmingly, clogging by sediments brought in with runoff caused the failure. Microorganism growths in poorly drained soils and oils in runoff can also cause failure (Horner and Horner, 1990). This poor operating experience led Schueler et al. (1992) to advise against using infiltration basins and porous pavements and to use trenches only with careful geotechnical investigations and aggressive pretreatment protection and maintenance.

A study in Washington's Puget Sound found that successful infiltration basins were built on deep to excessively drained soils and not near seasonal high water tables or low spots in drainage catchments (Klochak, 1992; Gaus, 1993; Hilding, 1993; Jacobson, 1993). However, these basins risk groundwater contamination because metals retention was little to none in one soil type and incomplete in two others (Gaus, 1993). Most instances of poor infiltration were caused by water tables rising too near the surface. Vegetation was apparently not associated with infiltration, although plants can filter pollution, aerate soil, and improve the appearance if maintained properly.

Soil is the most critical consideration in specifying infiltration systems. Systems are generally built in the native soil; but when native soil is inappropriate, a soil system can be constructed with media like sand, peat, or a combination.

Infiltration systems normally convey most runoff directly into the soil to eventually enter the groundwater. However, an underdrain system can be installed below the infiltration system to collect water that does not percolate well through a restrictive subsoil layer. After being collected, the water can be widely distributed to increase the percolation potential. If the grade permits, it can be discharged on the surface, after being treated while passing through the upper soils. Constructed soil systems usually require underdrains. While these systems could be considered filtration practices, this guide considers them under infiltration, reserving the filtration category for units constructed in boxes and generally having a conventional surface discharge.

The most crucial issues in using infiltration devices, in addition to soil suitability, are avoiding clogging and the potential to contaminate groundwater. Infiltration facilities should be constructed in medium textured soils. They are generally unsuitable for clay because of restricted percolation and gravel and coarse sands because of the risk of groundwater contamination, unless effective pretreatment is provided. An impermeable soil layer close to the surface may need to be penetrated. If the layer is too thick, underdrains, and possibly imported soil to provide sufficient treatment depth, may be required (Entranco Eng. 1989). As a minimum measure to prevent clogging, infiltration facilities should require a pretreatment device to settle larger solids and reject runoff from eroding construction sites.

Among the various runoff treatment options, only soil infiltration systems have been reliable in removing soluble phosphorus (Minton, 1987). This result likely applies to other relatively soluble pollutants as well. Reduction depends principally on how effectively the system prevents runoff from directly entering surface water. Reduction can be complete if surface effluent is absent and percolating water cannot get to surface water through interflow in the unsaturated zone or via rapid transit of groundwater in the saturated zone. In other circumstances, dissolved pollutant reduction is incomplete but is still higher than with any other treatment method.

Expected Performance

This manual classifies performance of soil infiltration systems as follows:

- Natural soil column infiltration basins, trenches, and perforated pipes with and without underdrains;
- Underdrained systems with selected filtration media—sand and peat-sand; and
- Porous pavements.

■ *Natural Soil Systems.* In a natural system without underdrains, the system's hydrology (directness of connection with surface water) determines how much runoff is captured and how efficient the treatment. Alternative design rules for infiltration basins and their estimated runoff reductions and pollutant removals (Schueler, 1987) are to store and infiltrate either (1) 0.5 in (1.27 cm) of runoff per impervious acre contributing, (2) the runoff resulting from a 1-inch rainfall event, or (3) the two-year frequency runoff volume. Table 8.8 estimates pollutant removals.

With the first rule, Schueler estimates that 40 to 50 percent of the runoff volume would be captured in the soil over the long term. This would rise to 65 to 75 percent with the second rule, depending on the soil and the amount of impervious area (the NURP database used to make the estimates

Table 8.8—Estimated long-term pollutant removal rates (percent) for infiltration basins.

POLLUTANT	SIZED BASED ON		
	0.5-IN RUNOFF/IMPERV. ACRE	RUNOFF FROM 1-IN RAIN	2-YEAR STORM RUNOFF VOLUME
Total suspended solids	75	90	99
Total phosphorus	50-55	60-70	65-75
Total nitrogen	45-55	55-60	60-70
Metals	75-80	85-90	95-99
Biochemical oxygen demand	70	80	90
Bacteria	75	90	98

Source: Schueler, 1987.

VOL 12 5687

R0039995

represents catchments with 11 to 27 percent imperviousness). The third rule would likely raise the degree of volume reduction to appropriately 90 percent. Schueler cites Maryland estimates that widespread application of the first or second rule would maintain summer baseflow levels within about 90 percent of predevelopment conditions.

In developing a management plan for phosphorus-limited Lake Sammamish, Washington, Entranco Engineers, Inc. (1989) estimated potential reduction of particulate phosphorus at 100 percent and soluble phosphorus in natural basins at 75 to 90 percent. Estimates for an underdrained system with 3 ft (0.91 m) of soil were 80 to 100 percent for total phosphorus and 50 to 85 percent for soluble phosphorus. These estimates are uncertain because backup data was lacking.

▮ *Underdrained Systems with Artificial Media.* A number of underdrained sand and peat-sand media configurations installed and tested differ in the layering of sand of various grain sizes, peat, and gravel. Meyer (1985) also proposes a layer of crushed limestone to precipitate phosphorus. Horner and Horner (1990) review design and performance considerations for a side-wall filter (in contrast to a basin draining through the bed) not yet built. These devices have only been extensively employed in Austin, Texas. Reported levels of pollutant reduction percentages were

Total suspended solids—60 to 80 percent;
Total phosphorus—20 to 90 percent, with most reports above 60 percent;
Nitrogen, soluble phosphorus—inconsistent in a sand-peat filter to 96 percent in a sand filter;
Metals—30 to 100 percent depending on metal and medium;
Chemical oxygen demand—40 to 90 percent;
Organics—inconsistent, but approximately 85 percent when operating well; and
Bacteria—40 to 100 percent.

In Bellevue, Washington, a large soil filter system draining to Lake Sammamish has recently been constructed to serve a housing development. The system—which includes pretreatment with catch basins, grass swales, oil/water separators, and detention—is expected to capture more than 99 percent of the total suspended solids, 50 to 95 percent of the phosphorus, and 90 to 95 percent of the copper in urban runoff from developed portions of the site (Diessner et al. 1991). The system's performance is now being monitored.

▮ *Porous Pavements.* Schueler (1987) distinguishes between porous pavements providing full and partial infiltration. The latter involves some type of collection system to drain surface runoff that cannot be infiltrated. Schueler estimates potential pollutant captures at 80 to 99 percent for total suspended solids, total nitrogen, chemical oxygen demand, zinc, and lead and 65 percent for phosphorus, although the actual capture would again depend on soil infiltration.

Denver's Urban Drainage and Flood Control District (1993) recommends only the modular block type of porous pavement system. The design, consisting of perforated concrete slab units underlain with gravel, is specified for use only in low traffic areas like airports, parking lanes, and driveways, and paved paths without traffic.

Site Selection, Sizing, and Design

Since all infiltration systems rely on the ability to discharge water through the soil or an equivalent artificial medium and have the same general problems, most design aspects are similar, except for media specifications for artificial systems. The following guidance is applicable to all types, with additional information on artificial media where necessary. Reference sources provide more specific detail.

▮ *Site Selection for Natural Soil Systems.* Needs differ, depending on whether the infiltration system is intended for quantity control alone or for quality and quantity control. While quantity control is best achieved with a rapid percolation rate, this rate could be too fast to provide sufficient contact with the soil for pollutant capture. If the runoff is quite contaminated, if the groundwater table is relatively close to the surface, or both, rapid percolation risks groundwater pollution. Therefore, the safest practices are to

- Specify a maximum and a minimum percolation rate to protect groundwater and attain pollutant capture objectives, or
- Require runoff pretreatment to meet water quality objectives before the pretreatment effluent is infiltrated for quantity control.

Infiltration authorities recommend the following criteria to reduce the substantial potential for failure, safeguard groundwater, and achieve the desired urban runoff management benefits:

- The bed of the infiltration facility should be at least 3 to 5 ft (0.91 to 1.52 m) from the

VOL 12 5688

R0039996

seasonal high water table, bedrock, or relatively impermeable soil layer (5 ft is conservative and warranted, unless seasonal water rise is carefully determined; 3 ft is minimum).

- With any application, the percolation rate should be at least 0.3 to 0.5 in/hr (0.76 to 1.27 cm/hr); 0.5 in/hr is conservative; 0.3 in/hr is minimum.
- With any application, the soil should not have more than 30 percent clay or more than 40 percent clay and silt combined (Wash. Dep. Ecol. 1992).
- When the infiltration facility will provide all runoff treatment (except perhaps presettling of solids) and when it will drain to groundwater (i.e., there are no underdrains), the percolation rate should not be greater than 2.4 in/hr (6.10 cm/hr) (Wash. Dep. Ecol. 1992). This, and the preceding guideline, effectively makes only loams, sandy loams, and loamy sands eligible for installing water quality infiltration systems.
- The facility should not be constructed in fill material or on a slope of greater than 15 percent.
- Baseflows should not enter infiltration facilities. The contributing catchment must be relatively small, or any permanent or intermittent flows must be diverted. Schueler et al. (1992) recommends that infiltration basins serve 2 to 15 acres (0.81 to 6.06 ha) and specified catchments be no larger than 5 acres (2.02 ha) to drain to trenches (Schueler, 1987).

Infiltration basins frequently lack good data on the soils and associated hydrogeology (Klochak, 1992; Gaus, 1993; Hilding, 1993; Jacobson, 1993). Using regional soil survey data is always very risky, and specific on-site soils investigation must be performed. Since infiltration generally occurs below the preconstruction grade level, soils and hydrogeologic observations and tests must be performed at the final grade level. Even measurement at a single location within the prospective facility location can be inadequate to characterize the soil and its new percolation rate. Hence, measurements should be repeated at several points. Finally, techniques often used to establish percolation rates (e.g., single-ring infiltrometers) have been found lacking—a double-ring device is an improvement. Standard percolation tests should also be performed in excavated holes.

Sizing Calculations. Several possible bases are used to size infiltration devices. One is to select one of Schueler's (1987) sizing rules and a maximum allowable drain time. Schueler recommends a maximum of 72 hours, except for 48 hours in marginal soils. The Washington Department of Ecology (1992) adheres to the latter time. Another way is an approach based on Darcy's law, which expresses flow through a porous medium. The resulting equations for the surface area (A_s) and infiltration system volume (V_i) are

$$A_s = V_r / f_d \cdot i \cdot t \qquad [12]$$

$$V_i = \text{Inflow rate} - \text{Outflow rate} = V_r - f_d \cdot i \cdot A_s \cdot t \qquad [13]$$

where:
- V_r = Design storm runoff volume (ft^3);
- f_d = Percolation rate (ft/hour = inch/hour/12);
- i = Hydraulic gradient (ft/ft) = $(h + L)/L$;
- h = Height of water over infiltration medium when full (ft);
- L = Depth to water table or impermeable layer from infiltration medium surface (ft); and
- t = Time to drain from full condition (hour).

The design runoff volume can be established as discussed for wet ponds. With the difficulty in getting good percolation rate values, the Washington Department of Ecology (1992) recommends a conservative approach of making several on-site measurements at the infiltration medium level, adopting the minimum of those rates, and multiplying by a safety factor of 0.5. Better measuring techniques would allow dispensing with such conservatism—or at least dropping the safety factor.

Design Recommendations. The following recommendations are important to avoid past failures of infiltration systems:

- Construction runoff should never be allowed to enter an infiltration device.
- Banks and other areas must be thoroughly stabilized to prevent erosion into the device.

VOL 12

6689

R0039997

- At a minimum, pretreatment should be used to capture most of the runoff solids directed to an infiltration device. A recommended arbitrary removal criterion is 80 percent of total suspended solids.

- The facility should be at least 50 ft (15.24 m) from any slope greater than 15 percent and at least 100 ft (30.48 m) upslope and 20 ft (6.1 m) downslope of any building.

- The outlet orifice design must be consistent with the infiltration capacity (e.g., to avoid collecting more water than can infiltrate in 48 hours).

- After final grading, the bed should be deeply tilled to provide a well-aerated, highly porous surface texture.

- Plant a basin with grasses appropriate for conditions, and maintain the grass for both performance and appearance.

- The guidelines for wet ponds—introduction of flow at low velocity and with uniform distribution, side slopes, the emergency overflow, and safety—also apply to infiltration basins.

- Since constructed artificial soil systems are in their infancy, the following guidelines are subject to further testing (Horner and Horner, 1990):

  - A layered media structure seems to perform best. Most common are three layers, each about 1 to 2 ft (0.30 to 0.61 m) thick, separated by filter fabric. The upper layers have generally been various textures of sand or peat-sand mixtures. A crushed limestone layer has also been used for phosphorus reduction and pH adjustment.
  - Fibric peat is preferred over sapric peat because of the latter's poor hydraulic conductivity.
  - Surround the underdrain pipe with gravel or crushed rock.

Inspection and maintenance are also important for failure-prone devices like infiltration systems. Chapter 14 provides inspection checklists and maintenance standards.

Filtration Practices

Sand Filters

Sand filter chambers, similar to those used for many years in potable water and industrial treatment, have recently been introduced in urban runoff management. They differ from those described under infiltration practices by being installed in a box and having a surface effluent, instead of being a soil amendment with an underdrain system. These units are most appropriate in less than 5-acre (2.02-ha), mostly impervious catchments.

Figure 8.6 illustrates a design (Shaver, in press) being installed in Delaware, Maryland, and Virginia that consists of a sedimentation chamber followed by a filtration chamber.

▌*Sizing Calculations and Expected Performance.* Design criteria are still under development. Shaver (in press) recommends sizing the sedimentation and filtration chambers each at 540 ft^3 (15.29 m^3) per contributing acre. He further recommends a surface area for each chamber of 360 ft^2 (33.45 m^3) per acre and a sand depth of at least 18 in (45.72 cm).

Based on monitoring of three similar systems in Austin, Texas, the following pollutant removal efficiencies percentages are expected (Shaver, in press):

Total suspended solids	75 to 87%
Total phosphorus	19 to 61%
Total nitrogen	31 to 44%
Ammonia-nitrogen	43 to 77%
Nitrate + nitrite-nitrogen	-79 to - 5%
Lead	71 to 88%
Zinc	49 to 82%
Copper	33 to 60%
Chemical oxygen demand	45 to 68%
Fecal coliform	36 to 37%

▌*Design Recommendations.* Shaver's (in press) additional recommendations are

- Restrict the drainage area for any one filter to 5 acres (2.02 ha), which should essentially all be impervious.

- Make the outfall pipe from the sand chamber no larger than 6 in (15.24 cm) outside diameter, so that a minimum of 12 in (30.48 cm) of sand covers it. If a larger conveyance is needed, use more than one pipe.

Figure 8.6—Sand filter design.

Leaf Compost Filters

W and H Pacific (1992) has developed and tested a leaf compost filter in the Portland, Oregon, area. Monitoring 13 storms showed influent event mean concentrations to be reduced, on the average, by the following:

Total suspended solids	95%
Turbidity	84%
Chemical oxygen demand	67%
Total phosphorus	41%
Total Kjeldahl nitrogen	56%
Nitrate-nitrogen	34%
Ammonia-nitrogen	42%
Zinc	88%
Copper	67%
Total petroleum hydrocarbons	87%

Soluble phosphorus consistently increased across the filter. Work is now underway to improve the medium's anionic exchange capability (Stewart, pers. commun.). The device has not been independently tested, nor have design criteria been published.

Catch Basin Filters

Fiberglass (MacPherson, 1992) and activated carbon (Hutter, pers. commun.) filters intended for small-scale installations (e.g., catch basins) have recently been introduced on the market. Neither has been independently tested, but MacPherson reported concentration reductions of 90 percent for total suspended solids, 87 percent for lead, 77 percent for zinc, and 86 percent for copper. Specific design criteria have not been issued, but the fiberglass filter has been tested in flows up to 1 cfs, and the activated carbon filter is specified for use up to 0.13 cfs.

Series Treatment Combinations

Any treatment practices previously discussed can be combined in series arrangements, or treatment trains. This takes advantage of the capabilities of each and creates redundancy to increase the probability of capturing pollutants. The effectiveness of such systems will not be additive, however, because the first device in the series will trap the fractions easiest to remove, making subsequent reduction harder. For example, if two practices can individually capture 50 percent of a pollutant, leaving 50 percent present, the overall efficiency of a series of the two is not likely to be $0.50 + 0.50 \cdot (1 - 0.50) = 0.75$. Horner (1992b)

VOL 12

6691

proposes an equation for the performance of a series of two devices:

$$E_s = 1 - X \cdot (1 - E_1) \cdot (1 - E_2) \quad [14]$$

where: E_s = Series efficiency (fraction pollutant remaining);
X = "Penalty" representing the performance reduction in the second device because of its harder removal task ($X > 1$);
E_1 = Efficiency of first device if alone; and
E_2 = Efficiency of second device if alone.

However, information was insufficient on series studies to establish X from actual data. Using this equation and an assumed $X = 1.25$, E_s for the previous example is 0.69 (69 percent) instead of 0.75.

The literature contained four performance studies of treatment trains. In one report—phosphorus removal—Meyer (1985) describes an infiltration basin design with a sand/crushed limestone underdrain filter coupled to a constructed wetland. He expected 90 percent removal of dissolved phosphorus, but no performance data have been found. Oberts and Osgood (1991) report on a detention pond that discharges into a series of six constructed wetland chambers. The system reduced total phosphorus by 79 percent and dissolved phosphorus by 57 percent in the pond, and an additional 32 and 15 percent, respectively, in the wetland. Overall system efficiencies—77 and 48 percent, respectively—were lower than the pond alone because of flows to the wetland that did not pass through the pond. The pond was believed to be so efficient because of well-distributed inflow, low-dissolved-to-total-phosphorus ratio, and phosphorus complexation by organics.

Wulliman et al. (1989) discusses a system consisting of a pond, wetland, and infiltration basin that was planned to split detention pond effluent between the wetland and infiltration basin. Modeling predicted overall 52 to 87 percent phosphorus reduction, but performance data have yet to be reported. Holler (1990) reports on a wet pond-filter (soil, limestone, and sand) system. The average wet pond reductions of both total phosphorus and orthophosphate-phosphorus were 77 percent, while the filter yielded orthophosphate and further reduced total phosphorus by only 16 percent, for an overall system total phosphorus efficiency of 85 percent.

CHAPTER 9

Industrial Activities Runoff Management

Several federal programs provide a basis for national urban runoff management. They are briefly summarized in the following paragraphs.

Clean Water Act

In 1972, amendments were made to the Federal Water Pollution Control Act, referred to as the Clean Water Act (CWA). These amendments prohibited the discharge of any pollutant to navigable waters from a point source, unless the discharge was authorized by a National Pollutant Discharge Elimination System (NPDES) permit. The program's initial thrust was to treat discharges of industrial process wastewater and municipal sewage. These discharges were easily identified and recognized as significant sources of receiving system degradation. With control of these discharges, attention has turned to the problems of other less visible pollution sources.

National Urban Runoff Program

From 1978 through 1983, EPA conducted a comprehensive study of urban runoff—the Nationwide Urban Runoff Program (NURP)— which provided a better understanding of the nature of urban pollutants from various urban land uses. It consisted of 28 projects conducted by local government agencies across the country under the review and coordination of EPA. NURP, a landmark effort, developed quantitative data on levels of pollutants generated from urban land uses. The study focused primarily on monitoring runoff from residential, commercial, and industrial land and clearly presents information on the magnitude and spectrum of pollutants encountered in the urban environment. The NURP study results are contained in three volumes; the executive summary (volume 1) should be required reading for individuals involved in stormwater management (U.S. Environ. Prot. Agency, 1983).

Water Quality Act of 1987

The 1987 amendments to the CWA, or the Water Quality Act of 1987, contains provisions that significantly increase efforts to address water quality in urban runoff. Section 319 created a state framework to address nonpoint source pollution not covered by NPDES permits. Section 402(p) expanded the existing NPDES program to include stormwater.

Section 402(p) lists five types of runoff discharges required to obtain a NPDES permit prior to October 1, 1992 (CFR November 16, 1990, issue):

- A discharge related to a permit issued prior to February 4, 1987;
- A discharge associated with industrial activity;
- A discharge from a municipal separate storm sewer system serving a population of 250,000 or more;
- A discharge from a municipal separate storm sewer system serving a population of 100,000 or more but less than 250,000; or
- A discharge determined by the EPA administrator or a state to violate a water quality standard or significantly contribute pollutants to U.S. waters.

In addition to these activities, the 1987 CWA amendments require EPA to develop regulations governing runoff from additional sources. The five listed items are commonly called Phase 1 of the NPDES stormwater program. Additional sources will be addressed under Phase 2, which have not yet been finalized.

VOL 12

6695

VOL 12

November 16, 1990, Rule

On November 16, 1990, EPA issued permit application requirements for stormwater discharges associated with industrial activities. The regulations identify 11 industrial categories (EPA Region 3 Pollution Prevention Plan Development Workshop) which include

- Heavy manufacturing
- Light manufacturing
- Light industries (only through exposure of material or products to runoff)
- Recycling facilities
- Transportation facilities (vehicle maintenance, equipment cleaning, airport deicing)
- Construction projects (over 5 acres [2.023 ha] in size)
- Steam electric power generating stations
- Hazardous waste treatment, storage, and disposal facilities
- Mining/oil and gas

Design Considerations

The industrial activity category *excludes* from NPDES requirements runoff drained from areas located on industrial lands that are separate from the plant's industrial activities, such as office buildings and accompanying parking lots, *as long as that drainage is not mixed with runoff from industrial areas.* Most older industrial sites, by the nature of their drainage systems, will have mixed runoff. Industrial activity includes only runoff discharges from all areas where material handling equipment or activities, raw materials, intermediate products, final products, waste materials, by-products, or industrial machinery are exposed to runoff.

Permit Application Requirements

To obtain an application for an NPDES permit required for industrial activities, the following information must be prepared for individual permits. Group applications or industry-specific general permits may have different requirements. Contact individual states or EPA regions for specific requirements.

- A site map indicating drainage areas served by outfalls, drainage and discharge structures, paved areas, buildings, storage areas, structural control measures to reduce pollutants, materials loading, and access areas.
- An estimate of the impervious surface area, the total area drained by each outfall, and materials treated within the last three years.
- A certification that all outfalls that should contain runoff discharges from industrial activity have been tested or evaluated for the presence of nonstormwater discharges. This can be accomplished through
  - Visual inspection of storm drain inlets and outfalls—flow observations, stains, sludges, or other unexpected conditions;
  - Review and validation of pipe locations, connections, and flow directions from available construction plans, which must be field verified;
  - Dye tests to identify flow direction, since many situations, particularly older plants where drainage systems have been gradually added or replaced, will not have accurate plans and storm drain inlets; and
  - TV line surveys where illicit connections are suspected but their sources cannot be discovered.
- Existing information regarding significant leaks or spills of toxic or hazardous pollutants at the facility within the past three years.
- Quantitative data based on samples collected during storm events including
  - Total suspended solids
  - Total dissolved solids
  - COD
  - BOD_5
  - Oil and grease
  - Fecal coliform
  - Fecal streptococcus
  - pH
  - Total Kjeldahl nitrogen
  - Nitrate plus nitrite
  - Dissolved phosphorus
  - Total ammonia plus organic nitrogen
  - Total phosphorus

6596

R0040004

Pollution Prevention Plan

A pollution prevention plan is required in EPA's stormwater general permits and has been incorporated within most state general permits. The pollution prevention concept is also appropriate for individual permits and can include efforts relating to all phases of site use. Essential components of a pollution prevention plan are as follows:

- **Reduction of pollutants at the source.** Areas that can be expected to generate waste can include
  - Vehicle or equipment fueling areas
  - Vehicle and equipment maintenance areas
  - Painting operations
  - Vehicle and equipment washing
  - Loading and unloading areas
  - Aboveground liquid storage tanks
  - Industrial waste management areas and outside manufacturing
  - Outside storage of raw materials, by-products, and others
  - Salt storage facilities

  These areas should be individually inspected and considered for actions or modifications to existing plant operation to reduce their pollutant contribution. An example of effective control of waste generation can be as simple as covering the activity so the material does not mix with rainfall and run into the storm drainage system. During an inspection, check the following items:
  - Corroded drums or drums with plugs or openings (potential to fill with rain water and overflow)
  - Corroded or damaged tanks, tank supports, and tank drains
  - Torn bags or bags exposed to rain water
  - Corroded or leaking pipes
  - Leaking or improperly closed valves and valve fittings
  - Leaking pumps and hose connections
  - Broken or cracked dikes, walls, or other physical barriers designed to prevent stormwater from reaching stored materials
  - Windblown dry chemicals
  - Improperly maintained or overloaded dry chemical conveying systems

- **Recycling.** All of the following materials may be recycled either at the industrial facility or sent off-site for recycling:
  - Spent solvents
  - Paint thinner
  - Degreasers
  - Used oil/oil filters
  - Antifreeze
  - Cleaning solutions
  - Automotive batteries
  - Hydraulic fluid

- **Treatment of runoff.** This category includes segregating the activity to prevent runoff from draining untreated into a storm drain inlet. Segregation may be accomplished by installing a berm to prevent untreated flow into a storm drain or divert the flow into a runoff control practice. A berm alone is not adequate, however, unless evaporation is greater than rainfall. Otherwise the bermed area must have an outlet structure to drain the accumulated runoff. In these situations, use visual and possibly chemical analysis to determine if a controlled release will provide for water quality protection. The specific industrial activity may require using structural water quality controls. Controls include the following:
  - Detention basins—extended detention both dry and wet
  - Infiltration practices —use caution to prevent groundwater contamination
  - Filtration practices

- **Disposal through approved method.** Use this category when other options are unavailable or impractical. For example, in an area with water quality problems, dispose of runoff through the sanitary system. However, consider these points:
  - Temporary storage of the runoff until the sanitary system can accept the flow;
  - The nature of the pollutant being discharged into the sanitary system; and
  - Whether the wastewater treatment plant can accept and treat the pollutant being discharged.

Historical Problem Areas

Episodic Nature

The episodic nature of runoff presents a unique problem in addressing water quality concerns through the historic NPDES approach. In that program, outfalls have a controlled rate of discharge so monitoring and sample analysis is consistent. Urban runoff is generated by rainfall, which is variable in volume, time, intensity, duration, and direction. The episodic nature of rainfall presents problems in considering a specific site. The existing drainage system's capacity may be limited for larger storms and may cause backed up runoff to flow into an adjacent system or to flow overland off-site. To determine the level of storm the system can accommodate, the existing conveyance system must be evaluated.

Another problem with urban runoff versus the historic NPDES program involves monitoring. Because runoff does not always occur at a convenient time, collecting the samples at the appropriate time may be difficult. Results will also depend on the dry period between storms when pollutants accumulate. The longer a dry period lasts, the greater the potential for water quality problems in the initial runoff.

Other Pollutant Sources

The problems associated with historic point source discharges are fairly well understood. Less recognized is how pollutants from urban sources affect the quality of urban runoff. Pollutants that are generated from various land uses are described in Chapter 2.

One possible major source of pollutants is atmospheric deposition from wind blown or borne particulate or materials—often from adjacent properties. Another possible means of pollution mobilization is acid rain, which mobilizes metal contacts. One of the studies referenced in the NURP final report, the study on the Jones Falls watershed in Baltimore, Maryland, documented this concern. Watershed monitoring showed elevated levels of copper, possibly from copper downspouts of most area homes mobilized by acid rain. In Alexandria, Virginia, rain gages near the Capitol Beltway demonstrated a linear relationship of high acidity from fossil fuel combustion by automobiles (Warren Bell, city engineer, personal communication). In many areas of the United States, nitrogen is a major pollutant. Excess nitrogen in rainfall contributes to elevated levels of nitrates or runoff acidity.

Another pollutant source is from specific industrial activities. One electrical generating site in Maryland currently uses fuel oil. The operation is relatively clean; however, significant coal dust covers the state from previous coal use. The runoff pH is very acidic and can mobilize available pollutants (e.g., metals).

Another significant pollution source relates to disturbed areas or areas without ground cover. Many industrial sites have large areas of bare dirt caused by neglect or high traffic volume. This dirt is transported in urban runoff. In one plant, suspended solids loading in monitored outfall was due to general site instability from a lack of effective ground cover.

Age of the System

In many older industrial sites, storm drain pipe systems are undocumented, undersized, partially crushed or rusted, have unknown gradients, or the present plant staff is unaware of the system's location. Flow drainage areas, pipe capacities, and runoff flow path that exceeds the existing pipe system can all cause water quality problems.

In addition, the slope of overland flow may not be in the same direction as pipe flow. Generally, the NPDES permit requirements do not consider the size and flow capacity of the runoff drain system in conjunction with its drainage areas and how frequent the system is bypassed by larger runoff flows. This situation may result in significant discharges at locations where flow is not expected. Situations like these need to be carefully examined for modernization.

Lack of Site Space

Many small industrial sites are surrounded by existing development that could limit structural water quality control practices. These sites may have difficulty installing structural controls. The following section considers this problem. In many industrial sites with limited space, existing storm drains flow into or across the property from adjacent industrial sites. Runoff control problems are compounded when extraneous flows with degraded water quality are considered.

Recommended Approach

Many EPA documents discuss in detail individual site analysis for pollution prevention and rank an approach for dealing with a problem, regardless

VOL 12

6598

R0040006

of size of the site. The individual industry also can adopt a proactive approach with master planning. This approach involves determining the system's ability to convey runoff flows and its flow capacity. All land areas contributing urban runoff should be identified, including off-site areas draining onto the property. An accurate site elevation plan should be generated since visual inspection, often provided under the NPDES requirements, may be inaccurate.

After completing the inventory of drainage areas, identify the complete storm drain system along with pipe sizes, slopes, inverts, and inlet sizes. Gathering this information often necessitates walking the entire site, since many older sites have poor drainage system records.

The inventory should detail the existing land use, including pervious areas along with their cover conditions. Identify soils through the appropriate USDA SCS soil survey and conduct a hydrologic study, using local rainfall data, to determine the runoff rates and volumes for various storm conditions. Since storm drain systems are normally designed to handle peak runoff from a 10-year storm, consider initial storms in the 2-, 5-, and 10-year range to estimate storm drain capability.

Ideally, a geographic information system can incorporate information identified through these initial steps and future site intentions or actual modifications. This allows the plan to evolve along with site use. A GIS system is a valuable tool for any industry expanding or modifying a site, since alternative scenarios can be considered.

After delineating existing site information, consider consolidating outfalls to minimize monitoring requirements. Older sites often allow outfall consolidation with little site modification. Available analytical techniques can compute typical pollutant loadings for similar urban areas to ascertain expected pollutant types. This analysis, in addition to gaining information on potential sources of pollutant loads from the pollution prevention plan, is important if outfall water quality sampling necessitates additional structural control practices.

With the final site plan and an estimate of runoff rates, volumes, and quality at various outfall points, alternative water quality control practices can be considered, especially if monitoring data necessitates additional site control. Water quality estimates and site characteristics provide some guidance on the type of runoff practice appropriate for a specific drainage outfall. Therefore, a preliminary estimate of the type of practice for a given area and a rough estimate of the practice size can be developed and placed on the master plan.

Areal extents of possible management areas are important if future site expansion or modification is intended. Identify potential runoff management areas to reserve in case future management measures are necessary. If those areas are not reserved through the master plan, the industry may have difficulty complying with future regulatory requirements. Master site planning also assists the industry in making other land use decisions.

Programmatic Considerations

Permits

The NPDES stormwater program for most nonstorm use discharges does not necessarily fit the traditional point source compliance approach. The nationwide approach has been to rely on general permits so that permitting authorities can handle the large number of additional permits necessitated by the 1987 CWA amendments.

Issuing general permits is appropriate to initially implement the program and also can be part of municipal NPDES stormwater permits. But states should recognize that this program requires a long-term commitment. Eventually, state representatives should visit each site covered by an NPDES stormwater permit, evaluate its approach to site control, and determine if the pollution prevention plan provides adequate site control. Under permit authority and municipal stormwater regulations, industrial sites need to be visited initially by technical staff, probably an engineer, to evaluate the pollution prevention plan's technical merits. If the plan is adequate, an inspector can make follow-up site visits. These inspections should be conducted annually to ensure that control measures are a continual part of the site operation. Permitting is not the end result of the program—therefore, site monitoring is essential for program success.

Enforcement

To emphasize the program's importance to the regulated community, enforcement mechanisms must be in place and functioning. Since the NPDES program relies on issuing permits, the regulated community must recognize its responsibilities under the law. Enforcement procedures must

VOL 12

6699

R0040007

be developed, circulated to the regulated industries, and implemented.

These procedures should be simply stated and have graduated, progressive enforcement. They should spell out state and federal legal authorities and enforcement options, including penalties provided by the CWA.

Staffing

The NPDES should have at least two, and ideally three, separate functions in addition to typically regulatory functions (data entry, program management, support). Functions include technical assistance and runoff strategy review, periodic inspections, and educating the regulated community about pollution prevention strategies, approaches, and practices. An understanding and awareness of the types of practices will increase industry's willingness to implement those practices. Functions vary in their staffing needs, depending on the number of industries needing NPDES permits. While many states have assigned only one staff member to implement the entire program, that is not nearly adequate to ensure proper program implementation.

Technical assistance must be provided by staff trained in runoff management and pollution prevention. Ideally, assistance should come from engineers trained to review and guide the industry in the structural and hydrologic aspects of specific designs. The engineer must know pollution prevention strategies, from source reduction and recycling to individual runoff management practices, along with their strengths and limitations. This professional should also conduct workshops for industry representatives and design consultants on effective on-site water quality control. Since the industry is not required to submit pollution prevention plans for review, an engineer or technician should visit individual sites to ensure that the plans have been adequately developed and implemented.

Once a pollution prevention plan is endorsed, an inspector can make subsequent inspections. Again, the number of inspectors is determined by the number of sites to be visited. Inspections made periodically ensure that the pollution prevention plan is implemented and the structural controls are maintained and functioning. Periodic inspections remind the industry to operate the program as long as the site is being used.

Education, a factor frequently ignored, is important to the program's success. Education ensures that everyone involved understands the program's underlying rationale and uses acceptable approaches and design standards. Education also ensures communication between industry and the regulatory agencies and reduces the we/they mindset. Education of adjacent property owners may also improve communication and awareness of pollution prevention activities that an industry is undertaking. If resources are limited, education should be the single most important function emphasized.

Example Site

Delmarva Power and Light, an industrial site in Maryland, determined that a runoff management master plan would assist its efforts to comply with NPDES requirements and in overall site development.

The site, an existing electrical generating facility called the Vienna Power Plant, covered approximately 25 acres (10.11 ha) and had eight large stormwater outfalls covered under NPDES permits. Some 8 acres (3.24 ha) of bare soil contributed dramatically to the suspended solids loading.

The site's master plan presented expected loadings for various pollutants under existing site conditions. New design plans reduced outfalls to four. The plans also recommended site stabilization and runoff management practices for the proposed outfalls, in case pollutant discharges necessitated implementing practices. Pollutant loadings with runoff management practices were also developed so that the site owners could understand the expectations of water quality control versus existing conditions. Table 9.1 demonstrates the results.

Total output of sediments is estimated at approximately 125,000 lb (56,700 kg) per year. After planting vegetation, the concentration of suspended sediments and the total amount of runoff was significantly reduced, resulting in an annual sediment load of approximately 29,000 lb (13,154 kg). Erosion from the site has thus been reduced by about 96,000 lb (43,546 kg) per year. Implementation of on-site runoff controls could further reduce the suspended solids output by another 10,000 lb (4,536 kg). Site stabilization from permanent runoff quality controls represents a significant reduction in the site's pollutant export.

The outfall areas were prioritized for runoff quality control, with site stabilization the highest

Table 9.1—Annual pollutant loads (in pounds).

priority. Individual outfalls and the areas draining to them were considered for additional runoff management. One area that had consolidated four original outfall points is being treated by a constructed wetland to ensure reduced pollutant discharge. Management controls have been designed for other outfall points in case monitoring requires additional controls. While these practices may never be needed, the owner has set aside areas for possible use as vegetated swales, infiltration trenches, or sand filter systems.

The master plan development cost $42,000, including detailed design plans for the constructed wetland.

VOL 12

CHAPTER 10

Governmental Strategies for Urban Runoff

The first part of this manual discusses urban runoff management problems caused by changes in land use. Problems include changes in hydrology, erosion and sedimentation processes, and the nature and amount of materials that runoff picks up from the land surface and conveys downstream. State and local governments have implemented a variety of programs to address these problems. Programs have traditionally focused on preventing or minimizing flooding to protect homes, buildings, property, and lives of citizens. Consequently, drainage ordinances and programs have been established just about everywhere.

Part II covers institutional approaches to prevent, mitigate, or correct runoff problems. No single solution or institutional framework is recommended to solve runoff problems around the country. Flexibility is needed to establish or refine programs, based on the area's existing legal authorities and institutional framework. However, no matter what a state or local government chooses to implement, it should consider certain issues or program components. As runoff management program objectives are broadened beyond the traditional drainage focus to encompass water quality protection, runoff reuse, and open space/recreation, existing programs must evolve and become more comprehensive.

Establishing Runoff Management Strategies

Program Goals

The goals of a runoff management program must be established when the program is initiated. Until recently, this was easy since programs typically dealt only with runoff quantity problems. Since the traditional focus has been on draining runoff away from improved property as quickly as possible, runoff management has been referred to as "drainage." The increasing awareness of runoff quality problems by citizens and elected officials and Clean Water Act requirements has forced state and local governments to broaden runoff goals. Today, program goals should include quantity, quality, erosion prevention and sediment control, good aesthetic values, runoff reuse, and open space/recreation.

Even the goals of runoff quantity management are changing. This broadening includes control of both peak discharge rate and volume, especially in closed basins and for discharges to estuaries. Peak discharge control, which limits postdevelopment discharges to predevelopment levels, is evolving from control of a single design storm to several design storms. To prevent stream channel erosion, controlling the peak discharge from a two-year, 24-hour design storm is becoming more common, along with controlling the peak discharge for flood control purposes, usually a 10-, 25-, or 100-year design storm. Some runoff management entities, such as the Suwannee River Water Management District and the Florida Department of Transportation, are requiring control of the critical storm. This storm creates the biggest difference between predevelopment and post-development peak discharge rates and/or volume. Analysis of design storms—ranging from a one-year, one-hour storm to a 100-year, 24-hour

6704

design storm—is required to determine the critical storm.

Another consideration of a runoff management program is whether it minimizes runoff problems from new development, corrects runoff problems caused by existing development and land uses, or both. While most programs address both goals, priority and allocation of resource decisions must be made to address each problem.

The program's philosophy is determined by which goals it addresses and in what priority. The two basic philosophies of runoff management are prevention and cure. Preventing runoff problems rather than trying to cure them is easier, less expensive, and more effective. Unfortunately, runoff frequently is the "orphan infrastructure," and few resources are devoted to runoff management until some type of crisis—usually flooding with property damage and even injury or death—occurs. Even then, these problems often are corrected with quick fixes that may actually contribute to or worsen problems downstream. As a result, local governments and other providers are spending most of their efforts curing rather than preventing. Chapters 11, 13, 15, and 16 discuss aspects of this topic in more detail.

Program Tools

Urban runoff management uses many tools to prevent or correct problems. Additionally, its broadening objectives are producing new tools and refining existing ones. The program's goals play a major role in selecting the appropriate tools.

Runoff tools can be separated into two types—nonstructural and structural controls. Nonstructural controls help prevent runoff problems, while structural controls help mitigate the problems. Until now, most runoff programs have focused on flood control and relied on structural controls. Additionally, several nonstructural controls require changes in property—e.g., growth management, land use planning, zoning—often a controversial topic. Nonstructural controls include source controls that limit the types and amounts of pollutants in runoff. Many of these involve controlling or modifying certain aspects of human behavior such as using fertilizers, pesticides, or household cleaners. These controls, too, are highly controversial.

In broadening runoff management goals, structural controls often require reconsidering the usual BMP design, less emphasis and use of certain practices, and changing preferred alternatives. To improve pollutant removal, detention ponds must be changed to increase residence time and minimize short-circuiting, and shallow littoral zones planted with appropriate native wetland plants. Dry detention, used widely for flood control, provides little pollutant removal benefits because of its short detention time, bottom discharge control, and paved channels. In many locations, codes require that street curbs and gutters be used with storm sewers to eliminate runoff ponding, even for short time periods. Many localities are eliminating this requirement to promote infiltration, decrease runoff volume, and improve pollutant removal. Localities are promoting the use of roadside vegetated swales, especially in low-medium density residential areas.

Another consideration is how runoff controls are combined and integrated into a development. Increasing emphasis is being placed on the "treatment train" concept, in which several types of runoff controls are used together and integrated into a comprehensive management system. This is especially true when a project uses a wet detention pond as the primary control but promotes it as a visual and recreational amenity. To help prevent the wet pond from turning into an eyesore, swales rather than storm sewers can be used, and vegetated littoral zones added. Increasingly, small off-line depressional storage areas are being integrated into site plans, usually as part of the site's required open space and landscaping. Chapters 7, 8, 12, and 14 discuss these topics in more detail.

Program Approaches

Runoff management has two primary approaches:

- The on-site, piecemeal approach; and
- The comprehensive watershed approach.

Program goals determine which approach a state or local government selects. Selecting an approach also depends on the types of tools to be used to prevent or solve runoff problems. Finally, selection depends on the political will of elected officials and their financial commitment to the program. The piecemeal approach, the most widely used, is typically preferred when a program

- Is single-goal oriented, especially if it focuses on flood control;
- Is aimed at managing runoff from new development;

- Is oriented primarily on structural controls;
- Is preventable in nature, especially from new development; or
- Regarding the impacts of new development, has limited financial resources that prevent it from developing a runoff master plan.

The watershed approach, which is gaining popularity, is preferred when a program

- Is multiple-goal oriented;
- Is aimed at curing existing runoff problems;
- Is oriented toward using nonstructural controls; or
- Has adequate financial resources, usually from a dedicated funding source such as a runoff utility.

Many programs around the country begin with a piecemeal approach and evolve into a watershed approach. While reasons for this evolution vary tremendously, it is often related to citizen pressure or changes in state or federal statutory or regulatory requirements, such as

- Increasing attention and pressure to reduce the water quality impacts of runoff discharges;
- Downstream flooding caused by the random location of numerous on-site systems;
- Reducing costs by promoting the use of nonstructural controls; or
- Recognizing the relationship between land use changes and stormwater problems.

Chapters 11, 12, 13, 15, and 16 discuss these topics in more depth.

Common Aspects of a Runoff Program

Establishing an urban runoff management program typically includes considering and resolving a number of needs or program elements.

Legal Authority

The program must have adequate state and local legal authority to accomplish its mission and use all its tools. Runoff programs generally protect the public's health, safety, and welfare. However, authority is needed to create, adopt, and enforce ordinances and regulations. Provisions must be made to establish performance standards and associated design criteria for various control measures. The state should grant statutory authority for local entities to set up dedicated funding sources, such as a runoff utility.

Administration

Administration is a major component of a runoff program, with its organizational location a key consideration. A number of other questions must be answered. Will the program be part of the state's environmental or water agency? Within the agency, will the program be a distinct entity or part of a larger program, such as wetland and floodplain management? What relationship does the runoff program have to the NPDES or the nonpoint source program? Locally, will the program be a distinct entity or part of public works or streets and drainage? Will its maintenance be the responsibility of a runoff utility, public works, streets and drainage, or parks and recreation?

Another administration consideration concerns the program's function. Will the program have separate administrative, planning, permitting, engineering, and operation/maintenance groups? Who will evaluate and monitor the system's performance? Who will manage program finances and legal needs? Who will conduct public education programs?

Planning

Effective runoff services and infrastructure should not be haphazard—often the normal method of operation. Planning is an essential program element to maximize cost-effectiveness and help meet goals. A runoff master plan based on a community's land use plan should be developed to provide a long-term map for capital improvement and operation/maintenance needs, particularly when addressing both runoff quantity and quality. Typically, a runoff plan covers a 20-year period and is broken down into five-year phases. Developing a plan helps determine the capital improvement costs, provides an implementation schedule, and identifies funding needs.

Capital Improvements

Designing and constructing runoff conveyances, storage, and treatment facilities is expensive, especially without a long-term plan. Engineering

VOL 12 5706

R0040014

expertise is essential. More and more frequently, runoff programs have interdisciplinary staffs of planners, modelers, biologists, and landscape architects. Decisions must be made about whether to maintain this expertise in-house or rely on outside consultants. Regional facilities should meet additional needs such as open space, recreation, and public education.

Operation and Maintenance

For maximum benefits, structural controls must be properly maintained and operated. Policy questions include whether a local government should accept ownership of runoff facilities, especially for residential development; which facilities to own (e.g., those that provide service for both private and public lands); and, if ownership is not accepted, how to assure that systems are maintained and operated properly. In deciding whether to accept ownership of a runoff system, a local government must consider the type of facility and its maintenance needs. Today, development projects often incorporate runoff systems as green space or landscaping. Such areas need extensive, regular maintenance such as mowing to keep them aesthetically pleasing. In such cases, the local government must determine whether it wants to be subject to citizen complaints about the site's appearance.

Another consideration is how to handle material removed from runoff conveyances, especially runoff treatment systems. One question is whether such substances are considered hazardous or toxic waste. Tests performed on these materials generally indicate that they are not hazardous or toxic waste, so waste can be used for landfill cover. However, some very specialized runoff controls, such as oil/grease separators, may contain materials requiring special disposal.

Regulation

Generally, a runoff program includes regulations and a permitting program. Local governments must decide if the legal expertise required to develop, interpret, and enforce regulations should exist within the program or in another area. Permitting programs require staff with good public communication and interaction skills plus excellent, broad-based technical skills. Staff must apply and interpret complex technical rules and review site plans that will raise land use planning, hydrology, soils, geology, and engineering concerns. The site must be inspected regularly to assure that permit conditions are being met. Enforcement must be a priority to assure that regulations are followed. Enforcement can include many tools including stop work orders, administrative fines or tickets, and even prison. Governments must decide if enforcement will be conducted by general program staff or by specialized law enforcement personnel.

Monitoring and Evaluation

Regular evaluation procedures help determine whether the program is achieving its goals and being administered in an efficient, cost-effective manner. Procedures can include actual environmental monitoring such as water chemistry, biological communities, and sediment chemistry. Monitoring program objectives must be clearly decided when initiating the program. Decisions must be made about whether monitoring will be part of the runoff program or whether another agency or government will perform these tasks. Regular administration evaluations assure that regulated parties are treated consistently, equitably, and efficiently.

Education Programs

Since everyone who lives or works in a watershed contributes to its runoff problems, governments must undertake public education programs. Programs should be directed at the regulated community to help it understand the regulations and to increase compliance and efficiency in the permitting process. Plan reviewers, inspectors, designers, and contractors may need special training, and even certification programs. Education programs can often be conducted with professional associations such as the state engineering society, state bar, or general contractors association.

Educating the public about runoff programs, their purposes, and how every citizen must be a part of the solution is a crucial and continuing need. Citizens must understand how everyday activities contribute to runoff problems. Simple pamphlets inserted into utility bills, booklets, videos, and displays at local events have been used successfully. Special programs such as "stream (lake, bay) watch," "adopt-a-stream (lake, bay)," and "eco-neighborhoods" are proving successful in encouraging citizens to buy into programs. Youth group involvement in programs such as storm sewer stenciling is also highly effective.

VOL 12

6707

Technical Assistance

Runoff and watershed management programs rely on cooperation from many levels of government, the private sector, and citizens. As runoff programs become more comprehensive, new and complex problems arise. States and local governments need to provide technical assistance and take advantage of technical assistance offered by the federal government, other states, local governments, or private concerns. In many cases, a problem or control technique has already been addressed.

Good Science

One of the inherent needs of a runoff or watershed management program is sound, scientifically defensible information. This information is needed to develop regulations, BMP design criteria, accurate monitoring and evaluation techniques, and a better understanding of the relationships between land use changes and impacts on aquatic resources. Unfortunately, budget constraints at all levels of government have led to decreases in funding for essential scientific studies and research. To solve runoff problems, especially those caused by existing drainage systems, the nation must make a financial commitment to develop new control technologies, refine existing controls, and improve our understanding of the actual effects of intermittent discharges on aquatic systems and their biota.

Funding

As with any activity or program, adequate financial resources are essential to achieve program objectives. Legislators and local governments can enact the best laws and ordinances, but if resources are inadequate for implementation, legislation will not achieve the desired results. While protecting the environment ranks high in citizen polls, environmental programs do not fare well at budget time. One reason, of course, is intense competition for limited resources. Public health, safety, and welfare concerns such as crime, medical care, and education receive priority over environmental programs. For this reason, innovative alternative funding sources must be found for runoff and watershed management programs. State dedicated funding sources might include special fees on certain products such as cement, asphalt, oil, fertilizer, pesticides, or water; additional documentary stamp fees; or even specialized property or sales taxes. Locally, runoff utilities are the most widespread and equitable dedicated funding source. Additional funding sources can include permit, inspection, and impact fees.

CHAPTER 11

Regulatory Strategies for New Development

An overall governmental or institutional strategy for effective management must include several key program components, including the development, promulgation, and enforcement of regulations. These regulations are necessary to technically define the goals of the runoff management program and to insure that they are achieved.

This chapter focuses on the regulations typically required to address the runoff management impacts of new land development by implementing permanent structural facilities or control measures. The chapter discusses key regulatory needs or roles necessary to establish effective facility design, design review, and construction inspection programs for permanent runoff control practices.

Finally, the chapter reviews the numerous federal programs that directly and indirectly affect a state or local runoff management program, reflecting the growing federal role in runoff. This summary, which includes both positive and negative aspects of the programs, can serve as a reader's guide to the extensive and confusing array of federal programs that affect local runoff management issues.

Facility Design

After establishing the goals of a runoff management program for new land development, strategies to achieve them must be defined. As described in Chapter 8, strategies can use structural and nonstructural controls, either separately or, preferably, in combination. Program regulations ensure that these strategies are properly implemented through specific regulatory needs or roles. In using structural controls or facilities, regulations must ensure proper facility design. To help achieve this, the following regulatory needs should be addressed.

Performance and Safety Standards

The regulations must establish a facility's performance and safety standards. Performance standards involve the outflow characteristics required to comply with the regulations—and achieve the overall program goals. Examples of requirements are (1) that the peak rate of runoff discharged by the facility after site development should not exceed a certain level from a specified range of storm events, and (2) that an extended detention time must be established for frequent storms to promote pollutant removal, with a specified removal rate.

The inherent risks of water impoundment by structural facilities require that safety standards be established to ensure acceptable risks from the facility's presence and operation. Requirements range from emergency spillways that safely convey the runoff from extreme storm events through the facility to safety measures that facilitate both normal and emergency maintenance activities.

The regulations should also address long-term maintenance by specifying who is legally and physically responsible. The regulations should also provide procedures to conduct periodic facility inspections and to notify the responsible party of the maintenance need. They should also provide enforcement powers to compel those recalcitrants who ignore such notification. Finally, the regulations must address the possibility that the facility might not be maintained or be abandoned and provide for the possibility of government ownership and maintenance.

R0040017

Because facility performance, safety standards, and regular maintenance are so vitally important, regulations should be promulgated through official and legally binding forms—laws, ordinances, resolutions, and official regulations. These avenues will ensure that the regulations are not changed arbitrarily but only by informed consensus and official action.

Computational Methods and Data Sources

Unlike performance and safety standards, the details necessary to design and construct structural runoff management facilities are best promulgated in documents with flexible formats such as handbooks, manuals, and guidelines. This flexibility is due to several factors:

- The site-specific nature of runoff and the structural facilities used to manage it;
- The relative accuracy and varied suitability of the computational methods currently used (see runoff and soil erosion estimating techniques in Chapter 1); and
- The constantly evolving body of knowledge and experience on all aspects of structural runoff facilities.

Beneficial changes to the standard methods and details can more easily be made in handbooks and manuals to respond to the specific needs of the site and facility. These informal publications also recognize the designer's professional discretion and legal responsibility. In addition, new and enhanced methodologies, technologies, materials, and data can be incorporated into the facility design process, eliminating the time-consuming and bureaucratic procedures of modifying existing laws, resolutions, and ordinances. In fact, these documents should acknowledge and encourage designers to develop and use improved techniques and features.

Regulatory discretion for design aspects such as computational methods and structural details requires competent and responsible personnel to design, oversee, and approve the facility. The next section provides more information on facility design review.

Regulations are required so that runoff management program goals can be achieved by safely constructing structural management facilities. Those promulgating design regulations must distinguish between standards and requirements fundamental to the program's goals and objectives and those that should be flexible to respond to scientific and practical improvements in runoff management. Regulations should not be subject to change without informed and official deliberations. In any case, competent and responsible personnel and an open attitude toward program enhancement are vital.

Facility Design Review

The second role of runoff management regulations is to provide an objective and thorough design review process. This is particularly true if discretion and flexibility have been incorporated in the facility design standards. Since discretion demands knowledge and responsibility, the program must include provisions for a timely, thorough, and objective design review prior to construction. The following guidelines are recommended:

Legal Responsibilities

Before developing review procedures and requirements, the legal ramifications of the design review process and implied by approval of the design should be addressed. In seeking the advice of legal counsel, clearly state the objectives of the review process. Make clear that, unless otherwise stated, the facility's designer is ultimately responsible for the performance, safety, and longevity of the structural facility—not the design reviewer, whose interests and authority are limited by the overall runoff program.

Because of the liability issues, designs should be supervised, approved, and certified by a licensed professional such as an engineer or architect. Seek legal counsel in all legal aspects of a runoff management program. Issues might include the extent of certification required on documents and computations submitted for approval, the time limit of the approval, and the extent of changes allowed before resubmission is required.

Minimum and Recommended Requirements

Regulations should establish both minimum and recommended submittal requirements for facility designs seeking approval. Minimum submittal requirements ensure that those conducting the design reviews have enough information to perform their task. Minimum requirements also ensure that the application process is fair and allow applicants to accurately budget the time, effort, and expertise needed for approval. This accuracy helps establish fair and adequate review fees.

Recommended or optional submittal requirements can help more complicated projects or designs. Optional requirements include preapplication meetings between the designer and reviewer during the design process to address more complex project features. If used properly, these meetings can save considerable design and review time and lead to more effective structural facilities. This is particularly true if the preapplication meeting—and the entire design review procedure—operates in an open and cooperative manner and all design aspects, including the need for and type of facility selected, are objectively reviewed.

A comprehensive design review procedure should include a process to review and appeal denials and rejections. This process should include decision-review meetings between applicants, designers, and reviewers. These meetings can often resolve problems promptly and efficiently; save time, effort, and emotions; and preserve support for the runoff program.

Wherever feasible, regulations should establish maximum time limits for design reviews. While time limits can sometimes be onerous to individual reviewers, developers, and applicants, they allow both the reviewing agency and the applicant to better budget staff time and expenses. Time limits also provide the reviewer an incentive to obtain the required design information from the applicant. Programs that establish maximum time limits must also clearly define what constitutes a complete submittal, and allow the reviewer adequate time to determine completeness. The program should also allocate adequate time for logging, filing, notification, and other administrative procedures.

Level of Review

The design review process also entails deciding the level of review to conduct. This could range from a reviewer's simple check of plans, data sources, and computational arithmetic to a comprehensive and independent analysis of the proposed structural facility. Often, a combined approach is best, with the reviewer making arithmetic checks of standard or less critical design computations and independent computations of more critical aspects. The proper mix of review techniques depends on the legal responsibilities of the review process, the specific aspects of the design being reviewed, and the implications of design error and/or facility malfunction.

Self-Examination and Monitoring

This aspect of the design review process, including time spent by review personnel and the problems encountered, will help identify shortcomings, inefficiencies, and deficiencies in the process. This could include the extent of required submittal data, staff knowledge and training, and various administrative procedures. In many instances, the self-monitoring process can be used to identify deficiencies in the knowledge and/or abilities of the applicant or designer. These deficiencies can then be addressed through techniques ranging from more descriptive application forms and instructions to seminars and workshops on design, submittal, and review procedures and requirements.

Interaction and Dialogue

A truly effective design review process includes some interaction and dialogue with the design community that it oversees and facility construction and maintenance personnel. Such interaction—formally at regularly scheduled meetings and workshops or informally through professional or trade organizations—can help identify and correct review practices and specific facility requirements that are causing design, construction, or maintenance difficulties. The complexity of runoff processes and the growing scope of the programs intended to manage it make such a proactive approach to problem identification and resolution vital to the success of any regulatory program.

Facility Construction Inspection

Once the runoff facility design has been developed, reviewed, and approved, the facility must actually be put into service through construction. The importance of this point, however obvious or simple, should not be overlooked. Until a structural control measure is constructed and begins functioning, it has absolutely no effect on runoff and solves no runoff need or problem. Too frequently, facility design or review procedures become ends in themselves. The program goals are not realized by the production of a set of plans

VOL 12 6711

R0040019

stamped "approved," but through construction and operation. Therefore, not only should the regulatory aspects of structural runoff facilities be focused on producing an effective, safe, efficient, and durable facility, they should also be focused on getting it constructed.

The same is true for construction inspection programs. The primary focus must be on constructing effective, safe, and durable structural facility. The return on investment is not realized until the project is constructed and functioning.

Legal Issues

In many ways, the regulatory needs of a construction inspection program are similar to those for facility design review. Prior to program start-up, all legal aspects and implications of the program must be thoroughly reviewed and accepted. This includes satisfactorily addressing the legal implications of the inspection process and the approvals it produces. All involved must understand that, unless otherwise stated, the ultimate responsibility for safe and proper construction rests solely with the builder, not with an inspector who has limited program interests and authority.

Construction Inspection and Reporting

A formal construction inspection and reporting procedure includes provisions for preconstruction and project start-up meetings, inspection schedules, documentation and dissemination of findings and observations, periodic progress and problem solving meetings, and postconstruction documentation and certification. As with preapplication meetings during the design review process, preconstruction meetings can be key to efficient and productive construction. These meetings can provide all parties an opportunity to familiarize themselves with the various procedures, personalities, and potential problems before construction begins and in the relatively calm environs of a meeting room rather than the immediate and highly-charged atmosphere of a construction site.

The regulations should provide a clearly defined role by describing the construction inspector's responsibilities and authority and suggest periodic review meetings to address problems and plan construction phases. The regulations should also require that the as-built drawings of the facility be subject to the review and approval of the inspecting agency. Finally, the regulations should provide certification procedures to officially designate the project's completion. This designation helps contractors and owners, who may need to terminate construction performance bonds and other sureties, and design review and construction inspection agencies.

Interaction

An effective construction inspection program includes interaction and interchange among facility designers, builders, and maintenance personnel. This interaction can take place formally at regularly scheduled meetings and workshops or informally through professional or trade organizations. It allows difficulties in design, construction, or maintenance to be identified and corrected. The complexity of runoff processes and the growing scope of management programs make proactive problem identification and resolution vital to success.

Federal Programs Affecting Runoff Management

Since passage of the 1972 Clean Water Act, a variety of agencies have introduced numerous federal programs to manage and protect water resources. Many of these programs directly affect runoff management by reducing its impact on aquatic systems, not only at the federal level, but also at state and local levels. Unfortunately, some of these programs—especially older ones—have single focus goals and/or legal mandates. These often conflict with the multifaceted environmental protection goals of more recent programs, particularly those that seek the holistic ecological goals of watershed management. Attaining runoff and watershed management goals will depend, in part, on modernizing existing laws and programs to make goals more consistent with those of more recent laws emphasizing environmental protection. The success of this modernization process, in turn, will depend upon how well we can integrate existing laws into watershed-based runoff management programs.

Before we can undertake such a process, we must understand each of the various federal programs that affect the development of local, state, and even federal runoff management programs and regulations. The following section lists the numerous federal programs that can affect, adversely or beneficially, the management of runoff and other nonpoint sources of pollution.

VOL 12

6/12

R0040020

VOL 12 6/1/3

U.S. Environmental Protection Agency

Clean Water Act

■ **Section 104, Water Quality Cooperative Agreements.** Supports programs and projects for the prevention, reduction, and elimination of pollution. Some eligible activities include special water quality studies, investigations of pollution control techniques, river corridor watershed management planning, and pilot and demonstration projects. Special programs funded through Section 104 include

- **Near Coastal Waters.** Improves the environmental conditions of near coastal waters through a watershed management approach. Eligible activities include developing and implementing regional strategies in targeted areas.
- **State Wetlands Program.** Increases the ability of state programs to protect wetland resources. Eligible activities include developing new state wetland protection programs or refining existing programs, watershed protection demonstration projects, state wetland conservation plans, and section 404 program assumption assistance.
- **Wetlands Protection Program.** Receives funding for activities in targeted watersheds such as advance wetland identification, public education, and enforcement.
- **Assessment and Watershed Protection Support.** Provides very limited funding for watershed planning priorities, regional targeting, and monitoring in support of section 305(b) reports.
- **Section 104(g).** Encourages the establishment or enhancement of small community outreach programs.

■ **Section 106, Water Pollution Control.** Administers programs to prevent, reduce, and eliminate water pollution. This is the primary federal grant funding source for state water quality management programs. Eligible activities include nearly all aspects of the prevention and abatement of surface and groundwater pollution—planning; monitoring; permitting; enforcement; and training, public education, and technical assistance.

■ **Section 205(j)(1).** Authorizes water quality management planning programs by states. Eligible activities include identifying pollution control methods to protect and restore waterbodies and monitoring programs conducted statewide or in targeted watersheds. Funded by a 1 percent set-aside of the state's Title II grant funds, it is being replaced by section 604(b).

■ **Section 303, Water Quality Standards and Implementation Plans.** Requires states to develop, adopt, and enforce water quality standards that are at least as stringent as those adopted by the EPA and that will protect, maintain, and restore the chemical, physical, and biological integrity of all waters. It requires the regular review and, if needed, revision of water quality standards; the establishment, allocation, and enforcement of total maximum daily loads for certain waterbodies; and a continuous state water planning process.

■ **Section 304, Information and Guidelines.** Requires EPA and the states to establish water quality criteria and effluent guidelines for a wide variety of substances, especially hazardous and toxic ones. It requires states to develop a list of waters needing control strategies for toxic and other pollutants.

■ **Section 305, Water Quality Inventory.** Requires EPA to biennially report to Congress on the environmental quality of the nation's water resources and identify waters that do or do not meet their designated uses. States develop State Water Quality Assessment reports (305(b) reports) and submit them to EPA, which uses the information as the basis for its report.

■ **Section 314, Clean Lakes Program.** Establishes projects and programs to control pollution sources to lakes and to protect and restore the quality of lakes. Eligible activities include identification and classification surveys of all publicly owned lakes, state lake water quality monitoring and assessment, and public education. Lake restoration projects typically include three phases: a diagnostic/feasibility study; a restoration/protection implementation program; and postrestoration monitoring.

■ **Section 319, Nonpoint Source Program Implementation.** Supports activities that implement the states' EPA-approved nonpoint source management plans. These include basic program implementation tasks that help institutionalize the program within a state; watershed nonpoint source management program implementation within targeted watersheds; nonpoint source control practice installation at demonstration sites; and groundwater nonpoint source assessment and management programs.

■ **Section 320, National Estuary Program.** Authorizes development of comprehensive conservation and management plans, usually over a five-year period, for specific legislatively designated estuaries. It does not provide funding to implement approved plans, although other CWA funds (e.g., 319, Title II and VI) may be used.

■ **Section 402, National Pollutant Discharge Elimination System.** Establishes regulatory programs for point sources of pollution but exempts most agricultural activities. This program was originally designed to reduce pollution from point sources such as domestic and industrial wastewater discharges. This program now includes certain runoff discharges from specific industrial activities, including construction sites, and runoff discharges operated by local governments with a population over 100,000.

■ **Section 404, Permits for Dredged or Fill Material.** Establishes a regulatory program to control the discharge of dredged or fill material into navigable waters (wetlands). This program is administered by the U.S. Army Corps of Engineers, using permitting guidelines developed in coordination with EPA. The section allows a state to administer the program, with EPA having veto power.

■ **Section 604, Title VI Water Quality Management Planning.** Requires each state to reserve 1 percent of the State Revolving Loan Fund grant for water quality management planning activities required by section 205(j) and 303(e). Eligible activities include projects to determine the nature, extent, and causes of water quality problems; to identify cost-effective and acceptable point and nonpoint source controls; and to develop implementation plans.

Federal Safe Drinking Water Act

■ **Section 1443, Underground Injection Control.** Establishes federal and state programs to protect groundwaters from these sources. It provides grants to states to fund all types of related activities.

■ **Section 1442, Wellhead Protection.** Provides technical assistance and funding to states and local governments designing and implementing wellhead protection programs. Eligible activities include delineation of wellhead protection areas; identification, mapping, and sampling of contamination sources; public education; and development of ordinances.

U.S. Department of Agriculture

■ **Agricultural Conservation Program (ACP).** Administered by the USDA Agricultural Stabilization and Conservation Service (ASCS), ACP is designed to control erosion and sedimentation and encourage voluntary compliance with federal/state requirements to solve point and nonpoint source pollution. It provides financial assistance to individuals in all U.S. counties to implement conservation practices. Recently, water quality improvement has received special emphasis. However, allowable BMPs and funding amounts are set by county and state committees, which are usually dominated by agricultural interests.

■ **Conservation Reserve Program (CRP).** Administered by the USDA ASCS, CRP is intended to return certain agricultural lands—which are highly erodible or otherwise critical in protecting and restoring water quality—to a conservation use, typically as grass or forests. Farmers receive payment per acre to conserve these lands for a contracted period, typically 10 years.

■ **Wetlands Reserve Program (WRP).** Administered by the USDA ASCS, WRP is intended to restore and protect farmed or converted wetlands. Farmers receive direct payments and conservation planning and technical assistance to install necessary restoration practices on areas they agree to maintain under a conservation easement.

■ **Resource Conservation and Development Program (RC&D).** Administered by the Soil Conservation Service, RC&D encourages and improves the capability of state and local entities in designated rural areas to plan, develop, and implement programs, typically in targeted critical areas.

■ **Soil and Water Conservation.** Administered by the USDA SCS, this program provides technical assistance to the public through total resource planning and management to improve water quality and natural resources and reduce pollution sources. USDA SCS also publishes detailed soil surveys for each county and provides a variety of useful natural resources management information.

VOL 12

6/7/14

■ **Watershed Protection and Flood Prevention (Small Watershed Program, PL-566 Program).** Administered by the USDA SCS, it provides technical and financial assistance to state agencies and local governments to develop and implement plans that protect, develop, and use land and water resources in small watersheds. Recently, this program has been broadened to emphasize protecting and restoring water quality, especially from flooding, erosion, sedimentation, and use/disposal of water problems.

U.S. Department of the Interior

■ **National Water Quality Assessment Program.** Administered by the U.S. Geological Survey, it addresses a wide range of major water quality issues, with special emphasis in the next few years on pesticide impacts on water resources. The program will include nationwide surface and groundwater quality monitoring and assessment.

■ **Water Data Program.** Administered by the USGS, it consists of four water quality monitoring networks, the most important of which is the National Stream Quality Accounting Network (NASQAN). Data on stream flow and height, lake stage and storage, groundwater levels, well and spring discharge, and the quality of surface and groundwaters is collected and stored in National Water Data Storage and Retrieval System (WATSTORE).

■ **Federal State Cooperative Program.** Establishes a partnership for water resources investigations between the USGS and state and local agencies. This program is the foundation for much of the planning, development, and management of the nation's water resources.

■ **Coastal Wetlands Planning, Protection and Restoration Program.** Administered by the U.S. Fish and Wildlife Service, it provides funds to acquire coastal lands or waters and to restore, enhance, or manage coastal wetland ecosystems. Projects must provide for the long-term conservation of these lands and waters.

■ **Land and Water Conservation Program.** Administered by the National Park System, it was established to create and maintain a national legacy of high quality recreation areas. It provides funding for federal acquisition of authorized national park, conservation, and recreation areas and to state and local governments to help acquire, develop, and improve outdoor recreation areas.

Federal Highway Administration

■ **Federal Aid Highway Program.** Assists state agencies in developing and improving an integrated, interconnected transportation system. Funds may be used for planning, research and development (including BMPs), restoration, roadside beautification, and wetland mitigation. It provides funding for erosion and sediment controls needed to minimize highway construction impacts but not typically to treat and manage highway runoff. However, the Surface Transportation Program authorizes funding for highway runoff quality controls and for mitigating damage to ecosystems, habitat, and wildlife.

U.S. Army Corps of Engineers

Civil works projects are specific line-item congressional appropriations in the biennial Water Resources Development Act. They provide help to communities for a variety of water resource problems including flood control, coastal and shoreline erosion, environmental restoration, and water quality management. Projects must include mitigation of unavoidable environmental damages and must also consider environmental restoration through opportunities created with projects.

The following programs have great potential to adversely affect aquatic systems and impede runoff management to protect or restore water quality:

■ **Small Flood Control Projects.** Pursuant to section 205 of the Flood Control Act of 1948, the Corps is authorized to reduce flood damages through projects not specifically authorized by Congress. However, the Corps is restricted to making improvements to natural water courses—typically structural, such as bank hardening or dredging—and cannot consider watershed runoff improvements.

■ **Snagging and Clearing for Flood Control.** Pursuant to the Flood Control Act of 1937, it allows the design and construction of flood control measures that typically increase drainage and decrease water quality.

National Oceanic and Atmospheric Administration

■ **The Coastal Zone Management Act of 1972.** Allows states to prepare and implement comprehensive management programs for coastal re-

VOL 12

6/7/15

sources that balance competing demands on resource protection, protection of public health and safety, provision for public access, and economic development. States with federally approved programs receive federal grant funds to develop and implement a wide variety of coastal resource management initiatives.

- **Section 6217, Coastal Nonpoint Pollution Control Program.** Jointly administered with EPA, which is responsible for establishing minimum nonpoint source management measures. States with federally approved coastal zone management programs must develop and implement nonpoint source control programs to restore and protect coastal waters and must comply with the minimum nonpoint source management measures.
- **National Estuarine Research Reserve System.** Establishes and manages a national system of reserves representing different coastal regions and estuarine types. The reserves serve as field laboratories and public education centers.
- **National Marine Sanctuary Program.** Identifies areas of the marine environment of special significance and provides authority for comprehensive and coordinated conservation and management. It also provides for research and monitoring activities and public education.

Information Sources

Further information on these programs can be obtained from *Watershed Protection: Catalog of Federal Programs* (EPA-841-B-93-002), a 1993 publication of the U.S. Environmental Protection Agency's Office of Water, Washington, DC.

VOL 12

CHAPTER 12

Site Planning and Other Nonstructural Management Practices

In the long run, preventing runoff problems is easier and much less expensive than correcting problems later through expensive infrastructure construction and resource restoration. This chapter presents a variety of effective management practices that can be used to prevent runoff problems. These preventive controls, called nonstructural management practices or best management practices, include regulatory practices, such as buffer zones or limits on impervious areas, and source controls, such as public education, growth limitations, and protection of sensitive areas to reduce runoff pollution sources. Unlike structural controls, which address runoff problems on a particular site, nonstructural controls are used throughout an entire community, watershed, or special protection zone.

Most nonstructural BMPs are associated either with land use changes or with educating citizens to encourage a change in lifestyle activities. Accordingly, local governments primarily develop and implement nonstructural management practices and programs, although state and regional agencies can join the implementation team. Recently, federal agencies and programs have begun to emphasize pollution prevention activities.

The nonstructural management practices tool box contains a large number and variety of nonstructural BMPs. An urban runoff management plan for the Santa Clara Valley in California, for example, includes more than 100 potential nonstructural BMPs. Local governments and other users of nonstructural measures should screen BMPs to determine those most appropriate for a given area.

Historical Problem Areas

In most parts of the United States, many state and local governments have been discouraged from implementing programs to control or regulate land use and development. This reluctance developed because of an abundance of easily developed land and a lack of understanding about the negative impacts of growth and development on natural resources. With real or perceived concerns about potential property rights questions and sensitivity about restricting a person's use of private property, governments have proceeded cautiously in establishing land use controls, setting specific development design or performance requirements, or restricting citizen activities. Currently, eight states have implemented statewide growth management programs, and many state and local governments have instituted various types of zoning, permitting, or other programs that restrict activities or new development. However, developing and implementing these programs is frequently controversial.

Many source controls involve changing citizens' lifestyles or activities. Every citizen who lives in, works in, or visits a watershed contributes to urban runoff problems through everyday activities. Whether traveling in a motor vehicle on a paved or unpaved road, using fertilizers or pesticides, using household cleansers, or walking the family dog, each individual contributes pollutants to the watershed. Educating citizens to encourage

6717

R0040025

a change in habit is difficult. First, we must convince citizens that runoff is a pollution source, that their everyday activities contribute to this pollution problem, and finally that changing their ways helps prevent pollution.

Site Planning and Other Nonstructural BMPs

Institutional Framework

Local governments are typically the public entity responsible for reviewing and approving development plans. Local governments influence and guide urban development, depending on state laws and local ordinances, by identifying where and how development should occur through local land use plans and associated policies. These plans and policies are implemented through specific ordinances and mechanisms known as land development codes or regulations, which establish the legal basis for reviewing and approving development plans, monitoring implementation, and enforcement. Many nonstructural management practices—limits on site clearing and impervious areas, landscaping, buffer zones, and others—can be incorporated into local land development codes. (See Chapter 11 for summary of regulatory programs.)

Development plan review by local government addresses a wide range of public policy concerns including traffic circulation, safety, health, landscaping, tree protection, and public services. Plan review and approval protects natural resources, especially water resources, by addressing potential water quality degradation sources such as construction, runoff, and septic tanks. Plan review should also include preservation of critical areas and wildlife habitats. Local governments can prevent problems and solve existing and potential problems by implementing a comprehensive site plan review process. Effective development reviews lead to more efficient use of land, water, and cultural resources and can help eliminate or reduce difficulties experienced by landowners.

In developing regulations, local governments need to screen various nonstructural management practices to determine those most beneficial in a particular area or situation. Screening methods should include criteria specific for the watershed's conditions and for the goals of the watershed program. Typical criteria include

- **Pollutant control and effectiveness.** This criterion should be from pollutants of primary concern or known pollution problems. Consider reliability and longevity of the controls along with siting and design constraints.

- **Control acceptability.** Controls should be accepted by the public and by public agencies responsible for implementing and maintaining BMPs.

- **Technical and economic feasibility.** Some BMPs may require considerable technical expertise, staffing, and financial resources. Cost considerations should include planning, design, construction, operation, and maintenance.

- **Legal authority and considerations.** Local land development codes must provide adequate legal authority to implement and enforce requirements. Evaluate risks or liabilities that may occur in implementing control measures.

- **Existing government framework.** Governments vary greatly around the country. The roles, powers, and duties of multiple levels of local and regional governments greatly influence the effectiveness of a potential nonstructural BMP, especially one that relies on widespread implementation.

Although local governments have unique requirements and steps in the development review process, certain elements common in most procedures include

- **Comprehensive plan amendment.** In most cases, proposals for land development should conform to the local government's adopted land use plan and map. If the proposed development is not consistent with the plan, an amendment to the local plan or map may be necessary.

- **Rezoning.** Once the development and local plans are consistent, an official change in the site's designated zoning may be necessary.

- **Development plan review and approval.** Through this process, plans for land improvements, buildings, and related activities are reviewed for compliance with local land development regulations. This review can include multiple steps such as subdivision

VOL 12

6/7/8

R0040026

approval (e.g., conceptual, preliminary, and final plat). The process usually involves preparing a site plan, especially for commercial, industrial, and multifamily developments.

- **Engineering plans.** This step includes preparing and receiving final approval of designs for utilities, wastewater management, runoff management (including erosion and sediment control), roads, and building construction.

- **Building permits and approvals.** Necessary federal, state, regional, and local permits should be obtained before beginning construction. In many areas, no land clearing is allowed until certain permits such as clearing and grading, erosion/sediment control, and runoff management are obtained.

Planning with Nature

The United States' rich and diverse environment has a tremendous variety of natural systems, with many well suited to urban development. However, many systems have low tolerances for intensive development and, if radically altered, can no longer perform their basic functions. A main purpose of site planning is to encourage the use of comprehensive design principles that preserve the integrity of the natural environment. In this sense, site planning is a preventive measure and, frequently, a neglected element of land development.

Natural systems provide unique and beautiful environments that attract visitors and residents alike. These systems also supply, transport, cleanse, and store water; assimilate and filter wastes; modify and moderate the climate; provide storm protection and dampen floodwater; produce food; oxygenate and purify the air; recharge aquifers; build land; and provide recreational and economic opportunities. Perhaps the greatest benefit provided by natural systems is their self-maintaining capability. When used within their tolerance levels, natural systems provide a variety of services efficiently, dependably, and at no cost to humans. This self-maintaining capability is in direct contrast to most constructed systems that require money and energy to maintain. Like any other complex system, natural systems can operate efficiently only as long as their ecological integrity is maintained. If essential components are damaged or destroyed, or if the system as a whole is overstressed, the natural biological processes will break down and the system will fail. Therefore, economic sense dictates that each system fulfill its proper function and maintain peak efficiency by thoughtful, insightful resources management.

Principles of Runoff Management

The following principles should be used to develop a site plan:

- Preventing problems is much more efficient and cost-effective than attempting to correct problems after the fact. Sound land use planning decisions based on the site planning principles discussed later in this chapter are essential as the first, and perhaps the most important, step in managing runoff problems. All new development plans (e.g., subdivisions, shopping centers, industrial parks, office centers) and redevelopment plans should incorporate nonstructural management practices, including source controls, along with a comprehensive runoff management system.

- Every piece of land is part of a larger watershed. Since we all live downstream, a runoff management system for each development project should be based on and support a plan for the entire drainage basin.

- The runoff management system should mimic and use the features and functions of the natural runoff system, which is largely capital, energy, and maintenance cost free. Every site contains natural features that contribute to runoff management under existing conditions. Depending on the site, existing features such as natural drainageways, depressions, wetlands, floodplains, highly permeable soils, and vegetation provide natural infiltration, help control runoff velocity, extend the concentration time, filter sediments and other pollutants, and recycle nutrients.

Each development plan should carefully map and identify the existing natural system. Use natural engineering techniques to preserve and enhance the natural features and processes of a site and to maximize the economic and environmental benefits. Natural engineering is particularly effective when the runoff system is integrated into a site's landscaping, open space and recreational areas, or in "blue-green" developments using permanent lakes and cluster tech-

VOL 12

6719

niques. Engineering design can and should be used to improve the effectiveness of natural systems, rather than negate, replace, or ignore them.

■ The volume, rate, timing, and pollutant load of runoff after development should closely approximate the conditions before development. To accomplish these objectives, two overall concepts must be considered: (1) maintaining the perviousness of the site to the greatest extent possible; and (2) slowing the rate of runoff. Give preference to runoff management systems that use BMPs to maintain vegetative and porous land cover and include on-site storage mechanisms. These systems promote infiltration, thereby reducing, filtering, and slowing runoff.

■ Maximize on-site runoff storage. Storage provisions can reduce peak runoff rates; aid in groundwater recharge; provide settling of pollutants; lower the probability of downstream flooding, stream erosion, and sedimentation; and provide water for other beneficial uses. Where practical, the blue-green development approach should be employed, since it inherently provides storage, environmental protection, and enhanced community amenities.

■ Runoff should never be discharged directly into surface or groundwaters. Runoff should be routed over a longer distance, through grassed conveyances (swales), wet ponds, vegetated buffers, and other practices that increase overland sheet flow. These practices increase infiltration and evaporation, allow suspended solids to settle, and remove pollutants before they reach downstream receiving waters and groundwaters.

■ Plan, construct, and stabilize runoff management systems, especially those emphasizing vegetative practices, before development. This principle frequently is ignored, causing unnecessary off-site problems, extra maintenance, regrading, revegetation of slopes and grassed waterways, and extra expense to the developer. Construct and stabilize the runoff management system, including erosion and sediment controls, at the start of site disturbance and construction activities.

■ Design the runoff management system beginning with the project's outlet or point of outflow. The downstream conveyance system should contain sufficient capacity to accept the discharge without adverse downstream impacts such as flooding, streambank erosion, and habitat destruction. Downstream conveyance systems may need stabilization, especially near the system outlet. Another common problem is a restricted or submerged outlet. This can cause runoff to back up and exceed the storage capacity of the collection and treatment system, resulting in temporary upstream flooding. This situation may lead to hydraulic failure of the runoff management system, causing resuspension of the pollutants and/or expensive repairs to damaged structures or property. In such circumstances, more than one outlet or an increase in the on-site storage volume may be needed.

■ Whenever possible, follow the topography to construct the components of the runoff management system. This step will minimize erosion and stabilization problems caused by excessive velocities and slow the runoff, allowing for greater infiltration and filtering.

■ Runoff, a component of the total water resources, should not be casually discarded but used to replenish those resources. Runoff is a misplaced resource, with location and timing determining whether it is a liability or an asset. Given the water quantity and quality problems facing our nation, we must consider runoff an asset. Treated runoff can potentially provide many beneficial uses such as irrigation of farms, lawns, parks, and golf courses; recreational lakes; groundwater recharge; industrial cooling and process water; and other nonpotable domestic uses.

■ Whenever practical, integrate multiple-use temporary storage basins into the management system. Too often, planned facilities are conventional, unimaginative, aesthetically unpleasing ponds. Recreational areas (e.g., ballfields, tennis courts, volleyball courts), greenbelts, neighborhood parks, and even parking facilities provide excellent settings for temporary runoff storage. Such areas are not usually used during precipitation, so runoff ponding for short durations will not impede their primary functions.

■ Design storage areas with sinuous shorelines. Curves increase the length of the shoreline and create greater development opportunities, especially in using the blue-green concept of permanent lakes. The increased shoreline also provides more space for the growth of littoral vegetation to provide greater pollutant filtering, more diversified aquatic habitat, and greater attractiveness (aquascaping).

- Retain vegetated buffer strips in their natural state or create strips along the banks of all waterbodies. Vegetated buffers prevent erosion, trap sediment, filter runoff, provide public access, enhance the site amenities, and function as a floodplain during high water periods. They also provide a pervious strip along a shoreline to accept sheet flow from developed areas and help minimize the adverse impacts of untreated runoff.

- Maintain the runoff management system. Failure to provide proper maintenance reduces the system's pollutant removal efficiency and hydraulic capacity. Lack of maintenance, especially to vegetative systems requiring harvesting or revegetating, can increase the pollutant load of runoff discharges. The key to effective maintenance is to assign responsibilities to an established agency or organization, such as a local government or homeowners association, and to regularly inspect the system to determine maintenance needs. An even better tactic is to design a system that is simple, natural, and as maintenance free as possible.

The Site Planning Process

Site planning requires determining specific uses for definitive land areas and planning development to achieve a community character and an amenable quality of life. To achieve this end, assemble and analyze all pertinent site information—social, ecological, cultural, economic, political—to determine the project's ultimate design or feasibility.

Site planning can help preserve the site's integrity and diverse natural systems. Assessing the opportunities and constraints imposed by a site's features helps avoid or minimize potential problems and hazards, decrease construction and maintenance costs, and attain a community character that produces an amenable quality of life.

Innovative development techniques, such as planned unit or cluster developments, are extremely well-suited for site planning. Not only do these techniques reduce costs, they also allow greater flexibility and can incorporate natural and cultural resources into the development plan. These techniques foster a harmony between the development and existing natural systems, creating opportunities for amenities such as open space, recreation, and beauty not commonly found in developments.

Site plan contents will vary, depending on state requirements and local ordinances. However, site plans typically include a development plan and a street and utility layout. Most important, a site plan includes plans for grading, soil erosion and sediment control, runoff management, and landscape. Development and infrastructure plans created in harmony with the site's constraints and opportunities greatly influence their effectiveness in protecting site and watershed resources. Coordinate these elements to assure a logical sequencing of events. For example, a sediment basin in the erosion and sediment control plan can become a permanent runoff detention basin. Additionally, all initial and final elevations in the grading plan should be consistent with facilities in both the erosion and sediment control plan and the runoff management plan.

Developing a site plan requires a careful step-by-step analytical approach, which often includes the following steps:

- **Conduct a site evaluation.** Assess existing natural and cultural features and determine suitability for the proposed development activity.

- **Develop site maps.** These allow visual inspection and analysis of site features and their relationship to the alternative site development plans.

- **Collect additional information.** This is needed to finalize conceptual plans.

- **Review site plan goals.** Goals should properly address requirements of state and local laws, ordinances, permitting regulations, comprehensive plans, and land development codes.

- **Develop and integrate the individual components of the site plan.** Each component should include goals, desired performance, design considerations for chosen BMPs, operation and maintenance needs, costs, and scheduling.

VOL 12 6721

R0040029

Conducting a site evaluation is the heart of the site planning process. It includes collecting and analyzing the information to prepare a final development plan in harmony with both the natural and cultural communities. The following section discusses this process in more detail.

Site Evaluation

Site selection is the most critical stage of the development process. Developers must begin planning for a new project before the land is purchased to evaluate the suitability of potential sites. Usually a developer lacks the luxury of choosing an ideal location but must rely on what is available at a price that can return a reasonable profit. Whether the project begins with a site or an idea, the site's physical characteristics and location in the community will determine the feasibility of the concept. Site selection and evaluation must consider two important factors:

- The opportunities and constraints the site brings to the proposed development—elevation, hazards, soil types, water table elevation, runoff management, and
- The community impact, especially in adjacent and downstream areas.

In analyzing the site and its surroundings, include all natural, cultural, and aesthetic features that affect it and illustrate the information graphically (site maps). These features influence final site selection and provide clues to site personality that will help establish and select guidelines for later development. The following steps are useful in selecting a site or analyzing one already selected:

- Collect basic data for surface and subsurface features. Analyze and interpret aerial photographs, maps or charts, previous environmental and cultural resource studies, and field surveys. Much of this information can be obtained from local planning departments as a result of local government comprehensive planning efforts.
- Organize and present the basic data graphically. Recent advances in the technology and application of computerized geographic information systems facilitates mapping and analysis.
- Analyze and interpret maps singly and in combination. Identify critical areas needing preservation or special treatment; evaluate appropriate locations for buildings, roads, and utilities; and prepare alternative conceptual development plans.
- Interpret maps for planning decisions. Contact representatives of state and local government agencies for various jurisdictional determinations where appropriate.

Table 12.1—Site selection, analysis, and planning factors.

NATURAL FACTORS	
Climate	Solar orientation, wind, precipitation, and humidity
Geology	Bedrock and surficial
Physiography	Geomorphology, relief, and topography
Hydrology	Surface and groundwater
Soils	Classification of types, limitations, and capabilities
Vegetation and wildlife	Plant communities and habitats
Critical areas	Identification and protection
CULTURAL FACTORS	
Existing land use	Ownership of adjacent property and off-site nuisances; projected future land use of site and adjacent property
Traffic and transit	Vehicular and pedestrian circulation on or adjacent to site
Density and zoning regulations	Legal and regulatory controls
Socioeconomic	Market analysis, suitability
Utilities	Wastewater, stormwater, water, gas, steam, electricity, and telephone
Historical and archaeological	Historic buildings, landmarks, and archaeological sites
AESTHETIC FACTORS	
Natural features	Location, protection, views
Spatial pattern	Views, spaces, and sequences

VOL 12

■ Prepare composites map. These illustrate the general and specific development limitations and opportunities of the whole or part of the selected site.

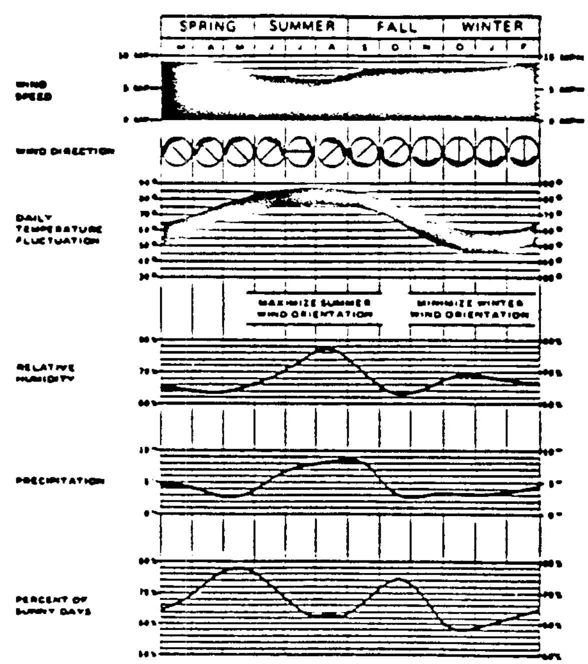
A number of important natural, cultural, and aesthetic factors should be considered in site selection, analysis, and planning (Table 12.1). The remainder of this chapter discusses each of these factors, along with design or development guidelines.

Natural Factors

Climate

Planning Considerations. The chief climatic control factors are latitude, physiography, temperature, and proximity to waterbodies. Climate is usually characterized within well-established probabilities. However, site planning must be concerned with extremes as well as averages. Floods, droughts, hurricanes, and coastal storm surges should all be considered during the development planning phase. Precipitation and temperature are major factors affecting vegetation. Proper building orientation can ameliorate hot and humid climates by taking advantage of shade and prevailing breezes. In colder climates, building orientation and positioning help reduce cold winds and provide solar reflection and heating. A summary of a site's climatic data (Figure 12.1) can help plan an environment for living.

Figure 12.1—Sample summary of site's climatic data.



Source: Simonds, 1978.

Design Guidelines

■ Arrangements, materials, and conformation of site plans and structures should be designed according to the climate and the site's microclimate—variations to the climate due to on-site factors such as water and trees.

■ Sites along lake shorelines and ocean coastlines, especially along the Gulf of Mexico and the Southeast Atlantic, are vulnerable to storms—including hurricanes—with high winds and storm surges. Coastal developments should preserve the remaining protective sand dunes, ensure that floor levels of structures are above flood levels, and carefully consider the potential effects of an intense storm or hurricane to minimize property damage and personal injury.

■ Use open patterns in hot and humid climates to take advantage of prevailing summer winds.

■ Take advantage of the cooling provided by waterbodies and shade trees when locating housing.

■ Shield heat-prone paved surfaces, such as streets or parking areas, in the shelter of structures that provide shading.

Sources of Information

■ **U.S. Department of Commerce, National Oceanic and Atmospheric Administration, Asheville, North Carolina.** This agency collects and compiles climatological data for many areas throughout the country. The amount of information varies, but most stations record daily temperatures and precipitation. Some stations have detailed monthly reports and an annual summary that tabulates records from stations statewide. Most major libraries receive these publications.

Geology

Planning Considerations. Although a site's underlying rock structure is used much less frequently than the surface soil layers, it is of critical importance. Surveying and analyzing subsurface

6723

geological conditions provides essential information that might affect development. This is especially true for karst areas that have thick formations of easily dissolved limestone, creating a high number of sinkholes.

The subsurface geology is a source of raw materials, a reservoir for water and waste disposal, and gives the land backbone—allowing it to support heavy structures. It also contains important mineral deposits. Improperly analyzing and using this resource can result in jeopardized water supplies, ineffective disposal systems, and damaged buildings and roads. Knowledge of subsurface geology is also needed to answer questions about the weight-bearing capacity, availability of potable water, physical limitations, suitability of the site, and infiltration potential on runoff control. An area's surface physiography is a direct result of its geology.

Development Guidelines

- Karst topography has important implications since sinkholes can form at any time. Therefore, geologic mapping and evaluation completed prior to design should consider all environmental factors that affect design and construction. This preliminary feasibility study should consider adverse geologic conditions (i.e., location of sinkholes and other limestone formations) and the economics of grading and other land modifications.

- Potential sinkhole formation should be evaluated. Roadways, structures, sewage lagoons, landfills, and runoff systems should not be located in areas likely to develop sinkholes.

- Recent evidence indicates that vast dendritic underwater networks connect many sinkholes, allowing rapid transmission of pollutants through this underground river system. Extreme care is needed to prevent introducing runoff/pollutants into groundwater, a major source of fresh water.

Sources of Information

- **Department or bureau of geology.** Most states have a geology department or bureau within a state resource management agency. This department will often have environmental geology maps and reports that provide basic data to create and execute sound programs for waste disposal, water resources and land management, building and highway construction, geologic hazards identification, and mineral extraction. Many departments also publish numerous in-depth studies for small areas, but site-specific investigations may still be needed.

- **Universities.** Many universities have geology departments with studies useful to the planner or developer.

- **U.S. Geological Survey.** This agency publishes many types of technical reports and maps useful in determining a site's geological characteristics.

- **Well Logs.** These records, prepared by well drilling contractors, identify the type of material and depth of various subsurface formations. Many states require these logs.

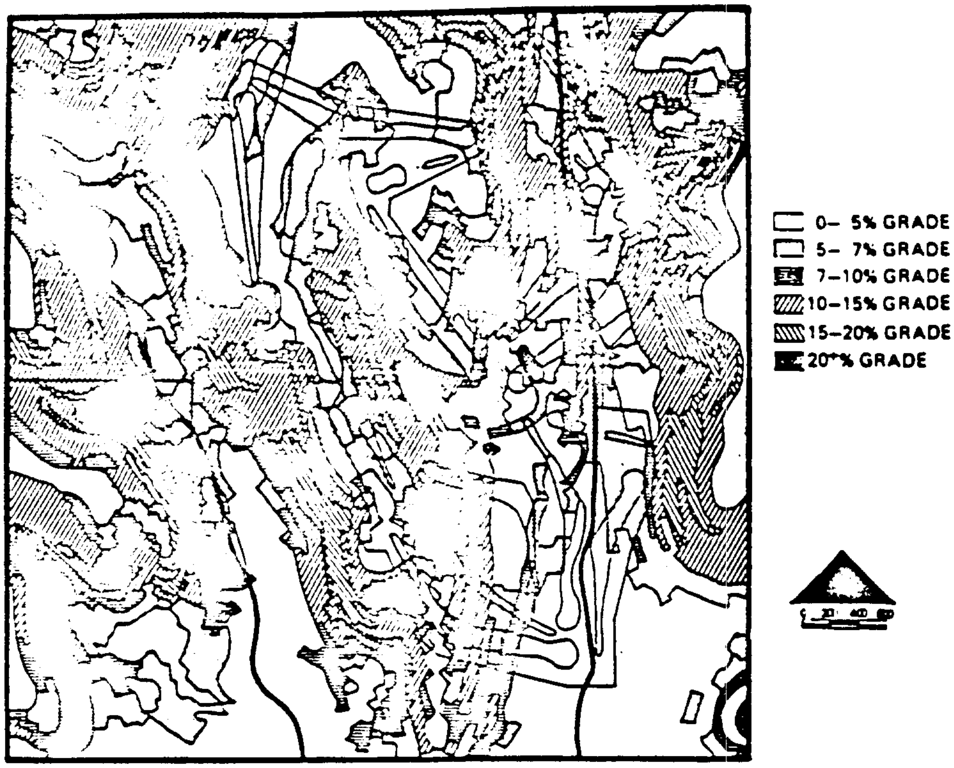
Physiography

Planning Considerations. Physiography is the study and description of landforms or irregularities of the earth's surface. Knowing the original topography, drainage, and vegetation of different landforms is important to minimize potential development problems and hazards in siting/design of building and grounds.

States generally have several major physiographic divisions, which can be further broken down into major landforms. These landforms and divisions are combined and described by the USDA SCS's major land resource areas (MLRAs). An MLRA is a land area characterized by particular soil patterns, including slope and erosion, climate, water resources, and land use. The Agricultural Handbook (U.S. Dep. Agric. 1976) describes each MLRA in the country.

The most important physiographic element to the developer is site topography. Topographic information is critically important because hills and valleys, plateaus and ridges, height, and slope degree all affect the area's ecology and suitability for development. Topography influences the type and cost of development, controls the direction and rate of water runoff, influences the overall utility layout, adds variety to the landscape, influences the weather and climate, and affects the types of vegetation and wildlife. A slope analysis (Figure 12.2) performed on hilly sites determines the best land uses for various portions. Moderately sloping sites are preferable to steep or level land. Improvement costs rise sharply on slopes over 10 percent, unless they are specially planned and treated. Preserving the area's natural amenities—trees, terrain, and views—can significantly reduce development costs.

Figure 12.2—Slope analysis for hilly site.



Source: Rubenstein, 1980.

Development Guidelines

- Obtain a topographic site survey before purchase. A thorough topographic survey will provide such physiographic data as the elevation, amount, and direction of slope, ridges, and valleys; location of rivers, lakes, sinkholes, and wetlands; outline of wooded areas, rocky areas, or outcroppings; and scenic vistas.
- Preserve the natural topographic features. This step involves preserving floodplains, streams, sinkholes, and other waterbodies by building well back from their edges, thereby creating common open space along shorelines.
- Let the topography guide the land use plan. A community designed in harmony with nature benefits from the services provided by nature, uses the natural landscape rather than creating a new, artificial landscape, and requires less time, effort, and expense.
- Control or prevent development on steep slopes, highly erodible soils, and areas with threatened or endangered species.
- Place roads parallel to the contours on ridges to minimize the need for cut and fill. Stabilize cut and fill banks with minimum maintenance materials to prevent continuing erosion problems.
- Use cluster development when sites contain steep slopes or other physiographic characteristics that would increase development costs or disrupt the natural systems.

Sources of Information

- On-site inspection. This visit is the cheapest, most thorough, and most reliable source of information. However, the inspector must be knowledgeable and experienced.
- U.S. Geological Survey. Topographic quadrangle maps are reliable for actual to-

pography, but the scale and contour interval are usually too large to be useful for smaller properties. The maps also show location of urban areas, constructed structures, highways, railroads, waterbodies, and other physiographic features.

■ **USDA SCS.** Detailed soil surveys, which include aerial photographs, delineate general slopes, wet areas, and other sensitive areas.

■ **Aerial photographs.** These photos can help one get the feel of an area, although thorough, accurate interpretation usually requires the services of a professional. Aerial photographs may be available from a state transportation or revenue department, regional planning commission, county tax assessor's office, or private firms authorized to sell aerial photographs.

■ **Local registered land surveyors.** These professionals can supply and interpret site topographic maps.

Hydrology

Planning Considerations

■ **General hydrology.** This science explores the behavior and properties of water in the atmosphere and on and under the earth's surface. The movement and exchange of water between the earth and atmosphere is called the hydrologic cycle. Although most areas receive adequate annual precipitation, a large portion is returned to the atmosphere by evaporation from land and water and by transpiration from plants. Continued growth and development create more impervious surfaces, which increase urban runoff, much of which is then discharged to surface waters that ultimately flow into the sea. This represents a tremendous loss of valuable fresh water. To avoid water shortages and prevent lowered water quality, water management must become a primary factor in decisions affecting land use, population distribution, and the protection of our country's natural resources.

■ **Surface waters.** Surface runoff varies from place to place, depending on the timing and amount of precipitation, soil, topography, and nature of underlying rock formations and on whether the waters are lakes, estuaries, or coastal. Stream density is low where water, moving downward to the aquifer, is enhanced by thin or porous soils overlying the limestone. In other areas, stream density is high. In some systems, especially broad swamps or floodplains, the water moves slowly in broad bands. Some streams are almost entirely spring-fed and have a well-sustained flow. The flow of other streams consists largely of runoff or groundwater inflow. Flow varies greatly, with little or no flow during dry periods and high flows and floods during wet periods.

■ **Wetlands.** One of the country's most valuable resources, wetlands provide a natural way to manage and store water and maintain water quality. As extremely productive ecosystems, wetlands are vital fish and wildlife habitats. They provide a variety of benefits—such as cleaning water to maintain water quality, storing and dampening floodwater, recharging aquifers, modifying the climate, and providing recreational, educational, and aesthetic values—with no cost or maintenance. Unfortunately, many wetlands have been drained or altered so that they no longer provide these benefits. Development should not destroy or alter remaining wetlands; it should preserve or, where feasible, restore them by using their services (e.g., wastewater treatment, runoff management).

■ **Floodplains.** Flooding is a natural characteristic of all rivers, but one of unknown probability. Floodplains formed naturally as waterbodies exceeded their normal levels during periods of high precipitation. Because floodplains provide a place for floodwater storage and detention and reduce floodwater velocities, they function as nature's safety valve. Before humans changed the landscape, there were floods but no flooding problems. But since we began to encroach upon floodplains, problems have occurred, waterbodies have become degraded, and injuries and damages have escalated. Floodplain planning and management reduce these economic losses and the need to build expensive structural runoff management systems.

Floodplains also perform valuable environmental functions including wildlife habitat; recreational, aesthetic, and scientific needs; open space; groundwater recharge; water quality maintenance; and sediment control.

Development in floodplains usually reduces, modifies, or eliminates their ecological functions. It also places an economic burden on the general public, which must reestablish these functions through costly public works projects and pollution abatement controls such as runoff management systems.

■ Groundwater. This is one of the country's most valuable, and in many places abundant, resources. Many areas are underlain by thick, porous, and permeable layers of sedimentary rock that serve as prolific groundwater resources and yield tremendous quantities of fresh water. These underground reservoirs are called aquifers. The two main aquifer types depend on their geologic development condition. One type is the nonartesian or unconfined aquifer, not covered by an impervious layer, the upper surface of which is sometimes referred to as the water table. Withdrawal requires pumping or directly using exposed surface water. This surface aquifer is usually recharged by local precipitation and is vulnerable to contamination from overlying land uses.

The other type is the artesian aquifer, confined above by a less porous or impermeable layer and under sufficient hydrostatic pressure to cause the water to rise over the containing layer to outlets such as springs or sinkholes. The potential for aquifer contamination is present where connections or inlets are made from the land's surface to the artesian aquifer, either naturally or artificially.

Because artesian aquifers supply many people with drinking water, sinkholes and other inlets to the groundwater system must be protected from pollution. Many areas have maps that depict the approximate altitude of the top of the rock or sediment that composes a particular aquifer. These maps can determine where the aquifer rock is exposed at or near the land surface. Development in such areas must be carefully planned to prevent aquifer contamination.

Many aquifers are recharged in areas where the aquifer's hydrostatic pressure head is lower than the water table. These areas should be protected by special development review requirements—such as the Wellhead Protection Ordinance—to ensure that the recharge potential is not diminished (i.e., by limiting impervious surface area) and that inappropriate land uses, which employ potentially polluting substances, are not allowed within the area.

In coastal areas, special care must be taken to prevent salt water intrusion into the aquifer. In these areas the aquifer's permeable limestone is shielded against upward intrusion of salt water by relatively impermeable beds of clay and marl but not against lateral encroachment of seawater. Such encroachment can result from overdrainage by canals or from overpumping the aquifer. Proper planning and water management are becoming increasingly important in protecting our nation's supply of potable groundwater.

General Design Guidelines

■ Postdevelopment runoff from the site should approximate the rate of flow, volume, and timing of runoff that would have occurred following the same rainfall under predevelopment conditions to preserve riparian areas and streambanks.

■ Thoroughly map all waterbodies, recharge areas, and natural water retention/storage areas as part of the topographic survey. This survey determines existing drainage patterns, delineates wetlands protected by law, defines the area of floodplains in which special building regulations may apply, and identifies vital recharge areas. Depending on the size and type of development, some delineation, description, and engineering evaluation of the surrounding watershed may be appropriate.

■ Preserve the existing natural runoff management system. When incorporated into the area's overall runoff management plan, natural systems provide water quality and storage benefits more efficiently and less expensively than a constructed system. The natural runoff system components may also provide open space and recreational opportunities.

■ Restore and rehabilitate degraded wetlands. Reestablishing the natural hydrology and integrating the wetlands into a final component of the site's runoff management system realizes many natural benefits of wetlands, including runoff pollution removal through retention and detention.

■ Lands that contain waterbodies should be developed using techniques such as planned unit developments or clustering. In planned communities, sensitive areas such as flood-

VOL 12

6727

R0040035

plains and wetlands are preserved to provide their natural functions, including runoff pollution control. Additionally, planned developments can reduce site development costs and provide residents with an enhanced quality of life.

- Preserve or restore natural shorelines and stabilize shoreline vegetation. In the natural state, shorelines are relatively erosion-resistant and represent an equilibrium of many forces. The irregular convolutions fulfill important functions such as holding soils, reducing surface runoff and erosion, percolation, filtering runoff, and providing food and habitats for aquatic organisms.

- Avoid alteration of natural stream channels. Disturbances can devegetate and destabilize the stream channel and bank, causing loss or alteration to the habitats of aquatic animals.

- Plan water-related developments to maximize the land potential and still protect natural resources such as riparian habitat. In Figure 12.3, Plan B allows for scenic vistas from the highway, maintains part of the shoreline for public use, provides public and private access, and increases property use, thereby increasing the developer's potential return.

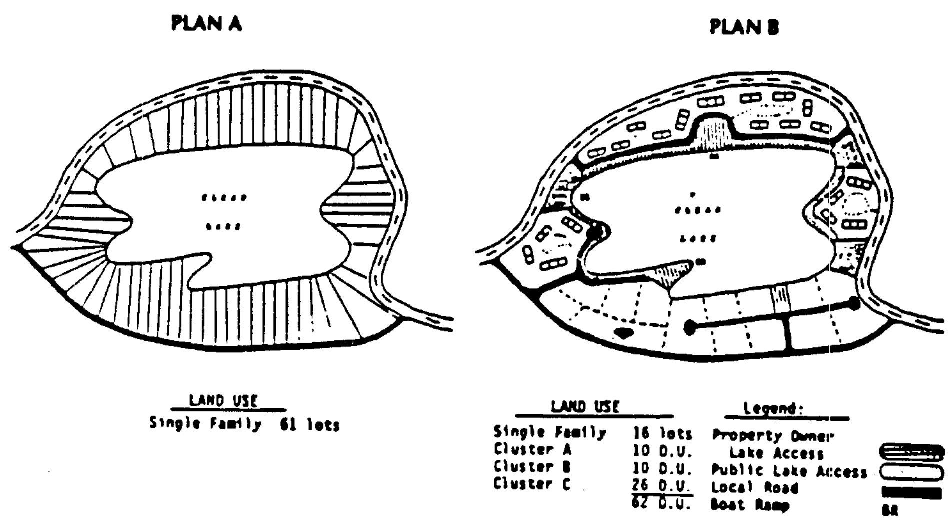
- Establish buffer zones, either fixed or variable—the size depends on soils, slopes, and floodplain—along all waterbodies. Buffer zones protect adjacent developments from the water and protect the water from the developments.

- Vegetated filter strips that filter runoff before it reaches the water should be left in a natural state or reestablished if clearing has occurred. Alternatively, a swale and berm system can be set back from the shoreline. This system slows and filters runoff from the development and can be used as a recreational area (e.g., jogging trail) during dry periods.

- Waterfront property frequently has steep slopes as it descends to the water. Areas without natural vegetation can be terraced, increasing potential use and reducing runoff and erosion. This is especially effective when a swale and berm system is incorporated into the terrace system.

- Do not remove shoreline vegetation to create a sandy beach. Removing vegetation destroys roots that stabilize soils and eliminates the natural filter and habitats for aquatic animals. If shoreline vegetation has already been removed, local native plant varieties suitable for the site conditions can be

Figure 12.3—Plan to maximize land potential and protect natural resources.



D.U. = Dwelling units
Source: Livingston et al. 1988.

replanted. Access to water is best accomplished via boardwalks, decks, or pier structures. If a sandy beach is essential, remove vegetation only on a small part of the shoreline—less than 20 percent or as allowed by state or local regulations.

■ To minimize maintenance and reduce nutrients introduced into the waters, maximize the use of native plants in landscaping, especially those requiring little water (xeriscape). Avoid using introduced varieties and lawns requiring fertilization, especially in waterfront areas.

■ If on-site wastewater disposal systems are used on waterfront properties, place them as far as possible from the water, preferably in front yards. Base minimum setback requirements on soil, geology, hydrology, groundwater, and other characteristics that influence environmental effectiveness and safety. Alternative on-site disposal systems, such as aerobic units, may be required in some areas to protect the environment from nutrient and pathogen loadings. In other areas, site conditions may make on-site systems unreliable and likely to cause adverse health and environmental impacts.

■ Groundwater recharge areas should have low-density development with limited impervious surface. To augment the recharge ability of a developed area, retain runoff onsite and allow it to infiltrate. If possible, treated wastewater should be recycled and allowed to percolate into the soil (i.e., use treated effluent to irrigate lawns, open spaces, or golf courses).

■ In areas with high water tables, avoid contaminating the groundwater. Use on-site disposal systems only with 4 ft (1.22 m) of suitable soil between the drainfield bottom or percolation pond and the water table to ensure that the effluent is properly filtered.

■ Fill should not be placed within the 100-year floodplain, as this increases flood heights and velocities. It also moves sediment into receiving waters, causing associated problems. In addition, locate only low-intensity land uses (i.e., open space, recreation, silviculture, and agriculture) with appropriate best management practices within the floodplain.

Information Sources

■ **U.S. Geological Survey.** With offices throughout the country, the USGS maintains a highly diversified database on water resources, ranging from hydrologic record networks to interpretive investigations of water resources.

■ **State departments or bureaus of geology.** These agencies may publish the results of local geological, hydrogeological, or water resources investigations.

■ **Water management districts or boards.** Some states have established regional water management (watershed) districts or boards with broad responsibilities to protect and manage water resources. They often conduct scientific investigations and administer certain types of water planning, management, and regulatory programs.

■ **State environmental protection, water quality, health, or natural resources agencies.** These agencies have a variety of resource management information and data, including pollution source permitting information. Agencies usually offer technical assistance, as well.

■ **USDA SCS.** With offices in nearly every county, USDA SCS provides technical assistance, conservation planning, and implementation services to local landowners. It also publishes detailed soil surveys that identify soil types and locate vegetation and waterbodies.

■ **Local governments.** Many city and county governments have water resources departments with considerable knowledge of local hydrology and water quality and quantity conditions.

■ **Regional planning councils or councils of governments.** These agencies often review and approval large developments and prepare and coordinate implementation of regional water management plans or programs. They usually serve as clearinghouses for planning and technical information and publications.

■ **U.S. Environmental Protection Agency.** EPA regional nonpoint source coordinators can provide resources and technical information. Regions work with state, federal, regional, and local agencies on pollution control efforts.

Soils

Planning Considerations. In many instances, major soil-related problems are discovered after a site has been selected, with construction well under way or completed. These problems can cause construction delays and increase the project's total cost. By consulting a soil survey during the planning process, alternative designs can be prepared and sites selected. Knowing soil types, topography, and surface drainage patterns is beneficial in planning and designing almost any type of land development project; it is essential for erosion control planning.

With soil maps and accompanying supporting data in soil surveys, developers can determine the soil conditions in proposed construction areas. Modern soil surveys provide great savings of time and money and result in improved designs, more effective planning, and more accurate preliminary cost estimates.

A USDA SCS detailed soil survey is especially valuable in determining a site's suitability for a particular land use. These surveys contain aerial photographs that map soil classifications and other information. Detailed soil surveys also contain interpretations of soil characteristics, information on the soil suitability for selected urban uses such as wastewater treatment, community development, transportation facilities, recreation development, and water management. However, interpretations do not replace specific on-site investigations for engineering design and construction. Interpretations should be used primarily for land planning, evaluating land use alternatives, and planning site investigations prior to design and construction. Important soil properties and characteristics include permeability, infiltration, seasonal wetness and the water table, depth to bedrock, texture, shrink-swell potential, erodibility, and slope. Variations in soil properties affect the soil's ability to support heavy loads, serve as a medium for wastewater or solid waste disposal, percolate rainwater, hold its shape and slope after excavation, or grow vegetation.

Important soil characteristics needed for planning include

- **Erodibility.** This is the major soil consideration for erosion and sediment control. An erodibility factor (K) indicates the susceptibility of different soils to the forces of erosion. A soil survey report lists the K factor for each soil type within the survey area. These K factors are used in the Universal Soil Loss Equation to determine soil loss from an area over a period of time due to splash, sheet, and rill erosion. K factors can be grouped into three general ranges:

0.23 and lower	low erodibility
0.23 to 0.36	moderate erodibility
0.36 and up	high erodibility

Soil particle cohesiveness varies with different layers of the same soil, causing varying degrees of erodibility at different depths. Therefore, excavation depth must be considered in determining soil erodibility on a construction site.

- **Permeability.** Permeability is a major factor influencing erosion. Soil permeability is the quality that enables soil to transmit water or air. Deep, permeable soils are less erodible simply because more rainfall soaks in, reducing surface runoff. Permeability, which varies with different layers, must be considered when excavating. Antecedent soil moisture conditions also affect soil permeability.

The hydrologic soil group (HSG) is a direct indication of the soil's infiltration rate. Soils are grouped into four hydrologic soil groups, according to their infiltration and transmission rates:

A. Soils with high infiltration rates even when thoroughly wetted—low runoff potential.

B. Soils with moderate infiltration rates when thoroughly wetted.

C. Soils with slow infiltration rates when thoroughly wetted.

D. Soils with very slow infiltration rates when thoroughly wetted—high runoff potential.

- **Texture.** Soil texture refers specifically to the proportions of clay, silt, and sand smaller than 2 mm (.08 in) in diameter contained in a soil mass. Soil texture is a primary factor in erodibility and is reflected in the erodibility factor. Erodibility increases with greater silt and very fine sand content and decreases with greater sand, clay, and organic matter content. Soils with high clay content are generally more resistant to detachment; but once detached, clay particles are easily transported. These clays and silts are very difficult to settle out once they get into the water column, sometimes necessitating the

VOL 12

6730

R0040038

use of coagulating agents to prevent their discharge into conveyances or receiving waters.

- **Shrink-swell potential.** Certain soils have clays that shrink when dry and swell when wet. In this situation, special foundations are required to allow for this variation. Identify these soils by consulting the soil survey and take the necessary precautionary steps.

- **Flood hazard.** Although soil survey information does not replace hydrologic studies, it does estimate where floods will likely occur. The hazards of flooding and ponding for various soil types are rated in soil surveys, and flood-prone areas are shown on survey maps.

- **Soil reaction (pH).** Soil survey information includes the pH of the individual soil layers. This factor is used to plan vegetation on disturbed areas, especially critical slopes.

- **Wetness.** Soil surveys have many types of data available including natural soil drainage, depth-to-seasonal water table, and suitability of winter grading for various soils. With this information, engineers can determine such things as seasonal limitations on using heavy, earth-moving machinery and estimating flood hazards or damage to underground structures due to soil wetness.

- **Depth to bedrock.** Soil surveys indicate bedrock types and where bedrock will be encountered at a depth of less than 5 to 6 ft (1.52 to 1.83 m). This information is helpful in determining location, time, and cost of excavation.

- **Slope.** Soil surveys record slope ranges and identify areas where cuts and fills are needed. The longer and steeper the slope, the greater is the potential for soil loss due to increased velocity of surface runoff.

Soil surveys are also helpful in interpreting the effect of soil properties on various land uses. For example, an interpretation may determine that soil can be used as topsoil, road fill for highway subgrade, or sand and gravel. The interpretations also show soil limitations for such purposes as building foundations, highways, streets, roads, parking lots, pipelines, underground utility lines, and septic tank absorption fields.

Often the survey will provide adequate information; sometimes it may only provide warnings or indications of soil-related problems likely to be encountered. In this case, a more in-depth, on-site investigation may be needed.

Design Guidelines

- Use the detailed soil survey or map the soils to help develop the land use plan. Knowledge about the location of wet soils, high water tables, clay soils, erodibility, and slope can help prevent many problems.

- Use USDA SCS and/or Soil and Water Conservation District expertise to develop a conservation plan that minimizes erosion, sedimentation, flooding, and nonpoint source pollution. The USDA SCS has soil, plant, and water resource data; technical information; and standards and specifications for BMPs that apply to most local areas.

- Follow the USDA SCS's "seven principles of erosion and sediment control":

1. Plan the development to fit the site's topography, soils, drainage patterns, and natural vegetation.
2. Minimize the extent and duration of the area exposed at any one time.
3. Apply erosion prevention control practices to minimize erosion and on-site damage.
4. Apply perimeter control practices to protect the disturbed area from off-site runoff and to prevent sedimentation damage to areas below the development site.
5. Keep runoff velocities low and retain maximum amount of runoff on-site.
6. Stabilize disturbed areas immediately after final grading.
7. Implement a thorough maintenance and follow-up program.

Information Sources

- **USDA SCS and Soil and Water Conservation District.** USDA SCS generally has a state office along with regional and county/district offices and detailed soil surveys for many counties. It continues to map soils in those areas without soil surveys. In addition, the USDA SCS/district provides technical assistance in conservation planning and other issues to local landowners. The state office usually publishes a directory of USDA SCS offices and staff.

VOL 12 5731

Vegetation and Wildlife

Planning Considerations. As more people become urbanites, the value of plants and animals in a development increases. Aesthetically, landscaping and its accompanying wildlife provides residents with a sense of well-being and enhances the quality of life. The living resources in a well-planned development can effectively bridge the gap between the created and the natural environment.

Plants and animals also prevent and solve environmental problems in a development. For example, the variety and abundance of plants and animals in an area are important indicators of natural conditions and can interpret a site's constraints and opportunities (Table 12.2). Vegetation and wildlife also provide many other benefits (Table 12.3).

The importance of vegetation as an economic incentive has risen greatly in recent years.

Table 12.2—Vegetation indicators of site conditions.

ABSENCE OF PLANT COVER	SPARSE HERB AND SHRUB COVER	THICK HERB AND SHRUB COVER	BRUSH AND SMALL TREES	BLADE AND REED PLANTS	HIGHLY LOCALIZED TREE COVER

VOL 12

Table 12.4—Comparison of specific site effects.

VEGETATION AND WILDLIFE AREAS	6,000-ACRE PLANNED DEVELOPMENT	6,000-ACRE UNPLANNED DEVELOPMENT
Acres of semimature woodland developed[1]	8	35
Acres of mature woodland developed[2]	35	90
Miles of tree-lined roads incorporated into developed areas	1.3	.9
Miles of tree-lined roads widened	0	1.3
Acres of wildlife habitat developed	10	235
Number of interruptions in wildlife corridors	0	4

[1] Clearing semimature woodland at $650 per acre would cost $5,000 in the planned community and $23,000 in the sprawl community.
[2] Clearing mature woodland at $1,600 per acre would cost $56,000 in the planned community and $144,000 in the sprawl community.

Source: Quennel, 1972.

More developers are incorporating existing vegetation into site plans because of the high costs of land clearing and landscaping. The initial cost per acre may be higher when working around trees and other natural areas. However, because the total number of acres cleared and the amount of landscaping is smaller, the total cost is reduced. Table 12.4 compares the cost of a planned and an unplanned development.

Residential preference surveys identify parks and green spaces as important reasons to choose one neighborhood over another. Realtors have found that wooded lots consistently bring higher prices than those without vegetation. For example, in residential areas, a mature shade tree may have an estimated value of $1,000 to $3,500; other plantings may improve the real estate value of an average lot by $3,000 to $7,000.

Resource Inventory. The diversity in landforms and climate has produced a variety of habitat types that contain different combinations of plants and animals. Investigating a site's biological communities is essential to understanding the site's importance to the integrity of the ecosystem. Identifying and assessing plant and animal resources is an important part of site planning. Species could be identified and mapped, along with other site inventories such as hydrologic, physiographic, geologic, and soil surveys. Ultimately, these parameters must be considered together to develop a land use plan that balances ecological constraints and benefits with intended uses.

Vegetation. Natural vegetation is an important resource and habitat for wildlife. Inventory vegetation using a quality rating scheme from aerial photos and/or data from field surveys. Where the site is small (100 acres [40.47 ha] or less), interpreting photos may be as time consuming as field surveys. The following factors should be considered in analyzing a site's vegetation:

1. The number of distinct plant communities and their distribution;
2. The uniqueness of each plant community;
3. The presence of subareas that have recently been disturbed (e.g., clear cutting, cultivating, grazing, burning, bulldozing);
4. Accessibility of the area; and
5. Correlation with the site's physiographic features.

The inventory is used to document what plants occur naturally on the site, identify the forces and processes controlling their distribution, and determine where to find certain plants or plant groups. If the site has been environmentally degraded or overtaken by exotic species, readily determining the natural vegetation and environmental relationships may be impossible. Consult with local botanists, state foresters, and other

6733

trained professionals or examine historical records and photos to establish types and distribution of native vegetation.

■ **Wildlife.** Local wildlife can be inventoried directly by taking a population census or indirectly by assessing the quality of local habitats. Habitat analysis is the simpler approach, as the analysis can be performed from secondary sources (e.g., aerial photography). Consider the following terrestrial ecosystems factors in the analysis:

1. The number and types of plant communities per unit area,
2. The number of forest or woodland openings,
3. The presence of water,
4. The presence of movement corridors,
5. The size of the area, and
6. The variety of the wildlife appropriate to the habitat.

The value of wetland areas that support a rich variety of wildlife primarily depends on water quality. As with terrestrial ecosystems, perform separate habitat analysis for species requiring different habitats.

To take a population census, seek the help of trained wildlife observers. Census methods range from direct observation to analysis of indirect evidence. Regardless of the method, survey wildlife populations at several points in time to account for natural environmental fluctuations.

Special consideration must be given to endangered species and their critical habitats. Agencies such as the U.S. Fish and Wildlife Conservation Service, the State Department of Natural Resources and the State Committee on Rare and Endangered Plants and Animals list endangered species. However, state statutes will usually specify which organization's list is officially recognized.

▮ *Design Guidelines.* The resource inventory and site surveys should examine basic structural, functional, and locational patterns. If the area is in a natural state, these elements probably work effectively to support the living community. If the area is a constructed landscape, the natural systems may be degraded and work marginally, if at all. In either case, the plan should aim for compatibility between natural and constructed environments. A degraded natural system can be strengthened or even fully restored by a carefully planned development. For example, ditched and drained wetlands can be revitalized by introducing pretreated runoff.

The following principles will help developers plan for wildlife and vegetation, in consultation with local biologists familiar with the areas:

■ **Transition zones.** This zone between two habitats—such as the area between two forests or between a forest and a waterbody—is extremely important to wildlife. It supports wildlife not found in either habitat. Often the transition zone provides an exclusive habitat for a very selective, sometimes endangered, species or community of species.

■ **Water.** Proximity to water enhances an area's ecological productivity. Swamps, marshes, and bogs support a rich variety of plants and animals—many of which are valued as game species. Saltwater wetlands are important breeding grounds for fish and crustaceans.

■ **Alternative habitats.** Other habitats where wildlife may relocate have potential impacts, especially on endangered species.

■ **Timing of construction.** Construction should be timed to avoid critical periods in vegetation and wildlife reproduction, especially for threatened or endangered species.

■ **Choice of plantings.** Wildlife existence, both in number and quantity of different species, depends on habitat availability. Choice in planting or preserving specific habitats can effectively encourage certain wildlife species. When transplanting, include varying age classes of trees and shrubs. Select native species, especially those that require little fertilization, pesticides, or water, instead of troublesome exotic species.

■ **Animal-plant interactions.** Developments that reduce the wildlife that some plants depend on for reproduction may eventually eliminate these plants. For example, berry-producing plants depend on birds for seed propagation, and furry mammals often help distribute thorny seeds.

■ **Exotics.** Exotic species may compete with native varieties and eventually become nuisances. Sites with communities of exotic species may be good areas to develop and reestablish native communities.

Table 12.5—Comparison of six community types.

PROTOTYPE	COMMUNITY DESCRIPTION*	IMPACTS TO VEGETATION AND WILDLIFE
Type I: Planned Mix	20 percent of each of the following — single-family conventional, single-family clustered, townhouses, walk-up apartments. 2,000 units of each type. Neighborhoods are contiguous; large areas of open space are preserved.	Less species disruption where significant tracts of land are preserved as permanent open space.
Type II: Combination Mix	50 percent planned unit developments with contiguous and related land uses; 50 percent sprawl pattern. Housing mix same as Type I.	Greater disruption than in Type I. Open areas can be retained.
Type III: Sprawl Mix	Random, leapfrog development with many small lots vacant. Housing mix same as Type I.	Similar to Type I. Leapfrog development pattern bares only small pockets of undisturbed area.
Type IV: Low Density Planned	75 percent of dwelling units single-family clusters; 25 percent conventional, single family. Contiguous neighborhoods, but low density with vacant lots. Open spaces preserved, land uses comprehensively designed.	Low density development decreases amount of open land preserved in natural condition. Careful planning can protect areas of special significance as species habitats (i.e., woodland, swamp).
Type V: Low Density Sprawl	Most prevalent form of current development. 75 percent of dwelling units are conventional single-family; 25 percent are clustered single-family dwellings. Small percentage of passed-over land.	Virtually no land will be left totally undisturbed, thus eliminating habitats and causing a disruption in ecological balance.
Type VI: High Density Planned	10 percent of dwellings clustered single-family; 20 percent townhouses; 30 percent apartment; 40 percent high-rise apartments. Housing types are mixed with contiguous neighborhoods. Planned open spaces, related land uses.	Adverse effects lessened through careful planning to conserve special habitats and through high density development that preserves large tracts of undisturbed land.

* All communities contain 10,000 dwelling units
Source: Quennel, 1972.

■ **Fish.** Fish population in lakes and streams is closely tied to water quality and habitat. A decrease in dissolved oxygen concentration below 5 parts per million or major changes in flow character—including temperature changes caused by removing shade trees—may eliminate valuable game fish. Excessive runoff loadings—e.g., nutrients, metals, sediments—will increase aquatic plant problems and eventually cause fish populations to shift towards more "trash" species.

■ **Coastal vegetation.** Coastal vegetation along sandy and estuarine beaches protects inland areas against wind and waves. Dunes and mangrove areas provide physical barriers against high tides, wind, and waves. Marshes act as sponges, absorbing water during storms and high tides.

■ **Natural stormwater systems.** Modified natural stormwater systems reduce habitat for frogs, snakes, and salamanders. Preserve and incorporate natural areas into a comprehensive runoff management plan. This plan should incorporate a "treatment train" of runoff management practices, along with natural and landscaped areas, into a multipurpose amenity for the development plan.

■ **Compare planning approaches.** Land development has often disturbed natural cycles and flows of energy, producing undesirable economic and environmental effects. Table 12.5 describes six community development prototypes.

Structural Considerations

■ Runoff management areas should double as open space, landscape, and wildlife habitats. Because edge conditions are important, designs that maximize edges will be most successful in drawing and keeping wildlife. Plant native plants such as canes, marsh grasses, and riparian shrubs around basin edges. Many of these plants have beautiful flowers, allowing a designer to aquascape the shoreline to enhance visual amenities and increase property values.

- Direct roads away from high quality natural habitat areas, especially wetlands.
- Networks of waterways can be effective in interweaving the constructed landscape with wild areas.
- Maintain proper water level in wetlands with spreader swales and outlet control structures.
- Disturb the smallest area possible, retaining the maximum natural vegetation.
- Avoid clearing, scraping, leveling, and constructing seawalls and buildings on beaches and dunes.
- Construct observation blinds and interpretive nature trails through natural areas to provide recreation and enjoyment of wildlife.

Nonstructural Considerations

- Confine planted lawns and grass mowing to small areas to enhance seedling and wildflower growth and increase buffer effects.
- Retain wildlife corridors that connect habitats and water areas.
- Help protect and maintain areas with rare and unique natural features, including endangered species.
- Use open space, blue-green design space, and green space. They serve as recreational areas, wildlife buffer zones, and increase the aesthetic appeal.
- Where large-scale planned development is the predominant pattern, improved site design and landscaping makes it easier to retain the natural ground cover.
- Leave a buffer zone of vegetation in its natural state along the shore of waterbodies and adjacent to wetlands.

Information Sources

- **State game and fish commission.** Information on various species and habitats is usually available from state agencies. Agencies may have a special nongame wildlife program to further wildlife conservation by detecting and preventing population declines in animal species before they reach the verge of extinction. Agencies usually have information to assist the developer in considering wildlife.
- **USDA SCS/District.** The USDA SCS publishes lists and guides to native vegetation species or those well adapted to local conditions. The USDA SCS operates plant material centers around the country to study plants to determine suitability for conservation use (e.g., erosion control).
- **State universities.** Frequently, a state designates a state agricultural school. The school may have several agricultural and environmental resource programs and typically will focus on three areas—teaching, research, and extension. Normally, a college of agriculture and school of forestry conduct university level instructional programs; the Agricultural Experiment Center conducts basic and applied research; and the Cooperative Extension Program disseminates information through extension directors in each county. Numerous publications on successfully growing plants are available from these offices.
- **Natural Areas Inventory.** This is a joint project between a state agency (e.g., Department of Natural Resources) and The Nature Conservancy to provide a detailed, computerized account of a state's native flora and fauna. The inventory could provide a planner or developer with information concerning natural communities for landscaping, restoration, or preservation.

Critical Area Identification and Protection

Planning Considerations. A primary objective in site planning is to identify and locate critical areas. Typically, these are environmentally sensitive areas that, because of their inherent characteristics or location, create certain constraints on development. These constraints usually include environmental concerns and often include economic considerations. The site planning process creates a development plan that minimizes disturbing critical areas and works them into the plan as natural areas and other amenities. Critical areas may include steep slopes, highly erodible soils, stream corridors, shorelines, wetlands, floodplains, native forests, karst geology, high groundwater tables, and other similar areas.

▌*Design Guidelines.* If possible, avoid developing critical areas. Use them instead as natural areas, open spaces, and parts of the runoff system. When designing guidelines for critical areas

- Avoid alteration or construction within natural drainageways, stream corridors, wetlands, floodplains, natural depressional storage areas, or on steep slopes.
- Maintain and protect dense vegetation adjacent to waterbodies and wetlands to serve as natural buffers and filter strips.
- Establish setbacks from all critical areas where no development is allowed.
- Preserve or limit the clearing of shoreline vegetation, which helps to stabilize the shoreline, filter pollutants, and provide habitat for fish and wildlife.
- Preserve porous soils to take advantage of infiltration capacity.
- Avoid disturbing highly erodible or unstable soils to minimize erosion and sedimentation potential.
- Preserve and incorporate the natural runoff management system.
- Protect and incorporate native forests to provide shade and wildlife habitat.

Cultural Factors

A site's suitability and a project's success are closely related to cultural factors that have a direct effect on future inhabitants. The following factors are important in gaining public acceptance of proposed projects.

Existing Land Use

▌*Planning Considerations.* The pattern of existing area land uses should be investigated to ensure compatibility. The developer should meet with adjacent property owners and local planning department staff to discuss the future development under consideration and if it will conflict with uses on the proposed site.

Investigate off-site nuisances—i.e., visual, noise, or odors—and safety hazards. Visually disruptive elements may include power lines, water towers, industrial complexes, highways, and junkyards. Possible noise disturbances include heavy automobile, rail or air traffic, or noise made by stadium crowds. Objectionable odors may originate in landfills, wastewater treatment facilities, and polluted waters.

In studying the site's location in relation to adjacent properties and the community, determine and assess all existing linkages. Linkages involve moving people, goods, communication, or amenities through an area. Inventory community facilities—shopping centers, schools, hospitals, employment centers, residential areas and recreation—determine if they can adequately serve the site. If not, make plans to improve them through future development.

Density—an important environmental, sociological, and legal element in most types of development—influences privacy, freedom of movement, and social contact among people. Local governments usually have zoning regulations concerning density standards to help maintain a certain quality of life. A project's permitability by the state environmental agency may also be related to density factors.

▌*Information Sources*

- **On-site inspection of the surrounding area.** Observation is the easiest way to determine the existing land use.
- **Local government planning or zoning departments.** Contact these agencies at the earliest planning stage to determine if the proposed development is acceptable. Many potential conflicts and delays can be avoided by discussing development plans with local officials during the conceptual design phase. Review local comprehensive plans and policies to ensure consistency with the proposed development.
- **Regional planning councils or councils of governments.** These agencies, frequently involved with long-term land use planning, should be contacted early in the development process, especially for large projects or those of regional significance.

VOL 12

6737

Traffic and Transit

▌ *Planning Considerations.* If the type and size of development is significant, investigate the adequacy of existing transportation facilities. This investigation should determine the relationship of traffic patterns, whether adequate roads exist or must be supplemented, and whether public transportation is available. Large projects may require a trip generation survey to determine the proposed development's effect on existing traffic patterns. The survey should consider traffic's origin and destination, its purpose, the time of day, and the traffic volume generated by inhabitants or project users.

The conventional gridiron street pattern produces an unsafe, unpleasant circulation system with arbitrary street dimensions, through traffic, visual monotony, and lack of neighborhood identity. A curvilinear pattern or clustering arrangement in residential developments minimizes through traffic, disruption of the natural terrain and landscape, and expenses associated with road construction and other improvements. Well-planned curvilinear and cluster planning developments reduce the length of roads, utility lines, and sewer and water mains. Compared to conventional development, clustering can reduce the total road and impervious surface area and the cost of roads by 14 percent and utilities by 33 percent.

▌ *Information Sources*

- **Local governments.** Consult with local authorities to determine any long-range transportation plans and improvements. Obtain copies of local land development regulations (e.g., subdivision, zoning, and land development codes) that contain specifications for street rights-of-way and construction. Some local governments will also have traffic count information.

- **State department of transportation.** This department schedules highway improvements and publishes them in a long-term construction plan. It also conducts traffic counts and analyzes the data.

Density and Zoning Regulations

▌ *Planning Considerations.* Communities use planning and zoning to effectively balance land uses such as recreation, conservation, residential, commercial, and industrial development. Establishing appropriate development densities and intensities—number of buildings per acre and building bulk versus remaining land on the lot—is a fundamental problem. As density and intensity of development increase, so does the stress on natural and financial resources. The goal of community planning and zoning is to minimize these stresses and ensure that public facilities—such as street, school, sewer, water, and runoff services—are adequate. Sound site selection and planning principles are indispensable in achieving this goal. Planning and zoning regulations also benefit the developer by protecting the housing market.

Some state legislatures have enacted local government comprehensive planning and development acts to assure responsible growth. These regulations usually requires local governments to develop comprehensive plans to address future growth. Plans are implemented by adopting land development regulations such as zoning ordinances and land development codes.

▌ *Information Sources*

- **State land planning agency.** This agency implements the growth management program and works with local governments to develop and approve local plans. Various types of planning information and technical assistance may be available.

- **Regional planning councils or councils of governments.** These agencies may have regional policy plans that serve as a foundation for local comprehensive plans and include policies to minimize the regional impacts of large developments.

- **Local governments.** Obtain specific regulations such as zoning ordinances, land development codes, local comprehensive plans, subdivision regulations, and housing codes before selecting a site and designing the project.

Socioeconomic Factors

▌ *Planning Considerations.* To determine a project's feasibility, study the community and its socioeconomic structure. Social factors broadly affect community facilities and services. New facilities may displace homes, businesses, or community activities. A new highway may sever an area's cohesion by creating physical or visual barriers that affect business, property values, and character. Stormwater facilities, especially regional systems, can be viewed as detrimental to an area or neighborhood. Local governments need to assure that such systems are attractive, properly maintained, and well-designed to include recreational opportunities.

VOL 12

6738

R0040046

A market analysis can determine the socioeconomic feasibility of a project. Such studies help justify the need for the proposed development to local planning agencies. They also help ensure the developer a return on his investment. Generally, anticipate a building rate of 80 percent in 10 years, phasing development as demand warrants. Consider also the cost-effectiveness of rehabilitating income-producing historic structures listed in the National Register of Historic Places over new construction with the added benefit of investment tax credits.

Utilities

Planning Considerations. Every project should include provisions for six essential services—water supply, sewage disposal, solid waste collection, paved roads, runoff management, and utilities (electricity, telephone, gas). These services make a piece of raw land usable and shape its future resale value. Contact utility companies early in the site planning process to ensure that project needs can be met. Just as important, plan utility locations to minimize environmental disturbances on the site, and use appropriate erosion, sediment, and runoff controls during the installation of utilities to minimize adverse effects.

- **Potable water supply.** Water is probably the most critical basic need for community growth. Ensuring a continued, safe, adequate supply requires special planning. In addition to drinking water, most water systems provide fire protection, which requires high water pressure. If the area has no central water system, obtain information about the water quality for individual wells, the effect of many wells on the aquifer, and the potential for saltwater intrusion.

- **Sewage treatment and disposal.** In general, central wastewater treatment facilities should be provided for all lots under one-half acre (0.20 ha) and for any size lots not suitable for on-site disposal systems, either conventional or alternative designs such as aerobic units. Septic tanks should be used only on lots with proven adequate percolation rates, with slopes less than 12 percent, with bedrock and seasonal high water tables at least 4 ft (1.22 m) below the bottom of the drainfield, and with a distance of at least 200 ft (60.96 m) from any surface waters. Consider specific setback requirements for developments near water since the potential of these wastewater systems to degrade water resources depends on many variable, site-specific factors (e.g., soils, slopes, water table, geology, relative location).

- **Solid waste collection.** In rural areas, homeowners usually take refuse to a sanitary landfill or collection station. Urban subdivisions and commercial developments should include provisions for an authorized agent to collect solid waste to prevent litter and debris in runoff.

- **Streets and roads.** All roads should be built to county or municipal standards and dedicated to the local government for maintenance. In most cases, residential roads should be paved and include swales for runoff management. Storm sewers are needed only on more intensively developed projects; even then, swales could be a valuable component of the treatment train.

- **Runoff management.** The project should include a runoff management system that protects against flooding and ensures the water quality of receiving waterbodies. The system should meet local requirements (i.e., design storm) using the runoff management principles presented earlier.

Historic and Archaeological Resources

Planning Considerations. Thousands of recorded archaeological and historic sites, many listed on the National Register of Historic Places, demonstrate the nation's rich cultural heritage and colorful history. Many communities have historic structures of exceptional architectural quality and appeal. Many archaeological sites have high scientific and cultural value. As urban populations increase, so does the demand for more comprehensive protection of historic and archaeological resources. This demand should be considered in land development decisions.

Include an inventory of all historic and archaeological elements in development planning. Infrastructure planning is important because of the special requirements for preserving older buildings, streets, significant structures, and unique landforms. Architecture, landscape, and other design studies that affect the total environment should not conflict with existing cultural themes. On the contrary, development projects that blend into the cultural atmosphere can produce attractive and lucrative developments.

Historic structures and archaeological sites can have valuable and important community uses, while preserving their cultural value. Urban environments that are functional and offer a sense of community identity have many benefits for the developer, the residents, and the community.

▮ *Information Sources*

- **Local governments.** Consult local governments for assistance with identifying and restoring culturally significant buildings and other structures and sites. Many local governments have designated historic districts that impose special development regulations. A comprehensive plan may also be a valuable resource.

- **State government.** The state may have a bureau of historic preservation that records all existing historic and archaeological sites. It may also help evaluate an area's historic/archaeological significance and the impacts of development on significant sites.

Aesthetics

Aesthetic factors should also be analyzed on development sites. These factors can differentiate a "typical" development from one with extraordinary appeal and intrinsic beauty and value. A development with carefully considered and incorporated natural features and spatial patterns will have a greater appeal because of its community character.

Natural Features

▮ ***Planning Considerations.*** The landscape of the United States provides many sites with outstanding natural earth, water, and vegetation features. Incorporating mountains, rolling hills, oceans, lakes, streams, wetlands, forests, sinkholes, and springs into the development accents its architecture, reflecting the area's natural character rather than competing with it.

Spatial Patterns

▮ ***Planning Considerations.*** A site's spatial patterns include factors such as views or scenic vistas. Views, pleasing or objectionable, frequently bear heavily on a building's orientation. An outstanding view should be preserved or accentuated. Views must also be compatible with proposed activities and their relation to each other, because nuisances both on and off the site may disrupt them. Vegetation, slope, fences, or walls can screen objectionable odors, noises, or visual elements such as billboards, power lines, junkyards, or parking lots. Power lines can be placed underground, and parking lots can be depressed below grade and heavily landscaped.

Other Nonstructural Management Practices

Many of the varied nonstructural management practices and source controls available are good examples of common sense and a stewardship ethic. Nearly any technique that reduces the potential adverse impacts of our daily activities on a watershed's natural resources can be considered a nonstructural control. Following is a brief discussion of common nonstructural or source controls. Many can be incorporated into local land development codes, while others require a commitment of all residents for success.

Site Characteristic Practices

- **Buffer zones or critical area zones.** In these areas, special design and performance criteria may apply and a naturally vegetated zone is maintained. Land development codes often establish a minimum distance that the zone must extend from a sensitive feature, depending on a variety of site specific characteristics.

- **Setbacks.** Discrete distances—such as the distance between a septic tank and a well, shoreline, or stream—are established by state or local regulations and used to protect sensitive areas and meet environmental goals. Both setbacks and buffer zones can be protected by a variety of legal mechanisms including purchase, easements, or conservation easements.

- **Minimum natural area.** Some local codes specify a minimum portion (e.g., 20 percent) to be maintained in its natural condition, unless the site is already degraded, to preserve critical features and reduce overall development impacts.

- **Landscaping and tree protection.** Local codes often specify landscaping requirements (e.g., plant types and sizes) and protect certain trees, usually based on diameter and species, to reduce clearing. This protec-

VOL 12

6740

R0040048

tion reduces erosion, sediment, and runoff problems. These requirements, together with any requirements for minimum natural area, must be carefully integrated to assure compatibility.

■ **Shoreline vegetation management.** Shoreline vegetation protects and enhances waterbodies. Clearing for waterfront development should be limited to a minimum. Developers, waterfront property owners, and local governments should practice aquascaping by establishing diverse, aesthetically pleasing native aquatic plants along shorelines of runoff ponds, lakes, streams, and other waterbodies. Restoring these watershed resources can reduce the need for more expensive structural controls.

Characteristic Practices of Natural Runoff

Minimize Impervious Surface Area

Limiting impervious area is the most effective way to preserve a site's predevelopment runoff characteristics. Local codes may specify the maximum proportion of impervious cover allowed (e.g., 75 percent). Techniques include

■ Reducing building setbacks, which reduces the lengths of driveways and entry walks. This technique is most applicable along low-use residential roads where traffic noise is not a problem.

■ Reducing street widths by eliminating on-street parking or reducing lane width is most applicable to residential neighborhood roads.

■ Reducing sidewalks to one side or combining them with bicycle trails/walkways that go through back yard easements or natural areas. Whenever possible, these trails should be made of pervious materials.

■ Using pervious pavement materials, such as pervious asphalt or pervious concrete, gravel, or combinations of geotextiles with sand, gravel, and sod. Take care when using pervious pavements to prevent clogging. Special design, preparation, batching, pouring, and finishing procedures, along with long-term maintenance needs, require that these pervious pavements be used appropriately.

■ Using alternative development designs, such as cluster development, to reduce the length of roads, sidewalks, and other impervious areas.

Preserve and Mimic the Natural Runoff System

Traditionally, runoff systems were built solely to convey runoff away from homes, buildings, and developed areas as quickly as possible, with little regard for its effect on downstream land or water resources. Techniques that promote infiltration by slowing and filtering runoff include

■ Routing roof runoff to pervious areas, such as lawns, grassy swales, or depressed landscaped areas. Prohibit connecting downspouts directly to storm sewers or discharging downspouts onto parking lots, driveways, or other impervious areas.

■ Protecting floodplains, wetlands, natural depressional storage areas, and highly pervious sites. Incorporate them into the final runoff management plan as part of the treatment train.

■ Using grassy swales instead of storm sewers as runoff conveyances, especially in residential developments. Swales, especially those with check dams or raised driveway culverts, encourage runoff capture and infiltration. Use public education to teach citizens that water standing in a swale for a day is not bad and to prevent citizens from altering or using swales to dispose of yard materials or other garbage.

■ Using depressional landscaping techniques that allow small areas, including landscaped islands within parking lots, to provide some storage and infiltration.

■ Placing storm sewer inlets in grassy areas instead of paved areas. For example, a successful treatment train within a shopping center parking lot consists of landscaped areas around the perimeter that includes a grassy swale adjacent to the curb line. Regularly spaced curb openings (curb cuts) allow runoff to flow off the parking lot into the swale. The swale conveys runoff toward a storm sewer inlet, raised about 6 in (15.24 cm) above grade, and then to a wet detention basin. Depressed landscape islands with curb cuts contain storm sewer inlets, also raised 6 in.

VOL 12

6741

Good Housekeeping Practices

Practices that reduce sources of potential pollutants in runoff should be undertaken by all watershed residents. Public education is vital to acceptance and use of these practices.

- **Street or parking lot sweeping.** Particles that accumulate along streets and on parking lots should be removed before they enter the runoff waste stream. Mechanical broom sweepers effectively remove particles larger than 400 μm but cannot remove smaller particles that contain the majority of street pollutants. Vacuum sweepers, more efficient in removing smaller particles, are ineffective on wet pavements. While street sweepers undoubtedly remove large quantities of solids and other materials from streets and parking lots, their effectiveness depends on many factors. Using street sweepers regularly in highly impervious areas like central business districts may be one of the only effective BMPs for a highly developed area. Research must determine if materials collected by street sweepers pose any environmental threats and how to dispose of this material.

- **Detecting and prohibiting illicit connections.** Illicit connections of sanitary sewers, industrial discharges, commercial floor drains, sump pumps, and basement drains greatly contribute to water quality problems caused by runoff. These often serve as conduits that introduce solvents, oils, and even toxic materials into runoff. Local governments should conduct regular investigations (i.e., smoke tests, dye tests, dry weather flow sampling) to detect and eliminate illicit discharges.

- **Proper handling, use, and disposal of fertilizers and pesticides.** Controlling the rate, timing, and method of chemical applications can minimize use and limit runoff contamination in a watershed. Many state agricultural agencies provide educational materials on the proper type and amount of fertilizers needed for a particular landscape. U.S. Department of Agriculture agencies provide fertilizer and pesticide management guidance in selecting the most environmentally safe chemical and minimum effective dosage.

- **Proper handling, use, and disposal of household chemicals.** A wide variety of cleansers, oils, solvents, paints, and other household materials pose certain risks to the environment. Some wastes are legally defined as hazardous or toxic and must be disposed of using stringent procedures imposed by federal, state, or local laws. Some states have established programs such as amnesty days that encourage citizens to safely and freely dispose of potentially hazardous household wastes. Citizens need to know how to safely use and dispose of many household materials including antifreeze, gasoline, waste motor oil, car batteries, old tires, floor or furniture polish, most cleaning products, chlorine bleach, paints, paint thinners, turpentine, mineral spirits, wood preservatives, weed killers, and roach and ant killers.

- **Proper solid waste management.** Solid wastes and litter that accumulate on the land are easily transported by runoff. Properly collecting and disposing of solid wastes—and recycling appropriate materials—can greatly reduce runoff pollutant loadings. Litter laws, adopt-a-road or shore programs, and econeighborhood programs are effective in encouraging citizens to "clean their own nests."

- **Proper disposal of pet wastes.** The wastes our pets leave behind can be a major source of bacterial loading to our waters. Requiring owners to properly dispose of animal wastes can help reduce these loadings and keep our waters open to recreation.

- **Recycling used waste oil.** Many gallons of waste oil are dumped into storm sewers for disposal. However, this oil can be recycled and used for many activities. Many states, local governments, and private companies have established used-oil recycling programs and centers.

- **Organic debris disposal.** As laws limiting the landfill disposal of yard wastes become more common, the proper management of grass, leaves, pruned branches, and other debris becomes increasingly important. Composting by homeowners or at collection centers reduces organic debris and associated pollutants from the runoff waste stream. Additional benefits include increased soil organic matter, resulting in improved water and nutrient holding capacity, and nutrients, which reduce the need for fertilizers.

Roofing or otherwise enclosing areas. Loading docks, storage areas for raw materials, wastes or final products, and equipment maintenance and storage areas are likely pollutant sources carried in runoff. Roofing or enclosing these areas so they are no longer exposed to rainfall or runoff will prevent oil, gasoline, fuels, solvents, hydraulic fluids, sediment, organics, nutrients, and other pollutants from entering runoff. However, since roofing increases impervious area, this effect should be mitigated.

Proper siting and storage of materials. Many commonly purchased and used materials can contribute to runoff pollution. For example, many businesses store and sell bags of fertilizer and pesticides from pallets in an open parking lot. These bags often tear or rip, allowing material to spill onto the paved surface. A storm sewer inlet directly downstream provides a direct conduit to transfer this material to a downstream waterbody. Such areas may need roofing. At a minimum, storm drains should not be located downstream. Aboveground storage and secondary containment may be necessary for materials and in locations vulnerable to groundwater contamination.

Waste reduction and prevention. Waste reduction usually involves using several integrated techniques to eliminate or reduce the amount of potentially hazardous materials used at a site. It may involve source reduction through good housekeeping, technology or process changes, or modification of input materials; recycling, reclamation, and reuse of materials; and treatment to reduce material toxicity.

Proper spill prevention and containment. Facilities that store or use certain types of potentially hazardous materials may be required to prepare a written plan outlining their approach to preventing and containing spills. These plans document the operational procedures and management approaches. Pollution prevention plans typically specify procedures for preventing pollution caused by storage and use areas, manufacturing processes, treatment systems, or shipping areas; emergency containment and cleanup procedures to be used in case of spills, leaks, or other discharges; inspection procedures and schedules; and methods to maintain inventories of potentially hazardous materials from the time the material is received or manufactured until it is treated and discharged or shipped out.

Storm sewer screens. Simple screens of chain link fencing placed at the outfall point of storm sewers capture cups, leaves, and other large debris. Of course, these screens must be regularly inspected and cleaned.

Operation/Maintenance Practices

Unlike traditional drainage facilities, urban runoff treatment systems are designed to capture and retain pollutants, especially solids. The accumulation of these materials can seriously impair the system's operation and greatly reduce its effectiveness, resulting in pollutant discharge and possibly increased flooding. Therefore, the long-term operation, maintenance and management requirements, and costs for a stormwater practice should be important considerations in selecting BMPs. Additionally, institutional frameworks must be created to assure that runoff systems are regularly inspected and maintained.

Stormwater System Operating Permits

One way local governments can reduce their liability for pollutants discharged from their runoff system is to assure that discharges are already properly managed. In states where new development must install on-site runoff management systems, a stormwater operating permit system implemented by the local government or stormwater utility can ensure that runoff facilities are maintained and operated properly. Operating permit systems typically require annual inspections of privately owned runoff facilities and certifications that all needed maintenance has been performed. Additionally, local governments can review the implementation of runoff pollution prevention plans required for industrial runoff sources discharging into the local system.

Storm Sewer Inlet or Catch Basin Cleaning

These inlet devices capture large debris, along with smaller sediment and organic materials. However, pollutants can be washed out if inlet devices become too full and rainfall occurs. Regular inspection and periodic maintenance (i.e., general vacuum cleaning) is essential for maximum environmental benefits. More frequent cleaning is required at certain times, such as when leaves fall.

VOL 12

6743

Highway and Utility Right-of-Way Maintenance

These activities involve materials that add to runoff problems. Shoulders and roadside swale systems should only be scraped or excavated if necessary to maintain the integrity and safety of roads. Vegetation should be mowed or maintained as necessary to keep areas stabilized and the use of nutrients and pesticides should be reduced.

Winter Road Management

In areas with snowfall and extended periods of freezing temperatures, special maintenance activities are needed on roads and bridges to keep them safely open to traffic. Since the late 1940s, road salt has been one of the most popular road deicers, with more than 11 million tons used annually. However, snow removal and storage along with salt application and storage can corrode bridges, roads, and vehicles and contribute to several adverse environmental conditions, including damage to roadside vegetation, stratification of ponds and lakes, increased chloride levels in surface and groundwaters and contamination of water resources. These effects can be reduced or prevented by

- **Carefully siting snow storage areas.** Runoff or seepage from the snow pile should not go directly into surface or groundwaters. Ideally, these areas will be served by BMPs that capture pollutants attached to the snow and soil particles.

- **Minimizing or eliminating the use of salt (sodium chloride).** Determine and use proper application amounts. Consider alternatives to salt, such as calcium magnesium acetate (CMA), calcium chloride, urea, sand, potassium chloride, magnesium chloride, or other substances. Each has advantages and disadvantages, both environmental and economic.

- **Proper salt storage.** Some 80 to 90 percent of environmental problems from salt come from careless or improper storage. Elements of a good salt storage policy include

1. Not locating salt storage areas near waterbodies or other sensitive features.
2. Storing salt in permanent roofed structures. If salt cannot be stored indoors, use an impervious liner and a waterproof cover.
3. Storing salt on an impermeable surface, not bare ground.
4. Routing runoff from the salt storage area to an appropriate runoff management system.

Public Education Practices

Many previously discussed structural practices—swales, retention areas, and detention lakes—require public education programs to be readily accepted and used. Programs concerning the following topics or activities have proven effective:

- **Storm sewer stenciling.** Stenciling storm sewer inlets with messages such as "Dump no wastes, drains to lake (bay, river)" can greatly increase public understanding of the relationship between pollution sources and receiving waters. These programs often are conducted by youth groups or civic associations.

- **Econeighborhood programs.** These programs designate econeighborhoods and secure residents' commitments to follow good housekeeping practices.

- **Education displays, pamphlets, booklets, and utility stuffers.** Educational materials cover a wide variety of everyday citizen activities that can adversely affect water resources. Citizens need to understand how their activities around the home and yard can contribute to water quality problems.

- **Public awareness.** Public information and education can reduce nonpoint source pollution by changing individual behavior and lifestyles. An information program that educates citizens can also encourage them to become part of the solution. This chapter and Appendix C provide numerous sources of information for public awareness programs.

Recommended Reading

Many excellent sources of information are available on the use of nonstructural runoff management practices. Numerous urban and planning textbooks provide relevant material. Federal, state, regional, and local agencies have produced many helpful booklets and brochures on the cor-

VOL 12

6744

rect use of household and yard chemicals and other materials—these are frequently available from Agricultural Extension Service offices.

Many state, regional, and local governments offer detailed best management practices manuals, several of which are referred to in other chapters. Additionally, local governments have model land development ordinances and codes. Regional planning councils and councils of governments often have model land development regulations.

CHAPTER 13

Legal Authorities

A good runoff management program is founded on legal authority, design and implementation criteria, and adequate resources. This chapter is mainly concerned with legal authority.

The evolution of sediment control and urban runoff management programs has been gradual. In attempting to address local problems and concerns, several areas of the country have provided leadership. The runoff management issue has emerged from concerns over flood damage and public safety.

Historically, society has relied on water for transportation and commerce, necessitating significant development in areas adjacent to waterways. Over the last 200 years, the frequency and magnitude of flooding, the associated damages, and the potential for loss of life have inspired public efforts to reduce the adverse impacts. These efforts have naturally evolved into considering changes in upstream land use, since those changes affect impact on downstream flooding potential.

Early runoff management efforts relied on channelizing streams and constructing large regional detention facilities to control upstream peak discharge release rates and prevent increasing downstream flood frequency or elevation. Most early ordinances only controlled peak discharge rates from new development activities. Common criteria varied with policies to control the postdevelopment 10-year storm to the predevelopment 10-year peak release rate, and other similar variations.

Concerns about water quality and controlling sediment during construction were localized and occurred only when the magnitude of land development necessitated action. With the 1970s and the first Earth Day, the public gradually became aware, however grudgingly, of impacts beyond water quantity control. Approximately half the states have some form of erosion and sediment control laws, although few are aggressively implementing a program. Fewer states have implemented runoff management programs concerned with water quality. The problem in implementing comprehensive sediment control and urban runoff management programs for new development activities is not inadequate technology—the problem is a lack of commitment.

While most jurisdictions are familiar with the adage, an ounce of prevention is worth a pound of cure, many implement sediment control and runoff programs only after significant resource damage has been done. Many areas should implement effective programs now, before runoff impacts become so great that solutions are limited and costly. One major benefit of the 1987 amendments to the Clean Water Act and section 6217 of the Coastal Zone Act Reauthorization Amendment of 1990 is the increased national awareness of sediment control and urban runoff management needs and requirements. Still, state and local governments must recognize that these issues are important, even without federal initiatives. Efforts must be initiated to prevent existing water quantity and quality problems from intensifying.

Program Considerations

Identifying and Documenting the Problem

In initiating a sediment control and runoff management program, consideration must be given to identifying and documenting the problem. The impetus could be a water supply reservoir that is becoming fouled with nutrients or other pollutants, making drinking water treatment expensive.

VOL 12

6746

Most water quality programs—for example, Chesapeake Bay and Puget Sound—focus on downstream resource protection. The National Estuary Programs, the Clean Lakes Programs, and others provide examples of state, regional, and local government responses to documented problems.

Problems must be clearly identified and documented. For example, a resource problem in fisheries is a dramatic decline in clam landings over the last 10 years; the cause, however, is increasing development in contributing drainage areas. Another example is the dramatic decline in stripped bass landings in the Chesapeake Bay. The problem must be clearly defined before solutions are considered.

Prelaw Educational Efforts

Education is the key to garnering the necessary political support. To win support, the problem must be clear to the average individual. Individuals must buy in to the need and the personal impact of the proposal.

In Delaware, for example, individuals spent approximately six months on problem identification before beginning the sediment and runoff effort. The effort included documenting construction and degraded stream system problems with slides at public presentations to environmental groups, municipal leagues, Kiwanis clubs, engineering societies, and the general public.

Education should include the components of the proposal, the types of practices required, and the industries impacted. Supporters must clearly define the proposal and effectively respond to concerns. The proposal should answer all concerns; if not, it must be modified or the provision eliminated. A response should not transfer responsibility to another source or entity.

To succeed, the proposal and its components must be important to the agency responsible for its implementation. Reaching consensus before the law is formally considered avoids adversarial situations, which take an enormous amount of time and negatively affect implementation.

Sediment and Runoff Law

The sediment and runoff law should provide a framework for the overall program. The law should have general design criteria or technical considerations to avoid the need for future amendments and political review by individuals unfamiliar with the issues. Delaware's law and regulations provide an example (Appendix A and B). Components to be considered in developing a statewide or regional program or law include the following:

- A statement of policy followed by text that provides a specific approach to implement the policy.
- Definition of important terms to avoid misunderstanding in their use.
- Delineation of the types of activities regulated under the law. Clearly identify activities not intended for coverage to avoid confusion over their status. For example, if agricultural land management activities are not included, specify this exception.
- Outline of funding resources. If the program is funded through permit fees, define the authority to collect fees. Discuss legal mechanisms, such as a runoff management utility, as a future option.
- Definition of agency responsibilities. If the program is implemented at a state level, define the role of the state agency in conjunction with those local agencies; if implemented at the local level, define responsibilities of other related local programs.
- Specification of the effective implementation date. Programs directed toward new development activities usually incorporate an existing building permit process to ensure plan design and approval. In addition, situations where plans have been approved but not yet implemented must be defined and a cutoff point specified for older plan redesigns or reconsiderations in light of new requirements.
- Definition of responsibility for review of state and federal activities.
- Definition of enforcement procedures to ensure consistency among projects and to educate regulated individuals about their serious responsibilities under the law.
- Other local requirements, such as phasing the program into the region or watershed or requiring educational assistance on program implementation. For example, both Delaware and Maryland mandate education by requiring contractors to certify that a responsible representative has taken a state course in erosion and sediment control.
- Definition of penalties and appeals procedures.

Sediment and Runoff Regulations

As the law provides a broad paintbrush for an overall program, regulations provide specific detail for day-to-day program implementation. Detailed regulations provide a means to implement the law's general requirements. Delaware's sediment and runoff management regulations provide an example of statewide regulations (see Appendix B).

Some components to consider in developing statewide or regional regulations include the following:

- The scope of the regulations, mentioning specific areas of additional emphasis.
- Term definitions. Give careful consideration to each, as they often determine policy issues and answer numerous questions about aspects initially given broad interpretation.
- Specific exemptions, waivers, and variances. Variances are particularly important where increased flexibility is needed to fit a strategy to a specific site.
- Details of the process of permit application and approval time frames and obligations.
- Specific design criteria. Criteria should address the level of control, preferences in practices, and information required on each project. Each application should include information, specified in the regulations, to enable the approval agency to make and defend its decision.
- Detailed construction inspection and enforcement requirements. Enforcement must be progressive, not random.
- Definition of any appeals procedures or hearing requirements.

Advice from Impacted Industries

A first step in developing and implementing a sediment control and runoff management program is to open and maintain a dialogue with the impacted industries. These include homebuilders, contractors' associations, developers, and consultants. Representatives must understand the program goals and their legal obligations. To ensure industry involvement, the various entities should be asked to assign a representative to attend meetings and review draft documents prior to public release.

Another way to receive input is through required educational programs. Delaware requires contractors and inspectors to receive training on sediment control and runoff management. The state has successfully received feedback from the impacted industries in a nonadversarial forum and has modified the program as a result.

Detailed Design Guidance

The permit review process places consultants who represent land developers in a difficult position. To provide a cost estimate of their services, consultants must understand the system design obligations. This understanding can only be ensured through a good relationship and good design guidance developed or accepted by the permitting agency. Thorough guidance results in fewer problems with individual plan review, fewer submissions, and a greater assurance that the design meets the best available standards for success.

The guidance should include all acceptable options for sediment control and runoff management and contain illustrated details and case studies to explain design standards and procedures. Legally, the regulations should refer to the design guidance; guidance modification should include public review and comment. A meaningful guidance document should be developed when the program is implemented, not just adapted from somewhere else—unless the document reflects a clear understanding of the original principles.

Problem Areas

In areas with existing runoff management programs, more than one entity or agency involved in policy may create a problem. Conflicts can be extremely frustrating and take time and resources away from program implementation. However, conflicts often come from a greater awareness of linkages between two or more previously unrelated programs. While linkage often improves program performance, conflicts can overshadow this positive aspect, and both programs can suffer. For example, conflicts can occur between emerging NPDES programs and traditional sediment and runoff or nonpoint source control programs. Conflicts can also exist when sediment, runoff, and wetlands programs are linked with traditional public works programs, planning agency responsibilities, and any number of other potentially conflicting areas. All entities need to recognize the compatibility of these programs and that overall goals can be enhanced through communication.

VOL 12 6748

A major problem can occur when sediment control and runoff management responsibilities are added to an existing building permit program. Far from improving both programs, experience has shown that overlapping responsibilities can reduce the emphasis on one program and weaken the overall effort. Sediment and runoff programs, along with other programs, need individual attention to succeed. Individual identities must be defined within the organization, not just function as an add-on. For example, a sediment and runoff program added to a sewer line review and approval program can reduce the effectiveness of both programs, especially in inspection and enforcement. Inspectors need a defined area of responsibility, not a requirement to inspect a project for multiple reasons.

Since the sediment and runoff program is a regulatory program, enforcement action will occasionally be required. However, if permit or inspection agencies are reluctant to engage in enforcement, the program's credibility can be reduced. While most contractors and developers willingly comply with laws and regulations, they periodically challenge the requirement to implement an environmental control. Erosion and sediment control are seen as temporary practices, and the industry sees avoiding these controls as a way to cut costs. Providing an enforcement presence and a willingness to take action improves the chance of properly installing controls.

Implementing an effective sediment control and runoff management program costs money. Few programs are adequately staffed or funded. This is especially true if the budget depends on permit fees or if the program is part of an agency's overall budget and must compete with other important areas. A dedicated source of revenue should be developed to maintain a sense of continuity.

Finally, a single individual cannot implement a statewide sediment and runoff program, even through a system of general permits. These programs are important components of a whole urban environment and must be treated on a level equal to other urban programs.

Recommendations

Programs should be consolidated, or at least closely coordinated, with existing related programs. In addition, communication must be established with other agencies (i.e., local land use, public works, and building permit) and other environmental programs (i.e., wetlands, groundwater, drainage, or others) that could affect the sediment and runoff program. While agencies must be educated about the direction and importance of the sediment and runoff program, program staff must be sensitive to issues and priorities of these agencies—especially on the issue of wetlands and the location of runoff management structures. Diverse programs need to work together, especially in times of limited fiscal resources.

Education, a constant theme in this guide, cannot be stressed enough. Educational efforts and activities, which significantly enhance the chances of legislative or regulatory approval, must be continuous to remind people of the importance of runoff control, both during and after construction projects.

Programs must be consistent in their implementation. Projects must be reviewed consistently, and any variation in review or approval procedures should be documented to avoid challenges to the final decision. Consistency must also be applied to site review and enforcement procedures. Written enforcement procedures should be developed and circulated to the impacted industry so that all concerned will understand enforcement steps to be taken if required controls are not implemented. Enforcement procedures should be progressive, with severity increasing as noncompliance continues. Steps could range from withholding occupancy permits until controls are implemented to halting work until environmental controls are correctly installed. Civil and/or criminal penalties can also force site compliance.

A successful program requires an open line of communication to the regulated community. One vehicle, a regulatory advisory committee, is important not only in program development but also in day-to-day implementation and evolution. Advisory committee meetings provide an interested and sympathetic forum to uncover design or implementation problems. Regular meetings reduce the "we-they" syndrome.

Other Available Sources

This guide refers to numerous localities and states that have implemented programs. In addition, case studies are presented in Chapter 16. Contact individual agencies mentioned throughout the guide for additional information.

CHAPTER 14

Inspection and Maintenance of Runoff Control Practices

This chapter presents key elements and characteristics of both a comprehensive construction inspection and a postconstruction maintenance program, including preconstruction planning using postconstruction standards.

Effective runoff management using structural practices and facilities requires successful execution of all phases of development.

These phases include

- Comprehensive analysis of site conditions and potential adverse impacts and problems during the project planning phase;
- Accurate and intelligent design of practices and facilities for convenient maintenance that will prevent or minimize adverse impacts and protect aquatic resources during and after construction;
- Competent and comprehensive review of practices, facility designs, and plans during the permit application phase;
- Proper construction and implementation of the practices or facilities according to the approved plans and applicable permit conditions; and
- Proper operation and thorough maintenance of the practices or facilities after installation.

All of these phases can benefit significantly from increased understanding of the fundamentals of the runoff and soil erosion processes at the heart of any runoff management program, and from increased design, construction, and inspection skills and experience. Similarly, failure to competently complete any of the phases can lead to program failure and environmental damage.

Recent investigations and experience have highlighted the serious adverse impacts of inadequate planning, design, implementation, construction, inspection, and postconstruction maintenance. Correcting these weaknesses first requires comprehensive and aggressive inspection programs while constructing land development sites. These programs must do more than focus on the proper construction of permanent structural facilities intended to provide long-term management of site runoff. They must also concentrate on the proper installation and maintenance of the site's short-term erosion and sediment control measures. Finally, continuing inspection and maintenance programs are also needed to ensure effective and safe operation of the structural facilities after site construction is completed.

Despite the importance of construction inspection and postconstruction maintenance programs, several factors complicate or hinder their development. One is the legal authority to both perform inspections and enforce facility maintenance requirements (see Chapter 13). Although federal and state governments have begun developing inspection and maintenance standards, land development's diffuse nature and the country's long-standing tradition of local land use control require that local governments acquire legal authority. A second factor is the costs of these programs and local government's ability to meet them. A third is the inherent institutional and regulatory difficulty of adequately managing the diversity of permanent runoff management facilities and temporary soil erosion control practices currently available.

Although the subject is complex, the benefits of understanding how to develop a runoff management program are great. The chapter begins with an overview of key elements of the inspection and maintenance program. It explores the

VOL 12

6750

interrelationship between construction inspection and a facility's early planning, design, and permit phases, emphasizing the effect on long-term performance and maintenance. Much of this material is based on the *Stormwater Management Facilities Maintenance Manual* developed by the New Jersey Department of Environmental Protection and Energy (1989).

The remainder of the chapter contains two detailed presentations. One focuses on an inspection and maintenance program for construction site erosion and sediment control practices. The second focuses on permanent drainage and runoff management facilities at a land development site. It describes a program embracing both short-term inspection when the facilities are constructed and long-term inspection and maintenance to ensure effective operation. Both presentations emphasize inspector training and education, contain recommendations regarding program structure, and discuss key program elements. They also provide examples of field inspection checks. These presentations should give readers a head start in developing their own programs and, in particular, training the staff charged with program performance.

The presentations were derived from two courses at the University of Washington's Center for Urban Water Resources Management and Engineering Professional programs. Course manuals are available for erosion and sediment control inspector training (Reinelt, 1991) and permanent drainage system inspector training (Reinelt, 1992). Local governments and state agencies in the Puget Sound area of Washington State have worked actively to improve runoff management through effective inspection and maintenance and have contributed to these materials.

Inspection and Maintenance Overview

An effective inspection and maintenance program has a number of aspects. This overview discusses the importance of the key program elements—construction inspection and maintenance; the numerous aspects of preconstruction activities; enforcement options; funding techniques; and education and training.

Understanding Key Program Elements

The overall success of any runoff management program hinges on understanding each term. However, this cannot be done by simply quoting dictionary definitions because of the many aspects of land development involved in each. The following detailed descriptions should aid understanding:

■ ***Construction Inspection.*** This activity involves the careful field observation of construction activities and materials and their end products or measures. While construction activities—complexity, duration, manpower, and hazard—and construction materials—character, quantity, and cost—can vary widely, runoff management categorizes them in two ways. The first category includes activities and materials used to construct temporary erosion and sediment control (ESC) measures at land development sites. These measures control the amount of soil lost from erosion and minimize the adverse downstream impacts of subsequent sedimentation during site construction. The second category includes activities and materials used to construct permanent runoff management and drainage facilities that address both quantitative and qualitative effects on runoff produced by the developed site.

The key distinction between the categories is time. In the first, the effects of site development on soil erosion and sedimentation are temporary and limited to the construction period when soils are exposed to rainfall and runoff. As such, the measures and materials used are temporary and removed when the site is permanently stabilized. These measures range from temporary seeding and mulching of exposed soils to constructing sediment basins and barriers.

The second category deals with the more critical effects of the site's development on urban runoff quantity—volume, rate, and timing—and quality over the site's postdevelopment life. These measures, intended to minimize and mitigate development effects, must last as long as the site is used. Permanent measures include runoff detention and infiltration basins, storm sewer systems, and swale/channel networks.

Regardless of the timing or duration of the various measures, the construction program is responsible for ensuring that construction activity adheres to approved plans, designs, standards, and generally accepted construction techniques.

The importance of continuing inspections cannot be overstated. After temporary measures or permanent facilities are completed, continuing inspections ensure that measures perform as intended and remain in sound, safe condition. Inspections of ESC measures normally take place

VOL 12

6751

along with general construction inspection of the development site. Inspection of permanent facilities, however, must occur after site development and construction are completed; it therefore requires that an inspector take separate action. Effective inspections are usually combined with permanent facility maintenance.

▮ *Maintenance.* For both runoff facilities and ESC measures, this activity involves repairing, replacing, restoring, or replenishing the various components and materials of the measure or facility. Maintenance activities include preventive and corrective measures, with time the key distinction between the two. Preventive maintenance requires replacing components or materials before they cease to function adequately, often according to a schedule. Corrective maintenance is performed after failure or malfunction occurs, often quickly in an emergency. Obviously, preventive maintenance is preferred over corrective maintenance because of safety, time, cost, and overall effectiveness.

Maintenance keeps both the temporary ESC measure and the permanent facility functioning safely and at optimum efficiency levels. Maintenance can also correct design or construction deficiencies, improve performance, and enhance safety above constructed levels.

Preconstruction Inspection and Maintenance

Once the regulations have been satisfied on paper through planning, design, and permit stages, the project is ready for construction. The methods and materials used in construction must be competently inspected to ensure that the goals of the planning, design, and permit stages are met in the field.

ESC measures and runoff facility maintenance are vitally important. Structural facilities cannot perform their duties and achieve their goals without regular maintenance. Maintenance is particularly acute for structural facilities used to address runoff quality impacts. As particulate settling and removal efficiency has increased, the sediment and debris accumulation within runoff facilities has increased the maintenance need.

Runoff facilities also must be maintained structurally to ensure their continued safety and protect people and property. This is particularly true of facilities and measures that impound runoff, even for a short period. Structural failure causing release of stored runoff will usually result in greater downstream flooding and damage than would have occurred without the facility. This threat may greatly outweighs all benefits.

Inspection is also key to a maintenance program. Whether preventative or corrective, maintenance must be preceded by an inspection to evaluate the required procedures, materials, equipment, personnel, urgency, time, and cost. Effective and efficient inspection activities should be performed regularly and should emphasize prevention rather than correction. In addition, inspectors must be highly knowledgeable and experienced and take responsibility for the results of construction or maintenance. As such, inspector training is a vital component of any runoff management program. Training must be comprehensive, covering all aspects of the runoff management and soil erosion processes, from theory to practical applications.

Preconstruction stages and activities can cause significant construction and maintenance problems. Avoiding problems requires a close look at all preconstruction stages, from the regulations that define the structural measure or facility, through the technical planning and design stages, to the permit stage, where construction is authorized.

▮ *Regulatory Aspects.* Chapter 11 presented the various regulatory needs of a comprehensive runoff management program, including those for effective construction inspection and facility maintenance programs. This section addresses inspection and maintenance problems caused by the very regulations that initially created these programs.

While structural measures and facilities must be based on effective standards and accurate designs to achieve desired goals, the quality or level of standards, designs, and objectives means nothing unless the facility or measure is actually constructed. Unfortunately, in developing the various regulations, the importance of construction is sometimes lost or forgotten. While considerable effort is devoted to goals and how to achieve them, facility construction is sometimes treated as an afterthought or, even worse, a given or guaranteed end-product requiring little, if any, official attention.

The same is also true for facility maintenance. Despite the importance of maintenance to short and long-term performance, regulations requiring maintenance often lack purpose, effectiveness, or are simply nonexistent.

Therefore, consider the following in developing runoff regulations:

- Recognize the fundamental need for facility construction and maintenance to truly achieve program goals and objectives.

- Consider construction and maintenance of equal importance with planning, designing, and permitting. The regulations should promote the importance of inspection and maintenance at all stages and by all personnel.

- Regulations should officially designate a responsible party, frequently the development site owner, to have ultimate responsibility for the proper construction and continued maintenance. This official designation provides the opportunity for appropriate preparation and budgeting prior to actually assuming responsibilities. It also facilitates enforcement or other legal remedies necessary to address compliance or performance problems once the facility has construction approval.

- Regulations should clearly state the inspection and maintenance requirements during and following construction and address both temporary measures and permanent facilities. Construction requirements should be based on many standard construction practices and specifications, promulgated by various private organizations and government agencies, and fully comply with all applicable local, state, and federal laws. Inspection and maintenance requirements should also comply with all applicable statutes and be based on the needs and priorities of the individual measure or facility. A clear presentation will help owners and builders comply and inspectors enforce requirements.

- Regulations must contain comprehensive requirements for documenting and detailing construction and maintenance. For construction, this includes detailed, well-researched plans and specifications that fully describe the facility's construction. Plans and specifications should include pertinent information on locations, dimensions, elevations, materials, processes, and times. Drawings should be easy to use in the field under adverse weather conditions. Regulations should also require enough copies of plans and specifications to supply field and office personnel, builders, inspectors, and regulators. Provide a dissemination procedure guaranteeing that all involved have identical approved plans and specifications.

  Requirements are similar for maintenance. A facility operation and maintenance manual must be prepared containing accurate and comprehensive drawings or plans of the completed facility and detailed descriptions and schedules of inspection and maintenance. An emergency action plan should also be required for regional and other large runoff impoundment facilities. This plan should contain measures for various emergency conditions, such as structural failure, neglect, vandalism, or accident. The plan should also include the types and sources of repair materials and a list of individuals, agencies, and officials to be notified quickly if the facility appears to or actually malfunctions or fails. This list might include local and state government and public safety officials, downstream residents, and business owners. The plan should also contain the method of notification.

- The regulations should delineate the procedure for construction or maintenance noncompliance. This process should provide informal, discretionary measures to deal with periodic, inadvertent noncompliance and formal and severe measures to address chronic noncompliance or performance problems. In either case, the primary goal of enforcement is to construct a safe and effective facility—the enforcement action should not become an end in itself.

- Regulations must also address the possibility of total default by the owner or builder by providing a way to complete construction and continue maintenance. For example, the public might assume construction and/or maintenance responsibility. If so, the designated public agency must be alerted and possess the necessary staffing, equipment, expertise, and funding to assume this responsibility. Default can be addressed through bonds and other performance guarantees obtained before the project is approved and construction begins. These bonds can then be used to fund the necessary construction or maintenance activities.

- The regulations must recognize that adequate and secure funding is needed for all aspects of facility construction, inspection, and maintenance and provide for such funding. In fact, the program goals or accomplishments might be limited to available funding. Funding sources and techniques are summarized later in the chapter.

- To minimize overall inspection and maintenance effort and expense, the regulations should encourage and provide a way to regionalize runoff facilities. Situations where numerous independent on-site facilities are replaced by one or several regional facilities have been particularly effective for runoff quantity control and flood prevention. Regionalization also results in overall savings in planning, design, and construction efforts and costs and requires less total land disturbance. Finally, designing and implementing regional facilities requires planners, designers, regulators, developers, and residents to adopt a watershed approach to runoff. Such a comprehensive approach should be promoted at every opportunity.

Planning and Design Aspects. The efforts of planners, designers, and those who review and approve the final facility have a profound influence on inspection and maintenance activities. This influence is particularly true for permanent runoff management and drainage facilities, which are generally more complex and require greater effort from these groups. Temporary ESC measures may also be significantly affected, particularly regarding the measure selected and its location.

According to the New Jersey *Stormwater Management Facilities Maintenance Manual* (1989), approximately two-thirds of the maintenance problems encountered during a review of 51 constructed facilities were at least partly due to a combination of inadequate and misguided planning, design, and review. The result was increased maintenance effort and cost, reduced facility performance, and increased safety threats to both residents and maintenance personnel.

Fortunately, enlightened and focused planning, design, and review can improve inspection efficiency and effectiveness and reduce maintenance effort and expense. Therefore, inspection and maintenance should be a primary consideration throughout the entire planning, design, and review process, equal in importance to achieving required performance and safety.

The following inspection and maintenance issues should be addressed in planning, designing, and reviewing runoff management and ESC facilities and measures:

- **Durability.** The use of strong, durable materials, components, and fasteners will greatly reduce the maintenance required. These savings normally more than justify any additional expense incurred. Durability extends across the entire range of facility components—from basin and pond outlet structures where reinforced concrete remains the material of choice, to vegetative covers and landscaping where durability is defined by hardiness and suitability to local conditions.

- **Constructability.** "The road to maintenance headaches is paved with good planning and design intentions that somehow went awry" (New Jersey Dep. Environ. Prot. Ener. 1989). All concerned must remember that the structural measure or facility must be safely and properly constructed before it can provide any runoff management benefits. Therefore, runoff program goals and the ideas of those seeking to fulfill them must, within reasonable effort and expense, be constructable in the field.

  Required materials must be available and construction techniques feasible. Construction plans and specifications—the builder and inspector's instruction manual—must be clear, informative, and contain all necessary information presented in a format that assists, not impedes, field use. Anyone who has struggled in the field with construction plans on a cold, windy day knows that construction details and notes are easier handled on the same sheet than scattered randomly throughout the entire set of plans.

- **Maintainability.** Throughout the planning, design, and review or permit process, every attempt should be made to eliminate or facilitate maintenance, whether selecting facility goals or materials. This applies to the facility's location, materials, configuration, and the techniques and equipment necessary to construct and maintain it.

  Questions of maintainability should be raised about the vegetation used and the habitats or ecosystems created by and within a runoff facility. How complex are these systems? How difficult will they be to manage? Will those responsible for overall facility maintenance be able to do it themselves, know where to find help, and be able to af-

VOL 12

6754

R0040062

ford it? If the answer to any of these questions is no, the runoff facility may wind up harming rather than protecting the environment.

■ Accessibility. Small oversights in planning, designing, and reviewing a runoff facility or measure can result in big inspection and maintenance problems. To perform inspection and maintenance tasks, personnel must have access to the facility and be able to bring the materials and equipment with them. Access can be as simple as hatches in gratings and gates on fences or as complex as access easements across private property. The best intentions of the most dedicated inspector or maintenance worker will go unfulfilled if they or their equipment cannot get to the facility to inspect, clean, repair, or replace.

Efforts to facilitate access and enhance safety can often yield significant savings in inspection and maintenance. For example, mosquito control personnel are considerably more efficient if they can drive by a runoff facility and check for unintended standing water rather than parking, locking the vehicle, and walking several hundred feet or yards. This is particularly true when their inspection route includes tens or even hundreds of facilities—not uncommon in densely developed areas. Therefore, addressing accessibility simply by locating the facility to be viewed from the roadway can greatly reduce inspection efforts and expense.

To further fulfill inspection and maintenance needs, planners, designers, and reviewers periodically ask themselves the following series of questions:

■ *Who* will perform inspection and maintenance? Arrangements should be made during the preconstruction, not postconstruction, stage to identify, train, equip, and fund the required personnel. If not, one of the postconstruction stages may be "facility failure."

■ *What* must be done? What construction activities need to be monitored? What intermediate or final conditions need to be inspected? Will the inspector require a level or other surveying equipment? What facility components will require periodic inspection once construction is completed and the facility begins operation? What regular maintenance tasks must be performed? What emergency measures may have to be taken? What kind of material or equipment will be required?

■ *When* will inspection and maintenance be required? Certain maintenance tasks, such as grass mowing, may need to be performed regularly during spring and summer but not at all in winter. During the wet season, can muddy, saturated slopes be accessed? Will equipment be available for slopes? Are roads and paths wide enough to provide access? Dams and embankments may require annual or biannual inspections for structural integrity, while trash racks may need to be inspected after every rain. And, although all inspections cannot be scheduled in advance—a fact that upsets managers and financial staff—they are certainly advisable after a major storm or flood.

■ *Where* will the inspection or maintenance be performed? Do those responsible have both legal and physical access to the facility or measure? Where will the equipment and materials be staged or stored? Where will the grass clippings, sediment, trash, and debris be deposited? Locate these places prior to construction rather than during or, even worse, after construction is completed.

Structural ESC and runoff management measures and facilities require competent inspection and regular maintenance to perform as required and provide safety to workers and residents. The efforts of planners, designers, and reviewers directly affect the need for and complexity of such inspection and maintenance. Enlightened planning, design, and review that recognizes and seeks to improve this relationship can significantly reduce inspection and maintenance costs and increase their effectiveness.

Enforcement Options

A public agency will sometimes need to compel those responsible for facility construction or maintenance to fulfill their obligations. Therefore, the inspection program must have enforcement options for quick corrective action. Rather than a single enforcement measure, the program should have a variety of techniques, each with its own degree of formality and legal weight. The inspec-

VOL 12

6755

R0040063

tion program should provide for nonconforming performance and even default and contain suitable means to address all stages.

To avoid the need for enforcement measures, a spirit of cooperation should begin during the project's design review and permit stages by developing facility designs suitable to all parties. Education and training efforts and predesign or preapplication meetings can develop and promote such cooperation and allow each party to familiarize itself with the needs and interests of others.

Prior to receiving construction approval, the developer or builder should provide performance guarantees. The public agency overseeing the construction can use these guarantees, usually a performance bond or other surety in an amount equal to the facility's construction cost, to fund construction in case the builder defaults. As described under the next section, the developer or builder should provide sufficient funds to finance the construction inspection before the project begins. The dedicated inspection funds and the performance bond insure that construction can be completed regardless of the builder's ability or willingness.

Once construction has begun, the responsible public agency can issue a stop work order to compel the builder or developer to comply with project specifications and other requirements. Other techniques include withholding certificates of occupancy for completed portions of the development and formal civil or criminal action. Ideally, the cooperative attitude developed during preconstruction will continue through the construction period. This attitude, promoted through comprehensive preconstruction meetings and regular and informal progress and problem-solving meetings, can help avoid the need for formal and severe enforcement actions.

Public Funding Techniques

Funding techniques are critical to an effective inspection and maintenance program. The following paragraphs discuss four general techniques, each applying to specific inspection and maintenance efforts. The information is based largely on Chapter 6 of the *Stormwater Management Facilities Maintenance Manual* (New Jersey Dep. Environ. Prot. Ener. 1989). (See Other Sources for additional information on funding.)

Tax Revenues

Tax revenues are an obvious source of funding, particularly for the long-term inspection and maintenance of existing runoff and drainage facilities. The benefits and protection to the public from continued safe and effective operation of the facility justifies using revenues from general or specialized taxes. However, using these funds to inspect the construction or installation and maintain ESC measures at land development sites is more difficult to justify.

To use tax revenues, particularly from a general fund, the inspection and maintenance program must annually compete with all other programs included in the government's annual operating budget. This inconsistent and unreliable funding makes securing a long-term financial commitment to inspection and maintenance difficult and subject to political pressures. Nevertheless, tax revenues remain a popular funding source because the collection and disbursement system is already in place and familiar. In fact, this established and well-known system is often the first funding choice.

Turning instead to revenues from specialized taxes helps overcome some difficulties inherent in using general tax revenues. Relating the specialized tax program to runoff management and/or erosion and sediment control provides the necessary link between the revenue source and use. This method also avoids competing with other programs for general tax revenues. However, specialized tax programs must receive public and political support and legal authorization.

Utility Charges

Using utility charges to fund inspection and maintenance is a somewhat recent application of an already established financing technique. As noted in the *Stormwater Management Facilities Maintenance Manual* (1989), New Jersey began creating utility authorities and using charges collected within its service area to finance publicly owned water and sanitary sewerage systems in the early 1900s. Today, utility charges remain a popular financing technique in many New Jersey municipalities and counties. In addition, several municipalities and counties throughout the country have runoff management, drainage, and flood control authorities or districts to provide residents with runoff-related services.

Using utility charge financing has several advantages. By addressing only runoff needs and benefits, utility funding avoids competing with other programs and needs. Utility funding also demonstrates a direct link between the funding and the services it provides. This approach does, however, require an entirely new operating sys-

VOL 12 6756

R0040064

tem and organization that needs legal authorization to exist, operate, and assess charges. The effort required to create such an entity can deter many, although the continued success of established authorities and growth of new ones have done much to allay concerns over the effort required.

In a runoff utility, the user charges are often based on the need for services rather than the benefits derived from them. While charges are based on actual costs to inspect and maintain runoff facilities and measures within the service area, the assessed rate structure should relate to site characteristics. These include property area size, extent of impervious coverage, and other factors with a direct and demonstrable effect on runoff. To be fair, the rate structure should also remain simple and understandable to the rate payer.

Permit Fees

Collecting permit fees to finance runoff inspection and maintenance is a long-standing funding procedure. Most governmental entities—local, county, and state—can establish and collect fees and other charges to obtain operating funds for programs and services. Many inspection services, most notably the construction inspection of both ESC measures and permanent drainage and runoff management facilities, are financed at least in part through fees collected by permitting agencies. Unlike taxes or some utility charges, inspection costs are borne by those who need them.

The permit fee collection program should have a demonstrable link to the runoff management or drainage systems. The public agency should demonstrate a direct link between the permit fees collected and the permitted project—one method is using dedicated accounts for individual projects and facilities. Finally, the rate structure should reflect site characteristics—such as area size or imperviousness—that directly relate to the measure or facility by affecting runoff or erosion.

Dedicated Contributions

Like permit fees, dedicated contributions require those creating the need to bear the cost. Under this system, land developers must provide the necessary funding for inspection or maintenance before receiving construction approval. Funds are deposited in a dedicated account controlled by the responsible public agency. In some New Jersey jurisdictions, developers fund construction inspection of the ESC and permanent drainage and runoff management facilities as part of the land development. The contribution is based on a cost estimate made prior to construction. Throughout construction, inspector time sheets and expense reports monitor and record actual costs; additional funds are obtained as necessary. When construction is complete, any unspent balance is returned to the developer.

Other public agencies have used developer contributions to fund long-term facility maintenance. This approach is particularly appropriate in single family residential subdivisions, where numerous individual property owners served by a single runoff facility can result in confusion over who has maintenance responsibility.

The exact funding technique depends on many factors, including community attitude and knowledge, economic and political viability, and program needs and costs. Some techniques, including permit fees and dedicated contributions, may be more appropriate for short-term activities, such as construction inspection. Others—utility charges and specialized tax revenues—may apply to all phases of an inspection and maintenance program but require considerable effort and special legal authorization to operate.

Education and Training

An important key to a successful inspection and maintenance program is the level of understanding and knowledge held by those affected. This includes the builders and inspectors who create or install the measure or facility; the planners, designers, and reviewers who use sound preconstruction techniques; and the public and its elected leaders who provide the necessary funding.

As such, a comprehensive and effective education and training effort must be part of any inspection and maintenance program. Details of such training efforts are highlighted in the following sections, which detail key elements of programs for erosion and sediment control measures at construction sites and permanent runoff management and drainage facilities.

Erosion and Sediment Control Inspection Programs

A comprehensive construction site erosion and sediment control program consists of several elements—erosion and sediment control planning, plan review, contractor education, and inspection and enforcement.

VOL 12

6757

R0040065

The following sections cover ESC planning and inspection and enforcement, and provide examples of inspection guidelines for common practices.

ESC Planning

ESC planning is an absolute prerequisite for an effective program (see Chapter 12 for more details). A careful site analysis should produce a standalone plan devoted exclusively to this aspect of the project and executed with the same thoroughness and care as any other plan in the overall project.

Acquiring the familiarity with the site and proposed construction necessary to execute the ESC plan is an exercise in data collection and analysis. Information should be cataloged before laying out the ESC plan. Table 14.1 lists the data to be collected and the information to be cataloged.

An ESC plan consists of a narrative and site plans. It is the key element for implementing a comprehensive control program. Site plans are maps and engineering plans illustrating and specifying the project location, existing and modified site conditions, and BMPs. BMPs are usually spec-

Table 14.1—Preliminary information needed for ESC planning.

DATA TO BE COLLECTED	INFORMATION TO BE CATALOGED
■ Soils	■ Grading (location, amount)
■ Vegetation	■ Topographic changes
■ Topography	■ Clearing and grading limits
■ Groundwater table	■ Drainage changes
■ Neighboring waterbodies	■ Materials to be used
■ Adjacent properties	■ Locations of use and storage
■ Drainage routes and patterns (define subbasins)	■ Access points
■ Downstream channels and capacities	
■ Potential areas of serious erosion problems	
■ Existing development, utilities, and dump sites	

Table 14.2—Components of an ESC plan.

ESC PLAN NARRATIVE	SITE PLAN ELEMENTS
■ Project description	■ Data collection worksheet—shows topography, soils, and vegetation
■ Existing and modified site conditions	■ Data analysis worksheet—indicates drainage subbasins and primary drainage courses
■ Descriptions of ESC BMPs	■ Site plan development worksheet—shows existing and finished contours, roadways, and permanent runoff facilities
■ Descriptions of BMPs for pollutants other than sediments	■ Erosion control plan—shows BMP locations
■ Plans for permanent stabilization	■ Diagrams of representative BMPs—shows appropriate BMPs
■ Calculations	■ BMP operating procedures and maintenance schedules
■ Provisions for inspection and maintenance	

ified using a system of symbols defined in a legend. Table 14.2 lists the various elements of the ESC plan narrative and site plan.

Inspection and Enforcement

The most important needs of this program are dedicated staff, specific staff training, and administrative support. A dedicated revenue source, such as a runoff utility assessment, can best provide these needs. Staff should not have unrelated and distracting duties, like inspecting other facets of construction. Training should offer a background in legal and regulatory requirements, water quality, hydrology, soils, vegetation, and other related issues. Training should also provide detailed coverage of BMP requirements (see following section). Administrators must provide strong backing to staff filling a relatively new function that is sometimes unpopular with economic interests.

During program development, some additional issues must be clarified and incorporated as formal program elements. Recommendations are drawn from experience in the Puget Sound region, especially in King County and the cities of Bellevue and Redmond in Washington State. One issue is how to respond when measures in an approved ESC plan prove to be inadequate. Strong permit review should normally limit these instances, but unforeseen circumstances can arise. The jurisdiction should retain the authority to require additional measures if needed and note this option on each ESC plan.

Another issue is handling field change orders. Plan change requests should receive careful but expeditious consideration, generally after consulting plan review personnel. Variances from code requirements should be granted only under strict and specific conditions:

- The result should at least be comparable to the expected outcome with the approved method.
- Sufficient background information and justification should be presented to adequately assess the alternative.
- The variance should retain the ability to meet safety, function, appearance, environmental protection, and maintenance objectives, based on sound engineering judgment.
- The variance should be in the public interest.

The enforcement authority and system must be obtained, defined, and clarified to the regulated parties. A three-step system is successfully used by the city of Bellevue:

- A verbal warning, with a correction deadline;
- A correction notice, with specifications of corrections, a deadline, and a warning of noncompliance consequences; and
- A stop work order, with warning of noncompliance consequences.

ESC Practices and Inspections

The numerous ESC practices can be categorized in various ways. The most basic division is between erosion control practices, which prevent or minimize erosion, and sediment control practices, which attempt to recapture soil that has been released through erosion. Several categories represent general strategies for achieving either erosion or sediment control. Construction sites can also generate many other pollutants—petroleum products, solvents, paints, sanding dusts, pesticides, and fertilizers. These materials can often be efficiently managed in concert with sediments and inspected simultaneously with ESC inspection. Therefore, these practices represent another basic division.

Table 14.3 provides a listing of the most widely recognized and used practices (Reinelt, 1991). All but the sediment trapping techniques are preventive and are thus the most cost-effective options. However, the straw bale and filter fabric fences and sedimentation ponds among the trapping techniques are most commonly seen.

The following are inspection checklists for example practices, generally the most common, in each category and subcategory. The checklists indicate checks for installation and checks for follow-up visits to determine maintenance or replacement needs.

While an inspector performs much work in the field, some background work must be done in the office before going out to inspect an installation. This work consists mainly of consulting the ESC plan to determine the specifications. The plan should be retained on the construction site so the inspector or construction personnel can reference it.

Table 14.3—Commonly used erosion and sediment control practices.

PRACTICES	CATEGORIES	METHODS
Erosion Control	Natural vegetative cover	Phasing construction
	Temporary cover	Temporary seeding Straw mulch Wood fiber mulch Excelsior Mats and blankets
	Permanent vegetation establishment	Permanent seeding Sodding
	Stabilized construction entrance and roads	Quarry spalls
	Runoff control	Pipe slope drain Surface roughening Interceptor dikes or swales
Sediment Trapping Techniques	Sediment barriers	Filter fabric fence Straw bale fence Brush fences Gravel barriers
	Settling ponds	Sediment basin Sediment trap Permanent pond
Management of Other Construction Site Pollutants		Cement and concrete handling Material storage and handling Spill containment Waste management

A. Erosion Control

Natural Vegetative Cover

Phasing Construction. Clearing operations are done in stages to take advantage of existing cover before construction.

Installation checks

1. Are areas not to be cleared set off with plainly visible fencing?
2. Is plainly visible flagging placed at the drip line of trees to be protected (Figure 14.1)?
3. Are fills and cuts near protected trees treated as shown in Figure 14.1?
4. Is final vegetation established as soon as portions of the site can be made ready?

Maintenance checks

1. Do fencing and flagging need repair or replacement so personnel can see them well?
2. Do exposed or injured roots of protected trees need covering or dressing?

Temporary Cover

Portions of most construction sites often remain unworked for months at a time. During that time large amounts of soil could erode unless the areas are stabilized by temporary seeding, various kinds of slope coverings, or both. Slope coverings include mulches and commercial mats and blankets. Applying temporary cover to different areas several times during construction is often necessary.

Mulches, mats, and blankets serve several purposes in erosion control. They cover the slope temporarily to prevent erosion by raindrop impact and runoff friction, hold water to aid grass growth, protect grass seedlings from heat, and enrich the soil. Straw, hay, wood fiber, wood chips, and other natural organic materials can serve as mulches. Mats and blankets are manufactured from both natural and synthetic materials.

Temporary Seeding

Installation checks

1. Is the soil stabilized within the period specified by regulation? This period varies from place to place depending on climate patterns. In the Puget Sound area of Washington State, which receives most of its rainfall in the winter, the specified periods are within two days from October to April and within seven days from May to September.
2. If used without slope covering practices, is temporary seeding limited to slopes less than 10 percent and 100 ft (30.48 m) in length? If the slope exceeds either limit, is a mulch or mat slope covering used?
3. Has the seedbed been prepared with 2 to 4 in (5.08 to 10.16 cm) of tilled topsoil?
4. Is fertilizer use limited as much as possible? If used, is it applied in amounts limited to grass needs for the prevailing soil conditions?
5. Is mulch applied to newly seeded areas that can be subject to high temperatures and runoff before the grass is well established?
6. Is irrigation provided for seeded areas that might have insufficient rainfall for good establishment?

Maintenance checks

1. Is irrigation and/or reseeding necessary?

Straw Mulch. Straw mulch can be used without seeding or, for better erosion control, with seeding.

Installation checks

1. Is the straw spread a minimum of 2 in (5.08 cm) deep (corresponding to 2 to 3 tons [4.47 to 6.72 Mg/ha] per acre), and deeper on very steep slopes, adjacent to sensitive areas, and where concentrated flow passes over the slope?
2. Is the mulch anchored as needed by crimping, disking, rolling, or punching into soil or by moistening, tackifying, or netting?

Maintenance checks

1. Should mulch be replaced because it blew away or decomposed over time?
2. Should mulch be moistened to eliminate a fire hazard?

Wood Fiber Mulch. Wood fiber mulch should only be used with seeding and generally with a soil bonding agent.

Installation checks

1. Is extensive runoff expected before good grass growth will occur? If so, is an extra coarse grade of wood fiber mulch applied?
2. Is the mulch used with seeding and a soil bonding agent? Were the application guidelines followed?
3. Has wood fiber been applied to cover the soil completely, allowing no bare soil to show through? This amount corresponds to about 1 ton per acre (2.24 Mg/ha) and is adequate for most circumstances. Do special circumstances, such as seeding during hot weather, require increasing the amount by about 50 percent?

Maintenance checks

1. Is replacement needed as a result of loss over time?

Excelsior. Excelsior is made of fine wood shavings in a helical form. Because this form does not allow excelsior to lie in close contact with the soil, runoff drains beneath it and causes erosion. Therefore, it should be used only with seeding when needed to hold moisture and provide protection from direct sun in hot periods. Suppliers generally market several grades for sheet and channelized flow and different velocities.

Installation checks

1. Is excelsior used only with seeding?
2. Was an appropriate material selected, placed, and stapled according to manufacturer's recommendations?
3. On slopes, was excelsior placed 3 ft (0.91 m) over the crest or in an anchor ditch?
4. In ditches, was excelsior placed in the direction of water flow, with any seams offset 6 in (15.24 cm) from the ditch centerline?

- **Maintenance checks**

1. Is replacement needed as a result of damage or loss over time?

Mats and Blankets. Examples of materials produced in mat or blanket form are jute, woven straw, and synthetics. Mats can be used without seeding or with seeding for better erosion control. As with excelsior, suppliers generally market several grades for sheet and channelized flow and different velocities.

- **Installation checks**

1. Was an appropriate material selected, placed, and stapled according to manufacturer's recommendations?
2. Was the material placed in the direction of water flow, in full contact with the soil but not tightly stretched?

- **Maintenance checks**

1. Is replacement needed as a result of damage or loss over time?

Permanent Vegetation Establishment

Permanent vegetation should be established in each segment of the site as soon as possible after construction is completed. Grass can be established by seeding or sodding. Seeding is generally preferred, because of lower cost and greater flexibility in selecting grass species. Sod is often available only in limited varieties that may not be suitable for erosion control and other purposes, unless grown to order. Overseeding with preferred species can be performed in the spring, while grass establishment must be done with sod in the winter. Species should be selected based on local climate and soil conditions, using regional guides and consulting with regional experts.

Permanent Seeding

- **Installation checks**

1. Has the seedbed been prepared by loosening with a plow if subsoils are highly compacted, spreading 2 to 6 in (5.08 to 15.24 cm) of topsoil, and lightly rolling?
2. Is fertilizer use limited? If used, is it applied in amounts no greater than needed for the prevailing soil conditions?
3. Is mulch applied for protection if areas are seeded when temperatures can be high or runoff is likely to occur before the grass is well established?
4. Is irrigation provided for seeded areas if rainfall is insufficient for good establishment?

- **Maintenance checks**

1. Is watering and/or reseeding necessary?

Sodding

- **Installation checks**

1. Is the sod placed beginning in the lowest area and perpendicular to water flow?
2. Are sod strips wedged tightly together and joints staggered at least 12 in (30.48 cm)?
3. On a steep slope, is the sod stapled?

- **Maintenance checks**

1. Is overseeding needed, either to repair damage or to install a preferred grass species?

Stabilized Construction Entrance and Roads

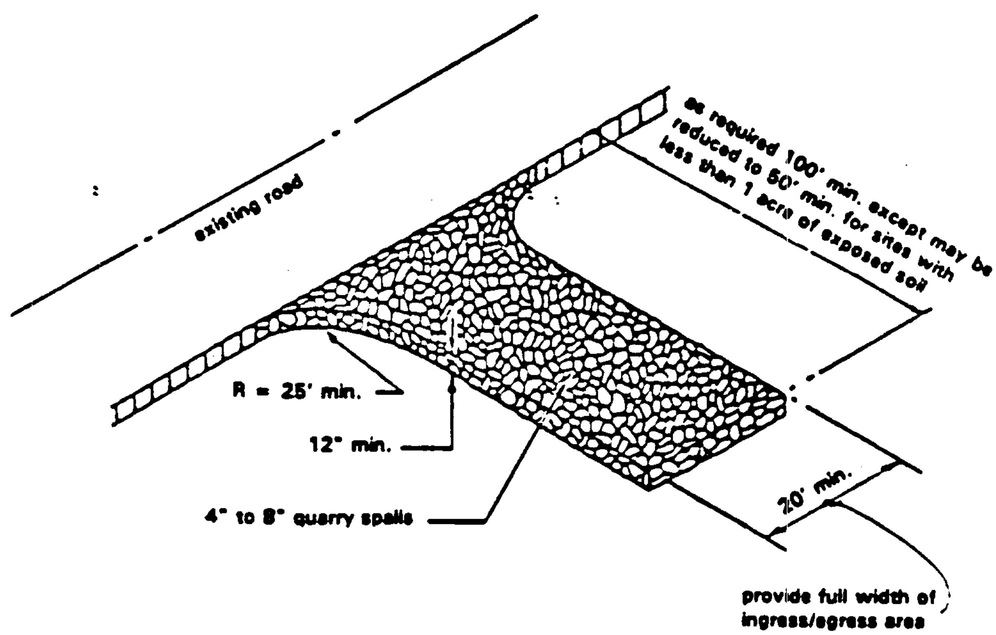
The entrance is the most important access route to stabilize, since it is the last point at which tracking sediment off-site can be stopped. If equipment travels extensively on unstabilized roads on the site, install a tire and vehicle undercarriage wash near the entrance on crushed rock. Treat wash water in a sediment pond or trap (Figure 14.2).

Stabilized Construction Entrance

- **Installation checks**

1. Is the entrance constructed with crushed rock 4 to 8 in (10.16 to 20.32 cm) in size and at least 12 in (30.48 cm) thick?
2. Is the stabilized entrance 50 ft (15.24 m) in length for sites up to 1 acre (0.4 ha) and 100 ft (30.48 m) for larger sites?
3. Is the stabilized entrance at least 20 ft (6.10 m) wide with enlargement to the street at a 25 ft (7.62 m) minimum radius curve?
4. If the entrance sits on a slope, is a filter fabric fence located down grade?

Figure 14.2—Stabilized construction entrance.



Source: Washington Dep. Ecol. 1992.

■ Maintenance checks

1. Is the entrance clogged with sediments, requiring top dressing the pad with 2 in (5 cm) of clean rock?
2. Must any sediments carried from the site onto the street be cleaned up?

Runoff Control

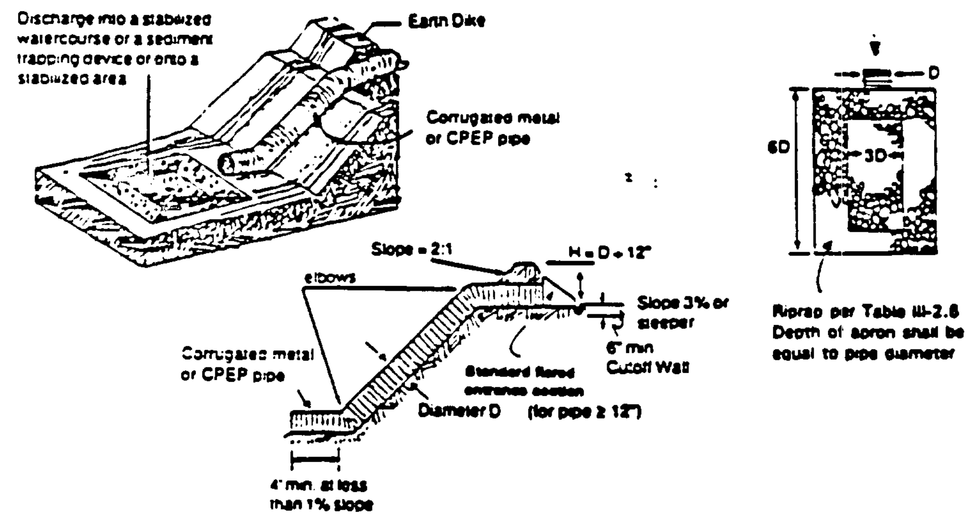
Runoff control represents various practices designed to keep water from contacting bare soil or, if so, controlling its velocity. Runoff control includes drains for surface and subsurface water, dikes and swales placed across slopes to interrupt and divert runoff, and roughness created on the surface to reduce velocity (Figures 14.3 and 14.4; see Chapter 11).

▮ *Pipe Slope Drain.* A temporary pipe slope drain is effective in preventing runoff erosion on a slope from a higher elevation. Upslope runoff needs to be collected and directed into the drain and then discharged in a controlled way to prevent erosion at the slope bottom.

■ Installation checks

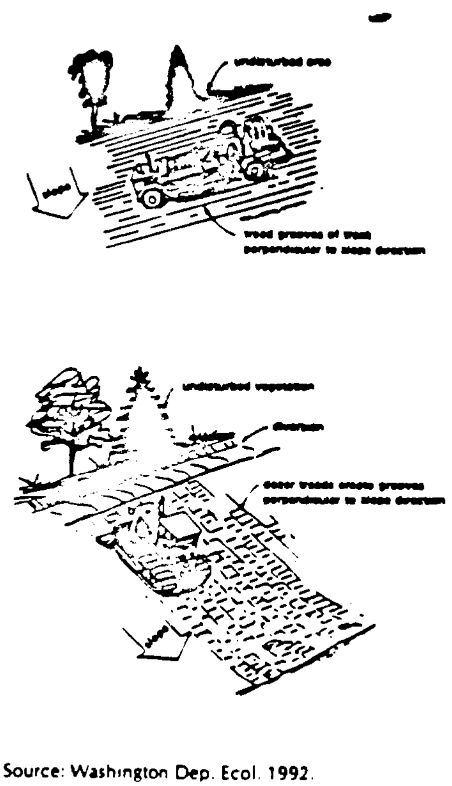
1. Are no more than 10 acres (4.05 ha) drained into a single pipe slope drain?
2. Was a minimum 6 in (15.24 cm) metal toe plate placed at the entrance to prevent undercutting?
3. Is runoff directed into the pipe with interceptor dikes at least 12 in (30.48 cm) higher at all points than the top of the pipe?
4. Is the slope toward the pipe on a grade of at least 3 percent at the inlet?
5. If the pipe is 12 in (30.48 cm) in diameter or larger, was a flared entrance section installed and connected securely to the drain with watertight connecting bands?
6. Was the soil thoroughly compacted at the entrance and under the pipe?
7. Were gasketed, watertight fittings placed between pipe sections? Were the sections securely fastened and the drain anchored to the soil?
8. Was the area below the outlet stabilized with a riprap apron?
9. If the drainage can carry sediment, is it treated in a sediment pond or trap?

Figure 14.3—Pipe slope drain details.



Source: Washington Dep. Ecol. 1992.

Figure 14.4—Maintenance standards for catch basins.



Source: Washington Dep. Ecol. 1992.

■ **Maintenance checks**

1. Is runoff undercutting or bypassing the inlet, requiring reinforcing of the headwall with compacted earth or sandbags?
2. Is erosion occurring at the outlet, necessitating rebuilding the apron?

I ***Surface Roughening.*** A roughened surface is an easy and cheap way to reduce runoff velocity, establish vegetation, increase infiltration, and trap sediment. The practice is not effective enough to be used alone—diversion is often necessary—but it can reduce the load on sediment trapping practices downstream. Roughening is best used on a slope with a horizontal-to-vertical ratio steeper than 3-to-1 that does not require mowing. The methods of roughening a surface all involve forming horizontal depressions with equipment. Methods include tracking perpendicular to the slope direction, driving treaded equipment along the slope direction to get grooves perpendicular to the slope, or tilling—preferred because it avoids compaction. On slopes with a ratio steeper than 2-to-1, a stair-step pattern should be formed.

■ **Installation checks**

1. Have all exposed slopes with a horizontal-to-vertical ratio steeper than 3-to-1 been roughened, with 40 to 50 in

(1.02 to 1.27 m) stair-steps on slopes steeper than 2-to-1?

2. Was the soil scarified if heavily compacted by the roughening?
3. Was the area seeded as quickly as possible?

■ **Maintenance checks**

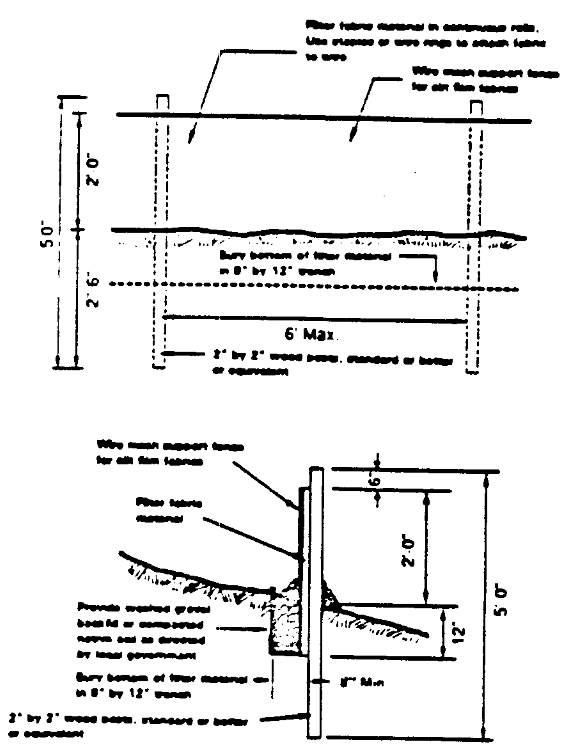
1. Have rills, gullies, or slumps appeared that should be regraded and reseeded?

B. Sediment Trapping Techniques

Trapping sediments once they are released requires slowing the transport velocity sufficiently so soil particles can settle. This means reducing the velocity below the settling velocity of the particles. Soil particles range in size from small clays to large sands. Settling velocity is related to the square of the particle diameter—halving the diameter approximately quadruples the time needed for settlement. Therefore, as particle sizes decrease, they become increasingly difficult to remove from a runoff stream. Thus, preventive techniques, more cost-effective than sediment trapping practices, are strongly preferred.

The two basic types of sediment trapping techniques are sediment barriers and settling ponds. Sediment barriers include the commonly used filter fabric and straw bale fences, brush fences, and barriers constructed of gravel. Both types trap sediments by ponding water. Although ponding is more obvious in ponds than in barriers, barriers have little ability to filter and can only slow the water long enough for some particles to settle. Thus, they can only trap relatively large particles, generally the larger silts and sands. The trapping ability of settling ponds depends on size. While ponds can theoretically be made large enough to trap any size particle, practical sizes generally limit efficient removal to medium and larger silts.

Figure 14.5—Filter fabric fence detail.



Source: Washington Dep. Ecol. 1992.

Sediment Barriers

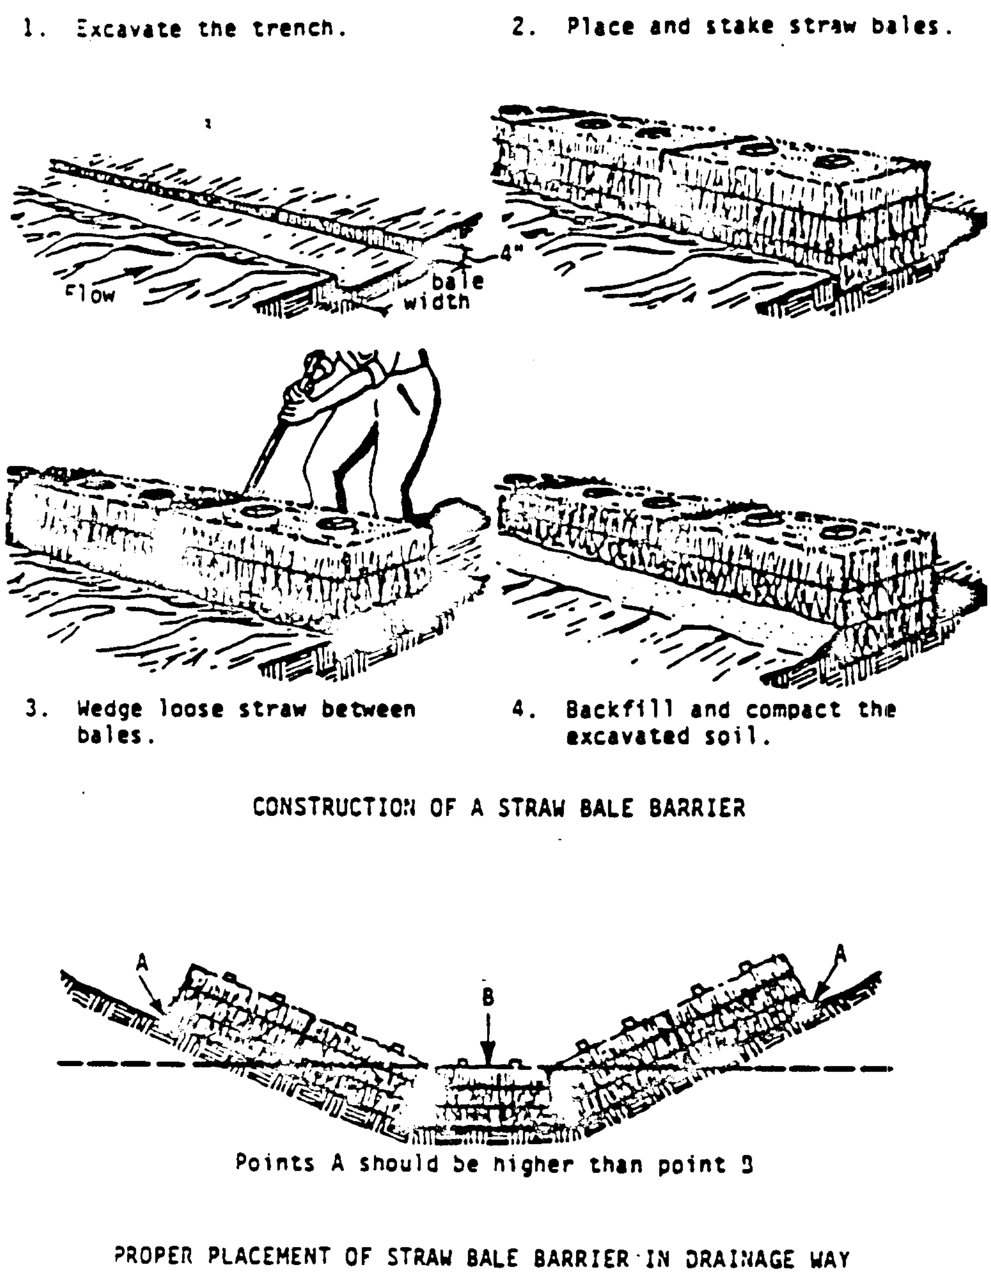
Several principles apply to the various types of sediment barriers. Maximizing a sediment barrier's ponding volume maximizes the sediment trapped. Therefore, barriers should be placed away from the immediate toe of slopes to increase the ponding area. Sediment barriers must be aligned on the contour, not up and down slopes. This alignment places them at a right angle to flow paths and increases ponding volume. Slopes draining to sediment barriers generally should not be more than 100 ft (30.48 m) long. Sediment barriers must be trenched in and staked to hold up under the pressure of the wall of water they will dam. Finally, sediment barriers do not provide effective sediment removal from concentrated flows. While straw bales are sometimes used in ditches, rock check dams are a better alternative for decreasing velocity in channels. Filter fabric and straw bale fences are illustrated in Figures 14.5 and 14.6.

Filter Fabric Fence

■ **Installation checks**

1. Are filter fabric fences used only in applications where
   - Maximum of 1 acre (0.405 ha) is served by a single fence?
   - Maximum gradient is 1-to-1 and slope length is ≤ 100 ft (30.48 m)?
   - Situation is sheet flow, never concentrated flow?

Figure 14.6—Proper installation of straw bale fences.



Source: Washington Dep. Ecol. 1992.

2. Is the fence aligned as closely as possible to slope contours?
3. Is the fence height above the soil no more than 3 ft (0.91 m)?
4. Are wooden posts 2 by 4 in (5.08 by 10.16 cm), and steel posts 1.33 lb/ft (1.98 kg/m), or the equivalent?
5. Are posts buried 2.5 ft (0.76 m) deep whenever possible and spaced no more than 6 ft (1.83 m) apart?
6. Is fabric attached on the upslope side with staples of at least 1 in (2.54 cm), tie wires, or hog rings?
7. Is the end of the fabric buried in a trench sized as shown in Figure 14.5 and backfilled on both the upslope and downslope sides?
8. Is splicing avoided? If unavoidable, is splicing done only at posts and overlapped at least 6 in (15.24 cm)?
9. Woven monofilament materials have the best properties for silt fencing. If a woven slit-film fabric is used, is 14-gauge reinforcing wire mesh with openings no larger than 6 in (15.24 cm) placed on the upslope side and fastened the same as the fabric?

■ Maintenance checks

1. Does the fence need restaking, reattaching, or replacing to maintain all previously cited conditions?
2. Is sediment removal needed before sediment reaches one-third fence height?

▌*Straw Bale Fence.* Straw bale fences, which tend to swell when wet, require frequent maintenance. Users should gain local experience on the expected service life of bales and replace them before they become ineffective. While not highly recommended, these fences could be somewhat effective if used according to the following guidelines:

■ Installation checks

1. Are straw bale fences used only in applications where
   - Maximum of 1/4 acre (0.1 ha) is served per 100 ft (30.48 m) of fence length?
   - Maximum slope gradient is 2-to-1 and slope length is 100 ft (30.48 m)?
2. Is the fence aligned as closely as possible to slope contours?
3. Are the bales bound with wire or alternatively with string placed around the sides, parallel to the ground?
4. Are bales installed in a 4 in (10.16 cm) trench as in Figure 14.6 and backfilled with 4 in (10.16 cm) of soil on the upslope side?
5. Are the bales forced tightly together and anchored with at least two stakes or rebars per bale, driven toward the previous bale, and flush to the top of the bale?
6. Are gaps wedged with straw spread on the upslope side?
7. Are straw bale fences used in channels with concentrated flow only when velocities are low, placed perpendicular to flow, and extended at least one bale length above the mid-channel bale (see Figure 14.6)?

■ Maintenance checks

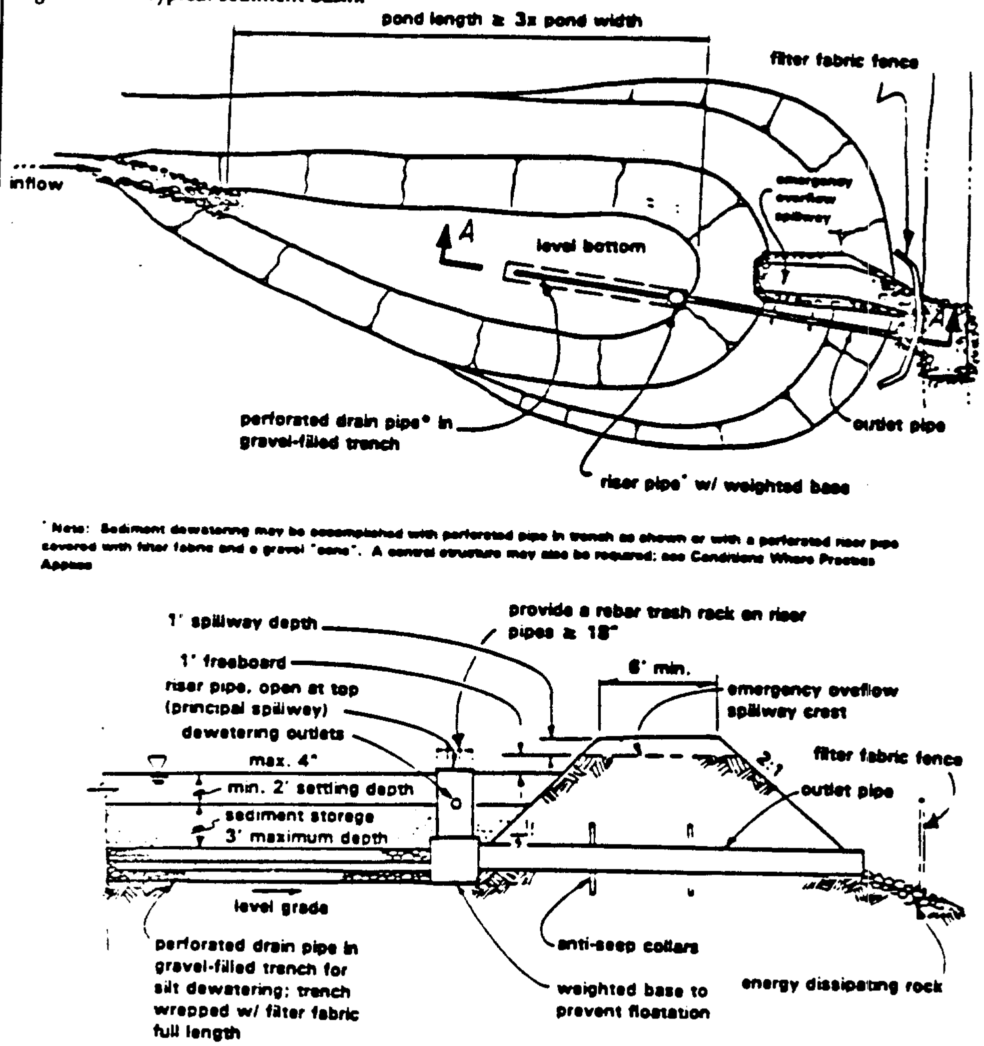
1. Must the fence be replaced to maintain all of the previously stated conditions?
2. Is removal needed before sediment reaches one-half the fence height?

Settling Ponds

Settling ponds have several advantages. They can function through all construction phases and have relatively low maintenance requirements if preventive erosion control is effective. Settling ponds can also be located to intercept runoff before and after the on-site drainage system is developed.

The three types of settling ponds differ in the their outlet structure. The term sediment basin is used for a settling pond with a pipe outlet that generally serves a drainage area of 3 to 10 acres (1.22 to 4.05 ha). A sediment trap is a settling pond with a stable spillway outlet and smaller service area. The third type is a permanent water quantity control pond used temporarily during construction. Used permanently, this pond could be designed to drain completely between storms. This operating mode is not effective for erosion and sediment control—residence time is too short for good particle trapping, and settled material

Figure 14.7—Typical sediment basin.



Source: Washington Dep. Ecol. 1992.

Section A-A

becomes resuspended during draining. Therefore, a temporary riser outlet must to be installed for construction use.

In designing and constructing a settling pond, avoid allowing water to short circuit. Short circuiting can cut the actual residence time far below the theoretical value and harm performance. Therefore, divide the pond into two or more cells, locate the inlet and outlet far apart, and install baffling to increase the flow path. Figure 14.7 illustrates a typical sediment basin.

Sediment Basin

Installation checks

1. Is the bottom graded level?
2. Is the pond no deeper than 7 ft (2.13 m) plus 1 ft (0.31 m) of freeboard?
3. Are side slopes no steeper than a horizontal-to-vertical ratio of 3-to-1?
4. Does the pond have an emergency spillway 1 ft (0.31 m) deep, a width two

VOL 12

67569

R0040077

to three times the number of acres served by the pond, and is the pond lined with 2 to 4 in (5.1 to 10.16 cm) of rocks?

5. Does the pond discharge through a riser pipe having multiple orifices at the top of the sediment storage zone?
6. Are inlet and outlet areas protected from erosion with riprap?
7. Is baffling installed if the length-to-width ratio is less than 6 or if the entrance velocity is high?
8. A two-celled pond, preferably with cells divided by sandbags or a rock berm and connected by a riser pipe like the outlet, can prevent short circuiting of flow. A less desirable arrangement is to divide the pond with a filter fabric fence. Is the more effective feature installed if specified in the design?
9. Can the pond be easily accessed to remove sediment? Is there a plan to safely dispose of sediment or use it for fill?
10. Is the pond fenced if it presents any safety hazard to children?

Maintenance checks

1. Is sediment removal needed before 1.5 ft (0.46 m) accumulates?
2. Are any outlet orifices clogged and in need of cleaning?
3. Are any embankments damaged and in need of compaction or rebuilding?
4. Has riprap or spillway lining material been lost and need replacing?
5. Do signs of excessive drainage to the pond require rerouting or pond enlargement?
6. Do signs of excessive sediment loading to the pond require stabilizing the drainage area?
7. Is sediment being disposed of in a conscientious manner?

C. Management of Other Site Pollutants

Construction sites can create pollution problems over and above erosion and sediments through paving operations, handling and storage of various materials, spills, and waste handling. Inspectors should also be aware of the potential for runoff contamination from these sources and inspect the site according to the following guidelines:

Cement and Concrete Handling

Inspection checks

1. Do concrete trucks have a designated wash-out area with a sediment trap?
2. Is exposed-aggregate driveway wash water drained toward a collection point at the side or into a sediment trap where it cannot enter a street drainage system?

Material Storage and Handling

Inspection checks

1. Are weather-resistant enclosures used to store and handle materials like paints, coatings, wood preservatives, pesticides, fuels, lubricants, and solvents, and for potentially polluting wastes?
2. Are procedures for handling materials and wastes and washing containers designated and clearly communicated?
3. Is a chemical inventory maintained, including material safety data sheets?
4. Are containers and enclosures inspected periodically for leakage?
5. What is the fueling process? Are overflow prevention methods used?

Spill Containment

Inspection checks

1. Has a spill control plan been developed and have supplies been obtained to implement it? Does the plan include
   - Who to notify if a spill occurs?
   - Specific instructions for different products?
   - Who is in charge?
   - Spill containment procedures?
   - Easy to find and use spill clean-up kits?
   - How a spill will be prevented from getting into a drainage system—for example, valving, diversion, absorption?
   - A disposal plan?
   - A worker education program?

▮ *Waste Management*

- **Inspection checks**

1. Have waste reduction practices been instituted—for example, reusing solvents, substituting for toxic products, minimizing quantities of materials used?
2. Have recycling practices been instituted—for example, waste separation for recycling, purchasing recycled materials?
3. Are hazardous and nonhazardous wastes separated and each disposed of properly and promptly?
4. Is there an employee education program on waste management?

Comprehensive Inspection Program for Permanent Drainage

As previously discussed, a comprehensive inspection program for permanent drainage practices and facilities should contain the following elements:

- Runoff management planning
- Plan review
- Construction inspection and enforcement
- Follow-up inspection and long-term maintenance

Runoff management planning ensures that each site entering the permit process is comprehensively analyzed. Chapter 12 contains a discussion of the extensive considerations of plan review. Inspection of completed runoff management facilities determines that they have been installed consistently with the approved plans. The next section covers programmatic aspects of follow-up inspection and long-term maintenance, which ensures that sites continue to operate properly.

Follow-Up Inspection and Long-Term Maintenance

An effective program should have the following features:

- An ordinance designating public authority and public and private responsibilities
- A tracking system
- An inspection schedule
- A maintenance schedule
- A safety program
- A citizen response program
- Proper waste disposal practices
- Maintenance contractor education

The following information principally draws on experience in King County, Bellevue, Olympia, and elsewhere in the Puget Sound region of Washington State.

▮ *Public vs Private Responsibilities.* While inspection is usually a public function, who is responsible for upkeep of privately owned facilities? One model establishes a multiyear bonding period, during which the developer has all responsibility. After this period and a demonstration of effective operation, the government agency responsible for runoff takes over operation and maintenance.

A second model leaves maintenance as a private function—by a commercial property owner or homeowners' association—with inspection by the public agency. If the private party does not meet the responsibility, the government assumes the responsibility and charges the costs. This strategy requires access to private maintenance contractors who are competent in performing the needed work. The frequent lack of qualified contractors requires government agencies to consider training and certifying them.

▮ *Tracking System.* King County offers a good tracking system model to organize long-term inspections and maintenance using a computerized information system. Each inspector is assigned an inventory of facilities to inspect for specific maintenance and receives a laptop computer for field use. The information system contains an identification number for each facility, its type (e. g., wet pond, infiltration basin), location, any special needs, and data on previous experiences. After each visit, the inspector enters a maintenance needs assessment in the computer database. The computer then generates a maintenance work order.

▮ *Safety.* Safety is a major consideration because of potentially harmful atmospheres in below-ground spaces, corroded supports, traffic, falling objects, sharp edges, poisonous plants and in-

insects, and lifting. A tester should check all conditions and test all enclosed spaces before entering. The safety portion of an inspection and maintenance program should include the following:

- Testing instruments for harmful atmospheres—e.g., explosive, containing hydrogen sulfide, lacking in oxygen
- Ventilating equipment
- Checking structural soundness before entering a manhole
- Traffic warning devices
- Ladders, safety harnesses, and hard hats
- Removing poisonous plants and insect nests
- Adequate personnel
- Safety training

Waste Handling. Major maintenance on large facilities should be scheduled when the least runoff is expected. Inspectors should require ESC practices like filter-fabric fences, sandbags, grassed drainage areas, and revegetation to prevent sediment escape during maintenance.

The vactor truck—which vacuums out storm sewers, drains, and inlets—is the maintenance workhorse. A problem with vactor trucks is the mixing of relatively clean and very dirty waste. A solution, but an expensive one, is to have "clean" and "dirty" trucks. Another issue is the disposal of both solids and separated "decant" water picked up by vactor trucks.

The best solution is to discharge decant water to a special station with sediment and oil separation equipment before the water discharges to a sanitary sewer. However, oil separators should not be cleaned at the same time as sediment accumulation chambers. Few such stations exist now, and most vactor waste is discharged directly into the sanitary sewer. This practice can result in pollutants entering surface waters because of inadequate treatment at the municipal wastewater plant and in toxic materials that can upset biological processes at the treatment plant. Guidelines, while needed, generally do not exist for disposing of solids. The best programs now send solids to a lined municipal landfill, unless they fail a "looks bad and smells bad" test. In that case, they are treated as hazardous waste.

Table 14.4—Permanent drainage practices.

CATEGORIES	PRACTICES
Stormwater devices	Oil/water separators Pipes and culverts Catch basins
Detention facilities	Wet ponds Extended/detention dry ponds Vaults and tanks
Infiltration facilities	Infiltration basins Infiltration trenches Porous pavements
Biofilters	Vegetated swales Constructed wetlands Filter strips

Permanent Drainage Practices and Facilities Inspection

Table 14.4 provides a listing of practices (Reinelt, 1992). The practices include some variations on common devices, depending on their intended function as specified by the *Stormwater Management Manual for the Puget Sound Basin* (Washington Dep. Ecol. 1992). For example, detention facilities include wet ponds, which have a quantity control function, and water quality wet ponds, which are treatment devices.

The following are inspection checklists for the most common practices and facilities in each category. While brief descriptions are presented here, runoff management manuals or textbooks can provide detailed descriptions.

As previously suggested, inspectors must perform background work—consulting the design plans to determine the specifications before going out to inspect an installation. Infrequent inspection and maintenance is a main reason for poor performance by runoff facilities. The frequency of follow-up inspections varies with the type of device and the installation circumstances. Each installation should have an inspection and maintenance plan developed before it goes into service. As a general rule, surface facilities should receive a drive-by inspection at least monthly and after any rain totaling 0.5 in (1.27 cm) or more in 24 hours.

Stormwater Devices

These devices are used to collect and convey runoff and as special-purpose facilities. Within the category are catch basins, pipes and culverts, and

VOL 12 6772

R0040080

oil/water separators. Inspection guidelines are provided for oil/water separators and tables of maintenance standards are included for the other types of facilities.

▌*Oil/Water Separators.* Figure 14.8 illustrates the three basic types of oil/water separators. The spill control unit (14.8A) catches small spills; it is not capable of separating dispersed oil. The American Petroleum Institute (API) separator (14.8B) is a baffled tank that can separate "free" (unemulsified) oil but requires a relatively large volume for effectiveness. The coalescing plate (CP) separator (14.8C) can separate free oil in a much smaller volume because of the large surface area provided by the corrugated plate pack. The following guidelines generally apply to all types, except as noted.

▬ Installation checks

1. Is the type appropriate for the service?
2. Is the unit sized and installed as specified in the plans?
3. Are adequate removable covers provided for observation and maintenance?
4. Is runoff excluded from roofs and other areas not likely to contain oil?
5. Is any pump being used placed downstream in order to prevent mechanical emulsification?
6. Is detergent use avoided upstream to prevent chemical emulsification?
7. For API and CP types, is a forebay provided and sized at 20 ft^2 (1.86 m^2) of surface area per 10,000 ft^2 (929 m^2) of drainage area?
8. For API and CP types, is an afterbay provided to place absorbents?
9. For the CP type, are the plates no more than 3/4 in (1.91 cm) apart and at 45 to 60 degrees from horizontal?

▬ Maintenance checks

1. Does the owner perform weekly inspections?
2. Are oil and any solids removed frequently enough—at least just before the main runoff period and after the first major runoff event?
3. Are absorbents replaced as needed—at least at the beginning and end of the main runoff season?
4. Is the effluent shutoff valve operational for closure during cleaning?
5. Are waste oil and solids disposed of as specified by regulations?
6. Is any standing water that is removed discharged to the sanitary sewer and then replaced with clean water?

▌*Pipes and Culverts.* Table 14.5 contains a summary of maintenance standards for conveyance facilities.

▌*Catch Basins.* Catch basins are routinely placed between drain inlets in streets and parking lots and the conveyances that transport water away to settle large solids. Table 14.6 contains a summary of maintenance standards.

▌*Wet Ponds.* A typical wet pond has a "dead storage" permanent or semipermanent pool and a "live storage" zone that fills during runoff events and then drains fairly quickly (see Figure 14.9). Designs differ depending on the purpose—quantity control, quality control, or both—but the checks made at installation and later during operation are generally the same, with the few exceptions noted.

▬ Installation checks

1. Does construction comply with local requirements for earthwork, concrete, other masonry, reinforcing steel, pipe, water gates, metal work, and woodwork?
2. Are all dimensions as specified in the approved plan?
3. Are interior side slopes no steeper than a horizontal-to-vertical ratio of 3-to-1 and exterior side slopes no steeper than 2-to-1?
4. Is the bottom level?
5. Are the spillways—between cells, if any, and the emergency outlet spillway—sized and reinforced as specified in the approved plan?
6. Can the drain empty the dead storage zone within four hours?

6774

Table 14.5—Maintenance standards for pipes and culverts.

DEFECT	CONDITIONS WHEN MAINTENANCE NEEDED	MAINTENANCE RESULTS
Sediment and debris	Accumulated sediment that exceeds 20 percent of the pipe diameter	Pipe cleaned of all sediment and debris
Vegetation	Vegetation that reduces free movement of water through pipes	All vegetation removed so water flows freely through pipes
Damaged	Protective coating is damaged; rust is causing more than 50 percent of deterioration to any part of pipe Any dent that decreases the end area of pipe by more than 20 percent	Pipe repaired or replaced
Debris barriers	Trash or debris plugging more than 20 percent of the barrier openings	Barrier clear to receive capacity flow
Damaged/missing bars	Bars are bent out of shape more than 3 in (7.62 cm)	Bars in place with no bends > 3/4 in (1.91 cm)
	Bars are missing or entire barrier missing	Bars in place according to design
	Bars are loose and rust is causing 50 percent deterioration to any part of barrier	Repair or replace barrier to design standards

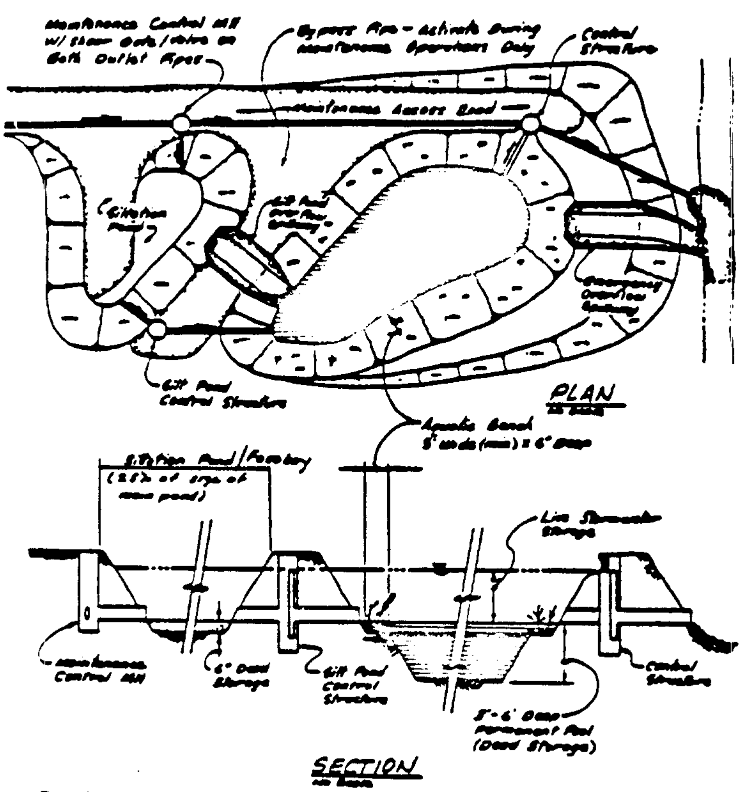
Figure 14.9—Typical wet pond.



Source: Washington Dep. Ecol. 1992.

Table 14.6—Maintenance standards for catch basins.

DEFECT	CONDITIONS WHEN MAINTENANCE NEEDED	MAINTENANCE RESULTS
Trash and debris (including sediment)	Trash or debris of more than 1/2 ft^3 (14.16 dm^3) located in front of the catch basin opening or blocking capacity of basin by > 10 percent	No trash or debris located immediately in front of catch basin opening
	Trash or debris in the basin that exceeds 1/3 to 1/2 the depth from the bottom of basin to invert of the lowest pipe into or out of the basin	No trash or debris in catch basin
	Trash or debris in any inlet or outlet pipe blocking more than 1/3 of the height	Inlet and outlet pipes free of trash or debris
	Dead animals or debris that could generate odors that would cause complaints or dangerous gases	No dead animals or vegetation present
	Deposits of garbage exceeding 1 ft^3 (28.32 dm^3) in volume	No trash or debris in catch basin
Structural damage to frame and/or top slab	Corner of frame extends more than 3/4 in (1.91 cm) past curb face into the street (if applicable)	Frame is even with curb
	Top slab has holes larger than 2 in^2 (12.9 cm^2) or cracks wider than 1/4 in (1.61 cm) (to ensure that all materials run into basin)	Top slab is free of holes and cracks
	Frame not sitting flush on top slab—i.e., separation of > 3/4 in (1.91 cm) of the frame from top of slab	Frame is sitting flush on top of slab
Cracks in basin walls or bottom	Cracks wider than 1/2 in (3.23 cm) and longer than 3 ft (0.91 m), any evidence of soil particles entering catch basin through cracks, or structure is unsound	Basin replaced or repaired to design standards
	Cracks wider than 1/2 in (3.23 cm) and longer than 1 ft (0.305 m) at the joint of any inlet/outlet pipe or any evidence of soil particles entering catch basin through crack	No cracks more than 1/4 in (1.61 cm) wide at joint of inlet/outlet pipe
Settlement/misalignment	Basin has settled more than 1 in (2.54 cm) or has rotated more than 2 in (5.08 cm) out of alignment	Basin replaced or repaired to design standard
Fire hazard	Presence of chemicals such as natural gas, oil, and gasoline	No flammable chemicals present
Vegetation	Vegetation growing across and blocking more than 10 percent of basin	No vegetation blocking opening to basin
	Vegetation (or roots) growing in inlet/outlet pipe joints > 6 in (15.24 cm) tall and < 6 in (15.24 cm) apart	No vegetation or root growth present
Pollution	Nonflammable chemicals of > 1/2 ft^3 (14.16 dm^3) per 3 ft (0.91 m) of basin length	No pollution present other than surface film

Source: Adapted from Reinelt, 1992.

VOL 12 6776

7. Are inlet and outlet areas stabilized to avoid erosion?

8. Are safety features provided such as a shallow bench surrounding the pond edge, barrier plantings to discourage approach by children, and/or fencing (unnecessary if sloped as recommended and other safety features provided)?

9. For a water quality pond, is the effective length-to-width ratio at least 3-to-1 and preferably 5-to-1? Are the inlet and outlet separated as widely as possible?

- **Maintenance checks**

1. Has a maintenance plan and schedule been developed?

2. Table 14.7 contains specific checks and maintenance standards, which also apply to other types of ponds.

Vaults and Tanks. Refer to Table 14.8 for a summary of maintenance standards for closed detention systems.

Infiltration Facilities

Infiltration facilities discharge most of the entering water into the ground. They include surface basins and trenches, below-ground perforated pipes, roof drain systems, and porous pavements. Inspection guidelines are given for infiltration basins in Figure 14.10 and a table of maintenance standards is included for infiltration trenches as well (Figure 14.9).

Infiltration Basins

- **Installation checks**

1. Does construction comply with local requirements for earthwork, concrete, other masonry, reinforcing steel, pipe, water gates, metal work, and woodwork?

2. Are all dimensions as specified in the approved plan?

3. Does the timing of basin construction avoid any runoff containing sediment from elsewhere on the site?

4. Is the basin preceded by a pretreatment device— presettling basin or biofilter—to prevent failure caused by siltation?

5. Is the basin at least 50 ft (15.24 m) from any slope greater than 15 percent and at least 100 ft (30.48 m) upslope and 20 ft (6.1 m) downslope of any building?

6. Is the outlet orifice design consistent with the facility's infiltration capacity—e. g., to avoid the collection of more water than can infiltrate in 48 hours?

7. Are the spillways—between cells, if any, and the emergency outlet spillway—sized and reinforced as specified in the approved plan?

8. Are all disturbed areas stabilized to prevent erosion?

9. After final grading, has the bed been deeply tilled to provide a well-aerated, highly porous surface texture?

- **Maintenance checks**

1. Has a maintenance plan and schedule been developed?

2. Table 14.9 contains specific checks and maintenance standards.

3. Is tilling necessary to restore infiltration capacity (regular annual tilling is recommended)?

Infiltration Trenches. Table 14.10 contains a summary of maintenance standards for infiltration trenches.

Biofilters

Biofilters, or vegetated land treatment systems, can be vegetated swales where water flows at some measurable depth. Biofilters can also be broad surface areas where water flows in a thin sheet, sometimes called filter strips. Constructed wetlands are also sometimes put in this category. The following guidelines generally pertain to swales and filter strips, although some exceptions are noted. To inspect constructed wetlands, refer to both these guidelines and those given previously for wet ponds.

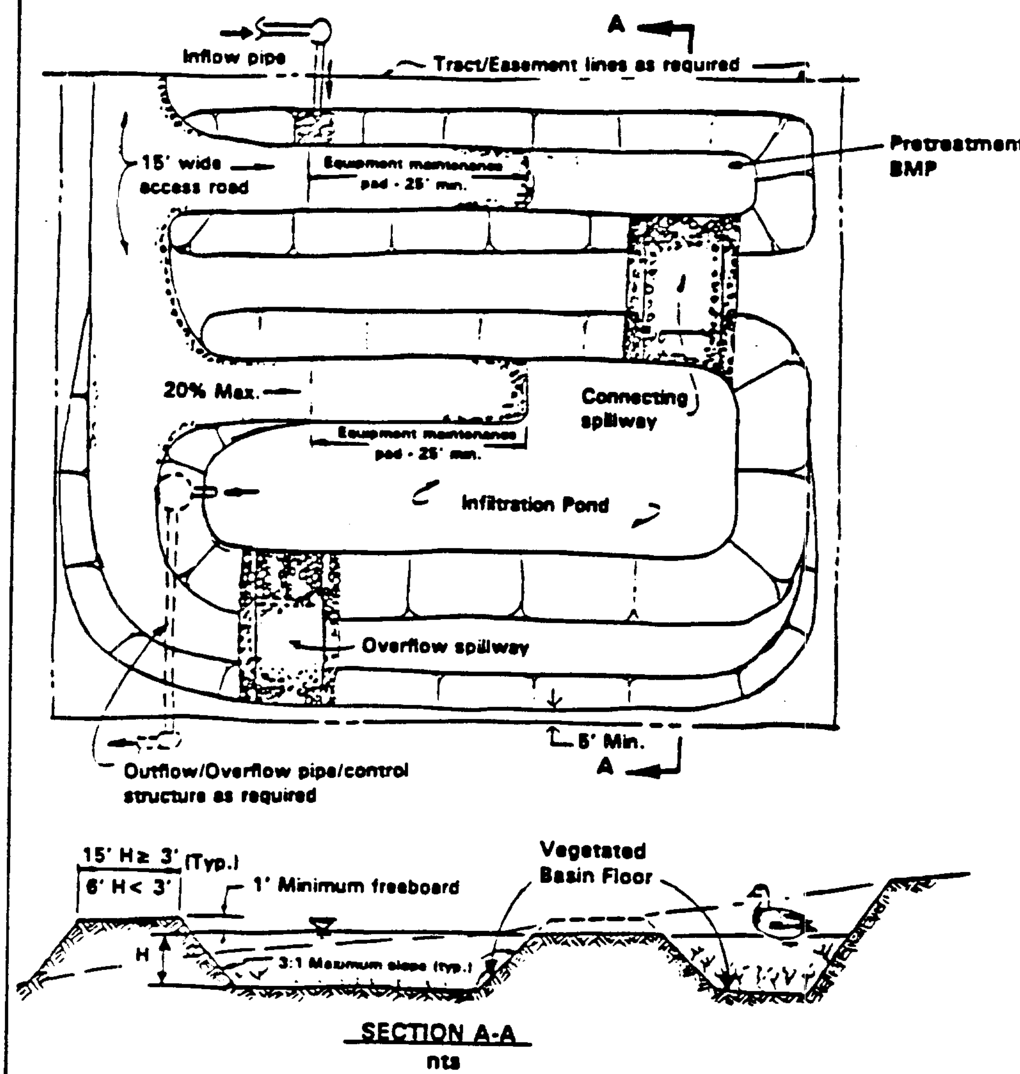
Biofiltration Swales and Filter Strips

- **Installation checks**

1. Are the dimensions and plantings as specified in the approved plan?

2. Is the vegetation cover dense and uniform?

Figure 14.10—Typical infiltration basin.



Source: Washington Dep. Ecol. 1992.

VOL 12

6778

R0040086

Table 14.7—Maintenance standards for detention facilities.

DEFECT	CONDITIONS WHEN MAINTENANCE NEEDED	MAINTENANCE RESULTS
Trash and debris	Any trash or debris that exceeds 1 ft^3/1,000 ft^2 (28.32 dm^3/92.9 m^2); no evidence of dumping should exist	Trash and debris cleared from site
Poisonous	Presence of any poisonous vegetation that constitutes a hazard to maintenance personnel or the public (e.g., tansy, poison oak, stinging nettles, devils club)	No evidence of poisonous vegetation; coordinate with local health department
Pollution	One gallon or more of oil, gas, or contaminants, or any amount that could (1) cause damage to plant, animal, or aquatic life; (2) constitute a fire hazard; (3) be flushed downstream during storms; or (4) contaminate groundwater	No contaminants present other than a surface film; coordinate with local health department
Unmowed grass/ ground cover	In residential areas, mowing is needed when the cover exceeds 18 in (.46 m) in height; otherwise, match facility cover with adjacent ground cover and terrain as long as facility function does not decrease	Grass/ground cover should be mowed to 2 in (5.08 cm); maintain dense cover on slopes and in bottom of dry ponds
Rodent holes	Any evidence of rodent holes if facility is acting as a dam or berm, or any evidence of water piping through dam or berm via rodent holes	Rodents destroyed and dam or berm repaired; coordinate with local county health department
Insects	When insects such as wasps or hornets interfere with maintenance activities	Insects destroyed or removed from site; coordinate with people who remove wasps for antivenom protection
Tree growth	Does not allow maintenance access or interferes with maintenance activity; if trees are not interfering with access, leave alone	Trees do not hinder maintenance activities
Erosion of pond side slopes	Eroded damage > 2 in (5.08 cm) deep where cause of damage is still present or potential for continued erosion exists	Slopes stabilized with appropriate erosion control BMPs (e.g., seeding, mats, riprap)
Sediment accumulation in forebay/pond	Accumulated sediment that exceeds 10 percent of the design forebay/pond depth, or every 3 years	Sediment cleaned out to design depth; reseed if necessary for erosion control
Dike settling	Any part of dike that has settled more than 4 in (10.16 cm)	Dike is rebuilt to design elevation
Rocks missing from overflow spillway	Only one layer of rock above native soil in an area of 5 ft^2 (0.47 m^2) or greater, or any exposed soil	Rock replaced to design standard
Inadequate spillway size	Emergency overflow or spillway not large enough to handle flows from large storm events	Increase capacity of spillway to current design standards

Table 14.7—continued

Missing, broken, or damaged fencing	Any defect in fencing that permits easy entrance to the pond	Fencing repaired to prevent entrance
	Damaged fencing including posts out of plumb by > 6 in (15.24 cm), top rails bent > 6 in (15.24 cm), missing or loose tension wire, missing or sagging barbed wire, missing or bent extension arms	Fencing parts that have a rusting or scaling condition affecting structural adequacy
	Opening in fencing that allows passage of an 8 in diameter ball	No opening in fence
Erosion under fencing	Erosion 4 in (10.16 cm) deep and 12 to 18 in (.31 to .46 cm) wide permitting an opening under fence	No opening under fence > 4 in (10.16 cm)
Missing or damaged gates	Missing or damage gate, locking device, or hinges	Gates, locking devices, and hinges repaired
	Gate is out of plumb by > 6 in (15.24 cm) and > 1 ft (.31 m) out of design alignment	Gate is aligned and vertical
	Missing stretcher bar, bands, or ties	Stretcher bar, bands, and ties in place
Blocked or damaged access roads	Debris that could damage vehicle tires	Roadway free of debris
	Obstructions that reduce clearance above road surface to < 14 ft (4.27 m) (e.g., tree branches, wires)	Roadway clear overhead to 14 ft (4.27 m)
	Any obstructions restricting access to a 10 to 12 ft (3.05 to 3.66 m) width for a distance of > 12 ft (3.66 m), or any point restricting access to a width of < 10 ft (3.05 m)	Obstructions moved to allow at least a 12 ft (3.66 m) access route
	Any road settlement, potholes, mushy spots, or ruts that prevent or hinder maintenance access	Road surface repaired and smooth
	Weeds or brush on or near road surface that hinder access, or are > 6 in (15.24 cm) tall and < 6 in (15.24 cm) apart within a 400 ft^2 (37.16 m^2) area	Weeds and brush on or near road surface cut to 2 in (5.08 cm)
	Erosion within 1 ft (.31 m) of the roadway > 8 in (20.32 cm) wide and 6 in (15.24 cm) deep	Shoulder and road free of erosion

Source: Adapted from Reinelt, 1992.

Table 14.8—Maintenance standards for closed detention systems.

DEFECT	CONDITIONS WHEN MAINTENANCE NEEDED	MAINTENANCE RESULTS
Plugged air vents	Half of the end area of a vent is blocked at any point with debris and sediment	Vents free of debris and sediment
Debris and sediment in storage area	Accumulated sediment depth is > 10 percent of the diameter of the storage area for 1/2 the length of storage vault or any point exceeds 15 percent of the diameter; for example, 72-in (1.83-m) storage tank would require cleaning when sediment reaches a depth of 7 in (17.78 cm) for more than 1/2 the tank length	All sediment and debris removed from storage area
Cracks in joints between tank/pipe sections	Any crack allowing material to be transported into the facility	All joints between tanks/pipe sections are sealed
Problems with manhole cover	Cover is missing or only partially in place; any open manhole requires maintenance	Manhole is closed and secured
	Locking mechanisms cannot be opened by one maintenance person with proper tools; bolts into frame have < 1/2 in (3.23 cm) of thread (may not apply to selflocking lids)	Mechanism is repaired or replaced so it functions properly
	Cover difficult to remove by one maintenance person applying 80 lbs (36.29 kg) of lift	Cover can be removed and reinstalled by one maintenance person
Ladder rungs of manhole unsafe	Local government safety officer or maintenance person judges that ladder is unsafe due to missing rungs, misalignment, rust, or cracks	Ladder meets design standards and allows for maintenance access
Catch basins	See Table 14.6	See Table 14.6

Source: Adapted from Reinelt, 1992.

Table 14.9—Maintenance standards for infiltration basins.

DEFECT	CONDITIONS WHEN MAINTENANCE NEEDED	MAINTENANCE RESULTS
Sediment buildup in system	Soil texture test indicates facility is not functioning as designed	Sediment is removed and/or facility is cleaned so that system works according to design; a forepay or presetting basin is installed to reduce sediment transport to facility
Poor facility drainage (more than 48 hours)	Soil texture test indicates facility is not functioning as designed	Additional volume added through excavation to provide needed storage; soil aerated and rototilled to improve drainage
Sediment trapping area	Sediment and debris fill more than 10 percent of sediment trapping facility or sump	Sediment trapping facility or sump cleaned of accumulated sediment
No sediment trapping facility	Runoff enters infiltration area without pretreatment	Add a trapping facility (presettling basin, detention pond, biofilter) before infiltration facility

Source: Adapted from Reinelt, 1992.

Table 14.10—Maintenance standards for infiltration trenches.

DEFECT	CONDITIONS WHEN MAINTENANCE NEEDED	MAINTENANCE RESULTS
Sediment and debris buildup in trench	By visual inspection, little or no water flows through the trench during large storms	Debris blocking infiltration trench removed; gravel in infiltration trench replaced or cleaned
Observation well	Observation well buried, covered, or inaccessible	The observation well/cap is accessible to the inspector for opening and inspection
Water percolates up from trench	Trench water or water with dye percolating to surface	Gravel and filter fabric in infiltration trench replaced or cleaned; trench functions according to design standards
Filter fabric exposed	Filter fabric is exposed or damaged	Filter fabric is replaced or repaired and covered with proper backfill material

Source: Adapted from Reinelt, 1992.

3. If the biofilter is a swale, is it parabolic or trapezoidal in shape, with side slopes no steeper than a horizontal-to-vertical ratio of 3-to-1?
4. Is the biofilter placed near buildings and trees so that no portion will be shaded throughout the day and possibly experience poor plant growth?
5. If the longitudinal slope is less than 2 percent or if the water table can reach the root zone of vegetation, is water-resistant vegetation planted to survive a standing water condition? Is an underdrain system installed to assist drainage (underdrains may not be practical with a large filter strip)?
6. If the longitudinal slope is in the 4 to 6 percent range, are check dams provided approximately every 50 to 100 ft (15.24 to 30.48 m) to reduce velocity (check dams may not be practical on a larger filter strip)?
7. If a swale is installed on a slope that exceeds 6 percent, does it traverse the slope so that no reach slopes more than 4 percent, or 6 percent with check dams?
8. Is the lateral slope entirely uniform to avoid any tendency for the flow to channelize?
9. Is flow introduced so that entrance velocity is dissipated quickly, flow is distributed uniformly, and erosion is avoided (e. g., by using a riprap pad or some means of level spreading)?
10. Was construction-phase runoff excluded or was the biofilter reestablished after construction? Are upslope areas stabilized to avoid erosion into the biofilter?
11. Is a bypass in place for flows larger than the flow rate the biofilter was designed to treat? Is the facility sufficiently large to at least pass the 100-year, 24-hour storm without eroding (a bypass is preferred to maintain treatment and prevent resuspension of settled material)?

■ **Maintenance checks**

1. Has a maintenance plan and schedule been developed?
2. Table 14.11 contains specific checks and maintenance standards.

References Cited

New Jersey Department of Environmental Protection and Energy. 1989. Stormwater Management Facilities Maintenance Manual. Trenton, NJ.

Table 14.11—Maintenance standards for biofilters.

DEFECT	CONDITIONS WHEN MAINTENANCE NEEDED	MAINTENANCE RESULTS
Trash and debris	Dumping of yard wastes; accumulation of nondegradable materials	Remove degradable wastes and compost; recycle other waste when possible
Sediment buildup	Accumulation exceeds 20 percent of design depth	Cleaned or flushed to match design; vegetation restored as necessary
Poor vegetation cover	Vegetation sparse and/or weedy; overgrown with woody vegetation	Aerate soil and plant; remove woody growth and replace
Erosion damage to slopes	Erosion > 2 in (5.08 cm) deep where cause still present, or potential for continued erosion	Find cause and eliminate; stabilize with appropriate erosion controls (e.g., seeding, mat, mulch)
Conversion to use incompatible with water quality control	Filled or planted inappropriately, or blocked	Discuss with nearby property owners and specify corrections to be made
Poor drainage	Water stands in swale	Determine cause; if high water table, consider rebuilding with liner or underdrain; if slope < 1 percent, use underdrain

CHAPTER 15

Watershed Management

Runoff management and nonpoint source pollution present many complex challenges to the water resources manager. This chapter discusses how to meet these challenges by using a watershed management approach to integrate land planning and other resources within the watershed.

The challenges, quite different from those encountered when managing traditional point sources of pollution, include

- Integrating land use management, since the change in land use creates the runoff problem;
- Educating the public about how everyday activities contribute to the runoff problem and how they must be part of the solution;
- Developing a management framework given that we all live downstream and that runoff flows are not constrained by political boundary lines;
- Obtaining the cooperation and coordination of neighboring political entities within a watershed;
- Managing runoff from new development and retrofitting the existing drainage system built solely to convey runoff away from developed lands to the nearest waterbody as quickly as possible.
- Coordinating point and nonpoint source runoff strategies and activities.

Additionally, constraints imposed by current runoff treatment technology—such as treatment efficiency, land needs, and maintenance needs—and by the costs of assessing and solving existing runoff/nonpoint source pollution problems call for a cooperative regional framework. Finally, a watershed management approach includes planning efforts to prevent problems and traditional regulatory efforts to mitigate adverse effects caused by land alterations and changes in land use. This approach permits extensive use of inexpensive nonstructural management practices.

Definition and Rationale

What Is a Watershed?

The term watershed refers to a geographical area in which water, sediments, and other materials drain to a common outlet such as a stream, lake, or estuary. This area is also called the drainage basin of a receiving waterbody. When a raindrop falls in this area, it flows until it reaches the downstream receiving waterbody.

Watershed dimensions depend on the waterbody. A large river's watershed may cover thousands of square miles, while each of its tributaries has a smaller watershed. The U.S. Geological Survey has segmented the nation into hydrological units, a standard way to define the many subbasins or small watersheds that combine to make up large watersheds.

What Is Watershed Management?

Watershed management is a flexible framework for integrating the management of all resources—land, biological, water, infrastructure, human, economic—within a watershed. Human activities are managed so they cause the least disruption to our natural systems and native flora and fauna. The crucial factor in managing runoff and nonpoint sources is integrating land use, water/runoff,

VOL 12

6784

and infrastructure management. Watershed management includes numerous facets—planning, education, regulation, monitoring, and enforcement. These facets should be accomplished on a watershed basis and involve a diverse set of stakeholders in the process.

Selection of watershed size depends on many factors—watershed ecological systems, groundwater hydrologic influences, type and scope of resource management problems and goals, and level of available resources. The institutional framework also varies greatly, depending on the legal framework established by state laws and local ordinances.

Why Watershed Management?

Solving our nation's runoff problems, especially retrofitting existing drainage systems to reduce pollutant loads discharged to receiving waters, presents many complex challenges. Correcting these problems is expensive, technically difficult, and requires a long time period. Accordingly, we need to reevaluate our current approach to runoff management and shift the emphasis toward more comprehensive, prevention-oriented strategies such as watershed management.

The following comparison illustrates the differences between the traditional, piecemeal approach to runoff management and a comprehensive watershed approach (Camp, Dresser, McKee, 1985).

The Traditional Versus the Watershed Approach

The Piecemeal Approach

The traditional approach for existing urban development is to address local runoff problems without evaluating the potential for the control measure to adversely affect downstream areas (see Chapter 10). In new urban development, runoff management responsibilities are delegated to local land developers, with each responsible for constructing runoff management facilities on the development site. Their goal is to control runoff from the development site with little regard to how the discharges affect the system as a whole or the effects on the local government infrastructure. This is a piecemeal or individual site approach to runoff management.

While the usual approach to urban runoff management is relatively easy to administer it has several disadvantages. The risk of negative effects, particularly in watersheds that cover several jurisdictions, is greater. The failure to consider downstream impacts in selecting runoff management facilities causes ineffective runoff control throughout the watershed. This approach incurs relatively high local costs for facility maintenance. In addition, unnecessary costs are used for small-scale structural solutions rather than using large-scale nonstructural solutions, which are typically much cheaper.

Other negative effects of piecemeal runoff management are the following:

- It only partially solves major flooding problem(s).
- It solves flooding problems in the upstream jurisdiction, but may create flooding problems downstream.
- Randomly locating detention basins may actually increase downstream peak flows.
- Maintenance needs and costs associated with numerous on-site runoff controls are very high.
- Significant capital and operation/maintenance expenditures may be wasted.
- Remedial structural solutions cost more than implementing proper management programs in the first place.
- Other watershed management changes in the hydrolic regime or in stream temperature may not be considered.

The Watershed Approach

The watershed approach develops a comprehensive watershed plan—a runoff master plan—to identify the most appropriate control measures and the optimum locations to control watershed-wide activities. The watershed approach typically results in the following combinations:

- Reviewing watershed and its characteristics overall to assess problems and potential solutions.
- Using regional systems where appropriate.
- Providing runoff conveyance improvements where necessary.

VOL 12

6785

R0040093

- Developing nonstructural measures throughout the watershed, such as acquiring floodplains, wetlands, and natural runoff depressional storage areas, limiting the amount of imperviousness, requiring grassed swales rather than storm sewers, and directing roof runoff to pervious areas.

- Coordinating point and nonpoint source program implementation.

Watershed master planning offers significant advantages over the piecemeal approach. It reduces capital and operation/maintenance costs and the risk of downstream flooding and erosion, particularly in multijurisdictional watersheds. It offers better opportunities to manage existing runoff problems and to consider and use nonstructural controls. Other benefits include increased opportunities for recreational uses of runoff controls, potential contributions to local land use planning, enhanced opportunities for runoff reuse, and popularity among land developers.

The major disadvantages of the watershed-level runoff master plan include

- Local governments must conduct advanced studies to locate and develop preliminary designs for integrated management facilities without fully knowing local plans.

- Local governments must develop and adhere to a future land use plan and properly design an effective mix of local and regional controls to capture runoff from present and future development and impervious surfaces.

- Local governments must often finance, design, and construct the regional runoff management facilities before most development occurs and provide for reimbursement by developers over a build-out period that can be many years long.

- In some cases, local governments may need to conduct expensive maintenance activities for regional facilities that the public views as primarily recreational.

However, another advantage of watershed management is that resource management goals can be resource oriented. This approach stresses prevention practices and programs to protect natural systems and beneficial uses of our waterbodies. These practices and programs are typically more cost-effective than trying to restore natural systems after they have been adversely affected by human activities.

Watershed management allows coordination of infrastructure improvements with point and nonpoint source management programs and, most importantly, provides a vital link between land use and water resources management.

Watershed Management Framework

Until recently, watershed management has faced many deterrents. Initially, the goal of a runoff management program was drainage—preventing flooding by quickly conveying runoff away from buildings and other developed areas, typically to the nearest waterbody. Restricting the use of private property through growth management/land use planning programs and regulations—the most cost-effective management option—has not been effective until recently. Little thought was given to the potential impacts of a land use change on the local drainage system or on the community at large. The generally accepted tenet was that development was good for the community, helped increase the tax base, and stimulated the economy—i.e., "growth pays for itself."

Other major deterrents to establishing comprehensive, integrated watershed management programs have been prevailing attitudes that foster turf wars and a lack of cooperation between state and local governments and, more important, between cities and counties. Each political entity believes it is an island unto itself. Far too little attention has been paid to intergovernmental coordination and cooperation.

Implementing watershed management programs requires a long-term commitment of time, energy, and money. Elected officials, responding to the citizens' cries to be frugal with their tax dollars, are reluctant to spend money on the planning studies required to implement watershed management programs. In only a few locations have elected officials recognized the long-term benefits and cost savings that can accrue by implementing comprehensive land use plans and runoff master plans.

Establishing a Framework

No single approach or institutional framework is available to establish a watershed management

VOL 12 6786

program. Establishing an institutional and legal framework would be easy if we could start with a clean slate. However, each state, county, and city has an existing legal framework and most differ greatly. Some states have comprehensive laws, rules, and programs. Other states do not have an adequate statutory or regulatory framework to form a foundation for watershed management programs. Therefore, a key to opening the watershed management door is flexibility. In some cases, the focus will be on enacting new laws; in other cases, the focus is on revising existing laws or ordinances to better integrate and coordinate programs and objectives.

Another key to a watershed management framework is patience. Enacting or modifying state laws or local ordinances is not an easy process. A long-term game plan must be developed and pursued with diligence. Each component of a watershed management program has its own controversies, assuring that public debate on many issues will be vociferous. Therefore, priorities must be established. Typically, priority setting depends on state resource problems and needs, public sentiment, and whether an issue becomes "sexy," thereby receiving coverage by the news media. In many cases, a particular piece of legislation will take several years to pass or revise.

To succeed, educating elected officials, state agency managers, and the public is a priority. Public participation and support are essential to build consensus. Many issues addressed by watershed management programs are complex and not easily demonstrated. Managers of runoff and other nonpoint sources of pollution, unlike the managers of traditional point sources, cannot point to pipes that continuously discharge effluents. Therefore, promoting watershed management programs requires multimedia presentations, not only to educate but also to entertain. You must *sell* the need for watershed management.

Taking advantage of opportunities that arise is another key to success. Unfortunately, opportunities often occur after a natural disaster that results in lost property or lives. After hurricanes Frederick and Andrew struck South Carolina and South Florida respectively, considerable public debate arose. Issues included building codes, land uses, and development within sensitive and susceptible coastal areas; whether to allow rebuilding in these areas; and whether public programs such as the National Flood Insurance Program should subsidize development. These debates, especially on costs and benefits, can help build support for growth management and land acquisition programs. Furthermore, flooding—and in a few locales, water quality problems—can be used to break the "hydro-illogical cycle" and gain support for runoff management programs and local runoff utilities.

In building a watershed management framework, establishing clear goals for the overall program should include

- Providing opportunities for preventive nonstructural controls, in addition to structural controls, to mitigate the impacts of human activities.
- Establishing clearly defined, holistic natural resource management goals.
- Setting priorities for a long-term legislative agenda.
- Encouraging public participation so that all parties buy in and feel a part of the solution.
- Integrating all available tools and resources into a coordinated, cost-effective, cooperative approach (i.e., integrate point and nonpoint source programs).
- Finding dedicated funding sources outside the main funding stream (general revenues) so that the watershed management programs do not compete against law enforcement, education, and other high priority societal needs.

In developing, selling, establishing, and implementing a watershed management framework and associated programs, keep in mind the following "big Cs" of watershed management:

- *Comprehensive* management of people, land use, natural resources, water resources, and infrastructure throughout a watershed.
- *Continuity* of runoff/watershed management programs over a long time period to correct existing problems and prevent future ones.
- *Cooperation* between federal, state, and local governments; cities and counties; the public and private sectors; and among all citizens.
- *Communication* to educate ourselves and elected officials about how everyone is part of the problem and must be part of the solution.
- *Coordination* of runoff retrofitting to reduce pollutant loading and other natural sys-

tems restoration activities; includes complementary infrastructure improvements (e.g., road projects) or development/redevelopment projects to maximize benefits and cost-effectiveness.

- *Creativity* in best management practices, technology, funding sources, and approaches to solve these complex, costly problems.
- *Consistency* in implementing laws, rules, and programs nationally and statewide to assure equity and fairness.
- *Cash* in large amounts and over a long time period to correct existing problems and prevent future ones.
- *Commitment* to solve our current problems and prevent future ones to ensure that our children have a bright future—a willingness to put our money where our mouths are.

Program Components and Legislative Needs

Watershed management integrates management programs that address the many differing human activities within a watershed. The following brief discussion of components and programs that are part of watershed management is not all inclusive—other programs address specific state or regional needs. In developing or implementing programs, take advantage of information and technology transfer clearinghouses and communicate with people in other jurisdictions that have implemented similar programs.

Watershed management programs include common aspects, such as planning, holistic goals, scientific/technical support, and implementation—regulatory and nonregulatory approaches. Extensive public participation is also needed in all aspects of the program—planning, developing and adopting rules, permitting, and inspecting and enforcing. Programs must also address obtaining adequate funding and staffing; training staff and the public, especially the regulated community; assuring inspection and compliance; and assuring long-term operation and maintenance of structural controls. Finally, programs must be evaluated regularly to optimize their environmental effectiveness, cost-effectiveness, and service efficiency. This evaluation requires a commitment to monitoring programs that can actually ascertain if the program's goals are being met.

Typically, these programs are implemented after a state law is enacted and a state agency is set up to address a specific concern. A legislative mandate usually ensures that a program has adequate legal authority, staffing, and funding support. Programs have been established by a state agency using its general legislative powers to pass a rule—for example, programs for pubic education, pollution prevention, and monitoring and prioritizing target watersheds. Given the current scientific data on runoff pollutants, erosion and sediment control and even runoff treatment programs can be established using general water pollution control authorities. However, these programs are staff and resource intensive and, at a minimum, require legislative approval of budget requests.

Common watershed management programs include both planning and regulation. While the difference between comprehensive planning and permitting are important, both are needed to manage growth effectively and protect the quality of our environment and the lives of our citizens.

Comprehensive Planning. Planning allows a community to make decisions about how and where growth will occur in the future. Comprehensive planning asks several questions: Is this the right location? Is this the right time? Is this the right intensity for the proposed land use? Comprehensive planning seeks to prevent problems—social, economic, environmental—before development occurs.

Permitting. Permitting is site-specific and seeks only to mitigate the impacts of the land use decision. It asks: How can we do the best job with this development on this particular site? Any regulatory program has inherent limitations that comprehensive planning can help overcome. Principal among these limitations is that permitting is piecemeal and does not consider cumulative effects. Therefore, regulation and permitting cannot substitute for planning.

Watershed planning and management programs must include two equal components: the land planning framework and the water planning framework (Figure 15.1).

The Planning Framework

A watershed management framework can be divided into three categories:

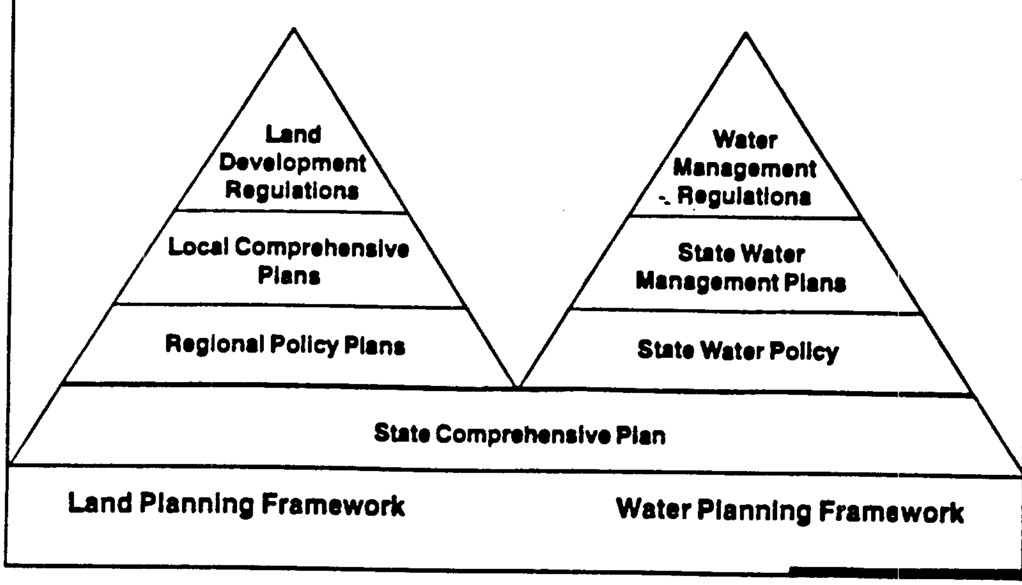
- Land planning and management.

VOL 12

5788

R0040096

Figure 15.1.—The land planning and water planning frameworks.



- Water planning and management
- General resources planning and management

Land Planning and Management Programs

Land planning and management programs are often called growth management programs. However, growth management, comprehensive planning, and land and environmental regulations are clearly distinct.

Growth management looks at broad issues and the interrelationship of systems—natural systems, infrastructure, land use, and people. It assesses our past success in providing for citizens' needs and determines the needs of new arrivals and how to meet them. Growth management encompasses comprehensive planning, natural resource management, public facilities planning, housing, recreation, economic development, and intergovernmental coordination.

Comprehensive planning is a governmental process to inventory resources, establish priorities and a vision of where the community wants to go, and determine how to get there. It is a systematic way of looking at the different components of a community, county, region, and state.

Regulations are the specific controls applied to different types of development activities to regulate and minimize their negative impacts. Typically, regulations are administered by all levels of government—federal, state, and local. Locally, land development regulations are the ordinances that implement the local comprehensive plan.

State Comprehensive Plan

A state comprehensive plan serves as the base of the land and water planning pyramids (Figure 15.1). A state comprehensive planning act establishes goals and policies for each of the plan's elements and requires the state land planning agency to prepare a general state comprehensive plan. Elements of a plan usually include water resources, natural systems, air quality, coastal and marine resources, land and wildlife resources, waste management, public facilities (infrastructure), transportation, mining, agriculture, education, and economic development. If the state's land planning framework includes regional planning councils or council of governments, those agencies would develop a regional plan.

Both the state and regional plans should be consistent with the goals and policies stated in the state comprehensive planning act. These goals and policies, set by the legislature, provide guidance to state, regional, and local governments in developing and implementing programs, rules, or-

VOL 12

6789

R0040097

ordinances. The planning pyramid should be consistent from its base to its apex. To ensure consistency and integrate agency implementation programs with the law's goals and policies, the law can require state agency functional plans. These plans form the basis for agency budget requests, which are related to the goals and policies of the comprehensive plan.

Growth Management and Land Development Regulation

The Local Government Comprehensive Planning Act (LGCPA), often referred to as the growth management act, establishes the key piece of the natural resources jigsaw puzzle. It provides the direct connection between land use management and water/natural systems management. Eight states—Oregon, Florida, New Jersey, Maine, Vermont, Rhode Island, Georgia, and Washington—have implemented state growth management programs (Gale, 1992). While these programs have elements in common, each state has different implementation requirements. Some states "require" while other states "recommend" local plans, consistency, or compliance. A LGCPA should address, at a minimum, the following questions common to the existing state growth management programs:

- What is the legislative authority and intent?
- Are local comprehensive plans required or voluntary? Do they require a schedule or planning period? Do they require specific or minimum elements?
- Are plan implementation, site planning, or land development regulations required?
- Must plan be consistent with state goals and policies? Are monitoring and enforcement required?
- Are state review and approval required? From which agencies or administrative process?
- Is compliance or monitoring required? Does the plan provide incentives, disincentives, or citizen enforcement?
- Does the plan limit the number and type of amendments, the frequency, or the amendment process?
- Does the plan provide for regular updates and implementation appraisals and their frequency?

Wetlands and Floodplain Protection

Wetlands and floodplains provide storage and treatment for watersheds. They provide a wide range of irreplaceable services at no cost, including maintenance and improvement of water quality; floodwater conveyance and storage; shoreline stabilization; water recharge and supply; sediment control; aquatic productivity; spawning and nursery grounds; habitat for shellfish, fish, waterfowl, endangered species, and other wildlife; and open space and recreation.

Unfortunately, the benefits provided by wetlands and floodplains are not fully appreciated. Instead, these areas are seen as unproductive, snake invested, mosquito havens with no socially accepted redeeming value. Consequently, only about 40 percent of our nation's original 215 million acres (87 million ha) of wetlands in the 48 contiguous states remain, largely the result of the conversion of wetlands and floodplains to agricultural lands.

Section 404 of the Federal Clean Water Act established a wetlands program to maintain, protect, and restore our nation's wetlands. However, nationwide general permits to conduct activities in wetlands are easy to obtain. In addition, agricultural and silvicultural activities are largely exempt. Another problem hindering the environmental effectiveness of this federal program is a lack of national consistency. Furthermore, other federal programs (e.g., section 205 of the 1948 Flood Control Act, National Flood Insurance Program) directly conflict with wetland and water quality protection efforts by promoting alteration and development of these sensitive lands.

A state wetlands protection act can be an important addition to a state's watershed management arsenal to fill the gaps in the federal program or expand the protection of wetlands and floodplains. A state wetlands protection program should *integrate with, not duplicate,* existing federal programs. Since the current federal wetlands permitting program is administered by the Army Corps of Engineers and U.S. EPA, the state water quality/environmental management agency typically implements the program at the state level. Frequently, the wetlands protection act is simply a new section within a state's existing environmental laws.

Components that should be addressed by a state wetlands/floodplain protection act include

- Establishing wetland protection/management goals and policies as the basis for wetland regulations and permitting criteria.

VOL 12

6790

R0040098

- Initiating goals and policies that foster cost-effective pollution prevention by stressing wetland avoidance rather than mitigation.

- Precisely defining a wetland. A wetland should be defined by three characteristics—the elevation and duration of flooding, the presence of certain wetland-specific plants, and hydric soil conditions. The law should clearly state that wetlands are "waters" similar to a river, lake, or estuary.

- Establishing a standard method to delineate wetlands. Wetlands represent the transitional edge between waters and uplands. Determining where a wetland and an upland begins is not easy—and is frequently controversial. Wetland scientists should be allowed to establish—through combinations of hydrologic, vegetation, and soil indicators—a process to "draw the wetland line."

- Requiring consistent statewide application of the definition and wetland jurisdictional delineation method by all government levels.

- Requiring or encouraging regional mitigation banks rather than on-site mitigation.

- Establishing a fair permitting process that assures public participation, equity, an appeals process, and decisions based on scientific and technical merit.

- Allowing, with strict pretreatment requirements, incorporation of certain wetlands into domestic wastewater and runoff management and reuse systems, provided the ecological characteristics of the wetland are protected, restored, or enhanced.

- Requiring the annual tracking of wetland losses and mitigation efforts, successes, and failures.

- Providing for state assumption of the federal section 404 wetlands program.

State and Local Land Preservation and Acquisition

Regulating and restricting the use of private property is controversial. However, the U.S. Supreme Court has ruled several times that state and local governments have that legal authority. In fact, the government is responsible for ensuring the health, safety, and welfare of the public. Restricting what can and cannot be done on a piece of property helps maintain property values and prevent contamination of air, land, water, and human resources. However, care must be exercised to avoid the taking of property. Land acquisition programs help ensure that this goal is met and that extremely crucial or sensitive lands within a watershed are preserved.

The federal government has set up several types of land acquisition programs to preserve sensitive lands, protect vital wildlife habitats, and establish recreational lands, such as national parks and wildlife refuges. However, federal budget problems and intense competition makes obtaining limited federal land acquisition funds difficult, especially for properties without national—or at least regional—significance. Additionally, federal programs generally require matching funds from state and/or local governments. Therefore, establishing state and local land acquisition programs can greatly increase the ability to purchase and protect sensitive lands and, equally importantly, capture limited federal funds.

State or local land acquisition programs require extensive citizen participation and support. They require asking individuals to tax themselves to raise money to purchase lands, preserve them, and provide recreational opportunities. Catchy phrases and acronyms are helpful to "sell" the program. Citizens must be convinced that they and their children will benefit and that funds will be spent wisely and cost-effectively. Land acquisition programs must avoid conflicts of interest and be administered with integrity and openness.

A state and local land preservation and acquisition act should contain the following components and considerations:

- Clearly defined program goals and policies. Such policies form a foundation to determine the types of properties to be purchased and how to establish purchasing priorities. The program's goals and policies should advocate preserving and restoring lands that contribute nonstructural environmental benefits. Additional resource management factors to consider in purchasing lands includes open space, recreational, and wildlife benefits.

- Integrated and coordinated federal, state, local, and private land preservation and acquisition programs. This component maximizes the ability to leverage funds from various sources. Establishing interconnected wildlife corridors and greenways should be a priority goal.

- Extensive participation by citizens, private conservation groups, and state and local governments to establish program regulations, administrative procedures, and—most important—land buying priorities.

- Long-term ownership and active land management once the property is purchased. The act should specify which agency will be in charge—an environmental agency, a parks and recreation agency, a fisheries or wildlife agency, or a private organization (e.g., Trust for Public Land). The act should determine if a land management plan must be developed and how land management will be funded.

- Dedicated funding sources. Purchasing and managing sizable amounts of land, especially with public access and use, requires large sums of money over a long time period. To obtain sufficient funds, a state or local government might choose to sell bonds, which allow it to raise large amounts at one time and pay bonds off like a mortgage. However, this decision requires a stable and predictable funding source over the life of the bond. Fees on real estate transactions, such as documentary stamps, and local option sales taxes have been used extensively.

Water Resources Planning and Management Programs

The United States is generally blessed with an abundance of clean water resources. Water is available whenever we want it, in whatever quantity we desire, and at a very low cost. Consequently, we have placed less attention and emphasis on water resources planning and management, especially from a holistic approach. In the past, water planning and management programs were implemented to address a crisis. However, our population's continuing growth exerts ever expanding demands on our vulnerable and limited water resources. Additionally, to manage unconventional pollution sources, such as runoff and other nonpoint sources, we need to reevaluate the way we manage water. Accordingly, water resource planning and management programs are receiving increased attention and evaluation.

Watershed management programs include water quantity and quality programs to protect and manage surface and groundwaters and general environmental protection programs. These programs usually contain pollution prevention and treatment aspects.

Environmental Protection

Most states have enacted some type of state environmental protection act to control traditional point source pollution. These laws, generally patterned after the federal Clean Water Act, are frequently revised as a new state environmental crisis or concern arises or as Congress amends the Clean Water Act. The Clean Water Act shows how, over a long period, laws can be revised to establish or refine existing or new environmental requirements or programs.

While state environmental protection laws include many similar requirements and mandates, they vary considerably because states approach the same problem differently. For example, some states enact separate erosion and sediment control and runoff management acts; other states combine these important watershed management components. In some states, the law governing the siting and use of on-site wastewater disposal systems is found within a state's general health code law; in other states, the law is within the environmental law. These watershed management components are discussed separately, even though their legislative authority is often integrated into a state's environmental laws.

State environmental protection laws generally contain components and considerations that establish

- The state environmental agency, its legal authority, and its powers and responsibilities.

- An environmental regulation commission generally composed of citizens appointed by a political body (e.g., the governor) that holds public workshops and adopts environmental regulations and standards.

- Permit evaluation criteria, permit fees, and administrative procedures, which include a legal administrative hearing process to appeal permitting decisions.

- Programs—with adequate legal authority, direction, and resources (i.e., staffing and funding)—to address general environmental protection and management of air, land, and water resources such as surface and groundwater.

VOL 12

6792

- Programs—with adequate legal authority, direction, and resources—to minimize the impacts of specific pollution sources such as wastewater and industrial discharges, solid wastes, hazardous wastes, and toxic wastes.

- Pollution prevention programs such as "amnesty days" that allow citizens to safely dispose of hazardous or toxic household wastes, used-oil recycling centers, waste reduction and assistance programs for industry, adopt-a-road (stream, lake, bay, shoreline), recycling, and farmstead assistance (Farm*A*Syst).

- Programs to restore environmentally damaged lands and waters, especially critical areas such as wetlands, floodplains, steep slopes, and eroding lands.

- Programs to monitor the environmental health and assess the effectiveness of watershed management programs. Monitoring programs should include sampling the water column, sediment, and biological community. Programs must provide information concerning long-term trends in environmental health and the health of selected waterbodies or natural systems.

Water Resources Planning and Management

Many states have enacted a water resources act distinct and separate from the state environmental protection act. States are recognizing that planning and managing water resources are essential to the continued survival of life on the planet and that water is a major determinant of economic development and quality of life. Water resources planning and management must consider both water quantity (i.e., supply, allocation, flooding) and quality. An effective state water resources act must be fully integrated with the state environmental protection act. State environmental protection and state/regional water resources programs must be coordinated, consistent, and complementary.

A state water resources act creates the framework for water resources planning and management programs by state, regional, and local governments (see Figure 15.1). Using goals and policies of the state comprehensive planning act, the environmental regulation commission adopts a regulation, or state water policy. This regulation contains general policy statements addressing a myriad of water resource topics, such as water supply and conservation, surface water preservation and management, and natural systems preservation and management. It guides the implementation of all water resource programs and regulations, whether by a state, regional, or local entity. The act could establish regional watershed management districts, set up by watershed boundaries. The districts conduct regional watershed planning, coordinate water management efforts undertaken by local agencies to ensure that watershed goals are cooperatively met, and operate regulatory and research programs.

A state water resources act should include

- Establishing watershed management districts to administer special regional (watershed) water planning and management programs and providing statutory authorities and responsibilities to give them broad powers to protect, manage, and restore surface and groundwater resources.

- Setting the institutional relationships between the state environmental agency, regional water management districts, and local governments. Strong oversight of programs, especially regulatory ones, implemented downwards is essential for program consistency.

- Developing a state water policy (SWP) to guide all state water programs and regulations and adopt them as part of the state's environmental regulation code.

- Basing the SWP on the goals and policies of the state planning act and ensuring that state, regional, and local water regulations and programs are consistent. Goals and policies of the local comprehensive plan should also be consistent with SWP.

- Providing the districts with dedicated sources of revenue to ensure long-term, adequate funding of all necessary water resource management programs. Sources used include ad valorem assessments (property taxes), fees on water use, permitting fees, and special assessments.

Supplemental Surface Water and Environmental Protection Programs

Several watershed management components can be included in the state environmental protection or water resources act or established in a separate statute.

VOL 12

6793

Erosion and Sediment Control Act/Program. Land disturbing activities are among the largest source of sediments and particle-borne pollutants. Preventing erosion and minimizing and capturing sediments, especially from construction sites, is an essential part of any watershed management framework (see Chapter 7). Since 1972, over 20 states have enacted erosion and sediment control laws and programs.

An erosion prevention and sediment control law or program should include the following components and considerations:

- A clearly defined legal authority, goals/performance standards, and responsibilities of the state, regional, or local agencies.
- Measures to ensure that publicly funded projects, especially highways, comply with all program requirements and use of these projects as models.
- A clear statement on whether utility construction, agricultural, and forestry projects are included in the program.
- Agency responsibilities and relationships. Typically, implementing an erosion and sediment control program involves a state agency and a regional/local agency, such as a soil and water conservation district or a local government. The state must oversee programs delegated to a local agency to ensure consistency.
- Adequate staffing and other resources to conduct research on effective control measures, developing scientifically sound rules, and conducting training and education programs for plan reviewers, inspectors, developers, engineers, and site contractors.
- A state training and certification program for plan reviewers, inspectors, and contractors is highly recommended since public agencies will not likely obtain sufficient staffing to conduct regular inspections of construction sites.
- Mutual integration of the state erosion and sediment program and runoff management program and the new federal NPDES stormwater permitting program.

Runoff Management Act/Program. Most states have implemented some type of runoff drainage program to protect citizens and properties from flooding. Some states have established special drainage districts or drain commissions regionally or locally. However, today we know that runoff is a major source of pollutant loadings to our nation's wetlands, rivers, lakes, and estuaries. Runoff management is evolving slowly from its drainage focus to a much more comprehensive, multiple objective program that addresses runoff quality and quantity. Runoff programs must prevent or minimize problems associated with new land use activities and also develop programs to reduce the pollutant loading discharged from older drainage systems. This latter objective is extremely difficult and expensive to address—therefore, watershed management is essential. Typically, a state runoff management program first addresses the problems associated with new land uses. It then evolves into a more comprehensive, watershed-based program and addresses retrofitting older runoff systems.

Components and considerations that should be addressed by a state runoff management act/program include

- A clearly defined legal authority, goals/performance standards, and responsibilities of the state, regional, and local agencies.
- Measures to ensure that publicly funded projects, especially highways, comply with all program requirements and use of these projects as models.
- Agency responsibilities and relationships. Typically, implementing a runoff management program involves a state agency and a regional/local agency such as a watershed management district, a soil and water conservation district or a local government. The state must oversee programs delegated to a local agency to ensure close consistency.
- State water policy should be used to set the program's general goals, minimum treatment performance standards upon which BMP design criteria will be based, and a biological or resource-based performance standard for reducing the pollutant loading from existing drainage systems.
- Adequate staffing for planning, coordinating, and permitting; enforcement and resources for research on effective control measures to develop scientifically sound rules; and adequate staffing to conduct training and education programs for plan reviewers, inspectors, developers, engineers, and site contractors.

VOL 12 6794

R0040102

- A state training and certification program for plan reviewers, inspectors, and contractors is highly recommended since public agencies will not likely obtain sufficient staffing to conduct regular inspections of runoff systems during or after construction. These programs can be integrated with the similar erosion and sediment control programs.

- Integrating the state runoff management program with the erosion and sediment control program and the new federal NPDES permitting program.

- Establishing a mechanism, such as runoff operating permits, to ensure at least annual runoff management system inspections. Inspections determine maintenance needs and ensure that systems are maintained and operated properly. This system could be operated by a local runoff utility and provide the owner of a properly maintained and operated system a utility fee credit as an economic incentive.

- Providing statutory authority to establish dedicated state and local funding sources for runoff management programs. State sources could include small fees on concrete, asphalt, fertilizer, or pesticides. Communities nationwide use runoff utilities with great success.

Watershed Prioritization and Targeting Act/Program. The growing number of water resource problems and the financial constraints faced by all levels of government strongly suggest a need to establish watershed prioritization and targeting programs. Many states have set up such programs, often as part of their runoff/nonpoint source management programs.

Considerations and components of a state watershed prioritization and targeting act/program include

- Clearly identifying which state, regional, and local agencies are involved in establishing priority watersheds. Public participation is essential to ensure citizen cooperation and buy in around the state and within the targeted watershed. Cooperation and joint ventures with private land conservation groups should be encouraged.

- Providing guidance on factors to consider in the prioritization process. These factors may include requiring that waterbodies be state or regionally significant or at a certain degradation level; a specific level of local government and citizen support, especially from land owners who need to install management practices; and the availability of local matching funds. Pristine waterbodies may also be given priority.

- Providing a legal mechanism for the appropriate state, regional, or local agency to adopt the priority list; ensuring that the list is reviewed regularly and updated or refined as needed.

- Providing a dedicated source of state, regional, or local funds to develop and implement a watershed management plan within a realistic time schedule.

On-Site Wastewater Management Act/Program. The nation's rapid population growth and accompanying migration to the suburbs and beyond has led to a tremendous proliferation in on-site wastewater disposal systems (OSDS). Often considered an inexpensive alternative to centralized wastewater collection and treatment systems, OSDS can cause or contribute to health and environmental resource problems that are difficult and expensive to solve. Like many areas of nonpoint source management, OSDS programs should stress prevention and correct problems caused by past use and misuse. Traditionally, state, county, and local health departments, rather than environmental or water resources agencies, have administered OSDS programs. However, OSDS are increasingly considered major contributors to impairment of aquatic systems.

A state on-site wastewater management act/program should include the following components and considerations:

- Clearly defined legal authority, goals and performance standards, and responsibilities of the state, regional, or local entities charged with implementing the program.

- Goals and performance standards that address traditional health concerns and consider the potential environmental effects of OSDS.

- Provisions to adopt regulations that govern the types of OSDS systems (i.e., drainfields, mound systems, aerobic units); the siting of systems (i.e., water table elevation, soil types, setbacks from wetlands/waters);

the design and performance of OSDS (i.e., secondary treatment or nitrates less than 10 mg/L); whether surface discharges will be allowed and under what conditions; inspections during construction and throughout the use of the system; and maintenance.

- Regular inspection (every two to three years) and maintenance (e.g., pump out, drainfield) to help ensure that OSDS continue to function properly. One mechanism is to establish OSDS management districts with defined service areas, funding sources, and legal authorities.

- Another method to assure that OSDS continue to function properly is to require inspections, upgrading, and maintenance of systems when a property is sold.

General Resources Planning and Management

One complication in implementing watershed management frameworks and programs is their complex, interwoven nature. Many aspects of watershed management transcend the simple classification scheme outlined in Figure 15.1. These include the need for broad-based natural resource management programs and environmental education programs. Many states have established separate agencies responsible for management of land, fish and wildlife, agriculture, mining, and for providing parks and recreation. Often a state forestry department is responsible for acquiring and managing state forest lands. These activities and programs typically are essential to watershed management. Close coordination and cooperation between these agencies and the other primary natural resources management agencies ensure that programs do not conflict and maximize the benefits and cost-effectiveness of all programs.

Additionally, while nearly every natural resource management agency has some type of environmental education program, these programs are often narrowly focused. The growing importance of nontraditional pollution sources such as runoff and nonpoint sources requires developing and implementing a broad-based environmental curriculum that begins teaching children in kindergarten and continues all the way through senior high school. Each individual must understand the basic interrelationships of air, land, and water and how everyday activities degrade our natural systems. The best way to establish the ethic of stewardship is by educating our youth.

State Watershed Management Initiatives

Several states have developed and implemented some or many of the watershed management components previously discussed. In recent years, states have begun integrating ongoing programs into a comprehensive watershed management framework. Chapter 16 provides case histories from the states of Florida, Delaware, and New Jersey. The Puget Sound Management Program in Washington State and the Priority Watershed Program in Wisconsin are also good examples of watershed management initiatives.

North Carolina's ongoing efforts demonstrate one way that existing programs, especially planning and regulatory, can evolve into an integrated watershed approach. The North Carolina Division of Environmental Management (NCDEM) has developed a plan in which basins—not stream reaches—are the basic unit of water quality management. According to the U.S. Environmental Protection Agency (1991), the objectives of North Carolina's Basinwide Water Quality Management Initiative include

- Identifying priority problem areas and pollution sources that merit particular pollutant control, using modifications of rules (e.g., basin criteria) and increased enforcement.

- Determining the optimum water quality management strategy and distribution of assimilative capacity for each of the 17 major river basins within the state.

- Preparing, in cooperation with local governments and citizens, comprehensive basinwide management plans that set forth the rationale, approaches, and long-term management goals and strategies for each basin.

- Implementing innovative management approaches that protect the state's surface water quality, encourage the equitable distribution of assimilative capacity, and allow for sound economic planning and growth.

The whole-basin initiative is a fully integrated approach to water quality assessment and management. It integrates planning, monitoring, modeling, point source permitting and control, nonpoint source control, and enforcement within

VOL 12

6796

R0040104

a basin. NCDEM has rescheduled its NPDES permit activities to occur simultaneously with permit renewals, which are repeated at five-year intervals within a given basin.

Difficulties in implementing a basinwide approach include setting priorities, establishing a rotating schedule among the basins, and correlating management needs (e.g., monitoring, planning, permitting, and enforcement) with staff and resource allocations. North Carolina prioritized and scheduled its 17 basins by considering the nature and extent of known problems, the basin's important human use, data availability, and balancing staff workload.

North Carolina will perform a 15-step process for each basin as follows:

1. Compile all existing relevant information on basin characteristics and water quality.
2. Define the water quality goals and objectives for waterbodies within the basin; revise as more data are obtained.
3. Identify the critical issues (e.g., water supply protection, shellfish harvesting) and current water quality problems within the basin; determine the major factors and sources (i.e., point, nonpoint, habitat degradation) that contribute to the problems.
4. Prioritize the basin's water quality concerns and critical issues; ensure public participation and input from other government agencies and nongovernment groups.
5. Define the subbasin management units using basin hydrology, physiographic boundaries, problem areas, and critical issues.
6. Identify the need for additional information.
7. Collect additional information.
8. Analyze, integrate, and interpret the information collected; revisit steps 2 through 5 in light of new information.
9. Determine and evaluate the management options for each management unit in the basin.
10. Select final management approaches for the basin and targeted subbasins.
11. Complete the draft Whole-Basin Management Plan; perform additional modeling and other analyses to finalize wasteload allocations.
12. Distribute the draft plan for review and comment and conduct public hearings.
13. Revise the plan as appropriate in response to comments; facilitate adoption by the Environmental Management Commission.
14. Implement the management approaches, including point and nonpoint source controls.
15. Monitor the program's success, and update the plan every five years.

VOL 12

CHAPTER 16

Runoff/Watershed Management Case Histories

This chapter presents several case histories that include important components of watershed management programs.

Florida's Watershed Management Program

Florida is blessed with a multitude of natural systems—longleaf pine-wiregrass hills of the panhandle, sinkhole and sand ridge lakes of the central ridge, the Everglades "River of Grass," and the coral reefs of the keys. Abundant surface water resources include over 20 major rivers and estuaries and nearly 8,000 lakes. Plentiful groundwater aquifers provide over 90 percent of the state's residents with drinking water. This, along with the state's favorable climate, explains why many consider the Sunshine State a favored vacation destination and why Florida has experienced phenomenal growth since the 1970s. Today, Florida is the fourth most populous state and still growing rapidly, although not at the rate of 900 people per day (300,000 per year) that occurred throughout the 1970s and 1980s.

However, Florida's natural systems—especially its surface and groundwater resources—are extremely vulnerable and easily damaged. This is partially the result of the state's sandy porous soils, karst geology, and abundant rainfall. Florida experienced the negative impacts of unplanned growth as early as the 1930s. The southeast coastal water supply was threatened by saltwater intruding into the fragile freshwater aquifer that supplied most of the potable water for a rapidly expanding population. By the 1970s, unplanned land use, development, and water use decisions were clearly altering the state. If left unchecked, this development could have led to profound, irretrievable loss of the very natural beauty that brought residents and tourists to Florida. Extensive destruction of wetlands, bulldozing of beach and dune systems, continued saltwater intrusion into freshwater aquifers, and extensive pollution of the state's rivers, lakes, and estuaries were only some of the negative impacts of this rapid growth.

Fortunately, Florida's citizens and elected officials educated themselves and began developing programs to protect and manage the state's natural resources. Florida's serious and comprehensive efforts to manage its land, water resources, and growth coincided with the increasing strength of the national environmental movement of the early 1970s. Florida's natural resources management programs, consisting of 25 individual laws and programs enacted over a 20-year period, make up Florida's watershed management program. In many cases, these laws have been integrated into existing laws or adopted as regulations by various state, regional, or local agencies.

The evolution of Florida's watershed management program has followed a typical sequence. Concern about a specific pollutant or problem creates a resource/environmental management program that usually begins by focusing on new sources (site basis). Over time, as new sources are controlled and the program administration and effectiveness increase, the focus shifts to cleaning up older sources (watershed or regional basis). The focus then shifts to integrating the program with similar ones to eliminate any duplication and improve efficiency and effectiveness. Figure 16.1 provides an overview of the interrelationships among the various programs and regulations outlined in the next section.

Following is a chronology of how Florida statutes and programs, the cornerstones of its overall watershed management efforts, were established and revised.

Evolution of Florida's Watershed Management Program

1970

- Chapter 370, Florida Statutes (F.S.). Created the Coastal Coordinating Council, the first state effort at integrating state and regional programs in protecting and using coastal resources. Initial efforts from 1970 to 1975 focused on a comprehensive resource-based coastal protection program.

1972

- Package of land and water planning, regulation, and acquisition programs.

  - Chapter 380, F.S. Created the Developments of Regional Impact (DRI) and Areas of Critical State Concern (ACSC) land planning and management programs.
  - Chapter 373, F.S. The Florida Water Resources Act established five regional water management districts (WMD); designated the Department of Pollution Control as the oversight agency for the WMDs; required the development of a state water plan; and allowed for the regulation of the water resource. WMDs, financed by ad valorem property taxing authority of up to 1 mil ($1/$1,000 value), set in the Florida constitution. The Northwest Florida WMD millage capped at .05 mil.
  - Chapter 259, F.S. The Land Conservation Act established a program, commonly known as the Environmentally Endangered Lands Program, which authorizes the state to purchase critical and sensitive lands. It was envisioned as a 10-year program, investing $200 million, and funded by the sale of state bonds.

1973

■ Chapter 403, F.S. The Florida Environmental Protection Act renamed the Department of Pollution Control as the Department of Environmental Regulation (DER) and broadened its powers, duties, and programs. This law, the state's general environmental protection act, is amended almost annually as new environmental concerns and needs arise and existing programs evolve.

1975

■ Chapter 163, F.S. The Local Government Comprehensive Planning Act (LGCPA), the state's first growth management legislation, was recommended by the first Environmental Land Management Study Committee (ELMS I). The law required all cities and counties to prepare a comprehensive plan and submit it to the state's land planning agency, the Department of Community Affairs, for review. This agency sends the plans to other state agencies for review and comment. However, the LGCPA contains no teeth—local governments are under no statutory requirement to revise their plans by incorporating comments and recommendations made by reviewing agencies. Furthermore, localities are not required to pass land development regulations to implement their plans.

1976

■ Implementation by EPA of section 208 of the 1972 Clean Water Act required development of areawide water quality management plans. This was the first national program to assess and control nonpoint sources of pollution. In Florida, millions of federal grant dollars allow the DER and 12 designated area agencies to undertake extensive research on nonpoint source impacts, sources, controls, control effectiveness, and costs This data provided the scientific basis to develop and implement a statewide rule in 1982 that requires runoff treatment for new development and redevelopment projects.

1978

■ Chapter 380, F.S. This added Part II to the Florida Coastal Management Act, which required establishing a program based on existing statutes and rules to receive federal approval under the federal Coastal Zone Management Act of 1972. After approval of the program, NOAA-Office of Coastal Zone Management federal grants funded many initiatives to better protect and manage coastal resources. One established an estuarine watershed management program that emphasized sediment mapping. This led to the development of innovative, reliable coastal sediment sampling, analytical, and assessment techniques.

1979

■ First components of the state's areawide water quality management plan, the agriculture nonpoint source plan, and the silviculture nonpoint source plan were submitted to and approved by U.S. EPA. These called for a nonregulatory approach, with a regulatory backstop, if best management practices required by farm conservation plans were not implemented or if the forestry BMPs required by the state's adopted silviculture BMP manual were not followed.

■ Chapter 17-4.248, Florida Administrative Code (FAC). The state's first stormwater rule, adopted by the state Environmental Regulation Commission (ERC) as a rule of the DER, was a temporary regulation until ongoing research on BMP design and effectiveness was completed. The rule's adoption was controversial, but data collected during section 208 program studies conclusively showed that runoff, especially from urban land uses and highways, is a pollutant and therefore should be controlled. Florida's continuing rapid growth made treatment of runoff imperative, with BMPs required for new runoff discharges that would be "a significant source of pollution."

■ Chapter 253, F.S. This was amended to establish the Conservation and Recreation Land (CARL) Trust Fund, which provided additional funding to purchase environmentally endangered lands and other lands deemed appropriate and in the public interest by the governor and cabinet.

1981

■ Through action taken by the governor and cabinet, the Save Our Coasts land acquisition program was established. The program proposed spending $200 million over 10 years to purchase coastal lands such as beaches, shorelines, and sensitive areas. Funding was provided by the sale of state bonds backed by documentary stamps as authorized in Chapter 375, F.S., which sets policy on how the Land Acquisition Trust Fund was to be administered.

■ Chapter 373, F.S. This was amended with the creation of the Save Our Rivers land acquisition program. Administered by the WMDs, this program proposed spending $320 million over 10 years to purchase wetlands, floodplains, and other lands necessary for water management, water supply, and the conservation and protection of water resources.

1982

■ Chapter 17-25, FAC. This policy was adopted by the ERC after two years of rule adoption workshops and 29 official rule drafts. The rule was technology rather than water-quality based, although the state's water quality standards remain as a backstop, should a runoff discharge cause violations. A performance standard of 80 percent average annual load reduction is recommended based on BMP effectiveness and cost data and to establish equity with the minimum treatment levels for point source discharges. The rule created design criteria for various types of BMPs, including retention, detention with filtration, and wet detention. The rule also created general permits for certain types of BMPs (e.g., retention, detention with filtration) built to the design criteria. The South Florida WMD implemented the rule allowing runoff treatment requirements to be merged with runoff quantity (flood control) requirements in one permit.

1984

■ Chapter 403, F.S. Revised to create section IX, known as the Henderson Wetlands Protection Act. This legislation expanded the authority of the DER to protect wetlands; established administrative procedures to allow landowners to obtain legally binding "wetland lines"; allowed DER to consider fish and wildlife habitat, endangered species, historic and archaeological resource, and other relevant concerns in wetland permitting; allowed certain wetlands to be incorporated into domestic wastewater and runoff management systems; transferred wetland regulation for agriculture and forestry activities to the WMDs; and required the WMDs to protect isolated wetlands and consider fish and wildlife habitat requirements.

■ The Southwest Florida WMD receives delegation of the stormwater quality permitting program from DER, thereby integrating these permits into the district's existing stormwater quality permitting program.

■ In the late 1970s and early 1980s, an extensive appraisal of Florida's growth management system concluded that the existing system was not working. Shaped by the Final Report of the Governor's Task Force on Resource Management (1980) and the second Environmental Land Management Study Committee (ELMS II), a totally new blueprint for managing growth emerged. The ELMS II Committee recommended a package of integrated state, regional, and local comprehensive planning; reforms to the Developments of Regional Impact law; and coastal protection improvements. The legislature responded by enacting several laws between 1984 and 1986.

■ Chapter 186, F.S. The State and Regional Planning Act mandated the governor's office to prepare and present a state comprehensive plan to the 1985 legislature. It also required the state's 11 regional planning councils to prepare regional plans and provided $500,000 for plan preparation.

1985

■ Chapter 187, F.S. The State Comprehensive Plan was envisioned to be a leadership document —the foundation of the entire planning process— with strong, measurable, strategic goals that would set the course for Florida's growth over the next 10 years. Each state agency was to prepare a functional plan, based on the state plan, upon which its budget appropriations would be made. Unfortunately, one of the most important elements of the state plan, the development and adoption of a capital plan and budget, was never prepared. However, the plan contained important goals and policies in 25 different areas, including water resources, coastal and marine resources, natural systems and recreation, air quality, waste management, land use, mining, agriculture, public facilities, and transportation.

Important and relevant goals included

- Ensuring the availability of adequate water supply;
- Maintaining functions of natural systems, and
- Maintaining/enhancing present surface and groundwater quality.

Important and relevant policies included

- Eliminating the discharge of inadequately treated wastewater and runoff;

- Protecting natural systems in lieu of structural alternatives and restoring modified systems;
- Promoting water conservation and the use and reuse of treated wastewater and runoff; and
- Establishing minimum flows and levels for surface waters to assure protection of natural systems.

1985-1986

■ Chapter 163, F.S. Amended with enactment of the Local Government Comprehensive Planning and Land Development Regulation Act of 1985. This law required all local governments to prepare local comprehensive plans and implement regulations consistent with the goals and policies of the state and regional plans. Numerous state and regional agencies were to review the local plans and submit their objections, recommendations, and comments to the Department of Community Affairs for transmittal to the local government. The amendment required that the local plans be revised to incorporate the objections, recommendations, and comments. Furthermore, local governments faced state sanctions that could result in the loss of state funding if adopted local plans were not consistent with the state and regional plans.

Florida's revised growth management system is built around three key requirements: consistency, concurrency, and compactness. The consistency requirement establishes the integrated policy framework, whereby the goals and policies of the state plan frame a system of vertical consistency. State agency functional plans and regional planning council plans must be consistent with the goals and policies of the state plan, while local plans must be consistent with the goals and policies of the state and appropriate regional plan. Local land development regulations (LDRs) must also be consistent with the local plans, goals, and policies. Horizontal consistency at the local level ensures that the plans of neighboring local governments are compatible. Consistency is the strong cord that holds the growth management system together.

Concurrency is the most powerful policy requirement built into the growth management system. It requires state and local governments to abandon their long-standing policy of deficit financing growth by implementing a pay-as-you-grow system. Once local plans and LDRs are adopted, a local government may approve a development only if the public facilities and services (i.e., infrastructure) needed to accommodate the proposed development can be in place concurrently with development impacts. Public facilities and services subject to the concurrency requirements are roads, runoff management, solid waste, potable water, wastewater, parks and recreation, and if applicable, mass transit. Level of service standards acceptable to the community must be established for each type of public facility.

Compact urban development goals and policies are built into the state comprehensive and regional plans. These policies include separating rural and urban land uses, discouraging urban sprawl, encouraging urban in-fill development, making maximum use of existing infrastructure, and encouraging compact urban development.

1986

■ Chapter 403.0893, F.S. This provision, the only surviving section of a runoff management bill developed over a 10-month process, attempted to put into statute a cost-effective, timely process to retrofit existing drainage systems to reduce the pollutant loadings discharged to waterbodies. Only the section creating explicit legislative authority for local governments to establish runoff utilities or special runoff management benefit areas was enacted.

■ The St. Johns River WMD adopted Chapter 40C-42, FAC, and the Suwannee River WMD adopted Chapter 40B-4, FAC. Adopting these regulations and adding staff to implement these programs allowed DER to delegate administration of its runoff treatment rule to these WMDs.

1987

■ Chapter 373, F.S. This new section, the Surface Water Improvement and Management (SWIM) Act, established six state priority waterbodies. It directed the WMDs, under DER supervision, to prepare a priority waterbody list and develop and adopt comprehensive watershed management plans to preserve or restore the waterbodies. While it provided $15 million from general revenue sources and required a match from the WMDs, it did not establish a dedicated funding source, making the program dependent upon uncertain annual legislative appropriations.

1988

■ Chapter 17-43, FAC. Under this provision, the ERC adopted the SWIM rule. The provision sets forth factors to consider in selecting priority waterbodies, specifying the format for SWIM

VOL 12

6802

R0040110

plans to assure some consistency, and establishing administrative processes to develop and adopt SWIM plans by the WMDs and submitting them to DER for review and approval.

■ The State Nonpoint Source Assessment and Management Plan, prepared under section 319 of the Clean Water Act, was submitted to EPA and approved. This qualified the state for section 319 nonpoint source implementation grants for BMP demonstration projects and to refine existing nonpoint source management programs. This plan delineates the state's ecoregions based on river systems, selects ecoregion reference sites, and modifies EPA's Rapid Bioassessment Protocols and metrics for use in Florida.

1989

■ Chapters 373 and 403, F.S. These provisions, revised as part of the 1989 stormwater legislation, accomplished the following:

- Clarified the stormwater program's multiple goals and objectives;
- Set forth the institutional framework that involves a partnership among DER, the WMDs, and local governments;
- Defined the responsibilities of each entity;
- Addressed the need to treat agricultural runoff by amending Chapter 187, F.S., to add a policy in the agriculture element to "eliminate the discharge of inadequately treated agricultural wastewater and stormwater";
- Further promoted the watershed approach being used by the SWIM program;
- Unsuccessfully attempted to integrate the runoff program, SWIM program, and local comprehensive planning program;
- Established State Water Policy, an existing but little used DER rule, as the primary implementation guidance document for stormwater and all water resources management programs; and
- Created the State Stormwater Demonstration Grant Fund and provided $2 million as an incentive to local governments to implement runoff utilities.

1990

■ Chapter 17-40, FAC. State Water Policy underwent a total revision and reorganization to be used as a guide by all entities implementing water resource management programs and regulations. Section 17-40.420 included the goals, policies, and institutional framework for the state's runoff management program.

■ DER was designated as the lead agency with responsibility for setting program goals, providing overall program guidance, overseeing implementation of the program by the WMDs, and coordinating with EPA, especially the new NPDES runoff permitting program.

■ WMDs were named the chief administrators of the runoff regulatory program (i.e., quantity and quality). They prepare SWIM watershed management plans, which include establishing runoff pollutant load reduction goals, and provide technical assistance to local governments, especially in basin planning and developing runoff master plans.

■ Local governments were designated the front lines in the watershed management program since they determine land use and provide runoff facilities and other infrastructure. Under the policy, they are encouraged, but not required, to set up runoff utilities to provide a dedicated funding source for their programs. Their runoff responsibilities include preparing a runoff master plan to address needs imposed by existing land uses and needs created by future growth; operation and maintenance activities; capital improvements of infrastructure; and public education. They are encouraged to set up an operating permit system to annually inspect runoff systems to ensure that needed maintenance is performed.

Important goals included

- Preventing stormwater problems from new land use changes and restoring degraded waterbodies by reducing the pollution contributions from older runoff systems.
- Retaining sediment on-site during construction.
- Trying to assure that the runoff peak discharge rate, volume, and pollutant loading are no greater after a site is developed than before.

Important minimum treatment performance standards included

- 80 percent average annual load reduction for new runoff discharges to most waterbodies.
- 95 percent average annual load reduction for new stormwater discharges to "outstanding Florida waters," a special class of exceptionally high quality waterbodies.
- Reducing, on a watershed basis, the pollutant loading from older runoff systems to protect, maintain, or restore the beneficial uses of the receiving waterbody, according to the pollutant load reduction goal.

■ Chapter 375, F.S. This section was amended with the creation of Preservation 2000, a 10-year land acquisition program with a goal of spending $300 million per year. The legislation divided available annual funding among seven programs: CARL, Save Our Rivers, Florida Communities Trust, State Parks, State Forests, State Wildlife Areas, and Rails to Trails. Although the program was funded the first year by state bonds backed by an increase in the documentary stamp fee, the provision did not identify a long-term dedicated funding source. It made the program subject to annual legislative appropriations. Between 1972 and 1991, the state's land acquisition programs invested more than $1.5 billion to buy over 1.2 million acres (485,640 ha). Equally important, as a result of the state land acquisition programs, 14 Florida counties have created programs that currently commit up to $600 million for land conservation. Revenue sources for these local land acquisition programs include local option sales tax, impact fees, added property taxes, and local bonds.

1991

■ Chapter 40C-42, FAC. The St. Johns River WMD completely revised this provision to modify the design criteria for runoff treatment BMPs so they will achieve the minimum treatment levels set in the state water policy. Runoff reuse became essential for developments discharging to outstanding Florida waters.

■ Chapter 40C-44, FAC. The St. Johns River WMD adopted this provision to regulate certain agricultural pumped discharges (formerly regulated as industrial wastewater) and established design and performance criteria for these agricultural runoff management systems.

■ The Southwest Florida WMD initiated development of an agricultural runoff management program for certain types of agricultural activities, including row crops and citrus. The program included regulatory incentives to obtain technical assistance from USDA SCS or other qualified individuals to prepare and implement a farm-specific resource management plan that contains certain required BMPs.

1992

■ DER and the WMDs, in response to increasing demands on state waters and the increasing number of water quantity and quality problems, began developing district water management plans. Collectively, these district plans, together with the DER's plan, will create the state water management plan. These plans are based on the goals and policies set in state water policy and in the state comprehensive plan. For each of four major areas—water supply, water quality, flood protection, and natural systems protection—four key planning steps should occur: assess resources to identify current or anticipated problems, examine options, declare policy, and designate implementation strategies.

■ Section 314, Federal Clean Lake Program Lake Assessment Grant. This grant was obtained to delineate lake ecoregions, select lake ecoregion reference sites, and test/validate lake bioassessment sampling protocols and metrics.

1993

■ Chapters 373 and 403, F.S. These chapters were revised extensively and merge the Department of Environmental Regulation and Department of Natural Resources to create the Department of Environmental Protection (DEP), as a part of the Environmental Permit Streamlining bill. The goals of the streamlining bill were to eliminate duplication, especially in permitting; increase administrative and environmental effectiveness by increasing delegation of programs from DEP to the WMDs; and ensure greater program consistency and integration.

Key specific actions of the bill included

- Moving the Wetlands Protection Act from Chapter 403 to Chapter 373, F.S.

VOL 12

6804

This move delegated the wetland resource permits to the WMDs, except for certain projects that require other types of DEP permits.

- Merging the existing surface water/runoff management permit with the wetland resource permit to create an environmental resource permit.
- Redefining wetlands based on their hydrology, vegetation, and soils, and requiring the development of a single wetland delineation method to be used by DEP, WMDs, and local governments.

■ Recommendations of the third Environmental Lands Management Study Committee (ELMS III) were enacted into law, thereby amending several state laws. The act strengthens the state planning process by

- Requiring the governor to biannually review and analyze the state comprehensive plan and recommend any necessary revisions.
- Requiring the governor to prepare a new growth management portion of the state comprehensive plan. It will provide a more detailed and strategic state policy guidance for state, regional, and local governments to identify urban growth centers, set strategies to protect identified areas of state and regional environmental importance, and provide guidelines to determine where urban growth is appropriate and should be encouraged.

The governor's growth management document must be adopted by the legislature. However, to what extent local comprehensive plans, state agency strategic plans, and regional policy plans must be consistent with the state plan is unknown. The document is to be recommended by the governor and adopted as law by the 1994 legislature.

The act also provided greater flexibility and less requirements in local comprehensive plans for small cities and counties (less than 50,000); streamlined the plan amendment process by limiting the types of revisions requiring state review and approval; strengthened the local plan evaluation and appraisal process; terminated or made optional the DRI process in certain areas and revised the DRI process in other areas; and authorized a local option gas tax of up to 5 cents.

Recommendations

Florida has established a wide variety of laws, regulations, and programs at the state, regional, and local level. These are designed to protect, manage, and restore the state's incredibly valuable yet vulnerable natural resources, especially its water resources. Although these programs have helped reduce adverse impacts on natural resources resulting from the state's rapid and continuing growth over the past 20 years, many of Florida's natural resources have still been strained or degraded.

Some adverse effects were caused by activities that occurred before modern watershed management programs began, such as the channelization of the Kissimmee River and the creation of the vast drainage canal network south of Lake Okeechobee. Both of these conditions are contributing to the decline of Lake Okeechobee, the Everglades, and Florida Bay. Other adverse impacts directly related to 20 years of rapid growth and development are water supply and quality problems, declining habitat, and impacts on endangered species such as the manatee and the Florida panther.

Why are these adverse impacts still occurring, given the wide range of watershed management programs implemented in Florida? What can be done to reduce these effects and possibly restore already degraded areas? Following is a list of program deficiencies and recommendations to correct them:

1. While the statutes enacted by the legislature may be sound, governmental entities have insufficient resources to implement programs. The state's reliance on sales tax as a primary means to raise general revenues means that state revenues are tied closely to economic conditions. Relying on such sources during a recession, especially when the population is still growing, means that the state budget is nearly always in crisis. To compete for limited state resources and have adequate resources to achieve intended benefits, watershed management programs need dedicated sources of funding.
2. The statutes and programs are not fully integrated, leaving gaps in both land and water planning programs. In particular,

water and land planning and regulatory programs need better integration. The local government growth management program needs a close connection to state and regional water management programs. The requirements set forth in the state water policy and the district/state water management plans need to be incorporated by local governments in their land use planning programs. Local plans need to be consistent among all levels.

3. Greater emphasis must be placed on the long-term maintenance and operation of runoff management systems. Since these systems are part of the local infrastructure, local government must take a more active role. Establishing runoff operation permits as part of a runoff utility funded program is an excellent way of providing an economic incentive to a land owner to properly maintain and operate an on-site management system.

4. Greater emphasis must be placed on erosion and sediment control for construction sites and utility installation projects. Assuring the regular inspection of erosion prevention and sediment control practices is a major deficiency. A training and certification program for inspectors and contractor supervisors, similar to the Certified Construction Reviewer Program in Delaware, is needed.

5. Retrofitting existing drainage systems to reduce their pollutant loading is one of the biggest, most difficult, and most expensive challenges the state has faced. The state must develop new runoff treatment techniques that are not land intensive and fund demonstration projects to research new techniques.

6. While Floridians are among the nation's most educated citizens in water resources and runoff management issues, they need more education to provide support for watershed management programs. The state's environmental education program should establish a comprehensive natural resources management curriculum, beginning in kindergarten and continuing through high school. Additionally, because of the large number of people—especially retirees—moving to Florida, citizens need continuous education programs about the vulnerability and importance of Florida's natural resources.

Delaware's Sediment Control and Runoff Management Program

Prior to submitting any proposed legislation regarding runoff management or sediment control, representatives of the Delaware Department of Natural Resources and Environmental Control (DNREC) conducted an extensive educational program to document the serious nature of statewide water quantity and quality problems. This educational program was successful in that elected officials, impacted industries, and the general public acknowledged the need for a comprehensive approach to sediment control and runoff management. Statewide legislation was unanimously approved in four legislative committees and on the floor of both the state senate and house of representatives, due somewhat to its support by local conservation districts. In addition, the regulations providing the program details were approved with the assistance of a regulatory advisory committee after an extensive process and a public hearing with no negative comments.

The program's basic premise is that sediment control during construction and postconstruction, runoff quantity, and water quality control are components of an overall runoff management program that functions from the time that construction begins through the project's lifespan. The initial emphasis of the program, which began on July 1, 1991, was to prevent existing flooding or water quality from worsening. The intent is to limit further degradation until more comprehensive watershed approaches, as detailed in the state legislation and regulations, are adopted.

Program Structure

The structure of the sediment and runoff management program is based on the premise that ultimate program responsibility must rest with the state. In Delaware, DNREC is responsible for program implementation and is the ultimate approval authority. A local conservation district or other agency, such as a public works department, may request delegation of various program components, depending on its ability to implement them.

VOL 12 6806

R0040114

Four program components may be delegated:

- Sediment control and runoff management plan approval
- Inspection during construction
- Postconstruction inspection of permanent runoff facilities
- Education and training

Individual conservation districts receive preference for program components because of their historic involvement in conservation. Essential program components must be in place before any agency is awarded delegation. Delegation is awarded for a maximum of three years. During that time, the state formally reviews the program to determine whether to award delegation for another three years.

Before a local building or grading permit is issued, the sediment control and runoff management plan review and approval process must be completed. State regulations contain criteria for plan review and approval, and DNREC has developed or approved design aids and handbooks. The delegated local agency handles day-to-day inspection responsibilities. If projects do not comply with the plan, responsibility is transferred to the state, which carries out progressive aggressive enforcement. Enforcement options include civil and criminal penalties.

Control Practices

Site control practices are grouped into two categories—temporary practices during construction and permanent practices for postconstruction runoff. Sediment control practices designed for temporary site control must comply with the Delaware Erosion and Sediment Control Handbook. This handbook details numerous practices available, depending on their applicability. The plan review process ensures that the sediment control practices are appropriately located.

In addition to the traditional structural controls, several requirements in the handbook are important in providing overall site control. Sites must be stabilized if the disturbed areas are not actively worked for more than 14 days. To facilitate project phasing, no more than 20 acres may be disturbed at any one time. This provision can be modified for a specific type of project.

Water quality regulations require that 80 percent of suspended solids be removed. Permanent runoff management control requires a pond with a permanent pool of water. Wet ponds also have an extended detention requirement—the first inch of runoff to be released over a 24-hour period—in addition to controlling peak flows from larger storms. Ponds with a normal pool are preferred over either normally dry extended detention ponds or infiltration practices because they have documented performance records and can better reduce downstream nutrient loadings. If properly designed, wet ponds can also be a community amenity. Constructed wetlands are also considered a primary runoff treatment system in upland areas. However, Delaware does not encourage using existing natural wetlands for runoff treatment.

Another site control option is using infiltration practices. These practices are allowed but not encouraged because of their potential to clog and pollute groundwater. On sites that use infiltration practices, upslope and downslope impacts must be carefully considered during the plan review process. Because it has many benefits, runoff infiltration is a necessary component of a runoff management program. However, the design must include critical safeguards for filtering runoff to prevent groundwater pollution.

Runoff filtration must also be a program component, either as a single practice or combined with other practices, primarily infiltration. Common filtration generally consists of vegetative filtering over filter strips or through swale systems. On highly impervious sites, vegetative filters are often impossible. In these situations, a sand filter can provide initial water quality treatment. A number of sand filter design variations may be applicable from site to site, but the design must adhere to specific criteria for the system to effectively remove pollutants.

Unique Features

The Delaware program has a number of unique features compared to other state and local programs. The regulations require that, after development, runoff management practices must reduce the suspended solid load by 80 percent. Florida is the only other state to require a similar performance criteria. Delaware defined this reduction criteria after reviewing nationwide performance practice. While that performance level can be achieved with present technology application, long-term removal rates that exceed 80 percent may require extraordinary measures, such as water reuse. This measure could be required locally, but it is not practical statewide.

The concept of delegating program components is fairly unusual. Delaware can delegate each aspect of program implementation, with DNREC acting as a safety net in case a conservation district or a local government fails to adequately implement its part of the program. The initial delegation concept was developed in Maryland to inspect sediment control. Delaware law and regulations expanded that concept to encompass all aspects of program implementation. The state interaction with local programs has quickly become a partnership, with the state providing technical expertise and educational training and the conservation districts and local governments managing the program.

The Delaware program is unique in its use of private inspectors. Land developers are required to provide inspections on projects over 50 acres or as required by the state or delegated inspection agency to assist the governmental inspection agency. Inspectors must attend and pass an inspection course, inspect active construction sites at least weekly, and submit a report of findings and recommendations to the developer/contractor and the inspection agency. Approximately 170 individuals had been approved as of March 1993. The inspection agency must still inspect the site periodically to ensure the adequacy of site controls, but private inspectors reduce the need for frequent oversight. If the private inspector fails to accurately record site conditions or notify the contractor/developer or inspection agency of deficiencies, the inspector's certification could be jeopardized and enforcement action taken against the contractor/developer.

Another increasingly popular requirement in state sediment control programs is that contractors must have one or more responsible individuals certified as having attended a sediment control and runoff management course. The four-hour Delaware course acquaints contractors with the importance of good site erosion and sediment control and runoff management and their legal responsibilities. The certification program is extremely popular with contractors and reduces the "we-they" problems of many regulatory programs. Over 2,000 individuals had been certified in Delaware as of December 1993.

Evolution

The next phase of the Delaware program addresses runoff management from a watershed perspective. The regulation's designated watershed concept, when coupled with land use planning, wetland restoration, and other nonstructural practices, reduces existing flooding problems and improves water quality. Under the concept, one watershed in each county is designated as a model. Various aspects of this watershed are studied, including hydrology, water quality, and stream habitat and diversity. The study also considers alternative land uses and runoff controls and their impact on water quality. From this watershed study, the state and local government recommend a watershed protection approach—a blueprint for future resource protection—in designated watersheds. As of 1993, one Delaware watershed had been designated for additional resource protection efforts.

To expand the initial program, funding must also be addressed. The Delaware law and regulations provide a framework to expand traditional mechanisms with more innovative funding. The regulations contain significant information on using runoff utilities (user fees) as an alternative to permit fees or general funding. The runoff utility complements the designated watershed concept as a way to fund watershed studies; plan, design, and implement practices; and maintain completed structures.

While maintaining commercial structures is not a significant problem, since one entity is generally responsible for overall site maintenance, the maintenance of residential structures has not been satisfactorily addressed. Residential maintenance is generally the responsibility of a community association; however, the responsibility must become public to ensure proper maintenance. Shifting that responsibility requires implementing a dedicated funding source, such as a runoff utility.

To ensure resource protection, the issue of land use and its relationship to water quantity and quality must evolve. Significant effort must be expended to educate local government officials about the importance of wetlands, open space, greenways, cluster development, and other options to conventional "cookie cutter" zoning. The designated watershed approach provides specific details on the benefits of alternative land use approaches and their impacts on water quality and aquatic resources.

An effective runoff management program must have a multifaceted approach and implementation. It must also dispel the erroneous assumption that total resource protection is achieved through structural controls implemented after the entire site has been developed.

Land use limitations, dedicated open space, vegetated buffer areas, and reduced impervious areas are all components of an overall resource protection strategy—a structural control strategy alone will only reduce the rate of resource decline. Structural controls should be implemented as a first step, but continued evolution is vital to achieve true resource protection.

New Jersey's Runoff Management and Soil Erosion/Sediment Control

One of the most densely populated states, New Jersey has developed its runoff management and soil erosion/sediment control programs over several decades. These programs, which are some of the most comprehensive in the country, are the result of a continuing effort by the state government to address a range of flooding and other runoff problems. Due to the state's density, these problems have occurred earlier and with greater severity than in other less developed states. The programs' development has come mainly from in-state concerns and interests.

Programs are administered by the New Jersey Department of Environmental Protection (NJDEP), formerly the New Jersey Department of Environmental Protection and Energy. An active program of public education and information, which the NJDEP recognizes as key to developing a successful program, is included.

Much of New Jersey's dense development lies within a broad corridor between the New York City and Philadelphia metropolitan areas. Outside this corridor, particularly in the state's northwest and extreme southern portions, development levels are significantly less. Much undisturbed land remains. Other extensive areas are devoted to agriculture, the source of the state's designation as the Garden State. However, intensive development pressures are caused by the state's attempt to produce housing and jobs for a growing population.

New Jersey is composed of 567 municipalities—grouped into 21 counties—which exercise land use planning authority. This municipal authority has evolved gradually since World War II and was formalized in the 1975 Municipal Land Use Law (MLUL). This state law requires each municipality to develop a land use master plan to be implemented, in part, through its planning board and zoning board of adjustment. These two boards, following municipal zoning and land development ordinances, review and approve virtually all land development activity within the municipality. The MLUL requires that all municipal master plans be updated and readopted every six years. County governments also exercise some degree of approval authority over land development through state enabling legislation that predates the MLUL by some 20 years. This legislation grants counties the power to regulate proposed land development that affects county roads or drainage facilities.

In recent years, the state has attained some land use authority, either directly or through regional agencies created by the state legislature. These agencies include the Hackensack Meadowlands Development Commission in the northeast, the Pinelands commission in the southeast, and the Delaware and Raritan Canal Commission in central New Jersey. Other state laws, including the Coastal Area Facility Review Act (CAFRA), the Wetlands Act of 1970 (pertaining to coastal wetlands), the Waterfront Development Law, the Flood Hazard Area Control Act (described as follows), and the Freshwater Wetlands Protection Act have also allowed state government to regulate either the extent or details of land development along the coast and within floodplains, coastal and inland wetlands, and other environmentally sensitive areas.

Floodplain Management Programs

One of the earliest efforts by the state government to address runoff quantity problems was a 1929 law that prohibited the construction of any bridge, culvert, wall, building, or similar structure within "the natural and ordinary high water mark of any stream" without receiving prior state approval. By "preserving the channel and providing for the flow of waters," this legislation would "safeguard the public against danger from the waters impounded or affected by such structure." The state expanded its authority over the years by passing additional laws, including chapter 19, Public Law 1962, which authorized the state to delineate and otherwise identify floodplains and flood hazard areas to minimize flood damage through improper development. The state gained more authority in 1972 when it was empowered to regulate virtually all land development activity within the delineated floodways of streams and assist municipalities with similar efforts within contiguous flood fringe areas.

The 1978 Flood Hazard Area Control Act granted further review authority to the state and municipalities, while also coordinating the state's floodplain management activities with those of the federal Flood Insurance Program. This law, applied through the state's Flood Hazard Area Regulations, requires strict environmental constraints regarding site discharges, ground disturbance, and loss of floodplain storage through the NJDEP's Stream Encroachment Permit process. A direct effect of the restrictions on filling floodplains is that natural stream corridors and even entire floodplains have been increasingly preserved. This preservation, further enhanced by the 1987 Freshwater Wetlands Protection Act, maintains flood storage capabilities, habitats, and other environmental benefits. The Stream Encroachment Permit process has given the NJDEP procedural and technical expertise in runoff regulations and, indirectly, is an effective public information and education program.

Soil Erosion and Sediment Control Programs

New Jersey's soil erosion and sediment control program has been in effect since the 1970s. The 1975 Soil Erosion and Sediment Control Act (c. 251, P.L. 1975) was based on the legislative finding that "sediment is a source of pollution and that soil erosion continues to be a serious problem throughout the state." The legislation also noted that "rapid shifts in land use from agricultural and rural to nonagricultural and urbanizing uses, construction of housing, industrial and commercial developments, and other land disturbing activities have accelerated the process of soil erosion and sediment deposition, resulting in pollution of the waters of the State and damage to domestic, agricultural, industrial, recreational, fish and wildlife, and other resource uses."

In response to these problems, the act required the state Soil Conservation Committee—a division of the New Jersey Department of Agriculture—and the state's 16 soil conservation districts (SCDs) to develop and implement a "statewide comprehensive and coordinated erosion and sediment control program to reduce the danger from stormwater runoff, to retard nonpoint pollution from sediment, and to conserve and protect the land, water, air and other environmental resources of the State." The program requires virtually all proposed land developments that disturb more than 5,000 sq ft (0.046 ha) of land to prepare and submit a Soil Erosion and Sediment Control Plan to the SCD for review and certification. Regulated land development activities include

- Any construction that requires a construction permit under the State's Uniform Construction Code (excluding the construction of a single residence not part of a larger subdivision);
- Demolition of one or more structures;
- Construction of a parking lot;
- Construction of a public facility;
- Operation of any mining or quarrying facility; and
- Clearing or grading land for other than agricultural or horticultural purposes.

The Soil Erosion and Sediment Control plans must be developed as required in the *Standards for Soil Erosion and Sediment Control in New Jersey*, a detailed technical manual published by the State Soil Conservation Committee (New Jersey Dep. Agric. 1987). Following certification of the plan, the SCD is further empowered to conduct necessary field inspections during site construction to ensure that all erosion and sediment control measures are properly installed and adequately maintained.

If the site fails to comply with the plan during construction, the SCD municipality can issue a stop-work order. After construction is complete, a certificate of occupancy can be withheld until the project achieves full compliance. Separate state legislation specifies that the "Attorney General, on his own initiative or the respective county counsel, with the approval of the [county] board of chosen freeholders, may provide any and all legal services to any district" (NJSA 4:24-17.7) The act also authorizes SCDs to "adopt a fee schedule and collect fees from applicants for the certification of plans and for on-site inspections of the execution of certified plans" provided that such fees "bear a reasonable relationship to the cost of rendering such services."

The soil erosion and sediment control program has been highly successful. The 20-year-old program has enabled New Jersey to fully comply with the NPDES requirements of the 1987 Clean Water Act pertaining to construction and mining activities with little if any modification. The program's success is due, in part, to the original enabling legislation, which established a highly effective regulatory threshold (i.e., 5,000 sq ft [0.046 ha] of disturbance). It also provided the local SCDs with sufficient technical support

VOL 12 6/10

R0040118

through the Soil Erosion and Sediment Control Standards, legal support through the stop-work order and certificate-of-occupancy authority, and financial support through the fee schedule authorization. Including construction inspection costs in the fee schedule has been particularly effective in insuring that necessary soil erosion and sediment control measures are properly installed and maintained.

Runoff Management Programs

While its development began more recently, New Jersey's program to address the quantitative and qualitative aspects of runoff has built upon the success of the state's earlier floodplain management and soil erosion/sediment control efforts. The program began with the 1981 Storm Water Management Act (c. 32, P.L. 1981). This act and subsequent regulations directed municipalities, counties, and the NJDEP to address runoff impacts in several ways.

The legislation requires the state's municipalities to develop comprehensive runoff management plans for new land development within their borders. Such plans are to be designed to

- Reduce artificially induced flood damage;
- Minimize increased runoff from any new land development where such runoff will increase flood damage;
- Maintain existing and proposed culverts, bridges, dams, and other structures;
- Induce water recharge, where practical, where natural storage and geologically favorable conditions exist;
- Prevent, to the greatest extent feasible, an increase in nonpoint source pollution that would otherwise degrade water quality and render it unfit for human consumption and detrimental to stream biota;
- Maintain the integrity of stream channels for their biological, drainage, and other functions;
- Reduce the impact of land development on stream erosion;
- Reduce soil erosion from construction sites; and
- Preserve and protect water supply facilities and other water resources.

This comprehensive plan is to be developed in two phases. The municipality should incorporate a Phase I Stormwater Management Plan into its overall land use master plan. It should be implemented through municipal ordinances applied to new land developments by the Planning Board and Zoning Board of Adjustment approval process according to the Municipal Land Use Law. A Phase I plan must be based, in part, on an assessment of the municipality's environmental, technical, and institutional needs and be consistent with existing county, regional, and state plans and requirements. It must address the runoff impacts of major developments within the municipality by requiring, with certain exceptions, that the following performance standards be met:

- **Runoff quantity.** Reduction of the peak 2, 10, and 100-year discharge rates from the site after development to predevelopment levels.
- **Runoff quality.** Extended detention of the runoff from either a 1.25 inch (3.175 cm)/2-hour or 1-year/24-hour storm event so that at least 10 percent of the total runoff volume from the site still remains in the extended detention basin after 18 hours for single family residential developments or 36 hours for all others.

According to the regulations, the following are considered to be major developments and, therefore, subject to the previously stated performance standards:

- Any site plan or subdivision that will ultimately create at least 1 acre (0.41 ha) of impervious surface.
- Feeding and holding areas for specified numbers of farm animals.
- Petroleum or chemical pipelines, storage, or distribution facilities.
- Solid waste storage, disposition, incineration, or landfill.
- Storage, distribution, or treatment of liquid or radioactive wastes.
- Quarries, mines, and borrow pits.
- Land application of sewage sludge effluents.

The NJDEP is currently developing technical revisions to the Phase I plan requirements, in part to better match current Clean Water and Coastal Zone Management Acts. Phase I plans address the runoff impacts of new or future developments. Under Phase II, both existing and future developments and impacts are to be addressed through "a detailed analysis of alternative stormwater management approaches on an integrated or regional basis. The plan will consist of a system of nonstructural and/or structural stormwater management programs to mitigate flooding and nonpoint source pollution." Unlike Phase I, Phase II plans are to be developed by counties and municipalities at their own discretion based on needs and resources. As of 1993, seven Phase II plans had been or were being completed by various counties and funded, in part, by grants from the NJDEP. Two additional Phase II plans have been developed cooperatively by the NJDEP and USDA SCS.

Another important aspect of the Storm Water Management Act regulations is the attention to runoff facility inspection and maintenance. According to the regulations, all municipal runoff management plans should provide for facility inspection and maintenance, either privately or publicly. In the case of private responsibility, the plans must provide the means for public agencies to perform emergency maintenance in case the owner defaults or chronically neglects the site. To help municipalities address inspection and maintenance, the NJDEP prepared and published the *Stormwater Management Facilities Maintenance Manual* (1989). This manual, as previously discussed, was developed as part of a demonstration study with Ocean County, New Jersey, and contains detailed information on ownership, planning and design, regulatory, and financial aspects of runoff management facility maintenance.

In addition, the NJDEP and the New Jersey Department of Agriculture are publishing a new best management practices manual for stormwater management and nonpoint source pollution control (in prep.). This manual provides more comprehensive guidance than has been practiced statewide in the past. The manual is based on the importance of addressing stormwater and nonpoint source control at the start of the land development process to develop the most effective and efficient solutions. The manual stresses integrating preventative practices—such as land use planning, density controls, innovative site design, pollutant source controls, and waste minimization—with more traditional structural measures in a systems approach. In addition, the manual emphasizes the need for this integrated management system to be applied on a regional or watershed basis, and not merely site by site.

The NJDEP is also developing a stormwater management and nonpoint source guidance document for local governments. It is intended to introduce citizens and local officials to the scientific, technical, and legal aspects of stormwater, nonpoint source, and sediment control to increase their knowledge and ability to develop more effective local programs.

In recent years, the NJDEP has expanded the scope of the state's programs in response to internal concerns, citizen interest, and federal laws and regulations. In particular, the state developed the Industrial Stormwater Permitting Program to address the permitting requirements for such activities in the 1987 Clean Water Act. At the present time, a general stormwater discharge permit is available to eligible industries in addition to individual permits.

In August 1988, the New Jersey legislature adopted the Sewage Infrastructure Improvement Act (NJSA 58:25-23, et seq.), an initiative designed to further address stormwater and nonpoint source pollution problems. The act provides the means for municipalities and other public entities to survey, locate, and eliminate sources of pollutants entering storm sewers, waterways, and waterbodies. Under the act, 94 municipalities in four counties along and near the Atlantic coast are required to map their stormwater and sanitary sewer systems, locate and correct any interconnections, perform quarterly monitoring of outfalls to saltwater bodies, and abate nonpoint source pollution. Approximately $10 million has been allocated by the legislature to assist municipalities in meeting the act's goals.

Finally, the NJDEP has undertaken numerous demonstration and public outreach projects throughout the state, primarily through the Clean Water Act's section 319 program. These projects include the following:

- Barnegat Bay Watershed Management Plan
- New Jersey Water Watch Program
- Musconetcong Watershed Nonpoint Source Demonstration Project
- Barnegat Bay Watershed Intensive Monitoring Project
- Whippany River Watershed Management Plan
- Clean Water Information Series

Delaware's Erosion and Sedimentation Control and Stormwater Management Law

VOL 12

6816

Chapter 40, Title 7, Delaware Code

§4001. LEGISLATIVE FINDINGS AND STATEMENT OF POLICY

(a) Legislative Findings. The General Assembly finds that erosion and sedimentation continue to present serious problems throughout the State, and that the removal of a stable ground cover in conjunction with the decrease in the infiltration capability of soils resulting from the creation of additional impervious areas such as roads and parking lots has accelerated the process of soil erosion and sediment deposition resulting in pollution of the waters of the State. This loss damages domestic, agricultural, industrial, recreational, fish and wildlife and other resource uses. The General Assembly further finds that accelerated stormwater runoff increases flood flows and velocities, contributes to erosion, sedimentation, and degradation of water quality, overtaxes the carrying capacity of streams and storm sewers, greatly increases the costs of public facilities in carrying and controlling stormwater, undermines flood plain management and flood control efforts in downstream communities, reduces groundwater recharge, and threatens public health, welfare, and safety.

(b) Statement of Policy. In consideration of these legislative findings, it is declared to be the policy of this Chapter to strengthen and extend the present erosion and sediment control activities and programs of this State for both rural and urban lands and to provide for the control and management of stormwater runoff consistent with sound water and land use practices. These activities will reduce to the extent possible any adverse effects of stormwater runoff on the water and lands of the State. This policy, to be carried out by establishing and implementing through the Department of Natural Resources and Environmental Control, hereinafter referred to as the "Department," in cooperation with conservation districts, counties, municipalities and other local governments and subdivisions of this State, and other public and private entities, a statewide comprehensive and coordinated erosion and sediment control and stormwater management program to conserve and protect land, water, air and other resources of the State. This program shall be consistent with, and coordinated with other environmental programs implemented by the Department such as wetlands protection and groundwater protection.

§4002. DEFINITIONS

The following words, terms and phrases, when used in this Chapter, shall have the meaning ascribed to them in this Section, except where the context clearly indicates a different meaning:

(1) "Certified Construction Reviewer" means an individual who has passed a departmental sponsored or approved training course and who provides on-site construction review for sediment control and stormwater management in accordance with regulations promulgated under this Chapter.

(2) "Designated Watershed or Subwatershed" means a watershed or subwatershed proposed by a conservation district, county, municipality, or State agency and approved by

the Department. The Department may establish additional requirements due to existing water quantity or water quality problems. These requirements shall be implemented on an overall watershed or subwatershed master plan developed for water quality and/or water quantity protection.

(3) "Land Disturbing Activity" means any land change or construction activity for residential, commercial, silvicultural, industrial, and institutional land use which may result in soil erosion from water or wind or movement of sediments or pollutants into State waters or onto lands in the State, or which may result in accelerated stormwater runoff, including, but not limited to, clearing, grading, excavating, transporting and filling of land.

(4) "Person" means any State or federal agency, individual, partnership, firm, association, joint venture, public or private corporation, trust, estate, commission board, public or private institution, utility, cooperative, municipality or other political subdivision of this State, any interstate body, or any other legal entity.

(5) "Responsible Personnel" means any foreman or superintendent who is in charge of on-site clearing and land disturbing activities for sediment and stormwater control associated with a construction project.

(6) "Sediment and Stormwater Management Plan" or "plan" means a plan for the control of soil erosion, sedimentation, stormwater quantity, and water quality impacts which may result from any land disturbing activity.

(7) "State Waters" means any and all waters, public or private, on the surface of the earth which are contained within, flow through or border upon the State of Delaware or any portion thereof.

(8) "Stormwater" means the runoff of water from the surface of the land resulting from any form of precipitation and including snow or ice melt.

(9) "Stormwater Management" means:

(a) for water quantity control, a system of vegetative, structural, and other measures that controls the volume and rate of stormwater runoff which may be caused by land disturbing activities or activities upon the land; and

(b) for water quality control, a system of vegetative, structural and other measures that controls adverse effects on water quality that may be caused by land disturbing activities or activities upon the land.

(10) "Stormwater Utility" means the establishment of an administrative organization that has been created for the purposes of funding sediment control, stormwater management or flood control planning, design, construction, maintenance, and overall resource needs by authorized and imposed charges.

§4003. DUTIES OF PERSONS ENGAGED IN LAND DISTURBING ACTIVITIES

(a) After July 1, 1991, unless exempted, no person shall engage in land disturbing activities without submitting a sediment and stormwater management plan to the appropriate plan approval authority and obtaining a permit to proceed.

(b) Projects which do not alter stormwater runoff characteristics may be required to provide water quality enhancement even if the predevelopment runoff characteristics are unchanged. Criteria will be detailed in the regulations regarding level of water quality control and variance procedures.

(c) Each land developer shall certify, on the sediment and stormwater management plan submitted for approval, that all land clearing, construction, development, and drainage will be done according to the approved plan.

(d) All approved land disturbing activities shall have associated therein at least one individual who functions as responsible personnel.

§4004. APPLICABILITY

(a) The provisions of this Chapter shall not apply to agricultural land management practices unless the conservation district or the Department determines that the land requires a new or updated soil and water conservation plan, and the owner or operator of the land has refused either to apply to a conservation district for the development of such a plan, or to implement a plan developed by a conservation district.

VOL 12

6817

R0040125

(b) Unless a waiver is granted the construction of agricultural structures such as broiler houses, machine sheds, repair shops, and other major buildings shall require approval of a sediment and stormwater management plan, by the appropriate plan approval agency, prior to the initiation of construction.

(c) Utility projects that disturb less than 5,000 square feet are not subject to the provisions of this Chapter.

§4005. PROGRAM FUNDING AND FINANCIAL ASSISTANCE

(a) The Department, conservation districts, counties, or municipalities are authorized to receive from federal, State, or other public or private sources financial, technical or other assistance for use in accomplishing the purposes of this Chapter. The Department may allocate, as necessary or desirable, any funds received to conservation districts, counties, or municipalities for the purpose of effectuating this Chapter.

(b) The conservation districts, counties, and municipalities shall have authority to adopt a fee system to help fund program implementation. That fee system shall be implemented by the designated plan approval agency to fund overall program management, plan review, construction review, enforcement needs, and maintenance responsibilities. In those situations where the Department becomes the designated plan approval agency, the Department may assess a plan review and inspection fee. That fee shall not exceed $80.00 per disturbed acre per project. There shall be no duplication of fees by the various implementing agencies for an individual land disturbing activity and the fee schedule shall be based upon the costs to the Department, conservation districts, counties, or municipalities to implement and administer the program.

(c) Authority is also granted to the Department, conservation districts, counties or municipalities to establish a stormwater utility as an alternative to total funding under the fee system. The stormwater utility shall be developed for the designated watersheds and may fund such activities as long range watershed master planning, watershed retrofitting, and facility maintenance. This fee system shall be reasonable and equitable so that each contributor of runoff to the system, including State agencies, shall pay to the extent to which runoff is contributed. Criteria for the implementation of the stormwater utility shall be established in regulations promulgated under this Chapter. The implementation of a stormwater utility will necessitate the development of a local utility ordinance prior to its implementation.

§4006. STATE MANAGEMENT PROGRAM

(a) The Department shall, in cooperation with appropriate State and federal agencies, conservation districts, other governmental subdivisions of the State, and the regulated community develop a State Stormwater Management Program. This program shall take into consideration both quantity and quality of water, and shall be integrated with, and made a part of the amended State Erosion and Sediment Control Program to create a Sediment and Stormwater Program.

(b) In carrying out this Act, the Department shall have the authority to

(1) Provide technical and other assistance to districts, counties, municipalities, and State agencies in implementing this Chapter;

(2) Develop and publish, as regulation components, minimum standards, guidelines and criteria for delegation of sediment and stormwater program components, and model sediment and stormwater ordinances for use by districts, counties, and municipalities;

(3) Review the implementation of all components of the statewide sediment and stormwater program that have been delegated to either the conservation districts, counties, municipalities, or other State agencies in reviews to be accomplished at least once every three (3) years;

(4) Require that appropriate sediment and stormwater management provisions be included in all new erosion and sediment control plans developed pursuant to this Chapter;

(5) Cooperate with appropriate agencies of the United States or other states or any interstate agency with respect to sediment control and stormwater management;

VOL 12

5 8 / 8

(6) Conduct studies and research regarding the causes, effects and hazards of stormwater and methods to control stormwater runoff;

(7) Conduct and supervise educational programs with respect to sediment control and stormwater management;

(8) Require the submission to the Department of records and periodic reports by conservation districts, tax ditch organizations, county and municipal agencies as may be necessary to carry out this Act;

(9) Review and approve designated watersheds for the purpose of this Act;

(10) Establish a maximum life of three years for the validation of approved plans. The regulations shall specify variances which expand this time limitation in specific situations; and

(11) Establish a means of communication, such as a newsletter, so that information regarding program development and implementation can be distributed to interested individuals.

(c) The Department shall develop such regulations in conjunction with and with substantial concurrence of a regulatory advisory committee, appointed by the Secretary, which shall include representatives of the regulated community and others affected by this Act. The recommendations of this committee shall be presented at all public workshops and hearings related to the adoption of the regulations implementing this Act. Prior to final promulgation of regulations under this Act, the Secretary shall explain, in writing, any differences between the advisory committee recommendations and the final regulations. The regulations may include, but are not limited to, the following items:

(1) Criteria for the delegation of program elements;

(2) Types of activities that require a sediment and stormwater management permit;

(3) Waivers, exemptions, and variances;

(4) Sediment and stormwater plan approval fees and performance bonds;

(5) Criteria for distribution of funds collected by sediment and stormwater plan approval fees;

(6) Criteria for implementation of a stormwater runoff utility;

(7) Specific design criteria and minimum standards and specifications;

(8) Permit application and approval requirements;

(9) Criteria for approval of designated watersheds;

(10) Criteria regarding attendance and completion of departmental sponsored or approved training courses in sediment and stormwater control that will be required of certified construction reviewers and responsible personnel;

(11) Construction review; and

(12) Maintenance requirements for sediment control during construction and stormwater management structures after construction is completed.

(d) The Department may adopt, amend, modify, or repeal rules or regulations after public hearing to effectuate the policy and purposes of this Chapter. The conduct of all hearings conducted pursuant to this Chapter and the promulgation process shall be in accordance with the relevant provisions of Chapter 60 of this Title.

§4007. LOCAL SEDIMENT AND STORMWATER PROGRAMS

(a) Pursuant to regulations promulgated by the Department, each conservation district, county, municipality, or State agency may adopt, and submit to the Department for approval, one or more components of a sediment and stormwater program for the area within its jurisdiction.

(b) Requests for delegation of program elements shall be submitted within six months of the promulgation of State regulations, and by January 1 of subsequent years if delegation is desired at a future date. The Secretary shall grant or deny such a request on or before April 1 of the year for which delegation is sought.

(c) Delegation, once applied for, shall become effective on July 1 and shall not exceed three (3) years, at which time delegation renewal is required.

(d) A district, county, municipality, or State agency may develop the program in cooperation with any other governmental subdivisions.

(e) Initial consideration regarding delegation of program elements shall be given to the conservation districts, since the conservation districts, having unique capabilities and area-wide responsibilities, are in an ideal position to coordinate and implement local sediment and stormwater programs.

§4008. INTERIM PROGRAM

(a) Prior to July 1, 1991, requirements for sediment control shall be as provided in existing erosion and sediment control regulations promulgated September 26, 1980. Also, until July 1, 1991, any State or locally developed regulation or criterion for stormwater management shall remain in effect at the discretion of the implementing authority.

(b) Projects approved prior to July 1, 1991, but which are under construction after July 1, 1991, shall be subject to the penalty provisions contained in Section 4015 of this Chapter.

§4009. FAILURE OF CONSERVATION DISTRICTS, COUNTIES, MUNICIPALITIES, OR STATE AGENCIES TO IMPLEMENT DELEGATED PROGRAM ELEMENTS

(a) If, at any time, the Department finds that a conservation district, county, municipality, or State agency has failed to implement program elements that the Department has delegated, the Department shall provide written notice of violation to the conservation district, county, municipality or State agency.

(b) Within 60 days of receipt of the notice of violation, the conservation district, county, municipality or State agency shall report to the Department the action which it has taken to comply with the requirements set forth in the violation notice.

(c) If after 120 days of receipt of the notice of violation, the conservation district, county, municipality, or State agency has failed to comply satisfactorily with the requirements set forth in the notice of violation, the Department may suspend or revoke the delegated authority.

(d) If at any time, a program element delegation is being considered for suspension or revocation, an opportunity for a hearing before the Secretary or his designee shall be provided prior to such suspension or revocation.

§4010. STATE AND FEDERAL PROJECTS

After July 1, 1991, a State or federal agency may not undertake any land clearing, soil movement, or construction activity unless the agency has submitted a sediment and stormwater management plan to the Department and received its approval. The only variation to this requirement shall be when delegation of the plan approval process has been granted by the Department to a specific State or federal agency.

§4011. DESIGNATED WATERSHEDS OR SUBWATERSHEDS

(a) Watersheds or subwatersheds approved as designated watersheds or subwatersheds by the Department shall have the regulatory requirements clearly specified through a watershed approach to nonpoint pollution control or flood control. The watershed approach shall result in a specific plan, developed or approved by the Department, for the designated watershed or subwatershed that contains the following information:

(1) Stormwater quantity or quality problem identification;

(2) The overall needs of the watershed, not just the additional impacts of new development activities;

(3) Alternative approaches to address the existing and future problems;

(4) A defined approach which includes the overall costs and benefits;

(5) A schedule for implementation;

(6) Funding sources and amounts; and

(7) A public hearing process prior to Departmental approval.

(b) Upon approval of the designated watershed or subwatershed plan, all projects undertaken in that watershed or subwatershed shall have stormwater requirements placed upon them that are consistent with the designated watershed or subwatershed plan.

§4012. CONSTRUCTION REVIEW AND ENFORCEMENT

(a) With respect to approved sediment and stormwater plans, the agency responsible for construction review during and after construction completion shall ensure that periodic reviews are undertaken, implementation is accomplished in accordance with the approved plans, and the required measures are functioning in an effective manner. Notice of such right of construction review shall be included in the sediment and stormwater management plan certification. The agency responsible for construction review may, in addition to local enforcement options, refer a site violation to the Department for additional action.

(b) Referral of a site violation to the Department may initiate a departmental construction review of the site to verify site conditions. That construction review may result in the following actions:

(1) Notification through appropriate means to the person engaged in a land disturbing activity and the contractor to comply with the approved plan within a specified time frame.

(2) Notification of plan inadequacy, with a time frame for the person engaged in a land disturbing activity to submit a revised sediment and stormwater plan to the appropriate plan approval agency and to receive its approval with respect thereto.

(c) Failure of the person engaged in the land disturbing activity or the contractor to comply with departmental requirements may result in the following actions in addition to other penalties as provided in this Chapter.

(1) The Department shall have the power to issue a cease and desist order to any person violating any provision of this Chapter by ordering such person to cease and desist from any site work activity other than those actions necessary to achieve compliance with any administrative order.

(2) The Department may request that the appropriate plan approval agency refrain from issuing any further building or grading permits to the person having outstanding violations until those violations have been remedied.

§4013. APPROVAL OF CERTIFIED CONSTRUCTION REVIEWERS

(a) Based on criteria established by the Department through regulation and any additional criteria established by the agency implementing the plan review and construction elements of the sediment and stormwater program, the person engaged in a land disturbing activity may be required to provide for construction review by a certified construction reviewer.

(b) Individuals functioning as certified construction reviewers must attend and pass a departmental sponsored or approved construction review training course. The Department will establish, through regulation, the length of time for which the certification will last and procedures for renewal. The construction reviewers shall also function under the direction of a registered professional engineer licensed to practice engineering in the State of Delaware.

(c) The responsibility of the certified construction reviewer will be to ensure the adequacy of construction pursuant to the approved sediment and stormwater management plan.

(d) The certified construction reviewer shall be responsible for the following items:

(1) Provision of a construction review of active construction sites on at least a weekly basis, as determined on a case-by-case basis by the plan review and construction review agencies, or as required by regulations promulgated pursuant to this Chapter;

(2) Within five calendar days, informing the person engaged in the land disturbing activity, and the contractor, by a written construction review report of any violations of the approved plan or inadequacies of the plan. The plan approval agency shall be informed, if the approved plan is inadequate, within five working days. In addition, the appropriate construction review agency shall receive

VOL 12 6821

R0040129

copies of all construction review reports; and

(3) Referral of the project to the Department for appropriate enforcement action if the person engaged in the land disturbing activity fails to address the items contained in the written construction review report. Verbal notice shall be made to the Department within two working days and written notice shall be provided to the Department within five working days.

(e) If the Secretary or his designee determines that a certified construction reviewer is not providing adequate site control or is not referring problem situations to the Department, the Secretary or his designee may suspend or revoke the certification of the construction reviewer.

(f) In any situation where a certified construction reviewer's approval is being suspended or revoked, an opportunity for hearing before the Secretary or his designee shall be provided. During any suspension or revocation, the certified construction reviewer shall not be allowed to provide construction reviews pursuant to this Chapter.

(g) The failure to assign a Departmental approved certified construction reviewer to a land disturbing activity, when required by the approved plan, will place that project in violation of this Chapter and result in appropriate administrative and/or enforcement action.

§4014. TRAINING OF RESPONSIBLE PERSONNEL

After July 1, 1991, any applicant seeking sediment and stormwater plan approval shall certify to the appropriate approval agency that all responsible personnel involved in the construction project will have a certificate of attendance at a departmentally sponsored or approved training course for the control of sediment and stormwater before initiation of any land disturbing activity. The certificate of attendance shall be valid until the Department notifies the individual or announces in local newspapers that recertification is required due to a change in course content.

§4015. PENALTIES

(a) Any person who violates any rule, regulation, order, condition imposed in an approved plan or other provision of this Chapter shall be fined not less than $200 or more than $2,000 for each offense. Each day that the violation continues shall constitute a separate offense. The Justice of the Peace Courts shall have jurisdiction of offenses brought under this subsection.

(b) Any person who intentionally, knowingly, and after written notice to comply, violates or refuses to comply with any notice issued pursuant to Section 4013(2) of this Chapter shall be fined not less than $500 or more than $10,000 for each offense. Each day the violation continues shall constitute a separate offense. The Superior Court shall have jurisdiction of offenses brought under this subsection.

§4016. INJUNCTIONS

The Court of Chancery shall have jurisdiction to enjoin violations of this Chapter. The appropriate program element authority, the Department, or any aggrieved person who suffers damage or is likely to suffer damage because of a violation or threatened violation of this Chapter may apply to the Chancery Court for injunctive relief. Among any other appropriate forms of relief, the Chancery Court may direct the violator to restore the affected land or water impacted area to its original condition.

VOL 12

5822

VOL 12

APPENDIX B

Delaware Sediment and Stormwater Regulations

Department of Natural Resources and Environmental Control
Effective Date January 23, 1991 — Amended March 11, 1993

6823

Table of Contents

Section 1 — Scope

1. Stormwater runoff may reasonably be expected to be a source of pollution to waters of the State, and may add to existing flooding problems. The implementation of a statewide sediment and stormwater program will prevent existing water quantity and water quality problems from becoming worse, and in some cases, reduce existing problems.

2. Sediment and stormwater approvals are required for land changes or construction activities for residential, commercial, silvicultural, industrial, or institutional land use which are not exempted or waived by these Regulations. Requirements under these Regulations do not apply to agricultural land management practices unless the Conservation District or the Department determines that the land requires a soil and water conservation plan, and the owner or operator of the land has refused either to apply to a Conservation District for the development of such a plan, or to implement a plan developed by a Conservation District.

3. The Department intends that, to the extent possible, the provisions of these Regulations be delegated to either the Conservation Districts, local governments, or other State agencies. Those program provisions which are subject to delegation include sediment and stormwater management plan approval, inspection during construction, post-construction inspection, and education and training. Initial consideration regarding delegation of program components shall be given to the Conservation Districts.

4. The implementation of a stormwater utility represents a comprehensive approach to program funding and implementation. The activities which may be undertaken by a stormwater utility include not only assessment, collection, and funding activities, but also carrying out provisions of adopted stormwater management plans. These provisions may include contracting for such services as project construction, project maintenance, project inspection, and enforcement of installation and maintenance requirements imposed with respect to approved land disturbing activities.

Section 2 — Definitions

As used in these regulations, the following terms shall have the meanings indicated below:

1. "Adverse Impact" means a negative impact to land or waters resulting from a construction or development activity. The negative impact includes increased risk of flooding; degradation of water quality; increased sedimentation; reduced groundwater recharge; negative impacts on aquatic organisms; negative impacts on wildlife and other resources, and threatened public health.

2. "Agricultural Land Management Practices" means those methods and procedures generally accepted by the Conservation Districts and used in the cultivation of land in order to further crop and livestock production and conservation of related soil and water resources.

3. "Applicant" means a person, firm, or governmental agency who executes the necessary forms to obtain approval or a permit for a land disturbing activity.

4. "Appropriate Plan Approval Agency" means the Department, Conservation District, county, municipality, or State agency that is responsible in a jurisdiction for review and approval of sediment and stormwater management plans.

5. "As-Built Plans or Record Documents" means a set of engineering or site drawings that delineate the specific permitted stormwater management facility as actually constructed.

6. "Certified Construction Reviewer" means those individuals, having passed a Departmental sponsored or approved training course, who provide on-site inspection for sediment control and stormwater management in accordance with these regulations.

7. "Delegation" means the acceptance of responsibility by a Conservation District, county, municipality, or State agency for the implementation of one or more elements of the statewide sediment and stormwater management program.

8. "Department" means the Department of Natural Resources and Environmental Control.

9. "Designated Watershed or Subwatershed" means a watershed or subwatershed proposed by a Conservation District, county, municipality, or State agency and approved by the Department. The Department may establish additional requirements in these watersheds and subwatersheds due to existing

water quantity or water quality problems. These requirements shall be implemented on an overall watershed or subwatershed master plan that is developed for water quality and/or water quantity protection.

10. "Detention Structure" means a permanent stormwater management structure whose primary purpose is to temporarily store stormwater runoff and release the stored runoff at controlled rates.

11. "Develop Land" means to change the runoff characteristics of a parcel of land in conjunction with residential, commercial, industrial, or institutional construction or alteration.

12. "Developer" means a person undertaking, or for whose benefit, activities covered by these regulations are commenced and/or carried out.

13. "Drainage Area" means that area contributing runoff to a single point measured in a horizontal plane, which is enclosed by a ridge line.

14. "Easement" means a grant or reservation by the owner of land for the use of such land by others for a specific purpose or purposes, and which must be included in the conveyance of land affected by such easement.

15. "Erosion and Sediment Control" means the control of solid material, both mineral and organic, during a land disturbing activity, to prevent its transport out of the disturbed area by means of air, water, gravity, or ice.

16. "Exemption" means those land development activities that are not subject to the sediment and stormwater requirements contained in these regulations.

17. "Grading" means excavating, filling (including hydraulic fill) or stockpiling of earth materials, or any combination thereof, including the land in its excavated or filled condition.

18. "Infiltration" means the passage or movement of water through the soil profile.

19. "Land Disturbing Activity" means a land change or construction activity for residential, commercial, silvicultural, industrial, and institutional land use that can result in soil erosion from water or wind or movement of sediments or pollutants into State waters or onto lands in the State, or in accelerated stormwater runoff. These activities include but are not limited to clearing, grading, excavating, transporting and filling of land.

20. "Off-site Stormwater Management" means the design and construction of a stormwater management facility that is necessary to control stormwater from more than one land disturbing activity.

21. "On-site Stormwater Management" means the design and construction of stormwater management practices that are required for a specific land disturbing activity.

22. "Person" means any State or federal agency, individual, partnership, firm, association, joint venture, public or private corporation, trust, estate, commission, board, public or private institution, utility, cooperative, municipality or other political subdivision of this State, any interstate body or any other legal entity.

23. "Redevelopment" means a land disturbance activity that alters the use of land but does not necessarily alter the predevelopment runoff characteristics.

24. "Responsible Personnel" means a foreman or superintendent who is in charge of on-site clearing and land disturbing activities for sediment and stormwater control associated with a construction project.

25. "Sediment" means soils or other superficial materials transported and/or deposited by the action of wind, water, ice or gravity as a product of erosion.

26. "Sediment and Stormwater Management Plan" means a plan for the control of soil erosion, sedimentation, stormwater quantity, and water quality impacts resulting from any land disturbing activity.

27. "Stabilization" means the prevention of soil erosion by surface runoff or wind through the establishment of a soil cover through the implementation of vegetative or structural measures. Examples include, but are not limited to, straw mulch with temporary or permanent vegetation, wood chips, and stone or gravel ground cover.

28. "State Waters" means any and all waters, public or private, on the surface of the earth which are contained within, flow through or border upon the State or any portion thereof.

VOL 12

6825

28. "Stormwater" means the runoff of water from the surface of the land resulting from precipitation or snow or ice melt.

29. "Stormwater Management" means:

    A. for water quantity control, a system of vegetative, structural, and other measures that may control the volume and rate of stormwater runoff which may be caused by land disturbing activities or activities upon the land; and

    B. for water quality control, a system of vegetative, structural, and other measures that control adverse effects on water quality that may be caused by land disturbing activities or activities upon the land.

30. "Stormwater Utility" means an administrative organization that has been established for the purposes of funding sediment control, stormwater management or flood control planning, design, construction, maintenance, and overall resource needs by authorized and imposed charges.

31. "Tidewater" means water that alternately rises and falls due to the gravitational attraction of the moon and sun and is under the regulatory authority of Delaware Code, Title 7, Chapter 72. Examples of tidewaters include the Atlantic Ocean, the Delaware Bay, and the Delaware Inland Bays.

32. "Variance" means the modification of the minimum sediment and stormwater management requirements for specific circumstances where strict adherence of the requirements would result in unnecessary hardship and not fulfill the intent of these regulations.

33. "Waiver" means the relinquishment from sediment and stormwater management requirements by the appropriate plan approval authority for a specific development on a case-by-case review basis.

34. "Water Quality" means those characteristics of stormwater runoff from a land disturbing activity that relate to the chemical, physical, biological, or radiological integrity of water.

35. "Water Quantity" means those characteristics of stormwater runoff that relate to the rate and volume of the stormwater runoff to downstream areas resulting from land disturbing activities.

36. "Watershed" means the total or partial drainage area contributing stormwater runoff to a single point.

Section 3 — Exemptions, Waivers, and Variances

1. The following activities are exempt from both sediment control and stormwater management requirements established by these regulations:

    A. Agricultural land management practices, unless the local Conservation District or the Department determines that the land requires a new or updated soil and water conservation plan, and the owner or operator of the land has refused either to apply to a Conservation District for the development of such a plan, or to implement a plan developed by a Conservation District;

    B. Developments or construction that disturb less than 5,000 square feet;

    C. Land development activities which are regulated under specific State or federal laws which provide for managing sediment control and stormwater runoff. An example of this exemption would be specific permits required under the National Pollutant Discharge Elimination System when discharges are a combination of stormwater and industrial or domestic wastewater or which must comply with Parts 122, 123, and 124 of Title 40 of the Code of Federal Regulations. The Department shall ensure that all land developments which are regulated under specific State or federal laws are coordinated with delegated plan approval agencies to ensure compatibility of requirements;

    D. Projects that are emergency in nature and necessary to protect life or property such as bridge, culvert, or pipe repairs and aboveground or underground electric and gas utilities or public utility restoration. The emergency nature of a project may preclude prior plan review and approval, but subsequent inspection may necessitate sediment control or site stabilization in accordance with the provisions of this Chapter. The appropriate plan approval agency shall be notified orally or in writing within 48 hours of the initiation of such emergency activity.

The appropriate plan approval agency shall determine and approve of the emergency nature of a project. If the nature of the emergency will require more than 120 days to accomplish construction, formal approval shall be obtained for sediment control and stormwater management. These activities must still comply with other State, federal, and local requirements.

2. Appropriate Plan Approval Agencies may grant waivers from the stormwater management requirements of these regulations for individual developments provided that a written request is submitted by the applicant containing descriptions, drawings, and any other information that is necessary to evaluate the proposed development. A separate written waiver request shall be required if there are subsequent additions, extensions, or modifications that would alter the approved stormwater runoff characteristics to a development receiving a waiver.

   A. A project may be eligible for a waiver of stormwater management for both quantitative and qualitative control if the applicant can demonstrate that

      (1) The proposed project will return the disturbed area to a predevelopment runoff condition and the predevelopment land use is unchanged at the conclusion of the project; or

      (2) The proposed project consists of a linear disturbance of less than six (6) feet in width; or

      (3) The project is for an individual residential detached unit or agricultural structure, and the total disturbed area of the site is less than one acre; or

      (4) The proposed project is for agricultural structures in locations included in current soil and water conservation plans that have been approved by the appropriate Conservation District.

   B. A project may be eligible for a waiver or variance of stormwater management for water quantity control if the applicant can demonstrate that

      (1) The proposed project will not generate an increase in the 2-year post-development peak discharge rate of more than ten (10) percent above the 2-year predevelopment peak discharge rate and will have no adverse impact on the receiving wetland, watercourse, or waterway; or

      (2) Provisions will be made or exist for a nonerosive conveyance system to tidewater by either a closed drainage system or by open channel flow that has adequate capacity to contain the runoff events being considered as a requirement of these regulations; or

      (3) The location of a project within a watershed would aggravate downstream flooding by the imposition of peak control requirements.

      (4) The plan approval agency may grant a written variance from any requirement of these regulations if there are exceptional circumstances applicable to the site such that strict adherence to the provisions of these regulations will result in unnecessary hardship and not fulfill the intent of these regulations. A written request for variance shall be provided to the plan approval agency and shall state the specific variances sought and the reasons for their granting. The plan approval agency shall not grant a variance unless and until sufficient specific reasons justifying the variance are provided by the applicant.

Section 4 — Departmental Responsibilities

1. The Department is responsible for the implementation and supervision of the sediment and stormwater program established by Chapter 40, Title 7, Delaware Code. This responsibility shall include, but not be limited to, authority for the following actions:

   A. Provide technical and other assistance to Conservation Districts, counties, municipalities, federal, and State agencies in implementing this Chapter;

   B. Develop and publish, as regulation components, minimum standards, guidelines and criteria for delegation of sediment

VOL 12

6827

and stormwater program components, and model sediment and stormwater ordinances for use by Conservation Districts, counties, State agencies, and municipalities;

C. Review the implementation of all components of the statewide sediment and stormwater management program that have been delegated to either the Conservation Districts, counties, municipalities, or other State agencies in reviews to be accomplished at least once every three years;

D. Require that appropriate sediment and stormwater management provisions be included in all new erosion and sediment control plans developed pursuant to these regulations;

E. Cooperate with appropriate agencies of the United States or other states or any interstate agency with respect to sediment control and stormwater management;

F. Conduct studies and research regarding the causes, effects, and hazards of stormwater and methods to control stormwater runoff;

G. Conduct and supervise educational programs with respect to sediment control and stormwater management;

H. Require the submission to the Department of records and periodic reports by Conservation Districts, tax ditch organizations, county, and municipal agencies as may be necessary to carry out these regulations;

I. Review and approve designated watersheds;

J. Establish a maximum life of three years for the validation of approved plans. These regulations shall specify variances which expand this time limitation in specific situations; and

K. Establish a means of communication, such as a newsletter, so that information regarding program development and implementation can be distributed to interested individuals.

2. Matters of policy, procedures, standards, criteria, approvals, inspection, or enforcement relating to the Sediment and Stormwater Chapter shall be established by the Department subject to the jurisdiction of the Secretary of the Department. Sediment and stormwater programs or portions of programs which are delegated to the Conservation Districts, counties, municipalities, or State agencies shall include sediment and stormwater criteria consistent with the standards, procedures, and regulations of the Department.

   A variation of requirements by the delegated agency on a specific watershed will not be valid unless approved by the Department. All State and federal development in the watershed shall be reviewed subject to the same variations and requirements by the delegated State agency or Department as appropriate.

3. In situations where public notification and comment are required before an action is taken by the Department, the Regulatory Advisory Committee shall have an opportunity to review the proposed Departmental action and provide input to the Department regarding the action.

Section 5 — Criteria for Delegation of Program Elements

1. Conservation Districts, counties, municipalities, and State agencies may seek delegation of four program elements relating to the implementation of the statewide sediment and stormwater program. Delegation may be granted by the Secretary for review and approval of sediment and stormwater management plans, inspection during construction, subsequent maintenance inspection, and education and training. Program elements that are delegated shall be implemented according to Chapter 40 and these regulations.

2. The Secretary, or his designee, shall grant delegation of one or more program elements to any Conservation District, county, municipality, or State agency seeking delegation that is found capable of providing compliance with Chapter 40 and these regulations. The final decision regarding delegation shall be made only after an opportunity has been provided for public review and comment. Initial consideration regarding delegation of program elements shall be given to the Conservation Districts. The Conservation Districts, having unique capabilities and areawide responsibilities are in ideal positions to coordinate and implement local sediment and stormwater programs.

3. Requests for delegation of more than one program element may be accomplished by the submission of one request for all the elements requested. A concern by the Department over one element will not jeopardize delegation of other requested program elements.

4. To be considered capable of providing compliance with Chapter 40 and these regulations, applications for delegation of program elements shall contain the following requisite items.

   A. Requests for delegation of plan approval responsibility shall include the following information:

      (1) Ordinance or program information detailing the plan approval process,

      (2) Plan review check lists and plan submission requirements,

      (3) Sediment and stormwater criteria, including waiver and variance procedures, that meet minimum standards established by these regulations,

      (4) Adequate personnel allocations and expected time frames for plan review which meet the requirements of Section 8(9), and

      (5) Assurance that plan reviewers will attend Departmental training programs in related fields such as wetlands identification, subaqueous permits requirements, etc.

   B. Requests for delegation of inspection during construction shall include the following information:

      (1) Inspection and referral procedures,

      (2) Time frames for inspection of active land disturbing activities,

      (3) Inspection forms,

      (4) Assurance of adequate personnel allocations or a timetable to obtain adequate personnel,

      (5) Criteria for the Certified Construction Reviewer if utilized, and

      (6) Procedures and time frames for processing complaints.

   C. Requests for delegation of maintenance inspection responsibility shall include the following information:

      (1) Inspection and referral procedures,

      (2) Inspection forms,

      (3) Time frames, not exceeding one year, for inspection of completed stormwater management structures, and

      (4) Assurance of adequate personnel allocation or a timetable to obtain adequate personnel.

   D. Requests for delegation of education and training responsibility shall include the following information:

      (1) Types of educational and training activities to be accomplished,

      (2) Frequency of activities,

      (3) Names and backgrounds of those individuals conducting the training, and

      (4) Procedures and timetables to notify the Department of educational programs.

5. A Conservation District, county, municipality, or State agency which has been granted delegation of one or more program elements may establish alternative requirements which are compatible with or are more stringent than Departmental requirements. These alternative requirements may be implemented only when prior Departmental approval has been granted. These alternative requirements shall apply in lieu of the provisions of these regulations in the specific program element that has been delegated. Alternative requirements shall be implemented only after public notice has been provided which would allow for public review and comment prior to Departmental approval.

6. Delegation of authority for one or more program elements may be granted for a maximum time frame of three years. After three years a new application to the Department must be made. Over the time frame for which delegation has been granted, the Department will evaluate delegation implementation, coordinate review findings with the delegated authority, and determine if the new delegation should be granted.

7. A Conservation District, county, municipality, or State agency requesting or renewing delegation shall submit a written request to the Secretary on or before January 1 of the year immediately preceding the fiscal year for which delegation or renewal of delegation is sought.

VOL 12

6829

R0040137

8. The Secretary shall, in writing, grant or deny delegation on or before April 1 of the year during which delegation is sought. The Secretary may not deny a requested delegation unless opportunity has been afforded to the appropriate officials to present arguments. Delegation shall be effective July 1 of that year and extend no more than three years, unless renewed. In the event that the Department does not act on the renewal request by April 1, the delegated authority submitting the request would be entitled to continue operating for a subsequent three year time period unless action is taken by the Department to suspend the program.

9. If the Secretary determines that a delegated program falls below acceptable standards established by these regulations, delegation may be suspended after opportunity is afforded for a hearing. During a period of suspension, the program element shall revert to the Department for implementation. Funds set aside by a delegated agency, that were collected through fees established by the plan approval agency, shall be transferred to the Department for use if delegation is suspended.

10. A delegated authority may subdelegate program elements, with Departmental concurrence, to a stormwater utility or other responsible entity or agency.

11. The Department shall maintain, and make available upon request, a listing of the current status of delegation for all jurisdictions within the State.

Section 6 — Permit Fees, Maintenance Fees, and Performance Bonds

1. The establishment of permit fees, not involving stormwater utilities, shall be in accordance with the following items:

   A. Delegation of program elements will depend, to a large extent, on funding and personnel commitments. If the delegated jurisdiction has a source of funding that is provided through State General or local revenues, then the implementation of the delegated component will not necessitate the imposition of a permit fee to cover the cost of the delegated program component.

   B. In the event that one component of an overall sediment and stormwater management program is not funded through the use of general or special funds, a non-refundable permit fee will be collected at the time that the sediment and stormwater management plan or application for waiver or variance is submitted or approved. The permit fee will provide for the unfunded costs of plan review, administration and management of the permitting office, construction review, maintenance inspection, and education and training. The plan review or permit approval agency, whether delegated or the Department, shall be responsible for the collection of the permit fee.

   Unless all program elements in a county or municipality have been delegated to a single agency, the funds collected not supporting the plan review function shall be distributed to the appropriate agencies.

   C. The number of needed personnel and the direct and indirect expenses associated with those personnel shall be developed by the agencies requesting delegation in a specific jurisdiction in conjunction with and with the concurrence of the Department. Those expenses will then form the basis for determining unit plan approval costs.

   D. Prior to plan approval, a fee may be assessed by the appropriate plan approval agency for those activities approved prior to July 1, 1991, for which construction will initiate after July 1, 1991.

   E. Where the Department becomes the designated plan approval agency, the Department may assess a plan review and construction review fee. That fee shall not exceed $80.00 per disturbed acre per project.

   F. The use of Certified Construction Reviewers for sediment control and the submission of "As Built or Record Document" certification regarding stormwater management construction may reduce the inspection requirements for the delegated agency but may not eliminate that inspection requirement. Periodic overview inspections will still be necessary to ensure construction management.

VOL 12 6830

2. The imposition of a financial guarantee, based on existing local authority, may be required by the plan approval agency to ensure that construction of the stormwater management practices was accomplished according to the approved sediment and stormwater management plan. The developer, when required, shall submit to the plan approval agency a surety or cash bond, or irrevocable letter of credit prior to the issuance of any building or grading permit for construction of any land disturbing activity that requires a stormwater management facility. The amount of the security shall not exceed 150 percent of the total estimated construction cost of the stormwater management facility. The financial guarantee so required shall include provisions relative to forfeiture for failure to complete work specified in the approved stormwater management plan, compliance with all the provisions of these regulations, and other applicable laws and regulations, and any time limitations. The financial guarantee, fully or partially, shall not be released without a final inspection of the completed work and, when required, after submission of "As Built or Record Document" plans, and after written confirmation by the design engineer that construction was accomplished according to the approved plans. A partial release of the financial guarantee shall be allowed only to the extent that the work already accomplished would warrant such release.

3. A maintenance fee may be required on approvals granted for stormwater management structures that will be maintained by a Conservation District, county, or municipality. A fee mechanism shall be established prior to the final release of any required financial guarantee or final approval of the completed stormwater management structure by the designated construction review agency.

Section 7—Criteria for Implementation of a Stormwater Utility

The implementation of a stormwater utility will necessitate the development of a local utility ordinance prior to its implementation. There are essential components that an ordinance must contain to function as a funding mechanism for stormwater management and those components shall include, but not be limited to, the following items:

1. The financing of a stormwater utility with a user charge system must be reasonable and equitable so that each user of the stormwater system pays to the extent to which the user contributes to the need for the stormwater system, and that the charges bear a substantial relationship to the cost of the service. The use of county and municipal taxpayer rolls and accounting systems are allowed for the assessment and collection of fees.

2. The intent of the utility must be clearly defined regarding program components that are to be funded through the utility. Those components may include but not be limited to the following activities:

   A. Preparation of long range watershed master plans for stormwater management,

   B. Annual inspections of all stormwater management facilities, both public and private,

   C. Undertaking regular maintenance, through contracting or other means, of stormwater management structures that have been accepted for maintenance,

   D. Plan review and inspection of sediment control and stormwater management plans and practices, and

   E. Retrofitting designated watersheds, through contracting or other means, to reduce existing flooding problems or to improve water quality.

3. The authority for the creation of the stormwater utility and the imposition of charges to finance sediment and stormwater activities is conferred in Chapter 40, Title 7, Delaware Code. The application of a stormwater utility by means of a local ordinance shall not be deemed a limitation or repeal of any other powers granted by State statute.

4. The creation of a stormwater utility shall include the following components:

   A. The boundaries of the utility, such as watersheds or jurisdictional boundaries as identified by the local governing body,

   B. The creation of a management entity,

   C. Identification of stormwater problems,

   D. Method for determining utility charges,

E. Procedures for investment and reinvestment of funds collected, and

F. An appeals or petition process.

5. As established by local ordinance, the local governing agency shall have responsibility for implementing all aspects of the utility including long range planning, plan implementation, capital improvements, maintenance of stormwater facilities, determination of charges, billing, and hearing of appeals and petitions. The local agency also will have responsibility for providing staff support for utility implementation.

   In the event that an agency or department other than the one in which the utility is located is best equipped to undertake a particular task, the local governing agency shall ensure that appropriate interagency charges are determined such that all costs of stormwater management are reflected in the utility budget and that utility charges finance all aspects of stormwater management.

6. With respect to new stormwater management facilities constructed by private developers, the local governing agency shall develop criteria for use in determining whether these will be maintained by the utility or by the facility owner. Such criteria may include whether the facility has been designed primarily to serve residential users and whether it has been designed primarily for purposes of stormwater management. In situations where it is determined that public maintenance is not preferable, standards shall be developed to ensure that inspection of facilities occurs annually and that facilities are maintained as needed.

7. The use of charges is limited to those purposes for which the utility has been established, including but not limited to: planning; acquisition of interests in land including easements; design and construction of facilities; maintenance of the stormwater system; billing and administration; and water quantity and water quality management, including monitoring, surveillance, private maintenance inspection, construction inspection, and other activities which are reasonably required.

Section 8 — Permit Application and Approval Process

1. After July 1, 1991, unless a particular activity is exempted by these regulations, a person may not disturb land without an approved sediment and stormwater management plan from the appropriate plan approval agency. A grading or building permit may not be issued for a property unless a sediment and stormwater management plan has been approved that is consistent with the following items:

   A. Chapter 40, Title 7, Delaware Code, relating to erosion and sediment control and stormwater management, and

   B. These regulations, or duly adopted county or municipal ordinances that are adopted as a part of the delegation process and relate to the intent of these regulations.

2. A sediment and stormwater management plan or an application for a waiver shall be submitted to the appropriate plan approval agency by the developer for review and approval for a land disturbing activity, unless otherwise exempted. The sediment and stormwater management plan shall contain supporting computations, drawings, and sufficient information describing the manner, location, and type of measures in which stormwater runoff will be managed from the entire development. The appropriate plan approval agency shall review the plan to determine compliance with the requirements of these regulations prior to approval. The approved sediment and stormwater management plan shall serve as the basis for water quantity and water quality control on all subsequent construction.

3. The sediment and stormwater management plan shall not be considered approved without the inclusion of an approval stamp with signature and date, on the plans by the appropriate plan approval agency.

4. All sediment and stormwater management plans submitted for approval shall contain certification by the owner or developer that clearing, grading, construction, or development will be accomplished pursuant to the plan and that responsible personnel involved in the land disturbance will have a Certification of Training at a Departmental sponsored or approved training program for the control of erosion and sediment control before initiation of the project. The Certification of Training for responsible personnel requirement may be waived by the appropriate plan ap-

VOL 12 6832

proval agency on any project involving silviculture or fewer than four residential homes.

5. All sediment and stormwater management plans shall contain certification by the owner or developer of the right of the Department or delegated inspection agency to conduct onsite inspections.

6. A grading or building permit issued by a local jurisdiction may be suspended or revoked after written notice is given to the permittee by the responsible delegated agency or the Department for any of the following reasons:

   A. Violations of the conditions of the sediment and stormwater management plan approval;

   B. Changes in site runoff characteristics upon which a waiver was granted;

   C. Construction not in accordance with the approved plans;

   D. Noncompliance with correction notice or stop work order issued for the construction of the sediment control practices or the stormwater management facilities;

   E. An immediate danger exists in a downstream area in the opinion of the appropriate plan approval or inspection agency, or the Department; or

   F. Failure to submit stormwater management "As Built or Record Document" plans, when required, at the completion of the project.

7. Approved plans remain valid for 3 years from the date of an approval, unless specifically extended or renewed by the appropriate plan approval agency. The basis for extension or renewal may include, but not limited to, the following items:

   A. Failure to initiate the approved project for reasons acceptable to the appropriate plan approval agency such as funding or other agency permit delays; or

   B. Time duration for a type of activity that typically exceeds three years.

8. Projects which have been approved prior to July 1, 1991, and where site clearing has not been initiated on the project within two years, shall be resubmitted to the appropriate plan approval agency for review and approval subject to the requirements of these regulations.

9. Upon receipt of a completed application for sediment and stormwater management, the appropriate plan approval agency shall accomplish its review within 30 calendar days, and have either the approval or review comments transmitted to the applicant. If that 30 day time frame cannot be met, the appropriate plan approval agency shall notify the applicant of the reasons for delay, and an expected time frame not to exceed an additional 30 days, when that review will be accomplished.

Section 9 — Criteria for Designated Watersheds

The concept of designated watersheds is intended, not only to prevent existing water quantity and water quality problems from getting worse, but also to reduce existing flooding problems and to improve existing water quality or meet State Water Quality Standards in selected watersheds. Criteria is established for designated watersheds and that criteria will depend on whether the specific problems of the watershed are water quantity or water quality oriented. Water quantity and water quality concerns will be considered in all designated watersheds, but the overall emphasis for each designated watershed will depend on its existing and anticipated problems.

1. To initiate consideration of a watershed for Designated Watershed or Subwatershed status, a watershed shall be recommended by a Conservation District, county, municipality, or State agency, to the Department. Upon recommendation to the Department, all involved agencies at the local level will be contacted and their input received prior to any watershed study being initiated.

2. Included with the recommendation of a watershed for Designated Watershed or Subwatershed status to the Department shall be an identification of the specific problems that exist in the watershed so that the pursuit of a watershed study is warranted. Inclusion in these regulations as a Designated Watershed or Subwatershed requires approval by the Department that a significant water quantity or water quality problem exists that would necessitate this joint State, District, and local government involvement. Also, inclusion of a watershed as a Designated Watershed or Subwatershed will necessitate a public hearing

VOL 12

6833

R0040141

process. The process of problem identification shall be based on the following information:

A. To initiate a watershed study based on water quality considerations the following information must be submitted:

(1) Existing water quality data that has been collected as a result of the overall statewide water quality inventory process, or

(2) Other water quality data collected through specific sampling that was accomplished in the watershed, or

(3) Submission of a water quality assessment that was accomplished using a qualitative collection method of benthic macroinvertebrates.

B. To initiate a watershed study based on flooding or water quantity considerations the following information must be submitted:

(1) Estimated annual flood damage to either private, residential, commercial, industrial, or public properties, or

(2) Number of residences or industries in the floodplain, or

(3) The history of flooding in the watershed, or

(4) Measures already taken to minimize or reduce flooding, or

(5) Dangers to public health and welfare.

3. Upon modification of these regulations to include a watershed as a Designated Watershed or Subwatershed an advisory group will be established that will guide the overall watershed study. The advisory group will be appointed by the Secretary and will include State, District, and local representatives in addition to representatives of the regulated community and others affected by the results of the study.

4. The general components contained in the actual watershed studies shall be the following items:

A. Stormwater quantity or water quality problem identification,

B. The overall needs of the watershed including the additional impacts of new development activities,

C. Alternative approaches to address the existing and future problems,

D. A selected approach that includes the overall costs and benefits,

E. Schedule for implementation,

F. Funding sources that are available for the actual implementation of study recommendations, and

G. A public hearing process prior to final Departmental approval.

5. The following goals are to be obtained through the implementation of the Designated Watershed or Subwatershed program:

A. Reduction of existing flooding or water quality impacts,

B. Prevention of future flooding or water quality impacts, and

C. Minimization of economic and social losses.

6. Specific plan components of a water quality watershed study shall include, but not be limited to, the following items:

A. The limits of the watershed,

B. An inventory of existing water quality data,

C. An inventory of areas having significant natural resource value as defined in existing State or local studies as they may be impacted by the construction or location of stormwater control structures,

D. An inventory of areas of historical and archaeological value identified in existing State or local studies as they may be impacted by the construction or location of stormwater control structures,

E. A map or series of maps of the watershed showing the following information:

(1) Watershed topography,

(2) Significant geologic formations,

(3) Soils information,

(4) Existing land use based on existing zoning,

(5) Proposed land use based on expected zoning or comprehensive plans,

(6) Location of tidal and nontidal wetlands, and

(7) Locations where water quality data were obtained.

F. An evaluation of water quantity concerns so that flooding does not become a problem in the watershed.

7. Specific components of a water quantity based study shall include, but not be limited to, the following items:

A. The limits of the watershed,

B. An inventory of historic flood damage sites, including frequency and damage estimates,

C. An inventory of areas of significant natural resource value as noted in existing State and local studies as they may be impacted by the construction or location of stormwater control structures,

D. An inventory of areas of historical and archaeological value identified in existing State and local studies as they may be impacted by the construction or location of stormwater control structures,

E. A map or series of maps of the watershed showing the following information:

(1) Watershed topography,

(2) Soils information,

(3) Existing land use based on existing zoning,

(4) Proposed land use based on expected zoning or comprehensive plans,

(5) Locations of tidal and nontidal wetlands,

(6) Locations of existing flooding problems including floor and corner elevations of structures already impacted, and

(7) 100-year floodplain delineations, water surface profiles, and storm hydrographs at selected watershed location.

F. An evaluation of water quality concerns so that water quality degradation does not become a problem in the watershed.

8. The initiation of studies for Designated Watersheds or Subwatersheds depends on the availability of funding for the study. Once a watershed has been designated, the Department will make every effort to secure funding through federal, State, or local means.

9. The Department is designated as the agency responsible for administering designated watershed or subwatershed studies with the advice of the advisory group appointed by the Secretary. Recommendations based on the results of the watershed study will only be made with the overall consent of the advisory group.

10. The formal results of the Designated Watershed or Subwatershed study will require formal acceptance by the local Conservation District Board of Supervisors and the local governing body of the appropriate county or municipality.

11. Implementation of the results of the Designated Watershed or Subwatershed study will necessitate the development and implementation of a dedicated funding source such as a stormwater utility to ensure design, construction, and maintenance of needed structures is accomplished.

12. Those watersheds or subwatersheds designated due to existing water quantity or water quality problems include the following:

A. Dover/Silver Lake/St. Jones River and all drainage areas upstream of the Silver Lake dam.

Section 10 — Specific Design Criteria and Minimum Standards and Specifications

1. General submission requirements for all projects requiring sediment and stormwater management approval include the following information:

A. A standard application form,

B. A vicinity map indicating north arrow, scale, and other information necessary to locate the property or tax parcel,

C. A plan at an appropriate scale accompanied by a design report and indicating at least:

(1) Name and address of

(a) The owner of the property where the project is proposed;

(b) The land developer; and

(c) The applicant.

VOL 12 6835

R0040143

(2) The existing and proposed topography, as required on a case-by-case basis.

(3) The proposed grading and earth disturbance including:

(a) Surface area involved; and

(b) Limits of grading including limitation of mass clearing and grading whenever possible.

(4) Stormwater management and stormwater drainage computations, including:

(a) Pre- and postdevelopment velocities, peak rates of discharge, and inflow and outflow hydrographs of stormwater runoff at all existing and proposed points of discharge from the site,

(b) Site conditions around points of all surface water discharge including vegetation and method of flow conveyance from the land disturbing activity, and

(c) Design details for structural controls.

(5) Erosion, sediment control, and stormwater management provisions including:

(a) Provisions to preserve top soil and limit disturbance;

(b) Details of site grading, and;

(c) Design details for structural controls which includes diversions and swales.

D. Federal Emergency Management Agency flood maps and federal and State protected wetlands, where appropriate.

E. The appropriate plan approval agency shall require that plans and design reports be sealed by a qualified design professional that the plans have been designed in accordance with approved sediment and stormwater ordinances, regulations, standards and criteria. The appropriate plan approval agency may waive this requirement on a case-by-case basis.

F. Additional information necessary for a complete project review may be required by the appropriate plan approval agency as deemed appropriate. This additional information may include items such as public sewers, water lines, septic fields, wells, etc.

2. Specific requirements for the erosion and sediment control portion of the sediment and stormwater management plan approval process include, but are not limited to, the following items. The appropriate plan approval agency may modify the following items for a specific project or type of project. Modification for a specific type of project will require the concurrence of the Department before that modification may be applied and that modification shall be subject to public review and comment prior to adoption.

A. All plans shall include details of temporary and permanent stabilization measures including placement of the following statement on all plans submitted for approval. Following soil disturbance or redisturbance, permanent or temporary stabilization shall be completed within 14 calendar days as to the surface of all perimeter sediment controls, topsoil stockpiles, and all other disturbed or graded areas on the project site.

These requirements do not apply to those areas which are shown on the plan and are currently being used for material storage, or for those areas on which actual earth moving activities are currently being performed.

B. All erosion and sediment control plans shall comply with the Delaware Erosion and Sediment Control Handbook, dated 1989 and approved supplements. The supplements shall be subject to public review and comment prior to their incorporation in the Erosion and Sediment Control Handbook.

C. A sequence of construction shall be contained on all plans describing the relationship between the implementation and maintenance of sediment controls, including permanent and temporary stabilization and the various stages or phases of earth disturbance and construction. The sequence of construction shall, at a minimum, include the following activities:

(1) Clearing and grubbing for those areas necessary for installation of perimeter controls;

(2) Construction of perimeter controls;

(3) Remaining clearing and grubbing;

(4) Road grading;

(5) Grading for the remainder of the site;

(6) Utility installation and whether storm drains will be used or blocked until after completion of construction;

(7) Final grading, landscaping, or stabilization; and

(8) Removal of sediment controls.

D. The plans shall contain a description of the predominant soil types on the site, as described by the appropriate soil survey information available through the local Conservation District.

E. Unless an exception is approved on a case-by-case basis or an exception is approved for a specific type of activity by the appropriate plan approval agency, not more than 20 acres may be cleared at any one time. Once grading is initiated in one 20-acre section, a second 20-acre section may have stumps, roots, brush, and organic material removed. This will necessitate the phasing of construction on sites in excess of 20 acres to minimize areas exposed of ground cover and reduce erosion rates. Grading of the second 20-acre section may not proceed until temporary or permanent stabilization of the first 20-acre section is accomplished.

3. Specific requirements for the permanent stormwater management portion of the sediment and stormwater management plan approval process include, but are not limited to, the following items. The appropriate plan approval agency may modify the following items for a specific project or type of project. Modification for a specific type of project will require the concurrence of the Department before the modification may be applied and the modification for a type of project shall be subject to public review and comment.

A. It is the overall goal of the Department to address stormwater management on a watershed by watershed basis to provide a cost effective water quantity and water quality solution to the specific watershed problems. These regulations will provide general design requirements that must be adhered to in the absence of Designated Watershed or Subwatershed specific criteria.

B. All hydrologic computations shall be accomplished using the most recent USDA Soil Conservation Service Technical Releases 20 or 55. The storm duration for computational purposes shall be the 24-hour rainfall event. For projects south of the Chesapeake and Delaware Canal, the Delmarva Unit Hydrograph shall be incorporated into the design procedure.

C. Stormwater management requirements for a specific project shall be based on the entire area to be developed, or if phased, the initial submittal shall control that area proposed in the initial phase and establish a procedure and obligation for total site control.

D. Water quantity control is an integral component of overall stormwater management. Control of peak discharges will, to some extent, prevent increases in flooding. The following design criteria for peak flow control is established for water quantity control purposes, unless a waiver is granted based on a case-by-case basis:

(1) Projects in New Castle County that are located north of the Chesapeake and Delaware Canal shall not exceed the post-development peak discharge for the 2, 10, and 100-year frequency storm events at the pre-development peak discharge rates for the 2, 10, and 100-year frequency storm events.

(2) Projects in New Castle County that are located south of the Chesapeake and Delaware Canal, Kent County, and Sussex County shall not exceed the postdevelopment peak discharge for the 2 and 10-year frequency storm events at the predevelopment peak discharge rates for the 2 and 10-year frequency storm events.

(3) Watersheds, other than Designated Watersheds or Subwatersheds, that have well documented water quantity problems may have more stringent, or modified, design criteria that is responsive to the specific needs of that watershed. Modified criteria for that watershed must receive Departmental approval, and all projects reviewed and approved by the appropriate plan approval agency shall

VOL 12

6837

R0040145

meet or exceed the modified criteria. Proposed modification of criteria for a watershed shall be subject to public review and comment prior to implementation.

E. Water quality control is also an integral component of stormwater management. Control of water quality on-site will prevent further degradation of downstream water quality. The following design criteria are established for water quality protection unless a waiver or variance is granted on a case-by-case basis.

   (1) In general, the preferred option for water quality protection shall be ponds. Ponds having a permanent pool of water must be considered before a pond having no permanent pool. Infiltration practices shall be considered only after ponds have been eliminated for engineering or hardship reasons as approved by the appropriate plan approval agency.

   (2) Water quality ponds having a permanent pool shall be designed to release the first 1/2 inch of runoff from the site over a 24-hour period. The storage volume of the normal pool shall be designed to accommodate, at least, 1/2 inch of runoff from the entire site.

   (3) Water quality ponds, not having a normal pool, shall be designed to release the first inch of runoff from the site over a 24-hour period.

   (4) Infiltration practices, when used, shall be designed to accept, at least, the first inch of runoff from all streets, roadways, and parking lots.

   (5) Other practices may be acceptable to the appropriate plan approval agency if they achieve an equivalent removal efficiency of 80 percent for suspended solids.

F. All ponds that are constructed for stormwater management shall be designed and constructed in accordance with the USDA Soil Conservation Service Small Pond Code 378, dated September 1990, as approved for use in Delaware.

G. Any pond utilized for water supply purposes, or for irrigation, must obtain approval from the Department for that use pursuant to Chapter 60.

H. Where ponds are the proposed method of control, the developer shall submit to the approving agency, when required, an analysis of the impacts of stormwater flows downstream in the watershed for the 100-year frequency storm event.

   The analysis shall include hydrologic and hydraulic calculations necessary to determine the impact of hydrograph timing modifications of the proposed development, with and without the pond, on downstream dams, highways, structures, or natural points of constricted streamflows past which the timing effects would be considered negligible. The results of the analysis will determine the need to modify the pond design or to eliminate the pond requirement. Lacking a clearly defined downstream point of constriction, the downstream impacts shall be established, with the concurrence of the approving agency, downstream of a tributary of the following size:

   (1) The first downstream tributary whose drainage area equals or exceeds the contributing area to the pond; or

   (2) The first downstream tributary whose peak discharge exceeds the largest designed release rate of the pond.

I. Where existing wetlands are intended as a component of an overall stormwater management system, the following criteria shall apply:

   (1) The only disturbance to the wetland, for the purposes of these regulations, shall be that disturbance caused by the stormwater management pond embankment placement and construction; or

   (2) The applicant can demonstrate that the intended or functional aspects of the stormwater management facility and wetlands are maintained or enhanced, or the construction in the wetland for stormwater management is the only reasonable alternative.

   (3) All other necessary State and federal permits can be obtained.

J. Designs shall be in accordance with standards developed or approved by the

Department, which are subject to public review and comment.

K. Ease of maintenance must be considered as a site design component. Access to the stormwater management structure must be provided for in the design, and land area adjacent to the structure must be set aside for disposal of sediments removed from the structure when maintenance is performed. The land set aside for pond maintenance shall be sized as follows:

(1) The set aside area shall accommodate at least 2 percent of the stormwater management basin volume to the elevation of the 2-year storage volume elevation;

(2) The maximum depth of the set aside volume shall be one foot;

(3) The slope of the set aside area shall not exceed 5 percent; and

(4) The area and slope of the set aside area may be modified if an alternative area or method of disposal is approved by the appropriate plan approval agency.

L. A clear statement of defined maintenance responsibility shall be established during the plan review and approval process.

M. All ponds shall have a forebay or other design feature to act as a sediment trap. A reverse slope bench must be provided one foot above the normal pool elevation for safety purposes and all embankment ponds, having a normal pool, shall have a drain installed to facilitate maintenance.

N. The use of infiltration practices for the disposal of stormwater runoff is classified by the U.S. EPA as an underground injection control practice, class V injection well. The appropriate plan approval agency shall forward a copy of all such approvals and the results of all construction inspections to the Department's Underground Injection Control program manager.

O. Infiltration practices have certain limitations on their use on certain sites. These limitations include the following items:

(1) Areas draining to these practices must be stabilized and vegetative filters established prior to runoff entering the system. Infiltration practices shall not be used if a suspended solids filter system does not accompany the practice. If vegetation is the intended filter, there shall be, at least, a 20-foot length of vegetative filter prior to stormwater runoff entering the infiltration practice;

(2) The bottom of the infiltration practice shall be at least three feet above the seasonal high water table, whether perched or regional, determined by direct piezometer measurements which can be demonstrated to be representative of the maximum height of the water table on an annual basis during years of normal precipitation, or by the depth in the soil at which mottling first occurs;

(3) The infiltration practice shall be designed to completely drain of water within 48 hours.

(4) Soils must have adequate permeability to allow water to infiltrate. Infiltration practices are limited to soils having an infiltration rate of at least 1.02 inches per hour.

Initial consideration will be based on a review of the appropriate soil survey, and the survey may serve as a basis for rejection. On-site soil borings and textural classifications must be accomplished to verify the actual site and seasonal high water table conditions when infiltration is to be utilized.

(5) Infiltration practices greater than three feet deep shall be located at least 20 feet from basement walls;

(6) Infiltration practices designed to handle runoff from impervious parking lots or driveways shall be a minimum of 150 feet from any public or private water supply well;

(7) The design of an infiltration practice shall provide an overflow system with measures to provide a nonerosive velocity of flow along its length and at the outfall; and

(8) The slope of the bottom of the infiltration practice shall not exceed 5 percent. Also, the practice shall not be installed in fill material as piping

along the fill/natural ground interface may cause slope failure.

(9) Unless allowed on a specific project, infiltration practices will be used primarily for water quality enhancement only.

(10) An infiltration practice shall not be installed on or atop a slope whose natural angle of incline exceeds 20 percent.

P. A regional approach to stormwater management is an acceptable alternative to site specific requirements. As a substitute control practice, regional stormwater management structures shall be required to meet the following items:

(1) They shall have a contributory drainage area not in excess of 400 acres unless, on a case-by-case basis, a larger drainage area is approved by the appropriate plan approval agency;

(2) They shall have a permanent pool of water and provide for 24-hour detention of the first inch of stormwater runoff from the entire upstream watershed; and

(3) All other necessary approvals have been obtained that could be cause for site rejection.

Q. The predevelopment peak discharge rate shall be computed assuming that all land uses in the site to be developed are in good hydrologic condition.

Section 11 — General Permit Criteria

1. A general permit involves completion and submission of a form by a land owner, developer, or agent to the appropriate plan approval agency for signature. The minimum criteria for the form will be developed by the Department, and may be expanded upon by the appropriate plan approval agency. The form will contain standard conditions for erosion and sediment control that must be implemented on sites where a specific control plan is not required. The appropriate plan approval agency shall approve general permit requests within 5 calendar days of receipt.

2. The inclusion of an activity into the general permit classification does not relinquish that activity from the requirements of Chapter 40. Rather, the general permit precludes that activity from the necessity of a specific plan review for each individual project.

3. Approval of a general permit does not relieve the applicant from the conditions that are a part of the general permit approval regarding the implementation of control practices as required by the general permit. Failure to implement control practices pursuant to conditions included in the general permit may necessitate appropriate enforcement action as provided in Chapter 40 and these regulations.

4. Those activities eligible for general permits include the following:

   A. Individual detached residential home or agricultural structure construction where the disturbed area for construction will be less than one acre in size. Two or more contiguous lots being developed concurrently by the same land developer will not be eligible for the general permit.

   B. Forest harvest operations.

   C. Highway shoulder and side swale maintenance.

   D. The repair, maintenance, and installation of above and underground utilities.

   E. Commercial and industrial projects for erosion and sediment control only when the total disturbed area of the project is less than 1/2 acre in size.

   F. Modification or reconstruction of a tax ditch by a tax ditch organization when that tax ditch is not intended to serve new development, and which will not increase water quantity or adversely impact water quality, or change points of discharge so as to adversely affect the waters of the State.

5. The appropriate plan approval agency may place more restrictive conditions upon the general permits approval including the requirement for site specific plans for any general permits category. The imposition of more specific requirements for categories of projects shall be approved by the Department, and shall be subject to public review and comment prior to their imposition.

Section 12 — Certified Construction Reviewer Requirements

1. Projects reviewed and approved by the Department for sediment control and stormwater management, in general, shall have a certified construction reviewer when the disturbed area of the project is in excess of 50 acres. In addition any project, regardless of its size, may be required by the Department, or the appropriate plan approval agency, to have a certified construction reviewer on a case-by-case basis.

2. The Department or the appropriate inspection agency may require that any project, already under construction, have on site a certified construction reviewer if, on that project, significant sediment control or stormwater management problems necessitate more frequent inspections.

3. The certified construction reviewer shall function under the direction of a registered professional engineer licensed to practice engineering in the State of Delaware.

4. Individuals designated as certified construction reviewers shall attend and pass a Departmental sponsored or approved construction review training course. The course content will contain, at a minimum, information regarding the following items:

   A. Basic hydrology and hydraulics;

   B. Soils information including texture, limitations, erodibility, and classifications;

   C. Types of vegetation, growing times, and suitability;

   D. Erosion, sediment control, and stormwater management practices;

   E. Inspection and problem referral procedures;

   F. Aspects of State law, regulations, local ordinances, and approval procedures; and

   G. Sediment and stormwater management plan content.

5. The time frame for certification shall not exceed five years unless extended by the Department.

6. The responsibility of the certified construction reviewer will be to ensure the adequacy of construction pursuant to the approved sediment and stormwater management plan.

7. The certified construction reviewer shall be responsible for the following items:

   A. Provision of a construction review of active construction sites on at least a weekly basis;

   B. Within five calendar days, informing the person engaged in the land disturbing activity, and the contractor, by a written construction review report of any violations of the approved plan or inadequacies of the plan. The plan approval agency shall be informed, if the approved plan is inadequate, within five working days. In addition, the appropriate construction review agency shall receive copies of all construction review reports; and

   C. Referral of the project through the delegated inspection agency to the Department for appropriate enforcement action if the person engaged in the land disturbing activity fails to address the items contained in the written construction review report. Verbal notice shall be made to the Department within two working days and written notice shall be provided to the Department within five working days.

8. If the Secretary or his designee determines that a certified construction reviewer is not providing adequate site control or is not referring problem situations to the Department, the Secretary or his designee may suspend or revoke the certification of the construction reviewer.

9. In any situation where a certified construction reviewer's approval is being suspended or revoked, an opportunity for hearing before the Secretary or his designee shall be provided. During any suspension or revocation, the certified construction reviewer shall not be allowed to provide construction reviews pursuant to these regulations. The minimum time of suspension or revocation shall be 6 months.

Section 13 — Contractor Certification Program

1. The Department shall require certification of responsible personnel for any foreman or superintendent who is in charge of on-site clearing and land disturbing activities for sediment and stormwater control associated with a

construction project. Responsible personnel are not required on any project involving silviculture or fewer than four residential homes. Responsible personnel shall obtain certification by completing a Department sponsored or approved training program. Enrollment of existing and future responsible personnel is the responsibility of employers. Response to a Department notice of training and certification in accordance with the provisions of item 3 of this section shall serve as an application for training. The Department shall notify employers of responsible personnel as to the date and location of training programs for attendance by responsible personnel and other interested persons.

2. After July 1, 1991, any applicant seeking sediment and stormwater plan approval shall certify to the appropriate plan approval agency that all responsible personnel involved in the construction project will have a certificate of attendance at a Departmental sponsored or approved training course for the control of sediment and stormwater before initiation of any land disturbing activity. The certificate of attendance shall be valid until the Department notifies the individual or announces in local newspapers that recertification is required due to a change in course content.

3. After July 1, 1991, employers of responsible personnel may receive interim certification for responsible personnel during the period before attendance at a Departmental sponsored or approved training course by submitting an enrollment form to the Department. Interim certification shall be valid until the scheduled date of attendance for training of responsible personnel. These enrollment forms are available from the Department and the Conservation Districts.

Section 14 — Construction Review and Enforcement Requirements

1. The land developer shall request, at least 24 hours ahead of time, that the appropriate inspection agency approve work completed at the stages of construction outlined in the sequence of construction contained on the approved plans. Any portion of the work which does not comply will be promptly corrected by the developer after written notice by the appropriate inspection agency. The notice shall set forth the nature of corrections required and the time frame within which corrections must be made.

2. The land developer shall notify the appropriate inspection agency before initiation of construction and upon project completion when a final inspection will be conducted to ensure compliance with the approved sediment and stormwater management plan.

3. The responsible inspection agency shall, for inspection purposes, do all of the following items:
   - A. Ensure that the approved sediment and stormwater management plans are on the project site and are complied with;
   - B. Ensure that every active site is inspected for compliance with the approved plan on a regular basis;
   - C. Prepare and leave on site, or forward to the contractor, a written report after every inspection that describes:
     - (1) The date and location of the site inspection;
     - (2) Whether the approved plan has been properly implemented and maintained;
     - (3) Approved plan or practice deficiencies; and
     - (4) The action taken.
   - D. Notification of on-site personnel or the owner/developer in writing when violations are observed, describing the
     - (1) Nature of the violation;
     - (2) Required corrective action; and
     - (3) Time period for violation correction.

4. The Department may investigate complaints or refer any complaint received to the local inspection agency if the activity is located in a jurisdiction that has received delegation of sediment and stormwater management inspection. In conjunction with a referral, the Department may also initiate an on-site investigation after notification of the local inspection agency in order to properly evaluate the complaint. The Department shall take enforcement action when appropriate, and notify the local inspection agency in a timely manner of any enforcement actions taken.

5. The Department, at its discretion and upon notification to either the owner, developer, or contractor, may visit any site to determine the

adequacy of sediment and stormwater management practices. In the event that the Department conducts site inspections, the appropriate inspection agency shall be notified prior to the initiation of any enforcement action. The appropriate inspection agency shall establish a time frame to obtain site compliance. This notification shall, in no way limit the right to the Department to take action subsequent to any provision of these regulations or Chapter. Formal procedures for interaction between the Department and the appropriate inspection agency on site inspection and referral will be developed on an individual basis.

6. The appropriate plan approval agency may require a revision to the approved plans as necessary due to differing site conditions. The appropriate plan approval agency shall establish guidelines to facilitate the processing of revised plans where field conditions necessitate plan modification. Where changes to the approved plan are necessary those changes shall be in accordance to the following:

   A. Major changes to approved sediment and stormwater management plans, such as the addition or deletion of a sediment basin, shall be submitted by the owner/developer to the appropriate plan approval agency for review and approval.

   B. Minor changes to sediment and stormwater management plans may be made in the field if approved by the construction reviewer and documented in the field review report. The appropriate inspection agency shall develop a list of allowable field modifications for use by the construction reviewer.

7. Stormwater management construction shall have inspections accomplished at the following stages:

   A. Infiltration practices shall be inspected at the commencement, during, and upon completion of construction;

   B. All ponds shall be inspected at the following stages:

      (1) Upon completion of excavation to sub-foundation and where required, installation of structural supports or reinforcement for structures, including, but not limited to

         (a) Core trenches for structural embankments,

         (b) Inlet-outlet structures and anti-seep structures, watertight connectors on pipes, and

         (c) Trenches for enclosed storm drainage facilities.

      (2) During placement of structural fill, concrete, and installation of piping and catch basins;

      (3) During backfill of foundations and trenches;

      (4) During embankment construction; and

      (5) Upon completion of final grading and establishment of permanent vegetation.

8. The agency responsible for construction review may, in addition to local enforcement options, refer a site violation to the Department for additional enforcement action.

9. Referral of a site violation to the Department may initiate a Departmental construction review of the site to verify site conditions. That construction review may result in the following actions:

   A. Notification through appropriate means to the person engaged in a land disturbing activity and the contractor to comply with the approved plan within a specified time frame; and

   B. Notification of plan inadequacy, with a time frame for the person engaged in a land disturbing activity to submit a revised sediment and stormwater plan to the appropriate plan approval agency and to receive its approval with respect thereto.

   The Department shall notify the local inspection agency in a timely manner of what enforcement action is taken on the site.

10. Failure of the person engaged in the land disturbing activity or the contractor to comply with Departmental requirements may result in the following actions in addition to other penalties as provided in Chapter 40.

   A. The Department shall have the power to issue a cease and desist order to any person violating any provision of Chapter 40

VOL 12

6843

R0040151

and these regulations by ordering such person to cease and desist from any site work activity other than those actions necessary to achieve compliance with any administrative order.

B. The Department may request that the appropriate plan approval agency refrain from issuing any further building or grading permits to the person having outstanding violations until those violations have been remedied.

Section 15 — Maintenance Requirements

1. For erosion and sediment control, all practices shall be maintained in accordance with requirements specified in the Delaware Sediment and Erosion Control Handbook dated 1989 or as directed by the construction reviewer.

2. Prior to the issuance of any building or grading permit for which stormwater management is required, the responsible plan approval agency shall require the applicant or owner to execute an inspection and maintenance agreement binding on all subsequent owners of land served by the private stormwater management facility. Such agreement shall provide for access to the facility at reasonable times for regular inspection by an inspection agency and for an assessment of property owners to ensure that the stormwater management structure is maintained in proper design working condition.

3. The Department encourages, and will provide technical assistance to, any Conservation District or local jurisdiction who chooses to assume the maintenance responsibility for stormwater management structures on, at least, residential lands. Public maintenance provides a reasonable assurance that maintenance will be accomplished on a regular basis.

4. The owner or person responsible shall perform or cause to be performed preventive maintenance of all completed stormwater management practices to ensure proper functioning. The responsible inspection agency shall ensure preventive maintenance through inspection of all stormwater management practices. The inspections shall occur at least once each year.

5. Inspection reports shall be maintained by the responsible inspection agency on all detention and retention structures and those inspection reports shall include the following items:

   A. The date of inspection;

   B. The name of the inspector;

   C. The condition of

      (1) Vegetation,

      (2) Fences,

      (3) Spillways,

      (4) Embankments,

      (5) Reservoir area,

      (6) Outlet channels,

      (7) Underground drainage,

      (8) Sediment load, or

      (9) Other items which could effect the proper function of the structure.

   D. Description of needed maintenance.

6. Responsible inspection agencies shall provide procedures to ensure that deficiencies indicated by inspections are rectified. The procedures shall include the following:

   A. Notification to the person responsible for maintenance of deficiencies including a time frame for repairs;

   B. Subsequent inspection to ensure completion of repairs; and

   C. Effective enforcement procedures or procedures to refer projects to the Department if repairs are not undertaken or are not done properly.

Section 16 — Penalties

1. Any person who violates any rule, order, condition imposed in an approved plan or other provision of these regulations shall be fined not less than $200 or more than $2,000 for each offense. Each day that the violation continues shall constitute a separate offense. The Justice of the Peace Courts shall have jurisdiction of offenses brought under this subsection.

2. Any person who intentionally, knowingly, and after written notice to comply, violates or refuses to comply with any notice issued pursuant to these regulations shall be fined not less than $500 or more than $10,000 for each

offense. Each day the violation continues shall constitute a separate offense. The Superior Court shall have jurisdiction of offenses brought under this subsection.

Section 17 — Hearings

The conduct of all hearings conducted pursuant to these regulations shall be in accordance with the relevant provisions of Delaware Code, Title 7, Chapter 60.

Section 18 — Severability

If any section, subsection, sentence, clause, phrase, or portion of these regulations are for any reason held invalid or unconstitutional by any court or competent jurisdiction, such provision and such holding shall not affect the validity of the remaining portions of these regulations.

Acknowledgements

This report would not have been possible without the assistance of many people. The staff of the Clean Water Project at the Natural Resources Defense Council extends its sincere appreciation to all those who provided information and reviewed portions of the report in its draft stages. These individuals are too numerous to name, but include Tom Davenport and Jim Meek of the U.S. Environmental Protection Agency; Roland Geddes and Stuart Wilson of the Virginia Division of Soil and Water Conservation; Eric Livingston of the Florida Department of Environmental Regulation; Gaylon Lee of the California State Water Resources Control Board; Philip Wheeler of the Rochester-Olmsted County (Minnesota) Consolidated Planning Department; and Justin Ward, Tom Kuhnle, Sarah Chasis, Johanna Wald, Laura King and Ann Notthoff of the Natural Resources Defense Council.

We offer special thanks to the members of our Advisory Committee* for their invaluable comments on the report:

Advisory Committee

Edwin H. Clarke III	The Conservation Foundation
William Cox	Virginia Polytechnic Institute and State University
Henry Peskin	Edgevale Associates
Eugene Lamb	National Association of Conservation Districts
Walter Rittall	U.S. Department of Agriculture Soil Conservation Service

* While the Advisory Committee provided valuable advice and assistance in preparing this report, the opinions expressed herein are those of NRDC and do not necessarily represent the views of individual Advisory Committee members.

Preface

Poison Runoff is the product of two years of research made possible by a generous grant from the Virginia Environmental Endowment. The report was developed based on an analysis of hundreds of personal and telephone interviews, articles, reports and government publications. Through this report NRDC hopes to make a serious contribution to efforts to control what is euphemistically called "nonpoint source" pollution—and what we have more aptly labelled "poison runoff."

It has been known for many years that the sediment, nutrients, bacteria and toxics generated by various land use activities contaminate both our surface waters and our groundwater. Agriculture, urban development, silviculture, mining and livestock grazing continue to contribute to the decline in the quality of our nation's waters. In fact, many consider the contamination from these diffuse sources to be more significant today than pollution from industrial and sewage treatment plant outfalls. Waters such as the Chesapeake Bay literally are being choked to death by poison runoff.

While our understanding of the severity of this diffuse disaster has improved significantly, public response to the problem largely has not. For the third time since the passage of the Clean Water Act in 1972, the federal government is attempting to improve state and local control of poison runoff. Given our poor record in addressing this major water quality problem, it is clear that a serious search is needed for new solutions. *Poison Runoff* represents such a search.

Over the years, some consensus has emerged regarding the basic principles that should guide our efforts to control "non-point" source pollution to achieve the nation's water quality goals. Today many of these principles are being used successfully in state and local programs scattered across the country. But until now, no single publication has discussed all of these principles and described all of these programs in a single place.

Poison Runoff identifies these principles and documents and describes these successful programs. More important, *Poison*

Runoff discusses how to combine these ideas into a comprehensive program to attack the problem.

The report indicates that there is wide disparity in the stringency and effectiveness of nonpoint source management programs in this country. Although many people view poison runoff as a management problem with no real "preferred alternative" solution, our research indicated that some program approaches clearly are more effective than others. Therefore, the principles represented in this report form the foundation for the "minimum standards" that should be reflected in state programs to control poison runoff. A successful program need not contain *all* of the elements included in this report. Nor should a good program be limited to these ideas. But by following the basic principles identified in "Poison Runoff," and by drawing from the exemplary programs identified, state and local governments can begin to fight this serious water quality problem more effectively.

VOL 12

6856

How to Use This Report

Beyond the value of *Poison Runoff* as a general reference for persons interested in nonpoint source management, it also can be used by government officials and involved citizens to develop or to evaluate the adequacy of state and local programs (and program proposals) to control poison runoff. These programs include individual control activities as well as a state's overall effort to manage diffuse water pollution sources statewide—notably the Nonpoint Source Management Plan developed by each state pursuant to Section 319 of the Clean Water Act.

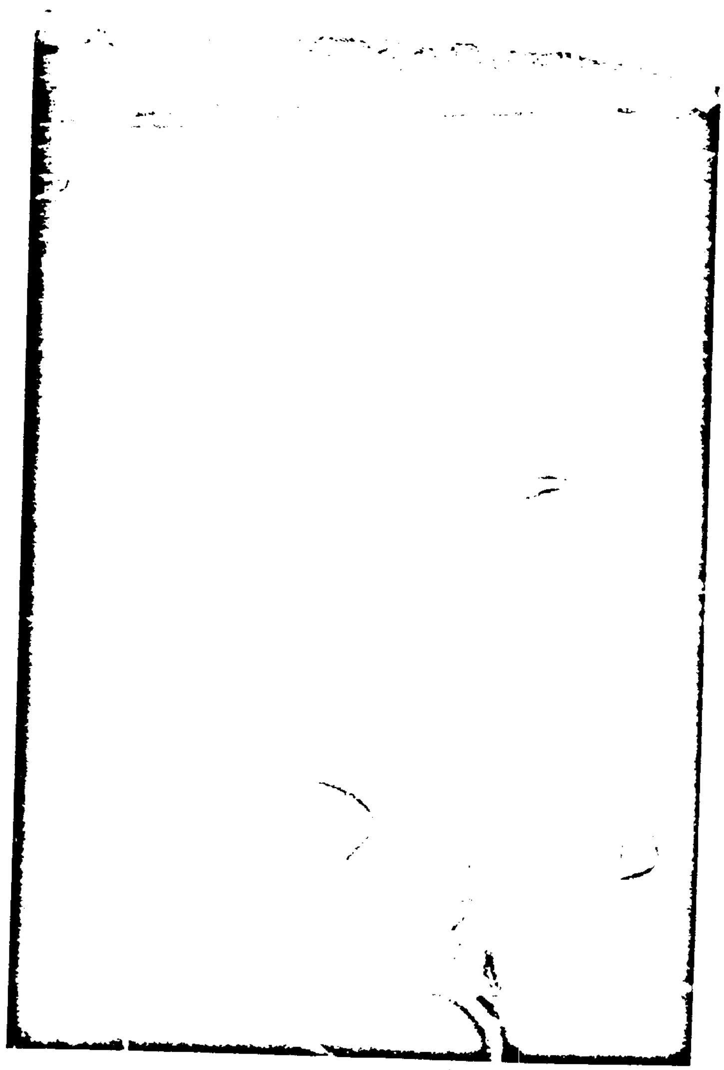
To use this report to evaluate specific state and local programs, first familiarize yourself with the various chapter titles, which correspond to the fundamental building blocks of a comprehensive program to control poison runoff. Those persons only interested in a specific aspect of a state's overall program (*e.g.*, agricultural pollution control programs) should locate the chapter in the report that corresponds with the program component in question.

For the most thorough discussion of that particular program component, the entire chapter should be reviewed. The first part of each chapter discusses the important issues concerning the component. It spells out the management principles essential to effective poison runoff control. The next part of each chapter describes current state, regional and local programs that illustrate one or more of these principles. Readers desiring speedier answers can turn to the final part of each chapter, which provides recommendations that summarize the findings for the particular program component discussed in the chapter.

Individual recommendations, examples and principles can be used to "dissect" each program component of concern. In so doing, the reader will be able both to identify the strengths and the weaknesses of the program, and to shed light on how it can be improved. Notes at the end of each chapter will lead the reader to additional sources of information.

Those persons interested in evaluating a state's overall effort to control poison runoff can follow the same procedure for each chapter in the report. As an example, the Case Study at the end of *Poison Runoff* uses the procedure outlined above to evaluate the Virginia Nonpoint Source Management Plan submitted to the U.S. Environmental Protection Agency in August, 1988.

Finally, a set of questions is presented after the final chapter of the report that summarizes all of the basic principles addressed throughout. By answering those questions, the reader will create a rough outline of the strengths and weaknesses of a state's or locality's poison runoff control program (or component). Thus, this summary can serve as the reader's own evaluation blueprint.



Vast land areas often contribute to the degradation of individual rivers, lakes or coastal areas.

VOL 12

6869

Chapter One

A Framework for Controlling Poison Runoff

Introduction

A large body of research during the last decade has produced evidence that nonpoint sources contribute a major share of many serious pollutants to our lakes and streams. Without controls, nonpoint source pollution will prevent achievement in a portion of water in at least 37 States of our 1983 goal of fishable and swimmable waters.

There is little doubt that nonpoint sources have a direct, serious impact on the uses Americans make of water. Nonpoint source pollution has appeared in community after community as a pathway for toxic and hazardous pollutants with direct effects on human health. We view with increasing concern the frequent findings of heavy metals in urban and mining runoff, and pesticides and herbicides in agricultural runoff. In many urban areas, nonpoint pollution has significantly raised the cost of providing safe domestic drinking supplies.

In many rural areas, nonpoint sources have contaminated family wells and livestock water supplies. Saline pollution, which is also nonpoint in nature, significantly impairs yields of many irrigated crops in western States....

> The country stands today at a crossroad in its progress toward the 1983 goals—while we have taken giant steps to clean up point source pollution, similar progress on nonpoint source control is lacking. The job of controlling nonpoint sources will not be easy. The political and economic problems to be solved in applying nonpoint controls ("best management practices" or "BMPs") are substantial. Although many State and local governments have already led the way by enacting sediment control, cost-sharing, forest practices or mine-drainage laws on their own initiative, many areas are not controlling nonpoint problems.... In the past eight years, we have just begun to fathom the true depths of our water problems.

This clear, compelling description of the nonpoint source problem—and the call for swift action—was delivered by the EPA Administrator at a Congressional hearing. The Administrator was Douglas Costle; the year, 1979.[1]

Nearly a full decade later the country still stands at the same crossroad, having taken barely a step forward. The severity of the poison runoff problem and the need for constructive, effective action is just as great, if not greater, than it was when these words were written.

By now the statistics have grown all too familiar: according to the most recent national survey, nonpoint sources accounted for approximately 65% of the stream miles for which States reported impairments of water quality;[2] 76% of impaired lake acres were attributed by the States to nonpoint sources.[3] In fact, the trend for lakes appeared to be worsening from 1984 (when the previous national survey was issued) to 1986; and nonpoint pollutants continue to be "by far the leading cause of use impairment" in U.S. lakes.[4] In estuarine waters, too, pollution from nonpoint sources is the largest single cause of the impairments cited by the States—accounting for 45% of the problem.[5] And the downward trend in estuarine water quality is still more pronounced than the trend for lakes.[6] Finally, ground water

VOL 12 6870

R0040178

contamination from agricultural activities was reported to be a problem by 79% of the States reporting on water quality.[7]

This epidemic of poison runoff includes a wide range of pollutants that stem from a broad range of activities. When thinking of erosion and other types of runoff from agriculture and construction sites, many people think only of soil particles and sediment. While this type of pollution alone can have drastic effects,[8] poison runoff also contains a wide range of even more insidious contaminants. A study conducted by Resources for the Future for the U.S. Geological Survey, the National Oceanographic and Atmospheric Administration, and EPA found that, of 16 common water pollutants studied, a number came principally from diffuse sources:[9]

Pollution	Poison Runoff Contribution
Iron	95%
Total Nitrogen	90%
Fecal coliform bacteria	90%
Chemical oxygen demand	70%
Oil	70%
Zinc	70%
Phosphorus	66%
Lead	57%
Chromium	50%

The high levels of nutrients (primarily nitrogen and phosphorus) in urban and agricultural runoff promotes excess growth of algae in lakes and estuaries—a process known as eutrophication. Algal blooms deplete the oxygen available for fish and other aquatic organisms, literally choking the life out of water bodies.

Poison runoff also contains pollutants that are acutely toxic to fish and wildlife, and that pose a threat to human health when they contaminate drinking water, fish and shellfish. Agricultural runoff (and groundwater infiltration) contains pesticides and other chemicals. At least 67 toxic pollutants have been detected in runoff from urban areas,[10] including heavy metals, pesticides, spilled petroleum and other chemical products, and other toxic organic pollutants. Runoff from construction sites

VOL 12

6871

Nonpoint Source Pollution - A Pointless Euphemism

Since the Clean Water Act uses the term *nonpoint sources* to describe land use activities that cause sediment, nutrient, bacterial and toxic water quality contamination, the use of the term (as well as its equally meaningless abbreviation—*NPS*) in programmatic as well as research literature has become every bit as ubiquitous as the pervasive problem it describes. The public, the politicians and the water quality managers have given this "diffuse disaster" a low priority in the past. Labeling our leading cause of water pollution with such a passive, undirected, "non-term" helps to perpetuate the notion that the problem is too vague, ill-defined and insignificant to warrant high priority. Therefore, wherever possible, this report largely replaces the use of the terms "nonpoint source" and "NPS" with "poison runoff" in order to describe more accurately its impact on aquatic (and in many cases human) life. It should be noted that, like "nonpoint source," "poison runoff" can be, and often is, used as a "catch-all" phrase to include the impacts of diffuse sources of water pollution on groundwater as well as surface water.

can be contaminated with construction chemicals, such as pesticides, petroleum products, solvents, asphalt, acids and salts.[11] Water contaminated by active and abandoned mining sites can be polluted by toxic metals such as lead, arsenic, zinc, cadmium, mercury and cobalt, as well as acid mine drainage.[12]

The purpose of "Poison Runoff," however, is not to document the gravity of this growing pollution problem. Numerous studies already have quantified the effects of diffuse sources of water pollution, and the costs of this pervasive poison in terms of water quality degradation, lost farm productivity, recreational resource impacts and wildlife habitat destruction, to name but a few.[13]

VOL 12

6872

R0040180

Nor is it the purpose of this report to try to persuade readers that the time has come to take action to control poison runoff. That decision has already been made—by Congress and by the majority of the states. This decision is reflected in the language of the Clean Water Act:

> it is the national policy that programs for the control of nonpoint sources of pollution be developed and implemented in an expeditious manner so as to enable the goals of [the Clean Water Act] to be met through the control of both point and nonpoint sources of pollution.[14]

Rather, the pages that follow are directed to decisionmakers and interested citizens who already have made up their minds that the time has come to confront and overcome the problems of poison runoff—people who are looking for creative and effective ways to implement solutions.

Admittedly, it will not be easy to eliminate pollution from agricultural and urban runoff, from mining and forestry, from grazing and construction and a host of other activities. The sources of this pollution are numerous and diverse. Poison runoff can stem from virtually every human activity—hence, from virtually every person. And major gaps exist in our knowledge and understanding of how much pollution derives from each source, the effects of this pollution, and the best control strategies.

This report does not claim that all of these scientific uncertainties about pollution transport, fate, effect and control have been resolved; instead, it gives guidance on how to make the most of the information presently available, while continuing to gather and refine the scientific database. Particularly when it comes to *preventing further water quality degradation*, additional study cannot be an excuse for more delay. And the size and ubiquity of the nonpoint source problem justify speedier and more aggressive—not hesitant and half-hearted—corrective action.

Poison Runoff answers many of the common questions that officials and citizens face about what should be the structure and content of local and state programs designed to control the land use activities that cause water pollution. In the pages that follow we describe what we hope is a comprehensive master plan for state and local officials, and interested citizens who want to develop and implement an effective, efficient and comprehensive program to control pollution generated by diffuse sources. We believe that if water quality management officials and others in state and local government follow the recommendations in this report, they will be well on the way to protecting our rivers, lakes and coastal waters from the pervasive effects of poison runoff.

Contaminated runoff cannot be controlled absent strong support for the principles and ideas contained in this report. Even the most effective "paper" programs can be rendered impotent without support from politicians and program administrators. In fact, some of the most promising programs described in this report have been hampered by a lack of enforcement or emphasis in some other vital program area due to state or local political circumstances. These pitfalls also must be considered (although they are not the subject of this report) by the grass roots organizer, the interested voter, and the intrepid public official charged with implementing an effective program.

Report Organization

The road to program failure is paved with unfocused goals and poorly-planned good intentions. *Poison Runoff* is intended to help avert such failures–to pave the way to effective control by walking decisionmakers and citizens through the many steps that lead to development of a program that is designed to comply with the requirements of the Clean Water Act (CWA) by achieving state water quality objectives. These steps include (1) determining precisely what the goals of effective control must be; (2) developing, implementing and enforcing the most effective tools and strategies to control polluted runoff from each type of source; and (3) combining these control strategies for each type of pollutant source into an effective, comprehensive and coordinated statewide plan.

A clearly articulated program goal is the key starting point for controlling poison runoff, and that is where *Poison Runoff* begins. To set the stage, decisionmakers need to focus on the exact nature of their mandate.

The Clean Water Act, the nation's most important water pollution control law, provides the states with both the clear

VOL 12

6874

R0040182

mandate and the legal authority for dealing with poison runoff. We therefore begin this report with a description of the Clean Water Act, and what it requires that states do to control poison runoff. Part One includes a "road map" of the CWA's requirements for controlling poison runoff (Chapter Two), which makes clear that the achievement of "fishable and swimmable" water quality must be the overriding management goal of each state's effort to control diffuse sources of pollution.

It is no secret that, to date, federal and state nonpoint source control programs have not succeeded in achieving this water quality goal. In Chapter Two we also present a brief general review of the existing poison runoff control framework under the CWA. This review pinpoints the deficiencies that have hampered success, and explains why it is not appropriate for state and local decisionmakers to expect federal action alone, or simple state and local implementation of existing federal programs, to substitute for effective new programs at the state and local level. In so doing, we establish a firm basis for the development of state programs that build effectively on beneficial aspects of existing federal programs, but are not hamstrung by the limitations of those programs.

State and local control of poison runoff requires a high degree of coordination and organization. Different governmental entities, such as water quality, agriculture, and transportation agencies, must work together. In addition, different levels of government–federal, state, regional and local–must coordinate and plan together. Municipal and county governments often are needed as partners in the control of poison runoff, as are logging, mining and grazing interests.

A state's control program must weave the various actors and managers together. In essence, it should consist of two major elements: (1) a series of *effective, efficient program components* to address each major type of source, and (2) *a planning and implementation infrastructure* that brings those components together to achieve the statewide goal of meeting water quality protection goals.

Addressing these two basic elements of an effective state program presents a classic chicken-or-egg dilemma: it is hard to say which one must come first, and neither one can do the job alone. In this report we address the specific components first. *Poison Runoff* covers the specific components before the planning and implementation discussion, largely because decisionmakers may find it easier to translate the planning and implementation suggestions into action if they already have the specific program components before them. Part Two of *Poison Runoff* addresses these key components in six chapters. The first three chapters in Part Two describe the best ways to control particular types of nonpoint source pollution:

Chapter Three - Agriculture;
Chapter Four - Land Use and Urban Runoff; and
Chapter Five - Silviculture, Mining and Grazing.

The next three chapters in Part Two address specific management tools for poison runoff control programs:

Chapter Six - Data Collection and Use;
Chapter Seven - Funding; and
Chapter Eight - Legal Considerations.

Part Three of *Poison Runoff* consists of two chapters designed to help decisionmakers plan and implement the components described in Part Two—to put all the components together into a unified, effective program. In the first chapter we describe the essential process of tying management of diffuse sources to the achievement of water quality goals, through reliance on the state's water quality standards program. In the next chapter we describe how to implement the program through the coordinated, integrated operation of state, regional and local institutions.

Some states and localities have developed innovative approaches to meet many of these difficult challenges—both the challenges of controlling specific types of pollution (covered in Part Two), and the challenges of planning for and implementing their overall management programs (Part Three). Wherever possible we present examples and anecdotal accounts of programs with effective management or planning components that could be adapted and adopted in other states and localities.

Where no single outstanding example exists, we cull from existing programs the most successful elements that can be built upon by decisionmakers. At the end of Part Three, we synthesize the recommendations developed throughout this report into a brief section of Evaluation Questions and Recommendations. Part Four consists of an application of these evaluation questions and recommendations to a particular state: we conduct an in-depth case study of the state of Virginia's program to control poison runoff.

Virginia was selected for NRDC's case study because approximately half of the Commonwealth is located in the watershed of the Chesapeake Bay, one of America's most productive—and most critically threatened—estuarine watersheds. Virginia also serves as a valuable case study because it is facing many of the problems associated with the management of diffuse sources of water pollution that all states will need to confront: it has some regions that are predominantly agricultural, as well as densely populated (and rapidly growing) urban areas. In addition, its Chesapeake Bay shoreline is being threatened with rapid overdevelopment. In the case study we make specific program recommendations for the state of Virginia, thereby offering decisionmakers from other states a clear model of how to apply the Evaluation Questions to their own circumstances effectively. The same exercise can be conducted by citizens who want to prepare a constructive critique of the nonpoint source program in their state or locality.

Once the reader has considered the many issues presented in this report, we hope that he or she will be prepared to analyze a state's or locality's present set of nonpoint source programs, by posing the key questions presented in *Poison Runoff:* Is the program specifically designed to achieve water quality goals based on the process required under the CWA? Does it require or encourage the most effective on-the-ground control methods? Are all of the necessary players (from state agencies to local zoning officials to the public) involved? Does it consist of a sensible mix of educational, technical assistance, regulatory and planning elements? Does it have adequate funding? Is it enforceable? Decisionmakers then should be equipped to make the adjustments necessary to improve their control of poison runoff so that they can meet the "fishable and swimmable" goals of the Clean Water Act.

14. Clean Water Act § 101(a)(7); 33 U.S.C. § 1251(a)(7). The Clean Water Act is the common term for the Federal Water Pollution Control Act (FWPCA). While predecessor laws date back to 1948 (P.L. 80-845), the FWPCA was enacted substantially in its present form in 1972 (P.L. 92-500). Major amendments were enacted in 1977 (P.L. 95-217), 1981 (P.L. 97-117) and 1987 (P.L. 100-4). The "CWA" is used here to refer to the Act as amended in 1972 and thereafter. The policy cited in the text was added to the CWA as part of the new nonpoint source pollution control provision contained in the 1987 Water Quality Act (WQA) amendments, WQA § 316(b), which is discussed in detail in Chapter Two.

Chapter Two

Nonpoint Source Pollution Control Under the Clean Water Act

Introduction

The federal Clean Water Act (CWA)[1] establishes the fundamental mandate for states to control water pollution, including pollution from nonpoint sources. While many other federal, state, and local laws and regulations are critical to the control of poison runoff,[2] the CWA and its implementing regulations establish the benchmark against which all of these programs must be measured.

The 1987 Water Quality Act (WQA) amendments to the CWA[3] added a number of new provisions addressing poison runoff. In particular, the WQA created new section 319 of the Clean Water Act, which requires states to develop comprehensive programs for the control of poison runoff. However, long before the 1987 amendments were enacted the CWA and EPA's implementing regulations already required states to control the water pollution generated by various types of land use.

In fact, while the 1987 amendments have been billed as a major new mandate,[4] they provided little in the way of additional *substantive authority or requirements* for controlling poison runoff. But the 1987 changes did reinvigorate control efforts by setting firm new deadlines for adoption of management programs, by highlighting the important role of programs to control this ubiquitous problem in restoring the Nation's surface and ground waters, by formalizing existing requirements in more precise statutory language, and by authorizing increased resources for control programs. Recent increases in efforts by EPA and the states to address poison runoff largely have been in response to the 1987 amendments.

This chapter includes a description of the fundamental legal requirements for nonpoint source control programs set forth in the CWA and in EPA regulations implementing the Act. Statutory and regulatory requirements in place before the 1987 amendments are described first, since the States may be able to draw on existing programs as a starting point for compliance with section 319. The specific changes included in the 1987 amendments are described next. The chapter concludes by distilling key legal principles from the CWA that should guide state development and implementation of programs to control poison runoff.

Nonpoint Source Control Requirements Before the 1987 CWA Amendments

Since 1972 the CWA has required that EPA and the states devise comprehensive programs to control water pollution from both point and nonpoint sources. Section 102(a) of the CWA requires the development of "comprehensive programs for preventing, reducing, or eliminating the pollution of the navigable waters and ground waters and improving the sanitary condition of surface and underground waters."[5] Similarly, section 201(c) of the CWA provides:

> To the extent practicable, waste treatment management shall be on an areawide basis and provide control or treatment of *all point and nonpoint sources* of pollution, including in place or accumulated pollution sources.[6]

While the CWA has permitting provisions for the control of pollution from point sources,[7] the means to enforce the control of poison runoff are considerably less precise.

Point sources are defined in the law as follows:

> The term "point source" means any discernable, confined and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, or vessel or other floating craft, from which pollutants are or may be discharged. This term does not include agricultural stormwater discharges and return flows from irrigated agriculture.[8]

(The last sentence excluding irrigation return flows was added in 1987.) By implication, a "nonpoint source" is *any* source of pollutants not included in the definition of point source.[9] As we explain below, the legal requirements and authority for control of poison runoff are linked to the basic goals and requirements of the CWA.

The Water Quality Standards Process

The most fundamental objective of the CWA is "to restore and maintain the chemical, physical, and biological integrity of the Nation's waters."[10] While the CWA sought to achieve this fundamental objective by establishing a national goal of eliminating the discharge of *all* pollutants into the nation's waters by 1985,[11] this lofty goal has proven elusive. In practice, success in cleaning up the nation's surface waters (*i.e.*, moving towards the zero discharge goal) is measured by reference to *state water quality standards*, which are developed, implemented and enforced under section 303 of the CWA.[12]

Water quality standards consist of two components: (1) beneficial designated uses for all waters, such as protection of fish and aquatic life or public drinking water supply; and (2) water quality criteria necessary to protect each designated use.[13] Water quality criteria set specific instream water quality measurements necessary to protect designated uses, and include both general narrative requirements and numeric criteria for individual pollutants.[14] In addition, water quality standards must include an "antigradation" provision designed to ensure that clean waters stay clean.[15]

In general, the CWA gives individual states considerable discretion in setting water quality standards. However, there are two major underlying requirements.[16] First, Congress established a minimum goal for allowable designated uses:

VOL 12

6884

R0040192

> it is the national goal that wherever attainable, an interim goal of water quality which provides for the protection and propagation of fish, shellfish, and wildlife and provides for recreation in and on the water be achieved by July 1, 1983.[17]

This requirement is commonly known as "fishable and swimmable waters." Second, water quality criteria necessary to protect designated uses must be based on purely scientific factors, rather than such considerations as economic or technological feasibility.[18] Where state water quality standards are inadequate, EPA is required to promulgate substitute federal standards.[19]

As interpreted by EPA, state water quality standards serve a dual purpose: "establishing the water quality goals for a specific water body and serving as the regulatory basis for establishment of water quality-based treatment controls and strategies ...."[20] These dual purposes, particularly the "regulatory" purpose, are critical to nonpoint source control programs for two reasons. First, compliance with water quality standards is the fundamental goal of all water quality programs. *Therefore, all programs to control poison runoff should—indeed, must—be designed to achieve compliance with water quality standards.*[21]

Second, *water quality standards form the principal legal authority for controlling pollution generated by various land use activities.* While point sources of pollution are subject to mandatory control requirements that exist independent of water quality goals,[22] controls on diffuse sources are grounded in the mandate to meet water quality standards.[23] This link is explained below.

Implementing Water Quality Standards

The primary tool for meeting, or implementing, water quality standards is set forth in section 303 of the CWA. Under section 303(d)(1)(A), states must identify all waters for which technology-based effluent limitations on point sources alone are not enough to ensure compliance with water quality standards.[24] Next, for each such water, states must calculate a "total maximum daily load" (TMDL) of pollutants (for each pollutant criterion violated) "at a level necessary to implement the applicable water quality standards with seasonal variations and a margin of safety...."[25] Finally, each state must incorporate these

VOL 12

6885

R0040193

TMDLs into its "continuing planning process" under section 303(e) of the Act.[26] As with the water quality standards themselves, EPA is required to review state TMDLs, and to promulgate a federal TMDL where a state TMDL is inadequate.[27]

TMDLs were supposed to apply to nonpoint sources through the operation of each state's comprehensive water quality management plan prepared under section 208 of the Act.[28] Comprehensive water quality management plans under section 208 must consider poison runoff from a number of sources, including agriculture, silviculture, mining, construction, salt-water intrusion, land and subsurface disposal of pollutants, and other sources.[29] As part of the 208 "planning process," guidelines for identifying nonpoint sources of pollution and for devising methods to control poison runoff, were published by EPA.[30] EPA also dispersed funds to designated state 208 planning agencies.

EPA's regulations further clarify the link between compliance with water quality standards and control of poison runoff. EPA defines the TMDL process as follows: "Loading capacity" is the maximum amount of pollution that a water can receive without violating water quality standards;[31] "Load allocation" (LA) is the portion of loading capacity that is to be "allocated" to nonpoint source polluters or to natural background sources;[32] the "Wasteload allocation" (WLA) is the portion of loading capacity to be "allocated" to point source discharges.[33] The TMDL is the sum of all LAs and WLAs.[34] In short:

> *Nonpoint Source Loads* plus *Background Sources* (LA) plus *Point Source Loads* (WLA) can never exceed the receiving water's Total Maximum Daily Load (TMDL).

Under EPA's regulations, states not only must identify waters that do not meet water quality standards and determine by how much those standards are exceeded; they also must allocate allowable loadings between point sources and nonpoint sources/natural background sources, and further must distinguish nonpoint sources from natural background wherever possible. And the regulations further require states to allocate controls on pollutant loadings among WLAs for point sources and LAs for nonpoint sources.[35]

The requirement that water quality standards be met by controlling nonpoint sources is clarified further in EPA's regulations for state water quality management plans. The regulations reiterate that states must include in their water quality management plans "best management practices" (BMPs) for poison runoff,[36] and more expressly relate its control requirements to achieving water quality standards:

> The plan *shall* describe the regulatory and nonregulatory programs, activities and Best Management Practices (BMPs) which the agency has selected as the means to control nonpoint source pollution *where necessary to protect or achieve approved water uses.*[37]

Still more significant is the requirement in EPA's rules that control strategies for poison runoff *include regulatory programs* where necessary to meet water quality standards, or where non-regulatory approaches are "inappropriate".[38]

Recent federal court opinions confirm that, even under the pre-1987 CWA, water quality standards apply to discharges from nonpoint sources. The Ninth Circuit Court of Appeals held in two separate cases that water quality standards must be considered in assessing the broad, nonpoint source effects of forestry operations.[39] Similarly, the Fourth Circuit recently upheld a decision by EPA to condition a grant for sewage treatment plant construction on a requirement to protect floodplain areas from development.[40] EPA reasoned that development in floodplains would cause nonpoint source runoff, and adversely affect the adjoining waters. The Court upheld EPA's action based on the Agency's broad authority to implement the comprehensive water quality goals of the Clean Water Act, including the goal of restoring and maintaining the chemical, physical and biological integrity of the nation's waters.

To summarize, the pre-1987 requirements of the CWA and EPA regulations may have an undeserved reputation for lack of fortitude.[41] Under EPA's preexisting regulations, states were required to establish water quality standards for all waters. Standards had to be set at levels necessary to meet fishable and swimmable uses wherever attainable. States were required to identify all waters where water quality standards were not met after applying effluent limitations on point sources. In these cases, additional water quality controls had to be imposed on point sources through more stringent limits, and on nonpoint sources through BMPs and other control strategies included in section 208 management plans. Finally, where nonregulatory approaches to reduce poison runoff were not adequate, states were supposed to resort to regulatory programs.

Implementation of the Pre-1987 Law

As explained above, comprehensive areawide water quality management plans under CWA § 208 were supposed to play a major role in overall water quality management, and in particular, in addressing pollution from contaminated runoff. The statute and EPA regulations provided ample authority for states to control poison runoff. In general, however, the areawide plans were not effective, and poison runoff generally remained unchecked.

Some problems in the 208 program sprang from deficiencies in the law itself. Most important was the fact that the program stressed planning rather than plan implementation.[42] While the CWA clearly required compliance with water quality standards regardless of whether pollution derived from point or nonpoint sources, no specific controls were mandated for nonpoint sources, as they were for point sources. Thus, while section 208 provided states with adequate *authority* to control poison runoff, it did not clearly *require* adequate program *implementation*. Many 208 plans simply remained on the shelves after they were completed.

Congress, too, deserves its share of the blame. Funding for 208 activities was spotty beginning in 1973, and was discontinued altogether in 1981.[43] As a result, to the extent they have been funded at all, poison runoff control programs have been funded by the states primarily through general revenues (*i.e.*, without dedicated sources of funding) and at levels that are relatively low in relation to other comparable environmental programs. Programs to control soil erosion and poison runoff are typically funded in the $1-5 million/year range.[44]

But the failure of 208 planning also resulted in part due to EPA's failure to carry out its statutory responsibilities. The issuance of EPA guidance documents and regulations often was

VOL 12

6888

delayed, and administration support for the program was limited and poorly coordinated.[45] Moreover, EPA failed to use its existing statutory authority effectively to require greater state efforts to control poison runoff. For example, under section 303(e)(2), EPA may not approve an NPDES program[46] for any state that lacks an approved continuing planning process, including all elements of an applicable section 208 plan—and a 208 plan must include poison runoff controls. Yet EPA did not use this authority effectively to require the proper implementation of section 208 plans. Similarly, EPA has made little use of its authority to force states to develop adequate wasteload allocations.[47]

In 1983, when legislation to address the void left by the collapse of 208 programs was being considered, EPA's official position was that the agency had no direct role in controlling poison runoff.[48] EPA did not support any federal grants to state or local nonpoint source management officials. And the Reagan administration actively opposed the provision of the 1987 amendments which created the Section 319 poison runoff control program, and authorized $400 million in federal funding over a five year period.[49] In light of this lethargic EPA attitude towards implementation of the 208 program and other efforts to control poison runoff, it is no wonder that the pre-1987 law was not effective.

Additional Requirements in the 1987 Water Quality Act

Despite the extensive existing requirements for controlling poison runoff described above, progress in reducing this pollution has been very slow.[50] The figures cited in the previous chapter demonstrate that, at least on the national level, the past ten years have seen little progress in reducing the impacts of this pervasive poison. Not satisfied with the progress that had been made,[51] Congress concluded that there was a need to strengthen—or at least to clarify—existing control requirements in the CWA.[52]

In the 1987 WQA, therefore, Congress addressed poison runoff head on with the adoption of *section 316*. Section 316 of

VOL 12

6889

the WQA has a number of subsections, each of which augments the CWA's focus on the problem of diffuse sources of water pollution.

Subsection (a) created a new *section 319* of the CWA. *Section 319* requires that each state develop and submit to EPA a comprehensive management plan to address poison runoff. (This provision will be described in greater detail later in the chapter.)

Subsection (b) highlights the control of poison runoff as one of the major goals of the CWA:

> it is the national policy that programs for the control of nonpoint source pollution be developed and implemented in an expeditious manner so as to enable the goals of this Act to be met through the control of both point and nonpoint sources of pollution.[53]

Subsections (c) and (d) provided additional grant funds for states and EPA to address nonpoint source pollution.[54] And subsection (e) amended section 304(k)(1) of the CWA to require that EPA enter into agreements with other agencies for "maximum utilization" of federal programs in order to control poison runoff.

The Requirements of CWA § 319

The bulk of the requirements added by the WQA are contained in new CWA § 319. In many cases, CWA § 319 restates, clarifies, or redefines existing requirements under preexisting law and regulations. But some new authority is added as well.

States are directed to identify waters that, "without additional action to control nonpoint sources of pollution, cannot reasonably be expected to attain or maintain applicable water quality standards or the goals and requirements of this Act."[55] This requirement, in effect, restates the law's pre-existing requirements, as implemented by EPA's regulations. However, it does require that states more precisely identify those waters that do not meet water quality goals due in large part to diffuse sources.

Each State also must identify specific subcategories of nonpoint sources, or even "particular nonpoint sources" that add "significant pollution" to each of the designated waters.[56] Again, this requirement echoes the law's preexisting requirements,[57] albeit in a more precise and pointed fashion. For each source of poison runoff identified, CWA § 319 requires the state to develop a detailed management plan to address the resulting pollution problem, including BMPs and other regulatory and nonregulatory programs.[58]

A related new incentive is a provision allowing downstream states that are on the receiving end of poison runoff to ask EPA to convene a "management conference" to bring the offending upstream sources under control.[59]

EPA also plays a critical role. Section 319 requires that EPA review and approve each state's nonpoint source assessment *and* management plan.[60] Where a state fails to submit a timely *assessment*–presumably a timely and *adequate* assessment–EPA is required to prepare such an assessment by August 1, 1989.[61] By contrast, the Act falls short of authorizing EPA to promulgate a federal *management plan* for controlling poison runoff.[62] Instead, when EPA disapproves a state management plan, the state has an additional 3 months to promulgate a revised plan.[63] The Act is silent on the ramifications of a second inadequate submission, except that states with inadequate plans are not eligible for CWA § 319 grant funds.[64]

EPA also issued guidance that states were to follow when preparing the assessments and management programs called for in the Act, in order to be eligible for federal funds.[65] EPA continues to provide technical assistance and other information to state and local nonpoint source management officials through publications, workshops, and informal meetings.[66]

Since the 1987 Water Quality Act was passed, the Administration has made little or no effort to obtain funding from Congress for its implementation. While EPA's Office of Water has been working to develop guidance to the States concerning the listing of impaired waters and the development of management plans in order to implement Section 319, the agency's failure to seek or obtain any federal financing for the States has sent a strong, negative message to state and local officials.

Nor has the pace of EPA's oversight of state water quality standard-setting kept pace with the need to address poison runoff. Although EPA officials recognize the relationship of

VOL 12

6891

R0040199

water quality standards to poison runoff,[47] few federal criteria directly applicable to nonpoint source pollution impacts have been developed and, as a consequence, the states have little federal guidance on which to base their own standard-setting. As a general matter, in the two years since enactment of the 1987 amendments EPA has continued to display its historical hesitancy to dictate poison runoff control approaches to the states, and has shied away from asserting a forceful leadership role in the development of State nonpoint source management programs.

One key example is EPA's implementation of the new requirements of section 319, which authorizes EPA to *disapprove* inadequate state management plans.[48] Instead of using this leverage to send states a firm message that the time has come to increase vastly attention to poison runoff control, EPA's guidance to the states on implementation of section 319 requirements places few meaningful "teeth" in the approval/disapproval process. Virtually no mention is made in EPA guidance of the need to develop new water quality standards, Load Allocations or water quality-based controls. Nor does EPA direct the states to rely on other sources of authority (such as use of the antidegradation standard to mandate the development of nonpoint controls) to bring about effective state program development.[49]

In sum, even in the best of all possible worlds the federal nonpoint source management role still would comprise only the first level of what must be a multi-tiered effort to control the pervasive problem of poison runoff.

While federal efforts can be of great use to state and local governments when effectively implemented, no federal program can or should purport to tackle the whole poison runoff problem—or even any single aspect of the problem—from start to finish. States need to be fully informed about what help is available from the federal government, so that they can take advantage of federal programs and integrate those programs into their comprehensive state management strategy. But states also must be keenly aware of what is *not* provided by the federal government, for it is here that the lion's share of state and local efforts will be needed.

VOL 12

6892

Distinctions Between Pre- and Post- 1987 Nonpoint Source Requirements

While in many respects CWA § 319 largely restates existing requirements, there are a number of significant differences advanced by the new provision. Most importantly, CWA § 319 strengthens the *substantive standard for nonpoint source control program effectiveness.* CWA § 208 requires control of diffuse sources "to the *extent feasible.*"[70] Reflecting that tone, EPA's water quality standards regulations require control programs to be "cost effective and reasonable" before states can justify lower designated stream uses, or before states can allow degradation of streams with high water quality.[71] By contrast, CWA § 319(a)(1)(C) demands that states reduce nonpoint source pollution "to the *maximum extent practicable* ..." (emphasis added).[72] This will demand a higher level of control and a more stringent standard of proof before degradation or downgrading can be permitted.

CWA § 319 also strengthens the regulatory link between poison runoff and groundwater contamination. As with poison runoff, many preexisting sections of the CWA are relevant to groundwater protection requirements, but little had been done to implement the mandate.[73]

Under the 1987 amendments section 319(b)(2)(A) now specifically requires states to develop BMPs "taking into account the impact of the practice on ground water quality." The Senate Report explained:

> States are required to consider the impact of management practices on groundwater quality. Because of the intimate hydrologic relationship that often exists between surface and groundwater, it is possible that measures taken to reduce runoff of surface water containing contaminants may increase transport of these contaminants to groundwater. The State should be aware of this possibility, when defining best management practices, especially in aquifer recharge areas.[74]

Other changes made by section 319, while largely procedural, nevertheless are potentially significant. First, section 319 reasserts many existing requirements of the CWA and EPA regulations in a single section, and requires states to develop a separate management plan to address poison runoff, instead of incorporating control efforts as one of many aspects of their other planning responsibilities.[75] To this extent, it may stimulate more detailed, comprehensive plans.

But more important, section 319 imposes specific deadlines. Completed lists of affected waters and management plans were required to be submitted to EPA by August, 1988.[76] And Congress required that states incorporate into their plans specific milestones and internal deadlines, stressing that schedules should "provide for utilization of [BMPs] at the *earliest practicable date.*"[77]

Section 319(b)(4) also seems to impose a more site-specific approach on planning by requiring states to develop and to implement their management programs, to the maximum extent practicable, on a "watershed-by-watershed basis."[78] Arguably, this requirement already existed in the mandate of section 303 and 40 CFR Part 130 to calculate TMDLs on a water by water basis. But again, Congress' effort to consolidate this requirement with respect to nonpoint sources in particular may stimulate a more focused effort.

Conclusions and Recommendations

Based on the above analysis, the CWA and EPA regulations establish the following fundamental legal principles that each State should use as its guide in developing and implementing its poison runoff control plans:

1. Management plans must be designed to achieve compliance with state water quality standards. This includes both the attainment of all existing designated uses, and upgrading designated uses where additional controls will allow higher beneficial uses to be met. Control programs should also be incorporated fully into each state's antidegradation program.

2. Control plans must identify all surface water segments that are not attaining designated uses or the minimum fishable and swimmable goals of the CWA, and in which nonpoint sources contribute any significant amount of pollution.

3. Control of diffuse sources of water pollution should be accomplished through a comprehensive planning and management approach. Management plans under section 319 should draw upon, and incorporate where possible, existing information and programs developed under sections 208 and 303 of the CWA.

4. For each affected waterbody, plans to control poison runoff should calculate the total pollutant load reductions necessary to achieve designated uses and the minimum fishable and swimmable goals of the CWA. Based on the total load reductions, states should calculate specific load reductions for poison runoff necessary to meet these uses and goals, and demonstrate how these reductions will be achieved.

5. Where nonregulatory programs are not adequate or feasible, regulatory programs must be developed to achieve the calculated load reductions.

6. Management programs must reduce poison runoff "to the maximum extent practicable."

7. BMPs and other controls must be achieved at the "earliest practicable date."

8. Wherever possible, management programs must be developed on a watershed-by-watershed basis.

9. Management programs must consider the effect of various control strategies and practices on groundwater contamination.

15. 40 CFR § 131.12. Antidegradation applies equally to point and nonpoint sources. U.S. EPA, *Questions and Answers on: Antidegradation,* August, 1985, at 6.

5896

16. Other minimum requirements for state water quality standards, such as implementation methods and an antidegradation program, are set forth in 40 CFR Part 131. EPA reviews state water quality standards for compliance with the minimum requirements of the Act and its own regulations, and must disapprove nonconforming standards. CWA § 303(c)(3), 33 U.S.C. § 1313(c)(3).

17. CWA § 101(a)(2), 33 U.S.C. § 1251(a)(2).

18. 40 CFR § 131.11. Under the Clean Water Act, economic and technological feasibility are considered in determining *how* to meet water quality standards, and to a lesser extent, in deciding what designated uses were attainable by 1983. *See* 40 CFR § 131.10(g)(6).

19. CWA § 303(c)(3), 33 U.S.C. § 1313(c)(3).

20. 40 CFR § 130.3; *see also* 40 CFR §§ 130.1(b), 131.2.

21. In fact, the degree to which poison runoff can be controlled dictates whether or not designated uses of individual waters are considered attainable:

> At a minimum, uses are deemed attainable if they can be achieved by the imposition of effluent limits ... and cost-effective and reasonable best management practices for nonpoint source control. 40 CFR §§ 131.10(d), 131.10(h)(2); 33 U.S.C. § 1315(b)(1).

In effect, a state cannot legally decide that the minimum fishable/swimmable goal of the Clean Water Act is not attainable in a particular surface water unless the state has developed a poison runoff control program that controls nonpoint sources to the maximum extent practicable, and *still* is unable to achieve fishable/swimmable water quality. Similarly, under EPA's antidegradation regulation, even where water quality is better than necessary to protect designated instream uses, allowing further degradation is prohibited unless, among other requirements, the state assures the achievement of "all cost effective and reasonable best management practices for nonpoint source control." 40 CFR § 131.12(a)(2); 33 U.S.C. § 1313(e).

22. CWA § 301, 402; 33 U.S.C. §§ 1311, 1342; *Crown Simpson Pulp Co. v. Costle*, 642 F.2d 323, 326-327 (9th Cir. 1981).

23. Of course, states are always free to impose more stringent controls than expressly required by the Clean Water Act. CWA § 510, 33 U.S.C. § 1370. Described above are provisions that *require* states to address poison runoff.

24. 33 U.S.C. § 1313(d)(1)(A). In addition, periodic state reports to EPA must identify the extent to which water quality standards are met. These reports must include a "description of the nature and extent of nonpoint sources of pollution," and recommendations on how to control poison runoff. CWA § 305(b)1), 33 U.S.C. § 1315(b)(1).

25. 33 U.S.C. § 1313(d)(1)(C).

26. 33 U.S.C. § 1313(e)(3)(c).

27. CWA § 303(d)(2); 33 U.S.C. § 1313(d)(2).

28. 33 U.S.C. § 1288.

29. CWA § 208(b)(2)(F)-(K), 33 U.S.C. § 1288(b)(2)(F)-(K). The specific poison runoff control requirements in section 208 are admittedly vague. For example, agriculturally and silviculturally related poison runoff must be identified "if appropriate," and pollution from these sources must be controlled "to the extent feasible ...." CWA § 208(b)(2)(F), 33 U.S.C. § 1288(b)(2)(F). Some leverage is added by CWA § 208(e), which requires that no discharge permit can be issued to a point source which is in conflict with a comprehensive water quality management plan. 33 U.S.C. § 1288(e); 40 CFR § 130.12(a). Thus, where an activity requires an NPDES permit under section 402 of the CWA and also involves poison runoff (such as a mining site), BMPs and other control measures can be enforced against the activity through the NPDES permit.

30. CWA § 304(f), 33 U.S.C. § 1314(f). These guidelines, developed pursuant to 40 CFR 131, consisted of documents published between 1976 and 1978 for use by state and areawide planning agencies that were involved in preparing water quality management plans to address poison runoff associated with construction, agriculture, silviculture, mining and hydrologic modification. *See, e.g.,* U.S. EPA, *Nonpoint Source Control Guidance, Agricultural Activities,* Washington D.C., February, 1978.

31. 40 CFR § 130.2(e).

32. 40 CFR § 130.2(f). The regulation requires that "[w]herever possible, natural and nonpoint source loads should be distinguished." *Id.*

33. 40 CFR § 130.2(g).

34. 40 CFR § 130.2(h).

35. 40 CFR §§ 130.7(b)-(c).

36. 40 CFR § 130.6(c)(4)(iii).

37. 40 CFR § 130.6(c)(4)(i) (emphasis added).

38. 40 CFR § 130.6(c)(4)(ii).

39. *Oregon Natural Resources Council v. U.S. Forest Service,* 834 F.2d 842, 851-852 (9th Cir. 1987); *Northwest Indian Cemetery Protective Assn. v. Block,* 795 F.2d 688, 697 (9th Cir. 1986).

40. *Shanty Town Associates Limited Partnership v. EPA,* 843 F.2d 782, 791-793 (4th Cir. 1988).

41. If so, the inadequate attention paid to poison runoff before the 1987 Amendments may have resulted more from a lack of serious EPA enforcement of existing requirements than from loopholes in the law.

50. U.S. EPA, November, 1987, *supra* note 44, at 20, 80-81, 118-124. This report is submitted biennially pursuant to CWA § 305(b), 33 U.S.C. § 1315(b).

51. *See Amending the Clean Water Act, Hearings Before the Subcomm. on Env't and Pub. Wks.*, 99th Cong. 1st Sess., *reprinted in A Legislative History of the Water Quality Act of 1987 (Public Law 100-4) Including Public Law 97-440; Public Law 97-117; Public Law 96-483; And Public Law 96-148*, November, 1988, at 1665 (remarks of Sen. Mitchell) [hereinafter cited as *1987 Legis. Hist.*]; *see also 1987 Legis. Hist.* at 2069 (remarks of Admin. Ruckleshaus).

52. Congress had previously identified NPS pollution as a major concern. *See* H.R. Rep. No. 911, 92d Cong. 2d Sess. 105-106 (1972) *reprinted in A Legislative History of the Water Pollution Control Act Amendments of 1972*, Cong. Res. Serv., at 792-793 (1973) [hereinafter cited as *1972 Legis. Hist.*]; H.R. Conf. Rep. No. 830, 95th Cong. 1st Sess. 70-71 (1977), *reprinted in A Legislative History of the Clean Water Act of 1977*, Cong. Res. Serv., at 254-255 (1978) [hereafter *1977 Legis. Hist.*]; *id.* at 545-546 (Senate debate on 1977 amendments, December 15, 1977; remarks of Sen. Culver). Apparently, these warnings were not heeded to Congress' satisfaction. Nevertheless, in CWA § 319(a)(2), Congress expressly recognized existing requirements, and encouraged states not to abandon previous efforts:

VOL 12

6899

R0040207

In developing the report required by this section, the State (A) may rely upon information developed pursuant to sections 208, 303(e), 304(f), 305(b), and 314, and other information as appropriate, and (B) may utilize appropriate elements of the waste treatment management plans developed pursuant to sections 208(b) and 303, to the extent such elements are consistent with and fulfill the requirements of this section.

53. This language became new section 101(a)(7) of the CWA.

54. The grant programs added or modified in 1987 do not actually modify the *regulatory* requirements governing NPS control.

55. CWA § 319(a)(1)(A), 33 U.S.C. § 1329(a)(1)(A). The Senate Report explains that the reference to both water quality standards and to the goals and requirements of the CWA reflects the fact that not all waters meet the Act's goals and requirements (*i.e.*, do not meet fishable/swimmable uses), and a desire that additional NPS controls be used to improve water quality and to upgrade these waters. S. Rep. No. 50, 99th Cong. 1st Sess. 35 (1985), *reprinted in 1987 Legislative History, supra* note 51, at 1456.

56. CWA § 319(a)(1)(B), 33 U.S.C. § 1329(a)(1)(B).

57. CWA §§ 208(b) and 305(b)(1), 33 U.S.C. §§ 1288(b) and 1315(b)(1).

58. CWA § 319(a)(1)(C) requires states to identify the *process* by which BMPs and other control methods are identified. The *control strategies themselves* are required by CWA § 319(b)(2).

59. This tool also has parallels in the existing statute.
See CWA §§ 103 (interstate compacts), 401(a)(2) (procedure for resolving interstate water quality disputes) and 402(b)(5) (permits affecting downstream states).

60. CWA § 319(d), 33 U.S.C. § 1329(d).

61. CWA § 319(d)(3), 33 U.S.C. § 1329(d)(3).

62. Also by contrast, EPA is authorized to promulgate substitute water quality standards and wasteload allocations where state submissions are lacking. CWA §§ 303(c)-(d), 33 U.S.C. §§ 1313(c)-(d).

63. CWA § 319(d)(2), 33 U.S.C. § 1329(d)(2).

64. CWA § 319(h), 33 U.S.C. § 1329(H). In addition, where
state plans are inadequate, local governments, with state approval, may submit their own plans to EPA, and may receive EPA technical assistance and a portion of the state's grant funds. CWA § 319(e), 33 U.S.C. § 1329(e).

65. U.S. EPA, *Nonpoint Source Guidance*, December, 1987.

66. *See, e.g.*, U.S. EPA, *Guide to Nonpoint Source Pollution Control*, July, 1987; U.S. EPA, *Creating Successful Nonpoint Source Programs: The Innovative Touch*, August 1988.

67. *See* Memorandum from Lawrence J. Jensen, Assistant Administrator for Water to All [EPA] Regional Water Management Directors (subject - Nonpoint Source Controls and Water Quality Managers), August 19, 1987.

68. CWA § 319(d); 33 U.S.C. § 1329(d).

69. *See generally* U.S. EPA, December, 1987, *supra* note 65.

70. CWA §§ 208(b)(2)(F)-(K), 33 U.S.C. § 1288(b)(2)(F)-(K).

71. 40 CFR §§ 131.10, 131.12.

72. Strictly, this language appears in the subsection dealing with the state's nonpoint source assessment. Subsection (b), which applies to the management plan, requires simply an identification of BMPs that will be used to control pollution from each source category. It is inconceivable, however, that Congress intended states to identify *different* sets of BMPs, subject to different substantive standards, in their NPS assessment reports and management plans, respectively.

73. *See* CWA §§ 102(a) (Administrator to develop comprehensive plans for groundwater protection); 104(a)(5) (Administrator to develop a water quality monitoring program for surface and groundwater); 104(l) (EPA study of pesticides in water, and alternatives to pesticides); 104(p) (cooperative study with Agriculture Department on reducing agricultural pollution); 105(grants to study reductions in pollution migration and agricultural pollution); 106(e) (no State grants to any State that has not provided for a program to monitor, to the extent practicable, surface and ground waters); 208 (areawide waste treatment management plans to be developed for areas having substantial water quality control programs, and to include controls to protect ground and subsurface water quality); 304(a) (Administrator to develop water quality criteria for effects of pollution on groundwater); 516(a)(Administrator to report to Congress on measures taken to develop comprehensive sec. 102 plans and sec. 208 programs).

74. S. Rep. No. 50, 99th Cong. 1st Sess. 36 (1985), *reprinted in 1987 Legis. Hist., supra* note 51, at 1457.

75. *See* CWA §§ 303 and 208, 33 U.S.C. §§ 1313 and 1288.

76. CWA § 319(c)(2), 33 U.S.C. § 1329(c)(2).

77. CWA § 319(b)(2)(C), 33 U.S.C. § 1329(b)(2)(C) (emphasis added).

78. 33 U.S.C. § 1329(b)(4). This requirement was emphasized in the Legislative History. *See* H.R. Conf. Rep. No. 1004, 99th Cong. 2d Sess. 144 (October 1986), *reprinted in 1987 Legis. Hist., supra* note 51, at 833.

PART TWO

Components of an Effective Poison Runoff Control Program

Developing effective strategies to control poison runoff requires looking at the "big picture," and choosing among many alternatives. Because nonpoint source control is an area where certain traditional approaches predominate, government agencies often do not undertake a serious search for alternatives.[1]

> ... the consideration of alternatives to particular policies is generally superficial at best. The typical reaction is to decide on a course of action....and then to justify it. A serious search for alternatives is seldom undertaken.[2]

All government officials involved in controlling poison runoff need to bring an open mind to the full range of technical and

[1] *See* Eads, George C., and Eric Van De Verg, "Alternative Policies For Cleaning Up The Chesapeake Bay: A Framework for Choice," *Second Annual Conference on the Economics of Chesapeake Bay Management,* Maryland Department of Economic and Community Development, Annapolis, Maryland, May 28-29, 1986, at 3.

[2] *Id.*

non-technical problems and solutions to poison runoff. Part Two of this report is designed to help overcome the temptation to get stuck in the rut of traditional–and ineffectual–approaches.

Control programs must incorporate a diverse set of legal, policy and program tools all of which can be combined in any number of ways. However, each tool has certain advantages and disadvantages. These pros and cons must be understood before informed decisions can be made.

Part Two presents information to assist decisionmakers in evaluating and choosing the best basic program components or "building blocks" that are at the foundation of any comprehensive effort to control poison runoff. Part Two consists of six chapters, each of which considers a fundamental component of poison runoff control and offers recommendations for improving its effectiveness as part of an overall management strategy. Many examples are given to demonstrate that states can improve the value of their control programs in order to meet the requirements of the Clean Water Act.

Chapter Three addresses effective programs to control agricultural water pollution. Chapter Four considers land use control and other factors contributing to poison runoff in urban settings. Silvicultural, rangeland and mining programs are the subject in Chapter Five. The effective collection and use of data in poison runoff control is analyzed in Chapter Six, and important funding considerations are covered in Chapter Seven. Finally, the legal issues that are germane to effectively controlling poison runoff, including state water quality laws, local land use powers and common law, are addressed in Chapter Eight.

Chapter Three

Agricultural Pollution Control Programs: A Time For Innovation

Introduction

What types of programs are most effective in reducing water pollution from cropland, livestock agriculture and irrigation return flows? There are wide differences in the *types* of pollution caused by agriculture and in the responsible transport mechanisms. The severity of the problem also varies significantly. Therefore, generalizations about the kinds of programs that are the most effective in reducing agricultural pollution are dangerous. Nevertheless, certain types of programs have distinct advantages over others.

Traditionally, programs to control poison runoff from agricultural lands have relied heavily, in fact, almost exclusively, on voluntary government cost sharing programs. Due to this historical trend, this chapter begins with an extensive discussion of the pros and cons of these programs. Following this evaluation is a discussion of programs to control agricultural poison runoff that rely on approaches other than voluntary cost sharing, such as regulatory-based design standards and incentive-based design taxes.

Voluntary Cost Sharing versus Mandatory Programs

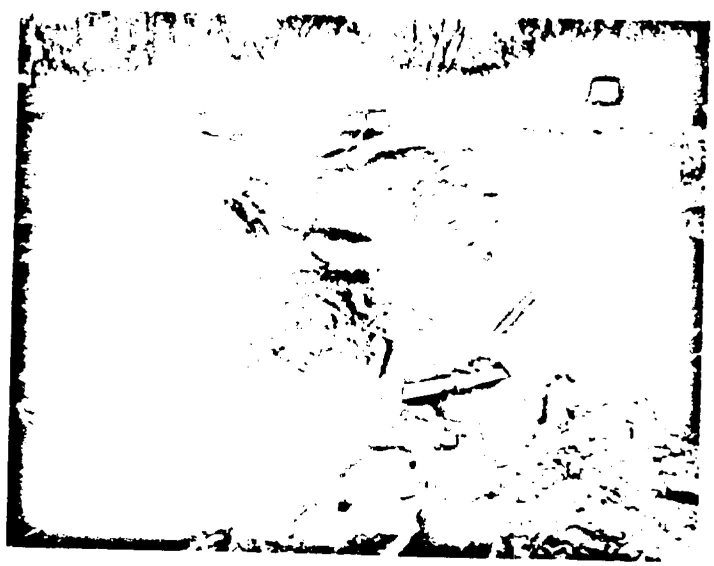
Current efforts to control polluted agricultural runoff rely heavily on voluntary cost sharing programs. Under these programs, government funds, education and technical assistance are provided to farmers to motivate them to implement structural or management prescriptions called Best Management Practices designed to reduce soil erosion or water quality degradation. The programs are voluntary, but government benefits are not available unless program requirements are met.

One of the most fundamental and most controversial issues in controlling the poison runoff and leachable contaminants caused by agriculture is whether a program based exclusively or predominantly on voluntary cost sharing, education and technical assistance is adequate to reduce agricultural pollution to the degree necessary, or whether mandatory controls are needed to supplement these efforts. A related question is whether such mandatory programs are rational, feasible and more effective than voluntary programs.

Past experience with voluntary programs to control agricultural pollution is not a perfect gauge to measure future voluntary efforts. In the past, many voluntary programs concentrated on reducing soil erosion rather than preventing water pollution, and only recently has water quality become a focus of some of these programs. Also, funding and state oversight of soil conservation (and in some cases agricultural pollution control) programs have improved somewhat over previous efforts.

Nevertheless, past experience tells us that certain fundamental aspects of voluntary cost sharing programs tend to limit their usefulness even with increased funding and oversight, and regardless of whether they are targeted to water quality problems. Conversely, even the limited experience with regulatory programs suggests that they have untapped promise, and should be reexamined seriously for controlling agricultural pollution.

Decades of voluntary cost share programs aimed at soil conservation and farm productivity have created expectations, on the part of farmers and policymakers alike, that voluntary approaches are preferable to mandatory ones for addressing



Streambank erosion can be attributed to cultivating to the edge of a stream or allowing unlimited livestock access to riparian areas.

water quality problems caused by agriculture.[1] As a consequence, little consideration has been given at the federal, state and local level to the use of mandatory approaches to control erosion, much less water pollution.[2]

But at least from a water quality perspective, an objective analysis of cost sharing demonstrates that the conventional wisdom may be wrong. In the words of one analyst, the voluntary approach has proven to be a "slow boat on waters that remain polluted with sediment, nutrients, and pesticides."[3]

In fact, many efforts to control poison runoff and prevent groundwater contamination under CWA § 208 were comprised largely of voluntary programs. Yet, the failure of CWA § 208 planning to improve water quality has been attributed in part to the voluntary nature of most state CWA § 208 plans.[4]

This does not mean that cost sharing has no place in an overall program to control agricultural pollution. Given the severity of contaminated agricultural runoff and the high cost of

VOL 12

6907

R0040215

many controls, cost sharing in one form or another may be useful if not essential in many cases. A successful agricultural pollution control program should employ a range of management approaches. However, cost sharing should not be used to pay for controls that the farmer can afford without public assistance.

Therefore, the problem that must be faced is the *exclusive* (or primary) dependence on cost sharing (and the attendant education and technical assistance programs) to address water pollution from agricultural activities. This problem is magnified manyfold when cost sharing programs are not tied directly to pollutant load reduction goals as part of comprehensive watershed-wide water quality protection plans. Moreover, state officials often justify cost sharing based on the premise that mandatory programs are impossible or are not authorized under the CWA. As indicated in the preceding chapter as well as the remainder of this one, neither contention is true. Neither cost sharing nor regulatory approaches need be "chosen" over the other; most important, cost sharing should not be offered as a basis for rejecting the use of mandatory programs as well.

Below, we examine in greater detail the relative merits and drawbacks of voluntary and mandatory programs to control agricultural water pollution. We begin with an explanation of the historic roots of voluntary cost sharing programs and the effects of this long history on current strategies. Next, we evaluate economic, practical, public policy and other factors related to the use of voluntary and mandatory programs to control agricultural water pollution.

Historical Factors

The most significant influences on state programs to control agricultural water pollution have come from the U.S. Department of Agriculture's (USDA) federal assistance and land management programs, rather than from EPA's water quality protection programs. As a result, for the most part state programs to protect water quality from agricultural contaminants resemble the farmer assistance *USDA* model intitiated in the 1930s far more than they do the water quality-based *EPA* model contained in the 1972 Clean Water Act.

The USDA is the agency with primary responsibility for federal efforts to reduce soil erosion from the nation's 530 million acres of cropland.[5] USDA programs with soil conservation and pollution control potential are administered through a complex network involving primarily three federal agencies: the Soil Conservation Service (SCS), the Agricultural Stabilization and Conservation Service (ASCS) and the Cooperative Extension Service (CES).[6]

The SCS mainly provides technical assistance to farmers who participate in both state and federal soil conservation and agricultural pollution control programs.[7] The ASCS provides administrative support for both federal and state programs, and provides the cost share funds available through certain federal programs, such as the Agricultural Conservation Program (ACP).[8] The CES conducts research and furnishes educational services directly to farmers to help them improve crop productivity, control pests and reduce soil erosion and water pollution.[9]

These USDA agencies are part of an elaborate voluntary agricultural assistance network established in the 1930s primarily to enhance agricultural production and to improve the lot of the farmer and farmer families.[10] Through the years, the role of this assistance network has expanded to include soil conservation and, more recently, water quality considerations. Some USDA agencies maintain offices at the federal, state and county levels.[11] Federal employees work at the local level with local units of state government called Soil and Water Conservation Districts (SWCDs).[12]

SWCDs, managed by locally elected and unsalaried citizens (often farmers), were established (based on a legislative model prepared and actively promoted by the USDA) during in the 1930s and 1940s to improve the delivery of USDA program benefits to individual farmers.[13] Enabling legislation that states passed in order to establish these districts was similar to the federal model, except that most state laws did not include regulatory land use powers and created districts based on political, rather than watershed, boundaries.[14] Thus, as state programs with agricultural pollution control objectives were integrated into the USDA/SWCD soil conservation and farmer assistance model, most remained voluntary in nature—providing

VOL 12

6909

R0040217

education, technical assistance and cost sharing to promote the adoption of BMPs designed to address soil erosion and water quality.[15]

Traditionally, "Technical Guides" and other planning tools used by USDA and associated SWCDs to design specific BMPs addressed primarily farm productivity and soil erosion concerns.[16] Addressing on-farm soil erosion concerns, however, is not the most effective means to address the *deposition of sediment* or pollutants dissolved in runoff or infiltration water, such as nutrients and pesticides.[17] Obviously, to the extent that soil erosion, as opposed to water quality, remains the primary focus of SWCDs' activities, the effectiveness of their programs to reduce water pollution from agricultural sources will be severely limited.[18] Recently, however, USDA has begun taking important steps towards addressing water quality concerns directly.

In its 1988-97 update of "A National Program for Soil and Water Conservation," USDA states that it will "elevate protection of water quality to second priority within existing USDA programs of research, education, and technical and financial assistance."[19] Among the activities planned to promote water quality protection are revisions to the "Technical Guides" to reflect groundwater protection, the development of an evaluation system to determine the impacts of BMPs on water quality, and improved training of SCS personnel in water quality protection techniques.[20]

While this new focus is necessary (and commendable), it does not ensure that required reductions of the poison runoff generated by agriculture will be achieved through a voluntary program approach. For instance, since the Guides are interpreted and implemented within the context of a locally managed and operated program and *only with the voluntary support of the landowner*, changing BMP specifications does not guarantee that the Guides will be followed faithfully or that enough BMPs will be implemented in a given watershed to attain compliance with water quality standards.

At the federal level, it is not clear how long it will be before activities to control nutrient, bacteria, pesticide *and* soil inputs into public waters are treated with equal importance compared to preventing soil erosion and improving farm productivity. This

VOL 12

6910

continuing uncertainty is evidenced by a recent statement by Peter Myers, Deputy Secretary of the Department of Agriculture, that the "principal objective" of the Soil Conservation Services is "to reduce soil erosion and the consequent adverse effects of sedimentation and depletion of the soil resource base."[21]

In summary, soil conservation and pollution control in the agricultural sector historically has relied on a "bottom-up approach based on voluntary participation and incentives."[22] The predominance of this approach can be traced to the long history of USDA agricultural and soil conservation programs, and the strong localized support for such programs.[23] Furthermore, USDA programs have been relatively successful in improving farm productivity—the primary goal for which they were created.[24] However, whether or not these programs (along with their state counterparts) are sufficient to comply with the critically important requirements of the CWA is another matter.

Participation in Voluntary Programs

In an approach dominated by voluntary programs, success in protecting water quality depends on individual farmers voluntarily accepting cost-share funds from local SWCDs and USDA to finance the installation of BMPs. Overall success depends on program-wide participation rates. More precisely, enough farmers in a given watershed must choose to employ BMPs that, in combination, will reduce pollution sufficiently to achieve water quality standards.

Unfortunately, there is little conclusive information on whether participation in voluntary agricultural cost sharing programs occurs at a rate adequate to achieve the load reductions needed to meet watershed-specific water quality goals. Participation in previous and current cost sharing programs targeted to soil erosion and productivity enhancement can be considered high, in that farmers may apply for all available program funds. However, this does not mean that adequate funds were available to achieve compliance with water quality standards, or that participation in a water quality-based program would be sufficient if high levels of farmer particpation were needed.

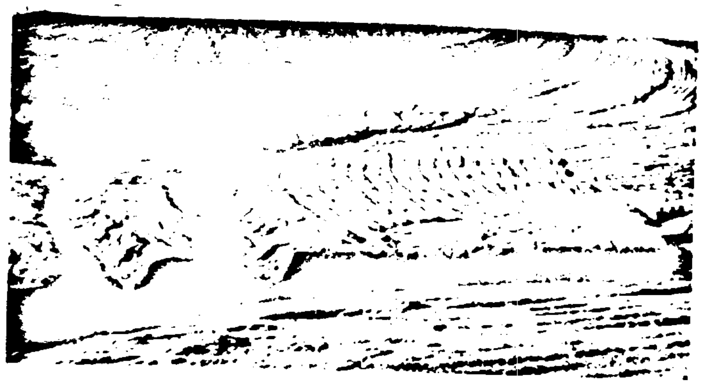
VOL 12

6 9 / /

In fact, available information suggests that participation in voluntary water quality-based cost sharing programs may be too low to ensure program success. For example, a 1985 study of several voluntary Rural Clean Water Program (RCWP)[25] comprehensive monitoring and evaluation projects (in which adequate farmer participation was essential for program success) reported that five years after the RCWP was enacted, only two of the five projects had reached needed levels of participation.[26] RCWP is a federal program with over $70 million provided for intensive watershed planning, monitoring and cost sharing in just 21 watersheds scattered across the entire country.[27] With some notable exceptions, most state cost sharing programs provide no more than $1-2 million/year in cost-share funds. The limited participation in these RCWP projects—despite relatively large infusions of federal dollars—suggests that far smaller state programs would have even lower participation rates.

Logically, participation rates in programs designed specifically to address water quality may be expected to be lower than those designed specifically to address soil erosion and/or productivity. Soil erosion (and to a greater degree, productivity improvement) programs often have (or are perceived to have) on-farm as well as off-farm benefits. Thus they offer a "self-interest" incentive for farmer participation. In contrast, programs to protect water quality—often considered an off-farm benefit—present less (or no) inherent incentive for farmer participation.

From a micro-economic perspective, the voluntary approach to agricultural water pollution control may not be adequate because (as explained below) the profit motive of the farmer and general economic trends in agriculture often will prevent the voluntary adoption of soil conservation BMPs if they are perceived as having a negative impact on farm income. And to the extent that programs that are designed to reduce surface water and groundwater contamination from agriculture offer only BMPs designed to achieve "off-farm" water quality benefits (and these BMPs are perceived by farmers as reducing profits more than those that provide "on-farm" productivity and soil conservation benefits), the popularity of voluntary BMP programs will be even lower.



Severe sheet erosion can result from improper tillage and crop rotation decisions.

The success of a voluntary BMP cost sharing program in reducing agricultural pollution is largely a function of farm income: it works (*i.e.*, has a high participation rate) only when the farmer's return on the BMP investment exceeds BMP costs.[28] As with other business pursuits, profits drive the farmer's decisionmaking. Therefore, many analysts view economics as the primary factor influencing a farmer's decisions about how to farm his or her land.[29]

Reliance on the provision of information to farmers and on the development of positive attitudes towards soil conservation and land stewardship, long the management philosophy of USDA conservation efforts, are "necessary but not sufficient conditions to bring about the adoption of soil erosion control practices."[30] Thus it is even more unlikely that positive attitudes would be sufficient to motivate farmers to implement and maintain measures that are designed primarily to provide "off-farm" water quality benefits through reductions in sediment, nutrient, bacteria and pesticide runoff. "[M]ost farmers, because of economic and market constraints, place high priority on productivity and efficiency criteria when making decisions about what farming

VOL 12

6913

R0040221

practices to use."[31] The importance of short-term survival leads to the general use of whatever farming techniques are perceived as maximizing short-term profits.[32] Unfortunately, some of these techniques incidentally degrade land and water resources.[33] Farmers under economic stress will:

> attempt to survive by ignoring soil erosion control practices or discontinuing practices that do not contribute to maximizing short-run output. Marginal land will be pressed into production; land devoted to such conservation practices as filter strips and crop rotation will be farmed; and existing land under cultivation will be farmed more intensively.[34]

Given the tenuous economic conditions in today's agricultural sector, it is not surprising that most farmers do not treat soil conservation and pollution control as a high priority. For example, studies have shown that farmers shun pollution-reducing "no-till" cultivation because they perceive it as risky.[35] They oppose practices that reduce nitrogen applications because excess nitrogen is often viewed as "insurance."[36] In fact, research has shown that farmers will continue to use land- and water-degrading practices even when they know they have an erosion problem, believe in soil conservation and are knowledgeable about conservation practices.[37]

Today it is popular to describe the on-farm economic benefits of soil conservation and pollution control BMPs.[38] However, while farmers need to be aware of potential economic gains (particularly long-term gains) from controlling poison runoff, they should not be given the false expectation that pollution control always translates into immediate profits. And where direct economic benefits to the farmer cannot be shown, participation in voluntary cost share programs is likely to drop. As explained above, voluntary cost share programs are often not effective as primary delivery mechanisms for state-wide agricultural pollution control programs because the implementation of many conservation practices (BMPs) may lower farm income.[39] With the possible exception of conservation tillage, "most research on the cost of soil erosion control in agriculture concludes that, for most farmers, the private costs of soil conservation exceed the private benefits...."[40] While controls designed to reduce the impacts of other pollutants such as nutrients and pesticides may have long term economic benefits to the farmer, initial reductions in profits to the farmer often are inevitable.

Moreover, farmers often do not make the connection between water pollution and any specific farm activities, particularly their own farm activities.[41] In one survey of farmers in the Great Lakes States, most said they "believed no relationship exists between farm fertilizers and pesticides, manure, or eroded soil and water quality."[42] Thus, when farmers *do* decide to employ innovative production measures, they often base their decision on profitability rather than conservation potential. And as mentioned previously, maintenance can also be a problem since farmers often neglect BMPs when economic conditions deteriorate.[43]

Finally, when farmers utilize BMPs to protect land or water resources, they often exaggerate the extent to which conservation practices are implemented.[44] All of these facts indicate that leaving conservation and water quality protection choices up to the farmer is not the optimal management approach, especially since, as indicated above, many controls often are *not* profitable to the farmer.[45]

These same factors would seem to indicate that farmers also will oppose regulatory controls. Curiously, however, this is not necessarily the case. Some farmers view increased regulatory control of agriculture as a legitimate exercise of government authority. Although research has not provided a model fully explaining farmers' attitudes towards regulation, some have speculated that farmers recognize that their past, relatively privileged immunity from environmental controls may be waning due to increasing public and governmental concerns over agricultural surface and groundwater pollution.[46] This reasoning was used to explain the results of recent polls indicating that 65% of the farmers in Iowa supported tighter regulations on the use of agricultural pesticides (over half favored tighter restrictions on fertilizer).[47]

Since farmers and their families often are the major victims of agricultural pollution, particularly groundwater impacts from agricultural chemicals,[48] the results of this study are not surprising. For example, unexplained headaches and chest pains, and foul-smelling drinking water were responsible for the decision of

VOL 12 6/9/5

R0040223

a farmer in Olmstead County, Minnesota to stop using pesticides and significantly limit his fertilizer use.[49]

On the other hand, some impacts of poison runoff are only felt miles away from the source, and controls often benefit some farmers at the expense of others.[50] This suggests that the agricultural community is unlikely to reach overall consensus concerning how pollution generated by agricultural activities should be controlled and that voluntary cost sharing will not be sufficient to bring about desired levels of BMP implementation.

Macro-economic Forces in Agriculture Discourage Voluntary Water Quality Protection

Certain enduring characteristics of U.S. agricultural production and the factors that influence decisions made by farmers will continue to limit voluntary acceptance of soil conservation measures and pollution controls. Agriculture depends on land as its basic capital input.[51] Unlike computer chips, steel or sulfuric acid, land is a resource that is fixed in a geographic space; its value cannot be altered by manufacturing it into a product or transporting it to another location.[52] In short, land cannot be centralized. Also, agricultural commodities generally have low prices based on highly elastic demand (*i.e.*, relatively small price increases by an individual farmer can greatly decrease his or her sales).[53] This tends to lead to overproduction and price instability.[54] Moreover, agriculture is a risky business because of uncontrollable and unpredictable climatic and other environmental conditions.[55] Finally, some of the economies of scale characteristic of many centralized industries are harder to achieve in agriculture (particularly row crop agriculture) because of the inevitable need for large quantities of land to produce a given amount of agricultural goods regardless of the overall size of the farm or the production inputs.[56]

These factors mean that agriculture generally produces low returns from investment, making large scale investment less likely than in more traditional industries.[57] Unfortunately, these structural and agronomic characteristics (price instability, low prices and high risk) that discourage centralization in agriculture also lead farmers to have short-term planning horizons and to engage in other "risk averse" behavior that results in environmental degradation.[58]

In addition to the implications of these economic factors, trends in farm management since World War II also:

> will tend to overwhelm approaches to soil conservation that rely on influencing farmer decision-making through cost-sharing, technical assistance and education.[59]

These trends include increased scale, mechanization, capital intensity and use of hired labor:[60]

> The result has been long-term trends toward row-crop and small grain monocultures; a reduced prevalence of crop rotation, particularly those involving legumes; separation of crop from livestock production;[61] and the intensification of crop production based on purchased petrochemical inputs.[62]

Implications for Poison Runoff Control Programs

These macro-economic changes in agriculture and the management trends discussed above are very important elements of the pollution control equation. The agricultural economy is *cyclical,*[63] whereas the need to protect water quality is *continuous*. Therefore, the cyclical downward trends in the agricultural economy can neither be combated by nor used to justify adhering to traditional, voluntary soil conservation and water pollution controls.[64] In other words, soil conservation and pollution reduction programs should be deliberately designed to remain in place regardless of short-term fluctuations in the agricultural economy.[65] Since poison runoff controls that are adopted and maintained voluntarily are likely to be abandoned under adverse economic conditions, state officials need to develop more permanent approaches (discussed in the following section) to ensure that the BMPs necessary for water quality protection are implemented.[66]

On the other hand, agricultural trends *should* be considered for their potential to increase or decrease water pollution. Understanding macro-economic trends in agriculture enables local, state, regional and national governments to develop taxation, marketing and economic development policies that better address water pollution needs.[67] In order to make use of these macro-economic trends, state and local poison runoff control officials first need to acknowledge the important relationship between state and regional changes in agriculture and programs to protect water quality. Tax incentives to convert cropland to timber stands could be created or increased.[68] Tax credits, venture capital, and technical assistance could be used to attract investors for the development of a regional animal waste processing and distribution industry.[69] Part-time production of specialty crops could be encouraged through state promotional campaigns, local land use management and tax incentives designed to create a favorable market climate for regional produce grown without farm chemicals. Besides state agencies, regional and local government entities also have important roles to play in promoting trends in agriculture that can have positive environmental benefits.

The Need to Apportion Costs Among Polluters and Taxpayers

While it is probably impossible to know all of the winners and losers in any particular pollution control program in agriculture, it is clear that a fair *distribution* of costs and impacts is important to successful program development.[70] Huge government expenditures would be necessary to provide enough cost sharing funds to accomplish pollution reduction goals.[71] The level of public funding needed just to cost share adequately the necessary *soil conservation* (not to mention *water quality protection*) BMPs could well be unacceptably high.[72]

For example, it has been estimated that at least 90 million dollars would be needed to address only soil erosion and animal-waste needs in Maryland.[73] Of course, government *can* decide to address agricultural runoff pollution by appropriating these huge sums. However, it cannot be claimed that voluntary cost sharing programs alone will suffice *unless* these expenditures are made and unless high participation rates are shown.

Moreover, such a massive infusion of government funding to pay for agricultural pollution control raises serious questions of equity. The general taxpayer is asked to subsidize pollution controls for an entire sector of the economy, without any analysis of whether these subsidies are needed. Arguably, cost sharing should be saved for situations where it is essential for maintaining the economic viability of the industry.

In fact, collecting taxes in order to provide cost sharing funds actually rewards farmers for correcting their polluting activities (at least to the extent that farmers will not accept payments unless the payments make them financially better off in the short term).[74] Rational farmers might choose to delay conservation activities in order to wait for higher levels of funding.[75]

Changes on the Nonpoint Source Management Horizon

Title 12 of the Food Security Act of 1985 (P.L. 99-198)[76] is an indication that the federal government is beginning to recognize the limitations of purely voluntary soil conservation and water quality protection programs. Four conservation provisions, implemented largely by the SCS and ASCS, were included in this new law to make the goals of USDA farm and conservation programs more consistent.

The Conservation Reserve (Subchapter IV) gives ASCS the authority to enter into ten-year contracts and to make annual rental payments to farmers who retire highly erodible land and land bordering water bodies from farming and plant it with a permanent cover crop, such as grasses, legumes or trees.[77] Under "conservation compliance" provisions (Subchapter II), farmers who plant annually tilled crops on highly erodible lands must implement locally developed and approved conservation plans by 1995 in order to remain eligible for price support, crop insurance and other USDA program benefits.[78] The "Sodbuster" provision (Subchapter II) also uses USDA programs to gain soil conservation benefits. To retain USDA benefits, farmers must follow a conservation system approved by the local soil and water conservation district when plowing fields that were not used for crop production between 1981 and 1985.[79] "Swampbuster" (Subtitle III) requires that USDA program benefits be withdrawn from all farmers who convert any naturally occurring wetlands to cropland after 1985.[80]

While these programs are targeted primarily at reducing soil erosion rather than at improving water quality, it is encouraging that agricultural programs that penalize poor land stewardship are being designed. The high visibility of these federal programs could stimulate the implementation of cross-compliance and other non-traditional programs at the state level. However, it remains an open question whether USDA is committed to moving away from primarily voluntary soil conservation approaches, much less towards water quality protection. After passage of the Farm Bill, the USDA Assistant Secretary for Natural Resources and the Environment stated that:

> [f]rom the outset I must emphasize that USDA is skeptical about the regulatory approach to correcting nonpoint-source pollution problems.[81]

In the summer of 1988, after a great deal of time and effort had been expended in USDA to begin implementing the "cross-compliance" provisions of the Farm Bill, this same official testified before a House Subcommittee that:

> USDA's primary strategy for dealing with nonpoint sources of water pollution is to encourage the *voluntary* development and application of Best Management Practices (BMPs) which restore and maintain productive uses of soil and water resources (emphasis added).[82]

Summary

Voluntary agricultural programs to control poison runoff are politically popular, and are a mainstay of the traditional soil conservation community.[83] However, voluntary cost-share programs usually have not been effective in improving water quality[84] because of many of the reasons illustrated above. More fundamentally, there have been and will continue to be many basic problems with using voluntary programs even for soil conservation purposes. Therefore, if even the broader goal of soil loss prevention is not promoted effectively through voluntary programs, it is axiomatic that such programs will not achieve water quality goals. And, as is discussed in detail later in the report, it is essential that water quality concerns drive programs designed to reduce the impacts of diffuse sources of pollution to suface water and groundwater.[85]

One of the important functions that USDA and associated state soil conservation agencies perform is to change behavior through "moral suasion" and informal information exchanges. It could be argued that any but voluntary programs could jeopar-

VOL 12 6920

dize this role by ruining the relationship between the farmer and the federal or state employee. However, non-voluntary controls are not mutually exclusive of these functions and could co-exist as part of a comprehensive water quality protection program. This is particularly the case if water quality agencies are responsible for the development and enforcement of such programs. SWCDs could maintain their relationship with the farmer while providing the state with technical assistance in evaluating problems, designing specifications and standards to protect water quality, and even assisting in inspection and enforcement activities.

Promising Alternatives to Voluntary Cost Sharing

Certain aspects of the agricultural sector lend themselves to mandatory pollution control programs. Some of these aspects are longstanding, while others result from recent trends in the structure of the modern farm.

Agricultural policies (including pollution control policies) often have been based on a vision of the small-to-medium size family farmer "working the land to provide a living for himself and his family, against almost insurmountable odds."[86] Although small "family farms" still exist and agriculture will never become as centralized as some industries, the vision of the "family farmer" is no longer accurate, either in terms of farm size or in terms of the environmentally benign picture it paints of agriculture.

Fewer, larger farms are producing a greater proportion of the nation's agricultural goods.[87] In 1984, 12% of the farms in the United States produced 68% of the agricultural cash receipts.[88] Today, family farms constitute less than 11% of moderate-size farms, compared to 21% in 1975.[89] Similarly, animal feedlots have decreased in number and increased in size.[90] There is a trend towards an agricultural sector split between very small, often part-time, farms and very large industrial operations.[91] One reviewer has remarked:

> Today's agricultural operations, especially those that produce the greatest share of the nation's food and fiber, are more accurately characterized

VOL 12

6921

R0040229

Conservation tillage is one of the most effective means of reducing erosion rates on farmland.

as industrial activities requiring sophisticated management and producing significant amounts of environmental pollutants.[92]

These changes in agricultural production can cause "regionalized" agricultural production patterns. For instance, one region may shift towards part-time "hobby" farming and the production of specialized vegetable crops, while another shifts into vertically-organized poultry and/or livestock production.[93]

VOL 12

6922

This shift provides opportunities for improved water pollution control. For example, one result of the trend towards vertically-organized animal production has been the concentration of potential pollutants (especially urine, manure and organic matter) into relatively fewer, smaller geographic areas,[94] creating conditions similar to those usually associated with point sources. Concentration makes these pollution sources easier to identify, manage and control.

The growth of "corporate" farming also affects the cost considerations of controlling poison runoff. Because large-scale agribusiness corporations have relatively easier access to capital, pollution controls can be undertaken with less of an impact on farmers' personal income and financial stability. Thus, pollution control costs can be measured against the profitability of a complete vertical production and distribution system—not the production aspect alone. Moreover, the traditional hesitancy to interfere with the family farm has influenced the differences in the way point and nonpoint sources of water pollution were controlled.[95] Thus, to the extent that trends towards agribusiness concentration continue, the political willingness to develop more direct, regulatory water quality protection requirements might increase.[96]

Other Approaches to Agricultural Pollution Control

While it is easy to identify the weaknesses of voluntary cost share programs as well as any trends towards making more prescriptive approaches both desirable and feasible, it is not quite so easy to identify what particular kinds of programs might work better. Fortunately, promising options are available. These options are summarized in Table 3-1.

For instance, in situations where foregone short-term net returns to the farmer initially are so high that some public financing is needed, *investment tax credits* have been proposed as a potential income transfer to help offset the losses incurred through shifting away from the use of chemical fertilizers.[97] The use of "cross compliance" measures such as those found in the Food Security Act of 1985 have been mentioned previously. Other generic program approaches that do not involve cost sharing are discussed below.

Table 3-1
Possible Options for Agricultural Pollution Control

Option	Summary Description
1. Investment Tax Credits	Tax credit for expenditures needed to implement BMPs
2. Cross-Compliance Measures	Eligibility for financial and other government benefits contingent on implementation of BMPs
3. Performance Taxes	Differential tax based on amount of pollution caused by practices on a particular farm
4. Performance standards	Minimum runoff or water quality requirements prescribed
5. Design standards	Specific structural or management controls prescribed
6. Design Taxes	Differential tax based on specific farm management practices
7. Pricing mechanisms	Modify prices of inputs such as irrigation water, fertilizers, or pesticides, to discourage overuse

Technically, cost sharing is a form of economic incentive, and incentives are praised by economists as more "cost-effective" than other management approaches. But cost sharing is a subsidy and, hence, not the "type of economic incentive... favored by economists" since they "may result in higher costs than necessary."[98]

Control of poison runoff and groundwater contamination is most efficiently achieved through a combination of management and structural changes in the farm and not "simple additions of BMPs."[99] Keeping this in mind, generally the most *practical* program approaches are probably a combination of *general design standards* and *design taxes* to bring about the level of control needed to achieve state water quality objectives.[100]

VOL 12

Strip cropping, or varying the tillage practices and crops grown in alternating "strips", can significantly reduce erosion rates on many farms.

6925

Design standards are imposed to prohibit or modify activities deemed to be environmentally unacceptable.[101] For instance, local governments could be required to develop and enforce ordinances that prohibit the application of pesticides near streams and lakes, the destruction of riparian vegetation, or the application of fertilizers or manure at rates that would threaten groundwater resources. In addition to design controls, performance criteria that prohibit any significant addition of pollutants from either point or nonpoint sources to state waters should be used when minimum design requirements are not adequate to control pollution from particular farms.

Design taxes consist of a variable tax, in which general polluting practices are taxed at different rates based on the relative environmental harm caused by the practices in a given area (*e.g.*, in areas with a particular soil erosion rate located within 200 feet of a stream).[102] With our present level of knowledge, it is not feasible to impose design taxes based on the water quality impacts of agricultural practices on individual farms.[103] However, *general* design taxes, under which farmers could be charged the same tax rates based on the predicted environmental impacts of various farm practices according to local topographical, soils, climatic and water quality conditions, can be developed and implemented.[104] For instance, farmers who choose to use conventional tillage, along with heavy fertilizer and pesticide applications, could be assessed a higher charge than a farmer who can verify the use of some beneficial form of conservation tillage in conjunction with an approved nutrient management and alternative pest control plan.[105]

While this type of design tax certainly holds promise, there is far less experience with its use than with design standards. The completely "rational" behavior of the farmer on which the success of design taxes depends has not been established conclusively.

Performance incentives and standards are a generic pollution control policy that also could be applied to agriculture. Unlike the farm-specific design incentives mentioned above, performance incentives would be directed at the individual farm's pollution flows and not its management practices, providing the farmer with the flexibility to adopt whatever BMPs were desired, so long as certain pollution flow criteria were met. Performance standards would consist of a requirement that certain minimum runoff or water quality criteria be maintained. Unfortunately, performance-based approaches are limited by a number of factors, including the effect of climatic variability on nonpoint source pollution flows and the difficulties of monitoring and enforcing such approaches. However, as improvements are made in our knowledge of the relationship between land use and water quality and the technology to detect certain changes in water quality, performance-based agricultural pollution controls hold some promise.

A useful analogy can be drawn from the approach EPA has developed to address the problems of hazardous waste treatment, storage and disposal facilities under the Resource Conservation and Recovery Act. As with farms, it is difficult to predict the precise level of environmental impact that will be caused by a given site. So, EPA has developed general *design standards* applicable to all such sites in an effort to provide an acceptable

VOL 12

6926

R0040234

minimum level of protection.[106] The same principle can be applied to design standards for agriculture.

To date, few, if any, states have developed significant pollution reduction programs applicable to agriculture based on *general*, much less *farm-specifc*, design taxes. However, one example is given below. By contrast, many states and localities have adopted some form of design standards for agricultural water pollution control. We provide many examples in the pages that follow. Along with the standards themselves, the implementation and enforcement of these programs are described where possible.

In addition to examples of these programs, the use of other *pricing mechansisms* to improve the efficiency with which irrigation water is used (and thereby reduce the transport of poison runoff) is also addressed. Finally, *farmland protection programs* are described because maintaining properly managed prime farmland is an important component to a successful pollution control effort.

Promising New Approaches to Agricultural Erosion and Sediment Control

Erosion Control Through Zoning: Olmsted County, Minnesota

Some states and localities have developed mandatory programs[107] to require certain conservation practices to be implemented under a given set of circumstances. Olmsted County, Minnesota developed such a regulatory program[108] in response to surface water contamination due to excessive erosion. Because urbanization had pushed farms onto marginal, hilly land, data from 1974-1978 indicated that erosion rates in the county were at an unacceptable level of 10 tons per acre even with the increasing popularity of conservation tillage.[109]

Based in part on experience in another county showing that zoning could help reduce agricultural erosion problems, Olmsted County used model zoning ordinances, provided by the Minnesota Department of Agriculture and the Association of Minnesota Counties, to control its farmland soil erosion problems.[110] Use of a county ordinance to control farmland activities rather than

VOL 12 6927

R0040235

urban activities was an important innovation that grew out of the County Board of Commissioners' recognition that local governments were being given more responsibility for resource management.[111]

Olmsted County adopted an ordinance that requires all farmers to implement those BMPs needed to reduce soil erosion to "tolerable" levels by developing and adopting an SCS-approved "conservation plan." This ordinance requires farmers to develop and implement a conservation plan, effectively prohibiting agricultural practices that cause excess erosion in fields and on stream banks.

The Olmstead plan is designed to address two major concerns. The first was that typical conservation ordinances are based on private complaints. Olmstead was concerned that this approach might unnecessarily harm farmers and cause resources to be spent on solving relatively minor erosion problems.[112] The second was that erosion control regulations might have unacceptable economic impacts on some farmers.[113]

In order to assure that enforcement focused first on the most serious erosion problems, a ranking system was developed. Using models and digitized soils and land cover data Olmsted County developed a system that assigns points to the land parcels not complying with the soil loss tolerances established in the ordinance itself, based on a variety of weighted factors including total erosion rates, ratio of erosion to "T" standards,[114] quality of pastureland, hydrologic characteristics and location within a flood control project watershed.[115] The total score for a particular parcel of land determines its enforcement priority (determining when particular farms should develop conservation plans or other erosion controls) and how violations should be treated.[116]

Potential adverse economic impacts were addressed by allowing the County Board four options to address violations of the ordinance:

1. to grant an extension of up to 120 days in the preparation of a conservation plan;

2. to grant an extension of up to two years in the implementation of conservation practices required in a plan;

3. to direct the Zoning Administrator to proceed with a civil suit seeking an injunction compelling compliance with the ordinances; or

4. to direct the Zoning Administrator to proceed with normal criminal enforcement proceedings.[117]

The extensive modelling that is necessary to estimate erosion rates and develop the priority ranking system is conducted with the Minnesota Planning Information Center's computer software and the county's digitized soils and land cover files, which are summarized to the level of one-tenth of an acre.[118] These data, along with models, were used to estimate sheet and rill erosion, wind erosion, the ratio of erosion to tolerable soil loss, poorly managed pastureland and the volume of runoff expected from particular land parcels.[119]

Because the information is in a variety of formats, it can be used to evaluate erosion on specific sites, and for broader planning purposes.[120] Ultimately, the county should be able to evaluate, as part of the site planning process (not as a set of constraints after site planning is completed), the land and water impacts of alternative subdivision designs to determine the most desirable sites for septic systems, buildings, roads, and drainage control systems.[121]

The Farmland Soil Erosion Ordinance allows a host of individuals and public officials to register complaints against landowners who are not complying with the standards established in the ordinance and developed through the computerized modelling efforts.[122] County enforcement of the standards is based on the priority ranking system also described above. The County Zoning Administrator is required to prepare an annual enforcement priority listing (which also takes into account complaints of excessive erosion). This list must be submitted to the SWCD and the County Conservation Committee, who then must investigate the areas on the priority listing and determine the level of compliance with the standards in the ordinance.[123]

Landowners found to be in noncompliance with the standards in the ordinance are required to develop Conservation Plans meeting the requirements of Technical Guides of the Soil and Water Conservation Districts.[124] Schedules are supplied for the completion of the plans and procedures are in place for the annual inspection of work carried out on the plan, for plan approval, and for appeals, variances and exemptions.[125] Enforcement is expedited because this ordinance provides for administrative proceedings to be used in considering cases of economic hardship, rather than automatically requiring the involvement of courts to consider such issues.[126] Also, since it was thought that judicial enforcement of criminal violations would be unlikely, the ordinance gives the Zoning Administrator authority to file a civil suit seeking an injunction against a violator.[127]

Besides those designed to reduce soil erosion, other mandatory programs have been proposed and developed to reduce surface and groundwater contamination from agricultural chemicals and bacteria. Examples of these programs are described in the following two sections.

Erosion Control Through Design Taxes: Pepin County, Wisconsin

Pepin County, Wisconsin is experimenting with the use of design taxes to address both soil erosion and agricultural runoff pollution. The goal is to provide positive rather than negative incentives to farmers. A five-year pilot program has been established in three Wisconsin townships by the Soil Conservation Service and the Pepin County Land Conservation Committee.[128] Using funds provided by SCS, a $3.00/acre property tax rebate[129] was offered to landowners who regularly tilled their soil if the land was treated (with the farmer assuming all treatment costs and responsibility) to reduce erosion to tolerable levels (T).[130] Ten percent of the program participants are randomly inspected for compliance each year.[131]

The program is based on the idea that tax relief should be offered to farmers who implement conservation practices with the *resulting tax burden* falling on the remaining operators not implementing conservation practices.[132] As more landowners enrolled in the program the tax differential would be set at a lower level and, with all landowners participating, the differential eventually would disappear.[133] However, because the Wisconsin state constitution requires uniform taxation of landowners, funds for the tax rebates had to be provided by outside sources (in this case, SCS).[134]

Compared to cost sharing programs, the results of the program seem promising. Acreage in the pilot townships coming under conservation practices more than doubled (12,598 acres to 30,126 acres) while increases in the township without the program were negligible (a 308 acre increase over an existing 23,204 acres already under conservation measures).[135] Adequately protected cropland in the pilot areas increased from 49.8% to 85.6% of total cropland acres, with 73.4% of all landowners with farms over 40 acres participating.[136] In contrast, only 22.6 percent of the farmers had participated in a cost sharing program in the last five years.[137] The costs of the program were: administrative - $12,000; technical assistance - $55,000; conservation practice planning, installation and inspection - $53,000; and tax credits - approximately $400,000.[138] An assessment of the tax credit project indicated that the hours needed for program administration and technical assistance were low compared to other types of financial incentive programs, such as cost sharing.[139]

Most participating farmers supported funding the conservation credit program through money used for current cost sharing programs.[140] The Pepin County Board, with support from all eight townships in the county, recently decided to support this program even after SCS funds are no longer available by having each township increase property taxes on all land in the county.[141] The state is transferring part of its cost sharing funds to the county for the development and implementation of the program.[142] To improve the disparity between the benefits received by farm and non-farm residents, part of the money will be used exclusively for nonagricultural water quality improvement projects.[143]

The major obstacle remaining in the development of this program is the requirement in the state constitution for uniform tax treatment, which prevents the application of higher property taxes to those landowners not implementing conservation plans.[144] In addition, the County Board, as well as others, recognize that "bad actors" are essentially rewarded under this kind of program relative to other farmers who implemented sound conservation practices before the program began. Finally, landowners who implement conservation practices may be financially affected in absolute terms because the value of their land will increase as a result of their good land stewardship practices,[145] leading to higher overall tax assessments.

There are two key reasons why the Pepin County program has been such a success. First, it was locally developed and implemented.[146] Second, it had high visibility in terms of reducing property taxes.[147] For instance, the percentage of farms participating in the pilot conservation credit program at the *local* level is much higher than the percentage participating in the *state* Farmland Protection Program (the state farmland protection program provides similar tax incentives for implementing conservation plans).[148] This is probably because the state program is administered in the state capital, is somewhat complex, and is based on income tax, rather than property tax.[149] Although obstacles remain, the high rate of participation, the involvement of local governments and the enthusiasm of program officials all indicate that taxes can be a significant tool to address pollution from agricultural lands.

Reducing Chemical Pollution from Agriculture

Measured by volume, sediment is the most prevalent pollutant from agricultural runoff. But it is agricultural chemicals that represent a major water quality threat. Fertilizers are a known cause of nutrient enrichment and groundwater contamination in many parts of the country, while concern over pesticide contamination continues to grow. Agricultural chemicals can contaminate surface water by attaching to soil particles or dissolving into surface runoff.[150] Contaminants also can enter groundwater or be transported to surface water through leaching.[151]

Some researchers feel that the most difficult pollution problem associated with nitrogen is nitrate contamination of groundwater.[152] Ironically, soil conservation practices that control surface runoff of nitrogen can increase nitrate leaching, which in turn can pollute groundwater or surface water (through the interaction of surface and shallow subsurface waters).[153] Therefore, control of nitrogen (and also phosphorus)[154] often should focus on "chemical management" to ensure that the "timing and

Applying chemical fertilizers to farmland can lead to water with an over-abundance of algae while depleting oxygen and aquatic life.

amount of nutrient are matched to crop needs" to minimize the nutrients available for leaching and surface runoff.[155] Because of the strong relationship between groundwater and surface water quality, any programs designed to address one will have to be coordinated effectively with the other.

Given the research estimate that 50 percent of applied nitrogen is not taken up by crops,[156] it is not surprising that the contribution of fertilizer to nutrient pollution is large. As mentioned above, efforts to control nitrogen must focus on the use of nitrogen fertilizer.[157] Over-application of nitrogen occurs because farmers set overly high yield goals for their acreage and do not take into account the nitrogen provided by crop rotations and manure.[158]

VOL 12

69333

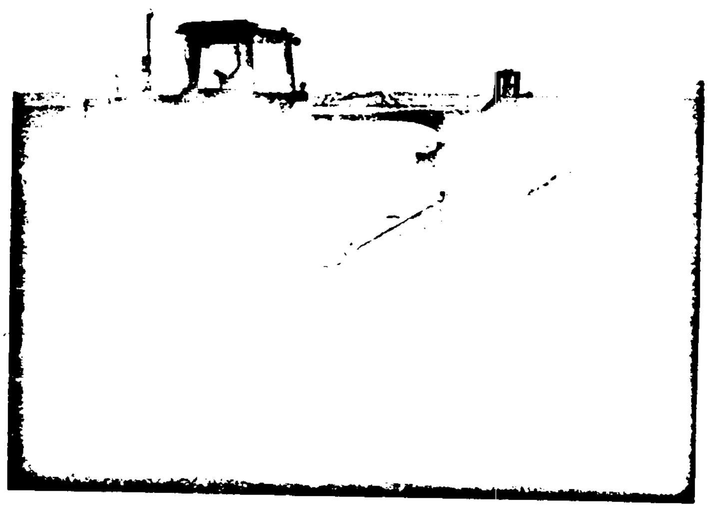
R0040241

Fertilizer nitrogen is both the largest and the most controllable nitrogen input into the farm system (although livestock are a significant source of nitrate, especially in areas with high livestock densities).[159] In addition, farmers often could save money by reducing their use of nitrogen.[160] This is an important factor because the low profit margins associated with agriculture mean that reduced input costs (such as those associated with commercial fertilizers) can be even more important to a farmer's financial situation than increased yields.

In addition to improving the timing and amount of chemical fertilizers applied, substituting organic nitrogen from cover crops and manure while concurrently reducing the emphasis placed on implementing soil conservation BMPs have been suggested as part of an overall plan to reduce the chemical addition of nitrogen and the water pollution it causes.[161] Organic nitrogen has advantages over inorganic nitrogen in chemical fertilizers because nitrogen bound to organic matter leaches at a much lower rate, can improve soil fertility and is available for additional plant uptake.[162]

Another important method to reduce nutrient (especially nitrate) inputs into surface water is the use of forested riparian "buffer zones." By trapping sediment, assimilating nutrients and promoting the conversion of nitrate nitrogen to nitrogen gas, forested buffer strips as narrow as 50 feet can "remove the majority of nitrogen and phosphorus from surface and subsurface runoff."[163] The importance of subsurface flow as a pathway of nutrients into surface waters and soluble nitrate as a fraction of total nitrogen makes forested riparian areas preferable as a nutrient reduction "structural" BMP to those that reduce primarily particulate-associated nutrients.[164]

The lack of controls on pesticide applications to protect groundwater also has been well documented.[165] Reducing pesticide contamination often involves simply not using persistent substances (or using them in smaller quantities) where they can migrate to surface water and groundwater resources, without first testing for the presence of the target pest (prophylactic use).[166] Reducing pesticide use also can be accomplished through:



Many farmers continue to use heavy applications of pesticides even though the long-term health and environmental impacts may be severe.

1. using alternative crop production patterns and techniques—for example, crop rotation can eliminate or limit infestation by certain pests, or improve soil conditions, resulting in heartier crops and more pest predators;

2. modifying agricultural practices, application equipment and use patterns—for example, by applying chemicals only at rates and times indicated by field testing and monitoring to determine pest levels, or by using cultivation practices that limit weed growth; and

3. replacing leachable pesticides with materials that are less mobile, persistent and toxic—for example, by substituting the use of natural predators for a dangerous pesticide or using another chemical that degrades into safer compounds more quickly.[167]

VOL 12

6935

Other possible program components to control pesticide use include:

1. taxes on the sale and/or manufacture of pesticides to fund monitoring studies and to build a statewide data base;

2. requirements for pesticide users to report when, where, and how much a particular chemical is applied;

3. registration of pesticides at the state level, including information requirements (chemical data and monitoring results) designed to determine their potential to leach into groundwater;

4. authority for states and localities to cancel pesticide registration in local areas if soil conditions and other factors indicate a serious leaching problem; and

5. encouragement of pesticide substitution, changes in irrigation practices, prevention of chemical applications near drinking water wells and integrated pest management.[168]

Thus, there is no shortage of possible mechanisms for controlling water pollution from agricultural chemicals. The question remains, however, how to develop programs to ensure that these techniques are applied in the field. Below, we describe existing regulatory programs to control surface and groundwater contamination from both fertilizer and pesticides.

Regional Design Standards for Fertilizer Use: Central Platte Natural Resources District, Nebraska

Nebraska is beginning to incorporate design standards into its agricultural pollution control programs in order to address the contamination of groundwater by nitrates from commercial fertilizers.[169] By statute, Nebraska created Natural Resource Districts (NRDs) that have taken over the responsibilities of SWCDs as well as all local and regional water-quality and resource protection agencies.[170] NRDs have broad powers that

VOL 12

6936

R0040244

include taxation and eminent domain and are required to implement a regulatory program designed to reduce water contamination.[171]

In response to increased awareness of groundwater contamination, the Nebraska Ground Water Management and Protection Act was passed to create a procedure by which Natural Resources Districts can designate groundwater control areas and subsequently adopt at least one of the controls stated in the Act.[172] These include: "reasonable rules and regulations as are necessary to carry out the purpose for which a control area was designated."[173] Groundwater management plans must be prepared for those areas not previously listed as control areas.[174]

One Natural Resource District, the Central Platte NRD (CPNRD), has developed a vigorous regulatory program in response to the high levels of nitrates found in many of the drinking-water wells in the area.[175] This program is designed to accomplish the following objectives:

1. extract the nitrates in the groundwater by utilizing them for the nitrogen needs of the crop;

2. fully utilize the residual nitrates in the soil profile for the nitrogen needs of the crop;

3. reduce fertilizer applications to account for nitrogen available in the soil and in irrigation water;

4. reduce the "opportunity time" for fertilizer to leach below the root zone;

5. encourage (and require) farm practices, techniques and the installation of equipment that have proven to be helpful in reducing groundwater nitrate levels and nitrate leaching; and

6. research new equipment and techniques that have potential for reducing groundwater nitrates.[176]

Areas within the NRD with groundwater quality problems are categorized based on the level of contamination; increasing degrees of regulation are applied as the level of contamination increases.[177] Land is classified as a Phase I management area if the average nitrate/nitrogen level (measured by the district's network of monitoring wells) is between 0 and 12.5 ppm.[178] Phase II areas contain average nitrate levels between 12.6 and 20.0 ppm, while Phase III areas have average nitrate levels exceeding 20.0 ppm.[179] Monitoring to determine average nitrate levels takes place periodically to determine if an area should be reclassified.[180]

In Phase I areas, the fall and winter application (before May 1) of commercial fertilizer is prohibited on sandy soils (defined as soils with a permeability rate of two inches per hour or greater for at least 30 of the upper 36 inches).[181] In addition, water and soil testing and other nitrogen management BMPs are encouraged.[182] Farmers in the District's Phase II area, which covers 440,000 acres, are required, in addition to Phase I requirements, to attend irrigation and fertilizer management classes to become certified in nitrogen management.[183]

Generally, an annual water analysis for each irrigation well (there are 4,500 in the Phase II area) and an annual deep soil analysis on each field are also required.[184] Fall application of fertilizer is banned under most circumstances but is permitted on heavier soils after November 1 if an approved inhibitor is used to improve the efficiency of nitrogen use.[185] Farmers are required to submit an annual report to the district indicating:

1. results of the water nitrate analysis for each well;

2. results of the soils analysis on each field or 40 acre tract;

3. the crop planned to be grown and the yield goal;

4. nitrogen fertilizer recommendations;

5. actual nitrogen fertilizer rate applied; and

6. the actual yield achieved by each field, with irrigation well locations indicated.[186]

While there are no Phase III areas in the Central Platte NRD at this time, Phase III regulations which would be triggered if any are identified have been written. Under Phase III regulations, fall and winter applications of commercial nitrogen are banned while use of fertilizer in the spring requires split applications (or the use of an inhibitor if 50% or more of the fertilizer is applied before the planting).[187] In addition, Phase III controls can include such "other reasonable regulations as the Board feels are necessary to resolve the problem."[188]

The CPNRD, as well as local fertilizer dealers, are assisting farmers in meeting these regulatory requirements by working with testing laboratories to develop a standard form that will contain the necessary sampling information; providing a tagging service to identify each well; and considering arrangements with fertilizer dealers to offer soil and/or water sampling as a service to farmers.[189] The Board of Directors of the CPNRD believes this regulatory program will have a positive economic impact because of the savings to individual farmers from better use of the nitrogen available in irrigation water and in the soil.[190] Although the program began in late 1987 and no comprehensive data is available to judge its success, those participating in the meetings and hearings that led to the adoption of the regulations "showed a strong interest in improving and protecting ... groundwater quality and support for the type of program the [CPNRD] proposed."[191]

Statewide Groundwater Protection Regulations: Wisconsin

Wisconsin has a groundwater management law that provides a simple yet effective regulatory framework for addressing agricultural (as well as any other) groundwater pollution.[192] By extension, the law could be modified to apply to surface water protection as well. The Wisconsin law provides for the development of groundwater standards in the form of "preventive action limits" and "enforcement standards."[193] These two standards must be developed and implemented for substances detected in, or with the potential to enter, groundwater.[194] Some substances are listed in the Act itself. Additional substances must be identified by a number of state agencies that regulate activities, facilities or practices related to the regulated substances. The Department of Natural Resources (DNR) must set the actual standards through regulation,[195] addressing the most important contaminants first.[196] Each substance to be regulated must be included in one of the following three categories:

1. Category 1 - highest priority substances and detected in levels exceeding available federal criteria;

2. Category 2 - those detected in groundwater but not in excess of available federal criteria; and

3. Category 3 - lowest priority substances that have a "reasonable probability" of being detected in groundwater.[197]

"Enforcement standards" define when a violation has occurred and require the activity, practice or facility that is the source of the violation to be subject to immediate enforcement action.[198] Preventive action limits are considered "warning levels" to determine the need for regulatory measures.[199] When a preventive action limit is met or exceeded, the regulatory agency with authority over the substance must evaluate the situation and take whatever action is necessary to maintain the concentration of the substance at the preventive action limit or, if it has been exceeded, at the lowest feasible concentration.[200]

After enforcement standards have been promulgated, regulatory agencies must review relevant rules regarding the activities, practices and facilities that are related to each substance and, if necessary, revise their rules to comply with the requirement to prevent violations of the standards.[201] Each agency must adopt a rule indicating the responses the agency may require of itself or responsible parties when standards are exceeded.[202] Rules regarding design and management practices must ensure compliance with preventive action limits and enforcement standards, if feasible.[203] Whenever a pollutant reaches or exceeds the preventive action limit or enforcement standard, relevant agencies must again review and, if necessary, revise their rules to ensure future compliance with these standards.[204]

When a violation of a preventive action limit occurs, involved regulatory agencies must evaluate the situation and implement activities that will:

1. where technically and economically feasible, minimize the concentration of the substance at the point where measurements are taken to determine standards violations (the point of standards application);

2. regain and maintain compliance with the preventive action limit, or if this is not technically or economically feasible, the lowest possible concentration; and

3. ensure that enforcement standards are not violated.[205]

If an enforcement standard is violated, however, the activity or practice using or producing the substance *must* be prohibited unless it can be demonstrated to the regulatory agency that an alternative control mechanism will achieve compliance with the standard.[206] Once compliance is achieved, the regulatory agency is responsible for ensuring compliance with the preventive action limit in the same location.[207]

The DNR, in cooperation with other regulatory agencies, must develop and maintain a groundwater monitoring and sampling system. DNR must notify the relevant regulatory agency when information indicates that a substance has been detected, a concentration of a substance is changing, or a standard has been violated.[208] DNR also must notify owners and users of potable wells of the testing results of any samples obtained from the well.[209]

The Wisconsin program has not been fully implemented, but the Wisconsin Department of Agriculture, Trade and Consumer Protection (DATCP) already has used it to help curb the use of the pesticide aldicarb. Current activities include increased groundwater monitoring requirements and a ban on certain aldicarb applications in areas where measured groundwater concentrations exceed 10 parts per billion (ppb).[210] Permitted uses of aldicarb have also been restricted. The pesticide cannot be applied more than once every two years, and is limited to an application of 2 pounds of the active ingredient per acre (down from 3 pounds).[211] In addition, it can only be applied by, or under the supervision of, a state-certified pesticide applicator.[212]

On the Horizon: A Proposal for Comprehensive Groundwater Quality Protection

Few comprehensive programs have been developed to address systematically the groundwater contamination caused by both fertilizers and pesticides. However, a generic management proposal has been made by a group of environmental organizations for a federal groundwater protection program that also can be translated into recommendations for state programs designed to prevent groundwater contamination.[213] This program calls for the development of a general goal to protect groundwater quality along with waste reduction and source reduction goals to reduce total loadings of various groundwater contaminants (including pesticides and nitrates)[214] by specified percentages.

Over a period of time, the proposal suggests the development best practical methods (BPMs) and best available alternative method standards (BAAMs) to be applied to various activities responsible for groundwater contamination.[215] The standards would be required immediately for new and substantially modified sources, and would be phased in gradually for existing sources.[216]

Groundwater standards and monitoring strategies are proposed as a means of determining "special protection" and "special correction" areas where protection requirements would be more stringent.[217] Other program components, such as groundwater mapping, source identification and well monitoring and replacement would help to ensure that the program would function effectively.[218]

Agricultural officials in Massachusetts have proposed to control pesticide contamination of groundwater through a process similar to the one described above. First, pesticides that pose a risk to groundwater would be targeted by identifying:

VOL 12

6942

R0040250

1. pesticides that are susceptible to leaching because of physical and chemical properties;

2. application factors that may contribute to leaching;

3. priority pesticide use areas and the amount of pesticides used in these areas; and

4. the land areas susceptible to leaching because of geologic conditions.[219]

Each pesticide that may pose a risk to groundwater then would be ranked according to the health risk based on toxicological reviews, environmental fate studies and drinking water monitoring.[220] A variety of actions could be taken to ensure that pesticide residues do not approach the "health based standard as determined through the toxicological review."[221]

The action undertaken would depend on whether concern is focused on the control of a single pesticide (*e.g.*, product registration) or on the protection of the groundwater resource in general (*e.g.*, statewide regulations).[222] Since the groundwater protection program would function primarily on a pesticide-by-pesticide basis, many regulatory responses would involve changes in the registration conditions of individual pesticides.[223] Potential controls include restricted pesticide registrations that would allow their use only under specified conditions to protect groundwater resources.[224] Registrations also could be revoked, suspended or limited in a specific geographic area.[225]

Although this particular proposal has not been adopted, the Massachusetts Department of Food and Agriculture recently proposed regulations to "prevent contamination of public drinking wells by pesticides that pose a significant toxicological concern and meet or exceed significant leaching potential criteria."[226] The regulations would prohibit the use, handling, mixing, loading or storage of any pesticide posing a significant toxicological concern that has a significant leaching potential or is incorporated below the soil surface in sensitive groundwater areas.[227]

Other Promising Agricultural Runoff Control Programs

Florida has a state regulatory program addressing the water quality impacts of *new* farms in the state. The Department of Environmental Regulation (DER) requires that new farming operations in the state comply with its requirements for stormwater permits[228] unless the farm is operated under the requirements of an approved conservation plan.[229] Many agricultural operations, such as "muck farms" that are periodically flooded and drained, must obtain Management and Storage of Surface Water (MSSW) permits based on computer modelling and a review of the operation by a water management district official.[230] These permits contain site-specific requirements for the maintenance of certain BMPs and the abatement of pollution problems for the purpose of complying with state water quality standards.[231]

In other states, programs are being considered or are under development that address farm chemical contamination. A bill was introduced in the Pennsylvania General Assembly in 1988 that would "establish requirements and an implementation schedule for the application of nutrient management control measures on agricultural operations."[232] The bill would establish a program requiring all farmers to submit and implement a "best management plan for nutrient control" in conformity with requirements and regulations adopted by the state Department of Environmental Resources (DER).[233] Although not in agreement with the specific details of the proposal, DER supports the concepts of the bill.[234]

In Arizona, legislation has been enacted that requires the Department of Environmental Quality (DEQ) to adopt General Permit rules that require the implementation of Best Management Practices for nitrogen fertilizer application.[235] By statute, the application of nitrogen fertilizer is a regulated activity which requires site-specific BMPs to be developed and used such that Aquifer Water Quality Standards are not violated.[236] Although permit requirements have not been developed at this time, the simple, straightforward nature of these program requirements indicates that the adoption of BMPs to manage fertilizers does not, by nature, have to be left completely to the discretion of the farmer. The program also shows that state environmental protection agencies can play an important role in the development and application of agricultural BMPs.

DEQ will propose rules requiring the implementation of a BMP plan that consists of an "on-site operational plan" and "appropriately implemented site-specific BMPs."[237] One of the purposes of the BMPs that will be developed will be to minimize the "movement of soluble nutrients to depths below the root zone."[238] While this program is still in the formative stage, it demonstrates the state authority that can be exercised when water resources are threatened.

Using Regulatory Controls in Livestock Agriculture

Livestock, including dairy and beef cattle, hogs, sheep and chickens, can contaminate surface and groundwater with nitrate, ammonia and fecal bacteria and also can increase drastically streambank erosion if the animals are allowed access to riparian areas.[239] Half of the 120 million tons of animal manure produced each year in the United States is generated by herds of *less than 100 cows* owned by hundreds of thousands of individuals.[240] These sources currently are not regulated under the CWA because, under EPA regulations, point source controls generally do not apply to herds of less than 1000 head.[241] Because water quality problems can result from small and medium-sized herds of cattle and other livestock, as well as from larger herds,[242] pollution control programs need to address all sizes of livestock operations.[243]

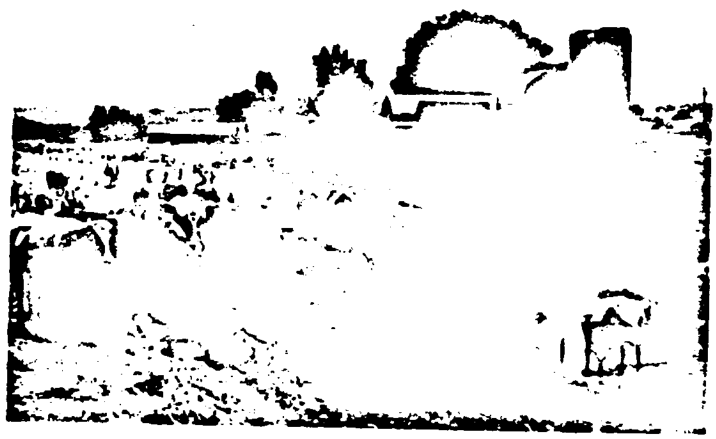
One hundred million cattle are raised unconfined on 40 percent of the U.S. land area (including both pastures and rangeland.[244] But the remaining 12 million head raised in confined feeding operations also can cause severe water quality impacts.[245] This section discusses pollution control programs for confined livestock feeding operations and the associated (unconfined) grazing of such livestock in limited pasture areas as distinct from rangeland settings.[246]

In general, few states have developed significant regulatory programs for controlling animal wastes from small, confined animal feedlots or from unconfined cattle production.[247] Howev-

VOL 12

6945

R0040253



Livestock agriculture accounts for widespread water pollution problems.

er, some activity is underway, and the potential for more progress is good given recent research concerning methods for reducing the water quality impacts of livestock production.

Generally, control of contaminated runoff from unconfined cattle production (in both range and pasture settings) can be accomplished by:

1. using an effective erosion control program (discussed previously);

2. tailoring grazing programs and stocking densities to localized climate, soil, vegetation, topography and geology;

3. locating high density grazing and holding pens away from streams and associated riparian areas;

4. dispersing feeding, watering and shelter facilities to reduce manure accumulation, soil compaction, and erodible pathways;

The use of animal waste as fertilizer can be an effective disposal method only so long as the application rate matches crop needs.

5. maintaining grass/vegetative cover downslope from animal congregation sites and along stream banks; and

6. maintaining good forage and ground cover.[248]

Pollution from small confined cattle feedlots can be reduced by:

1. locating the facility away from streams or drainage channels;

2. using diversion terraces and roof gutters to divert runoff away from the feedlot surface;

3. collecting solids carried off the feedlot and settling them out in channels or grass waterways where they can be

collected and land disposed in an environmentally sound manner;

4. installing a large filter strip to intercept runoff before it enters a waterway;

5. installing a holding pond to trap runoff where it can be collected and disposed of by irrigation; and

6. using manure nutrients as a fertilizer to improve soils.[249]

Examples of programs that implement this type of requirement are given below.

Regional and Local Regulatory Programs: California

In California, one of the state's Regional Water Quality Control Boards (Santa Ana) has established individual waste discharge requirements for *all* dairy or confined animal facilities.[250] Under this program, facility operators must obtain a discharge permit to ensure that the facility is designed according to the standards established by the Regional Water Quality Control Board.[251] Basic requirements include:

1. an inventory of the population of animals in relation to the design capacity of the facility;

2. collection of all water runoff from manured areas that results from up to a 25-year frequency storm;

3. zero runoff when irrigating with barn water or runoff water;

4. a limit of 3 dry tons of manure per year per acre of disposal land (disposal land is defined as land used exclusively to percolate barn and runoff water);[252]

5. manure applications to cropland must be based on the crop's requirements for nitrogen;[253] and

VOL 12

6948

6. an annual report signed by the owner (under penalty of perjury) revealing the volume of manure produced and the location and method of disposal.[254]

These types of requirements are becoming more popular in the rest of California.[255] In addition, several counties in California (including Tulare, Kern and Kings) have been working with Regional Water Quality Control Boards to develop zoning ordinances that would establish minimum acreage requirements for unconfined livestock production in order to reduce the density of manure in pastureland,[256] as well as ordinances requiring runoff generated in the dairy area to be kept onsite.

A State Approach to Regulating Livestock Agriculture: Iowa

Iowa also has developed requirements for all confined feedlots. These apply (regardless of size) to open feedlots exposed to rainfall, total confinement systems where precipitation is not a factor, and to facilities with a mixture of these two kinds of systems.[257] At a minimum, all open facilities must remove settleable solids runoff.[258] This is accomplished by requiring that the velocity of the feedlot runoff be reduced to certain levels through design standards for certain types and sizes of operations.[259]

In addition, operations permits must be obtained for open facilities with over 700 head of livestock and for closed facilities (or open facilities with natural streams running through them) with over 300 head.[260] Operations permits are patterned after federal requirements for large, confined animal feedlots (*i.e.*, retention of all waste flows from a 25-year frequency, 24-hour duration storm).[261] Iowa regulations recognize, however, that most problems do not result from single, large storm events, but from repeated rains that create small discharges or that discourage the farmer from removing manure, and from manure accumulation over the winter. Therefore, Iowa regulations provide options allowing the farmer to dispose of manure less frequently if larger storage structures and other means are used to address these problems.[262]

VOL 12

6949

R0040257

Total confinement systems of any size must meet a minimum standard of zero discharge into Iowa state surface waters. This usually is accomplished using storage pits located under or outside the containment structure.[243] Finally, manure collected through these requirements must be land disposed in a way that prevents contamination of surface and groundwaters.[244] Unlike the California program, disposal methods are not mandated. Guidelines are provided, however, to assist farmers in complying with the general prohibition against water pollution from land disposal.[245]

Creative Application of Sewage Disposal Regulations: Pennsylvania

The water quality impacts of livestock agriculture also can be regulated under sewage treatment programs. Pennsylvania's Clean Streams Law defines animal manure as sewage and thus prohibits its discharge into state waters unless that discharge is pursuant to a permit issued by the state Department of Environmental Resources.[246] Under state regulations, permits for the storage of animal manure are required unless the storage facilities are designed and operated according to state approved manure management practices. Permits for the land application of animal manure also are required unless application is in accordance with approved manure management practices.[247]

Summary

A significant problem with many of these feedlot and land application programs is that, even if mandatory and applicable to all sizes of operations, enforcement often relies on citizen complaints of acute water quality problems from feedlot discharges. More structural and automatic enforcement mechanisms are needed to enforce these standards.

Iowa, for instance, still bases the enforcement of its program on complaints. But in Iowa, water quality problems do not have to be identified to enforce design standards; only a violation of the standards themselves is needed to trigger enforcement.[248] California's program is based on requirements in state law for controlling runoff from confinement and manure application areas; some regions implement this objective through permit and reporting procedures to ensure compliance with standards and guidelines.[269]

Besides programs that reduce sediment and chemical contamination from non-irrigated crops and livestock agriculture, innovative approaches also have been developed to address pollution from irrigated cropland. These programs are described in the following section.

Improving Irrigation Efficiency to Protect Water Quality

Irrigated agriculture can affect ground and surface water quality through the addition of sediments, nutrients, pesticides, salts and other minerals.[270] In addition, fluctuations in the natural flows of rivers from irrigation reservoirs and diversions have caused damage to local populations of anadromous fish, wildlife habitat and recreation.[271] Most scientific studies on irrigation have focused on increasing crop yields and improving distribution systems, while relatively little attention has been given to controlling the water quality impacts of irrigation.[272] Problems are most severe in the arid and semiarid portion of the west where higher evaporation rates cause salts to accumulate near the surface of the soil.[273]

Natural water bodies receive irrigation water through open drains and ditches and underground tile drainage channels that collect return flows.[274] Irrigation water also can leach into groundwater.[275] Once this water leaves the farm, it can be used for other purposes, including wildlife habitat, reuse for irrigation, and drinking water.[276] Fundamentally, drainage is the disposal of unwanted or excess water to prevent plant injury, to minimize salt accumulation in agricultural soil and to allow early planting.

In some cases, reducing water volumes can greatly lower the quantities of trace elements transported by irrigation flows into receiving waters. This is so because the more irrigation water that comes in contact with the soil, the more pollutants potentially become available for transport. Thus, the efficiency of irrigation systems is an important consideration in preventing water pollution.[277] As with nitrogen, in some cases farmers simply may be using *too much* irrigation water. Correcting overuse could

Many important wetlands and wildlife habitat areas are affected by irrigation waters that have drained from surrounding agricultural areas.

save money as well as reduce pollution.[278] In other instances soil conditions are such that water quality can be impaired by relatively modest amounts of irrigation water. In such situations more severe solutions, such as purchase, transfer or modification of water rights, may be necessary to reduce drastically or to eliminate the use of irrigation water in a given area.

Concerns over efficiency and water quality arise from all aspects of irrigation, including river and reservoir operation; conveyance and distribution; on-farm application; cropping patterns; and return flow management.[279] Estimates of the need for irrigation water often do not consider fully changes in technology that could reduce water losses from evaporation, or the decreased water needs of improved strains of plants; the need for less "non-degraded" irrigation water as opposed to irrigation water that is high in salt content; and the increase in efficiency that would result from pricing irrigation water in accordance with its actual cost.[280] Methods to address the water quality problems associated with irrigation include:

1. restricting irrigation development in areas where water quality degradation is likely;

2. regulating the use of fertilizer or other agricultural chemicals that contaminate return flows (*e.g.*, this approach is exemplified by the program in Nebraska, discussed previously, that restricts fertilizer applications on irrigated cropland);

3. regulating when and how much water can be used; and

4. treating the irrigation water at various geographic levels (*e.g.*, individual farmer or regional areas), using those responsible for its degradation as a partial source of finance.[281]

Water quality problems caused by irrigation share many common characteristics with dry land agriculture. Therefore, many of the programs used for dry land agriculture could be modified to apply to irrigated farmland as well, and vice versa. Recent attempts to address the water quality impacts of irrigation have focused largely on improving the efficiency with which water is used, thereby reducing the quantity of water draining into surface- and groundwater systems as well as the pollutant loads associated with this water.[282]

The San Joaquin Valley in California has suffered major water quality impacts from irrigation, which in turn has threatened the viability of the extensive agricultural economy in the region.[283] In response, the State Water Resources Control Board, the San Joaquin Valley Drainage Program[284] and others are conducting research to assist the Central Valley Regional Water Quality Control Board in the development of a basin plan to restore the region's water quality.[285] Water quality "objectives" (*i.e.*, water quality standards) for selenium, boron, salts, and molybdenum, and dates for compliance with these objectives, have been recommended by the San Joaquin River Basin

Tile drainage can be contaminated with toxic substances that accumulate in agricultural soils.

Technical Committee (made up of staff from the State Water Resources Control Board and its regional Central Valley Water Quality Control Board).[286]

The Committee has recommended reducing drainage volumes, and consequently reducing pollution loads, through improving water management practices and implementing improved irrigation technology.[287] The Committee also has recommended the formation of a regional drainage district to improve coordination of irrigation activities in the area; provide flexibility in meeting water quality objectives; and reduce the costs associated with managing the area's water table and issuing individual permits.[288] Finally, the Committee has recommended the establishment of waste discharge requirements through permits, and requiring the adoption of BMPs to reduce pollutant loads.[289]

Institutional changes also are necessary to achieve significant reductions in the use of irrigation water in the San Joaquin

Valley. The high irrigation water subsidies provided by the federal government make the prices paid by farmers abnormally low, which in turn encourages inefficiency and overconsumption.[290] Substantial price increases would have to occur in order for the costs of water to be an effective incentive to reduce water use.[291] Other suggested institutional changes to promote water conservation include:

1. water transfers, which offer incentives for conservation by allowing the sale of conserved water for profit;[292]

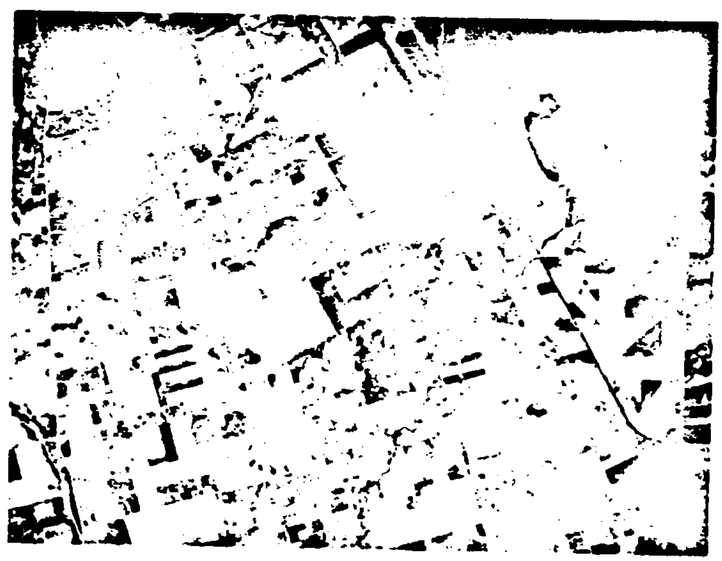
2. tiered water pricing whereby local irrigation districts charge higher prices for successive units of water; and

3. the expansion of water authorities to include drainage districts, groundwater control districts, or comprehensive water management districts, thus providing: (1) management, treatment and/or disposal of drainage water; (2) management of groundwater conditions through planned and controlled pumping; and (3) comprehensive management of surface-, ground-, and drainage water.[293]

Another way to improve the efficiency with which irrigation water is used is to provide tax incentives to operators who install equipment designed to use irrigation water more effectively. For instance, the tax code for South Carolina allows taxpayers to claim as a deduction the cost of purchasing and installing drip/trickle irrigation equipment (up to $2,500).[294]

Farmland Protection Programs, Conservation Easements and Leasing Arrangements

The destruction of prime farmland is an important (if indirect) contributor to water pollution because it forces the cultivation of more marginal land not well-suited for farming.[295] For this reason, farmland protection programs have great potential as an indirect means to reduce water quality impacts while at the same time controlling urban sprawl and generally increasing the effective application of land use controls. This



Farmland protection programs are useful only if landowners that benefit from the program are required to control adverse water quality impacts. These two photos show development of the same area over a 28 year period.

kind of program brings in farmers as *proactive* participants in solving pollution problems as well as other land use problems rather than just as subjects of regulation.

Comprehensive farmland protection programs encourage farmers to continue farming rather than sell their land to developers; discourage developers from obtaining prime farmland; and statutorily define land areas where the intrusion of conflicting land uses is discouraged or prohibited.[296] Collectively, these actions protect agricultural areas against encroachment of conflicting land use.

While a comprehensive discussion of farmland protection programs is beyond the scope of this study,[297] it is useful to describe briefly some of the innovations that have occurred in this area. A broad array of activities is being undertaken to protect prime farmland, but certain techniques have been more effective than others in preserving farmland and in reducing

The citrus farming area in the photo at left has been transformed into a dense suburban development.

agricultural water pollution. Successful farmland protection programs have three notable characteristics: incentives to encourage participation in the program; severe penalties assessed for withdrawal from the program; and effective enforcement.[298]

Farmland protection activities can range from simple tax incentives to complex "farmland districting" systems. Differential assessment mechanisms (called "use value" taxation) can tax farmland according to its value for agricultural use rather than for potential development use, thereby reducing the farmer's taxes—a technique used by nearly every state.[299] More complex and comprehensive programs can involve varying degrees of mandatory participation, zoning, or other land use controls designed to create agricultural districts where development is discouraged or barred altogether.[300]

Agricultural zoning can be used to preserve prime farmland through a state regulatory program mandating that localities zone certain types of lands for agricultural uses.[301] The zoning program can be carried out within agricultural districts that are defined to ensure that agricultural production in a given area is high enough to support the local service economy, which in turn supports the agricultural economy.[302]

Some county governments have begun Transfer of Development Rights (TDR) programs, which preserve certain agricultural land in exchange for allowing increased development in already urbanized areas.[303] Twelve states and some localities have established Purchase of Development Rights (PDR) programs, under which the right to develop agricultural land is purchased outright from the farmer or potential developer and is retained by the state or locality to preserve the land in its agricultural or natural state.[304]

One of the most widespread farmland protection activities, the "use value" tax assessment mentioned above, has proven not to be highly effective in protecting prime farmland, because the tax breaks to the farmers often are outweighed by the price that the developers offer for the land.[305] Other protection programs are needed to supplement the differential tax assessment approach. These programs might include the PDR and TDR programs mentioned above, as well as agricultural districting and comprehensive growth management programs, such as those in place in Oregon, California and Hawaii.[306] Penalties for withdrawal from programs should be substantial, and states should ensure that programs apply only to prime farmland.[307] For instance, Maryland and California use land productivity measures to determine the eligibility of farmland for differential use value assessment.[308] Finally, since agriculture itself is a source of water pollution, it is vital that any farmland protection program include provisions requiring that eligible lands be managed so as not to produce significant off-site damages.[309] Such a provision exists in the Wisconsin protection program, which requires participating farmers to implement approved soil conservation techniques that meet "T" standards for erosion control.[310]

In North Carolina, farmers can band together to form agricultural districts to protect their land from annexation or special tax assessments. But they must manage their lands "in accordance with the SCS-defined erosion control practices applicable to highly erodible land."[311] Keene (1984) has proposed a set of recommendations for the development of effective farmland protection programs. The recommendations are:

1. A state land planning agency with authority:
   a. to establish a comprehensive plan for the development and protection of the state's resources, including agricultural land, and
   b. to create urban growth boundaries around all major cities and towns located in or near agricultural reserves, within which fifteen to twenty years' anticipated growth can be accommodated.

2. A state agricultural land agency with authority:
   a. to regulate land use in agricultural reserves;
   b. to delegate the authority to regulate land use in agricultural reserves to local governments that enact regulations meeting state criteria, and
   c. to exercise a right of first refusal with respect to farmland that comes on the market and to buy it at publicly appraised fair market value and then to resell it to farmers at below market value.

3. Appropriate combinations of tax reduction and other economic compensation to owners of land that has a reduced market value because it has been placed in an agricultural reserve.[312]

On a more comprehensive scale, a regional system of open space preservation is being considered seriously by localities in the San Francisco Bay area to preserve up to 3.5 million acres of land (and related water resources) from the impacts associated with the region's high growth rates.[313] This approach calls for the development of a Bay Area Greenbelt to preserve farms and ranches, watersheds, parks and other recreation areas, and buffers between communities.[314] The plan for the Greenbelt incorporates expected housing, industrial and commercial land requirements for the next 50 years.[315] The plan may designate open spaces where development will not be permitted, while identifying "infill" spaces where future development will be

VOL 12

6959

allowed.[316] This regional approach to comprehensive planning provides many opportunities to address existing and potential pollution problems through sound land use management. Such comprehensive land use management approaches are discussed further in Chapter Four.

Conservation easements that preserve farmland also have been proposed as a way to improve indirectly the control of pollution while achieving other goals, such as production control and farm debt reduction.[317] Through the use of conservation easements, state and local governments, as well as conservation groups, can purchase certain rights on agricultural land, permanently barring water pollution-generating activities by incorporating easement provisions into the title of the land.[318] In exchange for certain rights to farm or develop land, outright payment could be made or a farmer's debt could be restructured and guaranteed by the state, according to the value of the rights conveyed in the easement.[319] Easement provisions could be tailored to suit the conservation needs in the area. These include:

1. limiting general or particular types of residential, commercial, or industrial development on prime farmland;
2. specifying the agricultural management of marginal land;
3. protecting natural habitat and wildlife on land not suited to certain kinds of agriculture;
4. reducing or barring irrigation in areas experiencing water shortages;
5. prohibiting grazing in forests and woodlands;
6. limiting tillage and crop production in natural waterways, floodlands and wetlands;
7. requiring filter strips in strategic areas; and
8. allowing public access for open-space recreation.[320]

Given advances made in BMP development and application, many other practices such as fertilizer, manure, and pesticide application controls also could be implemented to provide water quality protection to meet specific needs. USDA already recognizes the protection of surface and groundwater quality as legitimate purposes that conservation easements can be used to promote.[321] The use of easements is very promising, and becomes increasingly so as agricultural land values rise.[322] New Hampshire recently introduced legislation authorizing $10 million per year for five years to be spent to purchase easements in order to protect open space.[323] Massachusetts has restricted 18,674 acres of farmland to permanent agricultural use.[324]

Finally, leasing arrangements provide a method to improve water quality by creating an agreement between the farm operator and the landlord concerning the conservation practices on a particular farm.[325] Leasing arrangements that consist of written, multiyear agreements are preferred over oral, indefinite or year-to-year leases, and should allow the incorporation of a significant conservation and cost-sharing clause.[326] Longer leases are preferable because they provide more security to farmers and lengthen their planning horizons.[327] These clauses could be required when land is leased for agricultural purposes to specify the type of crop rotation and the BMPs to be used, as well as the division of the costs associated with the conservation practices.[328]

Of course, the landlord must have some incentive to include such provisions in a lease. A graduated lease premium has been suggested, whereby increasing payments would be made by a county or state to the landlord in exchange for increasing the length of the lease or having the lessee implement certain conservation practices with financial assistance from the landlord.[329] An important component of such a program is bringing an often uninformed and uninterested landlord into the long-term arrangement.[330]

Conclusions and Recommendations

Agriculture, including crop and livestock production, obviously can have many adverse effects on water quality, including sediment- and phosphorous-related surface water impacts from crop production; nitrate and bacterial surface and groundwater impacts from livestock production; and pesticide and nitrate impacts on both surface and groundwater. Therefore, effective programs to reduce the agricultural impacts of poison runoff and leachable contaminants must be able to implement a broad array of BMPs.

Voluntary programs based on cost-share incentives often will be less cost-effective and provide less overall protection than regulatory programs. Participation rates in current voluntary programs are often low. Even if effective, voluntary cost share programs require a massive infusion of government funds to tackle the widespread problem of pollution from agricultural runoff. And even if the necessary funds are available, serious questions of equity arise. The general taxpayer is asked to subsidize pollution control by the agricultural sector. Cost sharing rewards farmers for poor land stewardship, and punishes those with existing good stewardship practices. It places water quality protection goals at the mercy of an uncertain and unstable agricultural economy and often does not promote the best ways to control agricultural pollution.

A sound regulatory basis for design standards and taxes has been established in some states, regions and localities. These programs address pollution from cropland, livestock, and other agricultural operations. They have been effective in addressing a wide range of pollutants, including sediment, nutrients, bacteria and pesticides.

The programs described in this chapter give examples of how states and localities can implement the particular kinds of controls they need to address specific water quality problems. Here are the key recommendations drawn from these exemplary programs:

1. Unless states can demonstrate that voluntary controls (including cost-sharing, technical assistance and education) alone will result in the pollutant load reductions needed to achieve beneficial water uses in individual watersheds, and unless sufficient funds are available to achieve this result,

regulatory programs in the form of design standards and taxes should be developed, implemented and enforced.

2. Regulatory programs require one or more mechanisms to require or to induce farmers to implement adequate BMPs. These include:
   a. Design standards that require or prohibit certain practices;
   b. Design taxes based on farm management practices; and
   c. Performance standards that prohibit any significant off-site transfer of pollutants.

   The most effective programs may involve a combination of these approaches.

3. Technical assistance and education programs from the state (to regional and local program officials) as well as from sub-state officials (to the actual regulated parties) are important components of pollution control plans, but should not be used in lieu of regulations if serious pollution problems must be addressed.

4. Regulatory programs must require consistent and effective enforcement activities including: inspections; response to complaints; issuance of notices of violations; issuance of fines and other enforcement tools; an appeals process; and procedures for corrective action.

5. State and local officials should enforce agricultural water pollution control programs on a priority basis using all available information (*e.g.*, groundwater studies, geologic maps, cropping and farm management information, soil erosion estimates, etc.).

6. Nutrient and fecal bacterial contamination of surface and groundwater should be controlled through programs that:
   a. restrict the amount of fertilizer or manure applied to the ground;
   b. control the timing of these applications;

6963

c. require the development of forested buffer strips along streams; and
d. reduce the net amount of nutrients available for transport after crop needs have been met.

7. Programs to address water pollution from pesticides should include Integrated Pest Management (IMP) techniques. IPM components include:
   a. eliminating the prophylactic use of pesticides, *i.e.*, requiring testing for the presence of a target pest before a pesticide is used;
   b. replacing toxic, leachable pesticides with materials that are less toxic, mobile and persistent;
   c. using alternative crop patterns and techniques, such as crop rotation and crop species that are more resistant to pests; and
   d. controlling the amount and timing of pesticide use.

   States also should control pesticide pollution through taxes on pesticide sale and manufacture, and comprehensive regulatory programs that include area-specific problem assessments and restrictions on use and application along with pesticide registration and reporting requirements.

8. Livestock pollution control programs should require the control of runoff and leaching from confined feeding and storage areas regardless of herd size. Such programs should also require:
   a. control of livestock densities and locations;
   b. prevention of livestock access to riparian areas;
   c. regulation of the disposal of collected manure through land application;
   d. adequate dispersal of livestock facilities and location; and
   e. maintenance of adequate ground cover and forage.

VOL 12

6964

9. Water quality impacts from irrigation return flows should be reduced by requiring more efficient use of irrigation water and through regulations that control irrigation scheduling and the use of farm chemicals within the control of a comprehensive, multi-purpose regional drainage district. Irrigation subsidies should be eliminated or substantially reduced.

10. Farmland protection programs should go beyond traditional use value tax assessment programs and include a comprehensive state-level preservation plan (with local implementation) that preserves prime farmland using Transfer of Development Rights and Purchase of Development Rights programs, agricultural zoning and districting, and other land use controls.

11. Farmland protection programs should require that all lands receiving benefits from state and local programs participate in state programs to control poison runoff by requiring that off-site agricultural impacts be addressed adequately.

12. Conservation easements should be purchased from farmers for sensitive riparian land that cannot be managed feasibly through the use of the regulatory or tax-based programs described above. Easement provisions should be tailored so that the title to the farm requires the effective control of off-site water quality damages.

Notes - Chapter Three

1. Most states with programs designed to address agricultural NPS pollution rely primarily on voluntary cost share programs, along with education and technical assistance. U.S. EPA, *Report to Congress: Nonpoint Source Pollution in the U.S.*, Washington, D.C., January, 1984, at 3-7.

100. Dunn, James W. and James S. Shortle, "Agricultural Nonpoint Source Pollution in Theory and Practice," paper presented at the Conference on the Economics of Chesapeake Bay Management III, Annapolis, Maryland, May 27-29, 1987, at 17; *see also* Shortle, James S. and James W. Dunn, "The Relative Efficiency of Agricultural Source Water Pollution Control Policies," 68 *AJAE* 676 (1986).

101. Dunn and Shortle, 1987, *supra* note 100, at 17.

102. *Id.*

103. Dunn and Shortle, 1987, *supra* note 100, at 10-14. Some analysts predict that theoretically the most *cost-effective* approaches are *design incentives* in the form of *farm- specific* taxes at rates appropriate to bring about the desired level of conservation and pollution control on the part of the farmer. *See generally* Dunn and Shortle, 1987, *supra* note 100, at 8-14; *see also* Shortle and Dunn, 1986, *supra* note 100, at 676. Under such a system, a farmer would be charged a particular tax for his or her set of management practices based on their site-specific effect on water quality. According to the *theoretical* analysis, for a particular practice on a particular farm, an individual tax would be set at a rate just high enough to reduce pollution to desired levels, based on some measure of the water quality damages caused by the farmer's management choices. Taxes would be different for each practice based on each farm's individual environmental circumstances and the farmer would be free to choose how much pollution (and tax) was in his best economic interest. Dunn and Shortle, 1987, *supra* note 100, at 9-12. However, because of various factors relating to the difficulty of identifying an optimal tax schedule for each farm, in the agricultural context the *farm specific* design tax approach can be "of little practical interest because of the cost and complexity of the procedure." *Id.* at 10-14. It is also inconsistent with the fundamental approach of the Clean Water Act, under which there is no inherent "right" to pollute the nation's waters. The Clean Water Act envisions that pollutant discharges will continue only to the extent that there are technological limitations on our ability to control pollution. *See* S. Rep. No. 414, 92d Cong. 1st Sess. 42 (1971) *reprinted in A Legislative History of the Federal Water Pollution Control Act Amendments of 1972*, Congressional Research Service, at 1460 (1973). Decision-makers should be careful to differentiate control policies that are *theoretically* optimal from those that worked best *in practice*, given the present level of knowledge concerning the effect of farm management practices on water quality and the costs of BMP applications on farms. *See*, Dunn and Shortle, 1987, *supra* note 100, at 14.

104. Dunn and Shortle, 1987, *supra* note 100, at 17.

105. *Id.*

106. *See generally* 40 CFR 264; 42 U.S.C. §6424.

107. One author has proposed a model state program for setting standards and compliance schedules for soil erosion controls on farmland, with SWCDs responsible for setting local standards, surveying soil erosion and advising local governments of violations. Localities would be responsible for enforcement. Mandatory enforcement based on soil loss from individual farms would replace inconsistent enforcement based on complaints from damaged property owners. *See* Coughlin, Robert E., "Regulation of Soil Loss on Farmland: How Effective?," 40 *JSWC* 338-339 (1985).

108. To operate effectively, a regulatory program must have several components in place.

1. inspections;
2. response to complaints;
3. issuance of notices of violations;
4. issuance of fines;
5. an appeals process; and
6. procedures for corrective actions (including injunctive relief).

109. Wheeler, Philip H., Assistant Planning Director, Rochester-Olmsted County Consolidated Planning Department, "Olmsted County's Farmland Soil Loss Control," (no date), at 2-3; Zoning Ordinance Amendments Addressing Farmland Soil Erosion, Olmsted County, at §10.21(A) (hereinafter cited as Olmsted County Zoning Ordinance.

110. *See* Wheeler, (no date), *supra* note 109, at 3; Olmstead County Zoning Ordinance, *supra* note 109, at §10.21; Minnesota Department of Health, *A Guide For Local Health Professionals Involved in County Comprehensive Water Management Plans,* June, 1987, Part III, at 14-15.

111. *See* Wheeler, (no date), *supra* note 109, at 2-3.

112. *Id.* at 4. Enforcing soil erosion ordinances through complaints is not a adequate means of ensuring that minimum soil erosion controls are implemented. *See generally* Coughlin, 1985, *supra* note 107.

113. *Id.*

114. "T" value (for soil loss tolerance) is a measure of "the maximum rate of erosion that can occur on a soil without reducing the soil's capacity to support sustained economic production." U. S. Department of Agriculture, 1987, *supra* note 5, at 4-9. As mentioned throughout this report, soil erosion is often an inadequate proxy for poison runoff—specifically in approximating sediment delivery and agrichemical contamination. Crosson, 1985, *supra* note 2, at 31-33. However, this type of program could be modified to apply to poison runoff as well.

115. *Id.* at 6-7. Other related factors were incorporated into this point system. Factors were scored and weighted in the ranking system as follows:

1. the ratio of total erosion to tolerable soil loss was given a multiplier of one in the above ranking;
2. the total erosion score was given a multiplier of six (total erosion was considered a more significant contributor to off-site damages than the ratios of total erosion to tolerable soil loss limits);
3. poorly managed pasture was given an additional score of three;
4. areas with hydrologic runoff curve numbers greater than 81 were given a score of three;
5. areas within a flood control project watershed were given a score of nine. *Id.* at 6-11.

VOL 12

6974

116. *Id;* Olmsted County Zoning Ordinance, *supra* note 109, at 10.21(E).

117. Wheeler, (no date), *supra* note 109, at 11; Olmsted County Zoning Ordinance, *supra* note 109, at 10.21(G).

118. Wheeler, (no date), *supra* note 109, at 2, 4-10. There are 119 mapping units in Olmsted County describing soil, water and non-soil features. There are also 46 land use/cover classes identified in the mapping system that are distinguished on the basis of land use, erosion and runoff characteristics. Twelve types of cropland have been identified that include all possible combinations of rotations, contouring, terracing, and residue management. *Id.*

119. *Id;* Olmsted County Zoning Ordinance, *supra* note 109, at Appendix D-G.

Keeney, Dennis, "Nitrogen Cycle and Fate of Applied Nitrogen," paper presented at the Symposium of Plant Nutrient Use and the Environment, Kansas City, Missouri, October, 1985, at 16-18; *see generally* North Carolina Agricultural Extension Service, *Best Management Practices for Agricultural Nonpoint Source Control–IV. Pesticides*, September, 1984; North Carolina Agricultural Extension Service, *Best Management Practices for Agricultural Nonpoint Source Control–II. Commercial Fertilizer*, August, 1982.

152. Keeney, 1985, *supra* note 151, at 22.

153. Madariaga, 1986, *supra* note 16, at 4-6; Crowder, Bradley and C. Edwin Young, *Managing Farm Nutrients–Tradeoffs for Surface-and Ground-Water Quality*, U. S. Department of Agriculture, Economic Research Service, January, 1988, at 15. This relationship between surface water pollution and groundwater contamination is so important that CWA §319(b)(2)(A) requires that the BMPs identified in State Nonpoint Source Management Plans take "into account the impact of the practice on groundwater quality."

154. Although a good deal of phosphorus NPS pollution can consist of particles attached to sediment, there still are questions regarding the significance of dissolved phosphorus that can be controlled by typical erosion control techniques. North Carolina Agricultural Extension Service, 1982, *supra* note 151, at 37-39; Gianessi, Leonard P., *et al.*, "Nonpoint-Source Pollution: Are Cropland Controls the Answer?," 41 *JSWC* 216 (1986); U.S. Fish and Wildlife Service, *Nutrient Dynamics in the Choptank River Watershed–A Comparative Analysis of Subwatershed Exports*, Annapolis, Maryland, April 1988, at E-3 - E-4. Since phosphorus can often be controlled through the proper use of BMPs that control erosion, runoff and sediment deposition and/or controls similar to those that reduce surface water and groundwater contamination by nitrogen and pesticides, this section focuses on these latter two contaminants.

155. *See* Crowder and Young, 1988, *supra* note 153, at iv., 15-18.

Management Plan, (Volume 1), December, 1985, at 15. (hereinafter cited as *CPNRD Groundwater Management Plan*).

161. *See generally*, Shabman, 1988, *supra* note 38, at 10-18. This nitrogen control plan is more involved than the steps described above. Other aspects include:

1. deemphasize cost sharing no-till BMPs (because of their inherent profitability to the farmer) and increase the use of cover crops along with changes in other farm management areas such as crop rotation, animal waste utilization, etc.;
2. improve the use of wooded buffer strips and regional manure storage and distribution facilities (to increase the availability of manure fertilizer to fields where it can be used);
3. channel research to address the development of total farm management systems that account for nutrient cycling over time instead of "isolated" research issues;
4. carefully develop economic incentives to decrease the initial economic impacts that can come with input substitution (including investment tax credits, accelerated depreciation and low interest loans).

In an input substitution strategy, if direct cash subsidies (cost sharing) are used they should: be for a limited time interval; take into account the value to the farmer of the reduced need for commercial fertilizer; and require that commercial applications of fertilizers be considered as organic sources of nitrogen increase. *Id.* at 14-18.

162. *Id.* at 2-8.

Chapter Four

Land Use and Contaminated Urban Runoff Controls

Introduction

Contaminated runoff from urban areas presents unique management requirements. For example, most urban water pollution runs off or through government-controlled streets or stormwater systems. Therefore, programs to control poison runoff may require even more involvement by local governments than agricultural controls. Additionally, water pollution in urban areas is caused by a diverse set of sources whose management requires a broad range of program activities.

Like controls for other categories of poison runoff, however, urban controls must address *aggregate* pollution sources that individually contribute relatively minor pollution loads, but that cumulatively may have large impacts. Fortunately, urban residents may be more willing than rural residents to pay for controls and to accept the need for regulation.[1] In fact, unlike agricultural pollution control programs, there is little debate over the "voluntary vs. regulatory" issue in controlling pollution from urban areas. Specific regulatory urban controls (such as erosion and sediment control and stormwater management requirements) already are common, although many *general* urban program to control poison runoff still have significant voluntary components.[2]

An array of controls is available to address poison runoff generated in urban areas. In this chapter, these controls are grouped into three general categories:

1. land use controls;
2. stormwater control programs; and
3. erosion and sediment control programs.

The necessary elements of each type of program are described below, drawing on examples from model programs around the country.

Two general principles, however, transcend each type of program. First, comprehensive urban runoff controls cannot and should not be divorced from the routine functions of local government—in particular, zoning and comprehensive planning. For example, some experts have labeled zoning the most effective local means to control groundwater contamination.[3] Urban runoff problems also are addressed most effectively by sound land use planning, rather than by focusing only on structural stormwater controls.[4]

Similarly, urban controls can be imposed either before or after development and associated water pollution problems occur. Pre-development controls take advantage of comprehensive, non-structural approaches that can guide growth in ways that *prevent* pollution problems. Trying to manage urban stormwater after pollution problems have developed often is more expensive and less efficient than pre-development controls. But in areas where development already has occurred, "retrofitting" urban runoff controls often is essential.

Therefore, capital-intensive structural controls to retrofit existing development must be integrated with ongoing land use management programs designed to address problems arising from new development. Table 4-1 gives examples of available land use management tools for both pre-development and post-development control of contaminated urban runoff. These controls can be applied to protect critical environmental resources such as erosion- and flood-prone lands, wetlands, aquifers, steep slopes and streams.

Table 4-1
Potential Tools for Urban Poison Runoff Control*

Pre-Development Controls	Development Controls	Post-Development Controls
1. amount, density, nature, location and timing of development	1. grading and other soil disturbance controls	1. volume and rate of discharges to stormwaters systems
2. natural drainage features and buffer zones	2. infiltration devices, detention ponds and other stormwater controls	2. erosion and sediment reductions in developed areas and on streambanks
3. infiltrative soils	3. permeable surfaces	3. site-specific BMPs for individual areas: golf courses, refuse sites, etc.
4. vegetative cover	4. site stabilzation	4. easement purchases

Land Use Controls

General Principles for Controlling Land Use to Protect Water Quality

Perhaps the broadest and most versatile category of programs to control poison runoff comes under the general heading of land use controls. When used effectively, land use controls can prevent pollution problems by establishing land use patterns that are consistent with water quality protection, open space preservation and other environmental objectives, while at the same time providing for orderly and rational economic development.[3] The

VOL 12

6992

Uncontrolled land use development can devastate an aquatic system.

controls discussed in this chapter are applied largely at the local level.[6]

Land use controls can reduce water pollution loads in two ways. First, the rate of growth and the location and type of development can be controlled through the use of a zoning ordinance and Comprehensive Plan. Second, pollution generated by a *given* type or level of growth can be reduced by such techniques as subdivision ordinances, special overlay districts, and site plan reviews.

The Northern Virginia Planning District Commission evaluated the impact of the land use controls, and developed the following general guidelines on how to employ land use planning to protect water resources:[7]

1. *Per Capita Loading*—Generally, the greater the density the lower the *per capita* and the greater the *per acre* pollution loadings, indicating the usefulness of open space or cluster

development requirements in zoning and subdivision ordinances.

2. *Soil Permeability*—Since runoff is influenced by soil permeability,[8] land use planning should encourage large lot and medium density single family homes in areas with relatively permeable soils while requiring land uses such as shopping centers and apartments in areas with impermeable soils.

3. *Cluster Development*—Cluster developments can further minimize impervious surfaces and provide open space by tailoring lot placement and road design to reduce pollution loads.

4. *Growth Policies*—Growth in certain areas should be limited through the zoning ordinance, thereby reducing the pollution loads associated with certain densities or kinds of development.

Land use controls also can be employed to control the level of land disturbing activities (*e.g.* construction) in an area at a given time; allowable activities in and around a riparian area; construction on steep slopes; the use of erosion control practices on developing land; and the level of vegetation left on a site. Other controls can restrict the location of buildings or storage areas in relation to streams or aquifers (setbacks and recharge zone restrictions, respectively), or require the use of specific BMPs or compliance with performance standards that will improve runoff quality and reduce its quantity.

Three major types of land use controls are useful in controlling poison runoff in urban areas:

1. Zoning and Comprehensive Planning;

2. Subdivision Review; and

3. Site Plan Review.[9]

VOL 12

6994

Zoning is a land use control that dictates the density and type of development within a given area. Typically, zoning is imposed by local ordinance. By limiting development density or restricting land uses to those that are compatible with protecting water quality, zoning can be an important tool to control poison runoff.[10]

Overall local development is controlled through a *Comprehensive Plan* that takes into account a wide range of factors, including water quality and other environmental goals. Certain land uses generally are reviewed through a special use permit process, and design regulations or performance standards for various uses can be included in the ordinance.[11] Zoning maps generally delineate districts where certain land uses are allowed if in conformity with minimum standards such as lot size, building setbacks, and lot coverage requirements (*i.e.*, what percentage of lot surface can be covered by structures and pavement).[12] For example, zoning ordinances can impose setback requirements from water bodies, and can require lower density for riparian lots.[13]

Subdivision review involves reviewing subdivision maps and plots for conformance with rules and development standards for adequate building lots, streets, sewers, grading, and relationship to other properties and with the Comprehensive Plan and zoning map.[14] Subdivision review can include drainage and grading requirements and provisions for parks, buffer areas, and open space. It also can include requirements for innovative cluster developments that concentrate development in suitable areas while preserving sensitive land as open space.[15]

Site plan review and authorization means the municipal review of plans for individual new developments or expansions of current uses to ensure compliance with zoning requirements and other factors related to public health and safety.[16] Site development standards and BMPs related to water quality protection also can be imposed through the site plan review.[17]

In addition, a number of other land use controls may be helpful in controlling urban water pollution. These include:

1. transfer of development rights (TDR) to bar development in certain areas, with the provision that the rights to

VOL 12

6995

development can be applied in other areas not normally subject to such development;

2. the use of county or city Sanitary Codes to control on-site sewage systems and drinking-water wells;

3. watershed rules and regulations designed specifically to protect water quality;

4. ownership/easements to prevent or restrict development;

5. building codes to improve control of potential pollutants; and

6. regulations to prevent unsuitable land uses in flood prone areas and on steep, erodible slopes.[18] (Regulations also can be developed at the local level to prevent the destruction of wetlands, riparian areas or other sensitive environmental resources).

Table 4-2 describes briefly some of the specific land use controls listed above.

Table 4-2
Land Use Controls Valuable in Reducing Water Pollution Impacts*

Type of Land Use Control	Description	Examples
1. zoning	identifies allowable land uses and restrictions in particular areas	areas are divided into residential, commercial and other development zones; parks, greenbelts and open space are provided; high intensity uses are zoned away from waterways
a. use restrictions	in a given area, only land uses compatible with planning goals and objectives are allowed	industrial and high density development near waterways or sensitive environmental areas is prohibited
b. density restrictions	in a given area, maximum development intensity, as measured by dwelling units per area, is controlled	high density development near waterways is prohibited
c. lot surface restrictions	coverage establishes maximum amount of impervious surface per unit area	impervious surface is limited to 25% of each parcel
d. setbacks	building within a certain distance of a stream or other sensitive resource is prohibited	construction activity within 200 feet of a stream or wetland is prohibited

* Source: Adopted from Schenectady County Planning Department, *Groundwater Supply Source Protection - A Guide for Localities in Upstate New York* (no date). Specific numeric values, such as 200 foot setbacks, are given only as examples. Appropriate requirements will vary depending on location.

VOL 12

6997

Type of Land Use Control	Description	Examples
e. special use permits	"special" land uses authorized only on a case-by-case determination to allow the imposition of special restrictions	industrial activity in a particular zone is classified as "special use," authorizing the zoning board to review and modify individual applications and to impose special conditions
f. design and performance standards	prohibits certain land uses unless a specified set of criteria and standards is followed	zoning ordinance references BMP manuals and state water quality standards as minimum requirements that must be met in order to site a commercial development
g. special protection areas	delineates special areas to protect specific natural resources; special restrictions (including preservation) apply in these areas	groundwater or surface water "protection districts" are established where a set of special environmental protections apply (such as prohibiting on-site septic systems or the use of certain pesticides)
h. special overlay districts	similar to special protection areas except special restrictions are superimposed on (not a substitute for) underlying zoning characteristics	areas are established in the zoning ordinance where special density restrictions are applied to protect groundwater or surface water, in addition to other restrictions
2. Site Plan Authorization	review of individual development plans for environmental impacts; applies restrictions and/or incentives as necessary	planning board refuses to authorize a site for a shopping mall unless additional infiltration devices are used to reduce contaminated runoff
3. Subdivision Maps and Plats	place restrictions on the subdivision of land to account for water quality protection needs	new subdivisions are conditioned on the use of natural drainage features, open space, and other water quality protection measures

VOL 12

6998

Type of Land Use Control	Description	Examples
4. Local Sanitary Codes	set minimum design, location, and operation and maintenance requirements for septic systems, drinking water wells and sewer systems	use of septic systems is conditioned on calculations of mass nitrogen loadings to underlying groundwater; sanitary sewers must be kept separate from storm sewers
5. Watershed Rules and Regulations	establish comprehensive requirements within a particular hydrologic unit in order to protect water resources	comprehensive county program sets uniform requirements such as setbacks and zones of protection throughout entire watershed
6. Building Code	establishes specifications for the design and construction of residential, commercial and industrial sites; enforced by local building inspectors	uniform state building code requires industrial chemicals and materials stored outside to be covered; prohibits outside storage of used motor parts; prohibits use of building materials that contaminate stormwater
7. Floodplain Regulations	impose land use and other restrictions to control development in flood-prone areas and areas with steep, erodible stream banks	county ordinance prohibits new construction in 20- year flood plain on slopes greater than 10 percent

Land and Easement Purchase. The most drastic but most effective land use control to protect water quality is the use of eminent domain to purchase sensitive riparian zones, wetlands, floodplains, or other areas. This public land also provides aesthetic, recreational, habitat and other benefits. A less drastic and less expensive alternative is to purchase conservation easements, for example to restrict development along a coastline; or development rights, to allow existing uses to continue while preventing more intensive future development.

Of course, these strategies require significant expenditures. One way to pay for land acquisition is to dedicate taxes from land development elsewhere in the jurisdiction. And private conservation groups can be authorized and encouraged, by state or local laws and tax incentives, to purchase lands and easements to supplement government efforts.

Nevertheless, the amount of land that can be protected through outright purchase, conservation easement, or development restrictions is finite. Therefore, this strategy should focus on areas that require the greatest degree of protection. Governments should identify, prioritize, and acquire these areas as soon as possible.

Moreover, given these limitations, acquisition must be viewed as a way to *supplement*, not to supplant, the other land use controls identified above. Pollution from developed areas easily can overwhelm gains achieved through land acquisition.

Wetlands Protection. Preserving any open space is desirable to control poison runoff. Open space and related natural vegetation preserves natural drainage, thus reducing the total runoff in an area. And obviously, any area that is kept open will not be a source, or at least a major source, of poison runoff.[19]

For purposes of water quality protection, however, one of the most important types of "open space" is the natural wetland. Wetlands play a major role in natural hydrological systems. They protect water quality by controlling flooding, reducing erosion, recharging groundwater, filtering sediment, and reducing (by uptake into biological systems) nutrients and other pollutants.[20] Of course, from a broader land use perspective, wetlands provide a wide range of other public benefits such as important fish and shellfish habitat (including spawning areas for commercial and recreational fisheries), habitat for waterfowl and other birds and wildlife, water supply, recreation, environmental education, and aesthetics.[21]

An existing federal regulatory program, under section 404 of the Clean Water Act, is designed in part to prevent the loss or destruction of wetlands from the discharge of dredge and fill material.[22] However, the 404 program has, at best, been extremely incomplete in its ability to preserve wetlands for water quality protection. Section 404 contains a number of exemptions, most notably an exemption for "normal farming, silviculture, and

VOL 12

7000

R0040308

ranching activities."[23] The Corps of Engineers interprets section 404 as applicable only to discharges of dredge and fill material, and not to wetlands loss due to simple drainage.[24] And the program has been criticized widely due to inadequate implementation and enforcement, and a host of other problems.[25]

Because of these problems and limitations, wetlands in the United States continue to be lost at a frightening rate. Over the past two decades, wetlands losses averaged between 300,000 and 500,000 acres per year.[26] All told, since the mid-1950s, we have lost almost 15 million acres of freshwater wetlands and almost a half million acres of saltwater wetlands.[27] For freshwater wetlands the primary culprit has been agricultural drainage, while most saltwater wetlands losses have occurred as a result of development.[28]

Clearly, then, states cannot rely exclusively on the section 404 program to protect wetlands for water quality or other purposes. Other avenues are available, however, for state and local governments to protect wetlands.

For one, states could assume responsibility of the section 404 program from the Corps of Engineers. Under section 510 of the Clean Water Act,[29] states could implement this program more stringently and more expansively than the Corps. Alternatively, states could exercise their authority to deny water quality certifications for section 404 permits, under section 401 of the Clean Water Act, to protect wetlands when the Corps otherwise would have issued a permit.[30] However, given that these authorities have been available all along, but have been used sparingly, additional regulatory approaches at the state and local level may be appropriate.

Perhaps the most obvious way for states and localities to protect wetlands, consistent with the principles addressed in this chapter, is through comprehensive planning and zoning and other land use controls, including direct acquisition. Wetlands can be zoned for open space or watershed protection. Development can be restricted or prohibited in and within prescribed buffer zones around wetlands. Tax incentives can be provided to induce private landowners to preserve wetlands.

In addition, some states have enacted special legislation to protect wetlands. For example, currently most coastal states have land development elsewhere in the jurisdiction. And private conservation groups can be authorized and encouraged, by state or local laws and tax incentives, to purchase lands and easements to supplement government efforts.

Nevertheless, the amount of land that can be protected through outright purchase, conservation easement, or development restrictions is finite. Therefore, this strategy should focus on areas that require the greatest degree of protection. Governments should identify, prioritize, and acquire these areas as soon as possible.

Moreover, given these limitations, acquisition must be viewed as a way to *supplement*, not to supplant, the other land use controls identified above. Pollution from developed areas easily can overwhelm gains achieved through land acquisition.

Wetlands Protection. Preserving any open space is desirable to control poison runoff. Open space and related natural vegetation preserves natural drainage, thus reducing the total runoff in an area. And obviously, any area that is kept open will not be a source, or at least a major source, of poison runoff.[19]

For purposes of water quality protection, however, one of the most important types of "open space" is the natural wetland. Wetlands play a major role in natural hydrological systems. They protect water quality by controlling flooding, reducing erosion, recharging groundwater, filtering sediment, and reducing (by uptake into biological systems) nutrients and other pollutants.[20] Of course, from a broader land use perspective, wetlands provide a wide range of other public benefits such as important fish and shellfish habitat (including spawning areas for commercial and recreational fisheries), habitat for waterfowl and other birds and wildlife, water supply, recreation, environmental education, and aesthetics.[21]

An existing federal regulatory program, under section 404 of the Clean Water Act, is designed in part to prevent the loss or destruction of wetlands from the discharge of dredge and fill material.[22] However, the 404 program has, at best, been extremely incomplete in its ability to preserve wetlands for water quality protection. Section 404 contains a number of exemptions, most notably an exemption for "normal farming, silviculture, and

VOL 12

7002

laws that protect coastal wetlands.[31] In contrast, fewer than 20 states have laws to protect inland wetlands.[32] Both coastal and inland wetlands protection programs often restrict only certain types of activities or apply to wetlands of a certain type or minimum size.[33]

State programs to protect inland wetlands are particularly underdeveloped. As mentioned above, many states do not have any programs to protect these natural areas. And existing state programs often exclude significant activities from their coverage. For example, a recent review by the Virginia Division of Soil and Water Conservation of state inland wetlands programs revealed that programs typically exclude agricultural activities from wetland conservation requirements, despite the fact that agriculture is a major cause of inland wetland destruction.[34] However, the fact that many diverse programs have been developed to reduce or eliminate the environmental impacts of dredge and fill, construction, excavation and other activities in these important areas demonstrates that significant protection of inland wetlands is possible.

For example, in Washington State, the *state* program to protect wetlands exempts small wetlands and minor developments from regulation.[35] The exemption can result in significant cumulative impacts on wetlands.[36] In the Puget Sound *region* of the state the Department of Ecology is responding, in part, by developing new standards for local regulatory programs to protect wetlands, including standards to improve the protection of certain types and sizes of wetlands.[37] The inclusion of wetlands protection in state water quality standards also is being considered.[38]

The protection of non-tidal wetlands was an important legislative issue in Virginia in 1988. A bill was introduced in the 1988 legislative session that called for the establishment of a regulatory program to reduce the destruction through development and agricultural activities of non-tidal wetlands in the eastern part of the state.[39] However, the bill, which included many exemptions,[40] was opposed both by environmental and development interests and is not being carried over into the 1989 legislative session.

Avoiding Potential Pitfalls of Land Use Management for Water Quality Protection

By managing development within a watershed to produce land use patterns that minimize water pollution, proper land use controls can reduce the need for public expenditures for structural BMPs such as regional detention basins and street sweeping.[41] At present, however, traditional land use controls implemented by local planning and zoning agencies usually focus on amenity values (*e.g.*, aesthetics) rather than on public health or physical measures of environmental quality.[42] Thus, land use controls designed exclusively by local zoning authorities often do not stress water quality considerations.[43]

One way to overcome this shortcoming is to involve a local health or environmental agency in preparing land use controls to reduce poison runoff. Olmsted County, Minnesota, for example, involved the County Health Department in the development of zoning controls by directing the Health Department to develop its own subdivision ordinance (apart from the zoning authority's subdivision ordinance).[44] This ordinance applies to water wells and septic systems throughout the county (not just in the unincorporated parts of the county where the ordinance developed by the zoning authority applies).[45]

Another major potential drawback to the use of land use controls to prevent poison runoff is that uneven land use controls can encourage developers to shift development away from a community with strict standards and towards a community with no controls, poor standards or lax enforcement.[46] For this reason, consistent (although not uniform) and coordinated programs are needed in neighboring (or competing) jurisdictions.[47] Accordingly, the state should be involved in making sure that land use controls in *all* localities address water quality problems related to local development and land use.[48]

States can develop guidelines for controlling nonpoint source pollution and require the incorporation of these guidelines into local land use controls as minimum standards.[49] Statewide standards should address such issues as: (1) How much open space generally is necessary to reduce surface runoff in an area? (2) What minimum construction setbacks are adequate to prevent streambank erosion and to protect riparian vegetation?

(3) What densities are appropriate for the use of on-site septic systems? and (4) What types of intensive uses require special conditions? To the extent feasible, such state guidelines should require that site-specific factors, such as soils, potential water uses, and existing development be taken into account when water quality protection standards are established. In the absence of local cooperation, state-developed land use controls can be used and state funds can be withheld for local decisions not in conformance with the guidelines.[50]

Examples of Land Use Control to Protect Water Quality

The exact mechanisms utilized to implement these types of controls differ from locality to locality. Areas known for pioneering the use of land use controls for surface water and groundwater quality protection include the state of Maryland; the counties of Nassau and Suffolk on New York State's[51] Long Island; Dade County, Florida and the counties and municipalities of Cape Cod, Massachusetts.[52] Some of these specific programs for protecting "special areas" and general land use planning activities are discussed below.

Maryland's Chesapeake Bay Critical Area program[53] provides an excellent example of a state program implemented by local land use planning and aimed at protecting water quality through the preservation of a "special area"–land bordering the Bay's tidal tributaries. A state Critical Area Commission established criteria for classifying and protecting lands in a 1000-foot strip of land surrounding the tidal portions of Maryland tributaries to the Chesapeake Bay.[54] In order to administer its own program, a locality must adopt a program including zoning, site plan and subdivision review and other activities. The program must comply with the state criteria and obtain formal approval from the Critical Areas Commission.[55] According to the results of a detailed planning and evaluation phase, land is classified generally into one of three categories based on existing land use–each of which requires a different set of land use controls. (Details are provided in the endnotes.)[56] These controls can be tailored by the community to site-specific environmental and

VOL 12

7005

R0040313

economic conditions, while being scrutinized thoroughly by both state officials and the public.[57]

In Dade County, Florida, a Wellfield Protection Ordinance was developed, based on a mathematical groundwater flow model used to predict the travel times of groundwater in the recharge area of particular wellfields.[58] Since groundwater (and its potential contaminants) travels faster as it moves closer to drinking water wells, the ordinance provides for controls based on proximity to the wellheads.[59] These "zones of influence" are used as the basis for employing, with various degrees of stringency, zoning and other land use restrictions to prohibit underground storage tanks and other activities associated with water pollution from locating in the recharge zone of public wells.[60] This type of "impact zone" approach also could be used to protect surface waters.

In Massachusetts, the Cape Cod Planning and Economic Development Commission (CCPEDC) also defines zones of contribution for wellfields. Local governments use these zones in their zoning ordinances to limit the density and kind of development in critical recharge areas.[61] Performance standards of 5 parts per million (PPM) are set for nitrogen loading (to ensure that a health standard of 10 ppm is not exceeded). A site plan review process is used to consider the site-specific potential for water quality impacts from various development proposals, including those involving chemical storage and use activities.[62] Recently, the CCPEDC completed a comprehensive planning process to improve groundwater quality protection called the Cape Cod Aquifer Management Project (CCAMP).[63] It will begin implementing the study's recommendations shortly. In addition, CCPEDC is working to initiate a Geographic Information System so that local governments can input land use and other environmental information into a computerized database in order to improve their land use management capabilities.[64]

The Long Island Regional Planning Board (LIRPB) has provided perhaps the most valuable illustrations of localities attempting to develop and use both specific "special area" protection programs and general land use planning to reduce pollution. From the experiences (both successes and failures) of the LIRPB and its constituent local governments, a wealth of information is available both to guide officials to problem areas and to provide realistic solutions.

The LIRPB provides technical assistance to the counties and municipalities of Long Island in their activities to protect their sensitive sand and gravel glacial aquifers (particularly the areas that recharge the deep portions of the aquifer).[65] This groundwater resource supplies over 2.6 million residents with all of their fresh water needs.[66] LIRPB also advises localities on how to protect surface water resources.[67]

In 1978, the LIRPB established the concept of hydrogeologic zoning to allow counties and municipalities to use land use controls to protect water quality.[68] Through extensive research on the hydrology of the area's complex, interconnected aquifer system, zones have been identified that recharge either deep or shallow aquifers.[69]

The Nassau County Planning Commission reviews all proposed subdivisions within the unincorporated portions of the county and can require that 3% of a subdivision be dedicated as parkland (or that cash be paid to purchase lands for parkland).[70] The 3% requirement, of course, represents a fairly small portion of total developed land, and may not be sufficient to protect water quality. The concept of mandating minimum amounts of open space, however, is useful. The amount of land that needs to be set aside for watershed protection should be based on a more careful analysis of what is needed in the area in question to meet water quality standards.[71]

Suffolk County has purchased over 17,700 acres of environmentally sensitive land (including prime aquifer recharge areas, watershed management areas and wetlands) which are dedicated to open space. Additional lands being considered for acquisition were identified in a Bi-County Comprehensive Plan and in an Open-Space Policy Report.[72] To ensure that it remains undeveloped, much of the parkland is dedicated as "forever wild" under the County Charter.[73] The county also has prepared guidelines to be used by localities for managing land restricted by perpetual conservation easements.[74]

Six towns in Suffolk County have revised or are in the process of revising their comprehensive plans to reflect water quality concerns.[75] In Brookhaven, 13,000 acres of residentially zoned land within a recharge area have been reclassified successfully from a category requiring 1/2 to 1 acre lots to minimum lot sizes of two acres.[76] Southhampton has rezoned over 25,000 acres to require minimum lot sizes of five acres instead of two.[77] East Hampton and Islip have mandatory cluster ordinances for new residential development to protect groundwater and other environmental amenities.[78] The subdivision ordinances of several towns also require open space dedications to preserve sensitive areas.[79]

While communities on Long Island have fairly advanced site plan and subdivision review procedures,[80] evaluation by the regional planning entity (LIRPB) uncovered many problems that could apply to other localities. Generally, localities failed to consider water quality adequately in site plan and subdivision reviews.[81] Zoning and subdivision ordinances were not revised to account for potential water quality impacts and adequate authority to consider water quality was not delegated to responsible officials.[82] Procedures for granting variances to zoning ordinances and exemptions to the site plan review procedures were not developed with water quality protection in mind.[83] Many other problems were identified. Appendix A contains a detailed description of the findings of the evaluation.

Based on the problems identified in the study, the regional planning authority developed an extensive list of recommendations for localities to use in modifying their land use planning process. For instance, it was recommended that municipal codes *require* water quality to be considered as a reason for using local police power and that specific legal authority be provided for considering water quality in the site plan review process.[84] It was further recommended that zoning, site plan and subdivision ordinances be revised to reflect water quality concerns by altering land use densities to control nitrate loadings and by identifying critical areas where certain land uses would be prohibited or regulated through the required use of BMPs.[85]

Other recommendations included the development of Special Groundwater and Special Surface Water Protection Areas; concentrating development in existing high density areas; and establishing general development guidelines to control the exercise of the zoning and subdivision authorities and the site plan review process. (Details are given in the Endnotes.)[86] Many other recommendations (including those made to improve communication among relevant local agencies) were made. These also are provided in Appendix A.

Coastal Zone Management as a Water Quality Protection Tool

Although often categorized by states as separate from general local land use planning, coastal zone management is in many ways a type of zoning/land use control, with a special focus on protecting coastal water quality and other coastal resources. Perhaps this division has emerged because, while coastal zone management can be achieved by many kinds of local land use programs, it also is subject to a specific federal program. Although coastal management programs obviously focus on protecting *coastal* waters, good coastal management can set an example for general water quality protection through integrated resource management. Coastal zone programs can be used to apply all of the types of protections discussed above, such as setback and open space requirements, use restrictions, and special conditions on new development.

The Coastal Zone Management Act of 1972 (CZMA) was established in response to the very high rates of development in the nation's coastal areas, and out of concern about the environmental effects of this growth.[87] Before the CZMA was enacted, some states and localities (including Delaware, Maine, and the San Francisco Bay Conservation and Development Commission) had adopted laws and programs designed to prevent pollution from specific sources such as oil terminals, large scale developments, or landfills. Others (*e.g.*, California) had addressed the impacts of general coastal development.[88] States also had developed programs designed to reduce erosion rates on beaches and dunes.[89]

The CZMA, however, provided a national program to encourage environmentally responsible development through long-range planning and the establishment of clear, enforceable standards for growth and land use in specific areas.[90] While not all states have adopted programs under the CZMA (and while the CZMA is often interpreted not as an environmental

VOL 12 7009

R0040317

protection program but as a program to *balance* development and environmental goals),[91] some state and local CZMA programs provide good examples of how to protect coastal water quality. In this sense, the CZMA is a tool that can (and must) be utilized to comply with the water quality standards provisions of the CWA.

With water pollution in coastal areas increasing,[92] adequate CZMA programs are essential to protect coastal water quality. It should be recognized, however, that the water quality goals of the CWA *are* the water quality goals of the CZMA, and that the tools developed as part of a CZMA program must be used to achieve the goals established in a state water quality management program under the CWA.[93]

The degree of control that should be exerted at the state level varies according to the particular state. But the CZMA requires federal oversight to ensure that State CZMA programs are implemented adequately.[94] Federal oversight should ensure reasonably uniform minimum stringency among state programs, so that development is not attracted to states with weak programs.

Similarly, giving a great deal of discretionary authority to local officials yields a system where the degree of protection often varies from jurisdiction to jurisdiction.[95] Control over such variability must be exercised at the state level. At the same time, the need for strong, uniform state standards must be balanced with the need for adequate program coverage. Thus, while a state coastal zone protection program must require the involvement of local governments, it must also ensure that localities comply with minimum standards and are not able to sacrifice coastal resources for political purposes.

In addition, coastal protection programs should not allow overly liberal exemptions for small developments or seemingly innocuous proposals for expansion in coastal areas. Recent information concerning the *cumulative* impacts of small-scale development on local and downstream waterbodies points to the need for controls applicable to a broad range of activities, including general residential and commercial development.[96] Due to inter-jurisdictional pollution impacts and the inherent limitations of state and local programs designed to improve water quality,[97] there is a clear need for federal, regional and state oversight and conflict resolution mechanisms[98] as well as adequate *minimum* standards for state and local programs and permits.[99]

Of course, compliance with water quality standards also needs to be incorporated into state and local decisionmaking. State officials should review development proposals and local programs with an eye to, among other things, achieving compliance with these standards. Habitat and biological parameters have to be utilized in situations involving contaminated sediments, the combined impacts of several pollutants, or impacts associated with damaged or threatened biological resources. Therefore, land use and water use plans and programs must be integrated into a state, regional and local comprehensive coastal planning process, not unlike the general planning process described in Chapters Nine and Ten and the land use planning and urban runoff controls discussed earlier in this section.

Tools used in coastal management programs include the following:

1. regulatory permit systems;
2. land use controls through zoning and subdivision ordinances;
3. land acquisition and restoration;
4. promoting desirable coastal development; and
5. negotiation.[100]

State programs can require special coastal permits that apply to all development in the coastal zone (used in California from 1972-1976), special use permits (*e.g.*, coastal protection provisions in building permit programs) for particular activities, or permits for certain uses within sensitive areas (used in North Carolina).[101] Through the use of information about the water quality impacts of particular land uses, permits can be used to restrict, modify or

VOL 12

7011

R0040319

stop development in order to reduce cumulative water quality impacts.

North Carolina and California use such permits to prohibit or otherwise control large developments that might have an adverse impact on the environment.[102] An effective CZMA permit program provides a second line of defense against developers that might have "slipped" through a locality's land use review process. Permits can provide additional water quality protection through special conditions or through required mitigation measures.

Comprehensive planning and land use controls such as zoning and subdivision ordinances and land acquisition can be popular components of coastal protection programs (*e.g.*, California, Oregon, Florida).[103] Also, state and regional agencies can have major roles in reviewing and modifying local plans.[104] Planning aids developers and environmental interests alike by identifying important environmental impacts and potential conflicts, thereby saving time and money on project developments that would not be permitted, at least not without modification, mitigation or conflict resolution.[105] Coastal protection policies can be incorporated into local land use ordinances to meet water quality and special area protection objectives.[106] Studies of coastal areas and the establishment of land conservancies can be used to acquire important lands as state parks and preserves.[107]

State economic development policies can be used to guide low-impact growth into sensitive coastal areas and high-impact growth away from these areas.[108] Negotiations between state agencies with conflicting goals, as well as between private developers and environmental interests, also can be used to interject environmental concerns where they would normally not be present.[109] State and local governments can create permanent or *ad hoc* committees representing these different interests to review and evaluate specific proposals or ongoing program activities.

Two states that have developed coastal controls with specific application to the control of poison runoff are North and South Carolina. In North Carolina, state regulations require that the stormwater discharged from developments in coastal areas must be controlled using a variety of methods, to avoid violations of state water quality standards.[110] Potential stormwater control methods include specific impervious surface limitations, setback requirements, and stormwater treatment and disposal designs.[111]

The South Carolina Coastal Council uses a set of stormwater management guidelines when development proposals within the coastal zone are reviewed.[112] These guidelines represent the minimum acceptable level of stormwater management for developments that must be permitted or certified under the state's coastal zone management program. The guidelines specify the types of stormwater management systems that are required based on the location, lot coverage and land use associated with the development proposal.[113] Detailed design specifications are given for a variety of stormwater management (and other BMP) requirements that apply to particular types of development in certain areas of the coastal zone.[114]

Coastal protection in Florida provides a good example of the kinds of programs that can be used to protect sensitive areas, while at the same time pointing out the problems that can hamper effective coastal resources management at the state level. Recently, Florida's implementation of its Coastal Zone Management Program was criticized by the federal Office of Coastal Resources Management, which even suspended the state's 1988 grant under the CZMA until certain problems were addressed.[115] These problems, however, concerned the lack of emphasis placed on interagency coordination and state leadership, and not the range of programs available to address development impacts in coastal areas.[116]

Thus, the problems relate to *poor implementation* of existing program requirements—an important problem—but one that relates more to *site-specific organizational and political factors* than the actual content of various program requirements. The deficiencies associated with coastal zone management in Florida illustrate that even the most innovative and stringent programs can be crippled by poor leadership and enforcement.

Nevertheless, coastal management in Florida now embraces many significant programs and activities. State requirements for coastal protection must be addressed in local comprehensive plans.[117] Regional planning entities assist in evaluating and approving developments with significant regional impacts.[118] In

VOL 12

7013

R0040321

addition, specific state programs have been created to acquire sensitive coastal land, prevent beach erosion and prohibit construction in erosion-prone areas. A more detailed description of coastal zone management activities in Florida is provided in Appendix A.

California's coastal zone management program is considered by some to be the premier program of its kind in the nation.[119] While it is beyond the scope of this report to describe or analyze the California program comprehensively,[120] a few observations are useful.

The California program has gone through separate phases leading to the establishment of certified local coastal programs. The state role includes oversight, technical assistance and an appeals process for those who disagree with local decisions.[121] At first, the California State Coastal Commission and its six regional commissions regulated all development in the coastal permit area (1000 yards from mean high tide line) and prepared a statewide coastal plan applicable "inland to the highest elevation of the nearest coastal mountain range."[122] Now the Commission assists many local governments in preparing and approving their own coastal plans; hears appeals concerning local permit decisions; provides technical assistance; monitors local permits to assure compliance; evaluates local programs (every 5 years); regulates state tidal lands and ensures consistency with federal CZMA requirements.[123]

Early in the program, it was observed that the state commission had not developed strong working relationships with local planning officials.[124] Later, the state legislature shifted regulatory control back to the localities and mandatory policies were established at the state level to be used in guiding localities in developing a Local Coastal Program (LCP) consisting of a land use plan and an implementation program (zoning, subdivision review, etc.).[125] The original 1000-yard permit area was abolished, and permits now are required within the whole coastal area (as defined by the state).[126]

The success of this state-local planning approach in the coastal area requires that ongoing, working relationships be established between state and local levels.[127] Success also requires that the state enforce its land use planning requirements consistent with

VOL 12 7014

R0040322

land use goals and objectives; and that political pressure on local officials not be allowed to interfere with legitimate local coastal protection goals.[128]

The California State Coastal Conservancy complements the state commission and LCP officials by buying, selling, restoring, resubdividing, improving, developing or managing land in order to reduce the water quality impacts of development.[129] Funded through legislative appropriations, profits from state property transactions, grants from the Coastal Commission, statewide bond issues, payments required by the Commission as a precondition of development in lieu of mitigation measures and other sources, the Conservancy has undertaken several significant activities. These include:

1. *wetland restoration* - as a condition for filling wetlands, the Commission often requires a fee to be paid which is used by the conservancy to acquire off-site property, convert it into equivalent wetlands and hold the land until a permanent (often private) group can accept management responsibility for the land;[130]

2. *transfer of development credits* - as a condition for the right to develop certain appropriate sites in the Santa Monica Mountains, the Commission has established a transfer of development credits (TDC) requirement whereby developers must purchase the restricted development rights (many from those acquired by the conservancy) from land not suited for development; and

3. *lot consolidation* - land which is not desirable for park or recreation agencies or for development, is purchased by the Commission which alters or transfers the development rights associated with the land to another (more suitable) location before reselling the newly protected land.[131]

Summary

The link between land use and water quality has been recognized for years. However, bridging the management "gap" between these two concerns has been difficult because of

VOL 12

7015

R0040323

political, institutional and technical obstacles. Current developments in state, regional and local land use management indicate that the goals and objectives of the CWA can, in fact, be integrated successfully into land management through the innovative and aggressive use of the government's authority (and responsibility) to regulate land use.

Stormwater Management

Discrete discharges of contaminated urban runoff (euphemistically known as "stormwater") are regulated as *point sources* under the Clean Water Act.[132] But some stormwater or urban runoff contaminates groundwater or enters surface waters directly without ever being channelized into a point source. This section addresses how to limit stormwater quantity and to improve stormwater quality *before* it enters discrete conveyances to become a point source, or enters surface or ground waters directly.[133]

Considerations in Establishing a Stormwater Management Program

Controlling urban runoff requires that decisionmakers consider: (1) which sources to control; (2) what level of government is appropriate for implementing controls on urban runoff and stormwater; and (3) the proper program approaches for establishing specific controls and facilities. For instance, one management approach may be appropriate for controlling sources of runoff from areas that *already* are developed, and another may be better suited to areas undergoing, or potentially undergoing, development. Likewise, one set of controls may be needed to address pollution from general urban areas and another may be needed to control pollution from highways, railroad facilities, landfills and other governmental land uses.

In general, past efforts to control urban runoff solely with engineering solutions designed at the local level to reduce flood damages have not been adequate.[134] As urbanization has increased, merely building more and more drainage and discharge facilities to channel runoff immediately into storm sewers has proven to be environmentally and economically unacceptable.[135]

VOL 12 7016

Effective control of the stormwater generated in urban areas is central to improving water quality.

From an environmental standpoint, relying solely on structural controls is not effective. It does little to prevent habitat destruction and downstream flooding, and it ignores impacts on aquatic life and aesthetics.[136] From an economic standpoint, channelization and other large capital projects are so expensive that improvements have not kept pace with increasingly large flow volumes.[137]

Urban runoff is better controlled by retaining it on-site (preferably through infiltration into the soil)[138] or by detaining it in various kinds of ponds and marshes designed to serve reasonably sized drainage areas.[139] In this way, storm flows can be released in a coordinated fashion over time, making both water quality and water quantity more manageable.

Good stormwater management programs require a number of components. Effluent standards should be developed for discharges of contaminated runoff, and design, operation and maintenance standards must be established to provide the basis for an effective performance standard.[140] In addition, enforcement of stormwater provisions and inspection and maintenance of stormwater facilities are important (and vulnerable) components of the stormwater management process.[141]

All of these management needs require significant technical expertise, human and financial resources, extra-local institutional capacity and water quality management objectives and tools (including water quality and effluent standards) that often are not available at the municipal level. In order to coordinate the individual management entities and facilities in specific drainage areas, stormwater programs require the development of master stormwater systems that provide for optimum location and BMP choices for both on-site and regional facilities, as well as improved land use planning that uses the ability of floodplains and other natural areas to manage urban runoff.[142]

Without a *comprehensive* approach to stormwater management many problems can ensue. These problems range from poor coordination between political jurisdictions within a given hydrologic boundary to high costs, wasted resources, and over-reliance on structural approaches.[143] Programs that are designed to promote individual on-site stormwater management facilities are inferior to multi-jurisdictional watershed-wide approaches for many other reasons. For example:

1. randomly located detention basins can increase downstream peak flows and degrade riparian habitat through channel scouring;

2. individual basins do not combine the water quality and quantity aspects of managing runoff;

3. operation, maintenance and enforcement are difficult;

4. point-nonpoint source trade-offs cannot be made objectively;

5. the costs of a piecemeal program will probably be much greater than those of an effective regional management program; and

6. stormwater problems from existing sources cannot be addressed adequately.[144]

Most fundamentally, reliance on localities as the sole stormwater management entities is undesirable since such approaches tend to address stormwater problems in isolation, making the management problems mentioned above much more likely. Local governments may be the logical choice for the general *implementation* of urban runoff programs.[145] As discussed above, localities usually are responsible for land use planning and regulation, and are able to address a "manageable" number of nonpoint sources. However, without strong oversight it is unlikely that local programs will be coordinated sufficiently to achieve compliance with state water quality goals.

Besides fragmentation and the attendant management problems, other aspects of autonomous local stormwater programs point to the need for regional or state controls. For instance, many local programs focus on preventing flood damage—the typical local concern—and not on preventing water quality degradation. Flood control is a legitimate concern. But urban stormwater programs also need to address the smaller, more frequent storms that are responsible for persistent, continuing water quality impacts, and they need to develop monitoring programs to measure the impacts of these storm events.[146]

Although many urban programs to control poison runoff rely on local initiatives to establish the controls necessary to comply with water quality standards, local governments often are reluctant to take action because of the potential impact on economic development.[147] Many localities fund specific capital improvements on a one-time basis and neglect the maintenance of the facility once constructed,[148] which means that proper operation is often jeopardized.[149] Conflicts between entities within the watershed require an outside party to negotiate (or mandate) some compromise so that water quality and flood protection are not sacrificed.

VOL 12

7019

R0040327

These factors indicate that federal and state control is needed to *develop, evaluate and enforce* minimum requirements for local programs and to ensure that comprehensive, well-coordinated stormwater management is provided within watersheds.[150] Mechanisms also are needed to ensure that localities have the legal authority necessary to implement and enforce these minimum requirements, and to participate effectively in multiple jurisdiction programs.

Stormwater Utilities: An Institution Whose Time Has Come. Many stormwater management officials believe that one of the best and most equitable ways to develop a comprehensive local stormwater master plan is to establish a local stormwater management utility that charges rates for the financing of the stormwater program.[151] The stormwater utility addresses a number of important needs.[152]

Because adequate maintenance is so critical to successful stormwater management, one of the primary benefits of the utility is that it provides steady funds to develop, operate and maintain a stormwater management system.[153] Funding also is provided for retrofitting developed areas as well as for undertaking master watershed planning activities.[154]

Since a stormwater utility can be established according to hydrologic rather than political boundaries,[155] it can be used to develop and implement a comprehensive, rather than fragmented, stormwater management program.[156] Thus, the utility provides the basis for integrated, long-range planning and stable, adequate financing.[157]

Utilities can be financed by user fees calculated on the basis of area of impervious cover. In fact, a recent survey of stormwater utilities by the Maryland Department of the Environment indicated that most of the utilities investigated were basing fees charged to individual property owners on the total amount or percentage of impervious area associated with the property.[158] Monthly fees charged by the 25 utilities surveyed ranged from $1.25 to $4.40 for the equivalent of a single family residential parcel.[159]

This type of funding has the dual benefit of providing funds *and* encouraging developers to reduce the amount of impervious cover on a site.[160] The utility also can make the services it renders subject to an equitable charge to distribute costs to those using the system.[161]

The formation of a stormwater utility requires the collection and analysis of an adequate amount of water quality, land use and economic information and the establishment of an equitable billing system for all property served by the utility.[162] Establishing the utility may require considerable front-end expenditures for engineering, legal and financial studies, new staff and information management.[163] Public education and involvement is essential in establishing a stormwater utility, since public resistance to a new municipal charge is likely.[164] Education will also ensure that local officials participate in the development and implementation of the utility's activities.[165] Although not widespread, stormwater utilities have been successfully implemented in a number of areas, with service reaching populations that range from 20,000 to almost 700,000.[166]

In Florida, numerous stormwater utilities have been established or are being contemplated, and these institutions represent the framework for the implementation of future local master plans.[167] Other cities that have addressed stormwater management through some form of a stormwater utility include: Billings, Montana; Denver, Colorado; Aurora, Colorado; Tacoma, Washington; Corvallis, Oregon; Roseville, Minnesota; and Baltimore City and Baltimore County, Maryland.[168]

Boulder, Colorado established a utility in 1974 to guarantee annual revenues for purposes of master planning and capital improvements.[169] Fees are charged along with monthly water bills and are based on lot area, a computed runoff coefficient, site location and proximity to the floodplain.[170] Reduced rates are offered to commercial and industrial facilities using detention basins while rates are increased 40% for developments located in flood-plains.[171]

Bellevue, Washington was the first city in the nation to establish a stormwater utility for managing surface runoff and stormwater. Rates are charged according to the amount of runoff generated from a site, which in turn is determined by the percentage of the site that is covered by an impervious surface.[172]

VOL 12

7021

The Bellevue Storm and Surface Water Utility is shaped by the desire to use the city's natural surface water drainage system to convey and dispose of runoff. The utility contains an integrated system of pipes and stream channels to convey runoff, as well as lakes, wetlands, ponds and detention basins to control flows and to treat water.[173] Recognizing that structural drainage systems are incomplete solutions to stormwater management needs, Bellevue has begun to utilize BMPs as well as physical stormwater treatment.[174]

Toxic Poison Runoff: A Stormwater Management Challenge. The results of the Nationwide Urban Runoff Program (NURP) study, published in 1983, highlighted the significance of the toxic constituents of urban stormwater (including inorganic metals such as lead, copper, zinc and chromium and organic chemicals such as various pesticides and solvents).[175] Particulate metals represent the most prevalent toxic constituents in urban runoff. Although 60-95% removal efficiencies can be achieved for particulate metals,[176] removal of dissolved contaminants such as copper is lower (estimated at approximately 50% in the NURP study).[177]

Even this removal efficiency is only possible, however, if the stormwater management facility is selected, designed and maintained in order to address toxic pollutants.[178] Wet detention basins and detention (or infiltration) of runoff (where groundwater will not be threatened), are effective means to reduce toxics discharged to surface waters by stormwater runoff.[179] Detention basins must be designed to promote gradual reductions in flow velocity so that particulate matter settles adequately.[180] Long flow lengths must be provided and aquatic plants must be used in order to remove dissolved metals.[181] Finally, particulate metals must be kept bound to sediment, which requires that sediment pH be maintained near 7.0 in an oxygenated environment.[182] Therefore, the accumulation of sediment and decaying plants must be monitored and appropriate sediment-removal and other maintenance activities performed.[183] Contaminated sediment obviously must be disposed of in a manner that prevents pollution of surface or ground water.

Both the short-term and long-term effects of coastal development must be taken into account by poison runoff control officials.

Recharge devices to promote infiltration are useful in areas where groundwater contamination is not a threat.[184] In order to eliminate urban stormwater discharges completely, the "treatment" rate produced by the soil infiltration characteristics and surface area of the recharge device must be equal to or greater than the rate of the stormwater discharge.[185] If stormflows exceed this "treatment" rate, water quality improvements are needed in the stormwater that escapes infiltration.[186]

Obviously, the best way to prevent toxics in stormwater from contaminating surface water (and groundwater) is to prevent the toxic constituents from entering the stormflow in the first place. Evaluations of individual facilities can be performed to determine their potential for releasing toxics that could contaminate stormwater. Site-specific BMPs then can be incorporated as conditions in individual stormwater management permits. This is the case particularly with industrial facilities where proper materials storage, cleaning regimes, and manufacturing processes related to the industrial operation itself may be the only way to prevent discharges of some soluble organic pollutants to surface waters.

There are many Best Management Practices that can be used to prevent the contamination of stormwater from industrial and storage areas. In general, they are "the same traditional practices used by industry for pollution control, safety, industrial hygiene, fire protection, protection against loss of product, insurance company requirements, and public relations."[187]

Preventive BMPs include the development of a spill control committee and rules for effective reporting and cleanup of spills; a materials inventory system to track potential contaminants and investigate alternative materials or storage; routine visual inspections for leaks, spills or runoff associated with pipes, materials storage areas, tanks, etc.; containment facilities to prevent contaminated runoff from reaching waterways; and general good housekeeping so that all potential contaminants are transported, treated, stored and disposed with the prevention of poison runoff in mind.[188] These practices can be applied to industrial and commercial facilities whether or not they are "point" sources subject to permits under the CWA.

Model State and Local Programs

Some states have made significant advances in the development and implementation of stormwater controls. Two of these states, Maryland and Florida, are often considered "in front of the pack." Other useful lessons can be learned from programs in Puget Sound, Washington and Long Island, New York.

Maryland: A National Leader in Stormwater Management. Comprehensive stormwater management began in Maryland in 1982 with the passage of a state law[189] that requires each county and municipality in the state to adopt a stormwater management ordinance based on state criteria developed by regulation.[190] The purpose of these regulations is to establish state and local stormwater management programs:

> to maintain after development, as nearly as possible, the pre-development runoff characteristics and to reduce stream channel erosion, pollution, siltation and sedimentation, and local flooding.[191]

The Sediment and Stormwater Administration (SSA) is in charge of the overall program. The state reviews and approves local stormwater management ordinances as well as their implementation and develops stormwater management plans for state and federal construction projects.[192] SSA responsibilities also include inspection and enforcement (along with local authorities); development of guidelines and regulations; technical assistance and education, and research on stormwater control effectiveness.[193] Finally, the state is required to review the effectiveness of each initial local stormwater program and to conduct another review every three years thereafter.[194]

The required local stormwater management ordinance must address several areas in a fashion consistent with the regulations: submission and approval of a stormwater management plan; exemptions and waivers; criteria and procedures for stormwater management; proper implementation of an approved stormwater management plan; maintenance responsibilities and inspection procedures; and penalties for noncompliance.[195] Stormwater management plans are required for any land development not specifically exempted by regulation.[196] Allowable exemptions include additions and modifications to detached single family houses; developments of under 5,000 square feet; and residential developments of single family houses located on lots of 2 acres or larger.[197] Provisions for waivers of requirements for individual projects must be approved by the state and cannot adversely affect water quality.[198]

Depending on the particular county, local ordinances must require at a minimum that post-development peak discharge for a 2-year and/or 10-year frequency storm event "be maintained at a level equal to or less than the 2-year [or 10-year] pre-development peak discharge rate."[199] To accomplish this performance standard, a list of design criteria must be contained in each local stormwater ordinance.[200] In order to influence the stormwater management controls chosen by developers, state regulations require that preference be given to specific designs in the following order:

1. infiltration of runoff on-site;

2. flow attenuation by use of open vegetated swales and natural depressions;

3. stormwater retention structures (and no discharge to surface waters); and

4. stormwater detention structures (with discharge to surface waters only after treatment by settling).[201]

Use of a particular stormwater control by a developer requires that justification, based on site characteristics, be given as to why the preferable controls are not feasible.[202]

In addition to the local standards and specifications approved by the state, the regulations also provide minimum guidance for each of the acceptable stormwater management designs.[203] This guidance incorporates water quality concerns in various ways. For instance, off-site detention and retention structures generally cannot discharge into natural trout streams as identified by the state.[204] Also, the release rate from such structures cannot increase downstream channel erosion.[205]

Stormwater management officials must ensure that stormwater controls are inspected at regular, specified points during the construction process.[206] Municipal ordinances also are required to contain provisions for effective inspection, enforcement and maintenance.[207] Facilities must be inspected by local officials during their first year of operation and at least once every three years thereafter, while owners are responsible for preventive maintenance activities.[208]

Finally, officials are required to employ procedures to "ensure that deficiencies indicated by inspection are rectified" (including followup inspections and enforcement proceedings).[209] Penalties for noncompliance with minimum stormwater management requirements, including suspension of construction activities, must be included in all local ordinances.[210]

Florida: Statewide Stormwater Management. Florida's stormwater management program, which applies to all *new* development, is designed to ensure that the volume, rate, timing and pollutant load of runoff after development do not cause violations of state water quality standards.[211] The Florida Stormwater Rule is implemented by the state's regional water management districts so that the program can be coordinated with the district's surface water management permit programs,[212] which primarily affect water quantity.[213]

The Florida rule essentially is a performance standard driven by what is expected to achieve compliance with state water quality standards.[214] If permit applicants can meet the performance standard, it is generally assumed that state water quality standards will not be violated by stormwater discharges. However, more stringent controls can be imposed if it is determined that violations of water quality standards will result even after the performance standard is met.[215] Stricter treatment requirements are imposed on stormwater discharges to waters not in compliance with state water quality standards, and on discharges directly into waterbodies identified as Outstanding Florida Waters.[216] The standard was designed so that stormwater management systems would remove at least 80-95% of the annual pollutant load of sediments, nutrients and many heavy metals, similar to the minimum treatment level for point sources with secondary treatment.[217]

The actual general standard requires that, for development under 100 acres, the runoff from the first inch of rainfall or the first half-inch of runoff (whichever is greater) either be retained on-site (no discharge of the diverted water to surface waters) or detained (stored in treatment ponds and passed through a suitable filter).[218] Facilities draining areas over 100 acres must treat the first inch of rainfall (*i.e.*, there is no option to treat the first half-inch of runoff).[219] Larger developments are not allowed to treat the first half-inch of runoff because the "first flush" effect[220] usually decreases as the drainage area increases and as percent impervious areas decrease (because of unequal rainfall distribution and additive impacts of smaller drainages within the larger watershed).[221] Research is underway to verify the removal effectiveness of permitted systems.

Projects meeting this performance standard can obtain a general permit (over 90% of all facilities obtain the general permit), allowing work to begin if the district does not contact the developer to indicate that the proposal is inadequate.[222]

VOL 12 7027

Projects using other types of controls to provide equivalent treatment cannot obtain a general permit.[223] If stormwater controls are not being implemented in accordance with approved permits, the Department of Environmental Regulation may issue a stop work order to halt construction of the entire development.[224]

Recent changes to the rule allow general permitting for regional stormwater discharge facilities that are designed to treat runoff from multiple parcels.[225] In order to promote local stormwater utilities and comprehensive stormwater management throughout a watershed, individual discharges to such regional facilities are exempted from the permitting process.[226] These changes were designed to address some of the following problems that had been identified in the Florida Stormwater Rule:

1. difficulties with ensuring that property owners' associations have the administrative, legal, financial and technical means to operate and maintain facilities properly;

2. incomplete verification of the pollutant removal effectiveness of various systems permitted under the rules;

3. the grandfathering (exemption from regulations) of existing local government master systems built only for flood control purposes;

4. a fragmented approach to developing stormwater management capability; and

5. a lack of coordination among state, regional, and local governments, all with stormwater management authority.[227]

Perhaps the most significant problem with Florida's current program (as well as with many other states) is its general applicability only to *new* developments. The Florida DER, in cooperation with water management districts and local governments, is considering establishing priorities among watersheds based on ambient water quality and existing pollutant loadings, which then will be addressed by BMP implementation and other

VOL 12

7028

systems over a 25-year period.[228] Urban redevelopment projects would be required to retrofit old stormwater facilities with on-site treatment systems unless localities have established a master stormwater plan to provide regional treatment.[229]

Increased coordination between government levels and agencies also is being encouraged. Officials speculate that in the near future, local governments will be required to develop stormwater master plans that would be reviewed at the district level and integrated into regional master plans.[230]

Innovations in Stormwater Management

A Process for Initiating Comprehensive Stormwater Management: Washington State. The Puget Sound Water Quality Authority requires all cities and counties and all federal facilities and highway authorities in the Sound watershed to control stormwater to achieve water and sediment quality criteria.[231] Starting with the largest cities, each local government must develop programs for operating and maintaining existing stormwater systems, and must adopt ordinances for controlling stormwater from new developments. The Puget Sound program applies to all residential, commercial and industrial areas.[232] The program emphasizes controlling stormwater through source controls and BMPs before it is discharged into municipal storm sewers.[233] Each program must include, at a minimum, the following:

1. inventories of storm drains and land uses discharging to stormwater systems, and the identification of problem areas;

2. monitoring of problem storm drains identified in inventories;

3. programs for the operation and maintenance of storm drains, detention basins, ditches, and culverts;

4. investigations for illegal hookups and dumping, spill responses and remedial actions;

5. assurances of adequate local funding for the stormwater program through surface water utilities, sewer charges, fees or other revenue-generating sources;

6. agreements with neighboring jurisdictions that share watersheds;

7. ordinances requiring implementation of best management practices for new construction (*e.g.*, erosion/sedimentation controls, detention/retention basins, oil separators, housekeeping measures);

8. a public education program aimed at residents, businesses, and industries in the urban area;

9. provisions to require retrofitting of existing development or treatment of discharges from new and existing development if there are still discharges that cause significant environmental problems;

10. inspection, compliance, and enforcement measures; and

11. an implementation schedule.[234]

The State Department of Ecology (DOE) provides technical assistance and leadership in the form of design manuals and guidelines.[235] DOE approves, monitors for compliance and generally oversees the programs, and coordinates programs developed by localities with runoff impacts on another jurisdiction to ensure consistency.[236] Each program is "audited" every two years, and is a part of the priority watershed process described in Chapter Nine.[237]

Guidelines for urban stormwater programs have been prepared by DOE in cooperation with local governments to ensure that the requirements for local stormwater programs are satisfied in an effective manner. These minimum guidelines include:

1. procedures for conducting inventories of storm drains and combining this information with land use data;

VOL 12 7030

R0040338

2. monitoring requirements and protocols, if necessary;

3. review of operation and maintenance programs;

4. procedures for investigations, implementation of spill control measures, enforcement, and remedial actions;

5. methods for assuring adequate local funding for the urban stormwater program;

6. guidelines for agreements with neighboring jurisdictions because stormwater and watersheds do not always follow jurisdictional boundaries;

7. model ordinances for new construction;

8. requirements for public education programs;

9. requirements for retrofitting or treatment measures, if necessary;

10. guidelines for inspection, compliance, and enforcement measures; and

11. requirements for implementation schedules.[238]

Guidelines for developing local ordinances also will be developed, including procedures for DOE review and approval of ordinances and minimum requirements for runoff control.[239]

Finally, DOE will require the State Department of Transportation (DOT) to develop a program to control runoff from highways in the Puget Sound area.[240] Existing and new highways must be included in the program, and the DOT must comply with the requirements of local stormwater programs.[241] DOT must also proportionally fund the construction, operation and maintenance of any publicly or privately owned stormwater control facilities receiving discharges from DOT-owned property.[242] All NPDES permits for federal facilities, including military bases, must contain stormwater controls at least as stringent as those required for industrial facilities, including limits on toxics and particulates and requirements for monitoring and spill control.[243] DOE will request that EPA review existing permits for federal facilities to ensure that they comply with the same controls as those for industrial facilities under the Municipal and Industrial Discharges Program.[244]

A Watershed-Wide Retrofitting Effort: Anacostia. Addressing the stormwater problems caused by existing development is difficult. This difficulty is magnified when the existing development crosses many political boundaries. The Metropolitan Washington Council of Governments (MWCOG) is attempting to deal with these complications by assisting in the establishment of a stormwater management system in the 170 square mile Anacostia River watershed, located in Maryland and Washington, D.C.

Guided by a multi-jurisdictional group called the Anacostia Watershed Restoration Committee (AWRC), MWCOG is administering the development of a strategy to "improve water quality and restore aquatic habitat within the free-flowing and tidal portions of the Anacostia River."[245] An important part of this strategy is a three-year effort to retrofit the entire watershed through the Coordinated Anacostia Retrofit Program (CARP).[246]

Under this program, MWCOG "will assist local governments in selecting, designing, constructing and monitoring urban retrofit projects within the Anacostia Basin."[247] Initial activities include: an inventory of possible facility sites leading to a priority list for each local jurisdiction; implementation of up to 12 projects in the first year of the program; and technical support and design workshops describing new and innovative retrofitting techniques.[248] The high level of coordination and involvement by all jurisdictions and the technical capabilities of MWCOG demonstrate that retrofitting stormwater controls in existing areas is possible.

Regional Recommendations for Local Controls: Long Island. The Long Island Regional Planning Board has developed

VOL 12

7032

fairly detailed stormwater management provisions for inclusion in zoning and subdivision ordinances. Existing requirements for managing stormwater developed by various Long Island communities include:

1. runoff from each plot in a development must be self-contained or all stormwater must be recharged into the ground;

2. no water can be diverted so as to exceed the design capacity of existing stormwater systems;

3. no stormwater systems are allowed that would create flooding or a need for additional drainage structures; and

4. the existing drainage systems of sites undergoing redevelopment must be upgraded to certain specifications.[249]

The recommendations for improvement of local stormwater management developed by the LIRPB are provided in Appendix A.[250]

Summary

Control of contaminated urban runoff involves more than a system of pipes and channels to collect and transport flood waters so that they can be deposited in the nearest convenient waterbody. Pollution from urban runoff now is recognized as such a significant source of water quality degradation that it is virtually impossible to protect water quality without adequate stormwater controls. One positive aspect of stormwater management is the diversity of available control strategies and programs, and the flexibility with which they can be applied.

Erosion and Sediment Controls For Construction Activities

This section addresses factors to consider when designing erosion and sediment control (ESC) programs applicable to construction activities.[251] The types of BMPs necessary to control pollution from construction runoff are so well documented that they need no detailed review here.[252] Fundamental principles include:

1. Using diversion structures to channel runoff away from disturbed surfaces during construction;

2. Collecting and retaining or treating (through settling) any water that does contact disturbed surfaces (*see* stormwater section above);

3. Stabilizing exposed surfaces as soon as possible after construction is complete, if possible in phases, and ensuring that permanent stabilization is successful; and

4. Using good materials storage, spill prevention and other "housekeeping" practices to prevent runoff contamination by toxic chemicals such as paints, solvents, pesticides, metals from building materials, or fuels.

These basic concepts apply whether the construction involved is a building, a highway, or a bridge.

The more difficult problem is how to develop and implement an effective program to ensure that these BMPs are used. Elements of effective ESC programs are described below. Examples of existing state programs also are presented. Because the effectiveness of local programs can vary significantly depending on (among other things) municipal growth and economic development polices, a strong state presence is necessary.[253]

The significant differences in state erosion and sediment control (ESC) programs have been explored,[254] and in-depth evaluations of individual programs have been conducted.[255] However, few detailed studies have sought to develop a general outline of an effective ESC program structure. One study[256] has described some of the necessary aspects of an erosion and sediment control program. That study concluded that a fundamental element of an effective ESC program is adequate

Construction activities generate far more sediment per unit area than any other land use.

program authority.[257] What level of program authority is adequate depends, in turn, on several factors, including:

1. the range of nonpoint sources covered;[258]

2. the number of exemptions;

3. the clarity of legislative authority;

4. the management attitudes of program administrators; and

5. the adequacy of technical standards.[259]

ESC enabling legislation should be drafted to grant adequate powers to the officials charged with implementation and enforcement. Specifically, legislation should contain provisions authorizing ESCs to protect water quality, as opposed to simply control erosion or flooding.[260] The enabling legislation for the ESC program should make clear the mandatory nature of program requirements (*i.e.*, regulations rather than guidelines).[261] Local program administrators should be fully trained to understand and exercise the full scope of their authority to implement and enforce the program.[262]

Adequate resources also must be provided to ensure ESC program success. Specifically, sufficient funding and personnel must be provided to review site plans, evaluate runoff controls and perform inspections.[263] One way to improve funding is to charge fees for ESC plan reviews or for ESC permits.[264] State legislators or ESC program officials should consider allowing localities with few funds to recover through permit fees the *full costs* of administering an effective program.[265]

Technical assistance should be offered by the state to train local ESC personnel and private interests (*e.g.*, contractors) who must develop and carry out ESC plans and controls.[266] Training courses at construction sites, video tapes, press releases and seminars all could be part of a required training process for plan reviewers, inspectors, contractors and developers.

A certification program should be developed for private parties involved in preparing and implementing ESC plans.[267] ESC plan review and approval should be performed only by individuals trained as engineers or by equivalent technicians.[268] Finally, state technical assistance should include data collection and analysis. Localities need adequate information on soil types, slopes and drainage characteristics of the various construction sites covered by the program so that proposed ESC plans can be thoroughly evaluated.[269]

Administrative activities also are important. ESC programs should include program components to ensure that:

1. construction sites covered under the program are identified before earth-moving has begun;

2. a clear, consistent set of procedures is followed in carrying out the ESC program;

3. variance requests are considered consistently and are based on clear, narrowly-drafted guidelines rather than on political factors; and

VOL 12

7036

R0040344

4. programs are evaluated periodically and modified as necessary.[270]

Building or grading permit applications or site plan review procedures should trigger a process to determine if an ESC plan is required. If so, approval of these applications and procedures should be made contingent on the submittal and approval of an ESC plan.[271] ESC permits and plan approval should be required before any construction begins.[272]

Variance decisions and dispute resolution should be based on clear and objective factors. State government must retain the statutory authority to override local decisions and to implement a local ESC program in cases where local action is inadequate.[273]

Inspection and enforcement also is crucial to program success.[274] Effective inspection and enforcement requires an adequate staff; systematic inspection procedures; effective penalties and program intervention to correct violations. Initial installation and maintenance of adequate controls should be verified and monitored through an effective, mandatory inspection procedure that includes standardized schedules, documentation and checklists.[275] Enforcement actions also should be standardized in content and in their application to various kinds and degrees of noncompliance.[276]

Stop-work orders and administrative penalties are important for ensuring timely responses to non-compliance and to reduce the time, expense and uncertainty associated with judicial actions.[277] Citizen suits provide an added enforcement mechanism when municipal action proves ineffectual, and can supplement government enforcement resources.[278] When courts are used as part of an enforcement process, both civil and criminal penalties as well as injunctive relief should be available.[279]

Bonding requirements are needed to ensure that funds are available to correct problems when responsible parties fail to act.[280] Required bond amounts should be large enough to cover the full government costs of correcting ESC problems at the site.[281] Moreover, bond release should not occur until the site has been fully and permanently stabilized and the risk of erosion and sediment damage from construction activities has been eliminated.

Additional suggestions for effective inspection and enforcement of local ESCs are given below:

1. The number of site inspections should be based on the amount of activity at a site, the results of previous inspections and the experience of the responsible parties.[202]

2. A standardized inspection report should be presented to the project inspector while at the site to ensure that:
   a. the ESC plan is on-site;
   b. controls are in place and correctly installed and maintained;
   c. any monitoring or reporting requirements are followed; and
   d. off-site sediment transport is noted and corrective actions recommended.

3. Any violations should be noted in a report prepared on-site and made available to the contractor during the visit. A formal written report can follow later.

4. Major construction sites or sites in critical or sensitive areas should be visited after major storms to check ESC control effectiveness.

5. A final inspection should occur at all sites before bonds or other guarantees are released, utility service is authorized or occupancy permits are granted. Before funds are released the site should be stabilized, not just seeded.

6. Penalties should be large enough so that, if necessary, repairs to off-site damages can be successfully undertaken and proper ESCs installed; and each day of noncompliance should be treated as a separate violation.

7. Stop work orders should apply to the whole project, not just earth moving activities, to ensure that ESC problems

will be corrected even after earth moving activities have ceased but before the construction project is finished.

8. Damages and the size of performance bonds should be based not only on the amount of earth disturbed at a site, but also on the slope of the site, changes in grades, soil type, proximity to water, sensitivity of the surrounding area to damages well and other relevant factors.[283]

State Experiences With Erosion and Sediment Control

Several states have ESC programs containing many of the program aspects mentioned above.[284] Maryland has established a detailed set of regulations for state review and approval of various aspects of local erosion and sediment control programs and individual ESC plans.[285] For instance, regulations establish minimum requirements for an adequate inspection and enforcement component of an ESC program and under what circumstances the state must assume these responsibilities.[286]

By regulation, the state sediment and stormwater administration is required to consider specific aspects of each proposal for local assumption of the inspection and enforcement activities of an ESC program.[287] Local enforcement authorities are *required* to:

1. ensure that all approved ESC plans and permits are kept on-site;

2. ensure that all active sites are inspected for compliance an average of at least once every two weeks;

3. prepare written reports after each inspection providing specified information, including the type of enforcement actions taken in cases of violations;

4. notify a responsible party whenever violations are observed and describe the violation, any required corrective actions and the time period in which the violation must be corrected; and

5. investigate complaints of violations and, when confirmed, use enforcement procedures within 3 working days; and within 7 days, notify the complaining party of any actions taken.[288]

Local enforcement is supplemental and is overseen by the state. The state can investigate any complaints received by the local enforcement authority and may "initiate an on-site investigation in order to properly evaluate the complaint."[289] Also, the Sediment and Stormwater Administration "shall take enforcement action when appropriate ...." when its site investigation indicates that the complaint is valid.[290] Enforcement authority can be delegated to localities only for renewable 2-year periods.[291] Delegation can be suspended and assumed by the state when state officials determine that the standards established by the regulations have not been maintained by the locality.[292]

Localities also must have approved erosion and sediment control *ordinances*.[293] Here again, the state exerts considerable influence under the guidance of the regulations. The Sediment and Stormwater Administration must approve or disapprove such ordinances using a host of criteria that are based on compliance with the rest of the regulations as well as with the intent of the relevant state statute.[294] In addition to its initial approval of the local ordinance, the state also must review periodically the adequacy of local programs (including the ordinance and a field review of active construction sites) to determine if they meet to regulatory requirements.[295]

Enforcement actions *require* some combination of: cessation of *all* work on the site (except work necessary to correct the violation) if the violation persists after a specified date, and civil and criminal prosecution in cases where "reasonable efforts to correct the violation are not taken."[296] In addition, legislation recently enacted has authorized administrative penalties for violations of an ESC plan.[297] Maximum penalties are $1,000 per day up to $20,000 for each violation.[298]

In an important step, Maryland has made a strong commitment to move away from control only at the site perimeter. Instead, the Maryland regulations expressly require permanent or temporary stabilization[299] of the disturbed earth on the entire site. Under the regulations, virtually *all* land at a permitted site must be stabilized within 14 days of disturbance or redisturbance (perimeter controls, dikes, swales, ditches and steep slopes must be stabilized within 7 days).[300]

In addition, Maryland's regulations now require that an ESC plan be approved before any grading or building permits can be issued.[301] Federal and state land is subject to the program, as are single-family home sites unless they are built on lots two acres or larger.[302] Finally, applicants for ESC plans must certify that the personnel in charge of on-site clearing have attended a 4-hour ESC training program.[303]

Pennsylvania's program requires local agencies to inform the agency responsible for the ESC program of all requests for building permits, and requires that the permit be withheld until an ESC plan has been approved.[304] Violation of the ESC program are considered violations of the state Clean Streams Law and can be subject to fines of up to $10,000 per violation.[305] Each day of a continued violation is considered a separate violation under the law.[306] Changes under consideration in Pennsylvania's ESC program would give the State Department of Environmental Resources the exclusive right to administer an ESC plan for projects crossing political boundaries of conservation districts administering local ESC programs.[307] These changes also would prohibit most earth disturbing activities within 75 feet of a streambank in watersheds designated as either High Quality or Exceptional Value waters under state law.[308]

Other state programs provide for the identification of critical resource or erosion-prone areas; apply to federal land- disturbing activities and other commonly exempted land disturbances; allow state review, approval and (if necessary) implementation of local programs; require periodic inspections; provide for citizen actions to obtain injunctions; provide for administrative fines; and place damage awards in funds for program maintenance.[309]

The success of ESC programs depends heavily on local enforcement. State programs that incorporate the components described above will help to ensure that local ESC activities succeed in maintaining and improving water quality.

Summary

Erosion and sediment control (ESC) programs are perhaps the most established non-voluntary urban programs to control poison runoff. This probably stems from the relatively narrow activity to which such programs apply, as well as from the obvious nature of erosion problems at unprotected construction sites. But while there is a proliferation of ESC programs across the country, there is also wide diversity in the content—and the success—of such programs. State and local officials must recognize that merely instituting an ESC program does not guarantee that the targeted problem will be eliminated. Therefore, officials must ensure that the elements of successful programs which are spelled out in this section are incorporated into ESC activities.

Conclusions and Recommendations

Contaminated urban runoff must be controlled using a variety of management approaches. The control methods described in this chapter are already being implemented by states and localities across the country, using well-established regulatory tools and technical capabilities. Using the organizational and management approaches discussed in this chapter, as well as in Chapters Nine and Ten, states can exercise leadership and oversight that is effective in ensuring that localities undertake the area-specific controls that are necessary to reduce pollution impacts. Whether urban contaminants consist of sediment, BOD, bacteria, nutrients or toxics, programs are available today that effectively address threats to water quality.

Successful programs to control urban runoff must be based on the link between land use and water quality. Programs that prevent water quality degradation through good land use planning are preferable to post-development retrofitting that relies on expensive structural controls. But in many cases, pollution generated from existing development must be controlled. Fortunately, state and localities also can use tax incentives and other means to encourage private individuals and conservation groups to protect land and water resources through acquisition.

Urban program recommendations are summarized below:

1. Localities should use land use controls to achieve compliance with water quality standards. This should be accomplished through comprehensive and coordinated use of:
   a. zoning and comprehensive planning;
   b. site plan and subdivision review; and
   c. building codes.
   These tools should be used to control the location, rate and type of growth, and to minimize pollution where development occurs.

2. Localities should develop and use innovative and specialized land use tools, such as overlay zones, to protect riparian areas and ground- and surface water resources.

3. Local land use programs (and coastal resources protection programs) should address explicitly the water quality impacts of cumulative small (including residential) developments, not just large-scale or industrial development. As a supplement to land use controls, areas that are the most sensitive or contain the most valuable natural attributes should be protected through acquisition, either through outright ownership or conservation easements or development rights. States and localities also should use tax incentives and other means to encourage private individuals and conservation groups to protect land and water resources through acquisition.

4. Special programs designed to protect coastal resources, including coastal zone management plans, should be incorporated into local Comprehensive Plans.

5. State and regional oversight and review of local land use programs should be required to ensure compliance with state water quality standards and consistent levels of water quality protection, and to provide for conflict resolution and coordination within watersheds.

6. An effective stormwater management program that addresses both future and existing development should be

VOL 12

7043

R0040351

required as a basic part of a local effort to control poison runoff.

7. Stormwater controls (as well as other urban controls) should be required at the local level but overseen by state and regional entities to ensure that state goals and extra-jurisdictional impacts are addressed and that regional solutions are developed.

8. Stormwater controls should include both design standards and a performance standard requiring the site-specific removal of identified pollutants, so that the discharge from a site or facility does not violate state water quality standards.

9. A master drainage plan should be developed for all of the watersheds in a given area and incorporated as part of the stormwater management plan.

10. Stormwater management utilities following watershed boundaries should be the primary stormwater management institutions and, as such, should be managed cooperatively by the involved localities with state leadership and oversight.

11. Stormwater utilities should be funded through user fees based on a measure of stormwater impacts by individual sites, such as percentage or total area of impervious surface. Design standards for retention and detention basins should reflect the control of toxic substances.

12. Individual stormwater management permits should include the implementation of site specific BMPs when needed to address problems of toxic runoff.

13. Erosion control ordinances should specifically authorize the use of erosion and sediment controls (ESCs) to protect water quality.
    a. ESCs should require:

VOL 12

7044

R0040352

i. diversion structures to channel runoff away from disturbed surfaces;
ii. retention or treatment of any contaminated runoff;
iii. rapid and permanent stabilization of disturbed surfaces; and
iv. BMPs to prevent contamination of runoff by construction chemicals or other materials.

b. ESCs should include a performance standard to require additional controls in situations where minimum standards are not sufficient to meet water quality standards.

14. Clear and consistent ESC regulations should be adopted to ensure that:
    a. construction does not begin before an adequate ESC plan has been approved;
    b. inspections are carried out effectively at all construction sites; and
    c. variances are not granted or water quality compromised due to political pressure.

15. ESC programs should include:
    a. citizen suit provisions;
    b. stop work orders that can be issued after earth-moving operations have ceased;
    c. administrative penalties of sufficient size to finance any required corrective actions, as well as civil, criminal, and injunctive remedies;
    d. requirements for developers to submit performance bonds sufficient in size to perform necessary ESC work, with bond release only upon effective, permanent site stabilization; and
    e. adequate funding, training, and technical assistance.

4. *See* Livingston, Eric *et al., The Florida Development Manual: A Guide to Sound Land and Water Management,* 1988 (in press), at 4-9.

5. *See* Blatt, David J. L., "From The Groundwater Up: Local Land Use Planning and Aquifer Protection," 2 *J. of Land Use and Envtl. L.* 126-130 (1986).

6. The need for state oversight over local land use decisionmaking is discussed in chapters Nine and Ten.

7. Northern Virginia Planning District Commission, *Guidebook for Screening Urban Nonpoint Pollution Management Strategies,* November, 1979, at 29. Per capita loadings from lower density development are higher than per capita loadings from greater densities for nutrients and biological oxygen demand, not heavy metals. *Id.* at 30.

8. Soil permeability refers to the ease of water transmission through soil. It depends on particle size, density and pore space of soil. Generally, the finer the soil particles, the slower the permeability. Draggan, Sidney, John J. Cohrssen and Richard E. Morrison, *Geochemical and Hydrologic Processes and Their Protection—The Agenda for Long-Term Research and Development,* Praeger Publishers, New York, 1987, at 81-82. Building heavily on permeable soils, therefore, both wastes the inherent capacity of the soil to reduce stormwater runoff and risks contaminating groundwater resources. There is an obvious trade-off between increasing pollution loadings to groundwater to protect surface water resources and diverting stormflows (that otherwise would infiltrate (and contaminate) groundwater) to surface waters.

18. *Id.* at 27-30.

19. This general statement, of course, depends on the definition of "open space". The least impact will occur on lands that are preserved in their natural state, with no artificial development. Such land uses as urban parks or greenbelts, on the other hand, may include a mixture of natural areas with bike paths, golf courses, playgrounds, ballfields, and other uses of generally low intensity. But such uses may involve the use of fertilizers, pesticides, irrigation, and associated buildings and other structures. These land uses, therefore, are not free from contaminated runoff.

20. *See* Conservation Foundation, *Protecting America's Wetlands: An Action Agenda, The Final Report of the National Wetlands Policy Forum*, 1988 (hereinafter cited as *National Wetlands Forum*), at 9-10. It is questionable, however, whether wetlands can or should be used to "treat" heavy metals or other toxic pollutants.

69. National Research Council, *supra* note 9, at 153; Koppelman, Tanenbaum and Swick, 1986, *supra* note 65, at 2-10; Koppelman, Tanenbaum and Swick, 1984, *supra* note 9, at 1-5 (Land Use).

70. Koppelman, Tanenbaum and Swick, 1984, *supra* note 9, at 16 (Land Use); Robert Berry, Nassau Planning Commission, October 6, 1988 (personal communication). The portion of land that can be dedicated as parkland is only 3%. However, larger quantities of land could be required based on a detailed site-specific evaluation of land use characteristics and water quality.

71. To facilitate implementation, localities should set a fixed, minimum percentage, such as 10% of each development preserved as open space, with a provision to allow stricter requirements where necessary for an individual subdivision.

72. Koppelman, Tanenbaum and Swick, 1984, *supra* note 9, at 17 (Land Use).

85. *Id.*

86. *Id.* at 18-23 (Land Use). LIRPB has developed a list of the steps needed in the site plan and subdivision review process. Essentially, developing a site plan involves a series of distinct steps that include:

1. site selection;
2. data collection;
3. site analysis;

4. site plan development (conceptual plan, schematic plan, preliminary conference, plan revision, preliminary plan);
5. submission of preliminary plan to the municipality and other agencies, as required;
6. revision and refinement of the preliminary plan; and
7. submission of final plan. *Id.* at 47 (Site Plan Review).

Chapter Five

Silviculture, Mining and Rangeland Programs

Introduction

This chapter discusses programs designed to reduce poison runoff from silvicultural, mining and rangeland activities. Aspects of effective programs are identified based on general information as well as evaluations of individual state programs. Where possible, examples of programs that reflect some of these management needs are provided.

Poison runoff from silvicultural (forestry), mining and rangeland (grazing) operations are controlled through programs that often differ significantly from those designed to address agricultural and urban sources.[1] This difference could be due to many factors: often localized pollution impacts, relatively few polluters, and similar types of pollution (and associated BMPs) within each particular source category. However, the severity of pollution from timber cutting in Idaho and California, mining in Pennsylvania and Montana and cattle grazing in Oregon and Washington State all testify to the need to control these sources of pollution adequately.

Obviously, the control of poison runoff from silviculture, mining and grazing varies according to the specific environmental and management characteristics of each source category. However, the fact that each activity takes place on federal, state and private lands creates a common management requirement—the integration and coordination of control programs on all classes of land ownership.

Programs to Control Silvicultural Water Pollution

On state and private lands, controls on logging operations are imposed through state and local programs (commonly called forest practices). However, a large portion of silviculture in the United States is conducted on federal lands.[2] States still have a major role to play in controlling water pollution from federal lands through agreements between state forestry and water quality management agencies and the U.S. Forest Service (USFS) (as well as general state authority under the Clean Water Act).[3] State forestry programs to reduce silvicultural water pollution vary a great deal. They can include voluntary and regulatory programs, tax incentives, education, and technical assistance. Programs are designed to protect water quality, encourage reforestation, control the location and type of timber harvesting and protect forests from disease and fire.[4]

USFS has had limited success in protecting water quality through its planning and enforcement activities.[5] For example, severe fisheries and wildlife habitat impacts in the Clearwater, Boise and Payette National Forests in Idaho have occurred due to logging and road building sanctioned by USFS planners.[6] Similar adverse water quality impacts are documented from silvicultural operations on private and nonfederal lands.[7] While water quality protection is a *stated* objective of the National Forest Management Act and most state forestry programs, it is often questionable whether or not associated controls have been adequate to achieve this objective.

Programs to protect water quality in private and nonfederal forests are mostly voluntary, especially in the south.[8] Western and northeastern states, by contrast, have established a signifi-

VOL 12

7067

Forestry activities, particularly clearcutting and roadbuilding, often result in severe sedimentation and stream channel alterations.

cant number of regulatory programs designed to protect water quality.[9] However, officials in 21 states have identified the need for regulatory programs (as opposed to voluntary guidelines) in efforts to protect water quality in logging operations.[10]

Because this report seeks primarily to assist state and local water pollution programs, this chapter mainly addresses state forest practice programs. But since some states have attempted to negotiate with USFS to make various aspects of the state program apply to USFS activities, the information provided in this chapter also applies indirectly to the substance of those negotiations.[11]

Incorporating Water Quality Standards Into State Forest Practices Acts

As with other types of poison runoff control programs, silvicultural controls should be driven by water quality standards. If water quality standards are to be used meaningfully, state

VOL 12

7068

R0040376

programs can not contain exemptions or loopholes for compliance with water quality standards just because BMPs have been, or will be, implemented.[12] BMPs are only tools to be used in achieving state water quality standards.[13] They are not program goals in themselves.[14] States not only have the right but also the responsibility to ensure that state water quality standards are not violated because of silvicultural activities on all lands within the state, including private, state and *federal* forests.[15]

This water quality "performance standard" is vital because the range of potential BMPs needed to protect water quality is so large that it is very difficult to reproduce and enforce them as specific technical requirements.[16] In turn, however, the difficulties of large scale enforcement and administration of a performance standard make the use of an aggressive set of technology-forcing prescriptive BMPs an important minimum program requirement.[17]

In determining the potential for water quality standards violations, states should consider cumulative impacts[18] from surrounding operations and the impacts of major erosion events, such as landslides.[19] Mean sediment loadings averaged over a long period of time do not adequately reflect real water quality conditions.[20] In addition to numerical criteria, beneficial uses and physical, biological and habitat criteria all must be available in case costs or data limitations make the application of numerical criteria infeasible.[21] For example, water uses are impaired where benthic organisms or spawning beds are smothered due to sediment deposition, whether or not numeric water quality criteria are violated.[22]

Applying EPA's antidegradation regulation (40 CFR § 131.12),[23] or the required state analogue, can be particularly valuable. Antidegradation should be used to avoid the contamination of "pristine waters" (often the kinds of waters in forested land), particularly in the area of sediment pollution (the primary silvicultural water pollutant).[24]

Moreover, as mentioned previously, forestry activities can result in water quality standards violations even with the full use of field-level BMPs. Therefore, states must use their CWA authority to reduce or preclude logging and road building operations altogether in specific locations, or to control the timing of multiple logging operations in a single watershed, where

VOL 12

7069

R0040377

necessary to ensure compliance with water quality standards.[25] When the timing, location and intensity of a particular harvest are generally acceptable, *then* BMPs can be used to protect water quality.

Therefore, water quality standards should provide an objective basis on which to develop and review long- and short-term plans for specific harvesting proposals (both private and federal). State programs then can go beyond merely requiring specific field-level controls, to approving timbering proposals only when state water quality standards will be met.

BMPs, in this context, become more than individual site applications of particular technical controls. BMPs include planning and management activities that determine *where* and *when* timber harvesting can occur, as well as the technical standards to determine *how* timber harvesting will be conducted. This planning component is a vital part of state forest practice programs.

Unfortunately, the ability of current state forestry programs to achieve these objectives is limited by budgetary constraints. The median budget for state forest resource planning in 1985 was just $8,000.[26] Adequate state forestry programs, therefore, require significantly increased funding. Such funding could be obtained through permit fees, assessments based on the amount of timber proposed to be cut, or both.

Review and Enforcement Issues. Since individual silvicultural operations can have devastating water quality impacts, a mechanism is necessary by which water quality standards can be incorporated into state forest practices regulations in an enforceable manner. A water quality standards-based forest practices program requires the technical capacity to review and, if necessary, modify timber harvesting proposals. An effective inspection and monitoring process is needed to determine if a plan is being followed and is avoiding desirable impacts on water quality.

Timber plans should be reviewed by a multi-agency team with substantive authority over final decisions.[27] Water quality, fish and wildlife and silvicultural experts all should be a part of the review process.[28]

VOL 12

7070

State officials need to conduct site inspections, carry out monitoring activities, and if necessary, modify original plans and BMPs after logging begins.[29] Inspections must determine whether or not the requirements for both the prescriptive BMPs and the performance standards are being met. Thus, inspections should be conducted not only by silvicultural experts to determine compliance with BMPs, but also by biologists and water quality specialists to monitor the actual effects of logging operations on the waterbody.

To accomplish this, procedures must be in place to judge the overall health of the affected waterbody. Monitoring activities are necessary to understand the actual impacts of BMPs in order to alter prescriptive requirements, when necessary, and to carry out long-range planning and cumulative impact studies. Civil and administrative penalties, in addition to criminal sanctions, should be available since state forestry personnel are less likely to be willing to brand a fellow forester as a criminal than to levy fines.[30]

Case Study: California

California's forest practice program, generally considered the most aggressive in the nation,[31] provides examples of progressive state forest practices rules and regulations. However, even the advanced California program has shortcomings in protecting water quality. California's Forest Practice Act of 1973 established the current structure of the state program as applicable to private and nonfederal land.[32] The program is one of the few (if not the only) in the nation with a stated policy of treating timber productivity and water quality protection as equal, first priority goals.[33] (That so few states have made water quality protection a first priority in state forestry program is astonishing since, as explained in Chapter Two, compliance with water quality standards is a minimum, mandatory requirement of the Clean Water Act.)

In reality, however, rules and regulations are issued by the Board of Forestry (BOF), which is composed of five members of the general public and four members from the forestry and range and livestock industry.[34] It has been described as "... [leaning]

VOL 12

7071

R0040379

more to the industrial views than to the pleadings of environmentalists."[35]

The California forest practice program can be described as consisting of two basic components: 1) an administrative and management framework, and 2) substantive forest practice rules (BMPs). Both of these components contain interesting models for state silvicultural programs designed to control poison runoff.

The Board of Forestry must solicit the input of the California Departments of Forestry (CDF) and Fish and Game (DFG) and the State Water Resources Control Board (SWRCB) when developing new forest practice rules.[36] Recently, the BOF has been negotiating an agreement with the SWRCB to develop the silvicultural pollution control portion of the State Water Quality Management plan.[37] Many of the issues discussed below resulted from the interaction of the CDF (a multi-purpose management agency) with the SWRCB and the DFC (environmentally focused, resource protection agencies).

To maintain good professional and technical qualifications in the industry, all timber operators must obtain a state timber operator's license, which must be renewed annually. All practicing foresters must meet certain qualifications (including a minimum level of experience and the successful completion of a written exam) before they can be registered to practice in the state.[38]

The timber harvester and owner must file a timber harvesting plan (THP), to be prepared by a registered professional forester. The plan must be approved by the Department of Forestry before harvesting activities can begin.[39] The specific requirements of the plan are numerous, but generally must describe:

1. the site;
2. activities to be conducted;
3. methods to be used to avoid excessive erosion on sites near streams; and
4. provisions to protect unique areas.[40]

VOL 12

7072

R0040380

These plans must be sent to DFG, the relevant regional water quality control board (RWQCB) and the county where the land is located. Interdisciplinary review teams then are assembled to evaluate environmental impacts and compliance with forest practice rules.[41] CDF personnel act as the review team chairpersons and have sole authority to approve or deny the plan. If other team members disagree with approval or denial by the chairperson, they can file a report of nonconcurrence with the BOF. The chairperson then must respond to the complaints in writing although the final decision remains with the BOF chairperson.[42] County Boards of Supervisors, which at their request and with the approval of CDF can have county-specific forest practice rules promulgated by BOF, may request public hearings to discuss any plan filed for lands within their boundaries.[43]

Administrative deadlines are established for various points in California's regulatory process.[44] Under various circumstances, the program also requires inspections before, during and after the operation.[45] Any inspector can issue a stop work order if an operation is found to be (or is about to be) in violation of the program's rules and regulations.[46] A violation of the Act can be treated as a criminal offense, and any necessary costs incurred to correct violations can be attached as a lien on the property where the violation occurred.[47]

The BMPs included in the California forest practice program are extensive, and cover the following areas:

1. silvicultural methods;

2. harvesting practices and erosion control;

3. watercourse and lake protection;

4. hazard reduction;

5. fire protection;

6. forest insect and disease protection; and

VOL 12

7073

R0040381

7. logging roads and landings.[48]

Many of the rules prescribe certain restrictions such as the size of clear-cut stands in areas with various erosion hazards and reforestation requirements.[49] Other BMPs are less exact and prescriptive in nature, such as: "the number of [watercourse] crossings should be kept to a minimum"; "logging roads and landings shall be planned and located, when *feasible,* to avoid known unstable soils or known slide-prone areas" (emphasis in original); "existing crossings shall be used wherever *feasible*" (emphasizing original); and "[i]f those areas are unavoidable, site-specific measures shall be planned ... by the RPF to minimize slope instability due to construction."[50]

The watercourse and lake protection measures include:

1. a policy statement recognizing the protection of beneficial uses of water as a consideration equal in importance to the maintenance and enhancement of timber productivity;

2. rules regarding the placement and removal of debris in watercourses;

3. rules regarding the location of various roads and trails in relation to streams;

4. rules regarding the cutting of trees within the watercourse and lake protection zones;

5. requirements for mapping and classifying water bodies according to their beneficial uses;

6. rules regarding the width of watercourse and lake protection zones based on the classification of the waterbody and the slope of the surrounding land as well as information on the application of other BMPs; and

7. procedures for developing alternative watercourse and lake protection measures.[51]

One distinctive feature of the watercourse and lake protection rules for the Northern Forest District in California is a performance standard which states that:

> [d]uring timber operations, the timber operator shall not place, discharge, or dispose of in such a manner as to permit to pass into the water of this state, substances or materials, including, but not limited to, soil, silt, bark, slash, sawdust, or petroleum, in quantities deleterious to the beneficial uses of water.[52]

In addition, the State of California, through one of its regional water quality control boards, has adopted water quality standards for turbidity in northern California that are applicable to forestry activities.[53] These standards state that "[t]urbidity shall not be increased more than twenty percent above naturally occurring background levels," and that "[t]he suspended sediment load and suspended sediment discharge rate of surface waters shall not be altered in such a manner as to cause a nuisance or adversely affect beneficial uses."[54]

Even these relatively specific standards, however, pose problems in application due to a lack of internal consistency. For example, the performance standard *prohibits* discharges deleterious to beneficial uses (and supported by state WQS) while the prescriptive standard calls for *minimum* impacts from watercourse crossings and tractor roads.[55]

However, the California forest practice program has produced a number of desirable outcomes. Many Timber Harvest Plans (THPs) are modified as a result of the review process.[56] Preharvest inspections, thought to be the most important element in achieving compliance with the program, are performed by CDF for 80% of the THPs received.[57] CDF estimates that approximately 25% more land currently is reforested than would be expected without the program,[58] and CDF personnel believe that water quality is protected very well by the current system.[59] While the public and private costs of the program are high relative to the forest practice programs in other states, it is not thought to have reduced the level of investment by the timber industry in the state or to have contributed significantly to the cost of consumer products.[60]

VOL 12

7075

R0040383

Lessons from the Nation's Most Stringent Forestry Program. In spite of, or perhaps because of, the fact that California's forest practice program is considered among the most advanced in the nation, many important problems have been identified with its forestry pollution control provisions. These problems generally concern the influence of politics in the state forest practices program, the role of the resource protection agencies (such as the State Water Resources Control Board and the Department of Fish and Game) in the California Department of Forestry (CDF) decisionmaking process, and the enforcement of important program requirements. In this sense, the problems associated with silvicultural controls are similar to those in agricultural situations. The problems pertain generally to: the dominance of agencies traditionally in charge of a land-based resource; a lack of involvement of water quality and fish and wildlife officials; and enforcement of existing water quality protection requirements. The problems described below apply generally to any state suffering significant water quality impacts from silviculture.[61]

Because of mistrust between industrial and environmental interests, it has not been possible to develop a state- or region-wide land management plan for nonfederal forests, similar to those required for National Forests by the National Forest Management Act.[62] Each THP is normally evaluated individually without regard to the cumulative impacts of total harvesting activities within a watershed, and the rules and regulations include no mechanism to address large-scale geographic considerations (*e.g.*, which areas in a region are suitable for particular kinds and levels of harvesting).[63]

While the State Water Control Board and CDF currently are attempting to develop a cumulative impact review capacity,[64] an ongoing data collection process is needed to determine the ecological conditions in sensitive areas possibly subject to harvest.[65] This is necessary for long-range planning purposes and to provide in-depth, long-term and large-scale information for use in THP reviews by the multi-disciplinary team.[66] This process also would assist in setting priorities for timber harvest plan review and enforcement.

VOL 12

7076

Officials in California point to the need to improve long-range planning, and propose to develop a computer database to record the conditions of the natural resources within a given area and to estimate the impacts of THPs and decisions affecting the forest.[67] The database would include the location and types of existing and potential beneficial uses, important habitat, sensitive terrain, timber production and other land use locations and impacts.[68]

California's program also is hampered by the limited authority of the State Water Resources Control Board (SWRCB), the Department of Fish and Game (DFG), regional water quality control boards and local governments to affect the final decisions regarding the approval of Timber Harvest Plans.[69] After the multi-agency review, these entities effectively are precluded from any formal process to evaluate and influence the final revisions made in the Timber Harvest Plan by CDF, as well as from formal review of the final approved plan, which ultimately is controlled by the Board of Forestry.[70] An effort currently is underway to give the heads of these agencies the right to appeal final plans. This would broaden scrutiny of the plans by both the resource protection agencies and the public.[71]

The performance standards mentioned above, along with the stated intent of the section of the rules addressing watercourses, need to be applied consistently to the final review and revision of THPs–not only when violations of specific prescriptive BMPs have been identified.[72] The standards should be implemented through appropriate water quality or biological parameters, or beneficial use designations, and extensive data collection and analysis.[73]

The use of variances in the California program also has been criticized. In one evaluation, alternative and "in lieu" practices allowed nearly 50% of the program standards applicable to watercourse and lake protection requirements to be altered.[74] Such provisions should be used only when the prescriptive standards are not feasible (but alternative measures will provide adequate protection) or when the standards will not provide adequate protection.[75] Explanations for alternative actions should provide enough detail and justification for plan reviewers to make an informed decision.[76]

VOL 12

7077

Plan developers and reviewers often either do not properly recognize or do not admit to the potential adverse effects that timber operations may have on off-site beneficial uses, particularly those impacts not explicitly stated in the rules and regulations.[77] This has led to inadequate protection in many cases.[78] For example, the parts of the THP that address resource protection issues often are vague and unsupported.[79] In many cases, information about the impacts of various harvesting activities on natural resources is not available to plan developers and reviewers.[80] In addition, increased efforts are needed to provide guidance, training and other education to private and public parties involved in the state forestry program.[81]

California's program also has had compliance problems due to inadequate implementation requirements, poorly worded regulations and inconsistent enforcement.[82] Compliance has been a very significant problem particularly because THPs often contain poorly written, vague and unenforceable provisions and because program enforcement is not effective.[83] Recommendations for improvement include better compliance monitoring[84] and enforcement options that include civil and administrative penalties, not just criminal charges.[85]

The problems associated with California's relatively stringent forest practices program indicate the kinds of issues that states should consider when developing their own silvicultural programs. As evidenced by California's experience, serious management problems (and resulting water quality impacts) can occur even in states with the most advanced forest practice programs.

Summary

Although the intensity of timber operations varies radically among and within states, certain components are needed in any program designed to ensure that sediment and herbicides do not damage the beneficial uses of state waters. Long-range timber harvest planning is needed to account for both short-term and cumulative impacts of timbering, as well as to provide a rational basis for reviewing the adequacy of water quality and other resource protection measures. Performance standards should be used, along with prescriptive BMPs, to ensure that compliance

VOL 12

7078

with water quality standards is incorporated into individual timbering proposals. In addition to these general program needs, specific recommendations for state programs to control water pollution from timber operations are given at the end of this chapter.

Mining Water Pollution Control Programs

Poison runoff can be generated from most of the operations characteristic of mining activities, including exploration, development, extraction, transport, reclamation, product storage and waste disposal.[86] Pollution from these activities can result from a variety of mining settings: active and abandoned; coal and noncoal; and surface and underground.

Pollution from mining activities includes sediment, metals, acids, heat, and stream and habitat modifications.[87] Surface and groundwater are affected through suspended and dissolved solids that are transported to surface waters by direct surface runoff, and by infiltration and subsurface flow (baseflow).[88]

At the outset, it should be clear that many pollutant discharges from mining operations are from *point* sources. Clearly, these include piped discharges from milling, processing dewatering, and other operations. But any other contaminated waters on mining sites that are discharged to surface water from discrete conveyances constitute point source discharges.[89] This includes discharges from impoundments, sumps, channels, ditches and gullies.[90]

The implications of this legal distinction are very important. Mine operators can be required to control runoff by building sedimentation ponds, diversion ditches and similar controls. By diverting as much water as possible around active mining areas, the amount of contaminated runoff can be minimized. Any contaminated water that is collected in control facilities (which are regulated as point sources) is more easily subject to conventional water treatment methods. And any discharge to surface waters requires an NPDES permit.

In addition to point source controls administered under the CWA, the Surface Mining Control and Reclamation Act of 1977[91] provides a system for addressing environmental (including water quality) problems resulting from surface and underground

Both above- and below-ground mining cause water pollution in the form of sediment, channel alteration and acid drainage.

coal mining on private, state and federal lands. In many ways, this program (described below) provides a useful model for programs applicable to water pollution from noncoal mining.

The Bureau of Land Management (BLM) is charged under the Federal Land Policy and Management Act of 1976[92] with regulating the environmental effects of noncoal mining[93] on lands under BLM control. However, states are not ensured that such regulation will result in adequate control of poison runoff.[94]

States should ensure that federal programs are effective in controlling pollution from coal mining on all lands, and noncoal mining on federal lands. But states also need to address water quality problems caused by noncoal mining on state and private lands, which is not governed by any specific federal statute or program. While some technical research is available relevant to the environmental quality aspects of mining and mine reclamation,[95] there has been little analysis of how to manage effective controls on noncoal mining.

During the CWA § 208 planning process, however, EPA prepared several manuals that, among other things, describe the management and programmatic aspects of a mining-related nonpoint source pollution control program.[96] These documents are somewhat dated and were never used by EPA to enforce state controls. But they provide a useful framework for assessing and structuring mining-related efforts to control poison runoff.[97]

A Regulatory Process for Attaining Beneficial Uses

Like programs to control other kinds of poison runoff, mining controls (especially those applicable to abandoned or inactive mines) often may be constrained by institutional rather than technical barriers.[98] Common characteristics of EPA recommendations for controlling mining-generated pollution include: a prominent role for the state water management agency;[99] tying general programs and individual controls to the achievement of beneficial uses of water;[100] and integrating mining nonpoint source programs with water quality management and pollution control within the context of a watershed-wide pollution control plan.[101]

An initial (and essential) step is to revise water quality standards so that beneficial uses of water are protected from all mine-related pollutants.[102] Once this task is complete, specific programs can be developed to achieve these standards. The primary components of an effective mining-related program are also described in EPA guidance. These include:

1. a regulatory process to identify and require the use of BMPs to control pollution from all sources (including agency authority to modify all aspects of the mining operation with potential water quality impacts);

2. provisions to ensure adequate pollution control during all post- and inactive-mining periods;[103]

3. provisions to prevent and control surface and groundwater pollution, sedimentation, thermal pollution, dust sources and hydrologic disturbances;

4. a process to examine new control practices and to require their prompt adoption when practicable;

5. provisions to designate areas such as riparian or other sensitive areas intimately tied to water quality as unsuitable for mining operations or for denying permits (including the right of local zoning actions after other government permits have been obtained);[104]

6. penalties stringent enough to discourage violations and that make mine operators responsible for correcting adverse water quality impacts (whether willful, negligent or accidental);

7. as part of the permit approval procedure, a water quality management process to evaluate individual mining operations in relation to existing and future sources of water pollution (both point and diffuse sources); and

8. specific provisions to address the water pollution potential of roads, sediment basins, and other structures remaining after the mine-related activity is completed (including maintenance requirements).[105]

In addition to these management needs, an effective bonding requirement is necessary to ensure that sufficient funds are available to reclaim mine sites in cases where responsible parties are unwilling or unable to carry out reclamation requirements. Funds also must be available for the long-term maintenance of areas associated with the mining operation (such as waste piles) that have the potential to generate significant water pollution *after* normal closure activities.

Abandoned Mine Pollution Control Programs. Abandoned mine sites often can be the most significant contributors of mining-related pollution. For this reason, an effective program for abating the poison runoff from abandoned mines is essential to meeting water quality goals.[106]

VOL 12

7082

R0040390

Sources of pollution from abandoned mines include abandoned surface and underground waste and tailings piles, roads, storage and processing areas, already-polluted aquifers, and stream and lake sediments. From a purely technical perspective, these pollution sources are similar to the ones at active mining sites. Therefore, most of the physical pollution controls at active mining operations also apply to abandoned mines. An important initial step in addressing abandoned mines is to ensure that programs applicable to currently operating mines require adequate closure and post-closure activities so that additional water quality problems from abandoned sources are avoided.

From an institutional perspective, abandoned mines pose many challenges. Eliminating pollution from abandoned mines may be extremely costly. Where responsible parties can be identified, steps must be taken to force these parties to abate the ongoing pollution through legal action, if necessary. Where responsible parties cannot be identified or cannot abate the pollution, for example, due to insolvency, a more challenging problem exists. To address the water quality problems at orphaned mines requires the establishment of state funding mechanisms and site reclamation planning procedures. Decisions must be made as to how site owners, industry or taxpayers will share abatement costs.[107] Abatement principles and techniques need to be established, as well as strategies for implementation.[108] Individual abatement plans should be developed and implemented after priorities and schedules have been established for addressing specific watersheds and specific sites within watersheds.[109] Priority should be based on the levels and types of both point and nonpoint sources within the watershed, current and potential water quality, and other factors.[110] Finally, once abatement plans are being implemented, monitoring should be implemented to evaluate resulting water quality improvement.[111] Ways to address these issues are suggested by the programs described below.

SMCRA: A Model for State Mining Pollution Control Programs

Programs designed to address mine-related pollution could take many forms. SMCRA, however, provides a general model for controlling poison runoff in both coal and noncoal mining situations. Although many of the specific provisions of SMCRA have been described as unsuited to the control of very large or very small noncoal mining operations,[112] the SMCRA framework for collecting data, reviewing permit applications, establishing performance standards and enforcing program requirements is relevant to mining in general.[113]

Water quality is protected under SMCRA through a series of requirements contained in Titles IV, V and VI of the Act. These requirements address, respectively, reclamation of abandoned coal mine sites, regulation of active coal mining operations and prevention of coal mining in sensitive areas.[114]

SMCRA prohibits the surface mining of coal without a permit. To obtain a permit, mine operators must develop detailed plans to control the environmental impacts of the entire mining operation (pre-mining activities, the actual mining operation and reclaiming the mined land).[115] The permit must incorporate a number of specific environmental protection requirements, including measures to protect water quality.[116]

Water quality is protected during mining operations through a complex series of performance standards defined in the SMCRA legislation and specified in the attendant regulations. The regulations establish a comprehensive system of control designed to prevent pollutants generated in the mining process from reaching water sources. Basically, this system provides a hierarchy of controls ranging from the most to the least desirable. First, water pollution is *prevented* through the diversion of surface runoff around potentially contaminated sites such as active mining areas, roads and coal storage and spoil piles.[117] For surface runoff that does cross the mining areas, contamination is *minimized* by requiring stabilization, regrading and reclamation of the site during the operation as well as after all mining activity has ceased.[118] Finally, any surface water diverted through discrete conveyances or that otherwise becomes polluted is *collected* and *treated* so that any resulting discharges do not cause adverse water quality impacts.[119] In addition to the requirements SMCRA imposes on active mining operations, the law also provides for the establishment and maintenance of a fund to

VOL 12

7084

reclaim abandoned mine sites by, among other things, restoring the area's natural vegetative cover.[120]

Many of the environmental protection requirements of SMCRA refer explicitly to protecting water quality, often through the use of performance standards. For instance, there is a requirement that water pollution be prevented during certain land disturbing activities.[121] All surface areas, including spoil piles, must be stabilized and protected to control water pollution.[122] Permanent water impoundments must be consistent with existing water quality standards.[123] Stream hydrology and water quality must be maintained by controlling acid and toxic mine drainage.[124] Sediment loads must be minimized using "best technology currently available" and, in any event, be in amounts below "requirements set by applicable State or Federal law."[125] Many other provisions of SMCRA make it clear that compliance with state water quality goals and objectives is an important part of the overall program.

Permit applicants and the regulatory authority must provide notice of the plans to begin mining, and any affected parties (including individuals and state and local agencies) are entitled to an informal conference to discuss objections to these plans.[126] After the regulatory authority has issued a decision regarding the permit, those affected parties objecting to the decision (or some part of the decision) can request a formal adjudicatory hearing leading to a written decision that describes the final permit conditions.[127] (An appeals process also is provided.)[128]

SMCRA also establishes requirements that states must follow for federally-approved abandoned mine reclamation plans.[129] A state reclamation plan must identify areas to be reclaimed, the criteria for establishing priorities among reclamation projects, legal authority and program structure.[130] Water pollution control is one of the goals of the reclamation program.

A Federal Abandoned Mine Reclamation Fund is established to disburse money to approved state reclamation programs.[131] The fund can be used for a variety of reclamation purposes, including the purchase of land from uncooperative landowners.[132] The fund is financed through fees charged to active coal mine operators for each ton of coal mined (a variable rate is provided for coal extracted from surface and underground mines).[133]

In addition, SMCRA provides for the designation of land as unsuitable for coal mining.[134] A person who may be adversely affected can petition the state regulatory authority "to have an area designated as unsuitable for surface coal mining regulations..."[135] After a public hearing, a written decision must be furnished by the state regarding the status of the land in question.[136] A state must designate lands as unsuitable for all or certain types of coal mining if it determines that adequate reclamation of the site is not "technologically or economically feasible."[137] Operations that are incompatible with existing state or local land use plans or that could significantly damage "aesthetic values and natural systems" also can be prevented, as can those that might "result in a substantial loss or reduction of long-range productivity of water supply" (including aquifer recharge areas and land overlying aquifers).[138] The entire process that must be in place to designate lands as unsuitable for coal mining must "be integrated as closely as possible with present and future land use planning and regulation processes at the federal, state and local levels."[139]

Finally, an important component of SMCRA is its detailed, structured enforcement program. Most important, performance bonds must be posted before mining begins to ensure that funds are available to carry out any reclamation activities specified in the permit but not carried out by the mine operator.[140] Bonds are not released until the reclamation covered by the bonds is performed, and are forfeited for noncompliance. SMCRA also has requirements for inspections and monitoring to determine compliance with permit conditions,[141] substantial penalties for violations of permit requirements[142] and citizen enforcement of the requirements of the SMCRA program.[143]

Improving SMCRA Effectiveness. A number of problems have been identified with both state and federal implementation of SMCRA.[144] In implementing SMCRA itself, and in adapting SMCRA principles to noncoal mining, state and local water quality officials should correct these problems.

Water quality protection under SMCRA (and SMCRA-based programs applicable to noncoal mining) depends on strict compliance with various standards and requirements designed to control runoff and leaching.[145] Unfortunately, compliance and enforcement activities under SMCRA have been inadequate.[146]

Poor enforcement can affect compliance with performance standards, specific control techniques and data collection.[147] The size and complexity of the operation and the political influence of mining interests both can contribute to lax enforcement.[148] The permitting process and the designation of areas as unsuitable for mining also are sensitive to political influence.

Because state SMCRA programs cannot be approved unless they meet the minimum requirements set by federal law, there is little substantive difference in the relevant statutes and regulations in most states. Where there is a difference, it is usually in the number of positions and person-hours, and the level of funding devoted to carrying out a given task—such as permit reviews, site inspections and enforcement proceedings.[149] Since no two states have the same management requirements in these areas, each must assess its own needs and ensure that adequate resources are provided.

In the noncoal mining area, however, there is a wide difference in the stringency with which environmental amenities are protected at both the state and local levels.[150] While there is no current and comprehensive inventory, there seems generally to be a lack of programs that can serve as models for effective control of particular types of noncoal mining activities.[151] One exception is the program recently established in Wisconsin to control metallic mining and mine reclamation impacts.

Wisconsin Statutes Controlling Metallic Minerals Mining

Like SMCRA, Wisconsin's program controls environmental impacts through permitting, data collection, operations, financial responsibility and reclamation.[152] In fact, many aspects of Wisconsin's metallic minerals program go beyond those imposed under SMCRA. All metallic mineral mining is subject to the program.[153] Notification of intent to collect data (for purposes of obtaining a permit to mine) must be submitted to the Department of Natural Resources (DNR) along with background information including a preliminary project description and a future data collection quality assurance program.[154]

After the notice is submitted to DNR, a public hearing must be held to solicit comments (including those of the affected community) concerning potential environmental impacts, data collection needs, necessary pollution controls, and other factors.[155] After the hearing, DNR must inform the potential applicant of the specific data collection requirements (including methodology, type and amount of information and quality assurance measures) needed for submission of a formal permit application and environmental impact report, if required.[156]

Affected localities and the general public must have an opportunity to be present at a public hearing on the permit application (held by DNR), and must be provided with copies of the completed application.[157] A fee of $10,000 is charged to cover the cost of evaluating the application.[158]

As under SMCRA, a mining plan must be included in the application. The plan must detail the techniques for erosion prevention and drainage control (including a water management plan showing source, flow paths and rates, storage volumes and release points) as well as other water collection, treatment and discharge plans.[159] Minimum standards must be met to ensure that surface and groundwater is not contaminated through improper grading, backfilling and stabilization of the excavation, or inadequate diversion and drainage of water.[160]

The DNR must deny the mining permit if the operation would not comply with applicable ground and surface water laws and rules (including local zoning ordinances).[161] DNR also must deny permits if the site is deemed unsuitable for surface mining.[162]

Special requirements exist for the protection of wetlands. Generally, the site chosen for mining must constitute the alternative that causes the least overall adverse environmental impact and preferably avoids the use of any wetlands (but in any case minimizes their use).[163] Location criteria are used to keep mining operations out of floodplains, wetlands and areas that would result in violations of federal and state law.[164] Operations must be at least 1,000 feet from lakes and ponds and 300 feet from rivers and streams.[165]

A reclamation plan, describing how the mine site will be reclaimed and monitored to prevent pollution of ground and

VOL 12

7088

surface waters, also is required.[166] Once a permit is issued (but before the mining operation begins) the mine operator must file with DNR a bond or other security equal in amount to the costs of fulfilling the reclamation plan.[167]

Monitoring, inspection and enforcement provisions require the mine operator to assess environmental impacts and allow DNR to make unannounced state inspections[168] and to issue stop work orders.[169] DNR must review the mining and reclamation plans annually and require a resubmission of the mining permit as necessary to reflect changing environmental conditions or knowledge concerning the adequacy of the original plans.[170]

Other state regulations call for the development and implementation of plans to dispose of mining waste.[171] Waste disposal sites must be "located, designed, constructed and operated in such a manner so as to ... [c]omply with water quality standards."[172]

As with mining and reclamation, waste disposal sites require an operating license approved by DNR.[173] Significant data collection activities are required when preparing an application for a license.[174] A detailed feasibility report and plan of operations must be prepared before a waste site can be operated.[175] Consideration of local and regional land use and zoning issues is a part of this process.[176]

A set of groundwater standards governs the requirements for containing any harmful quantities of contaminated water on the waste site. For substances that do not have specific standards, the site cannot have a "substantial deleterious impact on a current beneficial use or on a significant future beneficial use."[177]

The regulations also provide for extensive and specific site planning and facility design and operation requirements.[178] Like the regulations for mining and reclamation, requirements for waste sites provide for inspections, monitoring, and financial responsibility.[179] In addition, a waste management fund is established, through fees on each ton of mining waste deposited in an approved site, to provide funds for the long term maintenance of approved sites.[180]

Summary

Mining is an intensive land use with the potential to create severe adverse water quality impacts. In fact, in some states with a history of widespread mining activities, such as Montana and Pennsylvania, mining-related pollution is among the major causes of water quality degradation in the state.[181] Unlike pollution from agricultural, urban or silvicultural sources, pollution from mining stems from relatively few individual sources. Therefore, water quality impacts from mining can be localized but very severe.

However, in some ways the localized nature of mining operations makes them easier to control than more dispersed sources, and programs are available to address poison runoff from mines. An essential component of an effective program is the political willingness to enforce water quality protection measures by ensuring that necessary human and financial resources are available and that available controls are implemented. The basic elements of an effective program to control poison runoff from mining activities are summarized at the conclusion of the chapter.

Rangeland Pollution Control Programs

Pollution from livestock grazing in rangelands is a major problem primarily in western states.[182] However, protecting water quality by limiting damage to riparian areas due to direct contact by livestock also is an important consideration in managing pasturelands[183] in eastern states. Of course, eastern and western livestock and grazing control programs may differ substantially.

Livestock grazing can affect water quality in a number of ways. Overgrazing can compact soils, decreasing water infiltration, thereby reducing streamflow during certain periods of the year.[184] Livestock grazing can increase runoff and erosion at other times so as to elevate sediment loadings and flood damage.[185] Grazing too close to the stream can destroy important riparian vegetation (thereby causing water temperature increases and unstable streambanks and flow volumes) and can introduce fecal bacteria, nutrients and sediments directly into the waterbody.[186]

Especially in the west, a large amount of grazing occurs on federal lands. But nonfederal entities (state, local and private)

VOL 12

7090

Improper livestock grazing can reduce groundcover and lead to sediment deposition and streambank destruction.

own the majority of the rangeland in the United States.[187] Therefore, it is important to assure adequate rangeland controls independent of land ownership. States also must coordinate the implementation of these controls. Within a given watershed, controls should be applied to a sufficient number of owners in a timely manner so that any potential benefits gained by good management in one ownership class are not negated by poor management or delayed implementation in another.

As discussed in Chapter Three, the basic controls needed in a pollution control program for unconfined livestock grazing (in either rangeland or pastureland settings) are fairly easy to categorize and understand generally. These include: the use of effective erosion controls; controlling livestock densities in particular areas; limiting access to riparian areas and streams; dispersing livestock facilities[188] to reduce manure accumulation, soil compaction, and other effects, and maintaining good forage and ground cover. Ensuring that such measures are taken and that streams are protected or improved to the point of achieving compliance with state water quality standards is complex and challenging.

Effective Programs for Control of Grazing-Related Water Pollution

Managing poison runoff from rangelands involves the application and coordination of controls on both public and private lands.[189] Current federal rangeland management practices do not ensure adequate water quality protection.[190] Moreover, the use of public versus private rangelands is so interrelated that enhancing or degrading one can cause similar effects on the other.[191] Along with state and federal involvement, it is also important that localities and private individuals participate in the development and implementation of rangeland programs.[192]

Federal rangeland must be managed for multiple uses, including not only economic uses such as grazing, but resource enhancement uses such as watershed and natural habitat protection.[193] This is not necessarily the case for private lands. However, the application of state water quality standards to waters running through both public[194] and private rangeland[195] means that, at the very least, nonfederal rangeland must be managed for water quality protection in addition to any other uses.[196]

Rangeland management needs to address both riparian and upland areas in order to protect water quality.[197] Water quality protection and restoration efforts must go beyond the stream and riparian area and take into account the carrying capacity[198] of particular range areas.[199] State officials need to assure that plans are developed and implemented to control the timing, location and intensity of grazing in a manner that is compatible with water quality protection objectives.[200] Structural controls, such as fencing, dams and channel modifications, should not replace sound rangeland management designed to prevent impacts to water quality and riparian habitat.[201] Such structural controls should only be used to supplement sound management in areas where past practices have caused acute problems and where habitat *restoration* is required.

While controls applied in particular rangeland settings may differ according to the owner and the ownership class, the general methods for maintaining range productivity and protecting stream quality are more or less universal. Broadly speaking, range improvements and land treatments are a primary method of improving range productivity and associated water quality by ensuring that the carrying capacity of the land is not exceeded by grazing activities. Their purpose is "to make the range more productive or to restore it to some real or imagined ecological state that has occurred in the past."[202] Although land treatments encompass methods that work both with and against the natural processes of the rangeland ecosystem, those methods that complement the ecosystem are most likely to contribute to the attainment of multiple use goals that include water quality protection.[203]

Depending on the specific purpose of managing the rangeland, land treatments and improvements can include a variety of activities. The activities can be characterized as: adjusting animal numbers; controlling animal use; and reseeding and rehabilitation.[204] The first two of these can be characterized more as management prescriptions while the second two involve more mechanical approaches. Controlling animal numbers and their use of the range can be accomplished through a variety of methods ranging from the simple (herding, placement of salt, development of new water holes, etc.) to the complex (limiting animal densities in particular pastures and areas, rotating the use of fields by season or intensity of use).[205]

Some of the more complex approaches, called *planned grazing systems,* divide the rangelands into similar units which are then rotated, deferred and retired in some combination based on an understanding of the unique soils, vegetation and ecology of the site.[206] Productivity also can be enhanced through the control of plants that have artificially displaced those that could improve forage in desired grazing areas.[207] Preferably, grazing areas should be managed for diverse, native plant species. Around the riparian area itself, fences, planned crossings and other structural measures can be used to supplement broader management prescriptions, especially in areas with severely degraded stream habitats.[208]

Land Use Planning for Pollution Control in the Rangeland Setting. All of the management needs mentioned above indicate that control programs for rangeland, as for other sources of poison runoff, require sound land use planning.[209] More specifically, the mix of federal, state and private lands and objectives tends to require a coordinated "resource management" approach among all governmental levels and interested parties similar to that described for silvicultural and mining programs.[210]

Rangeland controls in individual areas should be developed based on an extensive land use and water quality inventory and with the direct involvement of an interdisciplinary resource management team.[211] As with all other source categories, the establishment of water quality standards appropriate to range environments is a necessary first step in assessing problems and carrying out water quality protection measures.[212]

A classification scheme for ranking the existing and potential quality of riparian areas also is needed to set priorities for the implementation of controls and to select the appropriate BMPs.[213] This scheme should take into account the impacts on water quality of other activities in the surrounding watershed.[214]

In order to determine range management (including water quality protection) controls, it probably will be necessary to evaluate each grazing area with similar flora, soils, carrying capacity, and other factors for the specific needs in that region.[215] Controls on private lands are likely to differ from those on public lands because of the multiple use planning requirements for federal lands, although state regulation may be needed to ensure that private land managers do not damage public resources.[216] For example, the use of differential grazing fees[217] for upland and riparian areas could be useful on public rangelands but can not readily be applied to private lands.

Nevertheless, water quality improvement on nonfederal lands requires grazing management programs similar to those needed on federal lands. The Bureau of Land Management (BLM) is responsible for the management of the majority of the 250 million acres of federally-owned rangeland.[218]

In addition to the land use plans required of BLM,[219] the agency's regional and state offices also prepare individual permits and management plans that apply to particular rangeland areas (divided into 31,000 grazing allotments averaging 8,500 acres).[220] Permits specify the conditions (based on local or regional rangeland conditions) under which individual users of the public rangeland can graze cattle and sheep (*e.g.*, number and type of livestock, time and duration of use).[221] Management Plans that describe how grazing will be conducted in order to meet sustained yield and multiple use goals and special conditions established to improve rangeland conditions are prepared on many allotments.[222]

The BLM also prepares Allotment Management Plans (AMPs) to manage individual rangeland areas on federal lands.[223] These plans apparently have not sufficed to protect water quality on BLM lands.[224] However, if implemented with increased focus on water quality, AMPs could furnish a useful framework for water quality planning and riparian protection in state and private rangeland settings. These plans consist of the following:

1. an analysis of the present resource value and uses, including problems and conflicts;

2. objectives to be achieved which are specific and quantitative and which resolve or mitigate resource problems and conflicts;

3. a grazing system which will achieve these objectives;

4. range improvements to implement the grazing plan; and

5. monitoring and evaluation activities to determine whether or not objectives are being met.[225]

Under the leadership of state water quality and rangeland experts, comprehensive water quality and riparian enhancement plans could be established in partnership with private land owners and with assistance from USDA, BLM, U.S. Fish and Wildlife, and other federal agencies.

VOL 12

A Dearth of Model State Rangeland Management Programs

Unlike programs to control other types of poison runoff, NRDC failed to identify existing state activities that demonstrate innovative control of grazing-related pollution on nonfederal rangelands. Current efforts seem to focus on management activities on federal land, and many states have developed Memoranda of Understanding (MOU) with the Bureau of Land Management (BLM) providing for the management of public rangeland to protect water quality.

For example, Oregon (considered by many to be a leader in rangeland management) negotiated an MOU with BLM in 1978 that would allow the state Department of Environmental Quality to submit lists of priority waterbodies for special attention by BLM officials developing rangeland management plans.[226] However, the MOU is considered outdated and is being renegotiated.[227]

The BLM also is working with Oregon and Washington State resource management agencies on the development of a riparian enhancement plan to improve over 650 miles of riparian areas located on public lands through the development of site-specific riparian area improvement programs.[228] One of the goals of the plan is to "improve water quality to meet or exceed state water quality standards."[229]

Special treatments in riparian zones will be implemented along with controls applicable to upland areas.[230] The joint federal, state and local program will involve extensive data collection and monitoring to allow priority areas to be addressed ahead of others and to ensure that desired changes in water quality are achieved.

Oregon has established a cooperative network of state and federal agencies to assist in voluntary efforts by land owners to develop general grazing management plans.[231] However, overall little, if any, action is being taken systematically to address pollution from grazing on nonfederal lands in Oregon.[232] Apparently, this could change with the development of the state's Nonpoint Source Management Program under CWA § 319.[233]

7096

Summary

A lack of existing programs does not mean solutions to rangeland water pollution are not possible. And if solutions are available, political willingness to implement controls may be a more crucial issue.[234] Using the resource management concepts that have been developed (if not put into practice) in federal grazing programs, state and local officials could take into account site specific factors and could develop the controls needed to improve upland range conditions, riparian areas and, ultimately, the quality of state waters. Recognizing that such controls would apply to private, and not public lands, states would have to be careful to limit management prescriptions to those needed to achieve the water quality goals required under the CWA. In addition, states also need to ensure adequate oversight of BLM and USFS rangeland management activities since there is no assurance that federal officials will focus their planning efforts on the achievement of state water quality goals. Specific recommendations for controlling the water pollution caused by grazing are provided below.

Conclusions and Recommendations

This chapter addresses some of the requirements for controlling three types of poison runoff. Many characteristics are common to each type of pollution and, in many cases, each type of management program. The variety of factors affecting the problem of poison runoff in these three settings dictates that emphasis move away from a strict dependence on BMPs to address water quality issues, and towards the use of sophisticated resource management and land use plans. Interspersed land ownership patterns make close coordination of many federal, state and local control programs essential in order to address all significant problems and prevent controls used by one ownership class from being wasted because of inaction by another.

As with all types of poison runoff controls, a strong link must be forged between programs and water quality standards in order to provide a rationale by which states can gauge program performance. The following recommendations are provided to control the poison runoff associated with three important source categories - silviculture, mining and grazing.

Silvicultural Controls.[235]

1. A clear identifiable performance standard, based on compliance with state water quality standards, should be established and enforced (through the inspection process). The performance standard should supplement minimum technology-based standards.
   a. The relevant water quality standards should include, in addition to specific numeric criteria, an antidegradation policy and enforceable policies and guidelines for protecting beneficial uses, fish and wildlife habitat and sensitive stream parameters.
   b. Compliance with water quality standards should be assured not only through prescribed operational practices, but by controlling the location, timing and intensity of harvest, road building, and other operations. Where necessary to assure compliance with water quality standards, timber harvesting should be prohibited.

2. A long-term planning effort should be initiated to classify and estimate the conditions of natural resources and associated forestry impacts. It should be used to limit cumulative impacts and prevent water quality impacts on sensitive land areas and on pristine, or otherwise highly valuable, water resources.
   a. Watershed management plans offer the most effective way to control the long term aspects of silvicultural pollution and should be developed by regulatory agencies and industry so that entire hydrologic areas can be considered (including the habitat and water quality aspects of the entire area).
   b. State forestry and water quality officials should require that federal plans for National Forests conform to the water quality protection needs of the state.

VOL 12

7098

3. A set of guidelines for preparing individual timber harvest proposals should be developed and enforced to ensure that maps, descriptions, explanations, justifications and other information are adequate to allow the plan to be reviewed from the standpoint of environmental protection; plans should include, at a minimum, descriptions of the:
   a. site;
   b. proposed activities;
   c. means of compliance with all design and performance standards; and
   d. special area protections.

4. Silvicultural operations should be regulated by multidisciplinary teams, including specialists in silviculture, water quality, and fish and wildlife. The roles, responsibilities and authorities of each party in the timber proposal review process should be clear and should include:
   a. specific decisionmaking roles and responsibilities based on expertise, and a formal process for negotiating and appealing disagreements that arise in the timber plan review process; and
   b. adequate funding, staffing and training for each agency involved, and consistent agency procedures in different regions of the state to disperse and collect data and resolve conflicts more easily. Funding should be ensured through permit fees or timber harvest assessments.

5. After forest plans are approved, adequate inspection and enforcement are necessary to ensure compliance. Enforcement and inspection requirements include the following:
   a. adequate personnel;
   b. administrative, civil, and criminal penalties and stop work orders;
   c. frequent, unannounced inspections;
   d. involvement of multiple agencies in the inspection process;

VOL 12

7099

R0040407

e. agencies represented in the multiagency review team periodically must monitor implementation of timber plans and specific BMPs, to ensure that inspection procedures protect relevant resources adequately;
f. before a timber operation begins, the responsible private forester must meet with the timber operator at the site to discuss the timber plan; the timber operator should then verify, in writing, that he understands the plan and agrees to follow its provisions; and
g. timber operators must be required to perform in-house monitoring and supervision to ensure that protection measures are followed and data from this process can be retrieved by forestry personnel for use in planning and feedback activities.

Mining Controls.

6. Pollution controls should address all sources of mining runoff, including active and abandoned coal and noncoal mines, both above and below the ground.

7. The state water quality protection authority should participate in the development, implementation and enforcement of mining controls.

8. To the extent possible, the control hierarchy established in SMCRA should be used to address all mining-related pollution by requiring mine operators to:
   a. prevent contamination by diverting as much surface water as possible around active operations;
   b. minimize contamination of surface water that traverses active operations through contemporaneous stabilization and reclamation;
   c. collect and treat any contaminated water; and
   d. stabilize and reclaim all areas after mining ends.

9. In addition to specific design and operation standards, mining permit approval should be conditioned on compliance with water quality standards, after

consideration of both point and diffuse discharges from the operation. The location, timing, and intensity of mining should be controlled where necessary to achieve this goal.

10. Sites should be designated as unsuitable for mining where water quality standards or other minimum environmental requirements cannot be met.

11. Permit requirements and other program requirements should be enforced through:
    a. regular, detailed inspections, including unannounced inspections;
    b. compliance orders where violations are found;
    c. stop work orders, fines, and other enforcement actions where needed to achieve compliance; and
    d. performance bonds of adequate size to ensure proper reclamation, with bond release withheld until adequate, permanent stabilization and reclamation is completed.

12. An abandoned mine reclamation fund and program should be established.
    a. Where responsible parties are known (and are solvent), legal action should be take to require cleanup;
    b. Where responsible parties are unknown or are insolvent, cleanup of abandoned mines should be funded through permit assessments and tonnage fees from active mines;
    c. An abandoned mine fund should be used to reclaim mines in order of environmental priority, based on water quality, public safety and other factors.

13. Since state officials cannot assume that the control of mining on federal lands by the BLM and USFS will lead to compliance with state water standards, necessary state controls on federal lands should be achieved through the development and enforcement of detailed management agreements or other enforceable methods.

VOL 12

7101

Grazing Controls.

14. Programs to protect water quality in rangeland settings should take place in the context of a comprehensive, interdisciplinary resource management plan that integrates controls on both federal and nonfederal lands.
    a. State water quality officials should carefully review federal grazing permits and management plans for individual watersheds to ensure that adequate measures are being taken to maintain or improve water quality on federal rangeland.

15. Within this overall plan, subplans should be prepared and coordinated to achieve water quality standards within individual watersheds.

16. Management plans for grazing lands should protect water quality and overall habitat and productivity by:
    a. controlling livestock densities;
    b. controlling livestock location, especially access to riparian areas and water bodies; and
    c. ensuring adequate forage and ground cover, with diverse, native plant species wherever possible.

17. Structural and instream controls, such as fencing and controlled stream crossings, should be used for addressing acute water quality problems, but preference should be given to sound land use and management requirements.

Notes - Chapter Five

1. Together, programs to control poison runoff from urban and agricultural settings typically involve a variety of activities, including educational and research activities, regulatory programs and financial incentives that are applicable statewide through the involvement of a plethora of state and local agencies. In contrast, other nonpoint sources often are not controlled that way. For example, the federal Surface Mining Control and Reclamation Act (SMCRA), while a very detailed regulatory program, does not contain a mass of diverse, loosely coordinated program approaches; applies to a relatively well-defined (both geographically and substantively) set of activities; and is usually self-contained within a single agency of the state government.

2. The U.S. Forest Service, the Bureau of Land Management and other federal agencies collectively own 39% of all the forested land in the nation (72% of western forest lands are in federal ownership). U.S. Department of Agriculture, *An Assessment of the Forest and Range Land Situation in the United States* (Forest Resource Report No. 22), October 1981, at xiii, 15-16.

3. Both the Forest Service and the Bureau of Land Management are required by the Clean Water Act and the National Forest Management Act to comply with state water quality standards. *See* 33 U.S.C. § 1323(a); 43 U.S.C. § 1712(c)(8); *see also* Exec. Order No. 12,088, 3 CFR § 243 (1979), *reprinted in* 42 U.S.C.A. § 4321, app. at 172-174 (1988).

4. *See generally* Henly, Russell K. and Paul V. Ellefson, *State Forest Practice Regulations in the U.S.: Administration, Costs, and Accomplishment,* (Bulletin AD-SB-3011), University of Minnesota, Agricultural Experiment Station, 1986; *Management Agency Agreement Between the State Water Resources Control Board, State of California and the Forest Service, United States Department of Agriculture,* February 26, 1981 (hereinafter cited as MAA-USFS); *Management Agency Agreement Between the Water Resources Control Board, the Board of Forestry, and the Department of Forestry and Fire Protection, State of California,* revised December 11, 1987 (hereinafter cited as MAA-California); Idaho Department of Health and Welfare, *Forest Practices Water Quality Management Plan–State of Idaho,* January, 1988.

5. *See generally* U.S. EPA Region X, *Planned and Actual Impacts on Fish and Water Quality in Three National Forests in Northern Idaho,* November, 1987 (hereinafter cited as *Impacts on Fish and Water*); Anderson, H. Michael, "Water Quality Planning for the National Forests," 17 *Envtl. Law* 591-641 (1987); Anderson, H. Michael, and Craig Gehrke, *National Forests: Policies for the Future–Water Quality and Timber Management* (Volume 1), The Wilderness Society, Washington, D.C., August, 1988.

The CWA requires federal land management activities (including those in National Forests) to comply with state water quality standards. The National Forest Management Act (NFMA) provides the basic framework under which most USFS NPS pollution control activities are conducted. The NFMA requires that timber can only be harvested from a National Forest when (among other things):

1. soil, slope, or other watershed conditions will not be irreversibly damaged;
2. protection is provided for streams, streambanks, shorelines, lakes, wetlands, and other bodies of water from detrimental changes in water temperature, blockages of water courses, and deposits of sediment, where harvests are likely to seriously and adversely affect water conditions or fish habitat.

16 U.S.C. § 1604 (g)(3)(E).

These water quality protection measures are most directly addressed through the development, review and implementation of regional guides and forest plans. Regional guides establish tentative objectives for individual National Forests and the management standards for all the forests in a particular region. 36 CFR § 219.4(b)(2-3); Wilderness Society *et al.*, *National Forest Planning–A Conservationists Guide* (2nd ed.), 1983, at 17-18. Forest plans constitute the specific goals and management activities (including water quality protection activities) for each national forest over a particular time period. Final forest plans are developed through an exhaustive 10 step process including the identification of issues and concerns, development and evaluation of management alternatives, and selection and monitoring of the preferred alternative. Wilderness Society *et al.*, 1983, at 18-20.

6. Anderson and Gehrke, 1988, *supra* note 5, at 15-20. The USFS has resisted the adoption of strict state controls on forestry operations on federal lands. Specifically, the USFS has been reluctant to accept compliance with state water quality standards as a strict condition on forest plans and management procedures. *See Northwest Indian Cemetery Protection Association v. Peterson*, 565 F. Supp. 586, 604-605 (N.D. Cal. 1983), *aff'd*, 764 F.2d 581 (9th Cir. 1985), *reh'g granted, aff'd on reh'g*, 795 F.2d 688 (9th Cir. 1986).

7. *See generally* Henley and Ellefson, 1986, *supra* note 4; MAA-USFS, 1981, *supra* note 4; MAA-California, 1987, *supra* note 4; Idaho Department of Health and Welfare, 1988, *supra* note 4; Idaho Department of Health and Welfare, *Idaho Water Quality Status Report and Nonpoint Source Assessment–1988*, May, 1988; Montana Department of Health and Environmental Science, *Nonpoint Sources of Water Pollution in Montana* (draft), May, 1988.

61. Much of the discussion below is based on a review of the California forest practices program by an interagency task force (the Forest Practice Rules Assessment Team). *See generally Rules Assessment Team*, 1987, *supra* note 17; State Water Resources Control Board, 1987 *supra* note 29. Information was also gleaned from a report documenting a negotiating process to improve forestry programs in Washington state. *See generally* Northwest Renewable Resources Center, *Timber/Fish/Wildlife - A Better Future: Our Woods and Streams* (Final Report), Seattle, Washington, February 17, 1987 (hereinafter cited as *TFW*).

62. Lee, 1988, *supra* note 16; Henly and Ellefson, 1986, *supra* note 4, at 99; *see* 16 U.S.C. §§ 1600-1614. Washington state at least has the rudimentary framework for such large-scale planning. The state Forest Practices Act (Wash. Rev. Code § 76.09 (1986); Wash. Admin. Code R. Ch.222-08 - 222-50 (1986) has defined different forest practices as falling into five classes -Classes I, II, III, IV-General, and IV-Special. Basically, each class involves progressively more protective practices on land of increasing environmental sensitivity. The most sensitive lands are Class IV-Special, which "have a potential for substantial impact to the environment" and therefore are subject to the theoretically stringent requirements of the State Environmental Policy Act. Henly and Ellefson, 1986, *supra* note 4, at 71.

63. Henly and Ellefson, 1986, *supra* note 4, at 91-93, 99; *Rules Assessment Team*, 1987, *supra* note 17, at 12-4; see State Water Resources Control Board, 1987, *supra* note 29, at 41-43.

92. 43 U.S.C. § 1701 *et seq.*

93. These include metallic minerals, such as iron, copper, gold and lead as well as some nonmetallic minerals.

94. For a discussion of BLM management of mining claims of federal lands, *see generally* U.S. General Accounting Office, *Public Lands: Interior Should Ensure Against Abuses From Hardrock Mining,* March, 1986; U.S. General Accounting Office, *Federal Land Management: An Assessment of Hardrock Mining Damage,* April, 1988.

95. *See, e.g.,* U.S. Department of the Interior, Bureau of Mines, *Control of Acid Mine Drainage—Proceeding of a Technology Transfer Seminar* (Information Circular 9027), 1985; Wells, Larry G., Andrew D. Ward and Ronald E. Phillips, *Predicting Infiltration and Surface Runoff from Reconstructed Spoils and Soils,* University of Kentucky, Water Resources Research Institute, 1983; Evangelou, V.P., J.H. Grove and R.I. Barnhisel, *Identification of Soil-Water Chemical Parameters for the Prediction of Suspended Solids in Surface Water Reservoirs of Coal Mine Lands,* University of Kentucky, Water Resources Research Institute, 1984; Meadows, Michael E. and George E. Blandford, *Improved Methods and Guidelines for Modeling Stormwater Runoff from Surface Coal Mined Lands,* University of Kentucky, Water Resources Research Institute, 1983.

96. *See generally,* U.S. EPA, *Processes, Procedures and Methods to Control Pollution from Mining Activities,* 1973; U.S. EPA, *Criteria for Developing Pollution Abatement Programs for Inactive and Abandoned Mine Sites,* 1975; U.S. EPA, *Inactive and Abandoned Underground Mines,* 1975; U.S. EPA, 1977, *supra* note 86.

97. As indicated below, while many of these documents are over 10 years old, they still share many attributes of more recent developments in the control of other poison runoff problems—particularly in their emphasis on using water

quality standards as a guide to controlling *all* of the point and nonpoint sources within individual watersheds as part of a comprehensive water quality management plan. Much of the discussion provided below was gleaned from the final EPA guidance document for mining pollution control developed in the late 1970s. *See generally* U.S. EPA, 1977, *supra* note 86.

98. *Id.* at v-vi.

99. EPA calls for a regulatory process "which either specifies, or is effective in identifying BMPs appropriate to each mine-related [NPS]" and that assures that the BMPs "are, in fact, utilized and that water quality goals are achieved and beneficial uses protected ... State WQM [water quality management] agencies ... are responsible for seeing to it that control systems for current mine-related sources are developed and implemented which are sufficiently effective on-the-ground to achieve water quality goals and to protect designated beneficial water uses." *Id.* at 3-1. Agencies other than the water quality management agency involved in developing or implementing NPS controls should be responsive to the need to achieve any established pollution load reductions and to protect designated beneficial water uses. *Id.* at 5-2.

100. Like other kinds of poison runoff control programs, those pertaining to mining-related NPS pollution control should attain and maintain water quality goals and beneficial uses of water. EPA recommends that state water quality management agencies be responsible "for seeing to it that control systems for current mine-related sources are developed and implemented which are sufficiently effective ... to protect designated beneficial water uses." *Id.* at 3-1.

101. *Id.* at 3-15 - 3-17. As with other types of runoff management programs, controls should be developed on a watershed-wide basis to produce tangible water quality benefits.

102. *Id.* at 2-5 - 2-6. EPA guidance states that "[t]he standards should take into account stream biology and sensitivity of aquatic life, benthic deposit transport and resuspension impacts, and additive or synergistic and cumulative pollutant impacts, as well as locally critical design flow conditions." *Id.*

103. Runoff should be controlled from all kinds of abandoned mines, not just coal; and from deep mines as well as from surface operations.

104. A fully effective program should include the land use controls that can prevent poison runoff when point and nonpoint technology-based controls are inadequate. These controls include: a general prohibition on operations in sensitive areas; designation of areas as fully, partially or conditionally unsuitable for specific activities; permit denial procedures for individual mining operations; and local zoning requirements. U.S. EPA, 1977, *supra* note 86, at 3-12, 3-13. Using land use planning to initiate and guide the development of mining pollution control programs is a prominent theme in an important National Research Council publication on the relevance of SMCRA to noncoal mining operations. *See* National Research Council, *Surface Mining of Non-Coal Minerals*, Washington, DC, 1979.

105. U.S. EPA, 1977, *supra* note 86, at 3-6 - 3-8 (paraphrased).

106. Reclaiming abandoned mines is desirable independent of water quality, for reasons related to public health and safety, sound public land management, and aesthetics. While this report focuses on water quality, complete reclamation of abandoned mines provides a permanent solution to water quality concerns, and addresses these other environmental goals as well.

186. *See generally* Blackburn, 1984, *supra* note 184; Elmore and Beschta, 1987, *supra* note 184; Platts, Gebhardt and Jackson, 1985, *supra* note 184.

187. A recent USDA land use inventory classified 441,446,000 acres of land as nonfederal rangeland and 328,887,000 acres as federal rangeland. U.S. Department of Agriculture, *The Second RCA Appraisal–Soil, Water, and Related Resources on Nonfederal Land in the United States* (Review Draft), July-August, 1987, at 15-2. Of course, rangeland is a term used to define a particular ecosystem type. It is defined in the RCA Appraisal mentioned above as "[l]and on which the climax vegetation (potential natural plant community) is predominantly grasses, grasslike plants, forbs, or shrubs suitable for grazing and browsing." *Id.* This general definition should not be construed to mean that all rangeland is appropriate for livestock grazing. Not all rangeland is productive enough to provide the *quantities* of grasses that are suitable for grazing *cattle* or *sheep* (as opposed to natural species). Moreover, this type of grazing is not always compatible with the rangeland ecology.

211. *Id.* at 48-49, 55-82.

212. *Id.* at 58-59. In rangeland settings, important standards are sediment and turbidity, fecal coliform bacteria, and dissolved solids as well as biological and habitat measures.

213. *Id.* at 48-49.

214. *Id.*

215. *Id;* Box, 1984, *supra* note 189, at 1406-1408.

216. *See* Box, 1984, *supra* note 189, at 1398; Fairfax, 1984, *supra* note 191, at 1704.

217. Grazing fees, usually based on units called "animal unit months" or AUMs, are charged to those using public rangelands to feed cattle. *See generally* The Taylor Grazing Act, U.S.C. §315 *et seq.* Riparian areas are included in the allotment of AUMs, and since they are more productive than upland areas they tend to be grazed more heavily. Some have considered the possibility of structuring grazing fee systems so that they take into account how well riparian areas are being managed. Elmore and Beschta, 1987, *supra* note 184, at 262.

Beyond the need to use differential fees, it is also important that the *absolute* grazing fees charged by BLM and USDA reflect the market price of the services provided by public rangeland as well as any hidden costs associated with, among other things, land and resource degradation. The fees charged in the past have been far below fair market value and have not covered even the administrative costs for the grazing program. Report of the House Committee on Government Operations Together with Additional and Dissenting Views, *Federal Grazing Program: All is Not Well on the Range*, H.R. Doc. No. 593, 99th Cong., 2d Sess. 5-10, 36-38 (1986). Such subsidies, like those provided to private agricultural and forestry interests, not only generate private profits at public expense but also contribute indirectly to the degradation of the streams, rivers and other water resources associated with the range. *Id.* at 26-27, 36-38.

Not only do artificially low grazing fees encourage overgrazing on public lands (the most prominent form of mismanagement); they also reduce the funds available for range improvements, including the restoration of riparian areas. *See generally* Wald, Johanna and David Alberswerth, *Our Ailing Public Rangelands: Condition Report - 1985*, National Wildlife Federation and Natural Resources

VOL 12 7/1/86

Defense Council, December, 1985; Wald, Johanna H. and Faith T. Campell, *Testimony of the Natural Resources Defense Council Before the Subcommittee on Interior and Insular Affairs*, September 22, 1987. Thus, as with other problems with diffuse pollution sources, federal economic development policies must be addressed in order for effective management solutions to be developed.

218. The U.S. Forest Service controls a significant amount of federal rangeland used for grazing. Combined, the BLM and Forest Service have issued grazing permits or leases for approximately 365 million acres of rangeland in 16 western states. U.S. General Accounting Office, 1988, *supra* note 190, at 13. *See* Forest and Rangeland Renewable Resources Planning Act of 1974 (16 U.S.C. § 1604 *et seq.*). For a description of BLM rangeland management requirements, *see* the Public Rangelands Improvement Act of 1978 (43 U.S.C. § 1901 *et seq.*). This law establishes a national policy of managing and improving the conditions on public rangelands. The Federal Land Policy and Management Act of 1976 (43 U.S.C. § 1701 *et seq.*) requires the Secretary of the Interior (of which BLM is a part) to manage public lands for multiple uses and sustained yield through the development, use and periodic revision of land use plans.

Chapter Six

Information Collection and Use

Introduction

As described below, properly collecting and evaluating data is one of the biggest challenges that officials and citizens concerned with controlling poison runoff must face. Many control programs today lack an adequate capacity to collect and use data. Without adequate data management capabilities, programs can suffer from a host of fundamental problems, including: inaccurate problem assessments and load reduction targets; poor priority-setting that wastes limited resources; false claims of victory over pollution problems; and reluctance to use much-needed mandatory control programs.

Fundamentals of Poison Runoff Data Collection

Many states lack baseline information concerning the current impacts of poison runoff on water quality and the degree to which these impacts could be reduced.[1] But estimating the potential water quality impacts of a program to reduce poison runoff in a given watershed is important to program success.[2] Adequate data collection and analysis is essential to determine:

1. existing program effectiveness;

2. needed program modifications; and

3. potential program options.

In addition, estimates are needed of the pollutant load reductions required to restore beneficial water uses within each watershed.[3]

This chapter discusses the collection and utilization of data, with a focus on the use of information gained from monitoring and modelling water quality, land use and socio-economic factors. Although limitations in the quality and usefulness of information today severely affect the success of many management efforts, progress in this area is being made. The recent developments and research addressed in this chapter, as well as the descriptions of actual programs with good data management activities, will help to illustrate how improvements in this critical area are possible.

Data Need Not be Perfect In Order to be Used Effectively. In the past, some states have justified their reluctance to use mandatory control programs by pointing to a lack of precise data about cause-and-effect relationships in poison runoff (both the relationship of land use to water quality, and the relationship of BMPs to improvements in water quality).[4] According to this reasoning, regulatory programs are unfair and unjustified since proving the need for mandatory controls on each individual polluter is necessary but not feasible.

But a lack of utter precision in data collection and analysis is not a valid reason to limit program options to the purely voluntary. Data collection and analysis activities have been used repeatedly to establish, implement, and enforce progressive, often regulatory programs,[5] even when they did not generate absolutely certain results.

The stringency of controls need not be slavishly dependent on absolute numerical certainty concerning individual nonpoint sources. Once basic water quality impact information has been collected, control programs often can begin to be implemented. To be sure, additional monitoring and modelling information can and should *enhance* the control of poison runoff by leading to

VOL 12

7121

the development of new approaches; improving the targeting of programs; and providing feedback on potential and actual program effectiveness. But waiting for absolute certainty can lead to permanent paralysis.

As can be seen from many other environmental management activities, such as land use controls, air quality regulation, and hazardous waste facility siting, precise quantification of program impacts from individual polluters is not always a precondition for choosing particular approaches to controlling environmentally harmful activities. Most of the programs described throughout this study are based on reasonable, and reasonably-well documented, approximations of water quality impacts based on land use and hydrologic modelling, on surrogates for water pollution such as erosion and other land-based measures, or on general knowledge of the risks posed by a particular activity.

A narrow view of the purpose of data collection activities sometimes is based on the assumption that the only alternative to a voluntary program is a discharge *permit* program similar to the water quality-based NPDES program under the CWA. Under such a program, the runoff (and, theoretically, groundwater) discharges from each farm or other individual nonpoint source would be monitored or otherwise estimated; its water quality impacts gauged; and appropriate BMPs assigned as part of the permit to discharge (*i.e.*, to farm, to build, etc.).

However, approaches to reducing poison runoff need not be limited to the point source, water quality-based permit approach. Policy-makers should consider the technology-based approach that forms the "floor" for NPDES permitting as a more useful analogue. Under this model, when a significant problem from dispersed pollution sources comes from a particular type or class of activity, a basic control approach is developed. With additional information, regulators can develop and implement innovative controls or can reduce controls where information indicates they are unnecessary. Essentially, the role that data collection should play can be broken into a few simple steps:

1. measure water quality and compare findings to water quality standards;

VOL 12

7122

2. calculate total load reductions for each pollutant that are necessary to meet water quality standards, with an adequate margin of safety and taking into account seasonal and hydrologic variations;[6]

3. *estimate* total loads from each category or group of diffuse sources;

4. *estimate* load reductions that can be achieved using various levels of control;

5. choose and implement the appropriate controls needed to comply with water quality standards;

6. measure water quality periodically as controls are imposed, in order to verify the initial analysis; and

7. modify controls if necessary.

Some of the main aspects of this process are described in greater detail in the following section.

Monitoring and Modelling: Using Data Effectively

A formal process should be a part of each state's water quality standards program whereby beneficial uses of water (such as fishing, swimming, drinking water supply) are designated for each waterbody and stream segment, and periodic assessments are conducted in specific waters to determine whether these uses are being attained or maintained.[7] This involves not only evaluation of whether chemical water quality criteria are met, but also whether the overall physical and biological health of the aquatic system is sound. The process is described briefly below.

The appropriate process for using chemical water quality information for controlling poison runoff is the process of (1) calculating Total Maximum Daily Loads (TMDLs), and (2) establishing water quality-based controls based on those TMDLs.[8] While no single, uniform procedure for calculating the nonpoint

VOL 12

7123

R0040431

source component of a TMDL has been established by EPA, the Agency has published guidance on targeting controls. This guidance supports the approach of establishing pollution reduction goals and monitoring water quality to determine whether goals are achieved.[9] Although difficult, estimating needed reductions in poison runoff and developing appropriate control programs is a central part of many strategies to protect lakes, rivers and estuaries.[10]

The TMDL process requires that a state evaluate a variety of data and develop a prioritized list of waters that need new or revised TMDLs.[11] The TMDL process actually consists of two parts: the Load Allocation process (LAs), through which the State determines the degree to which particular nonpoint sources of pollutants must be reduced to attain beneficial uses, and the wasteload allocation process (WLAs), through which the state conducts the same exercise for point sources of pollutants.[12]

This regimen has been required by the CWA since 1972, yet few States have a fully developed TMDL and WLA/LA program.[13] To the extent that states have been reluctant to develop LAs for nonpoint sources, EPA bears much of the blame. EPA has not aggressively enforced its own load allocation regulations.[14] Moreover, while EPA has developed guidance on the data and monitoring required to conduct WLAs for *point* sources,[15] similar guidance for LAs and diffuse sources is only now being considered.[16]

A recent EPA report indicates that states need to reorient all of their monitoring activities more towards nonpoint source impacts.[17] The report found that data collection activities currently are focused on point sources to the exclusion of diffuse sources.[18]

Moreover, chemical water quality data provide an incomplete assessment of whether beneficial water uses are being achieved. Assessing the impacts of poison runoff requires biological, hydrologic, precipitation, topographic, census, land use and economic data as well as simple information on water quality.[19] There are numerous sources of such data that can be used in a management program. The Nonpoint Source Branch at U.S. EPA has identified over 20 sources of information that are readily available to state and local officials.[20] This information

VOL 12

7/1/24

also can be used in various ways to describe water quality, to estimate pollutant loadings, and to predict land use trends. Very often the information can be input into models[21] to predict estimated water quality impacts. While the value of some of these models still is the subject of debate, and some require large amounts of site-specific empirical data, models have been used effectively in a number of situations.[22]

Sources of water quality information collected at the state level can be loosely grouped into four categories: the state's *fixed station system* that characterizes general water quality as well as state-wide and site-specific trends; *intensive surveys* which are more detailed studies that are used (if existing fixed station data are inadequate) to determine beneficial use attainment and specific water quality conditions; *special studies* (often one-time surveys) that investigate specific problems within a large geographic areas; and *other sources* of data that help to describe water quality.[23] Within each of these categories, data can be collected using various methods. Types of data collection methods are:

1. chemical screening - collection of ambient (in-stream) chemical data appropriate to the beneficial use and representing the water column, sediment, and fish tissue;

2. bioassay - biological tests that assess ambient and pollutant toxicity on aquatic life and that screen for human health effects;[24]

3. biosurveys - evaluations of the health of the aquatic system that measure factors such as the size, number, distribution and diversity of fish, macroinvertebrates and other populations, and overall habitat analysis;[25]

4. professional judgment/direct observation - where limits in quantitative information dictate, the application of information from one watershed to another, substituting different types of data (*e.g.*, chemical for biologic in situations of aquatic life impacts) and other qualitative assessments; and

VOL 12

7125

R0040433

5. other data - modelling, citizen complaints, fish kills and other information are used to understand water quality conditions better.[26]

The first step in collecting water quality information is the development of an effective monitoring *strategy*. The EPA Nonpoint Source Branch has developed a useful guide to monitoring and evaluating poison runoff problems and programs.[27] Some of the general guidelines are presented below.

Water Quality Data Collection Plans

States and localities need baseline information to establish a benchmark against which to measure any long-term trends.[28] The first step is the selection of appropriate parameters to measure. Obviously, the State's long-range water quality goals will drive decisions about what parameters to monitor. Therefore, these goals must be defined clearly *before* baseline data are gathered.[29] When developing these goals, sampling error can be reduced by defining monitoring objectives as narrowly as possible, and by distinguishing between the testing of parameters (used primarily to determine pollutant loads and water quality impacts) and hypothesis testing (used primarily in program evaluation).[30] The choice of which parameters to monitor should be influenced by applicable water quality standards, the types of pollutant sources known to be present and the presence of certain naturally-occurring substances in the water.[31] In some instances, "surrogates" may be used as monitoring targets in place of specific problems caused by NPS pollution.[32] For example, chlorophyll *a* (a green pigment in plants used in the conversion of sunlight into energy) and phosphorus can be measured as surrogates for eutrophication.

Information concerning existing and projected land uses and the impact of various land use practices (including implementation of BMPs) is needed so that changes in water quality based on changes in land use can be estimated. Data also must be collected and evaluated for ongoing program implementation in order to determine compliance and enforcement priorities. This information includes population and agricultural census data;

VOL 12

7126

USGS, state and local land use and land cover information; state and local natural resource inventories; and state economic development information.[33]

The second step is to devise an overall monitoring plan. The plan must include both short-term and long-term data collection, since "snapshots" of water quality at any given time are not sufficient to draw reliable conclusions about pollution impacts or the effectiveness of controls. Some estimate of trends is needed to understand the impacts associated with poison runoff, including the effects of land use, climate and hydrology on water quality. Trend analysis also is needed to determine natural fluctuations in water quality over time, and the impact of management efforts on the long-term changes in water quality.[34]

Third, States need to expand their testing programs to look beyond the water column. EPA has found that information about sediment quality and biological and habitat conditions have not been collected in the past, but are needed to assess the problem of poison runoff and the effectiveness of controls.[35] The locations and sampling frequencies of the general fixed station network "have not been designed to support rigorous statistically-based conclusions about water quality over wide areas."[36]

Variability in many factors must be taken into account because it is extremely influential in determining the actual levels of poison runoff.[37] Long intervals between monitoring events coupled with the incremental manner in which BMPs and other controls usually are implemented can make it difficult to determine if changes in water quality are attributable to control programs. Perhaps more significant are the varying effects of climate and the impacts that different geographic areas have on poison runoff.[38] Changes brought about by individual storms and by changes in seasons are considered short and intermediate sources of variability, respectively. Both can be accounted for by designing monitoring programs properly.[39]

Monitoring above and below an area where BMPs have been implemented is probably more useful for establishing the severity of a nonpoint source problem than for evaluating the success of the control program.[40] This is so because changes in impacts over time can be determined reliably only if the monitoring strategy can account for variables associated with land use, hydrology and climate.[41] However, pairing watersheds (comparing water quality impacts in a control watershed with a similar watershed undergoing program implementation) may be the best quick way to measure improvements in water quality due to BMP implementation,[42] because paired watershed studies can be designed to take into account climatic and hydrologic variability.[43]

The proper location of sampling sites also is an important consideration. Determining proper site location is similar for point and nonpoint sources. For both baseline and intensive surveys, sampling stations should be located:

1. in areas with known or suspected water quality violations;
2. at major outlets from and inputs to lakes and coastal areas that have symptoms of eutrophication, to pinpoint cause and effect relationships;
3. in critical eutrophication areas within these water bodies to assist further in determining cause and effect;
4. at locations upstream and downstream from representative land uses to determine the effects of different general land uses on water quality;
5. at the mouths of significant tributaries to major streams or coastal waters to determine major pollution sources in these areas;
6. at representative sites in the above waters to determine general water quality; and
7. at sites of major uses such as water supply intakes, recreation, and fishing, to determine public health threats and to determine the general water quality in the area.[44]

Sediment and biological monitoring locations also are important. Sediment monitoring stations should be established to assess the accumulation of toxic substances.[45] Biological stations, needed to determine the impact of poison runoff on aquatic life, often will not coincide with the location of water column stations.[46] Normally, they should be located away from artificial structures.[47]

The desired number and frequency of samples depends on how the statistical and modeling data will be used as well as on the logistics of obtaining the samples.[48] It is beyond the scope of this report to describe individual designs for sampling or specific statistical techniques for analyzing the results of a sampling exercise. However, many methods have been developed to help determine the number and frequency of samples necessary to achieve specific levels of statistical certainty concerning the impacts of poison runoff.[49]

Officials also need information that allows them to analyze the cumulative impacts[50] of land uses within a watershed. While current management activities have been criticized as inadequate in addressing cumulative impacts,[51] a general outline for the consideration of cumulative impacts is available.

Collecting and evaluating the land use information needed to make judgments about potential water quality impacts requires significant involvement on the part of local land use planners.[52] For instance, information concerning individual developments is necessary, as are estimates of development patterns within entire hydrologic units.[53] Important environmental factors, such as hydrology, slope, soils and land use data also need to be assessed.[54] Water quality and habitat parameters should be evaluated to determine present trends, and estimates must be made of critical pollutant loadings.[55] From this background information, the impacts of various development scenarios on water quality can be determined by estimating the pollutant loads associated with alternative growth and control options.[56] By using this process, land use plans and controls and economic development policies can be chosen more intelligently according to their consistency with long-term state water quality objectives.[57]

Examples of Effective Data Management Programs

A wide range of strategies for collecting and using data have been developed around the country. These federal, state and local activities have helped to broaden the range of available controls. While some have only been suggested, others are being used today in state and local programs. Examples of these innovative approaches are given below.

Relatively simple strategies for targeting critical land areas for control efforts have been developed.[58] One method, which involves 9 steps, targets areas within watersheds from 2,000 to 30,000 acres in range, and allows planners to calculate the maximum water quality improvements that would be derived from a given level of BMP implementation.[59] Briefly, these steps are as follows:

1. quantitatively describe the nature and extent of water quality problems;

2. describe the hydrology of the waterbody of concern;

3. estimate pollutant reductions needed to protect, improve or restore the impaired waterbody using such measures as loadings, concentrations, frequency of standards violations, etc.;

4. estimate relative point and nonpoint-source impacts on water quality;

5. determine the largest nonpoint source contributors of pollutants based on information about development, land use practices, agricultural production practices, and other activities in the area;

6. determine the proximity of the nonpoint source to the water segment;

VOL 12

7/30

7. determine upstream pollutant contributions to the water segment;

8. determine where current controls already are in place; and

9. perform on-site evaluations of potential sources to determine peculiarities in drainage or hydrologic characteristics.[40]

This process can be carried out (or modified) with varying degrees of sophistication. Publications are available that provide data on what particular factors to consider and what conclusions to draw from particular monitoring and modelling results.[41]

Wisconsin's nonpoint source program[42] is required by regulation to develop load reduction goals and to evaluate alternative management scenarios. It uses *modelling* as a central feature of its watershed planning process. A critical part of the Wisconsin Nonpoint Source Pollution Abatement Program is the Watershed Assessment that requires:

1. an identification of the water quality problems or threats to water quality caused by nonpoint sources of pollution in the watershed;

2. an identification of water quality objectives for the watershed;

3. an identification of target levels of pollutant control necessary to meet water quality objectives;

4. an identification and ranking of significant nonpoint source types and contributing areas; and

5. an identification of priority management areas.[43]

To assist in this assessment process, the Wisconsin Department of Natural Resources developed the Wisconsin Nonpoint (WIN) model.[44] The WIN model uses up to five computer files to determine sediment delivery; field inventory

VOL 12

information (the largest and most difficult file to collect); stream inventory information; rainfall information; and crop rotation information.[65] This flexible model allows users to employ various land use, soil and hydrologic information to estimate existing and potential sediment delivery to specific streams within discrete portions of the watershed.[66]

The WIN model can be used in both the planning and the implementation phase of the Wisconsin Nonpoint Source program.[67] In the watershed planning phase the use of the model involves:

1. evaluation of existing water quality conditions and objectives;

2. inventory data collection;

3. model calibration;

4. evaluation of existing sediment sources;

5. evaluation of the management alternatives and resulting delivery; and

6. selection of a management plan.[68]

During plan implementation, the WIN model can assist in the evaluation of interim and long term results and help to identify the need for any plan modifications.[69] While the use of this model is only now being integrated fully into the watershed assessments, it will become increasingly valuable in the crucial "watershed management" approach used in Wisconsin.

Officials have developed procedures for estimating water quality conditions within a particular watershed and determining the potential impacts of various management strategies on these conditions. In one Wisconsin watershed, three tools (described briefly in Chapter Nine) were used to determine water quality problems. These were: the Hilsenhoff Biotic Index (HBI), which uses the insects living in the stream to estimate the degree of organic pollution; present and potential estimates of fishery uses through an inventory of stream flow, bed type, amount of riffles and pools, streambank conditions, temperature, pH, and other water quality parameters; and an assessment of the trophic status of lakes within the watershed using estimates of in-lake phosphorus and chlorophyll *a*, and turbidity and sunlight penetration measures.[70]

After the watershed was divided into 17 subwatersheds, assessments were performed to determine the contributions of pollution made by various nonpoint sources.[71] Estimates were made to determine which land areas potentially contributed the greatest sediment loads to each waterbody and what reductions could be expected from the implementation of soil conservation practices.[72] Streambank erosion estimates also were made.[73] All dairy operations were examined for their impact on water quality through the use of a USDA model modified by the Wisconsin Department of Natural Resources (DNR).[74] Estimates also were made of the amount of unsuitable land used each year for manure spreading.[75]

From these measurements, objectives for each waterbody were defined along with the pollutant load reductions needed to achieve the specific objectives.[76] Finally, the relative importance of each source category described above was ranked along with specific properties within each category that needed to be controlled in order to achieve the water quality objectives.[77] This determination was made by developing estimates of load reductions that could be achieved by controlling alternative proportions of the load from each source category.[78]

In Florida, under the Surface Water Improvement and Management (SWIM) Act, Florida's Water Management Districts have been challenged to determine (1) what point and nonpoint pollution load reductions are needed to restore and preserve the quality of priority waters, and (2) how those reductions can be achieved most effectively.[79] For instance, the draft SWIM plan for Lake Okeechobee prepared by the South Florida Water Management District uses results from modelling and monitoring to establish overall phosphorus load reduction goals and particular objectives for evaluating the success of various programs in individual subwatersheds.[80]

As mentioned above, eutrophication due to nutrient enrichment is often a difficult parameter to monitor directly. To address this problem, a method has been proposed to use the level of chlorophyll *a* present in water, which is a measure of algae production, as a surrogate water quality standard for eutrophication. This measure could be used to guide decisionmaking for watershed management programs and to estimate what controls are needed to achieve given levels of water quality.[81]

This standard measures directly the quantity of algae in a waterbody, while other parameters, such as clarity, nitrogen and phosphorus, are indirect measures.[82] Proactive controls should be based on a measure of the *mean*, rather than the *maximum* chlorophyll *a* levels in a system, because maximum levels of algal growth vary according to a number of other factors.[83]

In Olmsted County, Minnesota, county planners have developed an erosion control ordinance based on an extensive information gathering process and computer-assisted data management procedures at both the local and state levels.[84] This process is used as a basis for requiring early compliance with the ordinance for particularly erosion-prone areas, as well as for inspections to verify compliance.

Using data "cells" of one-tenth of an acre, Olmsted County generated land use information that distinguished 119 soil "mapping units" or soil types as well as a unit for water and other non-soil features.[85] Forty-six land use/cover classes were developed based on land use, erosion and runoff characteristics.[86] Twelve kinds of cropland were identified ranging from straight row continuous corn planting to permanent hayland, and including all mixes of crop rotation, contouring, terracing, and residue management.[87]

Using a micro-computer-based data analysis system developed by the state, a system of enforcement priorities was established by modelling wind erosion, sheet and rill erosion, and the runoff characteristics within the county.[88] Sheet and rill erosion, in turn, were modelled by adapting the soils and land use data to the Universal Soil Loss Equation.[89] Runoff levels were determined by adapting the 119 soil "units" to form hydrologic soil groups and combining those data with the land use/cover information.[90]

VOL 12

7134

Topographic and stream location information is used to determine runoff volumes and peak flows.[91]

Olmsted County also uses a Geologic Atlas, the development of which was funded equally by Olmsted County and the Minnesota Geologic Survey.[92] The atlas was developed to provide "accurate and retrievable information on: wells, springs, aquifers, sinkholes, glacial deposits and soil characteristics not mapped by the Soil Conservation Service."[93] Through the development of computer data bases and interpretive maps, assistance can be provided to local officials in the implementation of various pollution control and public health ordinances.[94] Additional data collection activities being considered include county-wide (or multi-county) private well testing programs to assist citizens and to monitor groundwater quality changes, and environmental studies of soils and groundwater at auto and metal scrapyards and old dumps to monitor for toxics contamination.[95]

The Washington D.C. Metropolitan Council of Governments has developed a manual for planning and designing urban BMPs, including information on data collection and utilization.[96] Details are provided for the cost-effectiveness, effectiveness in stormwater control and pollutant removal, maintenance requirements and other attributes of many of the most popular BMPs.[97] Methods are provided to screen BMPs for application to specific sites, and to calculate stormwater flows.[98] The manual provides information on pollutant export from urban development, based on data from the Washington, D.C. area National Urban Runoff Program (NURP) study, as well as national NURP data.[99] The methods can be used to determine the need for more precise modelling.[100] They also can be used to estimate the probability that pollutant concentrations (as opposed to total pollutant load) will exceed a given level. Several examples are given.[101]

The National Water Quality Evaluation Project of the North Carolina State University Agricultural Extension Service is currently reviewing literature to identify recent advances in methodologies to calculate nonpoint source loadings and associated water quality impacts.[102] Methods for calculating toxic and concentrated loadings to surface and groundwater in both the dissolved and sediment-bound phase are being examined.[103]

Conclusions and Recommendations

Poison runoff monitoring and modelling activities have limitations, especially when it comes to setting discharge standards for individual sources. But these limitations should not prevent the use of regulatory measures and other pollution controls. Where there is a willingness to develop new approaches to control poison runoff, data collection has been used to enhance management efforts rather than as an excuse for inaction.

Recommendations for data collection activities are as follows:

1. Regulatory programs can and should be developed using currently available data collection methods.

2. Monitoring and modeling protocols should be developed that take into account the proper statistical assumptions, the need for consistent measurements and analytical techniques, hydrologic variability and seasonal influences. To accomplish this, monitoring programs require:
   a. an adequate number of properly-located sampling sites; and
   b. an adequate frequency of sampling per site.

3. Generally, in developing a monitoring design, paired watershed studies should be used to measure changes in water quality due to BMP implementation, while monitoring above and below a watershed should be used to gauge the severity of a problem.

4. Monitoring and modelling should be designed to develop water quality goals (as well as to measure progress towards meeting these goals) within watersheds of a manageable size.

5. Cumulative impacts should be taken into account when assessing water quality impacts and estimating improvements that controls will achieve.

VOL 12

7136

6. Monitoring programs need to assess both chemical water quality parameters and the overall biological health of the aquatic system.
   a. In addition to ambient water quality assessments, evaluations of the biological health of aquatic systems should consider such factors as population size, diversity and distribution.
   b. Water quality parameters should be chosen on the basis of water quality standards, previous monitoring results, and types of pollutant sources. "Surrogate" parameters, such as chlorophyll *a*, can be used to measure water quality conditions such as eutrophication.

7. Water quality data can be used directly to design, modify, and measure the effectiveness of control programs as follows:
   a. *measure* water quality and compare findings to water quality standards;
   b. *calculate* total load reductions for each pollutant that are necessary to meet water quality standards, with an adequate margin of safety and taking into account seasonal and hydrologic variations;[104]
   c. *estimate* total loads from each category or group of diffuse sources;
   d. *estimate* load reductions that can be achieved using various levels of control;
   e. *choose* and *implement* the appropriate controls needed to comply with water quality standards;
   f. *measure* water quality periodically as controls are imposed, in order to verify the initial analysis; and
   g. *modify* controls if necessary.

8. To evaluate and predict existing and future impacts from poison runoff, states should collect and analyze data on land use, economic and census trends, hydrology, topography, geology, and other factors.

Modeling efforts to identify potential program target areas and to estimate possible program impacts also have become important in poison runoff management programs. At least 40 models exist to simulate the transport of nonpoint source pollutants in runoff and groundwater, to compare the value of different management scenarios and to simulate the impacts of these pollutants once they reach lakes, rivers and coastal waters. *See* U.S. EPA, *Guide to Nonpoint Source Pollution Control*, July, 1987, at 10-11. While the accuracy of many such models has been criticized, the use of models, in combination with data gained from monitoring, has led to the development of innovative programs in such areas as Wisconsin, Washington State's Puget Sound, the Chesapeake Bay and New England. For a discussion of nonpoint source modeling, *see generally* Giorgini, Aldo and Franco Zingales (eds.) Agricultural Nonpoint Source Pollution: Model Selection and Application, Elsevier, New York, 1986; *see also* Leonard, Ralph A. and Walter G. Knisel, Jr., *Selection and Application of Models for Nonpoint Source Pollution and Resource Conservation*, U.S. Department of Agriculture-Agricultural Research Service, Southeast Watershed Research Laboratory (no date).

22. Examples of effective applications of modelling include the use of the Wisconsin Nonpoint (WIN) model to (among other things) "evaluate the reduction of sediment from critical areas under various land management practices;" and the use of models by the South Florida Water Management District to estimate needed phosphorus load reductions and phosphorus/sediment interactions in Lake Okeechobee. *See generally* Baun, Ken, *The Wisconsin Nonpoint (WIN) Model (Version 1.0)—User's Manual*, Wisconsin Department of Natural Resources, August, 1987 (hereinafter cited as *WIN User's Manual*); *see* South Florida Water Management District, *Interim Surface Water Improvement and Management Plan for Lake Okeechobee* (draft), October 10, 1988. The use of these models is discussed further in this chapter.

83. *Id.* at 203-204. While precisely determining the true maximum chlorophyll *a* level for a given waterbody often is not feasible, statistical techniques have been developed that indicate the likelihood that a maximum chlorophyll *a* level will be exceeded at a given frequency, based on average (mean) levels determined through a specified number of samples or observations. Also, mean levels can be determined more precisely than maximum levels. Using this process, a water quality standard (in this case, an average, or mean, standard) can be set such that a desired maximum will not be violated within an acceptable degree of certainty. Statistically inferring violations based on average values is more feasible and accurate than attempting to measure maximum levels or the frequency of violations directly. The data gathered to *establish the*

VOL 12

Funding for poison runoff control programs can be provided through a variety of taxes—such as a fee charged for the purchase of inorganic fertilizer.

VOL 12

Chapter Seven

Funding: A Crucial Program Component to Which Everyone Must Contribute

7/146

Introduction

Poison runoff constitutes the largest type of water quality impairment for waters not supporting designated uses.[1] Yet many states spend less per year on programs to control poison runoff than would be needed to build, or even substantially modify, a single sewage or drinking water treatment plant. States often fund programs primarily through general appropriations. They have been slow to develop alternative funding sources, such as special taxes, or otherwise to shift some of the funding burden to localities or to classes of landowners who are *responsible* for the water quality problems.[2]

The price tag for controlling poison runoff is high, but so is the cost of inaction.[3] The annual costs of the instream damages of soil erosion only (excluding many biological impacts) have been estimated at $4.1 billion annually.[4] Adequate funding obviously is critical to the development of an effective and efficient control effort. High levels of funding are especially crucial for programs that depend on cost sharing to implement all or most of the BMPs that are needed to restore beneficial water uses.

As an example, the costs of installing all of the BMPs needed to restore and protect the waters in two Wisconsin watersheds of 214 and 128 square miles have been estimated by the state to be $7,574,679 and $4,181,000, respectively.[5] Not surprisingly, in areas where aggressive controls are being developed, officials have established a wide variety of sources to generate the necessary funds.

There are two categories of funding issues. The first could be labeled "cost-effectiveness": getting the most control benefits for the dollars spent. Cost effective programs to control poison runoff are the subject of other chapters in Parts 2 and 3 of this report. The second category of funding issues, which is discussed in this chapter, is *how* programs can and should be funded. In other words, who should pay for control programs, and how?

States Cannot Rely on Federal Funding[6]

When Congress added section 319 to the Clean Water Act in 1987, it *authorized* $400 million over four fiscal years to fund state nonpoint source management programs.[7] However, Congress has yet actually to *appropriate* any funds for this program. This omission is ironic given federal expenditures of tens of billions of dollars to reduce water pollution from municipal sewage treatment plants.[8]

States and environmental groups should (and undoubtedly will) continue to press Congress to appropriate the funds authorized in the 1987 amendments. But given the federal budget deficit, states at least should plan for the possibility that the federal coffers may remain closed. Moreover, as explained above, the authorized level of federal funding would fall far short of the overall program needs of 50 states, not to mention local jurisdictions.

Therefore, states need to find other ways to fund programs to manage poison runoff. Some innovative examples of how this can be done, and how funding mechanisms can be used as a

VOL 12

7147

stimulus to induce better behavior by those generating the pollution, are given below.

Management Improves When the "Polluter Pays"

Cost sharing and other programs that are financed through general revenues result in taxpayers bearing the costs of pollution control.[9] It is questionable whether the public will or should accept these costs, especially as the cost of controls increases.[10] Moreover, using general revenues to "buy" pollution abatement fails to promote cost-effectiveness.

Many (often most) polluters will not participate in cost sharing programs unless the rate of payments leaves them better off than if they had done nothing at all—a rate of payment that may be unacceptably high to taxpayers.[11] In fact, from an efficiency standpoint, cost sharing generally is not favored by economists because it can lead to unnecessarily high pollution control costs.[12] This is partly because, if taxpayers as a whole are the ones who pay to solve pollution problems caused by individual sources, those sources will have little or no incentive to prevent or control problems on their own.

The "polluter pays" principle, the idea that polluters should be primarily responsible for the direct costs of pollution abatement, is supported by many researchers and many state and local programs.[13] Individual polluters (whether private or public) are given an economic incentive to remove themselves from the category of "polluter". In this sense, funding is both a *tool* for reducing poison runoff and a *resource* to support other controls.

For instance, variable taxes[14] or other fees that increase according to the potential for a particular activity to generate water pollution, are considered to be one of the two *most* effective means of controlling levels of poison runoff, *if* they are set at sufficiently high levels.[15] An example is a fertilizer sale or application fee set at a level sufficiently high to deter excess usage. The application of fertilizer at levels greater than that needed for crop productivity can be taxed based on allowable limits set by soil tests, cropping patterns and safety margins.[16]

Where these costs could cause significant economic impacts on the polluting class, however, it may be appropriate for the beneficiaries of the control programs (*i.e.*, the public) to contribute to program funding requirements.

Estimating the approximate costs associated with controlling poison runoff are important steps in designing a management program. Formulas and models have been developed to estimate the costs to the farmer, developer, locality, and other parties of installing individual BMPs.[17]

Examples of Innovative Funding

Methods of financing the public costs of nonpoint source pollution control include taxes on fertilizers and chemicals, taxes on land development or land transfer for purposes of development, stormwater utility fees, general tax revenues and a host of fees, assessments charges and penalties.[18] The remainder of this chapter provides examples of some of the many methods available for generating sufficient funds to develop and implement aggressive runoff controls, while deterring behavior that results in water pollution.

In Wisconsin, over $36 million in state revenue was appropriated for controlling poison runoff between 1979 and 1987, with less than 20% of these funds going to administrative costs.[19] Currently, funding has stabilized so that each year approximately $6.7 million is appropriated for carrying out the state's Nonpoint Source Pollution Abatement Program.[20] This program is funded through the state's general revenues.

In addition, the Wisconsin Groundwater Management Act (GMA) establishes a process for the development of state programs to control both nonpoint and point sources of groundwater contamination.[21] The GMA also requires that a set of fees (which amount to over $1.5 million per year) be collected to assist in the development and implementation of state groundwater protection programs. Among these fees, summarized in Table 7-1, are charges applicable to pesticide manufacturers and distributors as well as to purchasers of fertilizer:

Table 7-1
Summary of Annual Fees Imposed Under the Wisconsin Groundwater Management Act*

A. Department of Agriculture, Trade and Consumer Protection

1. Pesticides

Basic fee: $100 license fee

Groundwater fee: $2,000 for each manufacturer of the active ingredients of a pesticide [40 manufacturers]
$300 for distributors [660 distributors]
$100 for distributors of only one pesticide [100 distributors]

Total groundwater fees collected: $288,000

[Fee collected before the end of the year for an annual license issued for the following calendar year. Fee first collected in late 1984 for the 1985 licenses.]

2. Fertilizer

Basic fee: $0.10 per ton for inspections;
$0.10 per ton for research

Groundwater fee: $0.10 per ton [1,300,000 tons]

Total groundwater fees collected: $130,000

B. Department of Natural Resources

1. Septage Haulers

Basic fee: $25 license fee for residents;
$50 for nonresidents

Groundwater fee: $50 per license [705 licenses]

Total groundwater fees collected: $35,300

2. Wastewater and Sludge Land Disposal

Basic fee: None

Groundwater fee: $100 per permittee [1,010 permittees]

Total groundwater fees collected: $101,000

[Fee proposed by DNR to be collected before the end of the year for the subsequent calendar year. Fee proposed to be first collected for calendar year 1985.]

The total fees collected are estimates based on recent information about each relevant activity. *Id.* at 21.

VOL 12

7150

R0040458

3. **Solid and Hazardous Waste Disposal**

Basic fee:	Generally, \$0.035 per ton for solid waste; \$0.35 per ton for hazardous waste; \$0.001 for mine waste rock within this range. Other fees apply to different wastes.
Groundwater fee:	\$0.10 per ton [6,300,000 tons] \$0.01 per ton for prospecting or mining waste [no current disposal]
Total groundwater fees collected:	\$630,000

[Fee collected in April for the total amount of waste disposed during the previous calendar year. Fee first collected for waste disposed on or after January 1, 1984.]

C. **Department of Industry, Labor and Human Relations**

1. **Private Sewage Systems**

Basic fee:	Basic sanitary permit fee is \$41; counties may charge more
Groundwater fee:	\$25 per permit [14,000 permits]
Total groundwater fees collected:	\$350,000

[Fee collected whenever a county issues a sanitary permit. Fee first collected for permits issued on July 1, 1984.]

2. **Petroleum Product Storage Tanks**

Basic fee:	\$32 or \$43 for plan examination, depending on size of tank; \$43 for site inspection
Groundwater fee:	\$100 per inspection [425 inspections]
Total groundwater fees collected:	\$42,500

[Fee collected when an application for plan approval is submitted to the DILHR. Fee first collected for plan approvals submitted on May 11, 1984.]

Total Amount Collected Annually for the Groundwater Fund: **\$1,576,800**

Groundwater legislation enacted in Iowa,[22] largely to address the water quality impacts of such pollutants as nitrates and pesticides, also reflects the "polluter pays" principle. Over \$42 million will be raised over a five year period through fees on a variety of products that can pollute groundwater.[23] Manufacturers of pesticides and fertilizers will pay annual fees ranging from \$250 to \$3000 depending on sales. Farmers must pay taxes amounting to \$0.75 per ton for nitrogen fertilizer. Thus, there is a direct link between the fee and the amount sold or the amount used.

The Florida point/nonpoint source waterbody restoration program (called SWIM for Surface Water Improvement and

VOL 12

7151

Management and described elsewhere in this report) currently is funded by general revenues. However, legislative attempts are being made to provide a dedicated funding source by earmarking 5% of the revenue of the "documentary stamp tax" for the SWIM program.[24] The stamp tax is a 1 mill (.1 cent for each dollar of appraised value) fee that must be paid to the state every time titles to real estate are transferred.[25] If this proposal is adopted, more than $25 million a year would be provided for the state SWIM program.[26] In light of the impact that urban development is having on the state's water quality, such a tax seems logical and reasonable.

There are other examples of property taxes used to finance control programs. Florida's nine Water Management Districts each has statutory authority to levy ad valorem property taxes to be added on to county property tax assessments.[27] These modest taxes (below 1 mill) provide the entire operating budget for the Water Management Districts.[28] For instance, a tax of under 0.4 mill provided the St. Johns River Water Management District with $28 million in operating funds in 1987.[29]

Property taxes have the potential to be an important source of revenue for carrying out programs. The Natural Resources Districts (NRDs) in Nebraska (large multi-purpose regional environmental management agencies)[30] also obtain their funding from property taxes.

Property tax revenue for water pollution controls can and should be used to fund Soil and Water Conservation Districts (SWCDs) since, without this authority, SWCDs are limited in the projects that they can undertake.[31] SWCDs currently do not have the right to levy property taxes themselves largely because the right of taxation was not originally a part of the model enabling legislation developed at the federal level and used by states in establishing the soil conservation partnership in the 1930s.[32] But states can and should amend their current laws to enable SWCDs to impose such taxes.

To a greater extent, within SWCDs, taxes can be collected to implement programs in localized watersheds. However, in most states with legislation that still contains either of these provisions, the taxes can only be established after a referendum is passed at the local level and specific state authorization is provided.[33] Therefore, an important (and legitimate) source of revenue is being neglected almost completely.

Local governments currently provide approximately 50%[34] of the operating funds of SWCDs (which are units of state government), making it difficult to incorporate federal and state goals into SWCD programs or for SWCDs to plan projects based on steady, predictable income.[35] SWCD dependence on localities for funding also detracts from the separate program activities that local governments need to undertake.

The National Association of Conservation Districts (NACD) urges local SWCDs to use their taxation power when it is available, and to seek this authority when it is not available.[36] The SWCD is a unit of state government that can work toward state and regional goals. The SWCD needs the right to tax without the approval of local landowners, since they often are the sources as well as the victims of pollution impacts from land use activities.

In addition to property taxes, local governments have available a host of fees that they can (and in some cases do) charge to raise revenues for pollution control. Many of the land use controls described in Chapter Four are commonly associated with permits that individual developers must obtain before land-clearing, grading or construction can take place. These include permit fees charged for submitting site plans or obtaining building, grading or erosion control permits, variances from zoning ordinances, etc. At a minimum, these permit fees should cover the costs of processing the permit, inspecting the site, and related enforcement tasks.

An important new local charge that is fast becoming popular is the impact fee, designed to compensate local residents inconvenienced by a development as well as to provide the roads, schools, and other services needed to accommodate the new growth. By some estimates, over $340 million per year[37] (probably more than was provided in agricultural costsharing by all 50 states) is currently contributed by developers in impact fees in return for a "green-light" on development projects.

"Impact" fees can be problematic if they are used merely to "offset" or compensate for environmental impacts. This approach runs the risk of putting a price on permission to pollute the water—an approach that is not consistent with federal or state water quality goals and objectives. State and local water quality officials must incorporate specific water quality goals into a larger and more comprehensive state-wide management program to ensure that "impact" fees are used to secure real water quality benefits. These fees should not be charged as "fees to pollute," but instead should be used to provide for controls in situations where development is a desirable local addition *as long as water quality impacts can be avoided.*

If done properly, assessing fees that could be used to prevent or even decrease the impacts of poison runoff from otherwise desirable developments or activities is a powerful tool for designing state and local controls. In situations where the impacts of a development or activity cannot be avoided completely, fees can act as an incentive to the would-be polluter to mitigate the impacts as much as possible.

Stormwater, sewer and septic system maintenance utilities can be used to provide funds for control programs. For instance, Bellevue, Washington established a utility specifically for the management of surface runoff and stormwater.[38] The utility currently charges rates based on the amount of impervious surface, and hence runoff, generated from a site.[39]

Finally, in the past many localities actually have *encouraged* additional water pollution by providing property tax breaks and other incentives to invite new industrial, commercial, or other development.[40] These types of incentives should be reduced or eliminated in cases where increased water pollution will result. Where development occurs, the increased tax revenues can be used to fund programs to control poison runoff.

Conclusions and Recommendations

Given the low level of funding currently provided by the federal government, state and local officials must examine alternatives to traditional general revenue sources in order to fund programs to control poison runoff. These alternatives should serve the dual purpose of deterring behavior that causes pollution and providing the resources to carry out controls.

The following recommendations summarize the main points of this chapter:

VOL 12

7154

1. Funding for controls should not depend primarily on general revenues, and cannot rely on federal funds.

2. Where possible, the groups responsible for water quality problems should contribute to program funding.

3. Where possible, funding should be used as a tool to dissuade groups from undertaking activities that generate pollution. Examples of such negative incentives include:
   a. taxes on pesticide or fertilizer use, and other farm practices that could result in water quality degradation;
   b. stormwater utility fees based on percentage of impervious cover;
   c. taxes on land transfers for purposes of development; and
   d. timber or mineral assessments based on the amount of land disturbed.

4. Property taxes (charged by regional water or environmental management agencies or local governments) are an important source of funds for controlling poison runoff.

5. SWCDs should be given authority to raise revenue for water quality protection within the entire district through levying property taxes.

6. Fees and charges associated with local land use controls, such as impact fees and surface and storm water management utilities are important funding sources and should be high enough to be a significant source of local revenue for achieving state water quality goals.

7. Permit fees should, at a minimum, offset the costs associated with processing and enforcing the permits.

Chapter Eight

Poison Runoff Control and State and Local Legal Considerations

Introduction

A variety of legal tools are needed to control poison runoff. In addition to Federal laws,[1] states need to make the best possible use of their own legal authority to control this pervasive problem. This chapter focuses on the state-level legal authority needed to control poison runoff effectively. The development and implementation of the programs resulting from these laws is discussed in the following Part.

Various controls can use or require several types of legal authority. First, State Environmental Policy Acts (SEPAs) can be used to review the water quality impacts of actions proposed by private, local, state and federal entities and to require that any identified impacts (including long-term "cumulative" impacts) be avoided or otherwise mitigated. Also, poison runoff from existing and proposed land use practices can be reduced by laws that require the imposition of *source controls* (or BMPs) to address specific pollution-generating activities and situations, such as construction and urban development. In addition, an array of land use laws can be passed to regulate the location, type, and density of activities so as to prevent or reduce poison runoff. Finally, the exercise of common law also influences how well poison runoff is controlled.

State officials should ensure that all necessary types of legal authority are available to employ the range of controls that are needed.[2] State programs that use only source controls, as exemplified in many respects by the traditional soil conservation model, will miss many important cost-effective control opportunities. Moreover, programs based only on traditional source control approaches (such as voluntary BMP programs) may have no teeth when they come into conflict with other state and local laws designed to *encourage* urban development, agriculture, mining activities or timber cutting.[3] Recent efforts by states and localities, and a good deal of academic opinion, attest to the environmental and economic value of relying on broader, more comprehensive legal authorities to control land use and government decisionmaking when developing and implementing state management plans to control diffuse sources of water pollution.[4]

The legal framework for effective management often can be implemented *using existing–but re-oriented*–legal authority. Zoning or development planning authorities, for example, can be re-oriented to consider and mitigate poison runoff as part of the planning and zoning equation. And the benefits from this reorientation may go far beyond water quality. Land use planning to prevent poison runoff frequently enhances aesthetics and improves recreational opportunities.[5] With thoughtful planning, controls can achieve more pollution control for less money or provide benefits external to water quality protection, such as improved economic development or open space recreation.

This chapter discusses how to make better use of the legal tools relevant to nonpoint source pollution control. First, ways to overcome obstacles to an effective legal framework are discussed. The chapter then describes briefly the application of SEPAs, source control statutes, land use and common law to programs designed to control poison runoff. Emphasis is placed

VOL 12 7/6/1

R0040469

on the opportunities to expand and integrate land use controls into existing state and local activities. For the most part, these uses of legal authority are extensions, reorientations or alternatives to current interpretations of existing laws. They do not represent major shifts in existing state source control or land use control laws. The chapter concludes with a description of the key attributes of an effective legal framework for controlling poison runoff.

Overcoming Legal Obstacles

As discussed in Chapter Two, the Clean Water Act and state water quality protection laws provide ample legal authority to develop, implement and enforce whatever state and local controls are needed to control poison runoff. At times, however, states inadvertently may have created legal barriers that inhibit the development and implementation of successful controls. Some of these problems can have substantial impacts. Fortunately, these barriers usually can be removed by amending existing laws.

1. *Adequate Delegated Authority*

First, state law must ensure that local governments have adequate authority to control poison runoff. For example, localities in many states, particularly those whose local powers are conferred according to Dillon's Rule, have been reluctant to use land use controls for environmental protection purposes because of a feared lack of legal authority.[6] Under Dillon's rule, local governments have "only those powers that are expressly granted, those that are necessarily or fairly implied from expressly granted powers, and those that are essential and indispensable."[7]

However, localities may well be underestimating their powers. The Standard Soil Conservation Act, adopted by many states to establish the authority of soil and water conservation districts (SWCDs), contains provisions authorizing the development of land use regulations to conserve soil and water resources.[8] To the extent that local governments can work with SWCDs to develop and implement such land use controls, a method is available to use local land use controls as a management tool.

VOL 12

7162

R0040470

While this authority has been retained in over half of the states, it seldom is used.[9] Therefore, in Dillon's Rule states, it is important that state law explicitly recognize the authority of local governments to utilize their land use powers to protect state waters and to comply with water quality standards.

2. *Preemption*

Second, state laws (such as erosion and sediment controls at construction sites or water quality standards) should not preempt the adoption of more stringent controls by localities. By ensuring that state law sets only *minimum* standards, states can allow localities to be more stringent as necessary to protect sensitive or valuable local features.

3. *Federal-State-Local Relationships*

Whether federal and state levels of government should become involved directly in managing dispersed pollution sources is another important issue. Because of the localized nature of the problem, a federal role that concentrates on overseeing and influencing state programs rather than on regulating individual polluters probably is the most effective.[10] For similar reasons, state laws should assign significant responsibility to localities and should concentrate on oversight and enforcement of local efforts (*e.g.*, developing minimum program requirements or load reductions, monitoring for compliance, assuring consistency in a watershed that crosses jurisdictional boundaries) rather than on the individual landowner.[11] In addition, funding and technical assistance should be provided to localities by the state to enable localities to develop such specialized controls.

Types of Legal Authority Applicable to Poison Runoff

State Environmental Policy Acts (SEPAs)

State environmental policy acts (SEPAs), which require state or regional reviews of activities with potentially adverse environmental consequences and the preparation of Environmental Impact Statements, present important opportunities for poison runoff control. They enable officials to ensure that developers consider alternative proposals and utilize innovative techniques—or limit projects—to mitigate water quality (as well as other environmental) impacts.[12] Of course, for these purposes, it is important that SEPAs and other similar laws extend to municipal as well as state actions so that private land use and development come under their coverage.[13] Some states, including Massachusetts and California, already require local agencies to prepare environmental impact statements in certain circumstances for government or private actions with greater than local significance.[14]

To perform this "watchdog" role, SEPAs should cover activities subject to governmental regulatory and licensing activities (as under the National Environmental Policy Act).[15] Obviously, activities that may either cause or promote water pollution should fall within the scope of such laws.

Generally, SEPAs worded in a fashion similar to NEPA have "low threshold" standards, making Environmental Impact Statements (EIS) necessary for public projects, such as state construction activities, as well as for state approval of potentially significant private actions, embodied in such public actions as annexation, changing a zoning ordinance, or approving subdivisions.[16] When both federal and state laws require the preparation of an EIS, the two processes should be coordinated.[17]

Specific criteria for reviewing EIS might include the application of such principles as best control technology, best management practices and maximum mitigation that must be used before a proposed activity can be approved by reviewing agencies or courts.[18] In addition to the pollution reduction achieved through the SEPA process, SEPAs are very important in raising the awareness and the understanding of local officials, developers and the public regarding the sources, and potential controls, of poison runoff.

Some localities in Long Island, New York use the requirements of the State Environmental Policy Act to obtain information about proposed development projects,[19] such as: a description of the project, topography and geology, water pollution and coastal impacts, and abatement measures.[20] This information is used to assess the potential environmental impacts (including water pollution) of a proposed development and as a basis for requiring modifications to (or prohibiting) the project.

"Source Control" Laws: Benefits from Mandatory BMP Implementation

Source controls reduce poison runoff through physical or engineering solutions, once a particular activity or land use has already begun. Although not sufficient by themselves, effective source controls are a necessary part of a successful effort to control poison runoff. Prime examples of source control laws include those to control erosion and sedimentation from construction activities and stormwater discharges from both existing and new urban development.

Erosion and Sediment Control Laws.[21] Erosion and Sediment Control Laws (ESCLs) applicable to construction sites are perhaps the most widely accepted and common method of controlling soil erosion through regulatory means. At least 24 states have enacted ESCLs over the past 15 years[22], primarily to control the off-site water quality impacts caused by construction activities.[23] These laws vary significantly in content. Enabling legislation can empower states with varying degrees of authority to develop guidelines, review and enforce individual permits and plans, and impose civil penalties.[24] (To be more effective for controlling sediment deposition, these enabling clauses should be revised to make clear that water quality protection is a specific goal of the ESCL.) In addition, most ESCLs allow at least some program authority to be granted to localities while also providing for state oversight of this local authority.[25]

ESCLs can be designed to apply to activities other than construction, including agriculture and mining.[26] For example, Pennsylvania's ESCL combines programs for erosion control in urban settings with agricultural erosion and runoff controls.[27] ESCLs also can be the basis for controlling post-construction erosion, sedimentation, and stormwater.[28]

It is important that the effectiveness of ESCLs for pollution control at construction sites not be diminished by excessive exemptions.[29] Another facet to consider is the relationship between ESCLs and stormwater management laws (discussed

VOL 12 7/65

R0040473

briefly below). Techniques (such as flow channelization) that control construction site runoff, but that lead to increases in stormwater flow or contamination should be prohibited by ESCLs.

Stormwater Management Laws.[30] State laws mandating stormwater management rapidly are coming into acceptance in more and more states, notably Maryland, Florida and Washington. Like ESCLs, of course, their effectiveness varies with the authority established in the enabling legislation. States need specific legal authority to control the unique characteristics of urban stormflows (other than the purely construction-related erosion and sediment traditionally covered by ESCLs) because a large variety of sources contribute to urban stormwater pollution.[31]

The CWA requires at a minimum that channelized stormwater discharges from municipal separate storm sewer systems that serve populations of over 100,000 be regulated as point sources.[32] Moreover, stormwater permits are required immediately for any stormwater discharge that "contributes to a violation of a water quality standard or is a significant contributor of pollutants to waters of the United States."[33] But in addition to meeting these minimum federal requirements, state stormwater management laws need to address problems not covered by these point source discharge controls. The Federal permit program will not cover any direct storm runoff (*i.e.*, un-channelized flow) or direct baseflow inputs into waterbodies. In addition, because of the intimate relationship between land use management and stormwater management, stormwater management laws should recognize the importance of local land use controls in managing urban runoff and protecting water quality.[34]

Because pollution impacts from urban stormwater are so closely associated with the process of runoff, stormwater management laws need to take a comprehensive approach to controlling all major forms of damage caused by runoff from both existing and new urban development. These include flooding, erosion/siltation, and other types of water quality degradation (including contamination by toxics, hydrocarbons or nutrients).

VOL 12

7166

Like ESCLs, state stormwater management laws should mandate state oversight and enforcement to ensure local compliance. State laws also should provide the necessary technical and human resources to implement stormwater controls.

Land Use Law

> Civil title to a portion of the earth does not confer absolute ownership....Private property is good because of the benefits it confers on the many, not because of the advantages it gives to the few.[35]

Many state programs to control poison runoff still are dominated by reliance on the limited imposition of BMPs after the fact—once land use patterns already have been determined largely without considering environmental impacts. This "ex-post" BMP application has limited value because "[p]ollution is an inherent by-product of land-development."[36] Thus, once certain land uses are established, the use of BMPs for controlling poison runoff will have limited success.[37] A second drawback of "ex post" BMP installation is that it fails to account for the cumulative impacts of individual land uses that by themselves are relatively harmless but collectively wreak havoc with natural systems and water quality.[38]

It has been stated that "[t]here are no substantial legal limits to state and federal regulation of poor land use practices that result in soil erosion."[39] But it is *local* political jurisdictions that historically have been granted most important land use planning powers (including those designed to reduce soil erosion) by state authorities.[40]

Local land use laws traditionally have not been utilized as tools for environmental management. Ironically, in many cases local zoning and other land use planning have *contributed* to water quality problems and overshadowed improvements in water quality that otherwise might have been gained as a result of federal point source control programs.[41]

Finally, however, the tide is shifting. Efforts now are underway to use land use law to control poison runoff. Some states and regions, such as Florida, Minnesota and Washington State's Puget Sound, are beginning to require that water quality

VOL 12

7/67

concerns (including poison runoff) be addressed comprehensively in local land-use planning.[42] Clearly, water quality concerns can be incorporated into local land use decisions if the requisite political support can be amassed.

These local efforts will complement statewide water quality management planning activities routinely undertaken by state governments. These activities focus on achieving specific, statewide water quality goals.

It makes sense that local land use planning (as well as federal land use planning and management activities)[43] should be treated as tools to achieve federal and state water quality goals, because water quality protection is both a federal mandate *and* an important local economic and public welfare goal. Zoning, subdivision development, the Local Comprehensive Plan, critical areas protection planning to protect groundwater recharge zones or other environmentally sensitive areas,[44] coastal zone or wetlands protection, and farmland conversion laws, are among the local land use laws relevant to controlling poison runoff which need to be integrated with the water quality management requirements of the CWA.

Officials have begun to employ expanded land use management authority to achieve more effective programs.[45] For example, Florida has developed a set of minimum requirements that local land use planners must follow in order to protect water quality.[46] Site plan reviews and subdivision ordinances that require developers to employ measures to reduce groundwater impacts have been established in Long Island, New York.[47]

Because general land development poses a recognized threat to water quality, focusing control programs away from basic land use planning is irrational as well as inefficient.[48] Land use decisionmaking logically should be considered by state water quality officials.[49]

It is no longer considered prudent for state and local lawmakers and planners to ignore the severe pollution that occurs when the basic planning, development and land use management decisions are made simply because localities historically have been granted relative autonomy in this area.[50] Indeed, there is every reason to believe that this local autonomy has led to many of the very water quality impacts that now must be addressed by land use regulation at all levels of government.[51] Many states, such as Vermont, Florida, Hawaii and Oregon, have enacted land use legislation to identify and reduce the environmental harm from both large-scale development projects with regional impacts, and long-term, small-scale development with potentially significant cumulative impacts.[52] The following discussion summarizes the basic principles that the land use laws described above should embrace, in order to protect water quality from poison runoff resulting from land development.[53]

A state's enabling legislation should spell out principles of planning that will govern local land use decisions. As a foundation, the legislation should state the principle that development must be compatible with surrounding natural features and that water, the hydrologic cycle, and the carrying capacity[54] of an area are the "framework of land use design and the guiding principle for allocation of land use."[55]

State laws should provide for state review, modification and approval or rejection of the environmental (including water quality) components of local land use plans. State laws should mandate local Comprehensive Plans, as well as interjurisdictional coordination and dispute resolution. Water quality standards should be the ultimate criteria by which the water quality aspects of these Plans are judged. Land use laws also should grant authority to local governments to enact specialized land use controls[56] designed to reduce poison runoff.

Area-Specific Land Use Protection Laws. A number of states and regions have enacted land use laws designed to protect special areas, such as Maryland's "Critical Areas Law" and Florida's Beach and Shore Preservation Act.[57] These laws provide important controls over diffuse pollution sources. To be most effective, they should require the creation of a formal state-level program approval process that ensures statewide consistency.[58] Obviously, such laws also should expressly adopt as a goal the attainment of water quality standards.

Farmland preservation[59] and "right-to-farm" laws,[60] which provide incentives and subsidies to farmers who keep their land in agriculture,[61] should be elements of many states' overall legal framework to control poison runoff. To be most effective, state

VOL 12 7169

R0040477

farmland protection laws should incorporate state water quality goals that focus on preserving *prime* farmland, as opposed to *all* agricultural land.[62] And receipt of program benefits can be tied to implementation of BMPs and other controls.

Common Law Remedies

As indicated below, the exercise of common law alone (in this case, primarily tort actions brought by injured parties against a polluter) clearly is not adequate to limit poison runoff to desirable levels.[63] However, states can encourage individuals who are harmed by poison runoff to use common law remedies to *supplement* the state's regulatory program.

Generally, the use of common law in reducing or eliminating any type of environmental degradation suffers from a number of serious limitations. These include: 1) limited ability to address damages external to any single plaintiff (*e.g.*, damages to the public in general or to future generations); 2) a relatively low number of plaintiffs bringing and winning damage suits; 3) a focus on compensating individuals after damages have occurred rather than on preventing pollution; and 4) a lack of technical or environmental criteria for use in making judgments.[64]

Poison runoff is particularly difficult to address with the common law. Often a large number of dischargers contribute incremental amounts of a variety of pollutants, and it can be impossible to identify the precise effluent characteristics of an individual polluter. Therefore, individual plaintiffs are likely to have difficulty proving that harm has occurred due to the actions of a single defendant or group of defendants.[65]

These limitations do not mean, however, that states cannot promote the use of common law remedies to supplement and reinforce the state's statutory programs to control poison runoff, and *vice versa*.[66] In particular, state statutes can create presumptions that make private tort suits easier to win. For example, statutes can provide that noncompliance with BMPs constitutes unreasonable conduct for purposes of private nuisance cases, or that activities that result in violations of water quality standards presumptively harm downstream water uses.[67] If the use of certain pesticides in sensitive groundwater recharge zones is prohibited, a statutory clause could deem the use of those

VOL 12

7170

R0040478

pesticides unreasonable conduct for purposes of any tort proceeding brought by injured parties such as owners of contaminated wells.

Conclusions and Recommendations

Effective state laws are essential to promote and further control of poison runoff. The following list summarizes the main management needs that should be incorporated into the general legal structure of a state:

1. States should not radically restructure laws to provide the legal authority needed to address poison runoff, but instead should re-assert and re-orient existing powers under federal and state water quality protection standards.

2. Enactment of comprehensive "source control" laws for reducing erosion and sediment from construction sites and stormwater runoff damages from existing and new development should be mandatory for local governments.
   a. Relevant laws should give local governments the primary responsibility for such programs and state oversight should ensure that local programs are effective in addressing state water quality goals.

3. Localities should be required (and given adequate authority) to employ their land use planning function to achieve state water quality goals based on an explicit state policy regarding the relationship between local development and the quality of state waters. State law should provide:
   a. requirements for the development and enforcement of land use management guidelines that localities must follow to address water quality issues in their Comprehensive Plans;
   b. authority for state review (and potential modification) of local plans to ensure that these guidelines have been followed and that state water quality protection goals are being met.

VOL 12

7/7/

R0040479

4. State Environmental Policy Acts (SEPAs) should require that state officials review the pollution potential (including cumulative impacts) of proposed federal, state, local and private actions, and require the consideration of alternatives that may lower the amount of pollution and appropriate mitigation measures when adverse water quality impacts are identified.

5. State law should enhance the value of common law as a means to reduce poison runoff by providing that:
   a. noncompliance with programs requiring the implementation of BMPs constitutes unreasonable conduct for purposes of private nuisance cases;
   b. violations of water quality standards presumptively harm downstream water uses; and
   c. the use of pesticides in areas where their application is prohibited constitutes unreasonable conduct in any tort proceedings brought by allegedly injured parties.

43. See Chapters Three, Four and Five for descriptions of federal land use management activities. States and localities can affect the poison runoff impacts of *federal* land use through their authority under the Coastal Zone Management Act and the CWA. States and localities also can influence federal actions by commenting on Environmental Impact Statements required by the National Environmental Policy Act, and draft federal land use plans required by various laws such as the Federal Land Planning and Management Act (FLPMA) and the National Forest Management Act.

44. States should consider laws establishing riparian and lake protection areas, where restricting development adjacent to waterbodies is necessary to achieve water quality goals. This type of planning recognizes that the health of rivers and lakes depends on the integrity of the banks and, often, the riparian vegetation.

PART THREE

Developing a Framework for Comprehensive Control of Poison Runoff

> Water policy, in general, should be formed from the interaction of the legal, political, fiscal, economic, ecological, scientific, and technological forces that converge on particular problem areas. Out of the conflict of these forces there should typically emerge a set of prescriptions which becomes codified in laws and regulations for the responsible agencies.[1]

Part Three discusses how to assemble the program components outlined in Part Two into a coherent, integrated management effort. A state management program should be more than an assemblage of separate programs. It should be a coordinated, integrated effort, ultimately controlled by water quality officials who understand how individual programs can be and have been incorporated into comprehensive state, regional and local

management efforts and driven by compliance with water quality standards.

Key commitments must be made at the federal, state, local and personal level before poison runoff can be controlled. These commitments can involve choices based on economics, ethics, and politics as much as on science and technology. In fact, effective controls may depend more on making political and management choices, than on solving technical problems. And certain unique features of poison runoff render these choices particularly complex.

First, as mentioned in Part One, the sources of poison runoff are ubiquitous, and the pollutants are very diverse. Thus, a far greater number of sources must be controlled than in many other environmental programs: a county full of farms and small condominium developments, rather than one or two factories, for example. Moreover, poison runoff is caused by polluters with widely different socio-economic and cultural characteristics. Government officials need to design innovative policies and programs that confront (not accommodate) these problems and capitalize on (not ignore) these changes at all appropriate levels.

Second, poison runoff stems primarily from land-use activities and patterns.[2] Land-use decisions and associated private property rights, especially those pertaining to agriculture, traditionally have been considered highly personal in nature.[3] The land use activities causing poison runoff have not been subject to extensive government regulation, unlike major industries.

In addition, whereas pollution control is viewed as the responsibility of state and federal government, land use traditionally has been the province of local government. Therefore, state officials must bring local governments into the management arena, to resolve conflicts among them and to oversee their

management decisions to ensure that water quality is not sacrificed for the sake of local economic development.

Many of the organizational and institutional issues associated with comprehensive management are analyzed in Chapters Nine and Ten, using examples of actual state and local programs wherever appropriate. Chapter Nine examines the need for poison runoff control programs to be shaped and driven by the achievement of specific water quality objectives in individual watersheds, through a planning process orchestrated by the state water quality management agency. Assembling and organizing the resources and players needed to carry out this planning process is the subject of Chapter Ten.

Chapter Nine

Setting the Framework for Poison Runoff Control Programs: Working Towards Water Quality Objectives

Introduction

Chapter Two of this report identified the fundamental legal requirements of the Clean Water Act in designing and implementing programs to control poison runoff. The CWA requires such programs to be designed to meet water quality standards; at a minimum, programs must achieve "fishable and swimmable" waters.

Much of Part Two focused on using water quality standards to dictate the stringency of specific programs and to justify the need for new BMPs or other control strategies for particular types of activity. For example, we recommend that silvicultural control programs be driven by the need to meet water quality standards in the watershed in question. Similar approaches are urged in designing pollution control programs for agriculture, land use, urban runoff, mining and grazing.

It is extremely rare, however, that an entire watershed will be affected only by one type of polluting land use activity. Watersheds may be affected in some way by the full range of pollutants generated by a variety of diffuse sources. Moreover, as discussed in Chapter Two, the Clean Water Act requires states to address poison runoff on a watershed-by-watershed basis, not by focusing only on an individual category of pollution, such as farming, grazing, or mining.

This chapter discusses two fundamental aspects of controlling poison runoff. First, the dominant characteristic or approach that drives the selection and development of specific programs should be the *achievement of water quality goals* in individual watersheds. The goal of achieving and maintaining state water quality standards should be explicitly spelled out in program plans.

Second, the choice of a lead agency for the management program as a whole is a central decision that will influence a state's overall pollution control effort. *The lead agency should have a strong background in water quality management* to ensure that controls are chosen, developed, implemented and enforced to achieve water quality objectives.

These two issues are discussed separately, along with examples of state programs that reflect these important management components. The chapter concludes with a set of recommendations.

Using Water Quality Standards to Drive Control Programs

Establishing Program Characteristics: A Focus on Water Quality Objectives

Many state poison runoff control programs are influenced significantly by an overriding concern that they remain essentially voluntary in character. In such cases the goal of using voluntary approaches, rather than the goal of protecting or enhancing water quality, can drive every phase of activity, from requesting and targeting funds, to developing and implementing management programs, to evaluating program success. This is not a productive manner in which to design a water quality protection program. No control program should be forced to fit into the arbitrary constraints imposed by the goal of remaining a voluntary program (or any *other* single "implementation policy").[1] Such approaches put the cart before the horse. *The goal of the program should be to attain compliance with water quality standards—whether they be narrative or numerical; or chemical, biological or ecological.*

Under a goals-driven system to control poison runoff, the only *a priori* constraints placed on selecting control strategies are those contained in the CWA and state water quality standards requirements. Such a system will not be biased towards any particular program approach. Advances in modelling pollutant loadings and in understanding BMP effectiveness can be incorporated into such a goals-driven plan[2]. The use of *many* effective management approaches, including regulatory programs, becomes feasible. Choices among strategies can be made in a fair, accurate and unbiased fashion.

As discussed later in this chapter, using compliance with water quality standards as the central focus of nonpoint source control activities guides and shapes the state, regional and local agencies' responsibilities. Simply put, water quality standards provide tangible criteria by which to make decisions and judge their effectiveness at *all* program stages.

Comprehensive control of diffuse pollution sources to meet water quality standards requires a number of basic components. First, states must have in place water quality standards that are

VOL 12

7/84

adequate to address the types of pollution and habitat degradation caused by poison runoff. Second, programs must have a mechanism for cataloging all, or at least all major, sources of poison runoff *in each watershed*, and wherever possible, determining what pollutant load reductions are necessary to meet water quality standards. Next, program officials must use this information to determine what combination of control methods is needed to meet water quality standards in each watershed, and to implement these requirements. In addition, a water quality approach can be used to prevent the degradation of clean watersheds, or further degradation of watersheds that currently do not meet water quality standards. Each of these basic components is discussed below.

Water Quality Standards for Controlling Poison Runoff

Most existing water quality criteria were developed to address point sources of pollution. To date, monitoring and modelling efforts have been oriented for the most part towards point source pollution.[3] Therefore, it has been difficult to determine when poison runoff was contributing to water quality violations, or when control programs were eliminating such violations.[4] As a consequence, today many programs to control poison runoff do not contain a strong, direct link to state water quality standards.[5]

Nevertheless, many existing water quality standards still are applicable to pollution from diffuse sources. This is true particularly where both point sources and dispersed sources contribute to violations of a particular water quality parameter, such as turbidity or criteria for individual metals. As explained below, applying criteria developed for point sources to nonpoint sources may simply require states to redesign their monitoring programs and wasteload allocation process to account properly for pollution contributions from various land use activities.

Poison runoff does pose a number of unique problems that are not addressed adequately by most existing state water quality standards. However, EPA and a number of states are working to develop water quality standards that are more closely related to pollution generated by diffuse sources.[6]

VOL 12

7/85

One major problem is the difficulty of developing instream water quality standards to address nutrients. The adverse effects of excessive nutrient inputs often are not felt in the receiving stream, but in some downstream waterbody, such as a lake or estuary. Nutrients collected in these waterbodies may result in eutrophication. But the relationship between nutrient concentration and eutrophication is not necessarily linear, and is affected by such variables as temperature, the amount of sediment-bound nutrients, and the presence of other pollutants.[7] Therefore, it is difficult to set a single, specific instream concentration for nitrogen and phosphorus that will protect downstream lakes or estuaries.[8]

One rough way to address eutrophication is through standards for dissolved oxygen (DO).[9] Since the effects of eutrophication are felt through reduced dissolved oxygen, excess nutrients are measured indirectly by lowered dissolved oxygen levels.[10] But there are a number of problems with using this approach alone. Given the lag between the time of nutrient enrichment and the onset of adverse effects, dissolved oxygen might not be reduced to levels that violate water quality standards until the damage is already done.[11] Moreover, in lakes and estuaries DO levels will vary diurnally and through the water column.[12] Therefore, it is important for DO measurements to be taken at the correct time of day and at the correct points in the water column. But given these complexities, using DO levels to calculate nutrient levels needed to prevent eutrophication may be extremely difficult.

Some states are using chlorophyll *a* as an indicator of eutrophication.[13] Chlorophyll *a* is a plant pigment used by algae to convert energy from sunlight, along with dissolved carbon dioxide and water, to food energy. As such, chlorophyll *a* is a direct measure of algae growth and can be used to measure eutrophication.[14]

An even more sophisticated approach is to use a combination of measurements, including chlorophyll *a*, turbidity, and nutrient concentrations to calculate a "trophic state index". This type of approach is being used in North Carolina and other states.[15]

Another major problem is that many types of poison runoff, including pesticides and toxic metals, are often bound to relatively heavy sediment particles.[16] These particles tend to be

VOL 12

7/1/86

R0040494

deposited in the sediment rather than dissolved in the water column. Thus, water quality criteria that measure pollutant concentrations in water may not adequately address these pollutants since they may accumulate in benthic organisms or be taken up through the food chain.

The obvious solution to this limitation is the development of sediment quality criteria.[17] While most states currently do not have sediment quality criteria, EPA is working on the development of guidance for sediment contamination,[18] and state plans to control poison runoff should consider the future adoption of such standards.

Finally, pollutant-specific water quality criteria alone do not adequately address damage caused by poison runoff. To address this limitation, as well as similar limitations of using numerical criteria alone to address point source pollution, EPA and various states are developing ways to measure the overall biological health of rivers, lakes and coastal waters.[19] Programs to manage diffuse sources of water pollution should use these biological criteria to identify problems, develop appropriate controls and measure program success.

Identifying and Allocating Nonpoint Source Pollutant Loads in Individual Watersheds

The critical steps in a water quality-driven nonpoint source program are: (1) to identify the sources of a particular type of poison runoff (or diffuse groundwater contaminant) in a watershed, (2) to allocate existing loadings from each pollutant, and (3) to determine the reductions from each source or category of sources needed to achieve water quality standards. Because it may be cheaper or easier to control loadings from some sources than others, this watershed-wide approach allows states to consider economic efficiency and equity while still developing a plan designed to meet water quality goals.

It is important that quantitative and measurable water quality goals be utilized, both in the general state control program and in determining suitable implementation projects for individual waterbodies.[20] If compliance with water quality standards is the overriding goal, *all* nonpoint and point source control needs must be combined into a comprehensive "watershed plan" that describes initially what controls are necessary within a given watershed to achieve and maintain beneficial uses.[21]

This concept is perhaps best explained by an example. Assume that a given watershed is violating water quality standards for total suspended solids. Some of the excess pollutants may come from point sources. But these sources already are meeting stringent control requirements, and the best available controls will not come close to meeting water quality standards.

In fact, assume that 60% of the total sediment load to the watershed is from a diverse range of nonpoint sources. Some of this sediment load comes from poorly controlled construction sites; some derives from agricultural erosion, mining, silviculture and urban runoff. A watershed-based plan to control poison runoff should identify each source or source category; *estimate* current loadings, and estimate additional load reductions that can be achieved through improved implementation of BMPs or other controls for each category of sources. The control methods for each source can be chosen based on any number of factors, including technological feasibility, cost, equity, and enforceability, so long as the *total* estimated load reductions are designed to meet water quality standards, with an adequate margin of safety.

To be sure, this process is neither easy nor precise. Depending on the type and intensity of controls, changes in ambient water quality from program efforts may not take effect for a number of years.[22] Using water quality standards to direct the control of poison runoff can be expensive and complex; and it differs significantly from the established activities of many state water quality management agencies.

These difficulties vary with the source category. For instance, because natural water quality in forested watersheds often is pristine, and significant water quality problems are caused by sediment and herbicide loadings (the major silvicultural pollutants), it can be relatively easy to determine what activities are responsible for beneficial use impairments.[23]

Determining whether violations of water quality standards are due to urban pollution loadings, and to what degree, may be more difficult due to various external pollution sources from outside (and within) the watershed under consideration. Variable storm intensities and frequencies, which can cause significant

VOL 12

7/1/88

temporary changes in water quality, also make the task more complicated.[24] These problems are even greater in agricultural settings.[25]

But despite these difficulties, it is possible to make estimates of *relative* point and nonpoint loadings and to impose treatment requirements on different sources necessary to attain or maintain a given beneficial use.[26] While this process will not be precise, it need not be precise to be effective. And given both the compelling need and the Congressional directive to develop comprehensive, watershed-by-watershed management plans to control poison runoff, complete precision should not be the enemy of an available strategy that makes significant progress towards meeting water quality standards.

The strategy outlined here has a number of clear benefits. Within the watershed, water quality standards provide a concrete goal to work towards because they define what level of pollution reduction is needed to protect beneficial uses.[27] This improves the selection and implementation of control strategies for the range and number of sources that must be managed.[28]

Moreover, unlike a strategy designed to implement a fixed, arbitrary number and type of BMPs, a water-quality driven strategy is not biased towards any given control method or implementation approach. Rather, the correct tools can be chosen for each source or each source category, and can vary among watersheds depending on need.[29] For example, the necessary calculated load reductions from agricultural sources may be achievable in a particular watershed solely with the use of voluntary cost-share programs, if adequate funding is available. In another watershed or another state, agricultural loads may be so great, or cost sharing funds so limited, that regulatory controls may be needed either across-the-board, in critically-affected watersheds, or on farms that contribute the greatest loadings.

Water Quality Standards, Land Use, and Antidegradation

It is easier to conceptualize the use of water quality standards to direct the selection and implementation of BMPs, as explained above, than it is to envision how water quality standards can be used to affect land use planning. Yet in Chapter 5, we

VOL 12 7/1/89

R0040497

recommended a strong link between water quality and land use planning and control.

Some types of land use controls are in fact closely analogous (or identical) to BMPs. Land use controls can consist of conditions placed on development, such as prescribed drainage controls, maximum percent impermeable surfaces, or buffer strips between construction and waterbodies. Methods exist to *estimate* the amount of pollution reduction that such methods will produce. With adequate knowledge of existing conditions in a region's surface waters, these controls can be imposed as needed to protect water quality on existing *or* new development.

Perhaps more important, estimates of the pollution loads that will result from new developments, in combination with other existing or proposed developments, can be used for purposes of *siting* facilities or determining desirable land use patterns. High impact facilities that will generate significant loads can be sited where they will have the least impact on surface waters. Open space or buffer strips can be planned where existing pollutant loads already are stressing a particular system. In extreme cases, a permit for a facility can be denied where water quality standards will be violated despite the best efforts to site and design the facility properly.

A special but extremely important case of applying water quality standards to proposed new activities is antidegradation. Under the Clean Water Act and EPA implementing regulations, all states must include in their water quality standards an adequate antidegradation regulation, and policies and procedures to implement that regulation.[30] Essentially, the antidegradation requirement prevents existing clean waters, *i.e.*, waters that are cleaner and healthier than necessary to protect and maintain designated water uses, from being degraded.

There are three "tiers" to EPA's antidegradation regulation.[31] Under the first tier, all existing water uses, and the water quality necessary to protect those uses, must be maintained and protected in all cases.[32] Under the second tier, where existing water quality is better than required by state water quality standards, that level of water quality must be maintained and protected unless it is determined that "allowing lower water quality is necessary to accommodate important economic or social development in the area in which the waters are located."[33] This determination can be made only after adequate opportunity for public participation.[34] Moreover, lower water quality may not be allowed unless the state requires the strictest applicable technology-based controls for point sources in the watershed, and "all cost-effective and reasonable best management practices for nonpoint source control."[35]

Finally, under the strictest third tier of the antidegradation regulation, high quality waters that constitute "outstanding National resources, such as waters of National and state parks and wildlife refuges and waters of exceptional recreational or ecological significance," must be maintained and protected at their existing high levels under all circumstances.[36] This is essentially a zero degradation requirement.

EPA's antidegradation regulation applies equally to water quality degradation from point and nonpoint sources. This regulation, therefore, presents a powerful tool for states and localities to impose strict BMPs, siting requirements, and other controls on any new developments that would otherwise lower existing high water quality.

Specifically, in no case can pollution loadings from a new development push a waterbody over the top, bringing a surface water that barely meets water quality standards out of compliance. Where existing water quality is better than required by water quality standards, any additional development is subject to strict controls or siting requirements to ensure that no detectable water quality degradation occurs, unless the narrow tier 2 exceptions described above are met.

Picking the Right Lead Agency

Using water quality standards to determine the adequacy of programs leads to other important strategic questions. What agency should be the leader in a state program to protect water quality from poison runoff, and how should this agency approach general management issues? While the ultimate responsibility for a state program rests with the state government, it is not so obvious *which* state agency should exercise leadership and oversight. The choice of a lead management agency will influence the character of and emphasis placed on programs designed

VOL 12

7/1/91

R0040499

to address water pollution resulting from *all* types of pollution generated by diffuse sources, including urban and silvicultural land uses.[37] How well one kind of nonpoint source is controlled often determines how well other sources (both point and nonpoint sources) need to be controlled.[38]

As a general rule, historically states that consider agricultural pollution problems the most significant have relied upon agriculture and soil and water conservation agencies to develop and administer their overall nonpoint source programs.[39] Today much of these states' programs to control poison runoff are still little more than elaborations of past voluntary soil and water conservation activities. As a result, the "new" programs rely on the same institutional, management and financial framework as did their older, non-water quality-based ancestors.[40] In contrast, states that address vigorously a mix of urban, agricultural, forestry and other water quality impacts usually have programs in which the state water quality management agency takes the lead.[41]

A state agriculture agency is an important institutional resource in an overall management program. However, even in states with large agricultural pollution impacts, water quality management agencies are better suited to serve as lead agencies in such programs for several reasons.[42]

First, as detailed elsewhere in this report, soil and water conservation programs do not achieve optimal water quality results because of their bottom-up voluntary approach and their lack of contact with water quality management activities grounded in the CWA. The non-regulatory SCS-style tradition can bias programs away from a water quality goals-oriented approach. State water quality agencies have greater resources and expertise to evaluate water quality protection needs, and actual program effectiveness.[43]

Second, since nonpoint pollution occurs within distinct hydrologic units while SWCDs usually conform to political (county) boundaries,[44] organizing program activities around the traditional agriculture agencies risks uneven and unsuccessful program implementation. Control efforts should ensure that the state and the localities within watersheds equitably and efficiently share program responsibilities so that nonparticipation by a few

VOL 12

7/1992

critical localities or landowners does not negate program benefits.[45]

A state-level program grounded in an agriculture agency will tend to concentrate on using the traditional network of SWCDs and the Cooperative Extension Service. Such a program may under-utilize other entities that could be significant forces for controlling nonpoint pollution as well as for data collection, implementation, enforcement, and evaluation efforts. Local governments, regional planning and water quality management agencies, and drainage districts, to name a few, all have important pollution abatement roles. In sum, the SCWDs are both too specialized and too committed to one approach to serve as *the* dominant vehicles for broad-based control programs. Table 9-1 lists the main advantages of a water quality agency-controlled program over a program administered by a state soil conservation agency.

VOL 12

7/193

R0040501

Table 9-1
Advantages of Water Quality Management Agency-Administered versus Soil Conservation-Administered Program

Water Quality Agency	Soil Conservation Agency
focuses on complying with water quality goals	tends to focus on non-water quality goals based on "delivery mechanism" (*e.g.*, cost-share dollars, farmers reached, BMPs implemented); must also balance water quality protection with traditional farm productivity and income support goals
possesses expertise and resources for water quality monitoring and modelling as well as enforcement and program evaluation	often lacks expertise in these water-quality management areas
can utilize regional water management and planning agencies and local governments in comprehensive watershed-wide programs	concentrates on existing agriculture services network (*e.g.*, Cooperative Extension and SWCDs) to carry out activities in a fragmented system not based on hydrologic boundaries; traditional "assistance" relationships with clients can inhibit recognizing the need to impose strict controls and the implementation of appropriate programs
not biased towards voluntary implementation policies	tends to rely on traditional, voluntary costsharing framework
not biased towards agricultural pollution problems	tends to focus efforts on most familiar problems (*i.e.*, agriculture pollution)

R0040502

Examples of State Programs Linking Planning to Water Quality

Different states and localities have linked water quality standards to nonpoint source programs in various ways. Here are some promising examples:

Florida. Florida is an example of a state whose water quality management agency has assumed a strong role in the development of its *general* management plan for controlling poison runoff as well as in *individual* control programs. As an illustration, Florida's CWA 319 Management Plan describes the role of the state Department of Environmental Regulation (DER):

> With respect to the NPS management, the department [DER] is the primary lead agency with major responsibility for establishing minimum treatment standards to assure that NPS discharges do not cause or contribute to water quality standards violations. Another major department role is to oversee and coordinate the implementation of NPS management programs delegated to other agencies to assure consistency in the application of regulations.[46]

Florida has begun to use water quality standards to develop controls in a number of ways. Compliance with water quality standards not only drives many individual programs in the state but also is an explicit goal in the proposed Florida Nonpoint Source Management Plan.[47]

A good example of a program driven by water quality goals (rather than by a preconceived notion of how it should be implemented) is Florida's SWIM program. This program incorporates both point and nonpoint controls to achieve compliance with state water quality standards.

In 1987, the Florida State legislature enacted the Surface Water Improvement and Management Act (SWIM).[48] This law requires Florida's five regional water management districts (WMDs) to prioritize waterbodies of regional or statewide significance, and to design and implement surface water improvement and management (SWIM) plans.[49] These plans encompass voluntary and regulatory programs that address both point and nonpoint sources. They include participation by local and regional governments and review by the state Department of

VOL 12 7/1/95

Environmental Regulation (DER).[50] Compliance with state water quality standards and protection of beneficial uses in particular waterbodies is the goal that determines the content of each plan.[51] Water quality criteria and ***holistic habitat and biological parameters*** are used to evaluate the adequacy of proposed programs.[52] Plans are developed for each prioritized waterbody, and address the minimum requirements of the Act:

1. Site description, history, hydrology;
2. Adjacent land use, pollution sources, permitted discharges;
3. Owners of point and non-point sources, and compliance timetables;
4. List of governmental units within one mile;
5. Description of potential restoration strategies to restore water to Class Three (water quality standards) or better;
6. Bibliography of relevant past and current studies;
7. Description of research and feasibility studies to determine restoration strategies, and a list and current status of active restoration and conservation projects;
8. Description of maintenance and management measures needed following restoration;
9. Schedule for restoration and management of waterbody; and
10. Estimated funding needed for restoration.[53]

Similarly, achieving compliance with water quality standards is also used in Florida as a criterion to issue and review urban stormwater permits.[54] All stormwater permits are issued with the proviso that if a discharge is contributing to a violation of water quality standards the Department of Environmental Regulation

VOL 12

7/96

is authorized to strengthen permit requirements as needed.[55] Also, local land use and development plans are reviewed for their anticipated impact on water quality, and plans can be disapproved or modified if violations of state water quality standards are anticipated.[56]

As modelling efforts improve, and as more resources become available, the specific water quality impacts of local land use goals and policies will be more carefully scrutinized.[57] Often, biological and habitat parameters are used if attainment of chemical water quality cannot be determined, or if applicable standards do not exist for particular pollution problems, especially in agricultural areas.[58]

Management and Storage of Surface Waters (MSSW) permits are used in both agricultural and nonagricultural situations that involve diversion, consumption and routing of water, such as highway projects, urban development, golf course maintenance, and agricultural operations.[59] One of the purposes of the MSSW permit is to control poison runoff. In the South Florida Water Management District, specific provisions of each permit are included in order to protect the beneficial uses of state waters through compliance with water quality standards.[60]

In order to fill gaps in standards and criteria, a recent review of water management district rules led the St. Johns River Water Management District to recommend developing special basin criteria for district waterbodies and sub-basins.[61] These criteria will provide additional protection to especially sensitive areas. The review also supported the development of a numerical, water quality-based nutrient standard for waters within the district.[62]

While overall, Florida (like many states) still lacks significant control over some agricultural surface and groundwater contaminants,[63] Florida has established an effective *means* to evaluate the water quality effects of point and nonpoint source problems both systematically and simultaneously. This evaluation is used to develop a comprehensive and scientifically defensible set of cleanup and protection proposals that are custom-designed for a particular waterbody.

San Francisco. In the southern part of the San Francisco Bay area, localities are working with each other, and with the area's Regional Water Quality Control Board and EPA, to determine the most effective methods to meet water quality standards for a variety of toxics coming from widespread point and nonpoint sources.[64] Based on data from a program of continuous monitoring of toxics loadings, permits for specific *nonpoint* sources may be required in the next 2-3 years.[65] These permits, like water-quality based NPDES permits, would be designed to achieve state water quality standards and would seek to distribute control responsibilities equitably among particular localities based on the results of the research currently underway.[66]

The recent Water Quality Control Plan for the San Francisco Bay Region lists water quality objectives that describe the level of water quality for each beneficial water use in the basin.[67] All "controllable water quality factors" are subject to the requirements of the plan if they contribute to adverse impacts on beneficial uses.[68] For each beneficial use, relevant objectives for poison runoff control include those pertaining to: taste and odor; suspended material; settleable material; biostimulatory substances (nutrients); sediment; turbidity; dissolved oxygen; bacteria; salinity; and toxicity (defined using chemical *and* biological parameters).[69] These objectives are used to shape the nonpoint source programs carried out at the state and local level, including the requirement that certain localities address particular urban runoff problems.[70]

Wisconsin. The Wisconsin Department of Natural Resources is responsible for developing the state's Nonpoint Source Pollution Assessment and Management Program under CWA § 319.[71] The Wisconsin approach to controlling diffuse sources of water pollution illustrates the advantages of a program with significant input by a water quality management agency that can address all forms of poison runoff and involve many levels of government.[72] The DNR administers the state Nonpoint Source Pollution Abatement Program,[73] and the soil and water conservation programs administered separately by the Department of Agriculture, Trade and Consumer Protection (DATC) are integrated with those of DNR.[74]

Wisconsin's Nonpoint Source Water Pollution Abatement Program focuses on identifying the generators of all nonpoint source water pollution within a given hydrologic unit and involving all of the local governmental entities in the unit to achieve specific water quality goals based on state water quality standards.[75] This is accomplished by picking priority watersheds and priority management areas, which then become the sites for pollution control projects.[76] These projects are selected through a formal process based on six criteria, presented below in Table 9-2:

Table 9-2
Process and Criteria Used in Selecting Priority Watersheds in Wisconsin*

Selection Process	Selection Criteria
1. numerical ranking of watersheds after technical evaluation of water quality and pollution potential by DNR	1. the severity of water quality problems
2. review and recommendations by regional committees	2. magnitude of pollutant load and potential for reduction
3. further refinement of priority list by a committee with interest group and state agency representation	3. landowners' willingness to participate
4. final selection of projects by DNR	4. willingness and capability of local agencies to carry out their roles
	5. willingness and capability of localities and other local units of government to control other sources of pollution, *e.g.*, erosion and sediment control programs
	6. potential public use and benefits that will result from the proposed watershed project

VOL 12

7200

After the selection process, an 8-10 year planning and implementation process begins. Approximately one year is used to assess and to inventory critical-source areas, develop specific water quality objectives, and prepare an implementation plan.[77] Using a variety of models and other data collection activities, DNR staff, with input by DATC, develop a technical assessment to:

1. identify water quality problems and determine specific water quality objectives;

2. identify significant nonpoint sources in relation to point sources and septic systems;

3. identify water quality improvements that can be achieved through various types of controls; and

4. identify the general management needs to achieve water quality improvements.[78]

The rest of the watershed strategy, termed the implementation strategy, is developed by state and local agencies and identifies:

1. the tasks necessary to address the needs identified in the technical assessment;

2. the agencies responsible for these different tasks;

3. the time for accomplishing each task;

4. the estimated hours of staff time needed to carry-out the project; and

5. the approximate costs of implementing the recommended controls.[79]

The Wisconsin program is run with strong input by the state water quality agency. It has an objective planning and implementation process that allows many governmental units to work together toward agreed-on water quality goals within a given watershed. In addition to its value as an organizational structure, the Wisconsin program also highlights the important cause-and-effect relationships between land use and water quality.

In Wisconsin, a central component of each priority watershed project[80] is the set of water quality objectives identified for the watershed's lakes and streams.[81] Use impairments are treated as more significant than violations of chemical parameters in designing control programs, since many affected waterbodies are trout streams with degraded habitat caused by the sedimentation of the stream bottom which may not necessarily be reflected in water column numerical concentration violations.[82] Consequently, biological indicators are often part of water quality objectives for individual lakes and streams.[83]

The Nonpoint Source Pollution Control Plan for Wisconsin's Sevenmile-Silver Creek Priority Watershed illustrates this use of water quality data to design specific programs. Five tools were used in assessing the water resources within each subwatershed and in developing water quality objectives. These include:

1. *Beneficial Uses and Use Impairment;*

2. *Physical Data* - considered when addressing water resource conditions and beneficial uses;

3. *Biotic Index* - the Hilsenoff Biotic Index (HBI) was used to classify water quality conditions according to insect populations;

4. *Stream Fishery Habitat Assessment* - using a variety of physical, chemical and biological indicators, an inventory was developed to determine present and future fisheries uses (with and without various control scenarios); and

5. *Lake Trophic Status* - phosphorous concentrations, chlorophyll-a levels, and secchi disc measurements (a turbidity measure) were taken to evaluate the trophic

VOL 12

7202

levels of lakes in the watershed with and without various control scenarios).[84]

After pollution loads have been estimated, a management plan can be developed that achieves water quality objectives by calculating necessary load reductions and identifying how and where these reductions can be achieved.[85]

Silviculture and Mining: Different "Watershed" Planning Approaches

To address silvicultural and mining impacts, EPA has conducted a study of using sediment quality criteria as a basis for the protecting of certain kinds of fish habitats.[86] The researchers concluded that, although it is difficult to use stream variables that can *quantify* the effects of sediment on fish and macroinvertebrates, threshold values for dissolved oxygen can and should be used in some circumstances as cut-off points beyond which serious damages to fisheries would occur.[87] In many other instances, given uncertainty and risk, EPA recommended the adoption of water quality standards allowing for *no* incremental increases in sediment fines until more is understood about the relationship between sedimentation and habitat degradation.[88] The study also concluded that "real and detectable relationships appear to exist between disturbances such as stream crossing" and sediment fines.[89]

California. In California, efforts are under way to include habitat conditions as part of the water quality standards that private timber operations must maintain.[90] Because of past difficulties in enforcing water quality standards, the California Board of Forestry is currently supporting the development of two kinds of monitoring in timber operations: compliance and enforcement monitoring to determine if the required BMPs have been implemented properly; and surveillance monitoring to determine if the BMPs, when properly carried out, are *in fact* protecting the relevant water quality conditions.[91] In order to link water quality standards with the preparation of Timber Harvesting Plans, the California Forest Practices Rule Assessment Team has recommended that performance standards be written in an enforceable manner so that the definition of a particular BMP is whatever action (or non-action) supports water quality protection goals.[92] Presumably this could preclude harvesting timber using certain methods or in certain areas.

Conclusions and Recommendations

State programs to control poison runoff must be carefully planned. They must be driven by water quality goals, and be flexible enough to implement innovative solutions that address all significant sources of contaminated runoff (and groundwater) through every useful channel. With this approach established, specific programs can be developed, implemented and evaluated with the confidence that all reasonable control options will be considered objectively. To summarize, the following general program needs must be addressed in order to ensure that state efforts to control poison runoff are shaped by such an approach:

1. State water quality management agencies should be given a lead role in designing, coordinating, and evaluating individual projects to control poison runoff as well as the overall state management program—especially in ensuring that these programs are geared towards compliance with state water quality standards.

2. Programs should set specific quantitative and measurable water quality goals and objectives based on achieving compliance with water quality standards. They should use monitoring and modelling techniques to verify and enforce compliance.

3. Programs should address specific problem waterbodies through a coordinated state, regional, and local approach, with a single state-level agency responsible for overall program administration.

4. Water quality standards should be used to determine the site-specific load reductions needed for targeting, program implementation and funding policies, and to justify the use of non-voluntary programs.

5. Physical, biological and habitat criteria should be used to determine when narrative water quality standards are being met if specific, numerical chemical criteria are not available or feasible.

6. Problem assessments and individual plans should be developed separately for each affected waterbody or group of waterbodies. Wherever possible, programs should apply water quality goals on a watershed- or waterbody-specific basis.

Notes - Chapter Nine

1. As discussed in several places in the report, a voluntary program alone often is not adequate to solve poison runoff problems.

The use of standard chemical water quality standards alone may not suffice in assessing silvicultural water quality impacts because sediment deposition is more likely to affect habitat and biologic parameters than ambient water quality. States are beginning to develop other types of standards to fill the gap. California, for example, is currently working towards the development of new methods to enforce water quality standards on private and federal forested land based on biological criteria and specific habitat conditions as standards against which it can measure whether beneficial uses are being protected. Chapter Ten

Putting the Pieces Together: Comprehensive Program Implementation

Introduction

Designing a program to control poison runoff that is driven by water quality goals is only half of the battle. The planning elements described in this report must be incorporated into a cohesive strategy, which then must be implemented effectively by a large number of actors. The path to success may be strewn with a number of political and managerial obstacles; overcoming these obstacles is as critical to the success of a control program as overcoming technical limitations.[1] Successful control of poison runoff requires a skillful allocation of responsibilities among the many actors who can enhance—or doom—control efforts.

Managing diffuse pollution sources is by nature more complex than many other environmental protection enterprises. For example, point source programs often are administered by a single state-level agency or, at most, a central agency and a group of regional offices that collect data, monitor compliance, investigate complaints and enforce permit provisions. But this approach may not be feasible in the case of poison runoff, where more agencies and levels of government are involved in the control of more sources of pollution. Moreover, unlike point sources, federal laws today do not establish uniform requirements that dictate how poison runoff control should be accomplished.

This chapter describes how to allocate and organize institutional resources efficiently and effectively into an overall program structure for restoring and maintaining water quality. The chapter first discusses general principles of allocating program resources, and then describes innovative approaches being used in Florida, Minnesota, and other areas.

Institutional and Organizational Needs

Centralized state program control is needed to ensure that conflicts between government levels can be resolved and gaps or redundancies in coverage do not waste precious resources.[2] Within state government, many agencies are involved in programs affecting water quality. These agencies are responsible for such areas as:

1. water resources planning;
2. water quality management;
3. natural resource protection;
4. land use and economic planning;
5. agriculture, mining, and highway construction; and
6. health and welfare.

The interstate (and international) nature of poison runoff often creates a need for a mechanism to develop, implement, monitor and enforce specific management commitments at the river basin level.

The Roles and Responsibilities of Program Officials

The state water quality management agency (usually the best lead agency for program management)[3] or any other agency charged with coordinating state efforts must provide a formal mechanism to coordinate the roles of all relevant agencies, ranging from regional planning agencies to SWCDs and county health departments.[4]

State land use organizations and regional units of state water quality management agencies are two important state governmental entities in controlling poison runoff. State land use agencies can develop water quality protection requirements for local Comprehensive Plans, prepare model ordinances and other guidance for localities, and provide data on regional and state shifts in growth patterns. Regional water quality management agencies can provide a focal point for implementing, monitoring and enforcing state-level programs within a given area. They also have additional resources and expertise with which to assist in program evaluation.

Since local governments cannot control activities outside their boundaries, regional planning organizations need to coordinate multi-level programs (many of which are not traditional water quality protection programs), disseminate technical information and foster cooperation among local jurisdictions. Within a state, regional solutions can be developed using regional planning boards or commissions, or similar entities. Multi-state planning obviously should come under the control of the involved state governments with guidance from the federal level. Since existing regional planning institutions usually do not conform to hydrologic boundaries and often lack substantial legal authority, state laws should *mandate* cooperative arrangements both within and among regional bodies. Otherwise, any voluntary compromise could sacrifice water quality for economic and development considerations.

Finally, local jurisdictions and the general public must take part in any poison runoff control program. Local jurisdictions are often primary (and essential) actors in the preparation and implementation of control programs.[5] Local citizens contribute substantially to the pollution problem, and must be a basic part of any effective solution. Methods must be devised not only to gain the input of localities and the public, but also to resolve conflicts[6] and, if necessary, to modify programs to reflect local and public concerns. A strong state role is needed to ensure that state water quality goals are maintained in any negotiated compromises within or between localities.

Coordination Among Different Agencies and Levels of Government

These various poison runoff control players should be viewed in terms of the *functions* that they perform. Generally, each function within a state program to control poison runoff should fall within one of the following types of activity:

1. Strategic Planning - setting broad goals and policies;

2. Management Planning - translating goals and policies into concrete objectives and creating the necessary organizations and the allocation of resources; and

3. Operations - the actual execution of programs and projects.

States should assign roles, responsibilities and relationships based on the functions each agency is best suited to perform. Figure 1 provides a simplified schematic diagram indicating one way to direct the flow of responsibility in a state control program. As the source of program authority, the state water quality management agency should assign responsibilities to other state agencies; to regional organizations; and, finally, to local governments.[7] Feedback and program accountability are provided generally by lower levels of government and from state agencies other than the water quality management agency.[8]

Figure 2 describes how the roles and responsibilities of a few of the different program actors can be conceptualized. For each step in the planning process (*e.g.*, data collection, developing and selecting plans, implementing control activities and evaluating successes) this design can be broken down into the specific tasks of each management entity. As the diagram indicates, each

Generalized Agency Responsibilities in Poison Runoff Management Program

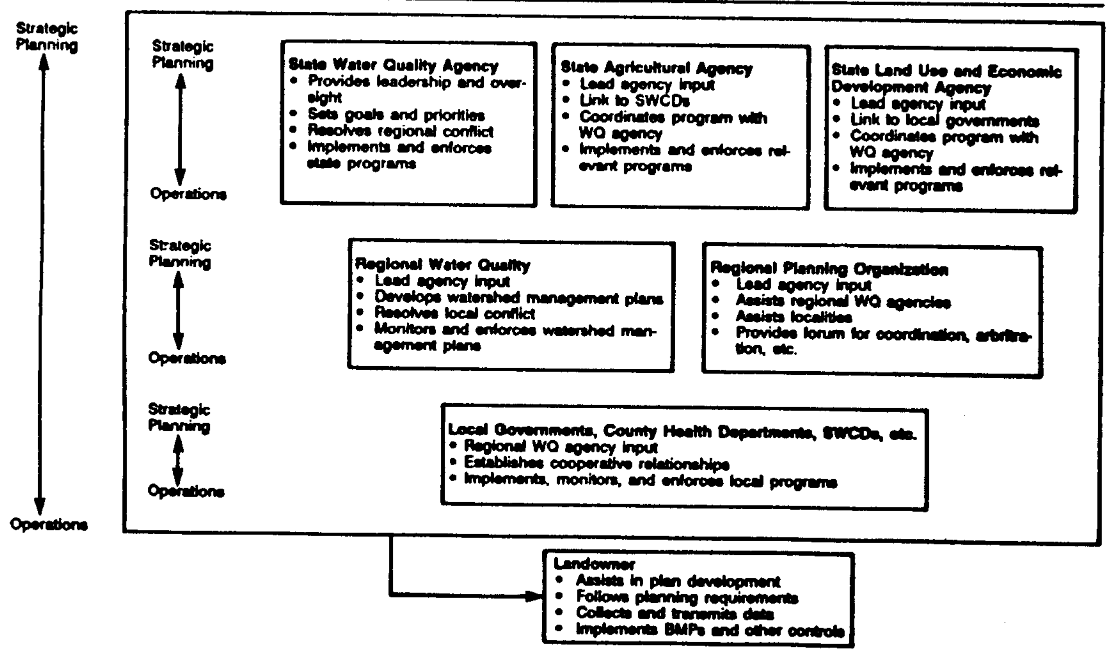

Figure 3
Example of Generic Agency Collections

Agency Connection	Planning Functions: Strategic	Management	Operations
Legislative/ Regulatory Connection	Requires state, regional or local entities to develop common goals and policies	Requires various program components (*e.g.*, enforcement) to be developed collectively	Requires programs to be executed and evaluated using common procedures or multiple agencies
Interagency Review Team	Identifies and solves potential problems within or between government levels	Allows the collective development or analyses of particular program proposals	Allows outside assessment of program successes and failures
Joint Work Plan	Clarifies issues and concerns early in the program development process	Formally establishes working relationships between agencies or government levels	Coordinates on-the-ground implementation activities

level of government is involved in a host of activities falling along the spectrum between strategic planning and operations, while the entire process also is organized according to this scheme.

Developing effective *connections* among state, regional and local governmental units is a pivotal requirement in a state management program and one that is only partially addressed by defining roles and relationships. Figure 3 provides a generic description of some of the agency connections that can be established, and how they can help to coordinate program activities.

What Works: Some Examples of Effective Approaches

Allocating and coordinating program resources will always depend upon the particular institutions and institutional relationships already in place in a state, as well as the poison runoff problems peculiar to that state. Nevertheless, an effective model in one state can be very useful to others seeking to learn from past successes (and mistakes). Examples of state and local programs with innovative institutional and organizational approaches to controlling poison runoff are set forth below. These approaches address particular problems differently, but they share the common trait of taking action to address an important (and difficult) institutional issue. While none of these examples individually incorporates *all* of the institutional and organizational needs identified in this chapter, each one illustrates innovative and effective mechanisms for addressing particular problems.

Florida: A Mandatory Process for Integrated State, Regional and Local Water Quality Protection

Regional Water Quality Management: A Coordinated Process Providing for Aggressive State Leadership and Oversight. Florida is a good example of how particular organizational and management tools can be used to coordinate the many levels of government that are involved in poison runoff control. The end product is site-specific action to achieve water quality objectives.

The development and organization of regional programs in Florida parallels the Surface Water Improvement and Management (SWIM) legislation.[9] Under this Act, the Department of Environmental Regulation (DER), Department of Natural Resources (DNR) and Game and Fresh Water Fish Commission (GFWFC) cooperate with Florida water management districts, each of which is required to develop a prioritized list of "surface waters of regional or statewide significance which require restoration or conservation."[10] Surface Water Improvement and Management (SWIM) plans must be developed for water bodies included on these priority lists.[11]

The SWIM Act provides a detailed set of criteria to be used in preparing the priority list of waters needing attention (Table 10-1), and this list is used as the basis for the involvement of all of the actors within the watershed that assist in the development of the SWIM plan. These criteria provide the means by which state and regional water quality management authorities can scrutinize and influence the contents of the plan, and the actions of public and private interests that affect the priority water bodies. The governing board of each district must hold public hearings and workshops before finalizing restoration strategies for particular water bodies, and must forward copies of the strategies and plans to the DER, other state agencies and appropriate local governmental units for review and comment.[12]

Yearly funding proposals, developed by the water management districts in cooperation with the DER, specify proposed activities and funding requirements.[13] Governing boards also are encouraged to appoint advisory committees to help develop and evaluate strategies and to increase public awareness and intergovernmental cooperation.[14]

Each of the key statewide agencies[15] is required to review each SWIM plan and to suggest modifications based on the criteria established in the legislation for that agency.[16] Several state agencies, along with the water management districts, are also required to review and strengthen their respective rules and enforcement programs to improve water quality protection.[17]

Funding for SWIM planning and implementation is provided by the SWIM Trust Fund, which is administered by the DER.[18] Money from the Fund cannot be dispersed unless the governing board of a water management district adopts a resolution that certifies the money is needed for planning and implementing SWIM plans.[19] A water management district must provide at least 20 percent of the amount of money needed for its SWIM program.[20] The SWIM Act authorizes water management districts to raise funds to develop and implement SWIM plans by levying *ad valorem* taxes at specified rates on property within the district.[21]

Table 10-1
Criteria for Developing SWIM Priority Lists Provided in the Florida Surface Water Improvement and Management Act*

1. The degree to which state water quality standards are violated. In reviewing this criterion, each District shall consider the following factors:
   a. The status and trends of water quality in the waterbody, including the nature and extent of pollution loading from point and nonpoint sources and the extent to which uses are impaired;
   b. Whether the waterbody can reasonably be expected to meet or maintain water quality standards without action to control point or nonpoint sources; and
   c. The nature and extent of sources of point and nonpoint pollution which contribute to the waters not meeting standards.
2. An evaluation of the nature and extent of conditions that adversely affect the waterbody, including, but not limited to:
   a. Nutrient balance of the waterbody;
   b. Trophic state of the waterbody;
   c. Existence or need for continuous aquatic weed control;
   d. Biological condition;
   e. Physical condition; and
   f. Reduced fish and wildlife values.
3. Threats to water supplies, especially agricultural and urban supplies, and recreational opportunities. In reviewing this criterion, each District shall consider the following factors:
   a. Whether uses of the waterbody are impaired, including whether the waterbody does not meet quality standards or requires control programs to maintain compliance with standards; and
   b. Whether conditions intermittently or frequently prevent a beneficial use.
4. Threats to or need for long-term protection of those exceptional or outstanding waterbodies which are currently in good condition.
5. The extent to which the plans, ordinances, and policies of local governmental units with jurisdiction over a waterbody are consistent with a District's efforts to restore or conserve a waterbody.
6. The feasibility of monitoring the success of restoration or conservation efforts in the waterbody.
7. The economic and environmental feasibility of accomplishments or restoration or conservation goals.

Local Planning for Water Quality Protection. Recent Florida legislation focuses on local government planning to (among other things) reduce poison runoff. Local governments in Florida are developing new Comprehensive Plans under the requirements of this legislation.[22] This planning process involves regional and state review of *local* Comprehensive Plans for conformance with *regional and state* plans, and with legislatively mandated local planning requirements.[23]

Localities whose plans are not approved at the state level become ineligible for certain funds, grants and revenue sharing.[24] Substantially affected local parties, including other local governments, also have the right to bring civil suits when local actions do not conform to requirements called for in local Comprehensive Plans.[25] While the state, regional and local planning process goes beyond water quality issues, several of Florida's planning requirements either directly or indirectly affect the way in which pollution is controlled at the local level. The minimum criteria for review of local plans are provided in Appendix A. Table 10-2 lists the components of local plans reviewed by the state agencies.

In addition to its substantive provisions, Florida's new Comprehensive Plan review process also includes important organizational and enforcement provisions. For example, Comprehensive Plans must be made internally consistent and must be coordinated with regional and state agencies.[26] Localities must identify and determine the effectiveness of all existing coordination mechanisms, including the subject areas covered, the nature of the relationships and the responsible offices.[27] Means for providing effective intergovernmental coordination must be identified.[28] Proposed growth and development in areas of concern must be identified and compared to comprehensive regional plans[29] to determine the needs for additional coordination.[30]

Comprehensive Plans must account for the impacts of a locality's proposed development upon other localities, the region and the state.[31] They must allow for "resolving conflicts with other local governments through the regional planning council's informal mediation process" and the "consistent and coordinated management" of multijurisdictional bays, estuaries and harbors.[32]

State and Regional Review of the Water Quality Implications of Local Plans: A Multi-Agency Task. The state Department of Community Affairs is responsible for assuring that local plans comply with general planning requirements, regional plans as well as the state comprehensive plan (SCP).[33] Also, relevant state agencies must assist the Department of Community Affairs in reviewing local plans for compliance with both general planning requirements and specific agency plans.[34] This can be a resource-intensive task. For instance, the Department of Environmental Regulation has approximately 12 full-time equivalent positions devoted to evaluating just the water quality implications of each local Comprehensive Plan.[35] Currently, these reviews are based only on general review criteria, and rely heavily on personal knowledge and judgment.[36] However, as resources, expertise and information increase, plans will be reviewed in more detail for their possible impacts on water quality in general and water quality standards in particular.[37]

VOL 12

7225

Summary. Florida's planning process is new and largely untested, and significant organizational problems still exist. Conflicts are caused because political boundaries do not conform to hydrologic ones,[38] and because water management districts sometimes do not coordinate activities with Regional Planning Councils and the DER.[39] It is too early to determine how these problems will be addressed.[40] But efforts are underway to improve coordination between the DER and the water management districts and to give DER an even stronger leadership and oversight role in water quality planning.[41]

But despite the unanswered questions and the problems associated with Florida's program, important progress already has been made. The tools have been established for comprehensive control of poison runoff, including local involvement in stormwater and groundwater management and environmental protection through land use planning, as well as regional and state coordination, oversight and leadership.

Minnesota: Local Water Quality Management Planning and Conflict Resolution

While Minnesota does not have a *mandatory* local, regional and state water quality planning process like Florida's, it does have a voluntary program that allows county governments to address poison runoff comprehensively and to enlist the participation of localities—all with a mechanism for effective oversight by the state.[42] Many counties (over 50) have undertaken this planning process, grouped into 6 regional areas for purposes of coordination within watersheds.[43] Under the Comprehensive Local Water Management Act (Minnesota Statutes, Chapter 110B) and its implementing regulations, Minnesota's planning process is administered and coordinated at the state level by the Board of Water and Soil Resources (BWSR).[44] The Board also has responsibility for conflict resolution, plan review and technical assistance.[45]

Local Water Quality Planning: A Method for Local Participation in Statewide Water Quality Protection. Each county that chooses to participate in the planning process must agree to meet the legal requirements of the act and review water and

VOL 12

7226

R0040534

related land resources plans for consistency with the comprehensive county water plans.[46] County governments must agree to exercise the authority needed to implement the plan.[47] Counties may enter into formal agreements with other counties to prepare comprehensive water plans under a joint powers agreement (Minnesota Statutes 471.59) and may delegate all or part of their authority to prepare the plan to a local unit of government, a regional development commission or resource conservation and development committee.[48]

A county, after adopting a resolution requiring the development of a plan, must inform all of the relevant governmental entities of its decision. Relevant entities include contiguous counties (and local subunits); watershed districts and watershed management organizations that have overlapping jurisdictions; the regional development commission, if any; and the state Board of Water and Soil Resources).[49]

A comprehensive water plan must meet several requirements defined in the law. Specifically, it must:

1. cover the entire county;
2. consider the entire watershed and principal groundwater systems;
3. be based on established economic and environmental principles;
4. be consistent with other water plans in the watershed and groundwater system; and
5. apply at least through 1995, and be updated routinely.[50]

Plans must describe eight specific areas. The scope of a local water plan is given in Table 10-3.

In addition to these substantive requirements, local water plans also must take into account surrounding localities and the efficient allocation of human and financial resources. These minimum requirements are provided in Table 10-4.

Table 10-3
Scope of the Minnesota Comprehensive Local Water Plan[1]

1. The physical environment and expected changes to it

[2] To provide consistency, data must meet the collection and identification guidelines of the Minnesota State Planning Agency (including map scales) and data of value to the state or other localities must be integrated into state land management information systems. Minn. Code Agency R. Ch. 9300.0040 (1987).

The Minnesota Comprehensive Local Water Management Act establishes a valuable planning process by which counties can address water pollution from diffuse sources. Perhaps the Minnesota Act's most significant progressive feature is the legal *authority* it grants to counties. Counties, municipalities and townships have the authority to raise taxes to pay for the development and implementation of comprehensive water plans.[51] The availability of a funding source greatly increases the prospects for success. Also significant is the Minnesota law's formal coordination and conflict resolution process covering the state, regional and local governments. Finally, the law requires that public participation be ensured during plan *development* as well as *implementation.*[52]

Table 10-4
Implementation Program for Minnesota Comprehensive Local Water Plans*

1. The plan must state how and when it will be implemented to meet the required objectives.
2. The implementation program may include data collection programs, educational programs, capital improvement projects, project feasibility studies, enforcement strategies, amendments to existing official controls and adoption of new official controls. If no action is to be taken to address identified problems or opportunities, the plan must explain why actions are not needed.
3. Staff and financial resources needed to carry out the plan must be identified.
4. The plan must state the time in which each of the actions contained in the implementation program will be taken.
5. If a county has made an agreement for the implementation of the plan (or portions of the plan) by a local unit of government within the county, that local unit must be specified, the responsibility indicated, and a description included of how and when the implementation will happen.
6. If capital improvement projects are proposed to implement the comprehensive water plans, the projects must be described in the plan. This description must include the following information:
   a. the physical components of the project, including their approximate size, configuration and location;
   b. the purposes of the project and their relationship to the objectives of the comprehensive plan;
   c. the proposed schedule for project construction;
   d. expected federal, state and local costs;
   e. the types of financing proposed, such as special assessments, ad valorem taxes, and grants; and
   f. the sources of local financing proposed for the project, such as subcounty, countywide, or multicounty.

Plan Approval and Implementation: The Local Authority Needed to Address Poison Runoff. The BWSR will distribute copies of the plan to relevant state agencies and will determine if the plan is consistent with the requirements of state

VOL 12 7229

law as well as with other comprehensive water plans wholly or partially within affected watershed units or groundwater systems.[53] After a plan is approved, local units of government must amend existing water and land use plans accordingly, using the recommendations of the county board.[54]

When the county begins to implement its water plan, it has additional authority to carry out the plan. This includes the authority to:

1. regulate water and land use in municipalities (independent cities) under certain circumstances;

2. acquire real and personal property needed to implement the plan and assess the costs of projects upon benefitted property within the county;

3. establish user charges for projects conducted under the auspices of the plan; and

4. establish special taxing districts within the county and issue bonds for the purpose of financing capital improvements.[55]

Informal and formal procedures are created by the Minnesota law to identify and to resolve any conflicts between the county water plan and local units of government within the county preparing the water plan; contiguous counties; and water management organizations, watershed districts, and joint powers boards sharing jurisdiction over watershed units and groundwater systems affected by the plan.[56] The law provides for an initial conflict resolution meeting, with the chair of the BWSR in attendance to resolve disputes informally. If a conflict cannot be resolved informally, then formal, binding conflicts resolution, with the BWSR acting as the final arbiter, is available.[57] Statutory conflict resolution procedures are in place to adjudicate any disagreements that may arise *after* the plan has been approved and adopted.[58]

After the plan is completed, it must be submitted to a host of governmental entities for review, comment, and in some cases, approval. These include:

1. all local units of government wholly or partly within the county;

2. all applicable regional development commissions;

3. contiguous counties and water management organizations; and

4. other counties, watershed districts, intercounty joint powers boards, and watershed management organizations that are within the same watershed unit or groundwater system as the county preparing the plan, and that may be affected by the plan.[39]

A public hearing must be held before the plan is submitted for state review (along with comments and associated changes to the proposed plan).[40]

Summary. Local water planning in Minnesota has been greatly enhanced by the comprehensive Local Water Management Act. A framework for state and regional participation and technical and financial assistance in local efforts to improve water quality is firmly in place. However, since very little money has been appropriated to encourage local water planning, the program's voluntary nature could discourage participation and result in a poor application of the planning requirements if citizens or public officials refused to raise funds through local taxation.[41] This problem could be overcome by increased state funding or by making the local planning effort a mandatory process, as it is in Florida.

Other Examples of Effective Institutional and Organizational Structures

Puget Sound: An Intra-State Regional Approach Providing for Oversight and Local Government Involvement. The Puget Sound Basin, in western Washington State, is a complex ecoregion consisting of a large fjord-like estuary, numerous bays, sub-basins and straits connecting the estuary to the Pacific

Ocean.[62] The basin has 2000 miles of inland marine shores, is drained by over 10,000 rivers and streams, and contains over 2.9 million people.[63] Recognizing the serious increases in pathogenic, toxic and sediment and nutrient-related water pollution in the Sound, the state legislature established the Puget Sound Water Quality Authority (PSWQA) to develop a plan to improve the management of the aquatic resource.[64] Nonpoint source control is an important component of this plan.

The most innovative aspects of the controls in the Puget Sound area are proposed in the Puget Sound Water Quality Management Plan.[65] The PSWQA recognized that existing programs for controlling particular poison runoff problems (agricultural, urban, etc.) were inadequate because they were voluntary, underfunded, poorly coordinated and not applicable to the full range of sources.[66] In response, the PSWQA established a cooperative local watershed planning process that uses existing and new *state* programs to address problems that require *statewide* control.[67]

The Plan calls for priority watersheds to be chosen by the State Department of Ecology (DE) based on nominations made by local governments, state agencies, environmental, public interest and agricultural organizations and others.[68] Using guidelines developed by the PSWQA, counties then identify and rank all watersheds for the development of future watershed action plans and submit the results of those rankings to the Department of Ecology.[69] The general public and affected individuals must be involved in this process through a separate citizen advisory committee, or by direct inclusion on the committee prioritizing the watersheds.[70] The committee must submit maps showing "watershed boundaries, identification of probable nonpoint sources, identification of all local jurisdictions and special purpose districts with territory within the boundary of each watershed, and identification of all affected tribes."[71] Objective criteria are used by county committees in selecting priority watersheds.[72]

PSWQA, with direct assistance from relevant state agencies, must prepare guidelines for use by watershed management committees in developing watershed action plans.[73] The county or counties within the priority watershed must convene a watershed management committee consisting of all affected political jurisdictions and special purpose districts.[74] Planning and implementation agencies for each pollution source within the watershed must be selected based on the territory governed, legal authority, and expertise.[75] If a lead agency cannot be agreed to internally, then DE, in consultation with the watershed ranking committee, can choose one.[76] The lead agency is responsible for:

1. convening meetings;

2. coordinating activities among local jurisdictions and other agencies;

3. assisting planning and implementation agencies in plan preparation;

4. compiling and publishing the plan; and

5. submitting the plan to DE for approval.[77]

Various programs provide grant funds and technical assistance for the development and implementation of the watershed plans.[78]

PSWQA encourages localities to strengthen the enforcement of water quality law by providing matching funds to counties, cities and local health agencies to improve investigations and prosecutions.[79] Localities are encouraged to use existing legal authority (*e.g.*, police power, health authority) to adopt ordinances or regulations that address farm practices, on-site septic systems or other local nonpoint sources.[80] State guidelines have been provided for controlling agricultural (mainly animal confinement and grazing), urban (including on-site septic systems and stormwater), and silvicultural pollution sources.[81]

An important aspect of the watershed action plan is its essentially mandatory nature. If local governments refuse to prepare plans, then the lead state agency either will prepare and implement the plans itself or will use its regulatory authority to direct localities to undertake the planning process.[82] This is an important feature since it is estimated that as much as half of the cost of implementing water quality improvement activities will be borne by local governments.[83]

Colorado: A Regulatory Framework for Regional Point-Nonpoint Pollution Trade-Offs. Colorado has devised an innovative planning framework to protect a drinking water reservoir from the threats of phosphorous contamination and eutrophication. Through the direction of the Northwest Council of Governments, local governments have developed a mechanism for allocating inputs of phosphorous to the Dillon Reservoir from point and nonpoint sources, instead of increasing phosphorus loads by competing for permits to increase sewage discharges.[84] Colorado allows a program trade-off or exchange of additional point source loadings if offset with reductions in loadings of poison runoff while still meeting target load reductions.[85]

The strategy was developed through modeling efforts that indicated the level of controls needed to meet a phosphorus standard of 7.4 micrograms/liter.[86] State officials maintain point source controls on POTWs, while local governments, bound together in an organization called the Summit Water Quality Committee, control existing poison runoff under the land use and zoning authority of the member localities. All new development must maintain stringent controls.[87] The general program structure is established in regulations by the State Water Quality Control Commission:

1. a wasteload allocation distributes phosphorus loading among point source dischargers based on annual loadings and a water quality standard of 7.4 micrograms/l;

2. point source dischargers are limited in terms of allowable concentration;

3. the state water management agency implements the point/nonpoint trading system through the NPDES permit program–for every 2 kilograms of nonpoint source phosphorus removed, 1 kilogram of phosphorus credit is

added to the point source annual limit (the 2:1 ratio serves as a safety margin).

4. NPDES permits must contain, at a minimum, the following provisions:
   a. a record of the point source credit amount;
   b. construction requirements for the point source control devices;
   c. monitoring and reporting requirements; and
   d. operation and maintenance requirements for the nonpoint source controls.

5. the credit program is not allowed to begin until regulations for controlling phosphorus from new nonpoint sources are implemented; and

6. both point source discharges and nonpoint source controls are mandatory parts of NPDES permits.[88]

As part of the process, the Summit Water Quality Committee:

1. identifies sites for nonpoint source control devices;

2. distributes phosphorus credits gained from the nonpoint source controls;

3. monitors streams, lakes, the nonpoint source controls, and point source discharges;

4. develops septic tank control programs; and

5. collects, from member jurisdictions, the revenues needed to operate the committee, to monitor the program and to construct, operate, and maintain nonpoint source controls.[89]

This program allows growth while providing an institutionalized, multijurisdictional system to establish and enforce the controls needed to maintain water quality standards.[90]

The Denver Regional Council of Governments developed a similar plan to halt the accelerated eutrophication of Cherry Creek Reservoir.[91] The Council used modeling to determine the phosphorus standard needed to reverse eutrophication in the lake.[92] It then developed a management plan based specifically on controls needed to achieve this standard. Because increased urbanization without adequate control of poison runoff would lead to a violation of the standard, a master plan was developed that required a basinwide reduction of at least 50% of yearly phosphorus loads.[93]

Similar to the Dillon Reservoir Program, the phosphorus management program is implemented by a Basin Authority created by an intergovernmental agreement that consists of counties, municipalities, and the water and sanitation districts that operate the wastewater treatment plant.[94] The Authority is responsible for constructing, financing and operating the nonpoint source controls. Under the program, local governments are required to adopt BMPs, which include erosion control ordinances, uniform drainage criteria, and septic system performance standards.[95] Detention, retention and filtration methods also will be used to accomplish a minimum goal of 50% reduction in diffuse phosphorus loadings.[96] After this goal is met, point-nonpoint trading, similar to that described above, can take place.[97]

The point-nonpoint pollution tradeoff programs developed to protect these two reservoirs in Colorado illustrate the technical innovation, program efficiency and funding sources that come from state leadership and cooperation between localities. These programs demonstrate that local governments and groups with competing interests (*i.e.*, point versus nonpoint polluters) can work together to address common water quality problems.

U.S.-Canada Great Lakes Water Quality Agreement. Contamination problems from nonpoint sources respect neither state nor international boundaries. While poison runoff must be controlled by individual states, localities and landowners, a framework for approaching interstate or international problems is essential. States have the authority to compel localities to act, but interstate and international lines of authority are far less clear cut.

It is important, therefore, that international and interstate water quality agreements be developed that provide mechanisms to hold member states and countries accountable for the commitments each has made. Otherwise, good intentions and will not be translated into tangible results.

The 1987 WQA provides a mechanism for convening interstate conferences to address interstate nonpoint source pollution impacts,[98] although it does not indicate how agreements between states should be structured. Recent (1987) amendments to the U.S.-Canada Great Lakes Water Quality Agreement illustrate how leadership, oversight and control can be established at either the multi-state or multi-national level.

Article VIII of the 1987 amendments establishes the responsibility of the United States and Canada, in cooperation with their respective state and provincial governments, to designate specific geographic Areas of Concern. For each Area of Concern, Remedial Action Plans (RAPs) must be developed that define the environmental problems to be addressed, including the beneficial uses that are impaired, and the degree and geographic extent of impairment.[99] The Agreement defines the terms "Areas of Concern" and "Impairment of Beneficial Use(s)."[100] The Plans must employ a "systematic and comprehensive ecosystem approach to restoring and protecting beneficial uses in Areas of Concern or in open lake waters."[101] In addition, RAPs must also include:

1. a definition of the causes of the use impairment, including a description of all known sources of pollutants involved and an evaluation of other possible sources;

2. an evaluation of remedial measures in place;

3. an evaluation of alternative additional measures to restore beneficial uses;

4. a selection of additional remedial measures to restore beneficial uses and a schedule for their implementation;

5. an identification of the persons or agencies responsible for implementation of remedial measures;

6. a process for evaluating remedial measure implementation and effectiveness; and

7. a description of monitoring activities to track program effectiveness.[102]

The International Joint Commission (IJC), the quasi-judicial body charged by the United States and Canada with monitoring progress under the Agreement, reviews and comments on RAPs at three different stages: when the problem is defined; when remedial and regulatory measures are selected; and when monitoring indicates that beneficial uses have been restored.[103]

In addition to specific Areas of Concern and associated RAPs, Lakewide Management Plans for specified critical pollutants must be prepared.[104] The Agreement also establishes minimum contents for the plans and gives the IJC the responsibility to review and comment on them.[105]

A separate section on nonpoint source pollution was added to the agreement in 1987 (Annex 13). This section requires the identification of "land-based activities contributing to water quality problems described in Remedial Action Plans for Areas of Concern, or in Lakewide Management Plans...."[106] In addition, watershed management plans must be developed and implemented. The United States and Canada (in conjunction with State and Provincial Governments) must:

> develop and implement watershed management plans, consistent with the objectives and schedules for individual Remedial Action Plans or Lakewide Management Plans, on priority hydrologic units to reduce non-point source inputs. Such watershed plans shall include a description of priority areas, intergovernmental agreements, implementation schedules, and programs and other measures to fulfill the purpose of this Annex ... Such measures shall include provisions for regulation of non-point sources of pollution.[107]

Annex 13 also calls for "programs and projects" designed to estimate diffuse loadings to rivers and to the boundary waters of the Great Lakes; the changes in land uses and land use management practices from control programs; and the resulting reductions in pollution loadings.[108]

Annex 16 requires the identification of existing and potential sources of contaminated groundwater entering the Great Lakes and the hydrogeologic conditions near the sources of contamination.[109] Standard sampling and analysis procedures must be developed to assess the degree and extent of contamination, and to estimate the loadings of groundwater contaminants to the Lakes.[110] When the problem has been identified, the sources of contamination must be controlled.[111]

The U.S.-Canada Great Lakes Water Quality Agreement establishes the consistency, coordination and oversight mechanisms that are essential in environmental management efforts of such size and technical and political complexity. Of course, the success of particular management efforts cannot be assured by such a framework since actual field level control mechanisms are not dictated by the Agreement. Still, the GLA is an important example of multi-national and multi-state planning through which the state and local approaches discussed previously could be implemented.

Conclusions and Recommendations

While none of the individual examples described above incorporates *all* of the institutional and organizational needs identified in this chapter, each one illustrates innovative and effective mechanisms for addressing particular problems. Taken together with the program aspects discussed in Chapter Ten, these examples can be used as the basis for developing state nonpoint source programs with the essential institutions, management capacity, and organizational relationships.

For instance, Minnesota provides an elaborate (although voluntary) local planning procedure for water quality protection. The Minnesota Planning Procedure could be incorporated into a mandatory state, regional and local planning process like the one in Florida. The Puget Sound mandatory watershed planning process also could be a model for local planning requirements. The Minnesota conflict resolution methods could be used to

VOL 12

7239

R0040547

address the inevitable local disagreements that would arise from such a mandatory program.

The regional water quality planning offered through the U.S.-Canada Great Lakes Water Quality Agreement, Florida's SWIM program and Wisconsin's Nonpoint Source Pollution Abatement program provide the regional context (both inter- and intrastate) needed to ensure state leadership and expertise, as well as consistency, in the development of control programs. The technical and financial assistance authorized through the programs in Minnesota, Wisconsin and Puget Sound provide the motivation and opportunity for localities to prepare effective and innovative plans. Of course, the attainment or maintenance of water quality standards should be incorporated into all of these state programs.

The important institutional and organizational aspects of a program to control poison runoff can be summarized as follows:

1. All jurisdictions that contribute poison runoff to waters should be *required* to participate in control efforts if water quality standards are not being met.

2. Localities should be required to address water quality problems within their own jurisdictions through their comprehensive plans, but this should be a subset of a coordinated watershed-wide effort.

3. Local control programs should constitute the major field-level activity, with regional and state levels providing criteria and requirements for program development, technical assistance, funding, conflict resolution, evaluation, and program approval or disapproval.

4. All involved local governmental units and affected local interests (*e.g.*, agriculture, environmental) should develop a single plan to be reviewed and approved at the regional or state level.

5. Binding conflict resolution mechanisms that base decisions on the objectives of the water quality plan (and adverse

VOL 12

7240

R0040548

economic and social impacts) must exist at the state or regional level.

Notes - Chapter Ten

1. Potter, Harry, "Inter-Organizational Relations, Constituencies and Nonpoint Pollution Policy," Proceedings of the Conference on Political, Institutional and Fiscal Alternatives to Accelerate Nonpoint Pollution Programs, Milwaukee, Wisconsin, December 7-9, 1987, at 12; Viessman, Warren, Jr., "Regional Options for Managing and Regulating Nonpoint Pollution," Proceedings of the Conference on Political, Institutional and Fiscal Alternatives to Accelerate Nonpoint Pollution Programs, Milwaukee, Wisconsin, December 7-9, 1987, at 1.

2. *See* Veissman, 1987, *supra* note 1, at 2-4.

3. See Chapter Nine for a discussion of the best lead agency for effective poison runoff control.

4. For example, some of these functions include data collection and analysis by regional water management agencies; design of management approaches; evaluation of the economic and social impacts of particular poison runoff control programs by SWCDs, and review of local Comprehensive Plans by state agriculture agencies. *See, e.g., Virginia Groundwater Protection Strategy Steering Committee, Final Report*, 1987; Puget Sound Water Quality Authority, *Puget Sound Water Quality Management Plan*, 1987. One tried-and-true approach to statewide coordination is to establish a Standing Advisory Committee of representatives from relevant state agencies. This has been done in the past to achieve effective groundwater protection planning at the state level, and some states already have used such committees for nonpoint source management programs. These Standing Committees should include a balance of state, regional and local officials, academicians, and environmental, industrial and other interested parties.

5. However, state and federal oversight is vital in encouraging and requiring effective local controls. Rogers, Peter and Alon Rosenthal, "The Imperatives of Nonpoint Source Pollution Policies," Proceedings of the Conference on the Political, Institutional, and Fiscal Alternatives to Accelerate Nonpoint Pollution Programs, Milwaukee, Wisconsin, December 7-9, 1987, at 28-32

6. *Id.*; Veissman, 1987, *supra* note 1, at 3.

7. For the purposes of this diagram SWCDs are considered local governments, even though technically they are usually units of state government.

8. Regional offices of the state WQM agency may need to be interposed between the statewide agency and other state-level agencies, since these regional water quality managers represent the central state WQM agency within particular geographic areas.

9. The use of general planning and water quality standards in Florida poison runoff control programs is also described in Chapter Nine.

28. Fla. Admin. Code 9J-5.015 (1986). These methods include intergovernmental agreements, joint planning and review agreements, special legislation and joint meetings or work groups. Fla. Admin. Code 9J-5.015(3) (1986).

29. *See* Fla. Stat. § 186.507 (1985). Florida law also requires the development of 11 comprehensive regional plans. *See generally* Fla. Stat. §§ 186.507-508 (1985); Fla. Admin. Code 27E-1 - 27E-4 (1986). The Comprehensive Regional Policy Plans (CRPPs):

> play a pivotal role or link between the State Plan and the Local Government Comprehensive Plans because local plans are required to be consistent with the [State Comprehensive Plan] and the appropriate CRPP. The CRPPs represent a further step in implementing the SCP, as well as a compiling and balancing the needs of local jurisdictions. It is this juxtaposition between the top down planning and the bottom up planning that makes these plans unique and essential. The CRPPs must implement the State Plan by reflecting and furthering its goals and policies from a regional perspective. The CRPPs are to be plans for the region; *i.e.*, a regional approach toward implementing the [State Comprehensive Plan].

SUMMARY

Criteria for Evaluating Programs to Control Poison Runoff

This report described ways for states and localities to control poison runoff from cities, farms, mines, logging operations, and a range of other sources. In most cases, the report draws on actual programs that are being implemented today by state and local governments around the country.

The ultimate goal of any state or local water pollution control program is to achieve compliance with water quality standards – to make rivers, lakes, and coastal waters safe for fishing, swimming, drinking and other uses. By combining the best examples of program elements discussed above into a comprehensive management effort, state and local governments *can* develop a good set of tools to address poison runoff. And proper implementation and enforcement of such a program should result in the attainment of water quality goals.

None of the examples cited in the report, *taken alone*, will suffice to achieve water quality goals. Nor are the examples given the *only* viable options to control poison runoff. Indeed,

R0040557

we hope that these successful examples are just the beginning—that newer and even more effective options will be developed as state and local governments attack poison runoff with more vigor. And specific program components necessarily will differ according to physical, political and economic differences in various regions of the country.

However, the basic principles demonstrated by these examples define the minimum, essential elements of an effective poison runoff control program. Even if the specific examples are rejected or modified, any control program that follows the basic principles discussed in this report, along with vigorous implementation and enforcement, should go a long way to address the complex and ubiquitous problem of poison runoff.

The specific recommendations in this report were divided into two main sections. First, we described the key *components* of good programs: ways to control specific types of pollution from agriculture, contaminated urban runoff and other land uses effects, silviculture, mining and grazing; and ways to implement these controls through adequate data collection and use, funding, and use of legal tools. Next, we described how to combine the building blocks into an effective, comprehensive program.

The following summary distills these specific recommendations into a checklist of criteria for programs to control poison runoff. These recommendations establish basic program goals. But they allow flexibility for states and localities to address specific problems in different ways.

This checklist can be used by various entities in different ways. State and local officials, both legislative and executive, can use them to develop and implement effective programs. State and federal officials can use them to evaluate the completeness and efficacy of local and state programs, respectively. Citizens can use them to evaluate the effectiveness of existing and proposed programs to control poison runoff, and to participate effectively when opportunities are provided for public comment.

Following the format of the report, first we outline basic principles applicable to the individual components of a good program. Next, we summarize the key principles that govern the assembly of the components into an effective overall program to control poison runoff.

Components of an Effective Program*

Agricultural Issues

1. If the state relies primarily on cost sharing in agricultural pollution control, is farmer participation (and funding) sufficient to ensure compliance with water quality standards?

2. Where voluntary programs alone do not suffice to meet water quality standards, are other controls, such as design standards and design taxes, used significantly to address agricultural pollution?

3. Is pollution from agricultural chemicals (including fertilizer and pesticides) addressed independent of programs designed primarily to reduce soil erosion? Do programs reduce agricultural chemical pollution by:
   a. controlling the amount and manner of chemical use; and
   b. requiring forested riparian buffers?

4. Do controls on livestock agriculture:
   a. apply regardless of size?
   b. preserve riparian areas?
   c. limit land application of collected manure and urine?
   d. provide for enforcement of livestock controls based on mandatory inspections and penalties rather than relying on citizen complaints?

5. Is pollution from irrigation water addressed by programs designed to decrease water use through rules developed by a comprehensive irrigation district or similar entity?

* Obviously, some specific recommendations may not apply to every program in every area. While these criteria define the basic elements of good programs to control poison runoff, a complete analysis of a particular program should be based on the more detailed criteria provided in the body of the report.

VOL 12

7251

6. Do state programs to control poison runoff exploit state and regional agricultural trends and use economic development policies to encourage less polluting or more easily controlled operations (*e.g.*, marketing assistance for hobby farmers, fruit growers and specialty crops; economic assistance in developing regional facilities for manure marketing)?

7. Is a comprehensive farmland preservation program available at the state level?
   a. Does the program require that landowners in the program address agricultural pollution adequately (cross-compliance)?

Land Use and Urban Issues

8. Is water quality a mandatory consideration in the development of local land use plans and controls?

9. Do local governments have the authority to develop controls more stringent than those required at the state level where conditions warrant?

10. Is state review of urban pollution control programs required in areas contributing to the nonattainment of beneficial uses to determine if load reduction needs in particular watersheds will be achieved?

11. Does the state require that polluted urban runoff be controlled through local ordinances (or other means) that are designed to address all urban contaminants, including toxics?
    a. Are stormwater controls administered through a utility or similar entity that conforms to hydrologically defined boundaries?
    b. Is state review of local stormwater ordinances and enforcement of minimum regulatory requirements mandatory?

12. Is an effective erosion and sediment control ordinance required at the local level?
    a. Is the state required to review the adequacy of local programs based on clear and appropriate criteria, and does the state retain the right to administer those local programs not meeting minimum state requirements?

13. Are coastal zone management programs integrated fully with the specific goals and requirements of the state nonpoint source management program?
    a. Are local development proposals reviewed and approved, denied or modified based on their impacts on state water quality standards, considering the cumulative effects of development within the coastal region?

Silvicultural, Mining and Rangeland Issues

14. Are effective state regulatory mechanisms available to control the water quality impacts of silviculture, including enforceable requirements to implement prescribed BMPs and to comply with state water quality standards?

15. Are individual timber proposals reviewed for compliance with the state program within the context of a long range planning effort?
    a. Does the plan ensure that water quality standards will be met given the cumulative effects of timber harvesting within individual watersheds?
    b. Do state officials coordinate the state forest practices program with U.S. Forest Service regulation of silviculture in National Forests?

16. Does the state Forest Practices Act require adequate inspection and enforcement, by multi-disciplinary teams of silvicultural, water quality and fish and wildlife experts, to ensure that minimum state standards are met?

17. Do programs to control poison runoff from mining specify compliance with particular design and performance standards to divert runoff, stabilize and reclaim land during

VOL 12

7253

and after mining operations, and collect and treat contaminated runoff? Are these standards designed specifically to meet water quality standards?

18. Do mining regulations ensure compliance through regular, detailed inspections, compliance and stop work orders, fines and performance bonds?

19. Is an abandoned mine fund available for reclamation purposes; used only in cases where responsible parties cannot be located; and operated according to a specified environmental priority list?

20. Are the program officials who control poison runoff from private mines also involved in overseeing the activities of Bureau of Land Management and Forest Service regulators to control mining on federal lands?

21. Are programs to control the water quality impacts of grazing integrated with similar efforts for federal lands into a comprehensive set of plans to achieve water quality standards within individual rangeland watersheds?

22. Do these grazing plans protect water quality and riparian habitat by controlling livestock densities, location and access to riparian areas? Do the plans ensure adequate upland forage and ground cover, and diverse native plant species?

Data Collection and Use

23. Do monitoring activities provide adequate trends data to measure changes in the long term impacts of poison runoff?

24. Within hydrologic units, are data used to identify problems, set priorities, establish pollutant load reduction goals, justify program intervention and develop controls based on their ability to achieve those load reduction goals?

VOL 12

7254

Funding

25. Are significant funding sources other than general revenues available for control of poison runoff?

26. Is the polluter expected to bear some or all of the costs of any cleanup or protection program, through such mechanisms as permit fees, resource extraction or use taxes, or design taxes?

27. Are funding mechanisms combined with financial incentives to modify or to eliminate practices that cause water pollution?

Legal Tools

28. Does the state have explicit statutory authority to require local governments and citizens to participate in control programs as an ongoing part of state efforts to achieve compliance with water quality standards?

29. Does state law require effective stormwater and erosion and sediment control programs that provide for mandatory state review and approval of any locally adopted programs?

30. Does state law provide that:
    a. noncompliance with the requirements of a nonpoint source program constitutes unreasonable conduct for purposes of nuisance suits?
    b. violations of water quality standards presumptively harm downstream uses?

Developing a Comprehensive, Coordinated Program

Driving Programs With Water Quality Standards

31. Are state water quality standards in place for all of the important pollutants associated with poison runoff?

VOL 12

7255

32. Are programs to control poison runoff designed explicitly to comply with water quality standards and to achieve specific pollution reduction goals?

33. Does the state water quality management agency play a lead role in ensuring that water quality standards are used in developing and enforcing nonpoint source programs in specific watersheds?

Comprehensive Planning and Management

34. Are specific plans to control each source of poison runoff integrated and carried out within a single "watershed plan" tailored to individual, well-defined hydrologic units (watersheds) of reasonable size?

35. Is there a comprehensive institutional mechanism to ensure coordination among local, regional, state and interstate efforts to control poison runoff?

36. Does the state exercise oversight and leadership, through enforceable conflict resolution measures, to ensure that local politics do not compromise control needs?

37. Are state water quality goals (*i.e.*, attainment of water quality standards) required elements of regional and local pollution control programs and economic development programs?

These principles can be applied to any state or local program to control poison runoff. Application of these principles can identify program strengths, weaknesses, and gaps, and can lead to specific recommendations for improvement. The following case study applies these principles to the Nonpoint Source Management Program submitted to EPA by the Commonwealth of Virginia under section 319 of the Clean Water Act.

VOL 12

PART FOUR

A Case Study in Poison Runoff Control

Pollution from Virginia contributes significantly to the decline of the Chesapeake Bay and other waters. Significant water quality problems in the Bay from nutrient and toxic pollutants are attributed to land management practices in Virginia.[1] According to state figures, poison runoff in Virginia impairs, or threatens to impair, the beneficial uses of 4294 miles of freshwater rivers and streams and almost 500 square miles of estuarine waters.[2]

In recent years Virginia has increased its focus on efforts to combat this poison runoff. Recently Virginia has established an office of the Secretary of Natural Resources and a Department of Waste Management. Increased funding is now being devoted to this effort: The Appropriations Act for 1988 provided budgets of $5.6 million for FY 1989 and $5.3 million in FY 1990 to address poison runoff from construction sites, agriculture, urban

[1] U.S. EPA, *Chesapeake Bay: A Framework for Action*, September, 1983, at 60-66. 109-110.

[2] Virginia Department of Conservation and Historic Resources, *Virginia Nonpoint Source Assessment Report*, April 1, 1988, at i-ii.

areas and other sources.[3] This figure is substantially higher than in previous appropriations.[4] And Virginia has participated in the highly visible Chesapeake Bay Program—a coordinated regional effort to clean up the nation's most productive estuary.

Because of the pervasive nature of poison runoff—and the complexity of solutions—establishing and running effective control programs will test the mettle of Virginia's politicians, agency officials and citizens. Virginia citizens and public officials accepted this major challenge with the submission of Virginia's § 319 Nonpoint Source Management Plan. They signified their belief that it is possible for state, regional and local government, as well as the general public, to band together to control poison runoff, to revive and maintain the health of Virginia's rivers, lakes and estuaries, and to do Virginia's part to restore the health and productivity of the Chesapeake Bay.

Given this belief and commitment, it is logical that the state choose those strategies and methods that will lead to an effective control program. This case study evaluates the efficacy of Virginia's CWA § 319 Nonpoint Source Management Plan in light of the principles and examples provided in the preceding report.

A Case Study: Virginia Nonpoint Source Management at the Crossroads

Introduction

This case study evaluates the Virginia proposed Nonpoint Source Management Plan[1] using the questions and basic principles provided in the preceding report. Wherever appropriate, Virginia's unique environmental, political and other circumstances and conditions are taken into account.

This case study is divided into two main sections. The first section summarizes[2] the existing and proposed state program for addressing poison runoff. The second section evaluates this program based on material specific to Virginia and by applying the general criteria and recommendations discussed earlier. Some aspects of Virginia's program also may serve as additional models for other state programs. These notable aspects of Virginia's program will be highlighted where appropriate.

Nonpoint Source Management in Virginia

For purposes of simplicity, Virginia's programs to control poison runoff are described using the structure provided in the state CWA § 319 Nonpoint Source Pollution Management Plan (§ 319 Plan)[3] submitted to EPA in August, 1988. After a brief introductory section, the plan addresses each specific source category of poison runoff: agriculture, forestry, construction, urban, resource extraction, land treatment and disposal (*e.g.*, hazardous waste management, septic tank permits, sewage sludge disposal) and hydrologic modification.

Virginia's Division of Soil and Water Conservation (DSWC), within the Department of Conservation and Historic Resources, developed the management plan and has "overall statewide responsibility for implementing" the plan and coordinating the activities of other agencies.[4] The overriding purpose of the program, established under the authority of the state Soil Conservation Districts Law,[5] is the "attainment of beneficial uses as measured by water quality standards compliance."[6] Priority is given to the Chesapeake Bay drainage basin in controlling both point and nonpoint sources of pollutants.

The Agricultural Pollution Management Subplan

The Virginia NPS Management Plan emphasizes the control of pollution by agriculture, which is the most significant overall source of poison runoff in the state.[7] The state General Assembly appropriated over $830,000 in FY 1984-85 and almost $1.2 million in FY 1985-86 for the state agricultural pollution control program.[8] Funds are used for a variety of purposes, including cost sharing, education, technical assistance, research and general administration. Because of the importance of the Chesapeake Bay, federal funds are provided to supplement the state effort in the Bay watershed.

The Virginia agricultural BMP cost sharing program is the centerpiece of the state's agricultural pollution control effort. Funds are allocated to state Soil and Water Conservation Districts (SWCDs) based on factors that can contribute to water quality problems (*e.g.*, intensive cropland cultivation, erosive soil conditions, and livestock numbers).[9] Within the Chesapeake Bay watershed, where most of the funds are allocated, funds to SWCDs are allocated according to their location in one of three regions classified as: intensive cropland agriculture (this area receives 50% of state Chesapeake Bay cost sharing funds); intensive livestock production (this area receives 30% of available cost sharing funds); and the general program area (this area receives the remaining 20% of funds).[10]

Through the SWCDs, farmers are encouraged to enter voluntarily into contracts with the district to implement one (or more) of the 20 state-authorized BMPs in exchange for a prescribed payment (usually a percentage of the cost of implementation or a flat rate). Program participation is induced largely through a variety of technical assistance and education activities.

State guidelines constrain SWCDs in how they implement the cost sharing program in several ways. In the Chesapeake Bay drainage area, location in the three different regions mentioned above restricts how much funding can be provided for certain types of BMPs. Districts within the cropland priority area must use at least 70% of their allocations on soil erosion BMPs while those in the animal waste priority areas must use at least 85% of their allocations for animal waste controls.[11] In districts where applications from farmers exceed available funds (a common occurrence), a cost-effectiveness formula is used to estimate which applications prevent a given amount of sediment loading to the nearest stream at the lowest cost.[12] Contracts cannot exceed $3,500 for cropland controls and $7,500 for animal waste controls.[13]

Virginia provided over $1.5 million in cost sharing funds from 1984 to 1986. During this period, in the critical Chesapeake Bay drainage, 1651 farmers enrolled over 66,000 acres in the program, reducing sediment delivery by 75,000 tons and phosphorus by 84,500 pounds. In Fiscal Year 1987-1988, $1.27 million dollars in cost sharing funds were dispersed in the Virginia program, and in Fiscal Year 1988-89, $1.23 million is available.[14] Outside the Chesapeake Bay drainage area, control efforts have focused on technical rather than financial assistance.[15] However, in Fiscal Year 1988-89, between $350,000 and $500,000 in cost sharing funds should be available for non-Chesapeake Bay drainage farms.[16]

VOL 12

7261

An important part of Virginia's effort to control agricultural pollution is the ongoing development of the "Virginia Geographic Information System" (VirGIS), which assists in the identification of lands with a high potential for sediment-related pollution. VirGIS is a computerized mapping system that incorporates data on soil, watershed, elevation, land use and ground cover, and uses equations designed to estimate the potential for sediment loadings from 1 hectare (2.47 acre) cells.[17]

Because of the inherent flexibility of geographic information systems, VirGIS has the potential to be useful in controlling poison runoff in a variety of ways. For example, it might assist in farm-level comparison of the water quality value of different BMPs.[18] But at present, Virginia uses VirGis only for state- and district-level personnel to target education and outreach programs more effectively.[19]

DSWC also provides various forms of technical assistance to SWCDs to improve the evaluation of cost sharing applications, to help farmers plan and implement BMPs, and to monitor program effectiveness.[20] DSWC and the Virginia Cooperative Extension Service (VCES) provide educational services directly to farmers in order to encourage those who normally might not participate in conservation programs to become involved in the state program to control erosion and water pollution. In 1986, for example, over 2,600 farmers who usually do not participate in government-sponsored conservation programs had personal contact with VCES personnel who discussed various aspects of the nonpoint source program.[21] In 1985, a nutrient management program was established to provide education and technical services as the primary state vehicle for addressing nitrogen pollution.[22]

The state has undertaken many demonstration and research projects. A rainfall simulator was developed to demonstrate the effectiveness of various kinds of BMPs and to collect data.[23] Over 600 people attended simulator demonstrations in 1986.[24] In 1986, a series of innovative BMPs were implemented at various sites to try out new approaches to controlling erosion and nutrient runoff.[25] Two demonstration watersheds have been selected to assess the impacts on groundwater and downstream surface water quality of implementing cropland and livestock

BMPs at all feasible sites throughout the watershed.[26] If these demonstrations prove successful, Virginia hopes to apply this approach to other watersheds in the state.[27]

Virginia's § 319 Plan contains descriptions of these and other activities to control poison runoff. A major goal of the § 319 Plan is a 40 percent reduction in the nutrient loadings to the Chesapeake Bay. This goal is derived from a commitment Virginia made, along with three other political jurisdictions, in the recently renewed Chesapeake Bay Agreement.[28] Other goals in the § 319 Plan are: reduction of erosion on all lands eroding at greater than soil loss tolerance (T) levels[29] by the year 2000; development of effective modeling and other tools to track agricultural nonpoint source loadings and to prioritize areas within the state for controls; and the provision of "effective educational and technical assistance programs which optimize voluntary implementation of best management practices."[30]

In the § 319 Plan the DSWC makes a general commitment to expand the role of VirGIS, the scope of demonstration programs and the use of educational efforts to promote the use of BMPs. The DSWC also commits to seek increases in staff and funding to provide additional assistance to SWCDs and to improve monitoring, modeling and BMP tracking capabilities.

The DSWC also pledges in the State's § 319 Plan to increase the involvement of various local, state and federal agencies in controlling poison runoff, including:

1. SCS (to develop a master statewide hydrologic subunit designation);

2. Virginia Department of Taxation (to require land enrolled under the state Use Value Assessment Law to have implemented a conservation plan to reduce erosion to below "T" values); and

3. USDA (DSWC will attempt to obtain state funds to increase per acre bids for lands to be entered into the federal Conservation Reserve Program (CRP) and to investigate the possibility of a state CRP).

VOL 12

7263

R0040571

Other activities proposed for DSWC include: investigating the establishment of a state revolving loan fund to provide low interest loans for animal waste management facilities;[31] establishing an Alternative Use Task Force to promote innovative uses of animal manure; and developing a pesticide user certification program for all DSWC and SWCD field personnel.[32]

In addition to DSWC, other state agencies are involved in the agricultural subplan. The Virginia Department of Agriculture and Consumer Services (VDACS) is responsible for coordinating the proper use, handling, storage and disposal of pesticides and pesticide containers. In the § 319 Plan Virginia commits to strengthening and expanding the concepts of Integrated Pest Management in its educational and pesticide certification programs. Also, the Virginia Cooperative Extension Service plans to increase a variety of informational and educational services for handling animal waste and using commercial and manure fertilizer nutrients.

The main federal agencies involved in the agricultural subplan are the Federal Department of Agriculture's Soil Conservation Service (SCS) and Agricultural Stabilization and Conservation Service (ASCS). In addition to SCS's own duties under federal programs such as the Agricultural Conservation Program (ACP) and the conservation provisions of the Food Security Act,[33] SCS will assist DSWC in developing VirGIS and using it to track BMP implementation within individual watersheds. After 1995, it will begin to "redirect existing staff priorities to efforts targeted strictly to water quality initiatives after 1995."[34]

In addition, SCS will seek to increase participation of Virginia farmers in the Conservation Reserve Program, with a target of enrolling 100,000 acres by 1990. The SCS commits to developing ten new watershed demonstration projects by the year 2000, including five that demonstrate animal waste management. The agency also commits to revising SCS field manuals and conservation standards and specifications to include various water quality considerations and to develop new BMPs "as necessary to achieve water quality improvements."[35]

ASCS also will undertake additional activities beyond those required under the federal ACP and the conservation provisions of the Food Security Act of 1985.[36] It will analyze and modify

VOL 12

7264

existing procedures for the ACP to address water quality problems and coordinate efforts with DSWC to provide joint or complementary cost sharing programs.

The Plan establishes a number of milestones to indicate the progress made in controlling agricultural pollution. Milestones include: nutrient analysis of 500 manure samples a year; statewide completion of the VirGIS system by 2000; statewide completion of the hydrologic unit submap by 1991; enrollment of 100,000 acres of land in the CRP by 1990; installation of 50 animal waste units and 500 nutrient management plans per year; and implementation of BMPs on 400,000 new acres of land per year.

The Urban Nonpoint Source Management Subplan

In the past, Virginia's urban program to control poison runoff focused on demonstration of urban stormwater management and erosion and sediment control BMPs to encourage their voluntary use by land developers and local government officials.[37] The CWA § 319 Urban Nonpoint Source Control Plan adds significantly to this earlier effort. Goals of the urban plan include: development of comprehensive stormwater management legislation and regulations; revision of urban BMPs to reflect innovative technologies, and their promotion through education and training programs; targeting of resources to priority urban areas, and promotion of the development of local Comprehensive Plans and zoning ordinances (and the incorporation of BMPs into land development ordinances) that provide water pollution control.

DSWC also will develop a system for estimating pollution loadings generated in urban areas and use these loadings to identify "urban priority areas." Localities will be encouraged to address poison runoff in Comprehensive Plans, to adopt BMPs in land development regulations, and to sign Memoranda of Understanding with DSWC to address these concerns.

The recently-enacted Chesapeake Bay Preservation Act[38] creates a new agency called the Chesapeake Bay Local Assistance Department (governed by an appointed Board) that must:

> promulgate regulations which establish criteria for use by local governments [in Tidewater Virginia][39] to determine the ecological and geographic extent of Chesapeake Bay Preservation Areas ... [and] ... in

VOL 12

7265

R0040573

granting, denying or modifying requests to rezone, subdivide or to use and develop land in these areas.[40]

Protection of high quality waters, prevention of increases in pollution and reduction of existing pollution are among the purposes of the criteria to be developed. Regulations must be promulgated by July 1, 1989 and Chesapeake Bay Preservation Areas must be established by July 1, 1990.

Also, recent legislation amended Virginia law specifically to allow localities to protect surface and groundwater resources with the comprehensive planning and zoning process.[41] Another amendment states that surveys and studies of groundwater and surface water and geologic factors must be part of local comprehensive plans.[42] Virginia law now states that groundwater protection areas may be designated for application of "reasonable groundwater protection measures."[43]

Besides DSWC and local governments, other actors are involved in controlling poison runoff in urban areas. Planning District Commissions (PDCs)[44] can provide technical assistance and education to localities that seek to control pollution through comprehensive planning and zoning. PDCs can become involved in coordinating or preparing "interjurisdictional watershed plans" and plans for urban priority areas (described earlier) to address poison runoff with the consent of the involved localities.

The Virginia Department of Transportation will cooperate with the DSWC to study the feasibility of using highway rights-of-way for the construction of BMPs such as detention basins. SWCDs and the SCS will provide training and education to technical staff within the agencies as well as to landowners and local officials. The Virginia Department of Health (along with local health departments) operates programs pertaining to the proper use of sewage treatment systems, the regulation of sewage at marinas and the condemnation of shellfish areas when contaminated by fecal bacteria. The state Council on the Environment is charged with the operation of the state's Coastal Resources Management Program.

Like the agricultural subplan, the state's urban subplan establishes milestones of progress against which to measure the fulfillment of these general goals. In addition to the control requirements established in recent legislation,[45] these milestones include dates for developing a proposal for stormwater management legislation, designating urban priority areas, updating the Urban BMP handbook and promoting the signing of Memoranda of Understanding between DSWC and localities in urban priority areas.[46] A variety of milestones also are spelled out for completing training, educational and demonstration activities.[47]

Erosion and Sediment Control (ESC) Subplan

DSWC administers ESC controls pursuant to the Virginia Erosion and Sediment Control Law.[48] This statute requires all counties, cities and incorporated towns to develop and implement a program to control erosion, sediment and stormwater runoff from land disturbing activities. Improving the DSWC's efforts to reduce the water pollution impacts from construction and other large-scale earth moving activities is addressed in Virginia's § 319 Plan. Specific goals in the Plan include: improving the effectiveness of the ESC regulations and controls (including implementation); increasing the knowledge and skill of those involved in the program; and achieving effective control on a minimum of 95% of regulated private construction projects by the year 2000.

DSWC plans to evaluate existing local programs to identify needed improvements, to revise ESC standards and regulations, and to seek revisions in the ESC Law. DSWC will require that state and local officials be certified as possessing minimum levels of knowledge and skill to implement the ESC program. It also will develop an educational program for state and local officials and the general public. Technical assistance will be provided to improve local plan review, inspection and enforcement capabilities. DSWC will be responsible directly for ensuring that state construction projects comply with ESC requirements.

Other state agencies, including the Virginia Department of Transportation, will seek to improve the application of the ESC program to their construction projects to provide a model of effective erosion and sediment control. The State Water Control Board (SWCB) and the Army Corps of Engineers issue permits for the discharge of fill material (often from various construction activities) into waterways under CWA §§ 401 and 404, respectively. The Virginia Marine Resources Commission (VMRC)

VOL 12

7267

issues permits for activities in state-owned wetlands and development in tidal wetlands, when there is no local wetlands board to assume this responsibility. These permits incorporate ESC practices as necessary. SWCDs and the SCS assist local governments in various aspects of their ESC programs in both official and advisory capacities.

As the central feature of the state ESC program, local governments will be encouraged by DSWC to improve their individual ESC programs in a number of respects. These include better compliance with existing statutory requirements, provision of necessary funding and personnel, improved inspection and enforcement and more extensive training and education.

Virginia expects the actions listed above to accomplish a number of tasks listed in the milestones section of the ESC program. In addition to fulfillment of existing statutory requirements, the § 319 Plan makes specific commitments to provide training seminars and other educational services; to revise the existing ESC standards; and to develop and implement a certification process for ESC officials. The Plan calls for developing a "generalized but reasonable methodology for estimating sediment load reductions" from the ESC program by July 1, 1990. Localities will identify "erosion impact areas"[49] within their jurisdictions and stabilize these areas by July 1, 1992. Finally, by July 1, 1995:

> local governments will achieve effective E&S control (minimal or no violations of law, regulations or standards and specifications) on a minimum of 70 percent of regulated private construction projects, and state agencies and local governments will achieve effective control on at least 95% of their own government-sponsored projects.[50]

Forestry Nonpoint Source Management Subplan

The Virginia Department of Forestry (VDOF) is the lead agency for the forestry portion of the state's § 319 Plan, with DSWC also involved in implementation of the various activities. The Virginia Cooperative Extension Service provides educational services to forest landowners and logging contractors on various water pollution issues. The goals of the § 319 Plan include: initiation of a monitoring and evaluation program to determine silvicultural sediment and nutrient loads to state waters; reduction of erosion from silvicultural activities by use of BMPs on all forested land; use of preharvest plans in 90% of cutting operationss by 1995; and assistance with corrective action in problem areas.

By December, 1989, VDOF plans to undertake a variety of activities to control poison runoff from silvicultural activities. In addition to the training and education programs, VDOF will develop a system for monitoring and reporting annual water quality improvements, inspecting all cutting operations to determine the level of and need for BMP implementation, and making recommendations for BMPs where necessary. Those lands under the direct control of VDOF will be managed using BMPs. Ties with logging associations will be strengthened to promote the use of BMPs, and procedures will be established to register and investigate citizen complaints.

By 1995, payments under the Reforestation of Timber (RT) Program will be conditioned on the use of BMPs.[51] A voluntary system will be developed for timber owners to notify VDOF prior to harvesting operations. Increased personnel and funding will be provided to improve monitoring and training activities and the consideration of poison runoff in recommendations made to landowners seeking advice from VDOF.

Federal agencies, including the Agricultural Stabilization and Conservation Service (ASCS), Soil Conservation Service and the Forest Service also provide some control of poison runoff in Virginia. This includes requiring the use of BMPs in some of the forestry practices that receive cost sharing funds from ASCS through the Agricultural Conservation Program and Forestry Incentives Program[52] or SCS technical assistance and education programs. The USFS includes BMPs in its contracts with commercial logging firms.

Although no specific milestones section is provided, the Virginia forestry plan commits to preparing an annual report. This report will quantify the cost sharing funds expended and the number of acres affected, the numbers of BMPs needed versus the number implemented, and sediment and nutrient load reductions.[53] If interim goals of 10% - 40% sediment reduction are not met between 1991 and the year 2000, the state will "submit appropriate legislation for mandatory Best Management Practices for silvicultural activities" to the legislature.[54]

VOL 12

7269

Other Nonpoint Source Management Subplans

Other sections of Virginia's § 319 Plan pertain to resource extraction, land treatment and hydrologic modifications. As these programs are less extensive, they are outlined only briefly.

Resource Extraction. The Department of Mines, Minerals and Energy (DMME) is the state agency with primary responsibility for the resource extraction program. DMME requires mining and gas/oil extraction permits, and is responsible for ensuring compliance with permit conditions. It also investigates citizen complaints, requires performance bonds to guarantee reclamation and maintains an inventory and prioritized list of abandoned and unreclaimed mined lands. The goals for Virginia's resource extraction (mining) subplan include reducing erosion and water quality impacts from active and abandoned coal and non-coal sites; considering water quality when setting priorities for reclamation activities; and providing training to the mining industry in nonpoint source control through the year 2000.

DMME will seek funding for the reclamation of 25 abandoned mine sites per year and will include sediment and other pollutant loadings as factors in developing the reclamation list. The agency also will seek regulations to encourage the reclamation of abandoned lands through the participation of active mining operations.

The SCS operates the Rural Abandoned Mine Program in Virginia and is committed to reclaiming 250 acres of land by the year 2000 (4-5 sites per year). The Virginia Cooperative Extension Service (VCES) provides various technical assistance, research and education services to improve the control of mining-related water pollution. The Tennessee Valley Authority provides coordination and financial assistance for reclaiming abandoned non-coal mines created before enactment of state non-coal mineral mining and reclamation laws.[55]

Land Treatment and Disposal. This part of the Virginia § 319 Plan addresses the following sources of water pollution:

1. on-site subsurface disposal (primarily septic tank drain-fields);

2. landfill disposal;

3. lagoons for storing and treating wastes;

4. land treatment of non-hazardous wastes and sludge;

5. management of hazardous waste;[56] and

6. reclamation.[57]

Construction of septic systems is regulated through a permit system operated by county health departments. Before a permit is issued, factors such as soil type, setback distances (from streams or property lines) and topography are considered. The Virginia Department of Health in cooperation with county health departments also undertakes sanitary surveys to determine the need for public sewers, and educational activities or enforcement actions when voluntary compliance is not adequate.

Nonhazardous waste landfills (pollution sources regulated under RCRA Subtitle D) soon will require permits with minimum requirements under proposed rules published by EPA.[58] These requirements include leachate control, groundwater monitoring, and landfill closure and post-closure care.

Most lagoons (sewage, sludge, and industrial and animal waste) are permitted by the State Water Control Board through the Virginia Pollution Abatement Permit (VPA) program which is used, when necessary, to regulate potential sources of pollution that are not strictly characterized as point sources. The Virginia Department of Health (VDOH) conducts the technical review for sewage and septage treatment and sewage sludge storage. Regulations for land treatment of sewage sludge and effluent are currently being revised so that sites suitable for treatment are chosen more carefully. Permits for treatment are to be granted only after public and local government review and regulatory agencies (SWCB and VDOH) are satisfied that ground and surface water quality is not threatened.

VOL 12

7271

Hydrologic Modifications. Poison runoff that results from the alteration of stream channels (to assure adequate water supplies, improve drainage, control floods, etc.) also is addressed in Virginia's § 319 Plan. The overall purpose of this portion of the Plan is to "minimize the adverse effects of hydrologic modifications on water quality through the use of BMPs."[39]

The SWCB issues a CWA § 401 certifications for discharges of dredge and fill material. Channel management projects are controlled by a SWCB policy stating that such projects should be operated "... to minimize and preferably avoid short and long term adverse environmental impacts."[40]

DSWC is responsible for ensuring that hydrologic and other BMPs are used to protect water quality during the construction of dams. Other agencies also carry out activities under the hydrologic modifications subplan. These agencies include: Virginia Council on the Environment (reviews applications associated with hydroelectric projects and reviews federal actions for consistency with the Virginia Coastal Resources Management Program); Department of Game and Inland Fisheries (reviews state and federal actions for impacts on fish and wildlife); and Soil Conservation Service (commits to use BMPs to minimize sediment loads from hydrologic modifications such as impoundment construction and channel modification).

Analysis of the Virginia § 319 Plan

It is obvious that poison runoff is an important concern in Virginia. The state Nonpoint Source Pollution Management Plan provides a comprehensive list of the programs and actions of many federal, state and local agencies that contribute to the effort to control poison runoff in Virginia.

Some elements of Virginia's § 319 Plan are commendable; and some can be drawn on by other states. However, much of the Virginia plan does not represent the "state of the art" in managing diffuse sources of pollution. More important, in some key respects, the Virginia plan is not consistent with CWA section 319.

Problems with the Virginia § 319 Plan do not arise from a lack of commitment or skill on the part of state officials.

VOL 12

7272

R0040580

Instead, they are based on historical trends in nonpoint source control established at the national level, and on state and local political influences that have constrained the range of solutions chosen by decisionmakers.

The following analysis highlights both positive and negative aspects of Virginia's § 319 Plan.[41] Specific recommendations are provided, where appropriate, to improve the plan and to conform Virginia's program with Clean Water Act requirements. While many of these problems could take years to address on a fundamental level, numerous positive steps also can (and must) be taken in the short term to begin the transition to an approach consistent with the CWA.

Virginia's § 319 Plan Represents Significant Improvements Over Past Efforts

A review of Virginia's Nonpoint Source Pollution Management Plan indicates that the state has begun to establish an effective capability to control poison runoff. Recent increases in funding and personnel devoted to controlling poison runoff testify to a significant state commitment to nonpoint source management.

Virginia's § 319 Plan contains several specific commitments with the potential for effective control of poison runoff. The state has developed legislation to address pollution of the Chesapeake Bay region through local land use planning and management. Stormwater legislation has been proposed to control contaminated urban runoff. In addition, the state's erosion and sediment control (ESC) program has been expanded and improved to address more effectively the water pollution problems at construction sites. Improvements also are planned in the federal and state guides that specify the designs of particular BMPs so that ground and surface water quality considerations are taken into account.

In addition, Virginia has undertaken an array of important research projects aimed at improving its knowledge and understanding of the relationship between land use and water quality, and the effectiveness of specific BMPs. This research has, in part, fueled many innovations in traditional approaches to control poison runoff. These innovations include enhancing the cost-effective use of state funds, and the development and use of models that identify lands for priority treatment. The § 319 Plan also establishes a significant level of coordination among many federal, state and local governmental agencies.

However, the Virginia § 319 Plan does contain important weaknesses that must be addressed in both the short and the long term. One of the most pervasive weaknesses of the Plan is its failure to comply with the basic nonpoint source control mandates in the Clean Water Act.

Controlling Poison Runoff Within the Context of CWA Water Quality Management Planning

The Virginia § 319 Plan does not comply with the water quality management process required by the Clean Water Act.[42] In particular, the Virginia plan lacks: a proper emphasis on water quality standards and water quality standards-based controls; a "watershed-by-watershed" management process; adequate direct involvement by the State Water Quality Control Board (SWCB); and appropriate procedures to use water quality information to direct control programs.[43] These issues are discussed below.

A Lack of Dependence on Water Quality Standards. As discussed in Part III of this report, water quality standards, in the form of beneficial water use designations and narrative, numerical, biological and habitat criteria designed to protect those uses, should be the cornerstone of Virginia's nonpoint source control program (Rec. 9-1, 9-4).* Water quality standards provide the authority to develop controls, and should be used to establish the specific pollutant load reduction goals for individual water bodies (Rec. 9-1, 9-3, 9-5).

With few exceptions, it is apparent that state water quality standards will not play a significant role in the development and implementation of controls in Virginia. On the first page of the

* Where appropriate, citations are given to specific recommendations made in the preceding report. For example, Rec. 9-1 refers to Recommendation 1 in Chapter Nine of the report.

proposed plan a general statement is provided regarding water quality standards:

> The attainment of beneficial uses as measured by water quality standards compliance is the overriding purpose of control programs identified herein for nonpoint sources of pollution.[44]

This laudable but vague statement, however, is not supported by the rest of the plan. No details are given on how specific controls will be used to attain beneficial uses in specific water bodies. As a result, it is not clear how (or if) this very fundamental goal can be achieved.

References to the achievement (or even the development or application) of water quality standards essentially are absent from the subplans for individual source categories. For instance, the ultimate goal of the agricultural subplan is not to achieve compliance with water quality standards in specific water bodies. Instead, the goal of the agricultural subplan is a vague balancing of environmental and economic interests:

> to reduce the off-site water quality impacts of agricultural activities to an environmentally non-significant level while still maintaining soil productivity levels and economically feasible farm operations.[45]

Similarly, the stated overall purpose of the urban subplan is:

> to assist local jurisdictions having control over urban areas in meeting the requirements of the 1987 Water Quality Act.[46]

While this goal cannot be criticized *per se*, the urban subplan never translates this general statement into a method for achieving compliance with water quality standards.

Given these loose purposes, none of the more specific goals of the agricultural or urban subplans (or any of the other subplans) even mentions water quality standards. Since water quality standards are rarely *mentioned* in Virginia's plan, whether or not the plan will *achieve* such compliance is not even an issue.

This inadequate focus on water quality standards is exacerbated by the fact that Virginia does not have adequate water quality standards for most pollutants generated by diffuse sources.[67] This deficiency might help to explain the lack of integration of water quality standards with the general and specific aspects of the Virginia § 319 Plan. Virginia's recent work on developing a water quality standard for nutrients (an important nonpoint source pollutant) only affects point source polluters.[68] This approach contrasts sharply with efforts in other areas to reduce the combined discharges of nutrients from point and nonpoint sources to specific levels needed to achieve compliance with water quality standards.[69]

The SWCB reasons that it would be impossible to pinpoint responsible individuals and to enforce controls based on an evaluation of water quality standards violations.[70] As indicated earlier in this report, however, each polluter does not have to be proven individually responsible for a violation of ambient water quality standards in order to justify each additional BMP and control program. When water quality standards are violated due to the cumulative effects of a large number of diffuse pollution sources, the entire responsible community can and should be required to achieve the necessary load reductions to eliminate these violations. Controls can be imposed through the host of permitting systems and regulations discussed in this report.[71]

An Absence of Comprehensive Watershed Planning. It is apparent from a review of Virginia's § 319 Plan and Water Quality Standards regulations that Virginia has not established, as required by the CWA, the explicit authority to carry out and enforce a comprehensive watershed management process designed to achieve compliance with water quality standards in individual watersheds (Rec. 9-5). This authority should be made clear in the State plan as well as the State Water Quality Standards regulations.

The watershed provides the basis for determining what pollution load reductions are needed to achieve compliance with water quality standards for particular water bodies. As discussed in the previous report, a true watershed-by-watershed system develops nonpoint source controls commensurate with the estimated load reductions needed for each individual hydrologic unit, after analyzing all sources of all relevant pollutants. Once the necessary load reductions are determined, the state must

VOL 12

7276

R0040584

ensure that farmers, local governments, and other parties responsible for poison runoff achieve the necessary load reductions within a coordinated watershed plan.[72]

A watershed-by-watershed approach should also incorporate nonpoint source controls in a timely manner within the context of existing and projected point and other nonpoint loadings. There is little in the Virginia § 319 Plan to imply that this level of coordination will take place. There is also no way to coordinate control efforts between the source categories (*e.g.*, agriculture versus urban) or between point and nonpoint sources. Each nonpoint source subplan (agriculture, urban, etc.) is presented separately, generally without reference to the need to coordinate actions within watersheds to achieve beneficial water uses. There is an equal paucity of information concerning coordination with point source programs so that in individual watersheds management needs can be analyzed, and long term improvements can be planned, within a given timeframe.

A De-emphasized Role for the State Water Control Board. As explained above, it is essential that programs to control poison runoff be developed, implemented and evaluated based on their ability to achieve the quantitative load reductions that will lead to compliance with water quality standards within individual watersheds. Given this need, state and regional water quality agencies must assume an active, lead role in the state's overall effort to manage diffuse pollution sources (Rec. 9-6).

Without the fundamental involvement of water quality agencies, the state program to control poison runoff is likely to lack an adequate water quality focus. Water quality agencies have the expertise to determine which waters need attention, what pollutants are of concern, and how much of the contaminant level must be reduced to meet water quality standards. These agencies also have both the *authority* and the *responsibility* to take whatever actions are needed to achieve the formal objectives of the state's water quality management plan.

In Virginia, the Division of Soil and Water Conservation within the state Department of Conservation and Historic Resources is given the lead role in overseeing and evaluating the state § 319 Plan and is the chief agency charged with the

VOL 12

7277

development of the plan itself. Essentially this agency is generally responsible for determining how to address poison runoff in Virginia and how much control is adequate to comply with water quality standards. DSWC's role in controlling poison runoff is extremely important, and must continue. It does not substitute, however, for the functions that must be performed by Virginia's primary water quality management agency.

The SWCB is the Virginia agency responsible for water quality management. Yet the Virginia § 319 Plan apparently reduces the role of the SWCB to that of all the other agencies involved in specific components of the plan. In particular, the SWCB addresses individual types (usually point sources) of pollution covered by the Plan.[73] The only statements discussing the general role of the SWCB (in the introduction) provide SWCB with no formal, direct or comprehensive function in general program management:

> The DSWC will work closely with the SWCB to ensure that the nonpoint source control programs are consistent with programs required to achieve compliance with the state's water quality standards and goals and the requirements of the Clean Water Quality Act of 1987. The SWCB monitoring programs are supportive of DSWC in its evaluation of the overall success of the nonpoint source programs.[74]

These lone references to general SWCB involvement are vague and nonspecific. No provisions describe how SWCB will implement its authority with respect to the specific actions listed in the § 319 Plan. There is no indication how SWCB will ensure consistency of control programs with those required to achieve compliance with water quality standards, or how SWCB monitoring programs will support DSWC efforts to control poison runoff. This vague reference to the SWCB's overall role in program management contrasts sharply with the limited, highly specific roles established for SWCB in the actual substantive parts of the management plan. For example, the § 319 Plan states that SWCB is responsible for regulating animal feeding operations with "case-by-case" determinations and carrying out the NPDES aspects of federal stormwater regulations.[75]

At the most basic level, it appears that SWCB is not perceived, and more important, does not perceive itself as having the authority to undertake general nonpoint source management activities (except in isolated incidents of acute poison runoff events).[36] To be sure, SWCB most likely will undertake actions that can be construed as addressing the commitments listed above. However, the vagueness of these commitments, the paucity of information describing how (and how much) they will be fulfilled, and the degree to which the SWCB's role in nonpoint source management appears to fall short of that required in a successful water quality management plan all point to a significant lack of participation by the state water quality protection agency.

The SWCB should assume the responsibility to determine the water quality needs in particular watersheds, and to monitor and enforce poison runoff reduction requirements needed to attain beneficial uses. Where adequate water quality standards are not available, SWCB must develop and promulgate them. Thereafter, the SWCB (along with available Planning District Commissions) need to establish and carry out a process to communicate the pollution reduction needs in individual watersheds and provide a means to negotiate and enforce a comprehensive watershed plan agreed to by all involved localities and agencies.

If this process is to succeed, significant technical guidance and mandatory conflict resolution mechanisms must be developed and implemented by the parties involved in the watershed management plan. However, there is no mention of the need to develop or implement mandatory conflict resolution in cases where localities refuse to address extra-local problems. Since there is no real strategic role for the SWCB in the Virginia § 319 Plan, there is no process identified to coordinate the nonpoint source management activities of the SWCB and DSWC (either statewide or within individual watersheds). This problem should also be remedied.

The absence of a strong lead role for the SWCB in program development and management foreshadows, or perhaps causes, additional problems with Virginia's § 319 program. One of the most important of these problems is a departure from the use of water quality standards as the basis for establishing and maintaining specific activities to control poison runoff.

The Need for a Load Allocation Process. Virginia's § 319 Plan includes no process to calculate the total load reductions needed to meet water quality standards in each watershed or to allocate those load reductions among the range of diffuse pollution sources in the watershed. This is not to say that Virginia is unconcerned with identifying the hydrologic boundaries of the state's watersheds, since this is one of the activities in the § 319 Plan. However, the purpose of defining watersheds in the Virginia plan appears to be limited to improving the targeting of resources. It does not include estimating load reductions or identifying and implementing the controls needed to achieve those reductions.[7] Virginia "targets" more funds to areas that contribute relatively high levels of poison runoff. This improves the *relative efficiency of resource allocation* but does not provide a basis on which to determine if, for that particular water body, enough poison runoff reduction will occur to restore or maintain beneficial uses.

There is also little in the state plan that indicates how (or if) the SWCB or any other agency will identify watersheds where funds should be targeted based on *nonattainment of beneficial uses*, and what level of funding is needed or how these funds will be spent to achieve those uses. Most of the existing grounds for distributing funds are based on the *potential* for areas to generate sediment-related poison runoff rather than on ambient water quality. This approach fails to consider the types of load reductions needed in a particular area and the relative severity and importance of existing beneficial use impacts throughout the state. For example, erodible soils in a watershed *may* indicate a high *potential* for sediment loads, but nutrients nevertheless may be the most significant pollutant in the watershed. Funds spent to control sediment may not result in the attainment of water quality standards.

Summary of General Water Quality Considerations. Perhaps most fundamentally, the kinds of management problems discussed above stem from the confusion and false perceptions about the authority of the state to require control of poison runoff. For instance, the current nonpoint source management plan is authorized under the state Soil and Water Conservation

VOL 12

7280

District Law,[78] not under Virginia's water quality management statutes. The relationship of the Division of Soil and Water Conservation (DSWC) to the local SWCDs does not provide a mechanism for mandating that state and federal water quality goals be met, since the SWCDs are operated essentially through local consent. As an illustration, one of the duties of the Board that directs the operations of DSWC is:

> to coordinate the programs of the [soil and water conservation districts] *so far as this may be done by advice and consultation.*[79]

It is difficult to imagine how a state-driven water quality-based approach to controlling poison runoff could ever take place under the auspices of a program that is almost completely within the context of traditional, locally-oriented, voluntary soil and water conservation efforts. For example, since state water quality standards are not mentioned in the state soil and water conservation laws, compliance with these standards hardly can be considered an enforceable responsibility of either DSWC or individual SWCDs.

Also, state water quality management and land use laws do not *require* local governments throughout the state to prevent water pollution from poison runoff. In fact, local governments only recently were given explicit *authority* to address surface water and groundwater contamination in local comprehensive planning; and, even so, such authority still appears to be a discretionary local function.[80] Insofar as localities provide funds to SWCDs to carry out various activities, opportunity exists for coordinated water quality protection at the local level. But so much local autonomy exists that SWCDs will remain the entity most directly responsible for compliance with state water quality standards in many areas.[81]

To be sure, SWCDs are invaluable organizations in any plan to control poison runoff. In the context of their enabling legislation, however, it is not clear how they will be able (or willing) to control poison runoff to the extent needed to achieve compliance with water quality standards—given that controls in many areas may involve the need for significant direct state involvement and may be unpopular locally.

Virginia needs a system of "command and control" designed to ensure that water quality standards are met in individual watersheds. This requires the adoption of water quality standards to address the types of nonpoint source problems prevalent in Virginia, and the application of these standards through monitoring, watershed-by-watershed modeling and implementation of needed controls. The state water quality agency should play a key role in this effort.

Comprehensive Program Implementation

For a watershed-by-watershed approach to be successful, it is critical for a state nonpoint source management program to coordinate the participation of all government entities and affected citizens to ensure that load reduction goals are achieved (Rec. 10-1). Local land use planning is important to effective control of poison runoff and, thus, should be scrutinized by regional and state nonpoint source officials based on detailed planning requirements and review criteria (Rec. 10-2, 10-3). All control programs should be integrated into a single watershed plan, and the state should provide mandatory conflict resolution measures to ensure that agreements for strict controls are not sacrificed (Rec. 10-4, 10-5).

Unfortunately, the Virginia § 319 Plan does not provide for significant and effective coordination. As mentioned previously, Virginia is not proposing a watershed-by-watershed process. It follows, therefore, that the Virginia § 319 Plan does not include a process to coordinate the control programs of all involved parties into a single watershed plan. State criteria for the adequacy of such a plan also are lacking. As discussed below, although increased involvement by some local governments is expected, it is not clear in the § 319 Plan how localities are to be incorporated into a comprehensive watershed plan, or whether the state can review (and approve or disapprove) many proposed local controls. And also as discussed below, binding conflict resolution mechanisms are not proposed to ensure that pollution reduction in one part of a watershed is not offset due to weaker rules in another locality.

Nonpoint Source Pollution Management Subplans

Despite these general problems in the Virginia Nonpoint Source Pollution Management Plan, the individual subplans for each pollution category provide some useful programs and activities for addressing poison runoff. Important research projects and data collection activities are a significant part of most of the plans. Recent legislation (discussed later) has expanded significantly the ability of the state to address poison runoff. Still, the subplans presented in the state § 319 Plan are limited by a number of serious problems. These strengths and weaknesses are discussed below using the criteria set out in the preceding report.

Agriculture. An effective agricultural pollution control effort must recognize that new, regulatory approaches are often realistic solutions to water quality problems caused by sediment and agricultural chemicals and may be necessary to achieve the level of pollution control needed to meet water quality standards (Rec. 3-1, 3-2). Design standards can be used as minimum requirements, while performance standards can ensure that water pollution will be controlled when compliance with design standards is not effective in addressing a particular poison runoff problem (Rec. 3-2). Agricultural chemicals can be controlled by reducing the amount of chemicals available for runoff and leaching, the use of forested buffer zones, and economic development policies that promote an environmentally sound agricultural sector—not primarily through the implementation of erosion-based "conservation plans" (Rec. 3-6, 3-7). Livestock programs can require control of runoff and leaching from confined feeding and storage areas, of the application of manure on porous land, and of the destruction of streambanks and other riparian areas (Rec. 3-8). Finally, a comprehensive farmland protection program can be developed that offers substantial incentives to preserve *prime* farmland as long as poison runoff is effectively controlled (Rec. 3-10, 3-11).

As explained in Chapter Three, this does not mean that each of these controls *must* be used, much less used exclusively, in an adequate state nonpoint source control plan. But neither should such controls be rejected out of hand. More important, the

VOL 12 7283

R0040591

combination of agricultural pollution controls selected, whether voluntary, regulatory, or both, must be sufficient to meet water quality goals. Where agricultural pollution is severe, regulatory controls will often be needed as part of the mix of strategies used to meet water quality standards.

Virginia has not explored fully the potential of alternative approaches to cost sharing, using the principles and examples provided in Chapter Three. Virginia's agricultural subplan emphasizes improving the efficiency and effectiveness of *existing* state programs to control poison runoff rather than the development of new approaches. Perhaps the most conspicuous drawback of the subplan is the bias towards keeping its voluntary approach for reasons unrelated to water quality protection. In fact, the plan includes no attempt to demonstrate its sufficiency to meet water quality standards. Virginia, along with Maryland and Pennsylvania, has committed to exploring the "regulatory option" as part of an agreement developed through the Chesapeake Bay Program. In Virginia's § 319 Plan, however, no mention is made of such a study, and the exclusive emphasis on voluntary programs continues. This seems to indicate that the use of regulatory controls in the foreseeable future is not considered a serious alternative. Even the purpose of the agricultural subplan implies a voluntary orientation:

> to establish a direction and framework for agricultural interests (government agencies, industry and private sector) to address nonpoint source pollution loadings attributed to agricultural lands and operations.[82]

Federal documents that discuss Virginia's state agricultural pollution control program often stress its voluntary nature.[83]

The bias towards voluntary controls in agriculture is explained partially by a perceived lack of authority by state officials to use other kinds of controls. The absence of a cause-and-effect linkage between BMP implementation and water quality was an early justification for a voluntary approach to controlling poison runoff.[84] However, from the standpoint of water quality protection, this lack of knowledge will have at least as big an impact on the success of voluntary programs as on regulatory ones.

Partially because of its voluntary nature, it is not clear how the Virginia agricultural plan addresses groundwater and soluble contaminants. In a voluntary program, the BMPs used will be influenced not only by their value in protecting water quality, but also by their popularity among farmers. Most of the BMPs that are eligible for cost sharing funds (except animal waste control facilities) are designed to address sediment or sediment-attached pollutants. For instance, in the Cropland Priority Area (described above) a minimum of 70% of the funds allocated to SWCDs must be spent on soil erosion BMPs.[85]

Some of the BMPs used in Virginia, such as no-till cropping practices, can actually lead to an increase in the level of soluble fertilizers (mainly nitrates) and pesticides that are applied to a field and that become available for groundwater contamination or subsurface transport.[86] Also, controlling phosphorus and not nitrogen could reduce productivity in one area and thus make nitrogen more available downstream, since the two are used in specific ratios.[87] These kinds of concerns are not reflected in Virginia's agricultural subplan, in contrast to the recommendations provided in Chapter Three. In addition, nutrient management is addressed primarily through the provision of technical assistance and education, thereby allowing farmers who do not choose to participate in the state program to continue polluting state waters through the over-application of animal and chemical fertilizers.[88]

The State Water Control Board is not given any responsibility to develop Water Quality Standards for pesticides or to develop a comprehensive assessment of potential contamination (and associated management options) within the state. The Department of Agriculture and Consumer Services (DACS) will undertake several activities to improve the use, handling, storage and disposal of pesticides and their containers though education and technical means.[89] But regulatory efforts are targeted to pesticide storage facilities, and BMP Improvements will focus on improving spill containment and loading/mixing/rinsing sites, not the actual application of pesticides.[90] The agricultural subplan, therefore, does not provide a method to evaluate comprehensively general problems (both geographic and management) associated with pesticide application. Nor does it contain a management strategy (including the development of specific

VOL 12 7285

pesticide-control BMPs) to *ensure* that pesticide application will not contaminate state waters.

The bias in the state agricultural subplan towards controlling soil erosion as opposed to agricultural chemicals is emphasized by the data used in the cost sharing program. Most information about the effectiveness of the cost sharing considers tons of sediment and pounds of phosphorus (largely a sediment-bound nutrient) retained on the farm and ignores estimates of soluble chemical loadings.[91] The VirGIS data collection system addresses soil erosion and sediment loadings but not soluble (and leachable) nutrient and pesticide losses. Also, funds are allocated based on potential for erosion and sediment-related poison runoff.

This approach contrasts sharply with the findings and recommendations of a recent U.S. Fish and Wildlife Service study of the Choptank River watershed in Maryland.[92] The report found that most nitrogen pollution was in the nitrate form, which is often transported through shallow subsurface flow (baseflow).[93] Perhaps just as important is the conclusion that targeting for both sediment and nutrient (including nitrate) control BMPs is possible not only within watersheds but also within subwatersheds.[94] Even within subwatersheds, individual farms or groups of farms that contribute disproportionate loadings of poison runoff (including nitrate) might potentially be identified.[95] Priority subwatersheds can be established by setting nutrient concentration goals for tributaries at their confluence with the mainstream river based on the needs of the area's aquatic resources.[96] Those subwatersheds exceeding the goals would then be targeted for the appropriate BMP treatments.[97] Although such an approach is still imperfect, the Virginia agricultural subplan does not appear to explore even the potential for developing this kind of management capability.

The agricultural subplan does provide for a revision of the SCS Field Office Technical Guides so that BMPs and conservation plans will reflect water quality considerations.[98] But the subplan still leaves the development and implementation of BMPs mostly to the discretion of the local Soil and Water Conservation Districts (SWCDs). So, while it is admirable that water quality will be addressed more explicitly in the Technical

Guides, there is no real assurance at the state level that the Guides will be followed precisely, given the locally-led, voluntary nature of this program.

The subplan addresses *off-farm* (water quality) impacts more directly than some past nonpoint source programs. However, the plan does not address the possibility that voluntary participation could decline since participation often depends on the farmer perceiving that he will benefit economically (*i.e.*, receive *on-farm* benefits) from BMP implementation. An associated problem is that local SWCDs carry out the state BMP program, but do not operate under any regulatory responsibility (or authority) to achieve compliance with state Water Quality Standards in their respective watersheds.

The development of animal waste BMPs is being promoted through education, technical assistance and cost sharing. Although the final figures are not available, a recent EPA report states that only 51 farmers had participated in the program as of 1986 at a combined federal and state cost of over $500,000.[99] In contrast, there are at least 291 dairy operations in Rockingham County, Virginia alone[100] and up to 700 various livestock facilities (including those for raising chickens) in Rockingham, Page and Shenandoah counties.[101] Applicants for manure management cost sharing are chosen based on costs, manure and urine production, and distance and slope to nearest stream, without any input by the SWCB.[102] Nutrient management plans are required of farmers as part of the BMP, but are much more difficult to enforce because inspectors must visit the farms when the manure or chemical fertilizer actually is being land applied.[103] At any rate, only 5% of the BMPs are randomly "spot-checked" per year, as with the rest of those implemented through the Virginia cost sharing program.[104]

Although SWCB regulations maintain that no animal feeding operations shall maintain a *point source* discharge of "pollutants to state waters except in the case of a 25 year - 24 hour storm events," permits are required only at facilities serving a minimum number of animals and on a "case-by-case" determination made by the state for smaller facilities.[105] For instance, permits for meeting the discharge standard mentioned above (called Virginia Pollution Abatement permits) are required generally only for facilities where more than 300 slaughter and feeder cattle or 200 dairy cattle are confined.[106]

In any case, the regulations only apply to areas where no vegetation is maintained and do not cover the destruction of riparian habitat by cattle and sheep or the application of manure to pasture or cropland.[107] While it is suggested that land application limits be determined and followed, there is no compliance oversight for this process—only enforcement actions taken under the State Water Control Law in response to complaints of acute water contamination.[108]

The state permit program does not address the vast majority of farms (as many as 90%)[109] with fewer than 300 head of cattle. As mentioned in Chapter Three, improper control of small livestock operations can create significant water quality problems.[110] For these numerous operations, the only way that the SWCB determines if water quality problems are resulting from any aspect of the livestock operation is through responses to complaints made by private citizens.[111] Such complaints are a poor substitute for systematic assessment of existing problems and a mandatory program to address *all* of the sources of livestock-related water pollution.

The agricultural subplan does state that legislation will be sought to require all land enrolled under the "use value" tax assessment program to have an approved conservation plan to reduce erosion to below "T" values.[112] Although this is commendable, the plan does not provide an evaluation of other, more comprehensive farmland protection programs similar to those described in Chapter Three. It also does not prevent farmers receiving program benefits from contributing poison runoff not associated with erosion.

Cost sharing, education and technical assistance are all essential aspects of an effective program to control poison runoff. But such program components are only tools and do not provide an adequate framework within which to develop the goals and programs needed to *ensure* the attainment and maintenance of beneficial uses of water within individual watersheds. The innovative solutions to the problems associated with cost sharing that are described in the previous report are not reflected in the agricultural subplan.

Urban Runoff. Urban poison runoff control requires a host of important program components.[113] Localities must take water quality considerations into account when developing zoning and subdivision ordinances and must participate with other localities (and state agencies) in a comprehensive watershed management plan (Rec. 4-1, 4-2, 4-3). Because localities create water quality problems outside their political boundaries, a strong state role is needed to determine water quality protection needs, to negotiate and coordinate local control efforts and to resolve conflicts among and within localities without sacrificing water quality goals (Rec. 4-5). Localities in coastal areas need to cooperate with state agencies to address poison runoff through existing programs designed to enhance and preserve coastal resources (Rec. 4-4). A comprehensive stormwater management program must provide the means to ensure that local governments address the water quality impacts, including toxic contamination, of both new and existing development (Rec. 4-7, 4-8, 4-9, 4-10, 4-11).

In contrast to these needs, Virginia localities outside of the Chesapeake Bay watershed are not required to address water quality issues in their comprehensive planning process. In fact, as a Dillon's Rule state, only in 1988 was local government legally *authorized* (not required), by statute, to use comprehensive planning to protect surface water and groundwater.[114] Moreover, the state has provided no mandatory conflict resolution mechanism to ensure that localities do not sacrifice water quality for political or economic reasons. The urban subplan calls for the signing of Memoranda of Understanding (MOUs) with local governments in "urban priority areas" to incorporate "the most cost-effective BMPs and implementation mechanisms into their local programs."[115] Since there is no clear provision in the urban subplan for the development of watershed-wide plans and associated load reduction goals, the *need* for conflict resolution in the negotiation of these MOUs also is diminished. A MOU with a local government will be based, by definition, on local preferences, so it is understandable—but unsatisfactory—that no mandatory process is provided explicitly to address localities that choose not to address water quality issues.

VOL 12

7289

R0040597

Also in contrast with recommendations made in Chapter Four, the urban subplan does not provide any evaluation of current zoning, subdivision or site plan review ordinances or practices or make recommendations as to how they should be improved to address poison runoff and other environmental concerns more effectively. Although some Planning District Commissions (PDCs) have provided technical assistance on nonpoint source management to their members,[116] there is no formal commitment to expand the role of the PDCs (or SWCB) in any particular fashion, especially to the extent of acting in an official arbitration, conflict resolution or coordination role as part of a mandatory watershed planning process.

Controlling poison runoff in urban areas in Virginia has advanced considerably in the past two years. New laws were passed that provide the *potential* for increased control of polluted urban runoff. However, this means that significant work lies ahead in ensuring that the laws passed in 1988 are put to good use.

The Chesapeake Bay Preservation Act (CBPA) added a whole new dimension to the way which the state views local decisions affecting water quality within about half of the Chesapeake Bay portion of the state. The CBPA creates a new Chesapeake Bay Local Assistance Board (CBLAB), which must approve the criteria for development in areas designated by localities (and approved by the Board) as "Chesapeake Preservation Areas." The criteria for selecting these areas and regulating land use within them are of pivotal significance. However, the Act does not require explicitly that one of the *duties* of the CBLAB will be the maintenance and restoration of beneficial uses of water as defined in the State Water Control Law.[117]

The Board "shall be representative of, but not limited to, citizens with an interest in and experience with local government, business, the use and development of land, agriculture, forestry and the protection of water quality."[118] Therefore, in order to ensure that the Board acts fairly and objectively, the state needs to ensure that water quality interests are adequately represented on the Board, and are not outweighed by development interests. Also, in developing criteria, the Board must consider "the economic and social costs and benefits which can

VOL 12

7290

R0040598

reasonably be expected to obtain as a result of the adoption or amendment of the criteria."[119] Reliance on attainment of beneficial uses is important because this consideration of economics could cause water quality considerations to be down played in the development of regulations and the review of local plans.

Consistent with the principles established in Chapter Four, care must be taken to ensure that performance standards are used that require localities to protect beneficial uses of waters based on the findings of the SWCB.[120] To do this, the Board should work in conjunction with the SWCB so that the controls required in each local jurisdiction are tailored to achieve specific load reductions in individual watersheds. A simple set of design standards and land use tools provides some desirable consistency in program implementation. But applying these minimum requirements across all regulated jurisdictions cannot ensure compliance with water quality standards, given the site-specific nature of water quality degradation. Additional controls will be needed in specific areas.

Therefore, a strong emphasis should be placed on SWCB and CBLAB *review* of the adequacy of poison runoff controls proposed by individual localities to meet the water quality needs in specific watersheds. Otherwise, a set of inflexible design criteria might allow localities to claim that they are following the regulations even when compliance with water quality standards will not be forthcoming. In addition to the activities of the SWCB, it is also uncertain how (if at all) the CBLAB will coordinate its own goals and requirements with those of the state Coastal Resources Management Program.

Another important issue is the lack of a mandatory conflict resolution procedure in the CBPA and Virginia's § 319 Plan. Without such a mechanism, to be applied by an independent state entity, there is no guarantee that local political factors will not influence environmental considerations. And there is nothing in the § 319 Plan that indicates that mandated conflict resolution processes are being given due consideration elsewhere in the state.

As mentioned previously, the extra-local water quality consequences of many municipal and county decisions makes state-level participation in an urban nonpoint source management plan essential. The CBPA, however, establishes a role for the Commonwealth that is described as "supportive". The ability of the CBLAB to bring about local action is clear. Among the powers and duties of the Board are to:

> [e]nsure that local government comprehensive plans, zoning ordinances and subdivision ordinances are in accordance with the provisions of this chapter; (and)
>
> [t]ake administrative and legal actions to ensure compliance by counties, cities and towns with the provisions of this chapter.[121]

However, besides reference to the provisions of the state Administrative Process Act,[122] there are no special penalties that the state is entitled to use to ensure local compliance with the state criteria.

A final confusing factor is that the CBLAB is given "exclusive authority to institute legal actions to ensure compliance by local governing bodies with this chapter and with any criteria or regulations adopted hereunder."[123] This seems to imply that the program will not be tied to water quality standards because, if it were, the SWCB would require legal authority as well. As worded, the CBPA could be interpreted to mean that the SWCB does not have any authority in local water quality protection beyond the point source programs specifically referenced in the law. As mentioned previously, this limitation is a serious barrier to effective control of poison runoff.

The issues described above regarding the Chesapeake Bay Preservation Act apply generally to any state controls that are developed for the majority of the state that lies outside of the tidewater province. However, there are no similar statutes for local governments outside the tidewater area, making urban nonpoint source management concerns even more fundamental in the rest of the state.

The Virginia urban subplan does not call for the existing state Coastal Resources Management Program (CRMP) to be expanded. Nor does the subplan describe how the CRMP will be integrated with poison runoff controls implemented in the state's coastal areas, or how the CRMP will be used to comply with state water quality standards. In 1986, the state's Coastal

VOL 12

7292

Resources Management Program (CRMP) proposed "no new state programs, organizations, regulations and laws," finding that none were needed to comply with the minimum requirements of the Coastal Zone Management Act.[124]

In terms of general land use management and planning, the Virginia Coastal Resources Management Program is limited—especially with respect to mandated local involvement.[125] There is no indication in the urban subplan that revision of the CRMP to require specific coastal management programs in local land use planning activities was considered as a means to reduce poison runoff in coastal areas, or specifically to condition coastal development on compliance with water quality standards.

The CRMP describes existing state programs such as the Chesapeake Bay Program and the state efforts to control poison runoff, as well as programs to protect sand dunes and coastal wetlands that are usually administered at the local level.[126] Various programs provide technical assistance to localities and landowners seeking to limit shoreline erosion and federal grant funds to localities and regional planning authorities for waterfront development.

It is not clear, however, how the state CRMP makes existing programs having nonpoint source management benefits more effective by increasing their emphasis or through a more rigorous scrutiny of local actions in coastal areas. In fact, the urban subplan does not provide any indication of how existing activities authorized through the state CRMP have been evaluated to determine opportunities for improved control of poison runoff. Essentially, the state CRMP describes existing activities to control poison runoff as examples of improved coastal resources management while the state § 319 Plan describes existing CRMP activities to show improved nonpoint source management. This "double counting" does not, however, describe how *separate* programs and activities in one area can (or will) be modified or coordinated to enhance or improve the effectiveness of those in the other.

The portion of the urban subplan that addresses contaminated stormwater is equally unsettled. The urban subplan proposes to:

VOL 12

7293

R0040601

develop a proposal for enabling legislation for comprehensive storm water management programs combining erosion and sediment control, water quality control and flood control objectives.[127]

Although this proposal is still in its early stages and no design or performance criteria have been establish, draft language has been submitted. The proposal calls for a *voluntary* stormwater management program that localities may adopt as they see fit.[128] Because of the need for strong state leadership to ensure that stormwater ordinances are enforced and coordinated, and that watershed-wide solutions are developed, it is doubtful that a voluntary program will result in stringent, comprehensive local programs. Given the problems that have been identified with the state's *mandatory* erosion and sediment control program[129] and the intense efforts that have been necessary to enforce *mandatory* stormwater controls,[130] it is unlikely that federal and state water quality goals can be attained by a voluntary participation in a stormwater management program.

Without an effective local stormwater ordinance, the only relevant state requirements for controlling stormwater pollution can be found in the erosion and sediment control law and the associated technical handbook, which are designed not to address water quality, but to prevent flooding and channel erosion from excess stormflows. These provisions are vague, often are not enforced at the local level, and generally are inadequate for poison runoff control purposes.[131]

Finally, it is not clear how this new voluntary program will be integrated with the rest of the urban subplan. For instance, the Memoranda of Understanding into which localities will (it is hoped) enter with DSWC are supposed to contain "the most cost-effective BMPs and implementation mechanisms."[132] Although a well-enforced, water quality-based stormwater ordinance may be a very cost-effective "implementation mechanism", it is doubtful that the MOU can require such an ordinance since both the MOU and the stormwater programs are voluntary and are subject to bargaining between the state and consenting localities.

Other Nonpoint Source Management Subplans. The other subplans (forestry, construction, resource extraction, land

VOL 12

7294

R0040602

treatment and disposal and hydrologic modifications) are less detailed than those for the urban and agricultural categories. While the poison runoff problems associated with these categories are not necessarily widespread, they still can be important, particularly on a localized basis.[133]

Forestry. Poison runoff related to silvicultural activities must be controlled through coordinated state and federal planning and the application of BMPs implemented as part of an overall timber management plan designed to preserve the beneficial uses of streams and lakes within the watershed (Rec. 5-1, 5-2).[134] Before timber is harvested, an interdisciplinary group of professionals (including officials within the state water quality agency) should review cutting proposals to determine if adequate measures have been taken to preserve and protect water quality (Rec. 5-4). State forestry and water quality officials also need to work together to review federal plans for national forests to ensure that the state's interest in high quality waters is maintained (Rec. 5-2). All of these activities must be carried out through a planning process to identify the areas where significant timber harvesting is likely; to determine potential water quality problems and protection priorities; and to focus resources to improve the management of forestry resources in each indicated area (Rec. 5-2).

Although some progress is provided in the Virginia forestry subplan, there remains significant room for improvement. The state forestry subplan remains voluntary and even the consideration of a regulatory program could be postponed until the year 2000.[135] Logging interests do not even have to notify the state of their intent to cut timber much less use BMPs or protect state waters through compliance with performance standards.[136] Only by 1995 will Virginia have developed even a *voluntary* notification system.[137]

Each county has only one state silviculturalist to observe how well logging operations are carried out and to assist landowners in developing forest management plans (and then only at the landowner's request). It could be difficult for these state personnel to find out about timber operations before they have started,[138] especially if increased concern for water quality must be programmed into current workloads.

There also appears to be no systematic procedure for assessing the potential of private lands to contribute incrementally to poison runoff. The state does not appear to be considering evaluating the adequacy of poison runoff control on the significant amount of land managed by the U.S. Forest Service in Virginia. In addition, there is no indication that a long term planning process will be used to assess threatened areas in the state. Little in the forestry subplan reflects the need for interdisciplinary participation in control of water pollution from timbering. For instance, no mention is made of any involvement in water quality protection on forested lands by either the State Water Control Board or the State Commission on Game and Inland Fisheries.

Erosion and Sediment Control. Sediment generated at construction sites can be a serious pollutant in both rural and urbanized areas. Effective erosion and sediment control requires a strong state role in the development of regulations and guidelines and the review of local program effectiveness (Rec. 5-13). Local ESC officials are challenged to develop programs with sufficient inspections and stringent compliance enforcement (5-13, 5-14).

The Virginia General Assembly recently appropriated funds and passed legislation that allow the DSWC to increase significantly the staff of the state erosion and sediment control program and to improve the implementation and state review of local programs.[139] However, problems still remain. Some significant exemptions are allowed by state legislation, including single family homes and construction sites under 10,000 sq. ft.[140]

The Virginia plan also does not address directly how localities can be ensured of obtaining adequate resources to carry out ESCs. This is especially significant given that studies, carried out before the lofty goals of the CWA § 319 Plan were developed, found that many Virginia localities had inadequate resources to carry out an effective plan.[141] Inadequate resources and enforcement translate into poor inspection and enforcement of local programs.[142] There is also a lack of support in the judiciary to impose substantial fines for violations of local programs.[143] The state can only develop, and not implement, ESC plans when the locality refuses to act.[144]

Virginia's ESC program also lacks a full range of adequate enforcement tools. Administrative fines do exist but only if agreed to by the developer as a means of avoiding a civil or criminal enforcement action.[145] Stop work orders are available but apply only to land disturbing activities, not to other work (like much of the construction of buildings) that might be going on while the erosion or sediment problem remains.[146]

Guidance in several areas is missing. For instance, review of local plans by the state is required, but at an unspecified rate.[147] Inspections of construction sites must be performed by local officials but also on an unspecified basis, making it difficult for state officials to define when local officials are or are not conducting an adequate number of inspections. Many time limits associated with various compliance standards, including the requirement that landowners comply with orders by program officials to correct ESC problems, are not defined. Even the regulations themselves contain a significant variance clause that allows any requirements found in the regulations to be waived as long as local officials consent.[148]

The Virginia subplan for construction provides for improved technical assistance and education by DSWC to local governments to carry out the plan. It also has greatly expanded its capacity to review and evaluate local plans. It remains to be seen, however, if this structure provides systematically for the achievement of the goal of 95% compliance by the year 2000. In evaluating local programs and updating the ESC Handbook, DSWC should capitalize on studies that have been conducted pertaining both to problems with ESC programs in Virginia and effective programs in other areas. In the long run, additional legislation may be needed to make the program more aggressive at the state level and provide necessary local resources.

Resource Extraction, Land Disposal and Hydrologic Modifications. Developing an adequate program to address mining-related pollution requires a coordinated effort by both the state water quality agency and the mining regulatory authority (Rec. 5-6).[149] All forms of mining should be addressed through a process that identifies areas unsuitable for mining, regulates mining through land use controls and the control hierarchy established in SMCRA, and reclaims abandoned lands to prevent further water quality degradation (Rec. 5-7, 5-8, 5-9, 5-11). Adequate inspections and effective enforcement actions are vital; hence, detailed regulations, including performance standards, are needed to provide the minimum criteria that all mining operations must meet (Rec. 5-5).

The other two subplans (land disposal and hydrologic modifications) are not addressed in the proceeding sections of this report. These sources of water pollution often are not considered nonpoint sources or are addressed through specific programs provided for in legislation other than the Clean Water Act (*e.g.*, solid and hazardous waste facilities are regulated under Subtitles C and D of the Resources Conservation and Recovery Act). Problems related to these facilities also can be addressed through siting, zoning and other land use controls discussed in Chapter Four.

The case of nitrate and fecal contamination of surface and ground water by failing septic systems (a significant problem in Virginia) is a possible exception, but this problem also is addressed through land use regulation. For instance, based on an analysis of the cumulative impacts of development, the state or locality can require certain minimum lot sizes, depending on soil and topographic conditions and total allowable contaminant loadings, for individual septic systems.[150] Although no specific guidance has been developed in this study for many of the sources contained in these two subplans, comments are provided where appropriate.

With some exceptions, the subplans for resource extraction (mining), land disposal and hydrologic modifications appear primarily to restate existing program requirements. For example, the resource extraction subplan focuses attention on the environmental protection requirements of existing state regulations

VOL 12

7298

pertaining to mining. However, there does not appear to be a way to evaluate whether *existing* programs are adequate (or are being implemented adequately).

Current laws and regulations apply to both coal and non-coal mining as well as to oil and gas exploration.[151] However, unlike the legislation and associated regulations described in Chapter Five, much of the Virginia program applicable to non-coal mining is based on statutory and regulatory provisions that provide few details or guidance. Therefore, the success of the program in addressing poison runoff depends on how stringent local officials of the Virginia Department of Mines, Minerals and Energy choose to make permit requirements, inspections, enforcement actions and other program requirements.[152]

For instance, the environmental protection data requirements for permit applications and for permits are very limited compared with those of the Wisconsin program described in Chapter Five.[153] Review and approval procedures provide no details or criteria for evaluative purposes. General criteria for protecting wetlands and other sensitive areas also are lacking. This is especially significant because the SWCB does not appear to have any role in determining where reclamation is needed or influencing how the Department of Mines, Minerals and Energy carries out inspections or develops pollution control requirements for poison runoff.

For non-coal mining operations, the minimum inspection and enforcement provisions are equally vague. Although mine inspectors presently must cover an average of 55 mines,[154] the subplan does not propose expanding or even reviewing personnel needs to improve nonpoint source management. In addition, there does not appear to be a planning process in place to assess poison runoff problems and to determine needed controls within specific watersheds or areas where mining is unsuitable.

Perhaps the most important consideration of the land treatment and disposal subplan is the adequacy of the state program for on-site waste disposal (septic systems). But the subplan itself does not propose to review the adequacy of this program or how well it is being implemented at the county level. Instead it merely summarizes how the existing program works. There do not appear to be *any* new activities proposed for this particular problem, which is a major source of fecal bacteria impairments to state waters. Since bacteriological contamination is the most prevalent type of use impairment in the state, it is apparent that the current system of septic system control is not effective.

Virginia still controls pollution problems from septic systems primarily through requirements for a "perc" (percolation) test to determine if the soils in the area can absorb effectively the effluent from the septic tank, and through an evaluation of individual site characteristics. This process is controlled by county health department officials—not state water quality managers—who are not responsible for ensuring that state water quality objectives are achieved. No provisions seem available at the state level to account for the water quality impacts of the aggregate loading caused by mahy septic systems in one area or the incremental increases in these systems brought on through time by development pressure.

Similarly, the section on hydrologic modifications consists largely of restatements (as opposed to evaluations) of existing programs. Apart from rare exceptions, there do not appear to be any new activities or programs proposed by non-federal entities, which indicates that the state believes this poison runoff category is already being addressed adequately by existing programs.

Data Collection and Use

Critical to the success of a watershed-by-watershed approach in nonpoint source management is the proper use of water quality information.[155] Water quality data not only provide the information needed to establish water quality goals and priority areas within the watershed. They also establish the state's *authority* to require that necessary pollution load reductions be achieved on a watershed-by-watershed basis (Rec. 6-1, 6-4). As mentioned in Chapter Six, using water quality information to develop, implement and monitor controls can be the most challenging part of a program to control poison runoff. While it may not be possible to model precisely the actual and potential impacts of each individual source of diffuse pollution, successful modeling has been demonstrated on a watershed-wide basis, and progress continues to be made.

Unfortunately, Virginia's plan does not describe how ambient water quality information and watershed modeling are to be used to develop nonpoint source management programs for specific hydrologic areas. No references are made to establishing, for example, a procedure to monitor above and below the fall to determine the severity of the nonpoint source problem in a particular watershed. This omission is unfortunate and ironic given Virginia's leadership in demonstrating, by the creation and expansion of the land-based VirGIS information system for targeting resources (described earlier), innovation in the field of data collection and use.

The state § 319 Plan should recognize explicitly the need to use ambient water quality as the primary means of judging the success of nonpoint source controls in individual watersheds (Rec. 6-4). A proposal should be made as soon as possible that describes how water quality monitoring and modeling activities will be modified and used to develop comprehensive watershed plans. As part of these plans, water quality monitoring and modeling should be used to *require* both point and nonpoint source controls in watersheds where beneficial uses of water are not attained.

Funding

Besides general management and the particular plans for each source category, funding is also an important issue in controlling poison runoff.[156] Not only are significant *levels* of funding needed, but money for control programs should also be provided from a variety of sources, including the polluters themselves (Recs. 7-1 through 7-7).

Virginia has substantially increased funding for its nonpoint source programs in the past few years. But it seems unlikely that these levels are sufficient, especially given the approaches currently used. Virginia officials have estimated that $170 million in cost sharing funds would be necessary to install the BMPs that would address only erosion-related pollution problems and only in the Chesapeake Bay drainage.[157] This figure excludes the costs of controlling sediment in the remainder of the state as

VOL 12

7301

R0040609

well as the costs of controlling groundwater contamination from soluble fertilizers, pesticides and toxic chemicals from both agricultural and nonagricultural nonpoint sources throughout the entire state. Therefore, the approximately $1.25 million available for cost sharing (mentioned in a preceding section of this case study) in each of the next two years cannot be regarded as adequate.[158]

While the state expenditures for cost sharing described in the previous section are less than adequate, additional problems also can be foreseen based on how those limited funds are used. The majority of funds are used to pay for those popular BMPs that are designed to control erosion and sedimentation. Cropland-related nutrient enrichment is addressed almost entirely through technical assistance and education provided by the state Nutrient Management Program. At the rate at which farmers are brought into the state nonpoint source program using these approaches, it is difficult to discern at what point actual improvements in ambient water quality will be achieved in any particular location.

The agricultural subplan also does not reflect the negative environmental impacts that can result from cost sharing. By paying farmers to implement BMPs that can improve farmer profits and production, the state could be artificially perpetuating poison runoff problems. For purposes of cost sharing, a careful distinction must be made between BMPs that provide short term on-farm benefits and can be implemented by the farmer without any financial assistance, or provide longer term benefits that can be implemented with minimal assistance (or perhaps a low interest loan); and those that must be heavily subsidized because they provide no on-farm benefits. Having both farm prices and practices reflect environmental considerations is essential to the effective control of poison runoff, so cost sharing must be used carefully.

There also is little indication that funding sources within the state other than general revenues will be used to provide resources for the Nonpoint Source Program, or that parties responsible for poison runoff will be required to fund control programs. In fact, most of the discussion of funding in the agricultural section addresses the availability of federal funds,

VOL 12

7302

which cannot be tailored to Virginia's particular problems as easily or as effectively as state or local funds.

There is no provision in the plan to ensure that local governments contribute to the costs of controlling poison runoff in urban areas by allocating property tax or other revenues for stormwater or other nonpoint source controls. Other entities that could be viable taxing authorities, such as SWCDs and regional water quality control agencies, are not considered in the plan as potential taxing authorities to commit funds for either the general nonpoint source program at the state level or for the development of "watershed plans."

"Pollution control taxes" for polluting farm practices are not considered seriously as a potential source of program funds or pollution prevention. Although there is a possibility that fertilizer tax revenues will be re-allocated to the Nonpoint Source Program, neither this tax nor any other is being used to dissuade groups from undertaking land use activities that generate water pollution.[159] Although the fertilizer tax is a step in the right direction, the Plan does not state whether fertilizers will provide the high levels of funding required to implement through cost sharing all of the agricultural BMPs needed to meet water quality goals. In any case, there is no indication in the subplan that farmers will be required to finance some of the costs associated with controlling poison runoff.[160] Other charges, such as impact fees and other land use-based fees are not provided for in the § 319 Plan.

Legal Considerations

A legal system that is responsive to the need to control poison runoff is the foundation of all control programs. While totally restructuring a state's legal framework is unnecessary, comprehensive "source" control laws are needed to address contamination from stormwater and construction activities (Rec. 8-1, 8-2). Local governments should be required to prevent serious water quality impacts from land use development according to state criteria (Rec. 9-3). The state environmental policy act should be used to review all activities that could affect state waters and to require mitigation where necessary (Rec. 9-

VOL 12

7303

4). Finally, the exercise of the common law should bolster nonpoint source controls established through statutory programs.

Much of the preceding analysis provides a critique of the laws available in Virginia for controlling poison runoff. While many laws have been passed (or proposed) that improve the management of nonpoint sources, most of these laws, such as those applicable to land use planning, stormwater management and erosion and sediment control, could be improved. Similarly, although restrictions placed on localities because of Dillon's Rule have been eased by recent legislation, it remains to be seen if localities will capitalize on this opportunity by improving water quality protection activities.

Finally, the § 319 Plan does not expand the Council on the Environment's role in the Virginia Environmental Quality Act beyond the review of Environmental Impact Statements (EISs) for projects undertaken by certain state agencies and for comments made to appropriate federal agencies on projects that require an EIS under the National Environmental Policy Act. Therefore, substantial state-level control through VEPA is not available to control the individual or cumulative impacts of most private development.

Conclusion

The art and science of controlling poison runoff is undergoing another stage of growth after the initial activity that peaked in the late 1970s. No state alone has come to represent a model and, in fact, many have not progressed as far as Virginia in recognizing the significance of poison runoff. Nevertheless, there are significant problems with Virginia's plan to address poison runoff.

Some of the problems with Virginia's program can be fixed relatively easily and quickly, through increased resources or fine-tuning of existing programs. Other problems need more fundamental changes in approach. But as this report and case study have shown, none of the problems in Virginia or elsewhere is insurmountable.

We hope that the analysis in this case study, whether based on the detailed criteria set forth in the body of the report or the summary criteria provided immediately before the case study, will

VOL 12

7304

be of use not only to Virginia, but to all states and localities trying to improve their efforts to control poison runoff, as well as to government officials and citizens who review and comment on those efforts.

Notes - Case Study

1. This plan was submitted on August 4, 1988 to EPA Region III for federal approval.

2. It is not the purpose of this report to describe in detail all of Virginia's poison runoff control activities. The details of the programs outlined below are available in the documents cited.

3. Unless otherwise noted, the remainder of this section is based on - Virginia Department of Conservation and Historic Resources, *Virginia Nonpoint Source Pollution Management Plan*, August 4, 1988 (hereinafter cited as *Virginia NPS Pollution Management Plan*).

38. Va. Code §§ 10.1-2100 - 10.1-2115 (1988).

39. Tidewater is defined to include 28 counties and 17 cities. Va. Code § 10.1-2101 (1988).

40. *See Virginia NPS Pollution Management Plan*, 1988, *supra* note 3, at 5-6; Va. Code § 10.1-2107 (1988).

41. Va. Code § 15.1-489 (1988). The exact wording of the bill is: "Such (zoning) ordinance may also include reasonable provisions, not inconsistent with applicable state water quality standards, to protect surface water and groundwater."

42. Va. Code § 15.1-447 (1988).

43. Va. Code § 15.1-446.1 (1988).

44. Twenty-two PDCs were created through the Virginia Area Development Act. Va. Code §§ 15.1-1400 *et seq.* Planning District Commissions are regional planning organizations with limited authority to implement programs and services. Cox, William E. and Lorraine M. Herson, *Control of Nonpoint Source Pollution in Virginia: An Assessment of the Local Role*, Bulletin 158, Virginia Water Resources Research Center, November, 1987, at 15-16.

45. *See* Va. Code §§ 10.1-2100 - 10.1-2115 (1988).

46. A proposal for stormwater management legislation was to be developed by November 1, 1988. Urban Priority Areas are to be designated by December 31, 1992. The Urban BMP Handbook will be updated by October 1, 1990. Memoranda of Understanding will be promoted by December 31, 1993. *Virginia NPS Pollution Management Plan*, 1988, *supra* note 3, at 5-23 - 5-24.

47. *Id.* For example, updated urban poison runoff control educational materials will be distributed throughout the state by June 30, 1991. A training program will be developed by December 31, 1991 to inform local government personnel about revised urban BMPs and their implementation strategies. By July 1, 1990, the DSWC will begin a series of (at least) four urban BMP seminars for a "minimum total attendance of 160." *Id.*

48. Va. Code §§ 10.1-560 - 10.1-571 (1988).

49. Under the Erosion and Sediment Control Law, an "erosion impact area" is defined as "an area of land not associated with current land disturbing activity but subject to persistent soil erosion resulting in the delivery of sediment onto neighboring properties or into state waters." Va. Code § 10.1-560 (1988).

VOL 12

7308

50. *Virginia NPS Pollution Management Plan*, 1988, *supra* note 3, at 4-18. By the year 2000 the figure is supposed to rise to 95% of regulated private construction projects. *Id.*

51. The RT Program offers to pay 50% of the cost of replanting land that has been cut over with pine or other suitable soft woods. *See* Va. Code §§ 10.1-1170 - 10.1-1176 (1988).

52. The Forestry Incentives Program provides landowners financial assistance for site preparation, tree planting and stand improvement practices. *See* 16 U.S.C. § 2103.

53. Sediment and nutrient load reductions will not be calculated until 1990.

54. *Virginia NPS Pollution Management Plan*, 1988, *supra* note 3, at 3-5.

55. *See* Virginia Department of Mines, Minerals and Energy, *Minerals Other Than Coal Surface Mining Manual–Law and Regulations* (no date), Va. Code §§ 45.1-180 - 45.1-197.18 (1986).

56. Hazardous wastes are managed in Virginia under EPA authority pursuant to the Resource Conservation and Recovery Act. Since this potential source of groundwater contamination is already governed by federal regulations it is not addressed in this report.

57. This section of the plan refers to the incorporation of sewage sludge in the reclamation of land disturbed by mining. Most aspects of this process would be controlled by the Division of Mined Land Reclamation as part of the state's Coal and Surface Mining Reclamation Program established pursuant to the federal Surface Mining Control and Reclamation Act of 1977.

58. *See* 53. Fed. Reg. 33,114 (Aug 30, 1988). NRDC has sharply criticized the adequacy of these proposed rules. *See Comments of the Natural Resources Defense Council on U.S. Environmental Protection Agency's Proposed Rule for Solid Waste Disposal Facility Criteria*, November 30, 1988.

59. *Virginia NPS Pollution Management Plan*, 1988, *supra* note 3, at 8-1. CWA § 401 requires "any applicant for a federal license or permit to conduct any activity ... which may result in any discharge into the navigable waters [to] provide the licensing or permitting agency a certification from the state ... that any such discharge will comply with the applicable provisions of sections 301, 302, 303, 306 and 307 of this act."

60. *Id.* at 8-2.

61. This analysis is based on the criteria and recommendations developed in the preceding report, as well as specific comments submitted by NRDC on Virginia's NPS Plan. *See generally* Thompson, Paul and Robert W. Adler, *Comments of the Natural Resources Defense Council on Virginia's Proposed Nonpoint Source Pollution Management Plan to Fulfill the Requirements of CWA Section 319*, July 28, 1988. This analysis takes into account Virginia's written responses to NRDC's comments. *See* letter and attachment from

VOL 12

7309

Stuart Wilson, Environmental Program Supervisor, Virginia Division of Soil and Water Conservation to Paul Thompson, Natural Resources Defense Council, September 8, 1988.

62. The requirements of CWA §§ 208, 303 and 319 and 40 CFR Parts 130 and 131 are explained in Chapter Two of the preceding report.

63. These major thematic problems track the NRDC comments (mentioned above) at 1-29. More detailed comments on specific provisions of Virginia's plan, which are too narrowly focused to be of use in this report, are included in Attachment 1 to NRDC's comments.

64. *Virginia NPS Pollution Management Plan*, 1988, *supra* note 3, at 1-1.

65. *Id.* at 2-1. Interestingly, the *purpose* of the subplan however, is stated in a far different fashion than the *goal:*

> to establish a direction and framework for agricultural interests (government agencies, industry and private sector) to address nonpoint source pollution loadings attributed to agricultural lands and operations. *Id.* at 2-2.

66. *Id.* at 5-2.

67. Ron Gregory, State Water Control Board (Virginia), February 12, 1988 (personal conversation). For instance, although nutrients from agricultural fertilizers and livestock operations are a significant source of nitrogen and phosphorus enrichment of Virginia waters and the Chesapeake Bay, the water quality standard for "nutrient enriched waters" adopted by the SWCB address only phosphorus discharges by municipal POTWs. The standards do not apply to nonpoint source polluters, and in any case, does not address nitrogen contained in either point source discharges or poison runoff and baseflow. VR 680-14-02 (1988) - Policy for Nutrient Enriched Waters; VR 680-21-07.3 (1988) - Nutrient Enriched Waters.

68. See note 67.

69. See Report Chapter Nine.

70. *See, e.g.*, letter and attachment from Stuart Wilson, Virginia Division of Soil and Water Conservation, September 8, 1988, *supra* note 61, at 4:

> The VWCB can take enforcement action against any polluter, either point or non-point, who can be demonstrated to be causing water quality standards violations. Obviously, it is technically much simpler to place blame with point sources. In the case of non-point sources, we can and have taken enforcement actions. But when non-point sources are truly diffuse, the cause-effect relationship is much harder to establish, especially "beyond a reasonable doubt." To take an extreme example cited in NRDC's report, who would Virginia sue for causing deepwater deoxygenation in the Chesapeake Bay?

See generally Thompson and Adler, July 28, 1988, *supra* note 61.

VOL 1 2

7 3 1 0

71. An interesting analogy to this idea is the creation of a zoning law that restricts all (or some) dwelling to residential use because of traffic, safety and aesthetic considerations. In order to develop and pass that law information must be produced that shows (to some accepted level of certainty) that without the proposed restrictions undesirable conditions will result. Once the law (including its variance procedures) is enacted it applies to everyone equally. The authorities do not have to prove through lawsuit that every single person who proposes a nonconforming land use will bring about those conditions individually. Violations of water quality standards are the conditions that indicate to government officials the need (and authority) to take action.

72. See Report Chapters Nine and Ten.

73. *E.g.*, point source animal waste effluent, land treatment of sewage sludge, discharging of dredged and fill materials.

74. *Virginia NPS Pollution Management Plan*, 1988, *supra* note 3, at 1-4. The same section also restates the role of the SWCB:

> The State Water Control Board (SWCB) remains the water quality management agency in Virginia. As such they remain responsible for establishment of water quality standards for surface and groundwater, monitoring of streams to measure compliance with water quality standards, and overall water quality management. These responsibilities remain unchanged. *Id.*

77. Targeting improves the efficiency of poison runoff control programs and is therefore a desirable program component. It does not, however, determine necessary load reductions or provide coordination and cooperation within the watershed. Once the watershed planning process has been undertaken, *then* the state can target funds and resources both among and within watersheds.

7315

153. *See* Va. Code §§ 45.1-180 - 45.1-197.18 (1986); Virginia Department of Mines, Minerals and Energy, (no date), *supra* note 55, at 1-22 (Section II).

154. Catherine Pearsal, Virginia Department of Mines, Minerals and Energy, October 28, 1988 (personal conversation).

155. See Report Chapter Six.

156. See Report Chapter Seven.

157. Yagow, *et al.*, 1988, *supra* note 19, at 2.

158. Controlling erosion alone also does not ensure effective control even of pollutants which can become attached to soil particles. This is because there is not always a perfect correlation between movement of eroded soil and transport of such pollutants to aquatic environments. For instance, in the U.S. Fish and Wildlife study described earlier, phosphorus loss was not found to be strongly related to soil loss within the Choptank river watershed. U.S. Fish and Wildlife Service, 1988, *supra* note 92, at E-3. In another study of tributaries to Lake Erie, Ontario, one researcher concluded that lands should be targeted based on the specific pollutant of concern since, for example, "sources of high nitrate and phosphorus loadings are not usually the same area of high erosion." North Carolina Agricultural Extension Service, *NWQEP Notes*, November 15, 1988, at 3.

159. *Virginia NPS Pollution Management Plan*, 1988, *supra* note 3, at 2-5.

160. Under the existing cost sharing program, depending on the BMP, the state sometimes provides only a percentage of the cost associated with the installation of a BMP. *Chesapeake Bay NPS Programs*, 1988, *supra* note 8, at 28. However, many farmers would not likely volunteer to adopt a BMP unless they felt it provided economic benefits or, at least, did not decrease profitability.

VOL 12 7316

Appendix

Local governments play a key role in fighting poison runoff by gathering information, developing plans and implementing and evaluating field-level controls. This appendix offers some examples of promising local government programs to attack poison runoff. Two of the examples, in Florida and Minnesota, are parts of statewide land use management efforts designed to protect water quality. The third example is the program of comprehensive land use planning in Long Island, New York. Specific aspects of each program are discussed in the main report; more complete descriptions of these programs are given below.

Florida

Local NPS protection in Florida is mandated by the Local Government Comprehensive Planning and Land Development Regulation Act of 1985 (Comprehensive Planning Act). This land use planning process, described in Chapters Nine and Ten, contains a set of review criteria, embodied in regulations requiring certain "elements" in local planning documents, by which state officials can determine whether or not local comprehensive plans will have unreasonable impacts on state water quality standards. These are described below.[1]

The future land use element requires that existing and planned waterwells and cones of influences,[2] wetlands and surface water resources be identified on a land use map.[3] Objectives must be established that coordinate future land uses with the appropriate topography and soil conditions, ensure the protection of natural resources, and discourage urban sprawl.[4] The future land use element must provide for drainage and stormwater management, and the protection of potable water wellfields and environmentally sensitive lands.[5]

Another mandatory planning element must include policies to protect and conserve natural resources for the development of ports and airports.[6] Localities must collect data that identifies all facilities related to sanitary sewers, solid waste, drainage and potable water, their geographic service areas, the responsible operating entity and the current and projected level of service needs.[7] Land use regulations must provide for the protection of natural drainage features and natural groundwater aquifer recharge areas, and for water conservation and stormwater management.

The conservation element of local comprehensive plans is perhaps more directly related to local NPS pollution control than the other required elements. Table A-1 presents the water quality-related data collection activities required by the conservation element of local comprehensive plans.

Table A-1
Water Quality-Related Data Collection Requirements of the Comprehensive Plan Conservation Element*

Identify and Analyze the Following:

1. Rivers, bays, lakes, and wetlands including estuarine and marine waters, including information on the quality of the resources classified by the Florida Department of Environmental Regulation;
2. Floodplains;
3. Known sources of commercially valuable minerals;
4. Areas known by the local soil and water conservation district to have experienced soil erosion problems;
5. Fisheries, wildlife, marine habitats, and vegetative communities;
6. For each of the above natural resources, the element shall identify existing commercial, recreational or conservation uses, known pollution problems, and the potential for conservation; and
7. Current and projected water needs and sources for the next ten-year period based on the demand for industrial, agricultural, and potable water use and the quality and quantity of water available to meet these needs. The analysis shall consider existing levels of water conservation, use and protection and applicable policies of the regional water management district.

* Source: Fla. Admin. Code Ann. r. 9J-5.013(1) (1986).

The water quality objectives and policies that must be contained in the element are given in Table A-2.

Table A-2
Water Quality-Related Objectives and Policies of the Comprehensive Plan Conservation Element*

Objectives Shall Be Developed Which:

1. Conserve, appropriately use, and protect the quality and quantity of current and projected water resources and waters that flow into estuarine waters or oceanic waters.
2. Conserve, appropriately use, and protect minerals, soils and native vegetative communities including forests; and
3. Conserve, appropriately use, and protect fisheries, wildlife, wildlife habitat and marine habitat.

Policies Shall be Developed for Each Objective Which Address Implementation Activities for the:

1. Protection of water quality by restriction of activities known to adversely affect the quality and quantity of identified water sources including existing cones of influence, water recharge areas, and waterwells;
2. Emergency conservation of water sources in accordance with the plans of the regional water management district;
3. Protection and conservation of the natural functions of existing soils, fisheries, wildlife habitats, rivers, bays, lakes, floodplains, harbors and wetlands (including estuarine marshes and freshwater wetlands);
4. Designation of environmentally sensitive lands for protection based on locally determined criteria which further the goals and objectives of the conservation element; and
5. Management of hazardous wastes to protect natural resources.

* Source: Fla. Admin. Code Ann. r. 9J-5.013(2) (1986).

Programs developed in Florida to protect coastal resources provide a good example of the kinds of controls available to protect water quality in sensitive areas. The Florida program is integrated into the statewide comprehensive planning process,[8] which requires consistency and coordination among all agencies and government levels with local, regional or statewide coastal protection responsibilities, objectives and activities.[9] As described in Chapter Ten, the 1984 Florida State and Regional Planning Act[10] requires the preparation of a State Comprehensive Plan, which is embodied in Chapter 187 of the Florida Statutes. The

VOL 12

7320

ninth goal of the State Comprehensive Plan refers to coastal and marine resources and is accompanied by 10 policies:

> *Goal:* Florida shall ensure that development and marine resource use and beach access improvements in coastal areas do not endanger public safety or important natural resources. Florida shall, through acquisition and access improvements, make available to the state's population additional beaches and marine environment, consistent with sound environmental planning.

Policies

1. Accelerate public acquisition of coastal and beachfront land where necessary to protect coastal and marine resources or to meet projected public demand.
2. Ensure the public's right to reasonable access to beaches.
3. Avoid the expenditure of state funds that subsidize development in high-hazard coastal areas.
4. Protect coastal resources, marine resources, and dune systems from the adverse effects of development.
5. Develop and implement a comprehensive system of coordinated planning, management, and land acquisition to ensure the integrity and continued attractive image of coastal areas.
6. Encourage land and water uses which are compatible with the protection of sensitive coastal resources.
7. Protect and restore long-term productivity of marine fisheries habitat and other aquatic resources.
8. Avoid the exploration and development of mineral resources which threaten marine, aquatic, and estuarine resources.
9. Prohibit development and other activities which disturb coastal dune systems, and ensure and promote the restoration of coastal dune systems that are damaged.

VOL 12

7321

10. Give priority in marine development to water-dependent uses over other uses.[11]

State agencies must develop functional plans with objectives and procedures designed to ensure measurable progress towards state goals.[12] Regional Plans, consistent with state goals, must also be developed, reviewed and approved by the state.[13] Regional plans are used in evaluating developments with regional impacts.[14]

The comprehensive plans of coastal localities must contain a coastal management element that includes nonpoint source pollution.[15] In passing the Comprehensive Planning Act, the state legislature intended that "local government comprehensive plans restrict development activities where such activities would damage or destroy coastal resources, and [that such plans] protect human life and limit public expenditures in areas . . . . subject to destruction by natural disaster."[16]

The legislature gave special status to coastal protection by requiring the coastal management element to achieve the following specific objectives:

1. Maintenance, restoration, and enhancement of the overall quality of the coastal zone environment, including, but not limited to, its amenities and aesthetic values.

2. Continued existence of viable populations of wildlife and marine life.

3. The orderly and balanced utilization and preservation, consistent with sound conservation principles, of all living and nonliving coastal resources.

4. Avoidance of irreversible and irretrievable loss of coastal zone resources.

5. Ecological planning principles and assumptions to be used in the determination of suitability and extent of permitted development.

VOL 12

7322

6. Proposed management and regulatory techniques.

7. Limitation of public expenditures that subsidize development in high-hazard coastal areas.

8. Protection of human life against the effects of natural disasters.

9. The orderly development and use of ports to facilitate deepwater commercial navigation and other related activities.

10. Preservation, including sensitive adaptive use of historic and archeological resources.[17]

The element addressing coastal management requires an inventory and analysis of estuarine pollution problems and actions needed to maintain estuaries.[18] This assessment must include the identification of existing nonpoint source pollution problems and the impacts of development and redevelopment and of facilities proposed in other elements of the comprehensive plan on water quality and the accumulation of contaminants in sediment; a description of how existing pollution problems can be remedied; and the identification of "the state, regional and local regulatory programs which will be used to maintain or improve estuarine environmental quality."[19] Some of the specific water quality-related objectives and policies that are required are given in Table A-3.

Table A-3
Water Quality-Related Objectives and Policies of the Comprehensive Coastal Management Element*

Objectives Shall Be Developed Which:

1. Protect, conserve, or enhance remaining coastal wetlands, living marine resources, coastal barriers, and wildlife habitat; and
2. Maintain or improve estuarine environmental quality.

Policies and the Identification of Regulatory or Management Techniques are Required for:

1. Limiting the specific impacts and cumulative impacts of development and redevelopment upon wetlands, water quality, water quantity, wildlife habitat, living marine resources, and beach and dune systems;
2. Restoration or enhancement of disturbed or degraded natural resources including beaches and dunes, estuaries, wetlands, and drainage systems and programs to mitigate future degradation;
3. Establishing priorities for shoreline land uses, providing for siting water-dependent and water-related uses, establishing performance standards for shoreline development, and establishing criteria for marina siting which address land use compatibility, protection of water, economic needs, and feasibility;
4. Protecting estuaries which are within the jurisdiction of more than one local government, including methods for coordinating with other local governments to ensure adequate sites for water-dependent uses, prevent estuarine pollution, and control surface water runoff; and
5. Demonstrating how the local government will coordinate with existing resource protection plans such as resource planning and management plans, aquatic preserve management plans, and estuarine sanctuary plans.

* Source: Fla. Admin. Code Ann. r. 9J-5.012(3)(b)-(c) (1986).

Besides land use planning activities, Florida has also adopted other programs to protect coastal waters.[20] Under the Save Our Coasts program, Florida has acquired more than 88,000 acres of sensitive coastal land.[21] Lands are chosen for acquisition by a selection committee composed of representatives from relevant state agencies, according to a set of criteria established by the state legislature.[22] Also, state funds cannot be used for constructing bridges or causeways to coastal barrier islands not already

VOL 12 7324

R0040632

accessed by such structures, and the state is prohibited from allocating funds to expand local infrastructure unless this expansion is consistent with the coastal management element of the local plan.[23]

The State's Beach and Shore Preservation Act establishes Coastal Construction Control Lines (CCCLs) to prevent erosion and other damage to sandy beaches.[24] The CCCLs are delineated based on the 100-year storm surge. Construction on the seaward side of the line is strictly controlled (not prohibited) in terms of its potential to cause erosion based on tidal action, shoreline stability and other information.[25] Localities can administer the program through zoning and building codes which must be approved for this purpose by the State Department of Natural Resources (DNR), although DNR retains veto authority over exceptions granted by the locality.[26]

Another part of the Beach and Shore Preservation Act (added in a 1985 amendment) essentially prohibits all new construction in what is defined as the thirty-year erosion zone, which is based on the DNR projection of the seasonal high water line at the site thirty years after application of the permit.[27] As a compromise to property owners in this zone and to avoid claims of unconstitutional "takings" of private property, single-family dwellings can be built under certain restrictive conditions.[28] So far, these restrictions have not been challenged.[29]

A final restriction on building in coastal areas was added by the 1985 passage of the Coastal Zone Protection Act which established a coastal building zone where stringent construction standards must be utilized in sensitive coastal areas.[30] This zone is defined as the area from the high water line to a point 1500 feet landward of the CCCL for "high energy beaches" and to boundaries established for federal flood insurance purposes in other areas. Most natural islands can be covered completely by such a coastal zone.[31] Standards for locating, designing and building in these areas are contained in the state building code and the National Flood Insurance Program, and are supposed to be implemented by local governments using the local building code.[32] Because of the technical burden and expense that such an approach places on the local level, significant technical assistance and funding from the state are seen as essential to the

VOL 12

7325

success of the program.[33] This need, however, has a positive aspect. It brings together the two levels of government so that information on program strengths and weaknesses will be transferred across government levels.

Regulations recently adopted in Franklin County, Florida provide an example of what local governments can do to protect coastal waters. The county recently enacted an ordinance designed to protect coastal water quality by protecting wetlands and by guiding development and land use on adjacent lands to create a protective buffer zone.[34] The ordinance defines a Critical Shoreline District, which includes a Pollution Sensitive Segment (areas to protect important water resources from septic tank pollution) and a Critical Habitat Zone.[35] The district (all lands within 150 feet landward of county wetlands) is established for general purposes by land use maps, and is defined more precisely by the county planner for regulating individual parcels.[36]

Development in this critical area is controlled in a number of ways. The developer must obtain a permit which contains standards described in a development manual provided by the county.[37] In the Critical Habitat Zone, most development is prohibited.[38] Minimum development standards are also provided in the ordinance itself. These pertain to minimizing impervious surfaces, maintaining natural vegetation, locating and properly designing individual waste treatment systems, providing for stormwater management systems, and requiring infiltration BMPs and on-site retention and storage of stormwater.[39]

Inspections are also required for erosion and sediment controls, and the installation of underground storage tanks before they are covered; in addition, there must be a final inspection of all required stormwater management components which must be passed before a "certificate of occupancy" can be issued to allow use of the development.[40] The stormwater system must be maintained by the owner and inspected every year by the county.[41] Easements must be provided to allow the county to perform any necessary work that the owner is unwilling to carry out, in which case the county will place a lien on the property for the costs of the maintenance.[42] Permit applicants are charged a base fee of $100 with additional fees for multifamily or

VOL 12

7326

R0040634

commercial development based on the number of dwelling units, square feet of structural development, or numbers of lots.[43]

Minnesota

The local planning process in Minnesota (described in Chapter Ten) requires significant information collection and program development activities before the State Board of Water and Soil Resources will approve the final comprehensive local water plan. The planning and institutional aspects are considered in Chapter Ten, while the following section discusses the substantive requirements for local plan approval.

Each local water plan must be developed using a set of general management guidelines. These are provided in Table A-4.[44]

Table A-4
Management Requirements for Preparation of Comprehensive Local Water Plans Under Minnesota Statutes Chapter 110B*

1. Significant upstream and down-stream effects on surface water, and up-gradient and down-gradient effects on groundwater, should be fully considered;
2. Natural water storage and retention systems should be preserved and used to the maximum extent practical;
3. Water management decisions should be based on sound data and technical analysis;
4. The interrelationship between surface and groundwater, land and water use, and quality and quantity of water should be recognized;
5. Potential variations in precipitation, both short-term and long-term, should be fully considered;
6. Potential cumulative effects of proposed actions should be considered;
7. Prevention of potential water and related land resources problems should be emphasized;
8. The overall quality of the environment should be protected or enhanced;
9. The total benefits of water programs and projects should exceed the total costs;
10. Water management programs should be adequately funded to achieve high-priority objectives;
11. Comprehensive water planning should be coordinated with other related planning programs to fill management gaps and minimize duplication of effort;
12. Comprehensive approaches to identified problems and opportunities should be considered; and
13. Water conservation practices should be used to the maximum extent practicable.

* Source: Minn. Code Agency R. Ch.9300.0170, Subp.4 (1987).

In addition to management requirements, certain steps must be taken in order for the State Board of Soil and Water Resources to approve a plan. Table A-5 indicates the steps that should be followed in developing a water plan.

Table A-5
Steps in Developing
the Minnesota Comprehensive Local Water Plan*

1. Outline Preliminary Issues, Goals, Objectives
   a. Use public input
   b. Assess existing county plans
2. Collect Information
   a. About physical environment
   b. About surface water, groundwater, and related land resources
   c. About conflicts, issues, problems, opportunities
   d. About expected changes
   e. Compile plans and official controls of local units
   f. Gather plans and studies of regional, state, and federal agencies
3. Evaluate Information
   a. Assess resource information
   b. Define issues and opportunities
   c. Consider options
   d. Consider goals and objectives
4. Establish Goals, Objectives, and Actions
   a. Set goals
   b. Establish objectives to meet goals
   c. Develop priorities and action plan

* Source: Minnesota State Planning Agency, *The Handbook for Comprehensive Local Water Planning Under Minnesota Statutes, Chapter 110B*, November, 1987, at 15.

Plans must describe eight specific areas. The scope of a local water plan is given in Table A-6.

Table A-6
Scope of the Minnesota Comprehensive Local Water Plan*

1. The physical environment and expected changes to it;
2. Information about water and related land resources and their expected changes;
3. Objectives and actions to achieve these objectives;
4. Desired changes in state programs;
5. Conflicts with local governments;
6. Conflicts with other countries;
7. Plan implementation; and
8. An amendment procedure.

* Source: Minnesota State Planning Agency, *The Handbook for Comprehensive Local Water Planning Under Minnesota Statutes, Chapter 110B*, November, 1987, at 16.

A great deal of specific information and a number of activities are necessary in order to prepare a water plan under the statute. For each specific requirement, the state planning agency has offered guidance as to the purpose of the requirement as well as specific names and phone numbers of individuals and agencies who can assist in obtaining or preparing the necessary information or plan component. The information required is given in Tables A-7 through A-11. In addition to the extensive information gathering requirements, the plan also must contain elements addressing problems and opportunities, goals, objectives and actions, as well as the plan's implementation program. These elements describe what the county wants to achieve and how it will accomplish these goals and objectives. Tables A-12 and A-13 indicate the major features of these planning elements.

Table A-7
Specific Contents of Minnesota Local Comprehensive Water Plan: Physical Environment, Land Use, and Development*

Precipitation:
1. A map or list of the location of precipitation gauging stations in the county;
2. A map showing isolines of normal annual total precipitation in inches;
3. A map showing isolines of normal total precipitation in inches for the period May through September.

Geology and Water Resources:
1. A map or description of important aquifer systems, confining layers, and flow characteristics to the extent known;
2. A description of ground and surface water interconnections, such as recharge and discharge areas, where they are known;
3. A map of boundaries and flow directions of watershed units and minor watershed units;
4. A map of state protected waters and public drainage ditches, including the location of any existing dams and control structure.

Soils:
1. A general soils map and description of soils infiltration characteristics; and
2. A map of erosion-prone soils.

A Map of Original Vegetation:

A Description of General Topographic Relief of Watershed Units Based on USGS Topographic Maps:

Land Use and Public Utility Services:
1. A general map of existing land uses;
2. A map showing the areas served by storm sewers, sanitary sewers, and public water systems; and
3. A map or list by geographic indicator showing the location of community public water supply intakes and wells.

Land Ownership:
1. A map showing the ownership of local, state, federal, and Indian tribal lands; and

VOL 12

7331

2. A map showing lands with easements that relate to water resources, where that information is available.

Identification of Expected Changes to Land Use and Cover, Public Utility Services, and Other Changes Potentially Affecting Water Resources.

* Source: Minnesota State Planning Agency, *The Handbook for Comprehensive Local Water Planning Under Minnesota Statutes, Chapter 110B*, November, 1987, at 23-34.

Table A-8
Water Quantity*

Surface Water Quantity:

1. A description of high, mean, and low flows on streams;
2. A list of lakes where the state has established ordinary high water marks;
3. A list of permanent withdrawals from lakes and streams, including the location by geographic indicator, source, use and amounts withdrawn;
4. A list of lakes and streams in the county for which state protected levels or flows have been established;
5. A description of known water use conflicts, including those caused by groundwater pumping that affects surface water; and
6. The implications of surface water quantity.

Groundwater Quantity:

1. A list of wells covered by state appropriation permits, including the location by geographic indicator, amounts of water appropriated, type of uses, and aquifer source;
2. A description of known well interference problems and water use conflicts;
3. A list of state observation wells located in the county including geographic indicator, unique well number, aquifers measured, years of record and average monthly levels; and
4. The implications of groundwater quantity information for present and future water and land uses and an assessment of those implications.

* Source: Minnesota State Planning Agency, *The Handbook for Comprehensive Local Water Planning Under Minnesota Statutes, Chapter 110B*, November, 1987, at 37-69.0

VOL 12

7332

Table A-9
Water Quality*

Surface Water Quality:

1. A map or list of the state water quality management classifications for each stream and lake;
2. A summary of available lake and stream water quality monitoring data (examples include);
   a. Bacteriological contamination indicators,
   b. Inorganic chemicals,
   c. Organic chemicals,
   d. Sedimentation,
   e. Dissolved oxygen, and
   f. Excessive growth or deficiency of aquatic plants;
3. A summary of information from informal sources relating to surface water quality, such as fish kills; and
4. The implications of surface water quality information for present and future water and land use, and an assessment of those implications.

Groundwater Quality:

1. Summary of available water quality data, including routinely monitored sites; and
2. The implications of groundwater quality information for present and future water and land uses with emphasis on those with potential health-related impacts and an assessment of those implications (where possible, the information required in this item should be presented by aquifer system and geographic area).

* Source: Minnesota State Planning Agency, *The Handbook for Comprehensive Local Water Planning Under Minnesota Statutes, Chapter 110B*, November, 1987, at 37-69.

Table A-10
Special Land Uses and Conditions*

Eroding Lands:

1. A description or map by watershed unit of areas where eroding lands are causing sedimentation problems;
2. Water quality and quantity implications for watercourses, water basins, ditches, and wetlands of sedimentation and an assessment of those implications; and

VOL 12

7333

3. An assessment by watershed unit of the effects of land use and cover on quantity and quality of runoff.

Irrigation:

1. A map or list by geographic indicator of irrigated acreage; and
2. For any county containing more than 1,000 acres of irrigated land in any one township, the implications of irrigation for present and future lands and water use and an assessment of those implications.

Drainage:

1. A table listing the public drainage systems in the county and the amounts expended, by year, for repair work on each system;
2. An assessment of any significant water quality and quantity effects due to public or private ditch systems; and
3. A summary of any known water quality and quantity information from engineering reports and modelling efforts on ditches in the county.

Pollution Sources:

1. A map or list by geographic indicator of known closed and operating sanitary landfills, closed and operating open dumps, and Minnesota Superfund hazardous waste sites and a summary of available water quality information relating to these sites;
2. A map or list by geographic indicator of feedlots, abandoned wells not sealed in accordance with state statutes and rules, underground storage tank sites, and permitted wastewater discharges under Chapter 701, and a summary of available water quality information relating to these sites;
3. A list by geographic indicator of facilities that have hazardous waste generator identification numbers; and
4. The implications of pollutant sources for present and future water and land uses and an assessment of those implications.

Special Geologic Conditions:

1. A map of known geologic conditions, such as karst areas, buried valleys, or sand plains that may pose concerns relating to water quality or quantity; and
2. The implication of special conditions for present and future water and land uses and an assessment of those implications.

VOL 12

7334

R0040642

Table A-11
Related Land Resources*

Wetlands:

1. Maps of wetlands identified under the National Wetlands Inventory, where available;
2. A summary of plans for wetlands with controlled outlets, such as plans for draw-downs;
3. A description of the United States Army Corps of Engineers, Section 404 permit requirements affecting county waters; and
4. The implications of wetlands for present and future water uses with special consideration for water quality, flood attenuation, wildlife, and recreation, and an assessment of those implications.

Floodplains:

1. A map showing those areas delineated as floodplain by existing local ordinances or in proposed ordinances that have a due date established by the Minnesota Department of Natural Resources or the Federal Emergency Management Agency;
2. A map of areas with known flooding problems;
3. An estimate of average annual flood damages, if available; and
4. An assessment of the adequacy and enforcement of existing floodplain ordinances.

Shorelands:

1. A list of local units of government with unapproved shoreland ordinances;
2. A list of protected waters, and their shoreland classifications under Minnesota Statutes, section 105.485; and
3. An assessment of the adequacy and enforcement of the shoreland ordinances.

Water-based Recreation Lands:

1. A map and description of water-oriented recreation resources listed in the State Comprehensive Outdoor Recreation Plan;
2. A map of public water accesses;
3. A map and description of state or federally designated wild and scenic rivers and state designated canoe and boating routes; and
4. An assessment of the adequacy of water-based recreational lands for present and future use.

Fish and Wildlife Habitat:

1. A map and description of any state designated wildlife management areas and any lakes with state designated classifications for game or fish management within the county;
2. A map and description of any state designated trout lakes or trout streams within the county;
3. A list and description of the state ecological and management classifications and use attainability for lakes and streams, where available;

VOL 12

7335

4. A list and description of the conclusions and recommendations of biological surveys on reconnaissance studies, where available;
5. A description of state management plans for fish and wildlife areas, where available; and
6. An assessment of the adequacy of fish and wildlife habitat for present and future use.

Unique Features and Scenic Areas:

1. A map or description of unique features and scenic areas with relationships to water including state designated natural and scientific areas, areas containing county, state, and federal rare and endangered species, and other features such as waterfalls, springs, and historic mills; and
2. The implications of unique features and scenic areas for present and future water and land use, and an assessment of those implications of these planning elements.

* Source: Minnesota State Planning Agency, *The Handbook for Comprehensive Local Water Planning Under Minnesota Statutes, Chapter 110B*, November, 1987, at 37-69.

Table A-12
Problems and Opportunities; Goals; Objectives and Actions*

Identify Problems and Opportunities: For each watershed unit and groundwater system, where appropriate, the comprehensive water plan must identify any issues relating to water quality, quantity, special land uses and conditions, and related land resources. The plan must discuss assets or opportunities, as well as problems associated with each issue. At a minimum, a county must gather information about water-related problems and opportunities in the following manner:

1. Investigate those problems and opportunities disclosed at public meetings and in written comments;
2. Investigate those problems and opportunities that affected local units of government want to be examined;
3. Assess the information gathered in Tables A-7 through A-11; and
4. Assess the status and adequacy of official controls, plans, and other local, state, or federal programs concerning water and related land resources.

Establish County Goals: The plan must state goals for present and future water and land uses to set the framework for determining plan objectives and related actions.

Establish Objectives and Action Plan: The plan must state measurable objectives and a plan of action addressing the identified problems and opportunities for each watershed unit and groundwater system, where appropriate, for each of the following categories:

1. Opportunities and problems in surface and groundwater quality and quality;
2. Opportunities and problems associated with significant special land uses and conditions that influence water quantity and quality; and
3. Opportunities and problems associated with related land resources.

Establish Priorities:

1. The county must state priorities in the plan of action relating to water quality, water quantity, special land uses or conditions that influence water quality and quantity, and related land resources.
2. The plan must reflect the urgency of the problem or opportunity identified.
3. The plan must describe those actions that will be taken by the county alone, and those actions that will require the cooperation of other local units of government or state and federal agencies, and must state whether the county board has received commitments for that cooperation.

* Source: Minnesota State Planning Agency, *The Handbook for Comprehensive Local Water Planning Under Minnesota Statutes, Chapter 110B*, November, 1987, at 71-73.

Table A-13
Implementation Program*

1. The plan must state how and when the plan will be implemented to meet the objectives and carry out the actions identified in Table 15.
2. The implementation program may include data collection programs, educational programs, capital improvement projects, project feasibility studies, enforcement strategies, amendments to existing official controls, adoption of new official controls, etc. If no action is to be taken to address identified problems or opportunities, the plan must explain why actions are not needed.
3. Necessary staff and financial resources needed to carry out the plan must be stated.
4. The plan must state the time in which each of the actions contained in the implementation program will be taken.
5. If a county has made an agreement for the implementation of the plan (or portions of the plan) by a local unit of government within the county, that local unit must be specified, the responsibility indicated, and a description included as to how and when the implementation will happen.
6. If capital improvement projects are proposed to implement the comprehensive water plans, the project must be described in the

VOL 12

7337

plan. This description must include the following information:

a. the physical components of the project, including their approximate size, configuration and location;
b. the purposes of the project and their relationship to the objectives of the comprehensive plan;
c. the proposed schedule for project construction;
d. expected federal, state and local costs;
e. the types of financing proposed, such as special assessments, ad valorem taxes, and grants; and
f. the sources of local financing proposed for the project, such as subcounty, countywide, or multicounty.

* Source: Minnesota State Planning Agency, *The Handbook for Comprehensive Local Water Planning Under Minnesota Statutes, Chapter 110B*, November, 1987, at 77-81.

Long Island

The Long Island Regional Planning Board (LIRPB) evaluated the land use planning aspects of the counties and townships of Long Island to assess their water quality implications.[45] Many problems were identified in this evaluation that might be useful to state and local officials involved in NPS management activities. These include the observations listed in Table A-14.

Table A-14
Problems Identified in Long Island's Local Land Use Planning Activities[1]

1. Localities fail to consider groundwater and surface water in the site plan review process.
   a. Localities do not revise zoning and other ordinances (the basis of the site plan review process) to reflect water quality considerations in the comprehensive plan, and do not update zoning maps to reflect this water quality.
   b. Localities do not address the long-range, cumulative impacts of individual projects affecting water quality in small geographic areas.
   c. Localities fail to delegate power adequately to the reviewing agency to consider water quality issues by:

(1) not explicitly authorizing the use of the police power for water quality protection;

(2) not identifying critical water resources in zoning ordinances;

(3) not precluding many activities associated with water pollution in critical areas;

(4) not providing for proper enforcement of ordinances through the use of large enough fines, applicable to repeat violations, by both the site owner and the developer; and

(5) not developing ordinances prohibiting land clearing before the site plan has been approved.

d. Site plan ordinances are often too rigid and uniform and do not provide for flexibility to allow, for example, varying setback requirements to tailor requirements to the characteristics of the site and, in zoning coverage requirements, to take account of such constraints as steep slopes.

2. Zoning Boards of Appeals often do not have zoning variance procedures that:

a. utilize water resources protection criteria;

b. provide for coordination with planning boards; or

c. provide the information necessary to determine if the variance is compatible with state and county water quality, hazardous waste, building code, and sanitary rules and regulations.

3. The subdivision review process is often flawed because:

a. commercial and industrial subdivision plans are filed but not reviewed, municipalities waive the filing requirement for subdivisions of fewer than five lots;

b. ordinances do not include the authority to mandate clustering, and when this authority is available, it is often not utilized in sensitive areas; and

c. the design standards of some subdivision ordinances are outdated and do not provide for the maintenance of a site's existing topography, vegetation or natural drainage patterns.

4. Planning boards and zoning boards of appeals sometimes approve projects that do not meet federal, state and county laws.

5. Planning boards may grant preliminary approval of a subdivision before all required permits have been obtained and may act before receiving recommendations from citizen advisory committees or conservation advisory boards.

6. Some municipalities do not review site plans for single family homes in critical areas because the areas have not been identified and available information on how to protect these areas has not been utilized.

7. Plans are sometimes approved that are poorly designed, incomplete, or misleading; and some impacts are not taken into account because responsibilities are fragmented and coordination between departments is poor.

8. Site plan and subdivision review departments are sometimes understaffed and lack environmentally trained personnel.

VOL 12

7339

R0040647

9. An established procedure for the routine collection and exchange of information between departments is often lacking; technical reviewers often function only in an advisory role; and developers often submit incomplete information on subdivisions and site plans which results in fragmented, time-consuming attempts to obtain the missing data.
10. Building permits are sometimes issued without incorporating mitigation techniques prescribed in the site plan.
11. Site owners are often allowed to sign forms stating that compliance with the site plan will occur in the future, making subsequent enforcement difficult.
12. Conservation easements are sometimes not officially recorded, making future enforcement of the covenant difficult.
13. The State Environmental Quality Review Act (SEQRA),[2] is considered by many local officials to be the most effective way to mitigate environmental impacts not covered by specific legislation and regulations; however, the coordination needed to carry out the SEQRA process is often lacking because local officials often do not have the capability or willingness to utilize the SEQRA and site plan review process fully.

[1] Source: Koppelman, Lee E., Edith Tanenbaum and Carole Swick, *Nonpoint Source Management Handbook*, Long Island Regional Planning Board, Hauppauge, New York, 1984, at 35-40 (Site Plan Review).

[2] The New York State Environmental Quality Review Act is a state law requiring compliance by all county and local agencies and the review of actions that may have a significant impact on the environment. Type I actions are those that can be expected to have significant impact on the environment and require the submission of an Environmental Assessment Form (EAF) and may require an Environmental Impact Statement. Type II actions are those actions expected to have little if any impact on the environment. Localities may identify Critical Environmental Areas which designate all development within the area a Type I action. *Id.* at 15 (Land Use).

Tables A-15 and A-16 describe the recommendations developed by the Long Island Regional Planning Board (LIRPB) for localities to use in improving the water quality protection aspects of their local land use planning tools. The Board evaluated the land use planning aspects of the counties and townships of Long Island. Many problems were identified in this evaluation.

Table A-15
LIRPB Recommendations for Land Use Controls Designed to Protect Water Quality*

1. County health departments should identify non-polluting industries to assist municipalities in decisions regarding which industries to allow in critical recharge areas and other sensitive areas in their planning, zoning, site plan and building permit review processes.
2. Counties should "develop, enact, and enforce" controls to reduce surface water and groundwater pollution from land use activities in Special Groundwater and Special Surface Water Protection Areas, additional recharge areas with high quality groundwater, and areas where nitrate concentrations "are approaching six mg/l, or organic concentrations are increasing and where additional development at the present zoning densities and/or types may be expected to cause ambient groundwater concentrations or the potable water supply to exceed groundwater quality standards."
3. Municipalities should design and adopt revisions to comprehensive plans to protect water resources incorporating the following goals and objectives:
   a. limit development (especially industrial uses) in deep recharge and critical shallow recharge areas;
   b. high density, commercial and industrial land uses should be concentrated in existing high density, commercial and industrial areas, in areas downgradient of critical groundwater recharge areas and within existing contaminant plumes;
   c. in relatively undeveloped portions of recharge areas and in areas where current groundwater usage may result in saltwater intrusion, stream flow reduction, or wetlands destruction, decrease permitted residential densities of two to ten units per acre to one unit or less per acre or open space;
   d. limit the removal of natural vegetation and the creation of lawns in critical environmental areas;
   e. include the following development guidelines in the zoning and subdivision ordinances and site plan review process:
      (1) allow development that is consistent with existing land use patterns;
      (2) use state environmental laws, county health codes, local regulations, zoning requirements and performance standards to prevent or minimize environmental impacts;
      (3) require nitrogen removal systems for septic systems;
      (4) prevent any direct discharge of stormwater or commercial or residential wastes or products to surface waters;
      (5) require development to be connected to sewage treatment plants; and
      (6) require site development and operational controls, and monitoring and enforcement requirements for industrial uses in special protection districts.

VOL 12

7341

4. Municipalities should consider the establishment of Special Groundwater Protection Areas that would comprise relatively undeveloped deep recharge areas or shallow recharge areas underlain by saltwater which would require comprehensive and coordinated state, county and town management to maintain water quality. Individual municipalities should review boundaries and recommend modifications, undertake the planning, legislative and administrative actions necessary to manage the resource, and incorporate the district designations and policies into local land use, taxation and capital improvement programs. Areas have been defined based on one or more of the following:
   a. relatively undeveloped groundwater recharge areas where withdrawals have occurred or are likely to occur;
   b. areas underlain by relatively high quality aquifers where contamination is likely if the areas are developed according to existing zoning; and
   c. areas where extensive groundwater contamination limits or can be expected to limit the potable water supply.
5. Municipalities should also consider the establishment of Special Surface Water Management Areas comprising watersheds necessary to maintain high quality surface waters to provide the rationale for the imposition of controls necessary in areas subject to future development. These controls could be in the form of performance standards and development guidelines.
6. Municipalities should revise local zoning ordinances to reflect the changes described above. The following changes are suggested:
   a. Modify use designations and zoning boundaries.
   b. Establish special overlay districts for deep aquifer recharge areas and Special Groundwater or Surface Water Protection Areas precluding intensive uses except where adequate performance standards can be met.
   c. Require environmental assessments for any changes in zoning allowing for more intensive land uses.
   d. Enact mandatory clustering and site plan review provisions as a part of zoning/subdivision regulations with appropriate criteria and standards for preserving surface water and groundwater resources.
   e. Revise zoning ordinances to establish stringent performance standards, including those covering the development and operation of industrial activities.
7. Municipalities should enact site plan review regulations as part of their zoning ordinance and site clearance requirements as part of their subdivision regulations. Site clearance permits and the preservation of natural vegetation to minimize land clearing, lawn areas and golf courses in critical environmental areas should be required.
8. Municipalities should require the dedication of conservation easements as part of the site plan review process and subdivision regulations for new development in critical environmental areas. Easements should include buffer zones of a minimum distance of

50 feet from river, stream, lake or pond banks in undeveloped or partially developed lands adjacent to surface waters.

* Source: Koppelman, Lee E., Edith Tanenbaum and Carole Swick, *Nonpoint Source Management Handbook*, Long Island Regional Planning Board, Hauppauge, New York, 1984, at 18-23 (Land Use).

Table A-16
LIRPB Recommendations to Improve the Water Quality Protection Aspects of the Site Plan and Subdivision Review Process*

1. Municipalities should consider expanding the site plan review process to include the consideration of groundwater and surface water impacts (including cumulative impacts).
   a. Municipal codes should require the consideration of groundwater (surface water) protection as a reason for the use of the police power.
   b. Consistent regulations to control nitrate loadings should be developed, including the use of estimated nitrate loadings to establish permissible densities and taking into account the contribution of septic systems (LIRPB recommends that nitrate levels in developed areas not exceed 6 mg/l or 2 to 3 mg/l for partially developed or undeveloped aquifer recharge areas, or Special Groundwater Protection Areas).
   c. Local site plan review ordinances should provide specific legal authority to consider groundwater and surface water protection in the site plan review process.
   d. Zoning and other ordinances should be revised to assure consistency with the comprehensive plan, which should reflect the guidelines of 208 Waste Treatment Management Plans, including the consideration of land use densities in sewered and nonsewered areas, as well as cumulative impacts.
   e. In critical areas, specific zoning categories not compatible with the high quality recharge (or surface water) area should be identified. Zoning ordinances should adopt appropriate performance standards and be amended to prohibit or restrict incompatible land uses.
   f. Municipalities should adopt site clearance permit ordinances to prevent clearing road rights-of-way or the whole site prior to site plan approval.
   g. Zoning ordinances should be amended to allow site plan reviewers to modify existing criteria and standards, when necessary, to require appropriate water quality protection measures (*e.g.*, vary set back requirements, revise lot coverage requirements) or to utilize new information needed to maintain

VOL 12

7343

R0040651

the environmental objectives of the site plan review process.

h. Environmental ordinances should be reviewed to ensure that adequate fines are provided violators, as well as fines applicable to repeat offenders and to both the developer and site owner.

i. Local ordinances should be developed to incorporate performance standards to address the cumulative impacts of NPS loadings.

2. When considering changes in zoning, potential impacts on water quality should be considered by requiring a site plan and an Environmental Assessment Form for any changes proposed in a critical area and that any developer proposing a zoning change in the area be required to present evidence that the change will not result in increased groundwater (or surface water) contamination.

   a. The Zoning Board of Appeals (ZBA) should be prohibited from granting zoning variances in conflict with groundwater or surface water protection objectives, policies, etc.

   b. Local Planning and Environmental Agencies should advise zoning board members whether or not a proposed development is compatible with groundwater (or surface water) needs.

   c. Coordination between the ZBA and the planning board and other agencies should be improved; the ZBA should submit all variance applications affecting critical areas to the planning board for review and comment.

3. Review of commercial and industrial subdivisions should be required by law. Subdivisions of fewer than five lots should be reviewed. Outdated subdivision design standards should be reviewed and modified, if necessary, to provide adequate water quality protection, including provisions to maintain existing topography, drainage and vegetation.

4. Localities should begin the SEQRA process when the site plan review process begins and measures should be taken to ensure than the site plan conforms with any measure stipulated or otherwise indicated in the Environmental Impact Statement process.

Source: Koppelman, Lee E., Edith Tanenbaum and Carole Swick, *Nonpoint Source Management Handbook*, Long Island Regional Planning Board, Hauppauge, New York, 1984, at 42-65 (Site Plan Review). Where appropriate, additions to LIRPB recommendation are made to include the consideration of surface water quality by including (surface water) beside references to groundwater.

The LIRPB also evaluated stormwater management activities in the area and developed the recommendations for state and local stormwater management programs presented in Table A-17.

VOL 12

7344

Table A-17
LIRPB Recommendations to Improve State and Local Stormwater Management*

1. Limit development and the establishment of impermeable paving on publicly-owned lands located near surface waters and wetlands.
2. Prohibit any new direct discharge of stormwater into surface waters, freshwater or tidal wetlands. Use appropriate control measures for areas near surface waters.
3. Evaluate existing stormwater systems that currently discharge into surface water to determine whether systems can be modified to include additional control measures to minimize impacts upon surface waters and adjacent areas.
   a. Inventory direct discharges and assign remediation priority ratings based upon environmental impacts.
   b. Determine if there is sufficient land area to develop cost feasible energy dissipation areas, and sediment basins or retention areas to eliminate or reduce the direct discharge and accompanying sediment loadings into surface waters and wetlands, or to reduce peak runoff flows before discharge.
4. Acquire and maintain those streambeds and the surrounding watershed areas that have dried up due to sewering. The retention of these areas will facilitate the recharge of runoff, thus reducing the amount of streamflow following a storm and the subsequent high coliform loadings that would otherwise reach the bays.
5. Do not remove recharge basin vegetation since plant growth generally enhances infiltration. The root systems keep the soil layer loose and permeable and provide for the infiltration of water.
6. Amend local zoning ordinances to include a requirement for the establishment of adequate setbacks, 100 feet from the shoreline for areas adjacent to the edge of lakes, ponds, streams, rivers, bays, wetlands and in areas where the depth to seasonal high water table is less than three feet. Such areas should not be cleared of native vegetation except for cat briar, honeysuckle and other destructive vines. Any stormwater runoff generated from the site development upland and discharged into these areas should be discharged at a release rate that shall not exceed the stormwater runoff rate from the area in its natural state and discharged in manner so that no erosion and loss of vegetation occurs.
7. Require adherence to the following performance standards for all new site development:
   a. Protect and maintain the natural functioning of the site by maintaining the absorptive, purifying and retentive functions that existed on the site before construction began.
   b. Limit the post-construction volume and rate of runoff leaving the site to that calculated on the basis of natural or predevelopment conditions. The peak release rate of stormwater from all developments where retention is required for the designed

storm, should not exceed the peak stormwater runoff from the area in its undeveloped state for a storm of any intensity up to and including the 100 year frequency, and for rainfall during any duration. Calculations of the rate should be based upon an assumed runoff coefficient of 0.20, 0.25, and 0.35 for average slopes of 2 percent, 2-7 percent and over 7 percent respectively.

c. Design the drainage system so that the runoff release rate from natural drainage channels will not exceed the natural carrying capacity of the channel.

d. Limit the release rate for drainage systems serving new development. The volume and velocity of runoff discharge should not exceed the safe capacity of the existing drainage systems into which the discharge flows.

8. Require a stormwater management plan for any property when
   a. a plat is to be recorded.
   b. land is to be subdivided.
   c. an existing drainage system may require alteration.
   d. new development is proposed for more than one residential unit on a given plat.
   e. new development for any use other than single family residence is proposed.
   f. the rate or volume of runoff will be significantly increased.
   g. on-site water drains to a pond, stream or other surface water body or to a wetland.
